"In the last two centuries . . . there has been much more than a tenfold increase in speed and a corresponding increase in security, versatility and comfort. Our mechanical power and mechanical productivity have increased in far greater proportion. There has been an educational advance also, but it has not kept pace with this . . . The education of a fully educated man is not conspicuously better than it was two hundred years ago . . . We believe that we are now in the dawn of a phase of educational thrust corresponding to the mechanical thrust of a century ago."

In harmony with Mr. Wells' prophecy I foresee a longer period of education for youth, extending perhaps to the completion of a junior college course, say at the age of twenty. This will provide a general education including opportunity for trade and vocational training, but it should not be continued too long, because youth is anxious to begin his life work; he is "champing at the bit"; his zest and ambition must not be permitted to wane.

In addition to this general education, post-scholastic study will become much more common and will provide both for entertainment and for the development of handicraft, science, the arts and literature. It will continue through adult life. There will ensue a return of the craftsman, who will work for the pleasure of working and to produce useful and ornamental things in the making of which he will take a just pride. The pursuits of art and literature are appropriate home avocations. Study and research in the home are not impracticable, and for the more involved work laboratories open to the public could be provided, where voluntary research could be carried out with adequate equipment and technical guidance.

The professional engineer of the future will be more highly educated than in the past. His four-year college training will be devoted to the fundamental sciences with generous allowances for the liberal arts and humanities. His professional study will follow in what we now call "post graduate" years. He will then have a service period of several years before he will formally enter the profession. Only by such modifications of the present prevailing college training can the engineer of the next fifty years be adequately equipped, or can he attain to the plane of responsibility which will be open to him if he is qualified to occupy it.

Providing for the future, as his work necessitates, recognizing and applying the discoveries in science and appreciating that there is a vast realm of the unknown yet to be explored, from which new truths are still to be learned, the engineer must be progressive and at the same time sound; he must distinguish fallacies from truths. If he takes advantages of his opportunities during the next fifty years, the engineer will exert a greater influence upon the progress of civilization and the well-being of mankind.

The scope of our engineering societies must be broadened. They must maintain a high technical standard through interchange of the results of experience and research, as the Institute has so well done in the past, but they must also devote more time and energy to the study of economic, social and governmental problems, both national and international. Only by applying the facts, laws and lessons of science to the development and control of human nature, can our engineering societies maintain their position of leadership.

# Contributors to Social Progress

*James H. Herron,*
*President, The American Society of Mechanical Engineers*

**An address delivered in Montreal, on June 15th, 1937, during the Semicentennial Celebrations of The Institute.**

In the early days of the automobile, when its approach was heralded by much clatter and clang, and its passage left lingering memories in visible and odorous vapours, a gentleman observed a mixed group of children at play. By a stretch of his imagination he perceived they were dramatizing the new and curious type of horseless vehicle. As only children can do, a rather compact group was putting into action the chief appealing features of noise, structure and motion as best they could represent it. Trailing this group at some distance a lone little coloured girl came running after, but never gaining distance on the main group.

The gentleman thought here is a case of social distinction and class ostracism. Accordingly, he accosted the little girl and asked: "What is the matter; won't the other children let you play with them?" She replied, "Oh! I am playing automobile with them, too." "Well, what part do you represent?" "Oh, I am just the gasoline smell."

Social progress has many activities; some accelerating, some retarding. Some of them could be eliminated and their absence would not be felt. Others could be converted from impeding influences to stimulating adjuncts. And still others are characteristically essential to any advancement that may be made. It may be well to turn our eyes aside from the purely professional aspects of Engineering to let them wander over the picture of social advancement and determine what manner of adaptation engineering may have in the progress toward the ultimate goal. Is it contributory to this progress in a direct and essential way; or is it an outgrowth of what has transpired, as a necessary evil? Is it an integral part of the social mechanism or is it the gasoline smell?

It may seem trite or academic to cite in concise terms what in the minds of all seems to have a vague general meaning. "Society" and its derived terms are so common in the vocabulary of every one that it would seem a superfluous effort and a waste of time, if not also a presumption upon the intelligence of this assembly, to define it. Yet we must understand that what we mean is the intercourse of men, their actions and reactions toward each other, in communities.

Regarded in this light it is quite apparent that it has no fixed status but is ever in a constantly changing flux from what it was to what it will be in the future, environed and influenced by new relations as they develop. The influences that determine the social status at any given time are grouped under several headings listed as factors of social relations. Time will not be taken to discuss them specifically. To merely mention them must suffice. They are social customs peculiar to a community, economics, civil relationships, ethics and religion. It need not be pointed out that these are inter-active and each is a factor in determining the direction development shall take in any of the others. What the ultimate end of social progress may be no one may predict in any certain manner; but all agree that it is on its way toward an ever advancing goal, probably as inaccessible as the rainbow.

To view the past history of humanity there has been at least an apparent betterment for the populace as a whole and an expansion of that betterment to affect greater numbers. The shadows of oppression, restricted means of living and the narrow limits of personal pleasure and enjoyment have been dispelled by the greater offerings of freedom, broader living, and more time and more extension of choice of recreational delights. Progress is admitted. If engineering has had a substantial part in its promotion, it has been in the field of economics.

Engineering developments have set up a new economic structure; and the greatest concern of the present day is that of harmonizing and balancing the forces arising from the changed situation so that employment, production and consumption may keep pace with each other. Community customs have ceased to be sharply differentiated. Rural life has been given the advantages of urban culture. Country and city are now meeting on a fairly equalized plane of social interest and behaviour.

Civic organization has been compelled to adjust its operations to fit the onward press of mechanical advancement. New laws must be enacted, old laws must be revamped to fit the present needs. Greater responsibilities are imposed upon the government and new means and sources of taxation must be sought in order to meet the added burden of expense.

Ethical and religious customs are affected perhaps less by the forward sweep of the material forces, but none the less certainly because of smaller degree. Yet it is to be noted, that creeds are breaking down their walls of intolerance. It is apparent that dispersion of education and culture through the facilities offered by design and invention is exercising a leveling influence in both moral and religious intercourse.

Then how very apparent it is that engineering is not the befouling exhaust from the dynamic forces driving the social organization to its destined goal. Rather it is the very engine itself; the central sun of a system energized by its radiated power. The profession is recruited from all ranks. The humble son of poverty and adversity may aspire to contribute something to what has been already done. He may gain a place in illustrious renown with Lord Kelvin or Sir Robert Hadfield. The Dominion has furnished its share of men eminent in the profession and distinguished for their intellectual and humanistic efforts.

These men have made available the natural resources. Where water has offered a source of power, plants and machinery to utilize the energy have been devised. Uses have been sought out resulting in new enterprises. Means to carry this energy successfully for long distance have been discovered. Where minerals have been stored in natural deposits, they have been made available, by airplane, by steam line, by motor truck. The vast lumber resources and the grain of western provinces have both found an outlet to the world's markets. If waterways are needed a Welland canal shows what can be done. If open water is blocked by ice to interfere with navigation in winter, the engineer finds a way to break the icy grip and speed the vessel on its way. If the natural beauty of rugged regions, the piscatorial sport of inland waters, the restful haunts of sylvan scenes call to the touring vacationist, the roads have been prepared and sustenance made accessible.

The world is narrowed, time abbreviated, and all the people made more intimately connected. If a king takes leave of his loving and beloved subjects, his voice is carried to their ears in every part of the vast empire. If a king be crowned, the coronation ceremony is pictured in the public prints almost before the tumult and the shouting dies. To the vast multitude of loyal souls who shout "Long live the King," the new-crowned king addresses his thoughts and bespeaks the patience, loyalty and support every true leader of a people desires to have.

Truly a small world, an intimate world, and let us hope a sincerely sympathetic world!

On this semicentennial anniversary commemorating the organization of The Engineering Institute, it is significantly fitting and wholly desirable that we take cognizance of those worthy fellows who made the pioneering effort in co-operative action. Some have rested from their labours, but their good deeds live after them. Some of that charter group may still enjoy seeing the fruits ripening on the tree springing from the seed they planted fifty years ago. If such there be, may we wish them peace and tranquillity as their declining sun sinks in the west. As a proper tribute to their prowess and their achievement it is worthy that each member of the profession shall resolve that the standards set and established up to this time shall never be lowered either in the quality of the service or in the ethics of the practice.

If there is any outstanding idea to which the attention should be directed, it is one to which allusion was made earlier in this discourse. Mere mention was made that ethics as a social factor had shown less progress than most of the other factors. Mention was also made of the economic problem of adjusting labour, production and consumption relations. Here the ethical phase seems to carry in part the solution of what is a very perplexing situation.

There are social ills and misfortunes which progress has not eradicated nor in any great measure corrected. They are inherent in individual differences yet based on a rather universal human trait of acquisitiveness and self seeking. The evidences are manifest in greed, antisocial attitude, dishonesty and oppression. Individual traits, within limits, are modifiable and controllable no less than our social relations and institutions. The social-economic order may be changed by wisely guided imaginative construction and clearheaded co-operative action.

Many of our leading thinkers, and some of the best in the engineering field, have focused attention on these outstanding deficiencies of our social life. They have applied the same keen analytical powers to secure the proper perspective. The problem has been outlined, but the key to its solution is still lacking. The difficulties to be overcome, the obstacles to be surmounted are no more invincible, no more baffling than nature has presented to the engineer who has won the victory.

While not strictly an engineering activity, it appears that the fraternity has the organization, the energy and capability as well as a mandatory duty to correct the conditions. Educate out the desire of capital and labour for the greatest material return in exchange for the least expenditure of effort. It must be made clear that life has an objective, not in acquiring the means of a livelihood, but in the realization of spiritual values. A start has been made to assure a maintenance, to free the mind of the threat of future dependency, to allow a greater relief from the tension of a strenuous struggle, and to afford an unrestricted leisure for spiritual comfort. Any effort to secure these ends is a step in removing selfishness from our social order, and in setting up the principle of universal brotherhood and injunction to "love thy neighbour as thyself."

# An Appreciation

*Edward P. Lupfer,*
*Vice-President, American Society of Civil Engineers.*

**A Toast presented on June 16th, 1937, at the Semicentennial Banquet of The Institute in Montreal, at which His Excellency the Governor General was the guest of honour.**

*Your Excellency, Mr. President, Ladies and Gentlemen:*

It is my high privilege to appear before this audience as the representative of the American Society of Civil Engineers—designated by that Society to present to you a toast—a toast which shall, simply yet clearly, express to you the profound regard and affection in which that Society holds the Engineering Institute of Canada.

The American Society of Civil Engineers takes pride in being privileged to share with you the celebration of your Semicentennial, and I bring to you its heartfelt felicitations for your continued prominence and influence in the engineering world, and its wish for your undiminished success in future years.

Yours has been a remarkable record over this past half century, a record of high achievement in a high calling—a record of achievement founded upon faith for the future of your splendid Dominion—a record of achievement founded upon character—character in your individuals, which makes for the character of your Dominion.

For the moment, go back before the founding of your Institute, fifty years ago. For centuries prior to its founding, your predecessors, under yours and other flags of other nations, had carried high the torch of their profession whilst changing a virgin country into a habitable place in which to live.

These predecessors of yours, enriched with the best blood and brain the world could procure, who, prior to the formation of your Institute, had for generations been building from coast to coast, and into the far reaches of the North, shared few of the many appliances of modern living which you enjoy, but their dominant characteristic was their faith in the future of their land.

With St. Paul they believed, "that faith is the substance of things hoped for, the evidence of things not seen," and so, "they subdued kingdoms and wrought righteousness" in this fair land and out of their efforts came a breed of men who carried on—a breed of men who have character, who have the will to endure and to achieve. These men constitute the membership of your Institute, and upon the great cardinal virtues which their forbears firmly embedded in them—rests its integrity and its future.

And we who live across the invisible border *from you*, are proud *of you* and of your achievements. Unafraid and unashamed, we take this occasion to tell you so. For after all, we of these two countries are much alike, very near akin to each other, each sharing with the other its like problems, and neither departing from the high ideals which each has firmly established.

Such an occasion as this comes rarely. On this occasion our Society has a deep concern and interest in your Institute. The members of your Institute and of our Society work side by side, exchange ideas—face the same identical problems—face the future with faith—with faith in the integrity of each other.

Shortly before his retirement as Prime Minister of Great Britain, Stanley Baldwin spoke in Albert Hall on May 19th to 8,000 young men and women, gathered from every far flung colony and dominion of your great empire. It was in effect, Mr. Baldwin's farewell address, and was, in my opinion, one of the ranking speeches of the century. In it, in part, he stated that "Europe today is neither at war, nor at peace, but stands at armed attention."

We Americans, you as citizens of a great Dominion, a dominant segment of a matchless empire, we, as citizens of the States, do not now, and never shall understand that condition. *Our* countries are organized *for*, and dedicated *to*, peace.

This invisible unarmed border line between the Dominion and the States, is melted into an indistinguishable haze by the spiritual quality of mutual respect and affection—which binds us each to the other, and which, stands unequalled in world's history.

This understanding between us may have become too much, far too much of a commonplace to us—perhaps we both err in not being more articulate to the world, regarding this great heritage which we enjoy and take so casually for granted. In reality, it is our duty to stress to the world our gratitude to each other for the ties which unite us.

In the autumn of 1927, I had, as my guest in Buffalo, that rare character, Dr. Arthur S. Pringle, clergyman and scholar of England. Dr. Pringle was concluding his first visit to the United States, and was homeward bound from St. Louis where he had been a prominent speaker at the Congress on World Peace.

Dr. Pringle was vitally interested in the Peace Bridge which had been opened between our two countries but a few months before. Before leaving the city he wrote me as follows: "Here, in your own city, you have a noble and an enduring symbol of how peace can best win and consolidate her victories. The Peace Bridge—so recently opened by high officials of the United States, of England and of Canada—has for its terminal at one end, the site of a disused fort, and on the other the place where battle was once waged—a parable in steel and concrete, so to speak, of how the scenes and resources of war can be conquered and absorbed in the cause of humanity and progress, and should not such a monument be an abiding incentive to your country and mine to build between us a bridge of understanding and comradeship which must go far to insure the Peace of the World!"

Between us then, we possess a common touch of such priceless value that we dare not and must not withhold it from the world. Of this bond, we are both rightly proud—this bond, between the peoples of these two great democracies, that for one hundred and twenty years has never been broken.

And we two peoples, glorying in our freedom, our equality, our priceless independence stand closely united. Living as we do in perfect harmony, perhaps it is not too much to hope that the world at large *may* follow our example and gain our priceless peace of mind. To this end both your Institute and our Society would gladly pledge themselves.

And so, from across the border, we admire, and applaud your faith in yourselves—your dignity, your farsightedness, we admire your unafraidness—your independence—your formal simplicity—your solidarity. Feeling as we do about you, a feeling engendered and tested over many decades of neighbourliness, we look with confidence to walking beside you down the coming years, refreshed and strengthened and encouraged by your presence.

Mr. President—with great sincerity and pleasure, on behalf of the American Society of Civil Engineers, I now propose a toast to the Engineering Institute of Canada. God grant—in the years that lie before us, this sacred covenant which so closely binds these two great Societies, as well as these two great countries, may never be disturbed.

## Recent Graduates in Engineering

Congratulations are in order to the following Associate Member, Juniors and Students of The Institute who have recently completed their course at the various universities:—

### Nova Scotia Technical College

#### Prize Award

Young, Angus Francis, Sydney, N.S.—B.E. (Mech.); Association of Professional Engineers' Prize.

#### Degree of Bachelor of Engineering

Curry, Herbert Nicholas, Windsor, N.S.—B.E. (Mining).
Thompson, James William Joseph, Halifax, N.S.—B.E. (Ci.).

### The University of New Brunswick

#### Medal Award

Ross, Donald, Saint John, N.B.—B.Sc. (Ci.); The Ketchum Silver Medal for the highest standing in Civil Engineering.

#### Degree of Bachelor of Science

Baird, Malcolm Francis, Fredericton, N.B.—B.Sc. (Elec.).
Boone, Harold Percival, Fredericton, N.B.—B.Sc. (Elec.).
Dibblee, Frederick Allan, Woodstock, N.B.—B.Sc. (Elec.).
McMillan, Thomas Stewart, Jacquet River, N.B.—B.Sc. (Ci.).
Olts, George Lounsbury, Fredericton, N.B.—B.Sc. (Ci.).
Peacock, Robert Frederick, St. John, N.B.—B.Sc. (Elec.).
Ralph, John Arthur, Quebec, Que.—B.Sc. (Elec.).
Rawland, Arthur Gordon, Quebec, Que.—B.Sc. (Ci.).
Scott, James Munro, Quebec, Que.—B.Sc. (Ci.).
Springford, William Robertson Hearne, Fredericton, N.B.—B.Sc. (Elec.).
Wilkinson, William Cameron, Campbellton, N.B.—B.Sc. (Elec.).
Wilson, Murray Edgar, Moncton, N.B.—B.Sc. (Elec.).

### McGill University

#### Honours, Medals and Prizes

Bourne, James Douglas, Westmount, Que.—B.Eng. (Elec.); Honours in Electrical Engineering.
Dean, William Warren Hope, Alexandria, Ont.—B.Eng. (Elec.); Honours in Electrical Engineering; Montreal Light, Heat and Power Consolidated Prize.
Duranceau, Charles Arthur, Montreal, Que.—B.Eng. (Ci.); Honours in Civil Engineering; British Association Medal; Undergraduate Society's Third Prize for Summer Essay.
Pengally, Charles Desmond, Mandeville, Jamaica, B.W.I.—B.Eng. (Mech.); Honours in Mechanical Engineering; British Association Medal.
Seifert, Harold Lorne Bain, Quebec, Que.—B.Eng. (Chem.); Honours in Chemical Engineering.
Simpson, John Hamilton, Montreal, Que.—B.Eng. (Elec.); Honours in Electrical Engineering; British Association Medal; Montreal Light, Heat and Power Consolidated First Prize.
Taylor, Dudley Robert, Montreal, Que.—B.Eng. (Elec.); Undergraduate Society's Second Prize for Summer Essay.

#### Degree of Doctor of Philosophy

Swartz, Joseph Norman, Fort William, Ont.—B.Eng. (McGill); Ph.D., (Chem.).

#### Degree of Master of Science

Sproule, William Kelvin, Westmount, Que.—B.Eng. (McGill); M.Sc. (Met.).

#### Degree of Bachelor of Engineering

Baker, William Gordon, Outremont, Que.—B.Eng. (Chem.).
Block, Jacob Benjamin, Montreal, Que.—B.Eng. (Chem.).
Budden, John Hastings, Larkhill, Wilts, England.—B.Eng. (Elec.).
Candlish, Fairlie, Montreal, Que.—B.Eng. (Mech.).
Collingwood, John Cuthbert, St. John's, Nfld.—B.Eng. (Elec.).
Davis, Eliot Robertson, Winnipeg, Man.—B.Eng. (Mech.).
Dick, William Arthur, Quebec, Que.—B.Eng. (Mech.).
Drake, Thomas Stuart, St. Catharines, Ont.—B.Eng. (Mech.).
Duckett, William Anderson, Montreal South, Que.—B.Eng. (Elec.).
Exelrod, Bert, Montreal, Que.—B.Eng. (Ci.).
Horwood, William Osmund, Montreal, Que.—B.Eng. (Mech.).
Jacobs, David Sinclair, Montreal West, Que.—B.Eng. (Ci.).
Jones, David Carlton, Vulcan, Alta.—B.Eng. (Mech.).
Killam, Frank Richard, Vancouver, B.C.—B.Eng. (Mech.).
King, Donald, Montreal, Que.—B.Eng. (Elec.).
Kingsland, Edward Notman, Westmount, Que.—B.Eng. (Mech.).
Kirkpatrick, Robert Evans, Montreal West, Que.—B.Eng. (Mech.).
Lacombe, Jean Louis, Sherbrooke, Que.—B.Eng. (Ci.).
LeBel, Harry W. S., Namur, Que.—B.Eng. (Mech.).
Lochhead, John Starley, Montreal West, Que.—B.Eng. (Ci.).
Loiselle, Harold John, Outremont, Que.—B.Eng. (Chem.).
Lyons, Joseph Harvey Kent, Winnipeg, Man.—B.Eng. (Mech.).
MacGibbon, James Alexander, Brownsburg, Que.—B.Eng. (Mech.).
McLean, Murray Douglas, Montreal, Que.—B.Eng. (Elec.).
MacLeod, Gordon Ross, Montreal, Que.—B.Eng. (Mech.).
Macnutt, Ernest Gerrard, Westmount, Que.—B.Eng. (Mech.).
Maguire, James Cornelius, Outremont, Que.—B.Eng. (Chem.).
Mahoux, Raymond Jean, Montreal, Que.—B.Eng. (Mech.).
Martin, Henri Milton, Edmonton, Alta.—B.Eng. (Chem.).
Moseley, Shirley Charles Tilton, Lunenburg, N.S.—B.Eng. (Mech.).
Nicholson, John Haines, St. Lambert, Que.—B.Eng. (Chem.).
Nowlan, Brete Cassius, Jr., Montreal, Que.—B.Eng. (Elec.).
Parker, Edmund Norval, Winnipeg, Man.—B.Eng. (Mech.).
Payan, Charles Frederick, St. Hyacinthe, Que.—B.Eng. (Chem.).
Pinder, Harold Clay, LaPorte, Sask.—B.Eng. (Mech.).
Scriver, Bruce MacKenzie, Outremont, Que.—B.Eng. (Chem.).
Senicie, Michael, Ladywood, Man.—B.Eng. (Mi.).
Shector, Lindley, Outremont, Que.—B.Eng. (Ci.).
Smith, Allan Garfield, Outremont, Que.—B.Eng. (Elec.).
Sparks, Roderick Fraser, Ottawa, Ont.—B.Eng. (Mech.).
Thomson, John Alexander, Carlisle, England—B.Eng. (Elec.).
Wesley, William Grant, Outremont, Que.—B.Eng. (Elec.).

### Ecole Polytechnique

#### Liste des Diplômes Décernés aux Elèves de la 61e Promotion 1936-37

Cousineau, Yvon, Montréal, Qué.—B.A.Sc. (Ci.); Médaille d'Argent de l'Association des Anciens Elèves de l'Ecole Polytechnique; Prix Paul d'Aragon pour succès en Mines.
DeGuise, Yvon, Verdun, Qué.—B.A.Sc. (Ci.), avec "Grande Distinction"; Médaille de Bronze de l'Association des Anciens Elèves de l'Ecole Polytechnique.
Des Ormeaux, Dollard, Montréal, Qué.—B.A.Sc. (Ci.), avec "Grande Distinction."
Leblanc, Raymond F., Montréal, Qué.—B.A.Sc. (Ci.); Prix de la 50e Promotion de l'Ecole Polytechnique offert à l'élève qui a soumis la meilleure thèse industrielle de fin d'année.
Lecavalier, Jean Paul, Montréal, Qué.—B.A.Sc. (Ci.), avec "Très Grande Distinction; Médaille d'Argent du Lieutenant Gouverneur de la Province de Québec; Médaille d'Or de l'Association des Anciens Elèves de l'Ecole Polytechnique; Prix d'Architecture Ernest Cormier.
Pouliot, Paul Louis, Montréal, Qué.—B.A.Sc. (Ci.), avec "Distinction."
Rose, Paul Emile, Montréal, Qué.—B.A.Sc. (Ci.); Médailles de Bronze de l'Association des Anciens Elèves de l'Ecole Polytechnique.
Saintonge, Rosaire, Montréal, Qué.—B.A.Sc. (Ci.), avec "Distinction."
Simard, J. Marcel, Montréal, Qué.—B.A.Sc. (Ci.), avec "Distinction."

#### Ingénieurs Civils

Bolduc, Armand, Montréal, Qué.—B.A.Sc. (Ci.).
Buteau, Lucien, Montréal, Qué.—B.A.Sc. (Ci.).
Desmarais, Jean René, Montréal, Qué.—B.A.Sc. (Ci.).
Dufour, Gaston, Outremont, Qué.—B.A.Sc. (Ci.).
Frigon, Rosario, Shawinigan Falls, Qué.—B.A.Sc. (Ci.).
Lemieux, Roland A., Montréal, Qué.—B.A.Sc. (Ci.).
Mailhot, Gaston, Montréal, Qué.—B.A.Sc. (Ci.).
Richer, Baxter, Montréal, Qué.—B.A.Sc. (Ci.).
Roy, Louis Philippe, Montréal, Qué.—B.A.Sc. (Ci.).
Scheen, Marcel, Montréal, Qué.—B.A.Sc. (Ci.).

### Queen's University

#### Honours, Medals and Prizes

Carson, Robert John, Kingston, Ont.—B.Sc. (Ci.); Honours in Civil Engineering.
Elmsley, Clarence Mathieu Remy, Windsor, Ont.—B.Sc. (Mech.); Honours in Mechanical Engineering.
Hyde, Arthur Edwin, Hamilton, Ont.—B.Sc. (Met.); Honours in Metallurgical Engineering; Departmental Medal.
Scobie, Alexander Gordon, Hamilton, Ont.—B.Sc. (Chem.); Honours in Chemical Engineering; Departmental Medal; The E. T. Sterne Prize in Chemical Engineering.
Swingler, Russell Henry, Port Arthur, Ont.—B.Sc. (Mech.); Honours in Mechanical Engineering; Departmental Medal; L. M. Arkley Prize.

#### Degree of Bachelor of Science

Ahearn, William Jefferson, Ottawa, Ont.—B.Sc. (Elec.).
Andre, Kenneth Bailey, Kingston, Ont.—B.Sc. (Ci.).
Ansley, Frederick Charles, Toronto, Ont.—B.Sc. (Ci.).
Briceland, Emmett Vincent, Kingston, Ont.—B.Sc. (Mech.).
Crothers, Donald Coverdale, Kingston, Ont.—B.Sc. (Mech.).
Giles, J. Oscar, Sarnia, Ont.—B.Sc. (Mech.).
Gordon, John Edward, Dundas, Ont.—B.Sc. (Mech.).

Hertel, Alfred Barnard Frederick, London, Ont.—B.Sc. (Ci.).
Kennedy, Harold E., Toronto, Ont.—B.Sc. (Mech.).
Kent, Allan Douglas, Kingston, Ont.—B.Sc. (Mech.).
Marshall, Welsford Allen, Ottawa, Ont.—B.Sc. (Ci.).
Molland, Frederick William, Thorndale, Ont.—B.Sc. (Mech.).
Robinson, William Morecroft, Dundas, Ont.—B.Sc. (Mi.).
Sanders, George Ostrom, Cornwall, Ont.—B.Sc. (Mech.).

## Royal Military College

### Prize Award

Drury, C. H., Montreal, Que.—Graduate. Second-Class General Proficiency Prize.

### Graduates

Ross, J. H., Kingston, Ont.
Savard, J. G., Kingston, Ont.

## University of Toronto

### Degree of Doctor of Philosophy

Heatley, Albert Harold, Toronto, Ont.—B.A.Sc., M.A., Ph.D.

### Degree of Master of Applied Science

Corbett, Bruce Sherwood, Edmonton, Alta.—B.Sc. (Alberta). M.A.Sc.
Dembitzky, Thomas Morris, Toronto, Ont.—B.A.Sc., M.A.Sc.
McRae, Robert Bruce, Edmonton, Alta.—B.Sc. (Alberta). M.A.Sc.

### Degree of Civil Engineer

Sagar, William Lister, Toronto, Ont.—B.A.Sc., C.E.

### Degree of Bachelor of Applied Science

Bodwell, Geoffrey Lionel, Toronto, Ont.—B.A.Sc. (Ci.).
Christian, John Despard, Toronto, Ont.—B.A.Sc. (Mining).

## University of Manitoba

### Medal Award

Moule, Gerald W., Winnipeg, Man.—B.Sc. (Elec.); University Gold Medal.

### Degree of Bachelor of Science

Arnason, Einar, Winnipeg, Man.—B.Sc. (Elec.).
Henselwood, Edward Wilton, W. Kildonan, Man.—B.Sc. (Elec.).
McIntosh, William Gardner, Winnipeg, Man. B.Sc. (Elec.).
Miller, John Jackson, Winnipeg, Man.—B.Sc. (Elec.).
Robinson, Arthur Harold, Winnipeg, Man.—B.Sc. (Ci.).
Scarlett, Barnes Kossuth, Winnipeg, Man.—B.Sc. (Elec.).
White, William Barr, Winnipeg, Man.—B.Sc. (Ci.).
Wilson, Bertram Henry John, Winnipeg, Man.—B.Sc. (Ci.).

## University of Alberta

### Honours and Prize Awards

Edwards, Milton Chalbers, Edmonton, Alta.—B.Sc. (Elec.); Honours in Electrical Engineering.
Hindle, Walter, Edmonton, Alta.—B.Sc. (Elec.); Honours in Electrical Engineering.
Martin, Tom Elbert, Edmonton, Alta.—B.Sc. (Chem.); The Association of Professional Engineers of Alberta Prize.
Poole, John Edward, Edmonton, Alta.—B.Sc. (Ci.); Honours in Civil Engineering; The Association of Professional Engineers' of Alberta Prize.
Thompson, Arthur McCall, Edmonton, Alta.—B.Sc. (Elec.); Honours in Electrical Engineering; The Association of Professional Engineers' of Alberta Prize.
Waters, Donald Samuel Brooks, Calgary, Alta.—B.Sc. (Ci.); Honours in Civil Engineering.

### Degree of Bachelor of Science

Algot, Clarence Aldo, Derwent, Alta.—B.Sc. (Elec.).
Bogart, Evan Winston, Edmonton, Alta.—B.Sc. (Chem.).
Burke, John Abel, Lethbridge, Alta.—B.Sc. (Ci.).
Chambers, Robert, Edmonton, Alta.—B.Sc. (Elec.).
Connell, Gordon Allen, Edmonton, Alta.—B.Sc. (Chem.).
Elford, Wesley Fred, Foremont, Alta.—B.Sc. (Elec.).
Forsythe, Marshall Anthony, Clover Bar, Alta.—B.Sc. (Elec.).
Hurst, Charles Kenneth, Calgary, Alta.—B.Sc. (Ci.).
Kirkland, William Dalton, Edmonton, Alta.—B.Sc. (Elec.).
Klodniski, Nicholas Albert, Edmonton, Alta.—B.Sc. (Elec.).
Oliver, James, Calgary, Alta.—B.Sc. (Ci.).
Redmond, William Lawson, Edmonton, Alta.—B.Sc. (Mi.).
Stafford, James Walter, Edmonton, Alta.—B.Sc. (Elec.).

## Elections and Transfers

At the meeting of Council held on July 16th, 1937, the following elections and transfers were effected:—

*Member*

SANNE, Einar Trygue, chief dftsman., Montreal Locomotive Works Ltd., Montreal, Que.

*Associate Members*

ASTELS, Fletcher, B.S. (E.E. and C.E.), (Tri-State College), 474 Cooper St., Ottawa, Ont.
ALLEN, Archie Menzo, constrn. engr., Alberta Government Telephones, Edmonton, Alta.
BUTLER, Ernest, (Inst. Technology, Manchester), chief designer, Wayagamack Divn., Consolidated Paper Corpn., Three Rivers, Que.
EVANS, Beverley Abbott, B.Sc., M.Sc., (Univ. of Sask.), senior asst. engr., Dept. of Public Works, Canada, Saskatoon, Sask.
HARLING, Frank Norman, B.Sc., (McGill Univ.), engr., Canadian Industries Ltd., Montreal, Que.
MOLLER, Holger Peter, E.E., (Royal Tech. Coll., Copenhagen), elec. supt., Lake St. John Power and Paper Co Ltd., Dolbeau, Que.
McRAE, Ian F., asst. works manager, Peterborough plant, Can. Gen. Elec. Co. Ltd., Peterborough, Ont.
ODELL, Russell Kenneth, (Royal Naval College), chief, development divn., Bureau of Economic Geology, Department of Mines, Ottawa, Ont.
ORLANDO, Edward Eugene, B.Sc., (N.S. Tech. Coll.), sales engr., Canadian Westinghouse Co. Ltd., Montreal, Que.
PARE, A Euclide, B.A.Sc., C.E., (Ecole Polytechnique, Montreal), asst. engr., hydraulic service, Dept. of Public Works, Quebec, Que.
ROLPH, Frank Bernard, (Grad., R.M.C.), B.Sc., (McGill Univ.), engr. i/c field constrn., John S. Metcalf Co. Ltd., Montreal, Que.
STALKER, Andrew Douglas, (Queen's Univ.), asst. city water works engr., Ottawa, Ont.
WANGEL, Reinhold, C.E., (Tech. Univ. of Finland), designer, heating dept., Warden King Ltd., Montreal, Que.

*Juniors*

COLPITTS, Cecil Ashton, B.Sc., (Univ. of Man.), transitman, C.P.R., Calgary, Alta.
HENSON, George Stanley Gordon, B.Sc., (Univ. of Man.), dftsman., Winnipeg Electric Co., Winnipeg, Man.
LEFRANCOIS, J. Germain, B.A.Sc., C.E., (Ecole Polytechnique, Montreal), sales engr., Canadian Fairbanks Morse Co. Ltd., Montreal, Que.
PETERSON, Alfred, B.Eng., (McGill Univ.), instrument engr., Abitibi Power and Paper Co., Iroquois Falls, Ont.
TAYLOR, Thomas Allistair Ian Clar, B.Sc., (Univ. of Alta.), plant engr., Saguenay Power Co. Ltd., Isle Maligne, Que.

*Transferred from the class of Associate Member to that of Member*

BUCHANAN, Colin Archibald, B.Sc., (McGill Univ.), chief engr., Donnacona Paper Co. Ltd., Portneuf, Que.
PEARSON, Vernon, (Brassey Institute), mech. supt., Govt. of Alberta, Edmonton, Alta.

*Transferred from the class of Junior to that of Associate Member*

CRATCHLEY, Reginald Henry, office engr., Penitentiaries Branch, Department of Justice, Ottawa, Ont.
de JONG, Sybren Henry, B.Sc., (Univ. of Man.), compiler, Topographic and Air Surveys Branch, Dept. of Mines and Resources, Ottawa, Ont.
HARDY, Robert McDonald, B.Sc., (Univ. of Man.), M.Sc., (McGill Univ.), lecturer in civil engrg., University of Alberta, Edmonton, Alta.
McCORMACK, Donald Neill, B.Sc. (E.E. and C.E.), (Univ. of N.B.), engr., Spruce Falls Power and Paper Co. Ltd., Kapuskasing, Ont.
NEIL, John Stuart, B.Sc., (Univ. of Alta.), test engr., Canadian Western Natural Gas, Light, Heat and Power Co. Ltd., Calgary, Alta.
WILLIAMS, Richard Louis, B.Sc., (McGill Univ.), designer and estimator, Dominion Bridge Co. Ltd., Lachine, Que.

*Transferred from the class of Student to that of Junior*

LILLEY, Ledford George, B.Sc., (Univ. of N.B.), dftsman. Dept. Public Works of Canada, Saint John, N.B.
MATHIESON, John Richard, B.Sc., (Univ. of Man.), designer-dftsman., C. D. Howe Co. Ltd., Port Arthur, Ont.
PASK, Arthur Henry, B.Sc., (Univ. of Man.), asst. plant engr. Eagle Pencil Co. Ltd., Drummondville, Que.

*Students Admitted*

ANSLEY, Fred C., B.Sc., (Queen's Univ.), 826 Argyle Road, Walkerville, Ont.
FAST, Morris, (Univ. of Sask.), 785 Hartland Ave., Outremont, Que.
LAVERGNE, Emile Denis, B.S. in C.E., (Univ. of Mich.), 57 Fifth St., Shawinigan Falls, Que.
LOWLES, George Albert, B.Eng., (McGill Univ.), chemist, Canadian Industries Ltd., Montreal, Que.
MYERS, Gordon Alexander, B.Eng., (N.S. Tech. Coll.), 134 Henry St., Halifax, N.S.
PRITCHARD, Geoffrey Rowland, B.Sc., (Univ. of Man.), 175 Oakdale Place, St. James, Man.
TOWLE, Harold Martin, (McGill Univ.), 302 Cote de Liesse Road, Mount Royal, Que.
WELDON, George Horace, B.Sc., (Univ. of Man.), 267 Woodlawn St., Winnipeg, Man.

# BOOK REVIEWS

## Storage Reservoirs

*By George Bransby Williams, Chapman and Hall Limited, London 1937 9 by 6 inches 25/- Cloth 300 pages.*

The severe droughts of recent years followed by the floods in England, America and elsewhere, have aroused general interest in the question of the regulation of the flow of rivers. An obvious way of controlling the flow of a river is by building storage reservoirs on its catchment. Of all the forms of engineering enterprise, none has affected the welfare of the human race more materially than the design and construction of storage reservoirs. They have been built all over the world for all sorts of purposes. In India they provide the irrigation water that preserves many millions of the inhabitants of that country from the dangers of ruin and starvation to which their ancestors have been exposed for ages. They hold the water supply of the largest cities, and, feed the hydroelectric power stations from which an increasing proportion of the world's electric energy is derived. Reservoir projects for flood control have been carried out, or proposed, in some parts of America, and are now contemplated on a much larger scale to prevent the recurrence of disasters such as that which recently overwhelmed the Ohio Valley. The construction of storage reservoirs has become popular, a national, even an imperial question and concerns not only engineers. Their part is to design and construct the reservoirs, but the public has to find the money, and now the latter are beginning to realise that money spent on protection against droughts and floods will probably prove an economic insurance.

A treatise on this subject by Mr. George Bransby Williams gives an up-to-date description of the principles on which these reservoirs should be designed. The book is largely technical, and written for practising engineers, but much of it, for example the portions dealing with rainfall phenomena in various parts of the world, methods of estimating the volumes of water likely to be discharged in floods, the types of dams built in Great Britain, America, India and elsewhere, and an illustrated itinerary of a journey round many of the reservoirs and dams of Great Britain, will appeal to many who possess little engineering knowledge.

The book contains eleven chapters in all some 300 pages. It is well illustrated with a large number of exceptionally clear diagrams and also photographs. Of particular interest to the designing engineer are the chapters on single-arch masonary and gravity dams; multiple arch, reinforced concrete, earth, hydraulic-fill and rock-fill dams. Chapters VIII, IX and X cover regulation of storage, methods of construction and the treatment of water supplies.

## Foundations in New Orleans and Vicinity

*Compiled by the Soil and Foundation Survey, a project of the Works Progress Administrations of Louisiana. (Published by the Works Progress Administration of Louisiana, New Orleans, Lo.) 1937. 13 x 16 inches. Cloth 277 pages.*

"Some data in Regard to Foundations in New Orleans and Vicinity." is the result of investigations carried out at the suggestion of the Louisiana Engineering Society and while setting an excellent example to many cities fulfills, in the case of New Orleans, a long felt need for a comprehensive collection of data on foundation conditions and building settlements.

Numerous instances of settlement due to the deep, soft ground in that region, promise to make the records just published of permanent value.

The volume contains four main chapters covering the history and geology of the region and including a map of New Orleans 35 x 38 inches which locates the test borings—referred to in Chapter II. These 239 test borings are described by means of stratigraphs many being carried to depths as great as 400 feet. Chapter III covers pile foundations and IV spread footings. A large amount of information is also included in the records of the foundation construction and settlement of nearly eighty buildings, stacks, seawalls and bridges.

It is not intended that the data contained in this publication should be used as an authority for the design of similar structures but as a reference of actual factual data to be used by engineers and architects in solving foundation problems of similar kinds.

## Refrigeration Engineering

*By H. J. Macintire. John Wiley and Sons, New York. (Renouf Publishing Company, Montreal) 1937. 9 x 6 inches. $4.50. Cloth 415 pages.*

The author is professor of refrigeration in the University of Illinois and his book is intended to present the subject of refrigeration engineering to senior engineering students.

The expanded field of refrigeration has been treated from fundamentals, assuming a knowledge of thermodynamics. The early chapters containing the theory and covering such subjects as thermodynamics, theoretical cycles of compression machines, refrigerants, flow of fluids and heat transfer, insulation, evaporation and liquefaction and finally the adsorption and its allied cycles. The liberal use of illustrative examples has made the mathematical material easy to follow.

Chapter III on refrigerants and properties of saturated and superheated vapours contains some useful tables.

The last decade has seen a remarkable advance in the refrigeration industry bringing a clearer conception of the mechanism of certain phases of heat transfer with the result as the author points out, that the design of condensers and evaporators has been radically changed and improved.

Chapters IX to XV include material on the following subjects:—compression and automatic refrigerating machines, household machines, the erection, operation and testing of machines, air conditioning, cold storage, ice manufacture and special applications.

The book is well illustrated with diagrams and a considerable number of references to the sources of information are provided in the form of footnotes.

## BULLETINS

*Elevating Graders.*—An 8-page bulletin issued by the Caterpillar Tractor Company, Peoria Illinois, gives particulars of their engine driven plough and carrier, with 48 and 42 inch carrier belt.

*Diesel Engines.*—Caterpillar Tractor Company, Peoria Illinois, have issued a 32 page booklet giving examples of the uses and the large number of industries operating these engines.

*Welding in Construction Work.*—The Lincoln Electric Co., Cleveland Ohio, have issued a 12 page pamphlet giving examples of the uses of welding in construction work. This includes considerable data and various examples are illustrated.

*General Electric Motors.*—A 4-page booklet has been received from the Canadian General Electric Co., Ltd., giving a few particulars of a number of their standard types of motors and starters.

*Couplings.*—Dominion Engineering Company have prepared a 12-page bulletin with details of Gearflex couplings.

*Tractors Road Machinery and Engines.*—A 32-page bulletin received from the Caterpillar Tractor Company, Peoria Illinois illustrates the many types of construction work on which this equipment may be utilized.

*Mine Pumps.*—This 6-page leaflet issued by the Worthington Pump and Machinery Corporation, Harrison, N. J. describes the wide range of pumping equipment manufactured by this company.

*Sewage Sludge Gas Engines.*—An 8-page bulletin issued by the Worthington Pump and Machinery Corpn., Harrison, N. J. describes the use of sewage sludge gas as a fuel for engines.

*Paper Stock Pumps.*—These are described in an 8-page booklet issued by the Worthington Pump and Machinery Corpn. They are of the centrifugal type and are capable of handling paper at all consistencies.

*Air Compressors.*—An 8-page bulletin received from the Worthington Pump and Machinery Corpn., illustrates their vertical single stage air compressor giving particulars of the construction.

## How to Run a Lathe

The 33rd edition of the well-known machinists' manual, "How to Run a Lathe," has recently been announced by its publisher, The South Bend Lathe Works, South Bend, Indiana. The new edition has 160 pages containing information about modern lathe practice accompanied with more than 300 illustrations.

Copies are priced at 25 cents each, and will be mailed post-paid anywhere in the world.

## Congress of Engineers

**Paris—September, 1937**

In connection with the International Exposition which is being held in Paris this year, a Congress of Engineers will be held from the 26th to the 29th September at which foreign engineers will be welcome. Applications for membership (accompanied by a remittance of 75 fr.) should be addressed to:

M. Ferrier,
9 rue Pasteur,
Levallois-Perret (Seine), France.

In addition to the technical sessions, members can take advantage of special rates on the French Railways and at the Exposition—an extensive programme of technical visits is also being arranged to power stations, laboratories and industrial establishments.

Further information can be obtained from the Secretary of the Organization Committee, 19 Rue Blanche, Paris (IX )

## President's Visits to Western Branches

G. H. Desbarats, Hon. M.E.I.C., President of the Engineering Institute of Canada is leaving Ottawa on August the fifth for a visit to the Western Branches of The Institute. The following is his itinerary according to present plans.

Sault Ste Marie, Ontario, August 6th to 8th.
Fort William, Ontario, August 9th.
Regina, Saskatchewan, August 10th to 12th.
Lethbridge, Alberta, August 14th.
Calgary, Alberta, August 15th to 16th.
Vancouver, August, 20th and 24th to 26th.
Victoria, August, 21st and 22nd.
Edmonton, Alberta, August 28th.
Winnipeg, Manitoba, August 29th to 31st.
Port Arthur, Ontario, September 1st.

## Joint Meeting of the Institute and The American Society of Civil Engineers Hotel Statler, Boston, Mass.

**Wednesday, Thursday and Friday, October 6th, 7th and 8th, 1937**

### Outline Programme

(*Subject to minor changes*)

Wednesday—October 6th

*Morning:*

Registration.

Joint Session of the American Society of Civil Engineers and The Engineering Institute of Canada.

*Chairman:* Frank A. Barbour, M.Am.Soc.C.E., M.E.I.C.

Addresses of welcome from the State and the City will be given by the Governor of Massachusetts and the Mayor of Boston.

Responses by Louis C. Hill, President, American Society of Civil Engineers and George J. Desbarats, President, The Engineering Institute of Canada.

Brief addresses will follow by Dr. James Bryant Conant, President of Harvard University, and Dr. Karl Taylor Compton, President of Massachusetts Institute of Technology.

An address on The Cultural and Technical Background of the "New Architecture" will be given by Walter Gropius, Professor of Architecture, Harvard University.

At luncheon the speaker will be Colonel Willard T. Chevalier, Past-Director of the American Society of Civil Engineers. Colonel Charles R. Gow, M.Am.Soc.C.E., presiding.

*Afternoon:*

The afternoon will be devoted to a joint meeting, conducted by The Engineering Institute of Canada, *Chairman:* Fred. Newell, Member of Council, The Engineering Institute of Canada. The following papers will be presented and discussed:

**"The Substructure of the New Highway Bridge over the Fraser River at New Westminster, British Columbia,"** by Major Wm. G. Swan, M.E.I.C., Consulting Engineer, Vancouver, P.C.

**"Recent Developments at the Port of Halifax,"** by E. H. James, M.E.I.C., Consulting Engineer, Montreal, Que.

**"The Conception and Design of the Outardes Hydro-Electric Project."** by H. G. Acres, M.E.I.C., Consulting Engineer, Niagara Falls, Ontario.

On Wednesday evening entertainment will be arranged for members and guests, including ladies.

Thursday, October 7th

*Morning and afternoon:*

Meetings of the following six divisions of the American Society of Civil Engineers will be held simultaneously in four rooms:—

(*a*) Soil Mechanics and Foundation Division.
(*b*) Sanitary Engineering Division and City Planning Division.
(*c*) Surveying and Mapping, Division and Waterways Division.
(*d*) Engineering-Economics Division.

Among the various topics to be dealt with the following may be named:

**"Applications of Soil Mechanics to the Design of Levees in the Lower Mississippi Valley."**
**"The Application of Soil Mechanics to Building Foundations."**
**"The Pollution of Boston Harbour."**
**"Land Registration in Massachusetts."**
**"Recent Developments in Marine Borer Studies."**
**"The Hazards of Uneconomic Public Works Construction."**
**"The Economic Advantages of Orderly Planning of Public Works."**

In the evening a dinner and dance will take place in the Imperial Ball Room. Edward L. Moreland, M.Am.Soc.C.E., presiding.

Friday, October 8th

The closing day of the meeting will be devoted to inspection trips, including visits to Harvard University, and the Massachusetts Institute of Technology, followed by an excursion to the North Shore, Nahant and Marblehead. All the parties will meet at the New Ocean House, Swampscott, for a New England Shore Dinner at one o'clock.

For those who wish to go further afield, transportation will be provided to the Cape Cod Canal, which is being enlarged, and to the Quabbin Dam of the Metropolitan District Water Supply Commission, which is under construction by the hydraulic fill method.

Special excursions are being arranged for ladies as follows:

Wednesday, October 6th

Visit to the Isabella Gardner Museum, Boston.

Thursday, October 7th

Trip to Concord and Lexington with luncheon at Wayside Inn, Sudbury, Mass.

# BRANCH NEWS

## Border Cities Branch

*J. F. Bridge, A.M.E.I.C., Secretary-Treasurer.*
*F. J. Ryder, Jr.E.I.C., Branch News Editor.*

The last meeting of the Border Cities Branch prior to the summer adjournment was held in the Prince Edward hotel, Friday evening May 28th, 1937.

E. T. Harbert, A.M.E.I.C., chief designer of the Compressor Department of the Canadian Ingersoll Rand Company, Sherbrooke, Que., presented the members with an illustrated paper on "The Design of Air Compressors."

The paper was confined to the features of design as they affect the user. The pressure ranges of modern machines are vacuum to atmospheric; atmospheric to 2 or 3 lb.; atmospheric to 80 lb. to 7,000 to 8,000 lb. These pressures may be obtained by one of the following classes of machines: blowers, reciprocal centrifugal, rotary and hydraulic compressors. In selecting a machine the following conditions should be considered:

1. Capacity required (cubic feet of free air per minute.)
2. Power consumption.
3. Operating Pressure (100 lb. per square inch standard.)
4. Losses occurring in pipe lines, fittings and valves.
5. Intermittent use calls for storage receiver.
6. If air at two different pressures is required it is usually more economical to have two installations as reducing valves are wasteful of power.

Power consumption is based on isothermal formula.

The losses occurring are: friction of machine, heating of air, through intake valves, friction in pipe lines and reducing valves.

Types of prime movers used are: electric motor (most common), steam engine, oil engine, most of these being of the constant speed type.

Compressor valves are the heart of the compressor and have seen many changes. The more familiar types are: the poppet valve, corliss leaf, plate and channel valves.

New compressors as compared with older types are smaller, more efficient, occupy less floor space. The use of long sweep elbows assists in reducing friction losses in the pipe line.

Where storage receivers are used the capacity of tank is usually the capacity of compressor for one minute.

A very hearty vote of thanks was moved by J. E. Porter, A.M.E.I.C., and extended to Mr. Harbert by C. F. Davison, A.M.E.I.C., the Branch chairman.

## London Branch

*D. S. Scrymgeour, A.M.E.I.C., Secretary-Treasurer.*
*Jno. R. Rostron, A.M.E.I.C., Branch News Editor.*

The regular monthly meeting was held on the 20th May, 1937, in the Council Chamber, County Buildings, London.

The speaker of the evening was S. W. Archibald, M.E.I.C., and his subject "Flood Control on Western Ontario Streams."

W. C. Miller, M.E.I.C., presided, in the unavoidable absence of the Branch chairman, A. O. Wolff, M.E.I.C.

Mr. Miller, when introducing the speaker, who is one of the Branch members, referred to the disastrous flood of the River Thames on the 26th and 27th April last and pointed out, that although Mr. Archibald's paper has been prepared some time previously to those dates, it was now most opportune in view of measures which are at present under consideration for preventing any recurrence of such a catastrophe.

### Flood Control on Western Ontario Streams

The evolution of drainage and flood control measures in England was traced from the early enactments of the reign of Henry VIII to the present time, dealing particularly with the report of a special committee of the House of Lords presented in 1877, the report of the Royal Commission appointed in 1927 and the subsequent Land Drainage Act of 1930. Briefly, the findings of the Royal Commission of 1927 were very similar to those of the House of Lords special committee and recommended drastic revision and repeal of existing drainage and control legislation. Outstanding conclusions of the Royal Commission were: firstly, that all upland owners contributing water in any way by artificial means, were responsible to some extent for the safe passage of the waters from their lands to the sea. Secondly, that the financial interest of any lands in any drainage and river control works should be determined by the "annual value" of such lands. Thirdly, that to arrive at a comprehensive and satisfactory system of control, arterial streams and drainage channels should be designated as "Catchment areas" and the full control of such streams and the works thereon should be vested in catchment area boards composed of representatives of all municipalities and authorities interested. The recommendations of the Royal Commission were largely acted upon by the passing of the Land Drainage Act, 1930. The catchment areas recommended by the Royal Commission were approved and provision made for establishing others. The following are definitions taken from Land Drainage Act, 1930: "Drainage," except in the phrase "any enactments relating to the drainage of land," includes defence against water, irrigation, warping and the supply of water"; "Drainage authority" means any drainage board constituted, or to be treated as having been constituted, under this Act, or any other body of persons having power to make or maintain works for the drainage of land"; "Land" includes water and any interests in land or water and any easement or right in, to, or over land or water"; "Main river" includes any structure or appliance for controlling or regulating the flow of water in or out of the channel, and situate therein or in any part of the banks thereof other than any such structure or appliance which is vested in or controlled by an internal drainage board"; "Watercourse" includes all rivers, streams, ditches, drains, cuts, culverts, dykes, sluices, sewers (other than sewers under the control of a local authority within the meaning of the Public Health Act, 1875) and passages, through which water flows.

The extent of flood control measures necessary in the United States was stressed and illustrated by the following figures:

*Catchment Areas*

| | |
|---|---|
| Thames river at Byron, Ont. | 1,230 square miles |
| Grand river at Galt, Ont. | 1,360 square miles |
| Tennessee river at Ohio | 40,423 square miles |
| Ohio river at Mississippi | 203,782 square miles |
| Mississippi river | 1,231,492 square miles |

Quotations were read from notes on flood control issued by the United States War Department through the office of the Chief of Engineers, Washington, D.C., August 1936 which lists the methods of flood control under:

1. The construction of levees to hold the water off the land and confine it to established channels of discharge.
2. The enlargement of the discharge capacity of the natural channels by various means, such as straightening, widening and deepening; in other words, by an increase of the slope or cross-section of the natural channel.
3. The provision of means for the escape or diversion from the main channels into additional or auxiliary or emergency channels of flood waters in excess of the carrying capacity of the main channels.
4. The construction of reservoirs to withhold, temporarily, from the natural channels water in excess of their discharge capacities, releasing this stored water in such quantity, and at such times, that it may safely be carried in the natural channels.

From the discussion of the above methods in the notes, a conclusion is drawn that the construction of levees is the most direct and surest method but that a combination of levees and reservoirs might insure the most adequate and efficient protection.

Dealing with conditions and present problems in Ontario, the report of Grand River Drainage, Department of Lands and Forests, Ontario, 1932, was dealt with at length. The factors contributing to floods most blamed in the press and elsewhere are deforestation and artificial drainage. From the Grand River Drainage report it would appear that neither of these causes are as basic as they are usually considered. At a time when saturation of a large area exists and a combination of factors tending to produce maxima run-offs is present, serious and dangerous floods will occur little affected by either of the above causes. From a review of the history of the effort of the Grand River Conservation Commission to obtain relief and the legal difficulties and diversity of interest encountered by it, it was suggested that existing legislation in Ontario, namely the Municipal Drainage Act and provincial aid to Drainage Act, be carefully studied to see whether or not by minor amendments these Acts could apply to general river control, and particularly, flood control. The evolution of the Municipal Drainage Act and the extent of its application to the lands at the headwaters of the River Thames in particular, was explained. In respect to the uplands of the Thames river water shed in particular, artificial drainage has been and is responsible for the growth and development of one of the finest agriculture districts in the world and although clearing and draining of the lands speed up runoff, the condition does and must continue to exist, in the opinion of the speaker.

Amendments of 1936 Municipal Drainage Act, particularly section 1 d.d. "'Drain' and 'drainage' work shall include all protective banks, wall, crib works, dykes and other works ancillary thereto," was discussed. In the opinion of the speaker, the control of each western Ontario river devolves both privileges and responsibilities upon all residents within their water shed; that as in England, "Annual Value" should be the basis of assessment of property abutting upon a remedial work; that existing legislation be amended or implemented to provide for the establishment of river boards on arterial streams with responsibility and powers similar to the catchment area boards of England; and that the Provincial and Federal Governments be represented on said boards and contribute as is now done by the province under the provisions of the Provincial Aid to Drainage Act, and by the Federal Government to the extent that control of water is a national problem and according to benefits which might accrue to navigation channels in the future.

An animated discussion followed the speaker's address. About forty-three members and guests were present and many of them were vitally interested in the subject, as they had suffered considerable damage from the recent floods.

Space will not permit the writer giving a full account of the discussion, suffice it to say that the chief interest centred around such matters as government responsibility in matters of this kind, coupled with the question of navigability or otherwise of the streams involved; the provisions and limits of the Drainage Act; the advantage or otherwide of reforestation; the apportionment of cost, etc.

A hearty vote of thanks was proposed by H. F. Bennett, M.E.I.C., seconded by E. V. Buchanan, M.E.I.C., and unanimously carried.

## Moncton Branch

*V. C. Blackett, A.M.E.I.C. Secretary Treasurer.*

The annual meeting of the Moncton Branch of The Institute, was held on May 31st, 1937. The annual report and financial statement were presented and approved. The executive committee reported having held two meetings during the past year and also that there were four meetings of the branch. The membership at the present time consists of fifty-five members. The election of officers for the year commencing June 1st. 1937, took place. The incoming Chairman being E. B. Martin, A.M.E.I.C., and the Vice-Chairman B. E. Bayne, A.M.E.I.C.

## Sault Ste. Marie Branch

*N. C. Cowie, Jr.E.I.C., Secretary-Treasurer.*

A general meeting of the Sault Ste. Marie, Branch of The Engineering Institute of Canada was held in the Windsor Hotel, Sault Ste. Marie, Ont., on June 16th, 1937.

This was a special meeting arranged to coincide with the Semicentennial Meeting banquet being held at that time in Montreal.

A dinner, which was served by the hotel staff between the hours of 7.00 and 8.00 p.m., was enjoyed by the twelve members and guests attending the meeting.

The radio broadcast of the banquet proceedings, which was carried by the Canadian Broadcasting Corporation, was heard by the meeting between 8.00 and 8.30 p.m. Those present had the pleasure of hearing the address given to the Montreal meeting by His Excellency the Governor General of Canada, Lord Tweedsmuir.

Following the radio broadcast of the banquet speeches, the Chairman, Mr. C. W. Holman, A.M.E.I.C., called the meeting to order. Several items of current business were then dealt with by the meeting.

The Chairman then requested Mr. H. O. Brown, A.M.E.I.C., Vice-Chairman of Sault Ste. Marie Branch to take charge of the meeting. Mr. Brown introduced Mr. C. W. Holman as speaker of the evening. Mr. Holman, speaking on the work of the Committee of Consolidation, reviewed the history of the movement toward Consolidation, the work of the committee and the results of this committee's activities, as these have been reported in the Journal.

The meeting fittingly thanked Mr. Holman for his timely and interesting paper which was attentively followed by the members present.

Following the paper a social hour was spent in friendly discussion of a wide range of topics.

## Heat Loss Through Windows

Investigations on the heat lost through windows have been carried out within the past twenty years in the Research Laboratory of the American Society of Heating and Ventilating Engineers, at the United States Bureau of Mines, Pittsburgh, at the Universities of Illinois, Wisconsin, Michigan and California. In Europe, similar work has been reported from the Building and Fuel Research Stations of the Department of Scientific and Industrial Research in England, and in Germany from The Institutes of Technology at Danzig, Darmstadt, Munich, Stuttgart and from other centres.

A small amount of work has been devoted to the determination of the heat transmission of windows, and many tests have been made to determine the amount of heat lost because of the leakage of cold air into the house through the cracks around the sash or window.

A review of the literature on this important subject has been prepared by the Division of Research Information of the National Research Council at Ottawa. The report of 38 pages gives a brief account of recent investigations on heat losses through windows in dwelling houses. It contains a summary of information available, Part I on "Heat Loss Through the Window," Part II on "Heat Loss Through Cracks" and finally a section on "Application and Tests" and a bibliography. Information by means of which the accepted results were obtained is provided which gives a better understanding of the usefulness, shortcomings and the extent to which the results apply to Canada.

Because of the extreme climatic conditions that prevail in this country, house windows should, on an average, provide twice as much heat insulation and admit rather more light than windows in houses located in the same latitudes in European countries.

It is hoped the report will lead to an exchange of opinion as to how the best results may be achieved. Copies of the report will be mailed on request to—National Research Council, Ottawa, Ont.

## Specification for Structural Timber

The Canadian Engineering Standards Association has just issued its publication No. A 43-1937, "Standard Specification for Structural Timber."

In the preparation of the specification, a special endeavour was made to enlist the co-operation of all Canadian interests, and practically unanimous agreement was obtained before publication.

The specification is divided into three parts—Specification proper, Appendix I covering Working Stresses, and Appendix II covering Structural Grades and their Derivation.

The Association trusts that this specification will prove its usefulness, and recommends its adoption by lumber manufacturers and dealers, architects, engineers and construction interests generally.

Copies may be obtained from the C.E.S.A. Secretary's office, Room 3064, National Research Building, Ottawa. The price of the publication is twenty-five cents per copy, but on orders of fifty or more the price is 20 cents per copy.

## Welded Piping Design

Information on design and layout of piping for welded connections is contained in "Design of Welded Piping," a 200-page (6 x 9) booklet containing over 100 figures and tables, distributed by Dominion Oxygen Company Limited, Toronto and published by the Linde Air Products Company, New York.

Subjects treated of interest to engineers are fundamentals of welded joint design; welding metallurgy; standard welded pipe connections; design data on welding cast iron, galvanized iron, stainless steel and non-ferrous piping; advantageous layout; fabrication and erection considerations; welded anchors and supports; and welding speeds.

Features of interest to architects and draftsmen include standard joint designs; typical headers, expansion bends and riser connections; anchors and supports; a typical heating system layout showing symbols for welds; two sample time-saving specifications; and principal dimensions of pipe, flanges and welding fittings.

## List of New and Revised British Standards

(Issued during April and May 1937)

B.S. No.

188—1937. *Determination of Viscosity of Liquids in absolute (C.G.S.) Units. (Revison).*
Provides simple, rapid and accurate methods for the determination of viscosity by the use of relatively inexpensive and readily procurable apparatus.

728—1937. *Precast Concrete Hollow Partition Slabs.*
Deals with the quality of the materials used, dimensions of blocks and tests and methods of testing.

731—1937. *Flexible Steel Conduit for Cable Protection and Flexible Steel Tubing to Enclose Flexible Drives.*
Provides flexible steel tubing suitable for use as a protective conduit for insulated cables and as a mechanical protection to flexible drives.

733—1937. *Density Bottles.*
Gives details of the bottle for determining the density of a liquid together with standard methods for this determination and the measurement of liquid in bulk.

Copies of the new specifications may be obtained from the Publications Department, British Standards Institution, 28 Victoria Street London, S.W.1., and from the Canadian Engineering Standards Association, 79 Sussex Street, Ottawa.

## ERRATA

The following corrections should be made in the text of the paper on "Industrial and Manufacturing Development" by Fraser S. Keith, M.E.I.C., published in the June number of the Journal, pages 365 to 383:

Page 366—2nd paragraph—1st line—should read "Following the unfavourable seven, the five years up to 1884. . . ."

Page 368—3rd paragraph—7th line—should read "Nearly one thousand members or more than thirty per cent. . . ."

Page 372—2nd column—2nd paragraph—14th line—should read "Soap and candle making was the principal item in "Matters—Animal" which includes brush and broom, glue factories and tallow refineries."

Page 374—item "Organized Labour"—Last line of 1st paragraph 437,134 should read 137,134.

Page 377—1st line at top of page to right should read "Noranda development in north western Quebec."

Page 379—item "Primary Textiles"—2nd line should read "in western Ontario."

Page 380—1st paragraph—item "Rayon"—last line should read "persons employed in the silk and rayon industry with a total production of $28,045,000.00."

Page 380—2nd column—last line at bottom of page—omit.

# Preliminary Notice

### of Applications for Admission and for Transfer

July 26th, 1937

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

**Communications relating to applicants are considered by the Council as strictly confidential.**

---

The Council will consider the applications herein described in September, 1937.

R. J. Durley, Secretary.

---

*The professional requirements are as follows:—

**A Member** shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years inthe case of a candid ate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

**An Associate Member** shall be at least twenty-seven years of,age, and shall have been engaged in some branch of engineering for at least six years which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch ofengineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more year.

**A Junior** shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

**A Student** beshallat least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

**An Affiliate** shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

#### FOR ADMISSION

GRAY—HARRY ALDEN, of 1316 Dorchester St. W., Montreal, Que., Born at Pierre. So. Dakota, July 27th, 1908; Educ., B.Sc. (C.E.), Univ. of Man., 1935; 1926-29, rodman, C.N.R.; 1930-35 (summers), rodman, National Parks of Canada; 1935, dftsman. and res. engr., and 1936, asst. engr., Dept. of Public Works, Man.
References: J. N. Finlayson, J. F. Cunningham, N. M. Hall, G. H. Herriot, A. E. Macdonald, E. P. Fetherstonhaugh.

HARRINGTON—ARTHUR WILLIAM, of Elsmere, Albany, N.Y., Born at Watertown, N.Y., June 7th, 1888; Educ., Civil Engr., Cornell Univ., 1909. M.Am.Soc. C.E.; Summers—1906, contractor's asst., N.Y. State highway constrn.; 1907, asst. on borings, N.Y. State Barge Canal; 1908, sanitary inspr., N.Y. State Dept. of Health; —1909, leveler, city engr's. office, Watertown, N.Y.; 1910-12, asst. engr., and 1912-14, supt. of constrn. for L. B. Cleveland, Watertown, N.Y. (charge of station constrn. for N.Y.C. R.R. at Potsdam, N.Y.); 1914-17, junior engr., U.S. Geol. Survey; 1917-18, sec'y. and president, B.B. Culture Laboratory Inc., Yonkers, N.Y.; 1918-20, 1st Lieut., San. Corps, U.S. Army; 1920-22, hydraulic engr., U.S. Geol. Survey, Albany, N.Y.; 1922 to date, district engr., U.S. Geol. Survey, Albany, N.Y., in full charge of all hydraulic investigations of U.S. Geo. Survey in New York State with frequent special assignments in other parts of the U.S.
References: J. B. Challies, O. O. Lefebvre, L. G. Denis, J. T. Johnston, R. G. Swan, R. J. Durley.

HOOGSTRATEN—JACK, of Winnipeg, Man., Born at Winnipeg, Oct. 28th, 1908; Educ., B.Sc. (Civil), Univ. of Man., 1929; 1927, rodman, C.P.R.; 1929, dftsman., Dominion Bridge Co.; 1928, inspr., C.P.R.; 1930, dftsman., Cowin & Co.; 1929-34, instructor, engrg. dept., and 1936 to date, lecturer in civil engrg., Univ. of Manitoba, also at present, instr'man., Winnipeg Electric Co., Winnipeg, Man.
References: A. E. Macdonald, H. B. Henderson, D. M. Stephens, G. McDermid, G. H. Herriot.

IZARD—EDWARD WHITAKER, of Victoria, B.C., Born at Wisbeach, Cambridgeshire, England, Feb. 17th, 1888; Educ., Brighton Tech. College and Glasgow Univ.; Member, Inst. Naval Arch'ts. Assoc. Member, Inst. C.E. (London.) Member, Inst. Engrs. and Shipbldrs. in Scotland; 1906-08, ap'tice, shops, Yarrow & Co., London; 1908-11, drawing office, experimental and research work, Yarrow & Co., Glasgow, and John Brown & Co., Clydebank; 1911-12, i/c erection and running of 27 knot vessel by Yarrow & Co., for Argentine Navigation Co.; 1912-14, design of turbines and internal combustion engines, Diesel engine and torpedo destroyer trials, Yarrow & Co., Glasgow; 1914 to date, works manager, i/c of drydocking and repairs of passenger, cargo and naval vessels, Yarrows Ltd., Victoria, B.C. (1935-37, chairman of Victoria and Vancouver Is. Branch of Candn. Mfgrs. Assn., also member of executive council).
References: N. A. Yarrow, G. L. Stephens, G. Phillips, G. M. Tripp, R. C. Farrow.

WALSTON—TIMOTHY CRAGG, of 265 Dromore Ave., Winnipeg, Man., Born at Winnipeg, Aug. 24th, 1913; Educ., B.Sc. (C.E.), Univ. of Man., 1937. 1929-34, studying arch'ture at Univ. of Man.; At present architectural dftsman., Green, Blankstein, Russell and Ham, Architects, Winnipeg, Man.
References: A. E. Macdonald, H. B. Henderson, W. F. Riddell, R. W. Moffatt, E. P. Fetherstonhaugh.

#### FOR TRANSFER FROM THE CLASS OF ASSOCIATE MEMBER TO THAT OF MEMBER

LAWSON—HORACE HETHERINGTON, Major, of 25 Wellington St., Kingston, Ont., Born at Toronto, Ont., Feb. 2nd, 1889; Educ., Grad., R.M.C., 1910. B.Sc., Queen's Univ., 1936. O.L.S.; 1910-15, hydrographic surveying, Dept. of Naval Service, Ottawa; 1917 to date, associate professor of engrg., Royal Military College, Kingston, Ontario, i/c surveying course, mechanics of materials, graphic statics, mech'l. drawing. Also 1931 to date, private work as O.L.S. (*A.M. 1932.*)
References: L. F. Grant, L. F. Goodwin, L. M. Arkley, W. L. Lindsay, N. C. Sherman, A. Macphail, W. Casey.

TOOVEY—THOMAS WILLIAM, of Philadelphia, Pa., Born at Ovington, North'land, England, Sept. 21st, 1899; Educ., Rutherford Tech. Coll., Newcastle, 1914-17: R.P.E. of B.C. (by exam.), 1930; 1914-17, ap'tice, chem. lab., Armstrong-Vickers; 1917-19, Pilot, R.A.F.; 1919-21, research dept., Armstrong-Vickers, Elswick; 1920-21, i/c experimental iron foundry, Elswick; 1923-28, research dept., Can. International Paper Co., Hawkesbury, Ont., i/c of various depts,; 1928-34, chem. engr., B.C. Pulp and Paper Co., Port Alice, B.C.; 1934-37, consltg. work as sulphite expert, i/c constrn. and design of bleach plant, Harmanezer Papierfabrik, Harmanec, Czechoslovakia; At present, technical advisor to chlorine sales, dept. designing bleaching plants and gen. consltg. work, Pennsylvania Salt Mfg. Co., Philadelphia, Pa. (*A.M. 1933.*)
References: E. A. Wheatley, C. C. Ryan, W. A. Bain, S. Wang, S. H. Wilson, J. F. Plow.

#### FOR TRANSFER FROM THE CLASS OF JUNIOR

EVANS—JOHN MAURICE, of 936 Pratt Ave., Outremont, Que., Born at London, England, October 7th, 1905; Educ., B.Sc., (Elec.), McGill Univ., 1929; 1925-27 and 1928 (5 mos), radio testing of equipment, shift engr., beam station, Drummondville, Canadian Marconi Co.; 1927 (5 mos.), erecting fire towers and surveying, Can. International Paper Co.; 1929 to date, with the Shawinigan Water & Power Co., 1929-30, system planning, design of pole lines, transformers, etc., 1930 to date, power sales, industrial location studies, development of new loads, and at present, asst. to manager, Dept. of Development. (*St. 1929, Jr. 1931.*)
References: F. S. Keith, J. B. Challies, J. Morse, J. A. McCrory, J. H. Thompson, C. V. Christie, G. R. Hale.

#### FOR TRANSFER FROM THE CLASS OF STUDENT

BRIDGE—DAVID E., of 50 Fairholt Road So., Hamilton, Ont., Born at Kincardine, Ont., June 23rd, 1906; Educ., B.A.Sc. Univ. of Toronto, 1930; Summer work with Wentworth Motors, Harriston, Ont., North East Electric, Rochester, N.Y., Canadian Porcelain Co., Hamilton, and Detroit Edison Co., Detroit, Mich.; 1929-31, test course, Canadian Westinghouse Company; 1932 to date, instructor in mathematics, Hamilton Technical Institute, Hamilton, Ont. (*St. 1930.*)
References: D. W. Callander, J. R. Dunbar, W. L. Miller, A. R. Hannaford, E. G. Mackay, L. W. Gill, J. F. Bridge.

MACREDIE—JOHN ROBERT CALDERWOOD, of Rexton, N.B., Born at Fredericton, N.B., Aug. 4th, 1910; Educ., B.Sc. (Civil), Univ. of N.B., 1931; 1928-31 (summers), chainman and rodman, C.P.R. constrn. surveys, Sask. and Saint John, N.B.; 1932-34, chainman, land surveys, and private practice, land surveys; 1934, dftsman., D.N.D., Relief Projects; 1934-35, instr'man., baseline surveys; 1935, paving inspr., Milton Hersey Co., with N.B. Highways Dept.; 1936 to date, instr'man., N.B. Dept. of Highways. (*St. 1931.*)
References: E. O. Turner, J. Stephens, C. C. Kirby.

# EMPLOYMENT SERVICE BUREAU

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.

*All correspondence should be addressed to*

**The Employment Service Bureau, The Engineering Institute of Canada**
**2050 Mansfield Street, Montreal**

## Situations Vacant

MECHANICAL ENGINEER, with several years pulp and paper mill experience to act as assistant to mechanical superintendent for mill in the province of Quebec. Apply to Box No. 1608-V.

YOUNG CIVIL OR MECHANICAL ENGINEER, for manufacturing firm in Ontario, with at least three years experience in construction work to act as storekeeper, material checker, draughtsman and time clerk. Should be able to read blueprints. Apply to Box No. 1613-V.

MECHANICAL DRAUGHTSMEN. Situations vacant for experienced mechanical draughtsmen. Permanent employment for suitable men. Applications by letter only, giving full particulars of experience. Dominion Engineering Works Limited, P.O. Box 3150, Montreal, Que.

## Situations Wanted

CHIEF ENGINEER-CONSTRUCTION MANAGER, nineteen years construction maintenance operating, industriel plants, steam and hydro power, canals, water supply, etc., estimates, plans, specifications, supervision of construction. Apply to Box No. 36-W.

PURCHASING ENGINEER, graduate mechanical engineer, Canadian. Married, with fifteen years experience covering construction and operation, principally having to do with specification and ordering of equipment and materials for new construction and maintenance. Details upon request. Apply to Box No. 161-W.

INDUSTRIAL ENGINEERING EXECUTIVE, with wide experience including fourteen years in design, construction, maintenance and operation of pulp and paper mills and power developments. Now employed, desires change of location. Apply to Box No. 320-W.

STEAM AND MECHANICAL ENGINEER. Married. Wants position with industrial company within 100 mile radius of Montreal. Would prefer position in charge of maintenance. Can undertake plant layout work, handling steam lines, look after alterations or extensions, make installations on construction work. Previously in charge of similar work and can prepare own drawings. Have good all round knowledge of all trades. 35 years experience. Apply to Box No. 441-W.

CIVIL ENGINEER, B.A.Sc., age 44, structural, harbour, executive. At present designing 32,000-h.p. development in Newfoundland. Available in near future. Apply to Box No. 536-W.

DOMINION LAND SURVEYOR, and graduate engineer with extensive experience on legal, topographic and plane-table surveys and field and office use of aerophotographs, desires employment either in Canada or abroad. Available at once. Apply to Box No. 589-W.

ELECTRICAL ENGINEER, B.SC., E.E., age 38. Married. Ten years electrical experience; including, one year operation, one year maintenance, and four years on construction of hydro-electric plants and sub-stations. Four years electric maintenance and construction in pulp and paper mill. Also experience on highway construction and Geological Survey Available at once. Apply to Box No. 636-W.

ELECTRICAL ENGINEER, B.SC. E.E. '28. Two years with large electrical manufacturing company including test course, about two years in supervisory operating office of a large electrical power utility, and considerable experience in electrical and mechanical draughting. Location in Ontario preferable. Apply to Box No. 660-W.

ELECTRICAL AND CIVIL ENGINEER, B.SC. Elec. '29, B.SC. Civil '33. JR.E.I.C. Age 29. Experience includes four months with Can. Gen. Elec. Co., approximately three years in engineering office of large electrical manufacturing company in Montreal, the last six months of which was spent as commercial engineer. For the last year and a half employed in electrical repair shop. Best of references. Apply to Box No. 693-W.

YOUNG CIVIL ENGINEER, B.SC. (Univ. of N.B. '31), with experience as rodman and checker on railroad construction, is open for a position. Apply to Box No. 728-W.

MECHANICAL ENGINEER, JR.E.I.C., B.A.SC., Univ. of B.C. '30. Single, age 30. Sixteen months with the Allis-Chalmers Mfg. Co. as student engineer. Experience includes foundry production, erection and operation of steam turbines, erection of hydraulic machinery, and testing texropes and centrifugal pumps. Location immaterial. Available at once. Apply to Box No. 735-W.

## Situations Wanted

CIVIL ENGINEER, B.SC., M.SC., R.P.E.; Lieut. C.E., R.O. 16 years municipal, highway and construction, 5 years overseas. Married. Read, write and talk French. Will go anywhere. Apply to Box No. 737-W.

RADIO AND ELECTRICAL ENGINEER, B.SC., '31, JR.E.I.C. Single. Age 30. One year and a half actual field experience in power and lighting equipment. Extensive work in telephone and radio layouts in switchboard and installation depts. Particularly interested and experienced in sales and traffic work in telephone and radio company. At present supervisor over sales and service of radio and electrical company. Available on short notice. Location immaterial. Apply to Box No. 740-W.

PLANT ENGINEER or SUPERINTENDEBT, capable of supervising all phases of industrial plant operation, graduate electrical, eleven years diversified industrial experience including test course, four years on large Quebec industrial development, on construction and operation, also six years with prominent consulting firm supervising electrical and mechanical engineering projects. Age 31, single. Apply to Box No. 795-W.

CIVIL ENGINEER, S.E.I.C., B.SC. in C.E. (Sask. '32). Single. Age 27. Three years experience includes—instrumentman. compiling reports and draughting with a National Park; in charge of construction of water supply and sanitary sewer systems; assistant on city surveys. Excellent draughtsman. Available at once. Location immaterial. References. Apply to Box No. 818-W.

### Employment Service Bureau

The demand for engineers continues, although the number of enquiries received during the month of July did not equal those of the past six months.

During the half year ending July 30th, 1937, The Institute's Employment Service Bureau, placed over 130 engineers, which also means satisfying the requirements of a large number of employers.

Our list of men registered, as available or interested in new positions, is now greatly reduced.

Why not register?

It would be appreciated if those who have recently secured positions would advise the Employment Service Bureau.

MECHANICAL ENGINEER, JR.E.I.C., technical graduate, bilingual, age 35, married, experience includes five years with firm of consulting engineers, design of steam boiler plants, mechanical equipment of buildings, heating, ventilating, air conditioning, plumbing, writing specifications, etc. Five years with large company on sales and design of power plant, steam specialties and heating equipment. Available on short notice. Apply to Box No. 850-W.

STRUCTURAL ENGINEER, B.A.SC., A.M.E.I.C. Twenty-two years experience in design of bridges and all types of buildings in structural steel and reinforced concrete. Three years experience in railway construction and land surveying. Apply to Box No. 856-W.

CIVIL ENGINEER, B.A.SC. (Univ. of Toronto '27). Age 34. Familiar with house building cost, experience combines structural engineering, construction and house building and improvement, interested in obtaining a connection with firms investigating housing problems, making building loans or with a company engaged in construction or building costs. Apply to Box No. 910-W.

ELECTRICAL ENGINEER, B.SC. (McGill '28), age 34. Experience includes transmission line and rural distribution construction and design. Some installation of motors and equipment, also house wiring. Available immediately. Apply to Box No. 940-W.

ENGINEER SUPERINTENDENT, age 44. Engineering and business training, executive ability, tactful, energetic. Had charge of several large projects. Intimate knowledge of costs and prices, reports and estimates. Available immediately. Any location. Apply to Box No. 1021-W.

## Situations Wanted

ELECTRICAL ENGINEER AND GEOPHYSICIST. B.SC. (Man. '23), A.M.E.I.C. Married. Ten years specialized experience in the practical use of magnetic, electrical and mechanical instruments for the prospecting, surveying and mapping of mineral, oil and gas lands. Five years experience with telegraph, telephone and radio equipment. Capable of giving instruction in theory and practice in these lines and in college physics Available on short notice. Apply to Box No. 1063-W.

CIVIL ENGINEER, A.M.E.I.C., with over twenty years experience in field and office on construction, maintenance, surveying, location, etc., desires position preferably of a permanent nature. At present near Montreal, but willing to locate anywhere. Apply to Box No. 1168-W.

ELECTRICAL ENGINEER, B.SC. '34 (Univ. of N.B.), S.E.I.C. Age 24, single. Desires any kind of electrical work. Will consider any location. Apply to Box No. 1262-W.

CIVIL AND ELECTRICAL ENGINEER, Univ. of Man. '35 and '36. S.E.I.C. Experience in irrigation and mapping. Available at once. Location immaterial. Box No. 1418-W.

CIVIL ENGINEER, B.SC. 1910, A.M.E.I.C. Married. Twenty-six years experience on heavy construction work, both field and office; rails, roads, power house, hotels, bridges, etc. Location immaterial. Available at once. Apply to Box No. 1470-W.

CONSTRUCTION SUPERINTENDENT, M.E.I.C. Age 49. Married. Twenty-two years experience as engineer, superintendent and manager in charge of hydro-electric, mechanical production, structural steel erection, also considerable experience in steam plants, combustion, transmission lines, millwright work, complete mine installations, rock work, rock crushers and conveyors. Executive ability. Speaking French fluently. Location immaterial. Apply to Box No. 1482-W.

ELECTRICAL ENGINEER, B.Eng. (McGill '33). One and a half years experience in plant and production routine, and with considerable training in sales work. Bilingual, single, and available at once for any location. Apply to Box No. 1509-W.

ELECTRICAL ENGINEER, B.SC. '31 (Univ. of Alta.), JR.E.I.C. Age 28. Married. One year students' test course with C.G.E.Co. including testing and operation of transformers, meters, industrial control and switchgear apparatus. Two years as instrumentman on highway construction. Desires electrical utility, commercial lighting or air conditioning work, location immaterial and available at once. Apply to Box No. 1522-W.

CIVIL ENGINEER, B.SC. '32, S.E.I.C., P.E.N.B., DY.L.S.N.B., age 32. Experience in mining, both coal and metals, private and legal surveys, railroad construction, geology and building construction. At present in private practice in coal mining district. Desirous of changing location for position either in mining field or construction in Canada. or abroad. Apply to Box No. 1562-W.

RESIDENT ENGINEER, familiar with all types of surveys and construction work including, railway, roads, irrigation, drainage, buildings and air ports. Executive ability. Had charge of several large projects. Intimate knowledge of reports and estimates. Available immediately. Any location. Apply to Box No. 1567-W.

CIVIL ENGINEER, B.SC. '17, O.F.E. Married. Executive and administrative experience. Extensive office and field experience in harbour works, dredging; both steam and electric railways in location, construction and maintenance; telephone works in design, construction and maintenance of pole lines, wire, cable and conduit; highways in location, construction and paving; municipal works in roads, sidewalks, sewers and water mains. Intimate knowledge of estimating, unit costs, cost accounting and analysis. Some knowledge of air conditioning. Willing to locate anywhere. Available at once. Apply to Box No. 1587-W.

ELECTRICAL ENGINEER, B.SC. '27 (McGill), A.M.E.I.C. Age 36. Married. Bilingual. Three years experience in telephone work (installation of manual and automatic exchanges). One year electrical prospecting. Nine years experience with electrical power company. Apply to Box No. 1601-W.

EXECUTIVE TOOL AND PRODUCTION ENGINEER, desires to make a permanent change, graduate in mechanical (Queen's '23), A.M.E.I.C., married. Well abreast with modern production methods and present competition. Competent supervisor of tool and die design and construction; operations and methods, plant layout, efficiency and time study, toll and production estimating, tooling development foundry, machine shop and designing experience. Best of references. Apply to Box No. 1653-W.

ENGINEER, age 44, seeks connection as chief or plant Engineer, with pulp and paper, or textile concern. Apply to Box No. 1662-W.

## Water Levels in the St. Lawrence Ship Channel

In January, 1934, Hon. Alfred Duranleau, then Minister of Marine of the Federal Government of Canada, appointed an interdepartmental board with instructions to "gather all necessary information and data, and after consideration and study to report" in writing "its conclusions as to the cause of low water conditions in the St. Lawrence Ship Channel and the Harbour of Montreal and what action, if any, should be taken to improve these conditions," The Board has now made its Report to Hon. C. D. Howe, Minister of Transport, in whose Department the old Department of Marine has been merged. It is dated January 19th, but has only recently been made public; it is a voluminous document, and for this reason is not to be printed for public circulation. The Board is unanimous as to the causes of the low water level conditions, but not as to possible remedies, five members presenting a majority finding which recommends further dredging, and two other members presenting separate minority reports recommending in one case a gradual programme of development, and in the other case delay in the carrying out of all major work until economic conditions will justify the expenditure involved.

The third, and main, part of the Report, is a record of the many studies and investigations made into possible improvements of the ship channel below Montreal. It was in connection with these that 17,500 ft. of borings were specially made, and many other field studies were prosecuted. It may be noted for convenience that the length of channel between the Upper Harbour at Montreal and Quebec is just over 160 miles, about one-third of this having an effective tide, although tidal influence does reach to Montreal, being negligible, however, for all the upper reaches of the ship channel. The studies of the Board were into three possibilities; regulating dams with locks; regulating weirs and training works; and dredging.

Three proposals for the construction of regulating dams with locks were investigated in some detail at mileages 145, 110, and 11 (all from Montreal, as are the mileages mentioned hereafter). Estimated costs were 58, 53, and 37 million dollars respectively, excluding possible damage along the river banks. All dams were designed with twin locks 900 ft. long and 90 ft. wide. The resulting rises in water level at Montreal would be in the nature of 1.3 ft. for the first two proposals, but more in the case of the third proposal. All were discarded by the Board, however, as being definitely uneconomic, when compared with dredging, and especially in view of the possible land damage along the banks, and interference with the operation of ice-breaking operations in the early spring. The Board also considered various proposed steel movable dams, and other ingenious solutions to the problem, but dismissed all in view of alleged difficulties and hazards of operation, in addition to their doubtful economy.

Eight separate proposals for the construction of weirs were considered in detail, at locations varying from Champlain, 94 miles below Montreal, to Pointe au Trembles, at the foot of the Island of Montreal, some as weirs constricting the flow through openings in them to be built in deep uniform sections of the channel, and some as dams cutting off altogether the low water from channels now carrying a part of this flow around some of the many islands which are situated in the river bed. Estimated costs varied from 600,000 dollars to 7,500,000 dollars, the resulting gains in water level at Montreal varying also to a marked degree. The Board was not able to recommend the serious consideration of any one of these proposals, on the grounds that several were clearly uneconomic, while others were thought to be dangerous from the point of view of either increasing ice troubles in the early spring, or else making navigation in the restricted portions of the river hazardous.

The Board considered the submerged rock weirs which now exist in some of the channels into which the river divides at the head of Lake St. Peter in the vicinity of the port of Sorel; they were constructed in 1928-1931, and have recently been raised, with consequent serious and detrimental effects to navigation in view of increased channel velocities and erosion of adjacent land. The Board is unanimours in recommending that one of the existing weirs should be removed, and all the others lowered to 2 ft. above low-water level with one new small weir to be built across a side channel, the net results of which will be to reduce the improvement at present given at Montreal by these weirs (about 5 in.) by 20 per cent, with consequent benefit to navigation. The estimated cost of the works proposed will be 835,000 dollars.

The Board also considered in detail a proposed scheme of training works centring on Ile Ste. Therese, a large island located in the main channel at the foot of the island of Montreal. By means of two diversion dams, concrete structures containing Stoney sluice gates, across two small existing channels and 16,000 ft. of separation dyking, constructed as rock-filled concrete cribs resting on timber bearing piles, protected by rock fill, the river section could be divided into two approximately equal parts for the discharge of flood flows, whereas at low water periods it is calculated that the works would have the effect of raising the water level in Montreal Harbour by 1.65 ft., with only minor local inconveniences occasioned by the obstruction to cross-river traffic provided by the separation dyke. Sixty-one Stoney sluice gates, each 50 ft. wide, would be necessary for the diversion dams to be operated at high water periods. The estimated cost of the works is 10,508,000 dollars, the location being between mileage 11 and mileage 28 from the upper end of Montreal Harbour.

Dredging was considered in the light of the work done up to the present, one of the Board's first dredging studies being an investigation of the cost of completing the 35 foot project, to the old 1897 datum. It is estimated that this can be done in 1937 if funds are available at a cost of 1,600,000 dollars. The Board next considered what it would cost to dredge a 35 ft. channel below the newly adopted low-level datum of the Hydrographic Service based on the low-water levels of 1934, 2 ft. below the 1897 datum. This cost was found to be 13,521,000 dollars if completed to Quebec, but only 6,559,000 dollars if carried out as far as Cap de la Madeleine, below which tidal influence is felt so that ships of deep draught, at periods of low water, could wait here if necessary and proceed as the tide rose. The Board suggests as a result of its studies that such a channel will enable ships drawing 31½ ft. to go in and out of Montreal Harbour under all combinations of poor conditions except the most extreme.

The Board also considered, and unanimously recommended, that a realignment of the main ship channel should be dredged opposite the port of Three Rivers. The present channel is adjacent to the north shoreline, on which are located the main wharves of the port, some of which cannot be effectively used, and in consequence of which a slow order limits the speed of all vessels in this stretch of river. By the dredging of a new cut in mid stream, this disadvantage could be avoided; the cost is estimated to be 500,000 dollars.

Following a recapitulation of the schemes investigated, and a summary statement of various combinations of schemes which might be adopted, the Report concludes with some relevant studies of wharfage capacity in the harbour of Montreal. The harbour contains some ninety-nine berths, with a total length of 47,820 ft. Of these all built since 1910 were designed for an ultimate depth alongside of about 32½ ft. below the 1934 low-water datum plane. "However," the Report continues, "it must be pointed out that weaknesses have developed in the designs used, and none of the adjacent berths can now be deepened to the full depth contemplated, except King Edward Pier, the greater part of which has been reconstructed with reinforced concrete cylinders to rock." This is clearly a complicating factor, although contracts have been let recently for the reconstruction of several of the more important wharves so as to give a depth of 33½ ft. below the 1934 datum. A tabular statement is presented which shows that only about 20 per cent of the total wharfage will give depths along-side of 32½ ft. or over (corresponding to a depth of 34 ft. in the channel), unless the water levels in the harbour are raised by means of such works as those proposed at Ile Ste. Therese. If these training works were constructed, the percentage would increase to 46 per cent.

The final recommendations on this third, and vital, part of the Report are not unanimous, apart from agreement as to the necessity for the small works at Three Rivers (dredging) and Sorel (reconstruction of submerged weirs).

The general subject of water levels in the St. Lawrence has long been a vexed question. In the present Report it is noted that a Commission of Inquiry was appointed as far back as 1913 with regard to the question. An interim report was issued in 1915, and studies continued until 1919, but no final report was submitted. Since that time, the matter has been often to the fore in public discussion, especially during recent years. The Report now issued will go far to setting at rest many of the uninformed ideas which have found expression from time to time, and although the findings are so divided as to the solution of the problem, it is to be hoped that the information assembled by the Interdepartmental Board will go far towards bringing about a final solution of a problem which, in its effects, far transcends the immediate locality of the ship channel, being in every sense a matter of concern to the whole Dominion of Canada.—*The Engineer.*

## Second Symposium on Water Hammer (New York, Dec. 9th and 10th, 1937)

In 1931 the then status of water hammer theory was reviewed by a committee appointed by the American Society of Mechanical Engineers, Hydraulic Division, and as a result of their work a symposium on water hammer was held in Chicago in 1933. Eight papers dealing with various aspects of water hammer were presented. As a result of the widespread interest aroused by this work, a second symposium on water hammer will be held in New York on December 9th and 10th, 1937, under the auspices of the same committee, with the co-operation of the American Water Works Association. The committee includes associated members from the Engineering Institute of Canada, Professor Robert W. Angus, Hon M.E.I.C., and Professor F. M. Wood, A.M.E.I.C., and also from Australia, Brazil, France, Germany, Italy and other countries.

Contributions from engineers interested in the subject in the form of comments or suggestions, papers or reports, will be welcomed, and should be sent to the chairman of the Hydraulic Division, A.S.M.E., c/o United Engineers and Constructors Inc., 1401 Arch St., Philadelphia, Pa.

## Growth and Spread of Arc Welding in Canada

*A. S. Wall, M.E.I.C.,*

*Dominion Bridge Company Limited, Montreal.*

**Paper presented at the Semicentennial Meeting of The Engineering Institute of Canada in June 1937, in Montreal.**

SUMMARY.—**Outlines the development of arc welding in Canadian shops with notes on electrodes, fabrication procedure, stress relief, X-ray examination, and the training of operators. A detailed analysis of various types of joints is given.**

The Semicentennial Anniversary of The Engineering Institute of Canada, founded in 1887 as the Canadian Society of Civil Engineers, is taking place just about fifty years after the discovery of metallic electrode arc welding.

The process of arc welding, although discovered so many years ago, remained comparatively unknown until the urgent requirements of a world at war unveiled the merits of the tool and placed it in the foreground as a very convenient way to make repairs in place, saving valuable time by avoiding dismantling and replacement. At that time, and for several years later, the idea that a metallic electrode arc welding set was essentially a repair kit persisted and it was valued more or less in proportion to its user's success in application.

Gradually however, with succeeding years, engineers have learned that arc welding is not only a first class repair tool but that it may be used advantageously for permanently joining connecting parts of major structures.

In its evolution it has grown from a handy tool for the repair of defective steel castings to the means for connecting rolled steel parts to replace castings. It has developed from an easy way of repairing boiler tube sheets to a method by which the best quality of important pressure vessels are constructed. From its early use as a convenient way to plug misplaced holes it has risen in dignity until it is now playing a major part in the fabrication and erection of steel bridges and buildings. Its valuable features have made possible the development of original types of design to accomplish increased economy of material and amazing improvement in appearance.

The growth and spread of arc welded construction in the last few years have been almost sensational although, as previously stated, it was considered for so many years only as a superior method of repair. As a matter of fact it is still regarded as no more than that by a few; but those who have had the opportunity to use it as a fabrication agent to any great extent are very appreciative of its structural worth.

A brief outline of the experiences of a few Canadian companies in their development of arc welded fabrication will illustrate the strides made in the last ten years.

The Canadian Westinghouse Company began with a single welding set in 1923, using it largely for repair work. By 1925 it was necessary to find larger welding quarters, and again in 1927 the increased part of their product fabricated by the arc welding process necessitated further expansion. In 1930 still greater enlargements were made. The floor space used for welded construction at that date had increased more than 600 per cent since 1923. During this period the number of welding units had increased from one to twenty-five, and there are probably thirty in use to-day.

Some idea of this company's new trend of design may be given by a description of the changes made in large A.C. generators.

Starting in 1926 with relatively unimportant parts such as welded stairs and platforms, every succeeding order saw more and more welded fabrication. The main and exciter frames soon followed the platforms, with the lower bearing brackets as the next step. By 1930 the upper brackets and oil pots had become welded and in 1931-32 the *last casting, the spider,* became a welded assembly. Since then these larger machines have been designed for entirely welded fabrication.

The company's developments in the transformer field advanced rapidly with the advent of welded tanks. Welded construction of end frames, bases, and covers, etc., became standard practice just as quickly as the personnel could be trained and the shop equipped for it.

Their standard designs for synchronous motors from 100 to 3,000 h.p. are for welded fabrication and the spread of this type of construction for this company's wares grows daily.

The history of the growth and spread of arc welded construction in the shops of the Canadian General Electric Company Limited is similar to that just described, but is none the less wonderful.

It is only about twelve years since this company's use of arc welding was almost exclusively as a means of repairing and making small parts, mostly for factory maintenance.

Since then rapid progress has been made, until to-day the parts of large A.C. generators such as stator frames, upper and lower bearing brackets, rotor spiders, bases, etc., are all of welded construction.

In fact the size of structures now made by this company by means of welding is limited only by shipping clearances.

Probably one of the greatest contributions made by welding to the construction industry is in connection with larger rotating parts. On large generators, cast rotor spiders are very heavy and expensive, requiring costly patterns, foundry uncertainties and expensive machinery. With the development of welded designs thinner parts are used, allowing a considerable saving in freight in addition to that made by the elimination of patterns, excess metal, machining, etc.

Fig. 1—Arc Welded Transformer Tank, Canadian Westinghouse.

While the Canadian Locomotive Company Limited does not yet build standard types of steam locomotives of entirely welded construction yet the use of arc welding has increased greatly in their fabrication until now there are over one hundred and fifty different electric welding operations.

Thirteen welding units are necessary to meet the growing requirements of arc weld constructed work in this company.

At the Montreal Locomotive Works Limited, arc welding plays a similar part. Locomotive staybolt caps and sleeves, side sheets of fire-boxes and syphons are electrically welded.

The motive power departments of the railways use welding extensively.

In the Canadian National Railway shops most of the light plate work such as cabs, smoke deflectors, stoker conveyor troughs, tender tanks and swash plates, steps, etc., are fabricated by welding.

Riveted seams in their locomotive fireboxes have been completely superseded by butt welded joints and, in addition to this, the beads of back ends of all boiler flues are welded to the flue sheet.

Fractures in main frames or truck frames, bolsters or other steel castings are repaired by welding and bronze hub covers are welded to cast steel driving boxes.

Parts which are subject to excessive friction and wear, such as conveyor screws, intermediate buffer blocks, chafing plates, etc., are built up to standard dimensions by arc welding as engines pass through the shops.

In the Angus shops of the Canadian Pacific Railway the growth of the application of arc welding has become so great that now it is difficult to comprehend how operations were carried out efficiently without its use in the past.

Whereas in the early days arc welding in this shop was confined to the output of one electric welding set, there are to-day 40 arc welding sets in constant use in addition to gas equipment.

The early experiences of the Dominion Bridge Company Limited were like those of all the others. It first used arc welding commercially in the fabrication of light storage tanks. Other types of welded structures soon followed, notably embedded parts for hydraulic gates and parts formerly of cast steel. Arc welded products of the Dominion Bridge Company Limited now include pressure vessels of all descriptions up to those of the highest code classificiations requiring controlled oven stress relief and X-Ray examination. Mechanical parts such as gear blanks, large gear boxes, lift bridge sheave drums, crane trolleys, etc., are manufactured by this method. Welded steel structures for buildings of composite construction are a regular standard office and shop procedure; and bridges are fabricated by arc welding when that type of structure best suits all the requirements.

In 1917 the arc welding equipment of this company consisted of two old box welders taking current directly from the power line and fluctuating with every variation in line load.

To-day it has 45 machines in daily and often nightly use in its Lachine plant and each of its branches throughout Canada has arc welding facilities in proportion to its relative tonnage capacity.

The Lachine plant is equipped with two stress relieving ovens, the larger one having an end opening of 14 ft. by 17 ft.

The plant also has a 300,000-volt X-Ray machine capable of penetrating 3 in. of steel.

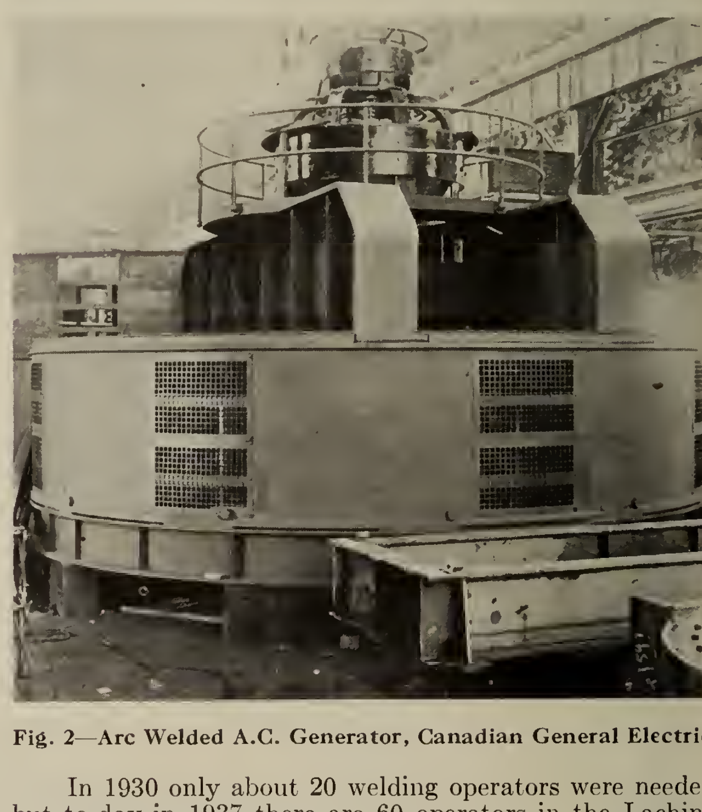

Fig. 2—Arc Welded A.C. Generator, Canadian General Electric.

In 1930 only about 20 welding operators were needed but to-day in 1937 there are 60 operators in the Lachine plant with several more in training.

### Reasons for Accelerated Development

The greatly accelerated growth of arc welded construction may be credited to improved welding machines, better electrodes, an increased knowledge of fabrication procedure, and better comprehension by engineers of the fundamental requirements necessary for its successful employment.

The builders of welding machines have supplied equipment to meet advancing requirements. Changes have been made chiefly to take care of the developments in types of electrodes.

Formerly 200 ampere machines with open circuit voltages of 25 were sufficient for the use of small bare electrodes. With the development of heavily coated electrodes, however, 300 and 400 ampere machines with open circuit voltages of 40 became necessary.

A.C. machines are being used much more than previously. Their chief advantage may be that they eliminate arc blow, but some authorities believe that they more consistently deposit a dense weld.

Electrodes have been so much improved that a choice may be had for any purpose. All grades from bare wire to the heavily coated electrodes used only for down-hand welding can be obtained. When other conditions are right these latter electrodes will produce joints equal in all respects to the parent metal. i.e. equal specific gravity, tension, shear and bending values, elongation, toughness and fatigue resistance. Some produce a molten metal surface of the meniscus type which helps greatly in obtaining pure weld metal by eliminating undercutting in grooves and thereby minimizing the necessity for chipping.

Electrodes may be divided into three main classifications.

One class of electrode is commonly known as "bare," but it always has a very light sull or lime coating. Although this coating is necessary, it exists only for arc stabilization.

Another class of electrode is one with a coating containing carbonaceous material which produces a gaseous atmosphere when burning. This electrode coating generates a gas which shields the arc from the atmosphere and leaves a slag which protects the molten metal. Electrodes of this type may be used for vertical fillet and vee welding as well as on the flat.

A third type of electrode is coated with a composition essentially of a mineral nature. Because of the relatively slower melting of the covering a cup forms at the tip of the electrode shielding the arc from the air and reducing heat losses. The slag which forms on the surface of the molten and hot metal in the groove acts as a blanket to insulate the weld while cooling. This type of electrode is essentially for welding in a groove in the flat position. When used by experts it will make very fine fillet welds on the flat, but this takes great skill.

### Fabrication Procedure

In the construction of arc welded parts the members of the shop staff have had to develop procedures to keep residual stresses at a minimum, control distortion, prevent cracking while welding, etc., in addition to fabricating in an efficient and economical manner by the new method.

They have learned when and how to pre-heat to prevent cracking, to make separate sub-assemblies as far as possible before assembling to the larger structure, and to use only sufficient current for the required fusion.

When it is necessary to clamp an assembly firmly in order to prevent distortion while welding, the whole is pre-heated if possible and the welds are peened to eliminate or minimize residual stresses.

If conditions permit, however, instead of clamping they provide guides to allow pieces to change in allowable limited directions. When they can, they prefer to allow controlled freedom of movement in as many directions as possible.

In welding an assembly they start at the centre and weld outwards; and they have learned to make the heavier welds or those which will strain the most, such as butt welds, first and to finish with the lighter welds.

Fig. 3—Arc Welded 60-Ton Crane Trolley Frame.

Fig. 4—Arc Welded Refinery Vessel 12 ft. dia. by 1⅝ in. Shell.

Where parts to be welded have several butt joints meeting at right angles at various points in the structure all the joints in one direction are welded first and then the remaining seams are welded from the centre outward.

These and many other schemes have been developed by the shops to control the quality of the product.

The development and use of rotating and other equipment for turning parts in the shop to positions for down-hand welding in order to take advantage of large electrodes and high currents has done much to promote welded fabrication.

### Stress Relief

In important pressure vessels, and mechanical parts designed to operate under conditions of dynamic loading, it is now common practice to relieve stress at a temperature of about 1,100 to 1,200 deg. F. This is done in large ovens capable of containing vessels or other structures about 12 ft. wide by 14 ft. high. The cross sectional capacity is governed by railway shipping clearances. By this operation residual stresses are reduced to a minimum and superior structures are produced.

### X-Ray Examination

For some types of vessels such as power boiler drums, high pressure and high temperature oil refining vessels, etc., it is required to produce proof of the quality of the welding in the joints.

This is accomplished by means of X-Ray examination. When this is done exographs of every foot of butt welding are made, and each film is examined carefully. When defects are found the faulty metal is chipped out and rewelded. The repaired portion is then re-exographed and the new film is studied to discover whether or not the new weld is satisfactory. By this means it is possible to produce practically perfect structures.

### Training of Operators

To-day with the increasing demand for welding operators, most large companies find it necessary to train their own welders.

This is done by running regular training schools where men are given a set course. This generally takes about three months, after which the newly trained men are put to work in the shop tacking and doing a certain amount of unimportant welding. By degrees they are schooled on actual work, but under careful supervision, advancing stage by stage until they are thoroughly trained.

All welders have to pass qualification tests and they are graded accordingly. Those who work on pressure vessels are specially qualified in accordance with the requirements of government departments having jurisdiction.

### Joints

The outstanding development in welded fabrication is in some measure due to the better understanding by engineers, in both office and shop, of the right way to design, detail and build structures in a manner suitable for arc welded construction. Original designs are now made for welded structures rather than designs for riveted structures with arc welding substituted for riveting.

Something of what the engineer should know about welding in order to design welded structures of various kinds is indicated in the following discussion of joints.

The design of joints requires a great deal more than merely to provide for a definite amount of weld metal proportioned by dividing a calculated amount of stress by a specified unit.

Engineers appreciate that under some circumstances certain types of joints may involve unnecessarily high shop and field costs; and they must be capable of choosing the best joint for any particular condition.

The preparation of the material for certain kinds of joints is as important as the actual operation of welding; and the assembler controls the quality of the joint as much as the welding operator. The assembler must be careful to leave proper clearances, allow sufficiently for expansion and contraction, secure properly to prevent distortion and when necessary pre-set to allow for distortion.

To get a clear understanding of the comparative analysis of the joint types to follow it may be well to accept the general conditions 1, 2, and 3, which follow:

1. The best condition for welding is down hand on a flat surface (Fig. 5). Penetration is greatest under such circumstances because the current is concentrated over the whole area of the electrode cross section and all points on its surface are equidistant from the surface of the flat plate. The deepest penetration is directly under this area and decreases to zero at the boundaries of the arc flare.

2. Assume penetration in a vee (Fig. 6) or groove to be not more than to the root of the vee or groove, i.e. to the shoulders of the prepared edges. At times, somewhat more penetration than this may be obtained, but the assumption is safe and reliable.

3. The arc will take the shortest path and therefore may leave an unfused part when conditions are favourable for it as in Fig. 7.

In the following comparative analyses of joints it is assumed that conditions 1, 2, and 3, previously stated, are correct. Although all of the joints discussed may be used in construction under right circumstances they should be chosen to suit the specific work they have to do and the position in which they must be made.

Figure 8 indicates two $\frac{3}{16}$-in. or lighter plates with square edges butted closely together. On the basis of our assumption (1) this should give a full penetration as electrodes of the right size will penetrate $\frac{3}{16}$-in. under suitable conditions; in practice however, full penetration is impossible to obtain without the use of a backing bar. If full penetration were attained the plate would be melted through and if it were not melted through there would not be full penetration.

This joint, however, may be satisfactory for some purposes where load stresses and distortions are negligible.

Where plates over $\frac{3}{16}$-in. in thickness (Fig. 9) are connected in the manner shown there will undoubtedly be incomplete penetration, as $\frac{3}{16}$-in. is about the maximum penetration obtainable with an assurance of sound welding.

At the unfused portions of the abutting plates there is a point of very severe stress concentration. Authorities have stated that the stress concentration at this point under tension loading is from eight to twelve times the average stress.

Under certain circumstances this would appear to be a very dangerous joint, particularly in tension or bending.

The joint shown in Fig. 10 is excellent when special care is taken and sufficient consideration is given to electrode diameter, current, arc blow, length of seam and ease of execution. These special conditions are necessary to make such a seam with perfect penetration and without slag.

Though structurally sound this seam, even with perfect penetration, would not pass some codes where chipping is

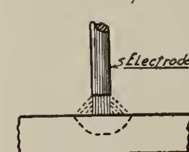

FIG. 5

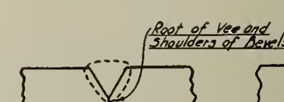

FIG. 6

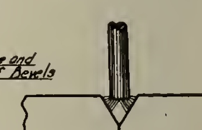

FIG. 7

FIG. 8

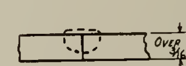

FIG. 9

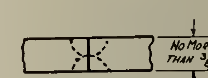

FIG. 10

FIG. 11

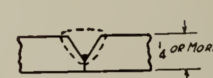

FIG. 12

FIG. 13

FIG. 14

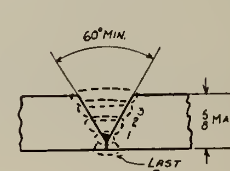

FIG. 15

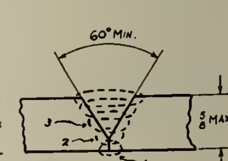

FIG. 16

specified. This weld may be made to satisfy such codes if one side is welded and the other side then chipped to solid weld metal and completed.

The weld as shown is good in tension, compression and bending and the square edges are particularly satisfactory for assembling.

Although the joint pictured in Fig. 11 will not have perfect weld throughout because of a segregation of slag and drippings at the bottom of the first pass it may be very satisfactory for cases where full strength is not the main feature. It is excellent for fast production, but it would not be acceptable to some codes because of the inevitable entrapped slag.

Figure 12 depicts a joint ¼-in. or more in thickness, welded from one side. Referring back to Fig. 6 and our condition 2 it will be noted that complete penetration is impossible here. This joint may be dangerous under load in a like manner to that shown in Fig. 9.

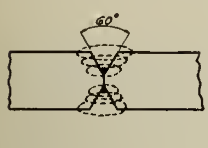

FIG. 17

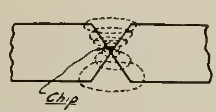

FIG. 18

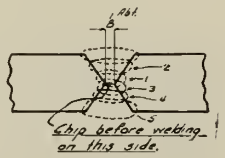

FIG. 19

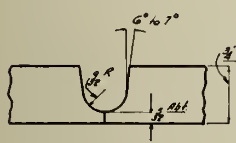

FIG. 20

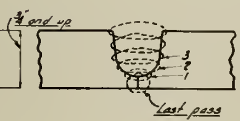

FIG. 20A

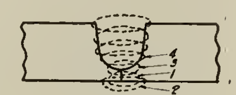

FIG. 20B

To make the joint in Fig. 13 practically perfect when welded from one side it is necessary to draw a light bead at the root with a small electrode very expertly handled. Subsequent passes may be made with larger electrodes.

This type of joint, however is difficult to assemble and provides very little resistance to contraction. There is likely to be an over-lapping of the adjoining edges with a consequent lack of penetration.

A perfect joint may be made by welding from one side when made as shown in Fig. 14, using a backing bar. The plates should be bevelled to a very small shoulder and be separated about the diameter of the electrode—slightly less for down hand and a little more for vertical welding.

In Fig. 15 the joint shown is bevelled from one side, leaving very small shoulders. The first pass is to the bottom of the vee and a small amount of slag may be trapped at the root. After the grooved side is completely welded the back of the joint is chipped to remove the enclosed slag, and then the last pass is run.

This joint can be made perfectly and can meet the highest code classifications.

The joint in Fig. 16 is almost the same as that shown in Fig. 15 and is of practically the same value regarding freedom from impurities. It differs in that the sequence of the passes does not require chipping. Because some codes arbitrarily specify the chipping of welds of certain classifications the use of this joint might be prohibited in many pressure vessels. It is excellent for vertical welding.

Figure 17 shows a joint which is very unreliable as far as full penetration is concerned, even though welded from both sides. Impurities will be left at the bottom of the grooves and they cannot be removed satisfactorily by chipping. There will almost assuredly be no penetration for the depth between shoulders.

A joint of the type shown in Fig. 18, bevelled from both sides and with the plates closely butting, which is required to be entirely free from entrapped impurities, will require chipping. Chipping of course is commonly done in high class work, but in this case too much work will have to be done as a great deal of parent metal will have to be chipped from the sides before the slag at the bottom can be removed and solid weld metal reached. A U-nosed chisel has to be used and it must be wide enough to take care of side undercutting caused by arc flare.

However, with the plates bevelled from both sides as in Fig. 19, and the edges separated as shown, it is possible and not too difficult to obtain a weld perfect from all standpoints. There may be some difficulty in running the first pass. After one side is completed it is necessary to chip to solid weld metal before making the first pass in the second groove. If much trouble develops in placing the first pass in the first groove very deep chipping will be necessary. The chipping however, is easy of access because there is ample room.

When we reach plates of ¾-in. and upward in thickness the most satisfactory form of joint preparation is that shown in Fig. 20. Welds of the highest quality, entirely free from slag and porosity can be obtained. Satisfactory joints may be made from the styles shown in either figures 20A or 20B.

For the method shown in Fig. 20A it has been found beneficial to run a very light preliminary pass on the ungrooved side of the joint. This is helpful in preventing subsequent cracking during welding and also in controlling the arc blow. After the groove is completely welded the back must be chipped to solid metal. This of course cuts out all the preliminary backing bead involving a small waste of weld metal. Where this joint is welded in the sequence indicated the chipping must be done from the inside if the structure is a vessel. Very often this is awkward and difficult, especially in small vessels. Three inside operations are necessary, i.e., welding, chipping, welding.

When the joint has the welding passes made in the order shown in Fig. 20B a perfect joint can be obtained with a little more ease than by the method shown for Fig. 20A.

Two passes are first made on the ungrooved side and then the bottom of the groove is chipped from the outer or grooved side. The second pass of weld has provided plenty of metal to stand thorough chipping and leave enough material for an efficient backing for the groove weld.

The first pass is easy to make because it is against the flat plate, hence there will be a minimized danger of impurities. On vessels the only inside work involved is the laying of the first two passes of weld. The subsequent

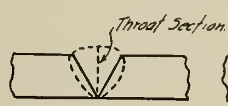

FIG. 21

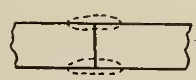

FIG. 22

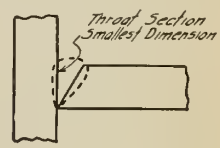

FIG. 23

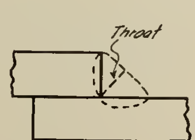

FIG. 24

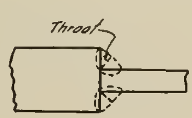

FIG. 25

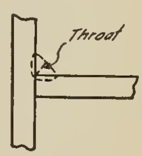

FIG. 26

chipping and all the groove welding is done from the outside under conditions of much more ease and comfort for the operator.

So far this has proved the most satisfactory method of making high class welded joints in thick metal.

The joints so far compared are all of the butt type and are the kind generally used in the construction of pressure vessels. Structural steel parts are more often connected by means of fillet welds. In general a butt weld may be described as one in which the throat section is normal to the sections joined as in Figs. 21, 22 and 23, while in a fillet weld the throat section is inclined to the surfaces of the sections joined as in Figs. 24, 25 and 26. Butt joints are now nearly always made with covered electrodes.

Bare electrodes are still used a great deal for making fillet welds but many companies are rapidly reaching the point where they use only covered rods for that purpose.

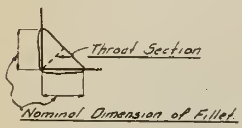

FIG. 27

FIG. 28

FIG. 29

The following comments on fillet welds therefore will have to be based on a consideration of both types of electrodes.

*Fillet Welds—Bare Electrodes—One Pass—(See Fig. 27).*

In earlier days of welding it was very common practice to use only one size of electrode, generally $\frac{5}{32}$-in. diameter, for most classes of work. This limited the size of the one pass fillet to about $\frac{1}{4}$-in. for good welds. Danger lay in attempting to make larger single pass welds with this size of electrode. To-day, however, *the size of the electrode is chosen to suit the fillet* to be made.

Bare wire electrodes of $\frac{5}{32}$-in. in diameter will make one pass fillets of about $\frac{1}{4}$-in., those of $\frac{3}{16}$-in. diameter will make a $\frac{5}{16}$-in. fillet, and $\frac{1}{4}$-in. electrodes will make $\frac{3}{8}$-in. fillets. *The choice of electrode size also depends on the thickness of the materials* to be joined.

Large electrodes cannot be used on thin plate because the heat required for the electrode will be too great for the metal.

When making fillet welds it is essential that fusion must be complete to the root. To accomplish this the welder must not allow the root to become cool at the point of deposition at any time during the operation. To maintain this condition it is necessary to vary the electrode to suit the fillet.

The difficulty of obtaining full root penetration with bare electrodes varies with the position of the fillet. When the weld is being made in a vertical position the root condition is easily satisfied.

*Fillet Welds—Bare Electrodes—Two Pass.*

In making two pass fillet welds with bare wire a very light string bead is first drawn along the root. This light bead easily affords full root fusion. The second pass is very easy to run because the ordinarily difficult root penetration has already been accomplished and arc blow conditions have been bettered.

*Fillet Welds—Bare Electrodes—Multiple Pass—(See Fig. 29).*

To make multiple pass, bare wire, fillet welds the same conditions for root penetration are observed as for two pass welds. Subsequent passes usually do not give much trouble, but particular care must be taken to get full penetration on horizontal surfaces.

Bare wire fillet welds may be made in all positions, i.e., flat, vertical and overhead.

*Fillet Welds—Covered Electrode—One Pass.*

With covered electrodes fillet welds on the flat may be made very easily. Larger electrodes may be used when covered, the greater heat being absorbed in making the molten metal more fluid.

The welding technique is of the simplest possible kind—a straight draw with high current.

Root penetration does not give the same trouble as with bare wire since arc blow is lessened and the molten metal is in a more fluid state because of the greater heat.

Fillet sizes of $\frac{3}{16}$-in. to $\frac{1}{4}$-in. may be obtained with $\frac{5}{32}$-in. dia. electrodes; $\frac{1}{4}$ to $\frac{5}{16}$-in. with $\frac{3}{16}$-in. dia.; $\frac{3}{8}$-in. with $\frac{1}{4}$-in. dia., and $\frac{7}{16}$ to $\frac{1}{2}$-in. with $\frac{5}{16}$-in. dia. electrodes.

*Fillet Welds—Covered Electrodes—Multiple Pass.*

Two pass fillet welds are rarely made when covered electrodes are used, since it is difficult to weave a second pass. Where very large fillets are necessary three or more passes are used.

With correctly chosen covered electrodes fillets are easily made in the flat position, but when they are used for vertical welding, the current must be cut to control the molten metal, as covered rods form an extremely fluid puddle.

In welding in a vertical position the general movement of the electrode may be either downward or upward.

It is difficult to obtain a good weld by downward vertical welding, but if it can be made the crystalline structure will be excellent. To make it the weld is deposited in thin layers and must proceed fast enough to keep ahead of the slag. The successive thin layers are self-annealing and consequently the quality of the weld is improved.

For upward welding with covered electrodes the fillet must be sufficiently large to allow of such a motion of the electrode tip (weave) that the trailing crater will always

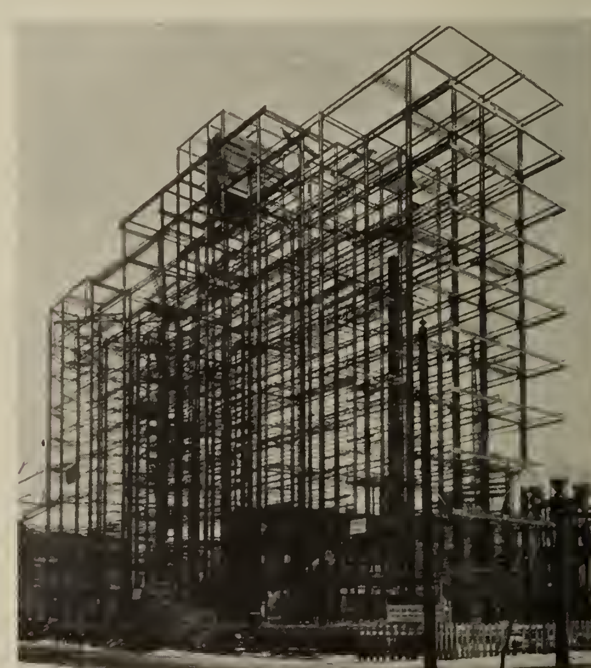

**Fig. 30—All Welded Steel Addition to Western Hospital, Montreal, Designed for Composite Construction.**

be stiff enough to carry the new molten metal above. If the tip of the electrode returns to the crater while it is still very fluid the metal will spill out.

Upward vertical welds can be made with fewer passes than the downward, and the slag is thick and easy to remove. Each layer of downward weld is covered with a thin tough slag which is difficult to remove. The weld made upward is easier to clean and is the one generally used for vertical welding with covered electrodes.

The remarks made above concerning vertical fillet welds are also true for covered rod vertical vee welding.

Practice has shown that a vee rather than a U is better for vertical welding.

### Composite Construction

Arc welding has made possible the development of the Kane System of composite structural steel and concrete construction.

In this system a steel skeleton is designed sufficiently strong to provide for all construction loads including the wet concrete. This steel later functions as reinforcing for the concrete beams of the structure. Relatively small sections may be used because no holes have to be deducted from the cross-section of the parts and minimum dimensions are not limited by the gauges and edge distances required for riveted types of structures. The open web system of the beams provides very convenient openings for duct work and piping. The Western Branch of The Montreal General Hospital was designed and built to this system. (See Fig. 30.)

**Fig. 31—Arc Welded Continuous Deck Plate Girder Bridge at Ste. Anne de la Perade, P.Q.**

### Welded Bridges

Steel bridges of a very pleasing appearance are easily developed by arc welding. In addition to the improved aesthetic effect a very definite saving in steel tonnage is possible.

The bridge at Ste. Anne de la Perade on the Montreal-Quebec highway is a very fine example (see Fig. 31). This whole structure, consisting of several continuous deck plate girder spans with the lower chords shaped to the lines of a flat arch, was shop fabricated entirely by the arc welding method and all field joints and connections were welded.

A saving of 15 per cent was made in the weight of the girders by designing them for continuity; and an additional 15 per cent in weight was saved by fabricating the structure by arc welding instead of riveting.

In connection with arc welded fabrication it is interesting to note that the Canadian Engineering Standards Association is developing a code to standardize the workmanship on arc welded structures by a scheme to qualify shops, supervisors and welding operators in order to develop a uniformly high quality of welded building construction throughout Canada.

### Conclusion

In concluding this article it may be well to repeat what has already been said by many others.

To obtain first class welding it is essential that there be intelligent design, sound shop procedure, adequate supervision, strict inspection by the shop's own inspectors while the work is being done, and a chain of responsibility from the chief engineer to the welding operator.

The future of welding is hard to predict, but if it be judged by the rate of its accelerated development in the last five years, it will embrace an amazingly large proportion of steel structures.

### Acknowledgement

The writer wishes to thank Mr. David Boyd of the Canadian Car and Foundry Company Limited and Mr. Gordon Cape of the Dominion Bridge Company Limited for helpful suggestions and also the companies mentioned in this article for information regarding their welding progress.

# Pre-Cast Concrete Units in Engineering Construction

*R. E. Chadwick, M.E.I.C.,*
*President, The Foundation Company of Canada Limited, Montreal.*

**Paper presented at the Semicentennial Meeting of The Engineering Institute of Canada, in Montreal, June, 1937.**

SUMMARY.—Discusses considerations governing the use of large pre cast construction units, such as caissons, cribs, floor slabs, concrete blocks, piles, tunnel sections and concrete bag work. Methods of transportation and protection against erosion are noted.

During the last five years the author has had occasion, as an officer of The Foundation Company of Canada Limited, to observe the handling of some rather large pre-cast concrete units in connection with a number of engineering works for which that Company held contracts. This refers to numerous pneumatic and open caisson contracts and, in particular, to the Toronto Water Works intake for which Messrs. H.G. Acres and Company, Limited, and Messrs. Gore, Nasmith and Storrie were the consulting engineers, and the reconstruction of berths 1, 2, 3 and 4 at Saint John, N.B., under plans and specifications prepared by Alex. Gray M.E.I.C., as chief engineer of the Saint John Harbour Commission.

In the Toronto operation, sections of pre-cast concrete pipe 8 ft. inside diameter, 9 ft. 8⅜ in. outside diameter and 100 ft. long, were cast in a yard some seven miles from the site of the work. These units, weighing 250 tons each, were towed, while suspended from the booms of a derrick boat, some two miles through Toronto harbour and about five miles through Lake Ontario, placed in a dredged trench and connected together by divers. In all forty-two sections of standard pipe were handled in this manner and, in addition, there were a number of specials.

In the Saint John contract 208 pre-cast concrete caissons were built in the St. John dry dock, and, also suspended from the booms of a derrick boat, were towed across the harbour and deposited in position for sinking. These caissons were 7 ft. inside diameter, 9 ft. outside diameter and varied in length from 55 to 70 ft. and in weight from 110 tons to 140 tons.

Practically all types of caissons, both pneumatic and open, may properly be classed as examples of pre-cast work, inasmuch as they are cast and cured in a position different from that in which they are finally used. They are often transported, by floating or otherwise, considerable distances, and are invariably moved vertically through being sunk to the required depth. The handling of concrete caissons weighing several thousand tons is quite common.

In the preliminary programme of the Semicentennial Meeting of The Engineering Institute of Canada, the subject of this paper is given as "Modern Methods of Precasting Large Construction Units, especially developing the idea that such units can be built better and more economically at a suitable construction yard than in situ." Perhaps the word modern might better have been eliminated as there is nothing particularly new in the use of pre-cast concrete. The use of large concrete blocks in harbour works would appear to have ante-dated our modern Portland cement, and certainly ante-dated modern reinforced concrete construction. Incidentally there is every reason to believe that these comparatively ancient block structures will outlive much of our more modern reinforced work. The term "large construction units" is used advisedly as it is not intended in this paper to deal with pre-cast units of small size.

During some twenty-five years' experience as an officer of a contracting company specializing, among other things, in all types of underwater construction, the author has been greatly impressed with the very decided advantages, in certain classes of work, of pre-casting concrete over pouring it in place, and it has been a source of amazement to him to observe the reluctance on the part of many engineers to adopt the pre-casting method, and the apparent suspicion with which each new proposal for pre-casting is viewed. In this respect Canada undoubtedly lags behind the rest of the world. Pre-cast concrete block work has been used extensively for many years in Europe, but has had a very limited application in Canada, yet it is an exceedingly economical and durable type of construction. Concrete bag work in large units, i.e. weighing upwards of 25 tons each, which might be viewed as a sort of semi-pre-cast system, is virtually unknown here, but in the opinion of the author it could be used with advantage in many cases to form an underwater foundation. It should be an exceptionally safe and economical type of construction in cases where work must of necessity be carried on throughout a long Canadian winter, and where it is necessary to contend with the slow setting of concrete in water that has a temperature only a few degrees above the freezing point. There are many other types of pre-cast construction that suggest themselves to anyone interested in the subject.

It is the intention of the author in this paper to call attention to the advantages of pre-casting and to cite some typical examples of pre-cast work. Wherever possible reference will be confined to structures that have been built in Canada, referring to foreign work only where it has been impossible to find appropriate examples in this country. It may be permissible also to suggest some new applications of the pre-cast system that have occurred to the author in connection with his own practice.

It is evident that the pre-casting system in the form of large units presupposes means of moving the unit into its final position. As might be expected therefore, pre-casting in the past has been largely confined to marine work and railroad work. In the former case the units can be handled on scows or by derrick boats, or can themselves be made floatable. In the latter case derrick cars or wrecking cranes of large capacity can usually be made available. In recent years the crawler crane has been widely introduced and this opens up a vast new field for the further application of pre-casting. The heavy multiple wheeled pneumatic tired trailer and the tractor have made it possible to transport heavy loads great distances with speed and economy, and it is surprising to observe the ease with which equipment of this class can be operated over what may be termed construction roads or, for that matter, over virtually no roads at all.

Transportation, then, is a primary factor and the limiting weight is important. This limit for floatable units is that for which either a dry dock or launchways is available or can be provided. For all practical purposes and in locations likely to be encountered, this imposes practically no real limit on the designing engineer. The pre-cast concrete crib in units weighing from two to four thousand tons is quite generally replacing the older type of timber crib in our deeper harbours, and it appears to have become standard practice in certain of our ports as, for example, Montreal.

For non-floatable units handled by water it is not difficult to rig for loads of 250 tons if the importance of the work warrants it. A scow of canal width and about 125 ft. long can be rigged with shear legs to take about 150 tons.

Our Canadian waters are well served with derrick boats of large capacity which are probably available to all contractors, with the actual owner acting in the capacity of a subcontractor. This at least is the policy of the author's company in respect to its marine plant. As typical of privately owned equipment available for work in the Great Lakes and St. Lawrence and on the Atlantic coast, there may be mentioned the Canadian Dredge and Dock Company's derrick boat *Leland*, capable of lifting and swinging loads of 100 tons, and The Foundation Company's derrick boat *Foundation Scarboro*, capable of lifting and transporting loads of 250 tons. These are believed to be the most powerful vessels of their respective types in Canada. In Halifax harbour there is the Halifax Shipyards' derrick boat *Lord Kitchener*, capable of lifting and swinging loads of 75 tons. In addition there are many dipper dredges that by the removal of the dipper sticks could be readily rigged to handle loads of 100 to 150 tons. Of publicly owned vessels Montreal has a floating crane with a capacity of 75 tons and Quebec one with a capacity of 50 tons, both under the control of the National Harbours Board, and both capable of exceptionally high lifts. There are, at widely scattered points on the Great Lakes, St. Lawrence and on the Atlantic coast, many derrick boats having lifting capacities of about 25 tons. Non-floatable units intended to be transported with the aid of pontoons might weigh anything up to 1,000 tons without requiring anything in the way of extraordinary equipment, and loads up to 300 tons could be handled with scows of very moderate size.

**Fig. 1—Transporting 250-Ton Section of Pipe, Toronto Waterworks Intake.**

Graving docks, floating docks or marine railways, all presumably suitable for the building of pre-cast floatable concrete structures, are located at Port Arthur, Collingwood, Kingston, Montreal, Sorel, Quebec, Port Hawkesbury, Pictou, Sydney, Lunenburg, Halifax, Liverpool and Saint John. In the Lower St. Lawrence and the Bay of Fundy the tides are of sufficient height to permit of the building of many types of both floatable and non-floatable units on almost any convenient tidal flat.

Concrete cribs of large size have been built in pontoons, on ordinary scows and on launchways, and so far as the author is aware, all these methods of building and launching have been uniformly successful. Floatable caissons have in many instances been built on the ice. Non-floatable units within the limit of the lifting capacity of available derrick boats can be built almost anywhere within reach of the water. In general, contractors in Canada are well equipped for this sort of work.

Floatable pre-cast units can be towed any distance in sheltered waters, the length of the tow being only that dictated by economic considerations. It should not be at all difficult to make them seaworthy to permit of their being towed through fairly open water. Non-floatable pre-cast units can be transported on scows under almost any conditions likely to be encountered, the limiting weight being only that for which lifting capacity is available.

The principal use of heavy pre-cast units by the railways would appear to be in the form of girders for short span bridges, and deck slabs for bridges of various types, and large size pipe for culverts. Of bridges of the pre-cast concrete girder type there is a typical example in Montreal in the Atwater Avenue subway of the Canadian Pacific Railway, with a single pre-cast girder and deck slab for each rail on a 36-ft. span, which is believed to be one of the pioneer structures of its type in Canada. The Canadian National Railways have used pre-cast members combining girder and deck slab quite extensively, as for example a slab 3 ft. 9 in. thick and 60 ft. long to carry Cooper's E 60 loading on a clear span of 48 ft. The slab is in two sections, each 7 ft. wide, and each section estimated to weigh 127½ tons. This structure is for a subway on the C.N.R. at Shawinigan Falls (see Fig. 2).

For pre-cast units to be handled overland otherwise than by rail, weights of 15 tons can be handled without anything in the way of extraordinary equipment. Weights of from 25 to 40 tons can be placed with two crawler cranes of moderate capacity. The record for overland transportation by trailer, so far as the author is aware, is a 12-ft. 8-in. inside diameter pipe line forming part of the Colorado River aqueduct, pre-cast in a central yard in sections 12 ft. long, weighing 43 tons each, and distributed over some ten miles of line. In all this project involved approximately 46 miles of large pre-cast pipe varying from 9 ft. 8 in. to 12 ft. 8 in. inside diameter.

Many of the advantages of pre-casting are obvious and are applicable to a wide range of structures. Other of the advantages are principally applicable to special types of structures. In still other cases the primary advantage of pre-casting is one of erection, as, for example, a bridge slab that can be placed in a railroad track that is carrying traffic under conditions that would absolutely preclude the use of a cast-in-place structure.

Of advantages of the first class, that is of general application, perhaps the most important is the fact that concrete mixed and poured in a well designed central plant is as a rule of superior quality. The proportioning, mixing, placing and curing are all done under the most favourable conditions. Practically every mechanical aid to good results can be utilized and efficient inspection of each operation is assured. Of primary importance also is the fact that the cost is reduced, and as a rule this reduction applies not only to the labour employed in handling materials, mixing and placing, but also to such items as power, plant depreciation and maintenance and repairs. Perhaps the greatest reduction in cost that can be effected in any single item is that applicable to forms. The cost of these in the case of pre-cast work is likely to be less even if only one or two similar units are built. If any considerable number of units is to be built the operation can be organized on a mass production basis and the cost of forms is reduced to a small fraction of the cost of this item in poured in place work.

In pre-cast work the mixing plant and casting yard can be located in a place that is convenient for the economical delivery of materials, and that offers facilities for the storage of reasonably large quantities of cement, sand and coarse aggregate and of finished units. The operations of setting up and stripping forms and of placing the concrete do not interfere with other operations, as in the case of casting in place, and are not themselves interfered with by operations that must of necessity be performed at the site of the work itself. A great deal of confusion and lost motion is inevitably eliminated. The cost of transporting a given tonnage in the form of completed units from a well located casting yard to the work is likely to be less than the transportation of the same tonnage of separate ingredients from the point of delivery to a mixer on the work, and of the same materials plus excess water from the mixer to the forms. Given appropriate conditions then, pre-cast work furnishes a superior product at a lower cost and, in addition, provides for more orderly operation with every prospect of being able to carry it out on a much faster schedule.

Of advantages applicable to special work by far the most marked are those applying to marine work, using the term in its widest sense as including work on, over or under the water, or that may be exposed to water. Here the superior quality of pre-cast concrete is of particular value. The finished work is subjected to severe exposure and to factors that tend generally to limit its life. Unquestionably pre-cast concrete, made and cured under ideal conditions, is much better able to resist these extreme conditions. The most dangerous exposure of all would appear to be that portion of a structure in sea water that is within the tidal range. Here concrete at its best has not had a particularly good record in climates with low winter temperatures such as exist in Canada, and under these conditions it seems open to question whether concrete is in any sense the durable material that the public generally has been led to believe. There can be no doubt as to the necessity for work of better quality than much of the work that has been done in the past. It is incumbent upon engineers and contractors, and upon all commercial organizations interested in the promotion of the use of concrete, to improve their methods and improve the quality of their product.

For all such work that is within the tidal range the author would strongly recommend pre-casting with proper curing. If in the position of being the engineer in responsible charge he would go further than this and would bar absolutely the use of cast-in-place concrete in the tidal range in Canadian waters for any structure where durability was an important consideration. Poured in place

Fig. 2—Preparing to place Pre-Cast Bridge Slab. Canadian National Railways.

concrete might be used inside a tight coffer-dam if the conditions were such that it could be properly cured, but even then pre-casting is preferable.

Perhaps it might not be out of place here to say a few words about protecting the surfaces of concrete that is in water and exposed to alternate freezing and thawing. The author is of the opinion that this should be done wherever possible, and generally it is both possible and practicable. There are bridge piers within the tidal range of the Bay of Fundy, perhaps the most severe exposure that could be found, so protected, that have proved wonderfully durable. Other concrete exists in the same general locality, not so protected, and presumably built under a rigid specification, that might fairly be classed as among the most perishable of construction materials. The author has seen one of several piers in a bridge where the concrete has been protected by timber cribwork, erode to what amounted to virtual destruction in an unbelievably short time, due to a single timber having been forced out of place by ice. The more the author sees of concrete in water the more convinced he is of the advisability of this protection, even in fresh water between the high and low water marks. For some reason concrete seems to have a relatively hard and durable surface skin and to be relatively perishable once this skin is removed by erosion or by alternate freezing and thawing while wet. This is seen in harbour works, in the spillways of dams and in bridge piers.

In fresh water as, for example, the Great Lakes and Upper St. Lawrence, steel sheet piling has proved to be a most effective form of surface protection. It is cheaper than steel plate, can usually be fabricated in the field, and the excess metal in the interlocks is of great value in resisting shocks from floating ice and from logs. The designer can often arrange it in a manner that gives a pleasing appearance. Wood is an efficient protection but unless continuously submerged it should be creosoted. In sea water the timber must be creosoted in locations where wood borers are likely to be found. Protecting concrete with wood simply means that the forms are made so that they are a part of the finished structure, and they should therefore be made of thicker material than would otherwise be used, and should be well anchored with galvanized fastenings. The author believes that brick, either vitrified or semi-vitrified, has been used as a concrete facing material in Europe but he knows of no case of its having been used in Canada as a protection against alternate freezing and thawing and would hesitate to recommend it, fearing that the mortar joints would be attacked. He knows of no case of chrome nickel iron, i.e. the so-called stainless steel, having been used for protecting concrete, but in his opinion this might have great merit. It would be expensive, but probably not so expensive as granite, and certainly not so expensive as rebuilding a costly concrete structure after a comparatively few years' service. Copper might be given consideration as a protective surfacing. Cast iron in the form of ribbed panels of suitable size should be very effective.

Reference has been made above to the advantage of pre-casting marine structures from the standpoint of obtaining concrete of a more durable character, and from the standpoint of the lower cost of forms and of mixing, placing and curing. The subject may be considered from the standpoint of another item of considerable cost. The saving through the elimination of cofferdamming and pumping is often tremendous. It requires little imagination and no figuring to reach the conclusion that a cast-in-place structure to replace the concrete cribs of the type commonly used in Montreal would be financially impracticable. Yet there has been little or no attempt in Canada to apply this principle of a floatable watertight concrete box to other structures in the water, such as, for example, bridge piers, pump houses, lighthouses and the like. The caissons of these structures have been floated to the site but there seems to be an unwillingness to use caissons except where it is deemed necessary to reach a depth impracticable with a cofferdam. One can visualize a hollow bridge pier built complete in a dry dock except for the centre filling, and floated to the site and sunk on a prepared foundation. One can visualize another type of pier in which the foundation would be two or more cylindrical caissons sunk through wells in the floatable pre-cast portion. This would give a very strong pier with the caissons acting somewhat like the roots of a tooth.

The caisson is a type of pre-cast work in which the author has been particularly interested for about twenty-five years. His remarks on this subject may lead to an accusation of being a propagandist on behalf of the company with which he is associated, but he must take that risk. As a means of providing a foundation in water that must be carried to even moderate depth, the caisson, pneumatic or open as the occasion demands, offers an absolutely sure and safe solution. This is said after due consideration, in the belief that the engineer who builds on a properly designed caisson foundation may rest assured that he will have no settlement of his structure that will reflect upon his professional reputation. There seem to be two beliefs in regard to caisson work that are quite widely held even in the professional mind, and that seem quite erroneous. The first is that caisson work is expensive, and the second is that a caisson must, if it is physically possible, be carried to rock. Unfortunately the second statement is often accepted as axiomatic and the first statement thereby becomes a fact. Where the depth exceeds say 35 ft. the caisson is likely to be an economical solution of the foundation problem, though this point of economic depth must vary somewhat with the conditions of each particular case. If a bridge caisson, for example, is carried say thirty feet into the ground, or that depth below any point of possible scour, it is the author's conviction that it can there be founded on any reasonably hard stratum with perfect safety, provided no extraordinary conditions exist. There is no necessity for carrying it to rock. This statement should be modified in the case of a bridge of unusually long span or in the case of an exceptionally soft clay or light silt overburden. If the caisson is of the dredging type and is carried about thirty feet through material that will give a reasonable amount of lateral support, it will usually be sufficient, for loads of anything up to 12 tons per square foot, to found it on any fairly thick stratum that is sufficiently hard to prevent dredging further with the ordinary heavy bucket. Unless the span be exceptionally long the load under a bridge pier seldom reaches 12 tons per square foot.

A caisson, like a pile, is unique in the fact that it gives, to one who can read the signs, an accurate indication of its carrying capacity as it is being sunk. Just as an experienced pile man can tell what a pile will carry by the way it drives, so an experienced caisson man can tell by the way the caisson acts where and how it must be founded to carry a given load. In all the author's experience he can recall only two cases of bridges of moderate span where the caissons could not with perfect safety have been founded at depths of less than forty feet. The interest on the money he has wasted in carrying caissons to quite unnecessary depths would place him among the fortunate beings who have moved to those places where income taxes are of secondary importance.

There is one more characteristic of the caisson that might be noted, and that is its ability to resist eccentric loading. Again barring extraordinary conditions, the effects of the usual lateral forces and of even quite large eccentricities can be completely ignored in the case of the caisson, as the opposing passive resistance of the soil is sufficient to overcome this if the caisson is carried even a moderate depth into the ground. Were this statement not correct our wood pole transmission lines would hardly withstand anything more than a comparatively gentle breeze. It is quite common to find specifications requiring extraordinary and quite unnecessary accuracy in the sinking of caissons, thereby forcing contractors to include in their estimates comparatively large sums for special rigging and guide frames which they know will be demanded to meet the specified requirements. Occasionally one sees a specification stating that a caisson must be sunk to exact position, a requirement that it is obviously impossible to fulfil, but one that is certain to add considerably to the cost of carrying out the work. The designer, if he be skilled at his trade, will know and anticipate the probable drift of a caisson and determine its size accordingly, and specify in exact figures what top and bottom drift has been allowed for in the design. Such a caisson will probably be built and sunk for less money than one that is designed too small in the first instance through lack of allowance for drift, and which requires extraordinary accuracy in sinking to make up for this deficiency. In the opinion of the author, the economical design of a bridge pier caisson in say 30 ft. of water and to be sunk say 30 ft. into the bottom, would have a margin around the base of the pier shaft of not less than 30 in. if sunk by the pneumatic method, or of 42 in. if sunk by open dredging. There would probably be no necessity for carrying this caisson to rock and a lot of needless expense would thereby be avoided, bearing in mind that the cost of excavation in the upper strata may be only a few dollars per yard, whereas the cost of carrying it through a perfectly good hard stratum at a depth suitable for founding, may easily exceed one hundred dollars per cubic yard.

Apropos of the allowable drift of bridge caissons the author, some years ago, with the concurrence of the chief engineer of one of our principal railways, had the opportunity of conducting an interesting full scale experiment. A number of similar piers were to be founded on dredging caissons sunk through a rather soft soil to a depth of about 60 ft. As he recalls, two of these caissons were of what might be termed standard design, with a minimum allowance for drift. Two caissons were made substantially larger, one with the extraordinary allowance of some five feet between the pier shaft and the sheeting of the caisson. It is no exaggeration to say that the sinking of this caisson measured in days took less time than one would ordinarily figure in weeks, and that the cost was unbelievably low.

The principal use of caissons in Canada has been in connection with bridge piers, and for this work two types have been used, the pneumatic and the open dredging. The term "caisson" is here used in its restricted sense to designate a vertical shaft with a horizontal cross section of whatever size and shape is required. The characteristic feature is that it is built to a certain height and is then sunk into the ground by excavating from the interior. The primary function of the caisson is to permit of an excavation being carried through a water bearing soil. As originally used, it often served only this purpose and the caisson proper, on the American continent at least, was generally built of wood with a pier of brick or stone built inside of it. With the introduction of concrete the caisson became the pier itself and took the form of a concrete shaft, with or without permanent outside forms of wood or metal.

The pneumatic caisson has a cup-shaped depression in the bottom called a working chamber, terminating in a rather sharp rim called a cutting edge. The working chamber is connected with the surface by two or more shafts used for getting men into and out of the working chamber and disposing of the excavated material. The water is kept out of the working chamber by compressed air, and to maintain this pressure the shafts are fitted with air locks. The open caisson has the cutting edge but has no working chamber. The shafts are larger and the excavating is done with a clamshell bucket working through them. If there is not too much water the excavation in an open caisson may be done by hand in the dry, the water being held by pumping, but generally the excavation is in the wet and no attempt is made to exclude the water. It frequently happens that a combination caisson is used, that is, one that is commenced as an open caisson and bottomed under the pneumatic process, a deck or a concrete plug being formed in the large dredging shafts to effect the conversion.

If the caisson be for example for a bridge pier, the working chamber in the case of the pneumatic process is completely filled with concrete. Usually the shafts also are specified to be filled but there does not appear to be any reason for this unless the conditions are such that the water inside the shafts might freeze, a condition seldom met with in practice. In the case of the open caisson the bottom is sealed with concrete placed under water, and the shafts also are often filled with concrete. Unless the conditions of loading be quite extraordinary it is difficult to find any logical reason for concreting the shafts, as a sub-base at or immediately below the water level will spread the load to the caisson walls and will eliminate any possibility of freezing. If weight be required, the excavated material is almost as efficient as concrete for filling, but inasmuch as the effects of lateral forces and eccentricity seldom reach the cutting edge, it is the exceptional case where extra weight is required or is desirable.

Pneumatic caissons are commonly used for building foundations in lower New York where the rock is from 50 to 100 ft. below street level and is overlain by quicksand. There are a few places outside New York, including Montreal, where buildings have pneumatic caisson foundations but unless the character of our buildings changes radically there is little justification for this type of foundation in Canada. The economic minimum size for a pneumatic caisson is about six feet and this, if carried to rock, can take a safe load of about 700 tons. It is seldom that in Canada there is a building tall or heavy enough to produce this concentration, and such a caisson is likely to be loaded to only about half its capacity. The concrete pile and the steel pile would appear to be a more economical solution.

Caissons may be used for another purpose than that of forming a foundation, i.e. for constructing a shaft through water-bearing soil. The soft ground portions of mine shafts are typical examples. Here the caisson has a large shaft that is not filled. If the pneumatic process is used a temporary deck is built in the shaft to form a working chamber. The bottom seal takes the form of an annular ring of concrete (see Fig. 3).

In Europe the pneumatic caisson has been used quite extensively in the construction of quay walls in harbour works, but so far as the author is aware there are only two instances of this application in Canada. At the Windmill Point wharf and at Alexandra pier, both in Montreal, walls have recently been built in front of the old cribwork by the pneumatic process to permit of dredging to a greater depth. At Windmill Point the caissons were 90 ft. long by 5 ft. 4 in. wide, sunk end to end to form a continuous wall. At Alexandra pier a continuous line of caissons 7 ft. in diameter was used. In both cases the new wall had to be carried some distance into the rock.

Caisson work, particularly by the pneumatic process, can be done today at a cost far below that of twenty-five years ago, in spite of the increase in the cost of both labour and materials. During the period between 1912 and 1914 the company with which the author is associated cut its costs on certain types of dredging caissons by about 30 per cent through improvement in design and in methods, and successfully adapted the open dredging caisson to conditions that had previously required compressed air, thus effecting a further reduction in cost. The modern types of air compressors introduced during the last five years have contributed to a substantial reduction in the cost of pneumatic work, and the same may be said of the recently adopted welded steel working chamber.

Perhaps a few remarks relative to the types of caissons to meet various conditions may not be out of place. A circular caisson is cheaper than a rectangular one, and the more closely the latter approaches a square the cheaper it will be. The minimum economic size for a circular dredging caisson would appear to be about 6 ft. inside diameter and of a pneumatic caisson about 6 ft. outside diameter, although these limits will vary somewhat with the depth and the character of the soil. The minimum for square caissons should be about the same. A rectangular caisson with a great ratio of length to width is decidedly expensive, and this ratio should preferably not exceed about seven to one. Assuming the minimum economic width to be 6 ft., the maximum economic length would be about 40 ft. In a dredging caisson the minimum thickness of the outside walls might be about 12 in. for small caissons and 30 in. for large caissons, and the maximum about 72 in.

A dredging caisson is well adapted to conditions where the soil is fairly soft or is of a sandy or gravelly nature

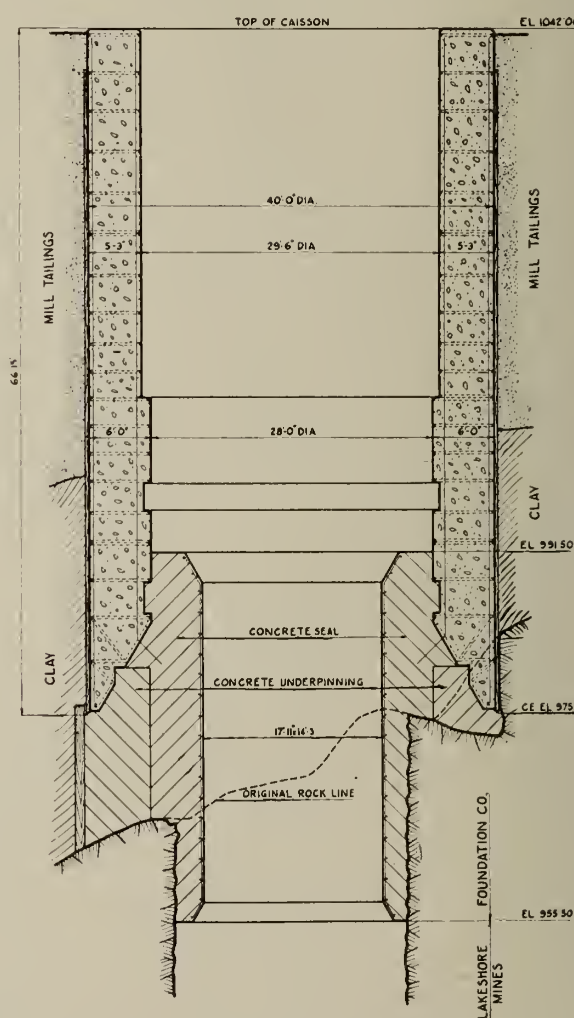

**Fig. 3—Pneumatic Caisson for Shaft, Lake Shore Mines.**

for a considerable depth, and where the foundation is not to be carried to rock. It is likely to be expensive if it has to be sunk through any considerable mass of large boulders and the cost may be prohibitive if it has to be carried through hardpan. Other than in a mine shaft or similar structure the conditions would seldom be such that an economic design would contemplate carrying a dredging caisson to rock. Should the rock be uneven this type of foundation may be found to be quite impracticable. The pneumatic caisson should be used where the load is such that the foundation must be carried to rock or any distance into rock, and particularly where the rock level is likely to vary more than about 3 ft. in the area covered by the caisson. A dredging caisson is not suitable for use close to and below an existing structure as it usually causes a subsidence of the ground around it.

**Fig. 4—Method of Launching Caisson at Halifax.**

It is believed that floatable concrete cribs of the modern type were first used in Canada on the Welland canal. They have since been used extensively in Montreal and were used in three wharves in Halifax. They are generally rectangular with interior longitudinal and cross walls dividing them into a number of rectangular cells. A portion of Windmill Point wharf is faced with cribs of slightly different design with the principal cells circular in plan. The standard crib as used in Montreal harbour is rectangular, 112 ft. long by 42 ft. wide by 42 ft. high. It contains 1,681 cu. yd. of concrete, 195,800 lb. of reinforcing and weighs complete about 3,600 tons. The launching weight is about one third of this.

Various methods of building and launching these cribs have been employed. One patented method used a floating pontoon, the bottom and sides of which served as forms for the bottom slab and the lower portion of the side walls. Another system used a pontoon consisting of a rectangular box somewhat larger than the finished crib, which was removed by lowering weights on to the four corners and sinking it until the crib could be floated free. Concrete cribs have been built on the decks of scows and launched by letting sufficient water into the scow to give it the required list. Many of the cribs used in Montreal were built by the Atlas Construction Company Limited in a graving dock on the Lachine canal, which is obviously an excellent method where a suitable dock is available. On a number of recent contracts in Halifax and Montreal the cribs were built and launched from ways. In an ingenious system used by E. G. M. Cape and Company in Halifax, and recently in Montreal, the crib is built on a level platform which can be tilted on its longitudinal axis to an angle corresponding with the slope of the standing ways which the platform engages when the required degree of tilt is reached (see Fig. 4).

These cribs are usually founded on a rubble mound topped off and levelled with finer stone. They are sunk in the required position and filled with selected material which is rock if available, otherwise any material of a gravelly or sandy nature. So far they have proved to be a successful and economical type of construction, but the author feels that there must still be a good deal of doubt as to their durability in salt water. To make them floatable the walls must be relatively thin, leaving the reinforcing rather vulnerable to attack, and once corrosion of the bars commences the effective destruction of the thin walls would seem likely to progress quite rapidly.

Structures similar to our concrete cribs have been used for many years in European harbour works, but their practice seems to have been to use much thicker walls and more substantial construction generally. This may be the result of a broader experience on the part of European engineers with masonry construction for quay walls and the like, and it is possible that we may have cause to regret the use of very thin walls in some of our structures.

The concrete crib seems to have been adapted in Canada to wharf work only, either in the form of a bulkhead or a pier. As stated earlier in this paper, there is no reason why the same principle should not be applied to bridge piers with pneumatic caissons sunk through certain of the cells, or with the base resting on piles cut off to the required level. An alternative arrangement might be to form a base of concrete deposited under water and screeded to a level surface, and on this found the floatable pre-cast section of the shaft that would carry the work above the water level. This was the method used in forming the foundation for the large pre-cast three way distributor for the Toronto Waterworks Intake (see Fig. 5).

Mr. Joseph J. Yates, bridge engineer of the Central Railroad of New Jersey, has kindly furnished the following

**Fig. 5—Three-Way Pre-Cast Distributor, Toronto Waterworks Intake.**

data of a remarkable bridge in which advantage was taken of the saving in time and in cost due to pre-casting the bases and the sidewalls of the sub-bases of the double track piers. The bridge is a four-track structure consisting of two double-track bridges side by side, each with a length of 7,411 ft. crossing the open water of Newark Bay. It is an important structure carrying some 300 scheduled passenger trains a day, in addition to the railroad's freight business, to its New York terminal. It is said, with its approaches and grade crossing eliminations, to have cost about $15,000,000. It consists of 41 main plate girder spans, twin vertical lift spans with flanking truss spans, and an approach viaduct. The lift spans are founded on pneumatic caissons. The other main spans, which are of present interest, were founded on timber piles driven in a dredged trench and cut off level. On each of these pile groups there was landed a floatable cofferdam, the bottom of which formed the base of the finished pier surmounted by a cellular structure cast integral with the base which formed the walls of the sub-base. On this was bolted a removable cofferdam in which the pier shaft was built (see Fig. 6). Some of these cofferdams were used as many as twelve times, indicating a remarkably efficient operation. The caissons were built and launched from ways in the usual manner.

Where the depth of water permits, there appears to be no reason why the scheme used on the Newark Bay bridge could not be carried still further in so far as the pre-casting is concerned. The cellular sub-base walls might be carried up to within a few feet of water level and the shaft proper commenced at this level. This would reduce the timber cofferdam to a very small affair.

Concrete block work might have a much wider application for marine construction in Canada than it has had in the past. It has been quite widely used on the Great Lakes for that narrow band between the high and low water marks, and with excellent results. Here poured in place concrete is not appropriate, as "honey-combing" at the water line seems to be the inevitable result, and the life of such concrete is often exceedingly short. Repairs to this narrow strip at the water line can be made with "gunite" during a period of exceptionally low water, but a structure carelessly built and subsequently patched is never so good as one well built in the first instance. Concrete blocks when used in the manner described are usually founded on a timber crib or on some kind of a platform carried on piles. They are usually surmounted by a copewall of poured-in-place concrete. It is suggested that this latter might also, with advantage, be made of pre-cast blocks with only a shallow band of cast-in-place concrete forming a curb at the top of the wall. With this construction it would be possible at moderate expense to take down the whole or any part of a wall when the course of blocks at the water line has lived its useful life, and rebuild it, using the upper course of blocks at the water line and the damaged blocks for the top course, with the eroded faces turned toward the back of the wall. If necessary any damaged blocks could be made good at this time with "gunite." In this type of construction it appears that a decided improvement could be effected by protecting the exposed face of the bottom course of blocks with wood or metal well anchored to the concrete.

In all such block work, the author believes, the individual blocks should be made as large as possible, the weight being limited only by the lifting capacity of available equipment. The cost of forms per cubic yard for large blocks will be less than the cost for small blocks, and the cost of placing a block weighing 25 tons will not differ greatly from the cost of placing one of 5 or 10 tons. Fewer joints will result from the use of large blocks, and in all masonry work the joints are particularly vulnerable to attack by the elements. If sufficiently large blocks are used, dowelling becomes unnecessary and can be eliminated. For small work it is suggested that blocks of 20 to 25 tons each might be appropriate, while for work of any considerable magnitude blocks of from 50 to 100 tons each would not be out of the way.

There would appear to be no great advantage in making pre-cast blocks hollow or cup-shaped as is sometimes done, and afterwards filling them with poured in place concrete. The saving to be made by using a leaner mix in the filling will probably be less than the extra cost of forms and the loss through having two separate operations where one would suffice. About the only factor that may be suggested in favour of the hollow block filled afterwards is that with equipment of given capacity it results in fewer joints per unit of face. Where the filling material can be rock, or where the conditions are such that no filling is necessary, the hollow block is obviously advantageous.

In the horizontal underwater joints of block work the author would propose the use of wood from ½ to 1¼ in. thick, creosoted if marine borers are present. This could serve as the bottom form when casting. Other suitable types of jointing material that suggest themselves are asbestos in combination with a suitable bituminous compound, which could be made in sheet form and cast on the bottom of the block. Vertical joints below water can, if necessary, be caulked with lead wool and grouted, but this would be required only under some extraordinary conditions. Generally speaking they can be left open. An inexpensive method of closing vertical joints at or immediately below the water line is to fill them with a continuous line of well driven wooden wedges.

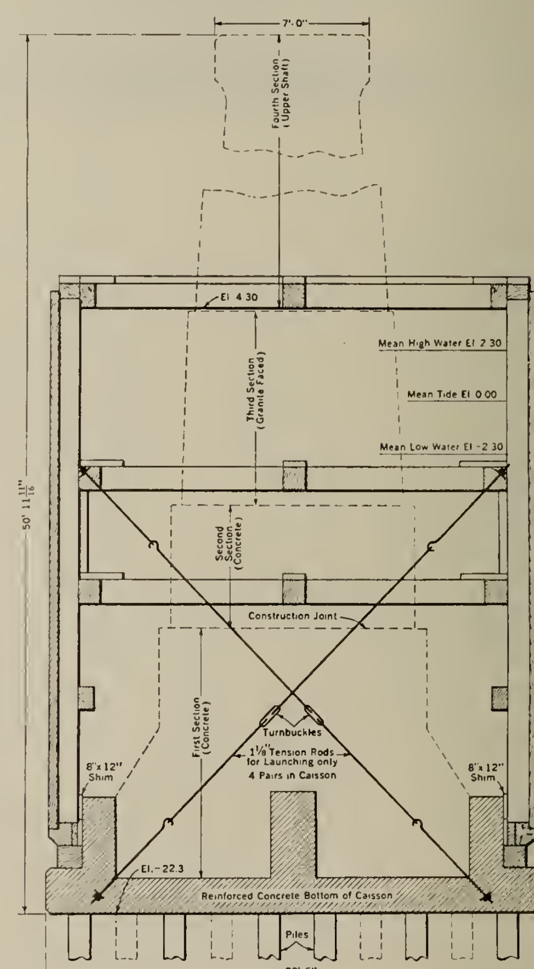

**Fig. 6—Section Through Concrete-Bottomed Cofferdam for Piers of Newark Bay Bridge. Jersey Central Railroad.**

Undoubtedly the most effective use of concrete blocks in Canada is in the Great Lakes wharves to which reference has already been made. There are some examples of this in Montreal harbour and there is every indication that where this system was used there is much less erosion at the water line than where mass concrete was used. The largest project in which pre-cast blocks were used is the Ocean Terminals at Halifax. Here the quay walls, founded at depths of from 30 to 40 ft. below water, were built of cellular concrete blocks illustrated in Fig. 7. An article in The Engineering Journal for October, 1918, gives the size of these blocks as 21 ft. 10 in. on face, 31 ft. from back to front, and 4 ft. 1½ in. high, and the weight 62½ tons. They have 8 in. reinforced walls and interior walls dividing

Fig. 7—Block Casting Yard, Ocean Terminals, Halifax.

the block into twelve cells. They were founded in part of the work on a rock foundation, and in the deeper parts on a rubble mound. The face cells and those in the centre of each block from front to back were filled with concrete. The remaining cells were filled with rock.

It is worth noting that the most recent addition to the ocean terminals at Halifax, the fish landing pier, is of concrete crib construction which has been largely developed since the original piers were built. Doubtless if the whole project were being built today, floatable cribs would be given serious consideration in place of the hollow block construction.

Before leaving the subject of pre-cast work in water one must not overlook the concrete pile, but it is to be feared that owing to its comparatively high ratio of exposed surface to cross-sectional area, it is not suitable for use in water in our Canadian climate unless some really effective and inexpensive method of surface protection is devised. Pre-cast piles about 8 in. in diameter have been used in the tropics with the knowledge that in a few years they will be ten or twelve inches in diameter due to a deposit of mollusks that seems to form a surface coating that is possibly more resistant than the concrete itself. In an eastern Canadian climate the reverse occurs, the alternate freezing and thawing resulting in a surface disintegration that quickly destroys a member of such small cross section, and particularly one that must be reinforced with the bars rather close to the surface. A pile 30 in. in diameter would be considered a large pile. A surface erosion of 4½ in. would cut its area in half and probably eliminate the entire effect of the longitudinal reinforcing. If the pile is 18 in. diameter an erosion of 2⅝ in. will cut its area in half.

It is rather expensive to protect the surface of concrete piles at the water level. If creosoted timber is used it should presumably be very well fastened with copper or bronze bands. It would be interesting to test the effectiveness of a stainless steel or copper protective covering on a concrete pile between high and low water, but this might be commercially impracticable on account of the high cost per ton of carrying capacity of the pile. For example, an 18-in. pile carrying 50 tons would require 13.6 sq. in. of protection per ton capacity per lineal foot covered, whereas the caissons used at Saint John would require only 2.66 sq. in. of protection per ton per lineal foot if carried to rock, or 5.33 sq. in. if founded on hardpan.

For use in the dry, the cast-in-place concrete pile would appear to be superior from practically every standpoint to the pre-cast pile, and it is at the same time less expensive. In general the pre-cast concrete pile in water would seem to be inappropriate to our eastern waters and more costly per ton capacity than other much more suitable types of foundation. On the Pacific one would hardly expect the concrete pile to compete with timber.

There are few examples of pre-cast concrete pile construction in Canada. The most important is Pier No. 2 at Halifax, a structure 800 ft. long by 235 ft. wide, in water from 34 to 57 ft. deep. The piles are 24 in. square in cross section and in length vary from 47 to 77 ft. The heaviest would probably weigh about 25 tons. The materials through which the piles were driven are stated to have consisted of from 5 to 27 ft. of soft mud and 2 to 12 ft. of hard clay and gravel overlying the rock. Lateral stability is secured by means of batter piles which have apparently proved quite adequate in spite of the very shallow penetration of the piles in anything other than soft mud. It is interesting to note that the piles were protected with 4 in. of creosoted timber between high and low water. While some repairs have had to be made to this structure, it may fairly be said that this sheeting has been on the whole effective.

The small cylindrical caisson is, in effect, a large pile, and in wharf work serves the same purpose as the pre-cast concrete pile. Unless the loads be very light, it is superior to the pile in every way. Having less exposed surface per ton carrying capacity it is more durable and is easier to protect from the elements. If the outside forms are made of wood well fastened with galvanized bolts to interior angle rings, these in themselves offer excellent surface protection. Steel plate at the water line is an efficient form of protection but it should be of some rust resisting alloy.

Unlike the large concrete pile, cylinder construction does not require expensive special equipment. An 8-ft. diameter cylinder weighs about 1½ tons per lineal foot, permitting a 25-ton crane to handle it in 16-ft. lengths. If larger equipment is available there is an advantage in having fewer joints. A strong scow about 125 ft. long can be rigged with shear legs that would permit of the ordinary sized cylinder being handled in a single section long enough

Fig. 8—Work in Progress, Berth 3, Saint John, N.B.

to reach from the bottom to well above the surface of the water.

The cylinder is sunk to a hard bottom by dredging, or it may be sunk as a pneumatic caisson. If it is to be founded above the rock level, the open dredging process is quicker and cheaper and equally effective. If it is to be sunk through a hardpan or boulder formation or into the rock, the pneumatic process should be specified. If the pneumatic cylinder is founded on hardpan an enlarged base can be formed. Without extraordinary expense, the diameter of this can be about 2 ft. 6 in. larger than the cylinder. A pneumatic cylinder 6 ft. in diameter belled out on hardpan can carry about 650 tons, or if carried to rock about 700 tons. There is therefore little incentive to carry it to rock if hardpan is available. An 8-ft. diameter dredged cylinder will carry about 600 tons.

**Fig. 9—Transporting Caisson from Drydock to Site, Saint John.**

As an alternative to carrying cylinders to the depth necessary to secure a suitable foundation, they may be carried to a depth sufficient to give the required stability, and steel piles may be driven inside them to the necessary bearing and a concrete plug poured to transfer the load from the cylinder walls to the piles. The author does not favour wood or pre-cast concrete piles in cylinders, as it is doubtful if enough of them could be driven in the comparatively small space available to develop the strength of the cylinder walls.

There are two outstanding examples of pre-cast cylinder work in wharf construction in Canada, the Ballantyne pier in Vancouver, built under plans of Mr. A. D. Swan by the Northern Construction Company, and Berths 1, 2, 3 and 4 at West Saint John, N.B., to which reference has already been made. The pneumatic cylinders used to face Alexandra pier and the open cylinders used at King Edward pier, both in Montreal, were cast in place.

Bag work has been described as a sort of semi-precasting system, one which, so far as the author knows, has not been used in this country. The term does not refer to cement bags holding some fraction of a cubic foot, but to large bags holding several cubic yards. These would be of canvas or jute, strongly made and of a size to fit quite loosely into a special bottom dump bucket somewhat similar to the bucket commonly used to deposit concrete under water. The method of operation would be first to place the bag in the empty bucket, then fill it with the required batch of concrete and close the top by sewing or lacing. The bucket would then be lowered to the bottom and gently discharged in the required position. In this manner a concrete foundation could be built under water in even a swift current without danger of segregation or of loss of cement, and without the formation of laitance. There will be no mechanical bond between the separate bags but they will conform closely to whatever surface they are placed on, and if sufficiently large will offer great resistance to lateral displacement. The author sees no reason why bags of this character should not be made to hold say 20 tons of concrete each, and can conceive of many cases where this type of construction would be particularly appropriate.

Pre-cast concrete pipe is so widely used that any description is superfluous, and it would seem sufficient to note some of the outstanding projects from the standpoint of size and weight of units handled. It is believed that the largest units handled in any considerable number by derrick boat were the 100 ft. sections of pipe for the Toronto intake, weighing 250 tons each, as shown in Fig. 1, although without doubt larger single units have been tackled. These were pre-cast on skidways and hauled by tackle to the water's edge within reach of the derrick boat. The operation was very successful. The heaviest sections of pipe handled overland were the 43 ton units on the Colorado River aqueduct (see Fig. 10). Concrete pipe of moderate size is now turned out on a mass production basis and it seems likely that this will supersede steel and cast iron in our future submerged pipe lines for anything in excess of about 24 in. in diameter. The intakes themselves and the specials can be conveniently built up in "gunite" or a combination of pre-cast concrete and "gunite."

From time to time tunnels have been built by dredging a trench across a river bed and depositing in this tubular sections, as was done, for example, in the Detroit-Windsor tunnel. Here the tubes were of steel plate construction encased in concrete poured through a tremie. In the Oakland-Alameda Highway tunnel in California the river section was made up of pre-cast concrete units 203 ft. long by 38 ft. outside diameter, with walls 3 ft. thick. Twelve of these sections were pre-cast in a dry dock, three at a time, fitted with end bulkheads and towed to the site and sunk in place (see Fig. 11). The weight of each unit was about 5,000 tons and its draft while floating about 25 ft. The system was completely successful and is doubtless much cheaper than any form of metal tube encased in poured in place concrete.

**Fig. 10—Unloading 43-Ton Section of Pipe, Colorado River Aqueduct.**

This discussion as applied to marine work has so far dealt with construction that is actually in the water. There is still another class of work to consider, that is, those parts of a structure that are over the water as, for example, the decks of wharves, the girders and decks of concrete bridges, etc. Here all of the previous arguments apply, some to a lesser and some to a greater extent. When dealing with salt water, the degree of exposure is admittedly less but is still sufficiently severe to demand the dense, impervious concrete that can more readily be produced in a central casting yard. The saving in the cost of forms is likely to be much greater than in almost any other class of structure,

**Fig. 11—Towing Pre-Cast Tunnel Section to Site, Alameda Tunnel.**

as when working over the water these must be as a rule supported on piles or the spans must be made long enough to use the finished substructure as the medium of support. In either event both the erecting and the stripping become exceedingly costly. If the work is of any magnitude a great deal of time and expense incidental to the erecting and stripping of forms is eliminated by pre-casting.

In decks and slabs one frequently hears the argument that in a pre-cast structure the effect of continuity is sacrificed. This argument seems much more theoretical than practical. If, as is frequently the case, the foundation is on timber piles, it is doubtful if the bearing value of the foundation, taken as a whole, is sufficiently uniform to give the complete benefit of continuity, and it would appear that to attain this one must almost have a foundation that is entirely on rock or on some comparatively unyielding and uniform stratum that is fairly deep and is not likely to suffer any disturbance during the life of the structure. If, to get the saving due to continuity, comparatively large areas are poured as a continuous operation, it seems reasonable to suppose that the shrinkage stresses go a long way in upsetting the theoretical calculations. If, as is generally specified, joints are made at the point of maximum bending moment, it again seems doubtful if the full effect of continuity is realized. One has only to observe the tendency of these joints to open up in the form of hair cracks to realize that the shrinkage stresses have completely cancelled the dead load compressive stresses. In pre-cast work the cumulative effects of shrinkage are entirely eliminated, and if conditions warrant it, continuity can be obtained in the principal members by connecting the negative rods together over the supports and pre-stressing them if considered desirable. Some sort of a yoke that will be operative with a reasonable amount of lateral displacement would appear to be the logical form of connection.

Before closing it would seem appropriate to refer to two rather remarkable instances of the use of pre-cast concrete. Both of these were what might properly be called "stunts" and as such have already received wide publicity. This reference is to the large open caissons for the Little Belt bridge of the Danish State Railways which were launched upside down, and the pre-cast concrete dam in connection with the Chute-a-Caron development which was built on end and tipped into the river.

The Little Belt bridge is an important structure crossing a strait called the Little Belt which joins the Baltic and the North seas. It contains a number of spans of considerable length and the depth of water at the pier foundations ranges from about 80 ft. to 120 ft., the tallest pier having a total height of 223 ft. from its top to the bottom of the caisson. The caissons for the main piers were of the dredging type and of novel design. They were 142 ft. long by 74 ft. wide, rectangular with rounded ends. The sides were formed by a continuous ring of steel cylinders encased in concrete and connected together with a thick concrete slab forming the deck of a working chamber, thus providing for the use of compressed air if required. One of the novel features of this caisson was that the ring of cylinders which formed a sort of cutting edge was scribed to fit the contours of the rock, thus making launching in the usual way somewhat difficult. This whole structure was therefore built on launching ways upside down and was launched as one would launch a ship, and it was afterwards turned through 180 degs. while afloat through manipulation of ballast.

In connection with the Chute-a-Caron development it was necessary to close off a channel in which the current was so swift that conventional methods were deemed to be difficult and possibly impracticable. The dam, in the form of a large concrete block scribed to fit the bottom of the channel, was built on end on one bank and this pre-cast structure was then tipped into the river.* As built this was 92 ft. high, 45 ft. wide and 40 ft. in maximum depth, and weighed approximately 11,000 tons. This scheme proved to be a complete success.

In closing the author wishes to express his appreciation for valuable information regarding railroad practice furnished by C. P. Disney, bridge engineer of the Canadian National Railways, and P. B. Motley, M.E.I.C., engineer of bridges of the Canadian Pacific Railway, and to C. S. Bennett, A.M.E.I.C., acting chief engineer in Halifax for the National Harbours Board, for information relating to Halifax Harbour. He desires also to express his appreciation to L. H. Burpee, A.M.E.I.C., of his own staff for the research work he has done concerning this subject.

# Freight Hauling in the Undeveloped Territories of Canada

*J. B. D'Aeth, M.E.I.C.*
*Engineer, Fraser-Brace Engineering Co. Ltd., Montreal.*

**Paper presented at the Semicentennial Meeting of The Engineering Institute of Canada, in Montreal, June, 1937.**

SUMMARY.—Gives brief notes on the cost of transport by canoe and dog-teams, and on road building in the bush, followed by a discussion of summer and winter freighting by water, horse-teams, motor trucks, and tractors with trains of sleighs.

Canada, comparatively speaking, is a young country, covering a large area, sparsely settled, having an unusually rigorous climate and endowed with great natural resources.

Our population of approximately eleven million, if spread over the entire land area of Canada's 3,466,556 square miles, would give a density of 3.17 persons per square mile, which is extremely low. Our population is approximately two and a half million less than that of the State of New York. Examination of a density population map of Canada, it is safe to say, would reveal that 95 per cent live within a belt formed by the International Border or the north shore of the Great Lakes and a parallel line 150 miles north, except in the prairie provinces of Saskatchewan and Alberta, where this belt should be increased to 300 miles.

In general, most of the territory north of this belt is undeveloped, and except for a few towns and camps, chiefly connected with mining and forestry, the country is inhabited by Indians, trappers, prospectors and hunters.

There is a great variation in temperature, being hot in summer and very cold in winter. Along the southern boundary of this undeveloped territory the summer temperature will occasionally reach 90 deg. or higher, but only for a few days. In winter, however, the temperature over much of it drops as low as 50 deg. below zero and will remain below zero for weeks at a time. Under average climatic conditions, the lakes and rivers begin to freeze over during the first two weeks of November, and the ice is generally thick enough to carry teams by the second week in December, and heavy loads about January 1st. The ice is usually good for freighting purposes up to April 1st. The snowfall varies considerably, being lighter in the prairie provinces than in Ontario and Quebec, where the total fall for the winter often amounts to between 8 and 10 ft.

Stretching across the continent are two railway systems. The Canadian Pacific is the southerly with a few branch lines extending into the north country. The Canadian National takes a more northerly route, and it is from this railway that most of the freighting into the undeveloped territories starts.

The country in which most of this freighting is being carried on is literally dotted with lakes and rivers, and in the low lying portions there is a great deal of muskeg. The land, except where fires have occurred, is well forested.

The foregoing is a brief description of the country in which freighting is being conducted for the development of our more remote natural resources of forestry, mining and water power.

Before proceeding to the more modern phases of transportation in such undeveloped territories, it might be interesting to look at the older methods of freighting, which are, to a limited extent, still in use to-day.

In summer canoes are used. These are usually 18 to 19 ft. in length with a beam of 46 in. and weigh about 160 lb. These will carry between 1,200 to 1,400 lb. of freight. Latterly, outboard motors are being employed, reducing the labour and increasing the speed.

The Hudson's Bay Company gives the following information regarding the freighting between Norway House and Island Lake, a distance by river of about 185 miles. Along the route there are ten portages, one of which is four miles long with the others varying from 100 yards to ¾ of a mile. The round trip usually takes ten to twelve days, depending upon conditions. Indians are employed and they supply their own food, canoes and motors. When the latter are used one motored canoe usually tows two or three others. For the transference of this freight the company pays 9c per lb. or at the rate of about $1.00 per ton mile. The rates for such work will vary, depending upon the difficulties of the route.

In winter toboggans or dog sleds are used. Five or six dogs make up a team when freighting by toboggan, while eight to ten are used on the Eskimo sled or kometik. The former is generally used over soft snow; on an unbroken trail it will make 15 to 25 miles per day, and on a broken one 25 to 40. On the other hand, the kometik is mostly used in the open on hard packed snow and will travel 25 to 40 miles per day.

Toboggans are loaded to about 70 lb. per dog, while the kometik may be loaded to 100 or 125 lb. per dog.

Kometiks are used between Moose Factory and Rupert's House, a distance of about 95 miles. It takes between eight to ten days to make the round trip, including a rest at Rupert's House and delays on account of weather. There are 8 to 10 dogs to a sleigh, on which is loaded from one thousand to twelve hundred pounds. The Indians supply their own food, sleighs and dogs, and are paid about $100 for the round trip, or $1.80 per ton mile.

### Freighting by Teams

Until comparatively recently, the horse drawn wagon or sleigh has been the universal means of freighting (the railways being excepted) and is still largely used. For short distances of two or three miles, the horse drawn sleigh on good iced roads still successfully competes with any mode of transportation.

Table I

Summer Team Freighting

Day's work 22 miles — Hauling outwards, return light.

| Miles hauled | 11 | 22 | 33 | 44 | 66 |
|---|---|---|---|---|---|
| Days absent from depot... | 1 | 2 | 3 | 4 | 6 |
| Pay load lb.*.............. | 1400 | 1267 | 1167 | 1067 | 867 |
| Cost per ton mile.......... | 80.2c | 89c | 96.5c | $1.05 | $1.26 |

Winter Team Freighting

Day's work 25 miles — Hauling outwards, return light.

| Miles hauled | 12½ | 25 | 37½ | 50 | 75 |
|---|---|---|---|---|---|
| Days absent from depot..... | 1 | 2 | 3 | 4 | 6 |
| Pay load lb.*.............. | 2400 | 2267 | 2167 | 2067 | 1867 |
| Cost per ton mile.......... | 41.2c | 49.5c | 51.9c | 54.3c | 58.6c |

*The reduction in pay load is due to the necessity of carrying food and supplies; the return journey is made without pay load.

An average 1,550-lb. horse will eat 26 lb. of hay and 24 lb. of oats per day, and in the summer on the ordinary portage trail a team will haul an average of 1,400 lb. about 22 miles per day. In winter on the same trail it will haul about 2,400 lb. and make about 25 miles.

It has been found that over a number of years the depreciation, maintenance, and miscellaneous costs pertaining to the upkeep of a horse and equipment amount to 45 cents per day over its working season, probably eight months of the year. Based on the above figures, and allowing $65.00 per month for teamster's wages, including board, and a 20 per cent allowance for time of barn boss and overhead, all of which amounts to $6.18 per working day per team, the rates shown in Table I have been worked out.

The distances have been taken to give full days travel from the main depot and return. The rates would, therefore, not be true for intermediate distances which would allow the teamster to return to the depot and have time to spare.

The Canadian International Paper Company has recently introduced a horse drawn wagon with pneumatic tires and ball bearing wheels, which under test has proved to be about twice as economical as the old iron-tired wagon and not nearly so hard on the horses.

The main features of the wagon are the 2¼ in. by 2¼ in. steel axles fitted with roller bearings and the 19 in. by 8 in. pneumatic tired wheels such as are ordinarily used on motor trucks. The rest of the wagon is constructed in the usual manner.

A comparative test gave the following result:—

| | 5 new type rubber tired wagons | 4 old type iron tired wagons |
|---|---|---|
| Total number of trips | 175 | 162 |
| Total distance loaded | 723.5 miles | 751 miles |
| Total cost | $665.00 | $810.00 |
| Total amount portaged | 305,000 lb. | 143,600 lb. |
| Average distance loaded per trip | 4.14 miles* | 4.61 miles |
| Range of loads | 1,100 to 3,000 lb. | 600 to 1,600 lb. |
| Average load | 1,775 lb. | 880 lb. |
| Average ton miles per trip | 3.67 | 2.03 |
| Cost per load | $3.80 | $4.97 |
| Cost per ton mile | $1.04 | $2.45 |

*For the first trip over a road cut by iron tires the loads were limited to between 800 and 1000 lb.

### Sleigh and Wagon Roads

In the past, winter portage roads have cost between $400 to $500 per mile, not including any bridges over 25 ft. span. Wagon roads usually cost between $750 and $800 for a 12 to 15 ft. right-of-way, roughly levelled off, including considerable corduroy, but no gravelling.

### Freighting Conditions

Freighting into undeveloped territories is carried on chiefly by companies engaged in forestry work, mining, and the construction of dams, hydro-electric power developments, transmission lines and pipe lines. Each enterprise presents its own problems and each has to be dealt with according to the conditions and requirements of the particular case.

The forestry industries have each year to freight in their camp supplies, which for a paper mill of any size amounts to a considerable tonnage. (It takes about 30 lb. of supplies of all kinds per cord of wood, and it requires approximately 1¼ cords of pulpwood to make a ton of newsprint.) For this purpose a good trucking road is usually built which is kept open for winter traffic. The motor truck has practically supplanted the horse drawn vehicle for freighting. Logs must be hauled from skidding yards to a drivable stream or a railway. If the operation from a skidding yard is to be only for one season, or of a temporary nature, then usually a winter road will suffice, but if it is to last for several seasons then a good truck road may be warranted. More than 98 per cent of the total hauling done by these companies is for the transportation of logs and less than 2 per cent for supplies.

In the case of the mines, the condition of the mine, whether a prospect or a producer, the type of ore produced and whether there is only one mine or several in the district, also its location in regard to a railway or a navigable route, are all factors in determining the method of freighting. If a mine is a producer it generally requires a year-round method of transportation, except possibly during the freeze up and break up seasons.

In regard to construction the conditions laid down in the specifications (usually the time of letting the contract, the ordering and delivering of material, and the length of time allowed to complete the work) govern the method of freighting. If year round freighting is too expensive, then winter or summer transportation must be adopted, in which case provision must be made for light freighting during the alternate season.

Confronted with a particular freighting problem, one should consider not only the requirements of the work in hand, but also the climatic and topographical conditions of the locality. The quickest and best way to become familiar with the topography is to fly over the proposed route with a map, noting thereon any special features. If a map is not available a photographic mosaic can be made which will be of great assistance in laying out the route.

### Water Freighting

Climatic and seasonable conditions have a big influence on waterborne transportation. The lakes and rivers are usually open for navigation from the 1st or 15th of May to the 15th or end of October depending upon the location and the season. High water generally occurs during June with the low stage in September, after which fall rains cause an increase in water levels.

Water transportation is the cheapest method of freighting for the longer distances when goods can be loaded direct on to boat or scow and conveyed to their destination over an unobstructed water course with only an unloading charge added. Unfortunately this condition is seldom obtainable, but due to cheapness of water freighting it is often possible to absorb some other charges and still handle freight at a cheaper rate than could otherwise be done.

Some of the methods employed to overcome obstructions to through navigation are:

(1) Marine railway. A railway is built across the portage with the track extending into the water at both ends. A carriage is run down the track into the water and the scow is floated on to it. The carriage with scow is then hauled over the railway and the scow is floated off at the far end. When these railways are used the scows are generally limited to about 15 tons capacity.

(2) Freight is unloaded from the scows on to a railway, car, truck or tractor, portaged across and loaded on to scows at the other end. A derrick is generally used to load and unload.

(3) An alligator tug or cable engine is often used to assist tugs and scows up rapids which are too swift for navigation under their own power.

(4) Locks and canals are seldom used except under ideal conditions, as they are usually too expensive.

The following are a few cases of water transportation into undeveloped territories.

Freight into the Pickle Crow district is transported by water between Hudson and Doghole Bay on Lake St. Joseph, a distance of 182 miles, divided into three stages. Hudson to Nattaway Falls, 97 miles; Nattaway Falls to and across Root Portage, 25 miles; Root Portage to Doghole Bay, 60 miles. In the second stage there are three marine railways and at Root Portage there is a four mile standard gauge railway. Here the cargo is unloaded, placed on flat cars, portaged across and again loaded onto scows. The charge for this entire operation is $23.00 per ton, or 12.8c per ton mile.

From Hudson to Red Lake, a distance of approximately 175 miles, in which there are five marine railways, the charge is $23.00 per ton, or 13c per ton mile. For the first stage of this route, a distance of approximately 110 miles, the charge is $10.00 or 9c per ton mile.

The Hudson's Bay Company—Mackenzie River Transport, quote rates for package freight on the Mackenzie River, which when converted to a ton mile basis give the results shown in Table II.

Table II

| | | | Per ton mile |
|---|---|---|---|
| Waterways, Alta., to Chipewyan | — 187 miles | — rate | 8.03c. |
| Waterways, Alta., to Goldfields | — 127 miles | — rate | 7.00c. |
| Waterways, Alta., to Ft. Fitzgerald | — 287 miles | — rate | 6.08c. |
| Waterways, Alta., to Ft. Smith Dock | — 303 miles | — rate | 13.2c. |
| Waterways, Alta., to Resolution | — 507 miles | — rate | 13.8c. |
| Waterways, Alta., to Hay River | — 582 miles | — rate | 13.75c |
| Waterways, Alta., to Simpson | — 816 miles | — rate | 13.5c. |
| Waterways, Alta., to Norman | —1,120 miles | — rate | 11.6c. |
| Waterways, Alta., to Aklavik | —1,661 miles | — rate | 7.23c. |

Between Fort Fitzgerald and Fort Smith there is a 16-mile portage. Large shippers can obtain a discount on the rates given.

On a short stretch of river and lake between Amos and Sullivan Mine, the rate is 25 cents per 100 lb. which over the distance of 45 miles is equivalent to 11 cents per ton mile.

A pulp and paper company which does some water transportation gives a cost of 3.8 cents per ton mile for transporting 794 tons of supplies a distance of 42 miles. This includes all operating and maintenance costs on boats, also their insurance and depreciation. It does not include any overhead expenses, or any shore costs such as maintenance of wharfs, warehouses, etc.

It should be mentioned that by far the largest water transportation business in our undeveloped areas is that of towing and driving logs for the forestry industries.

In a paper read before the Woodlands Section of the Canadian Pulp and Paper Association in 1930, entitled "Survey of Tow-Boats in Eastern Canada" by L. R. McCurdy, he states that "In eastern Canada the capital invested in pulp-towing boats is about $2,000,000." He also gives twenty-one examples of the cost of towing and from these has derived the following formula for the approximate cost of towing:

$$C = \frac{0.6}{M} + 0.5$$

Where $C$ = cost per cord-mile in cents

$M$ = number of millions of cord-miles towed.

This formula should only be applied where the quantity to be towed is over 500,000 cord-miles. For smaller quantities the cost per cord-mile rises too rapidly.

Three of the examples mentioned appear in Table III:

Table III

| | Example 1 | Example 2 | Example 3 |
|---|---|---|---|
| Total yearly operating cost, excluding depreciation, insurance, etc. . . | $27,170 | $6,283 | $3,595 |
| Average size of raft in cords. . . . . . . . | 6,000 | 3,000 | 1,400 |
| Distance towed in miles. . . . . . . . . . . . | 120 | 15½ | 19 |
| Cord-miles towed by boat. . . . . . . . . . . | 4,416,000 | 1,114,119 | 583,000 |
| Operating cost per cord-mile. . . . . . . . | 0.616c | 0.566c | 0.616c |
| Total yearly cost, including depreciation insurance, etc. . . . . . . | $30,920 | $11,863 | $10,095 |
| Total cost per cord-mile. . . . . . . . . . . . | 0.70c | 1.065c | 1.73c |

Summer Land Freighting

Summer transportation is chiefly a problem of roads and in this connection it must be borne in mind that the country is rather broken, and, generally speaking, has a large number of lakes and rivers, also that the low lying lands are usually swampy and consequently the roads must keep to the higher levels or else corduroy has to be liberally used. In the more developed mining areas the provincial governments are now building roads which formerly were undertaken privately.

Motor trucks, trucks and semi trailers, tractors and horse drawn wagons are the means used to convey the freight, and the choice of equipment will depend largely upon the type of road.

The pulp and paper companies have in the past few years amply demonstrated that, provided there is sufficient tonnage to warrant the expenditure, it pays to build good truck roads. These are not built to any particular standard, but are the cheapest roads that will serve their best

**Fig. 1—Caterpillar tractor equipped with Trail-Builder building a Logging Truck Road.**

interests, which is to attain the lowest total for all items entering into transportation costs. Actually, the main roads throughout their limits, while narrow, usually ten to twelve feet wide, are good.

With the advent of fast moving motor trucks for portaging supplies, better roads have come into being. They are more carefully located and an endeavour is made to keep the grades within reasonable limits. There is better alignment and, most important of all, the surface is receiving greater attention. For high speeds a smooth surface is essential. The result is that heavier loads are being carried at considerably higher rate of speed with consequent reduction in freighting costs. Speeds of twenty miles per hour can readily be maintained.

The United States Department of Agriculture, Forestry Service, has issued a "Forest Truck Trails Handbook 1935," which prescribes standards for the various classes of minor forestry highway projects and serves as a reference manual for their location, construction, and maintenance. This book is well worth reading by those interested in the subject.

In the last few years the method of road building has greatly improved and costs considerably decreased by the use of modern equipment, such as the high powered tractor with road builder or bulldozer attachment, heavy road grader, trucks, light crawler shovels, and portable gasoline compressors.

The cost of roads will vary considerably, depending upon the character of the country through which they are built. A few examples of the cost of truck roads are given:

*Case 1.*—In 1929-1930 a large lumbering concern in Ontario built an 8-mile extension of first class truck roads for $4,250 per mile which included the construction of a fairly large bridge. The right of way was cut 50 ft. wide through heavy pine timber. The roadway was stumped and graded for a width of 24 ft. and was heavily gravelled for 12 ft. Considerable rock work was involved. Side ditches provided the drainage with log culverts where necessary. The equipment used was:

A ten-ton caterpillar tractor for stumping right-of-way.
A super-mogul grader, drawn by the above mentioned tractor.
A portable gas driven air compressor.
A gas driven shovel, and motor trucks.

*Case 2.*—A woods manager of one of the pulp and paper companies, who has a particularly difficult Laurentian territory in which to build roads, states that since using modern equipment his road costs have dropped 20 to 25 per cent, and that his present costs are between $2,200 and $2,500 per mile. That he gets a much better road foundation and in so doing has considerably reduced his maintenance costs.

*Case 3.*—Fifty-three miles of road built four years ago, located 150 miles north-east of Montreal, and in a comparatively easy country for road construction, cost $1,563 per mile. Labour rates were $40 to $45 per month and board. The main features of the road were:

Right-of-way cleared for width of 32 ft., stumped for 28 ft., 22 ft. between ditches, and with a 10-ft. width of gravelled surface. There were 4 bridges of approximately 150 ft. each and 10 of between 75 to 80 ft. in length. These bridges consisted of crib piers supporting log spans 15 to 20 ft. long. The stringers were covered with cross logs and these in turn had two 30-in. planked running strips.

Maximum grade against the load, 11½ per cent.
Maximum grade with the load, 16 per cent.
Equipment used—Two No. 30 caterpillar tractors.
One No. 88 road grader.
One portable air compressor.
Two jackhammers.

*Case 4.*—A road being built by the same company through difficult country and to approximately the same standards, involving considerable rock work, but with the use of modern equipment of the medium powered type, is averaging $2,100 per mile.

In a recent paper on "Logging Roads"* by J. D. Gilmour, consulting logging engineer, he states that with powerful modern road making machinery, good truck trail roads can be built through the Laurentian Mountains at an average cost of $1,200 per mile ready for gravelling, also that the cost of gravelling will vary considerably, but can be averaged at $500 per mile. On jack pine sand plains there are stretches where good truck trails can be built for as low as $400 per mile.

These roads are used all the year round and require less preparation and maintenance and give better service than the snow and ice road built for winter traffic only.

Maintenance work should be continuous, and an endeavour made to anticipate trouble rather than have to repair heavy damage after it has occurred. The annual cost for maintenance on these roads varies between $50 to $100 per mile.

The Ontario company referred to in Case 1. portages its camp supplies a distance of 90 miles. In 1927 to 1929 the charge was 15c per ton mile, but as the roads were improved and hired trucks became cheaper the rate dropped to 9c.

The cost of operating four 2-ton Ford trucks carrying supplies and doing general trucking work etc., over a year's run of 55,500 miles was 11.85c per ton mile, or 14.8c per mile.

The details of these costs are:

| | |
|---|---|
| Wages | $0.0429 per ton mile |
| Gasoline | .0312 per ton mile |
| Oil | .0052 per ton mile |
| Tires | .0080 per ton mile |
| Repairs | .0312 per ton mile |
| Total | $ .1185 per ton mile |

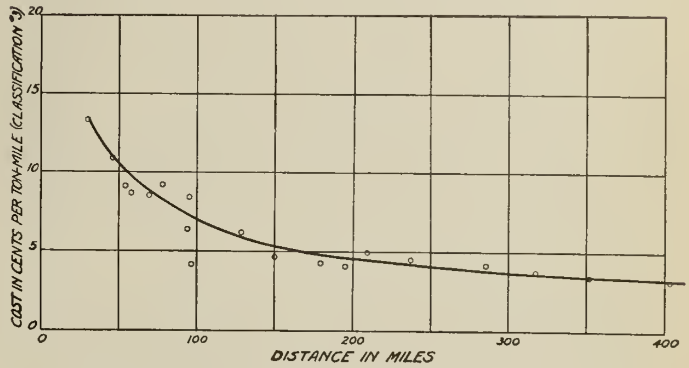

**Fig. 2—Cost of Inter-City Truck Freighting out of Montreal.**

Another logging company figures the cost of hauling supplies at 13.3c per ton mile.

Summer truck freighting in the Northern Quebec mining country runs about 30c per 100 lb. for 45 miles, or 13⅓c per ton mile over country roads.

Figure 2 gives a graph showing the charges per ton mile for inter-city truck freighting out of Montreal for goods under railway classification No. 3. The rates are for less than truck load lots.

In comparing these rates with those into undeveloped territories it must be remembered that in inter-city trucking freight is transported in both directions, that the roads are paved or well maintained, and that there are no road building charges to be written off in a few years, or, as in the case of winter transportation, in three months operations.

Tractors are seldom used for summer freighting, and when they are, it is generally under very adverse conditions. The nearest example of a summer tractor haul is one covering a period of twenty months and occurred several years ago. At that time the tractor was more in the development stage and is not to be compared with that of to-day. The haulage was over a dirt road with no attempt at surfacing, except to build up the soft spots with corduroy, bush and gravel. It was dusty in dry weather, and muddy in wet, and had an adverse maximum grade of 15 per cent.

The cost, covering 1,280,000 ton miles, exclusive of construction and maintenance of roads, but including all operating expenses, loading, maintenance of equipment, insurance, overhead and depreciation to extent of 50 per cent of the value of equipment, was 31½ cents per ton mile. In winter the average load per trip was 20 tons, 11 of which was on the tractor and the balance on a sleigh. In summer, the average load was 11 tons carried on the tractor.

### Winter Freighting

By far the greater amount of freighting in our undeveloped territories is carried on during the winter, primarily due to climatic conditions and also to the relative ease with which loaded sleighs may be hauled over ice and snow roads.

Advantage is taken of the frozen condition of the lakes, rivers and muskegs to transport goods to places which are practically inaccessible at other seasons except by aeroplane.

*Canadian Pulp & Paper Assoc., Woodlands Section, 1937.

Roads are the main feature governing the efficiency of winter transportation. Poor roads mean slow speeds, light loads, and heavy costs in maintaining equipment.

Winter roads may be divided into two classes, depending upon whether they are on land or over frozen bodies of water.

### Winter Roads on Land

In regard to the building of land roads, one should consider whether the road is to be used for one or more seasons, and the tonnage to be freighted should be known, since the type of road bed should depend upon the density of traffic.

Winter land roads will conform in general to most of the requirements for good truck trail roads. There are, however, a few other conditions relevant to such roads which should be borne in mind;

(1) To minimize trouble from drifting snow, it is advisable to locate the road through the more densely wooded areas and to keep on the windward side of lakes, rivers and open spaces.

(2) Where possible, avoid crossing swamps and muskegs. Often these surfaces do not freeze to any depth, especially if there has been an early fall of snow, and consequently give considerable trouble unless they are corduroyed. As muskegs generally are treeless they start to thaw early in the spring and often cut short the haulage season.

(3) If the road is to be used by sleigh trains, the radius of curves should be kept as long as possible. A minimum of 60 ft. radius on the level and 100 ft. on a grade is suggested. It is recommended that where curves occur on a grade, the grade should be reduced. This is specially noticeable when it exceeds 4 per cent. Iced ruts on a curve are a great assistance as the friction is reduced to a minimum and the sleighs are held in position on the road.

### General Requirements of Land Roads

If much hauling is to be done the right-of-way should be cleared for a width of from 20 to 30 ft. Twenty-five feet is a good width, unless extra wide sleighs are to be used. The right-of-way should be cleared of all stumps and

Fig. 3—Tractor-Train consisting of Caterpillar Tractor, Water Tank and 17 Sleighs (only part shown in photograph) of Logs containing 125,000 f.b.m.

projecting stones down to ground level. The brush and branches should be burned and any logs not used piled at the edge of the clearing. Humps should be levelled off and hollows filled in with earth or logs so as to give a generally uniform surface. On side hills, the road is usually made half cut and half fill, with logs being used to hold the fill. In such cases the road should not be less than 14 ft. wide. Rock work and heavy cuts and fills should be avoided as much as possible. All creeks and fast flowing rivers should be bridged. These bridges usually consist of log stringers spanning between crib piers. The stringers are covered with cross logs with running strips spiked down to them.

Under exceptional circumstances floating bridges are sometimes used. Hennessy and Hennessy Limited built two such bridges, located several miles north of the C.N.R. Transcontinental Railway. The design and construction display considerable ingenuity and resourcefulness, making the most use of materials readily available.

The bridges consist of nine main stringers of three logs each. These logs are the longest and largest that could be found in the vicinity, being about 60 ft. long and 2 ft. 6 in. to 3 ft. diameter at the butt and about 8 in. at the top. The three logs are staggered so that there are two logs past any joint. These logs are spiked to each other and securely bound together by ⅞ in. cables placed approximately at 4 ft. centres and made tight by wooden wedges. The nine main sets of stringers are anchored to shore and held together by cross logs averaging 8 in. to 9 in. in diameter and 27 ft. long, spiked to the stringers. On top of these cross logs are two running strips, each three feet wide and set to the gauge of the tractors. The logs forming the running strips are roughly adzed flat on two sides and are about 4 in. thick. These are spiked down to the cross logs. In between each of the three outer sets of stringers is placed a ¾ in. cable and these four cables are run from shore to shore and anchored. At the quarter points of the span, guys are taken upstream and anchored to shore, thus keeping the bridge in line. The road surface is iced over.

One of these bridges is floating in a rapid, and spans 350 ft. It supports a live load of 25 tons consisting of an 11-ton

Fig. 4—Tractor-Train plowing out the Road and Transporting a Transformer.

tractor and two loaded sleighs of 7 tons each. When crossing the bridge the tractor and sleighs travel in about a foot of water.

At the end of the season the bridge is cut loose from one of its shore anchorages and allowed to swing downstream, giving a free passage for the spring floods. In the fall the bridge is hauled back into position.

### Winter Road Surface

With certain minor variations, the type of winter roads most commonly in use are:

(1) Snow surface, snow base.
(2) Ice surface, snow base.
(3) Ice surface, ice base.

### Snow Roads

Preparation of the road is commenced when between six to twelve inches of snow has accumulated. The snow is broken down and compacted for the width of the roadway (usually about 10 ft.) by tractor, roller, or a long wooden V shaped plow. The road bed is given a final levelling off by hand, or by hauling over it a long drag with square cutting face which cuts off the remaining humps and deposits the snow in the hollows. By passing a tractor or lightly loaded sleighs over the road a few times a good compacted snow base will be established, and incidentally the plows or drags should be made to operate in either direction to save turning.

A first class snow road should be kept plowed out to keep the surface close to the ground. If desired, a rutting plow can be used, but usually the sleighs will soon cut their own ruts.

Snow roads of a poorer class, used only for light density traffic, have little done to them after the original breaking out and levelling up.

On these roads the tractors and sleighs follow the same path each time they pass over the road and compact whatever snow may have accumulated in the ruts. This results in the formation of two ridges, each about 20 in. wide, on which the sleighs and tractors must travel.

These ridges are not compacted tightly, are quickly affected by mild weather, and readily develop pitch holes.

The crawler type of tractor is the only one that can operate on this type of road. If the tractor gets off the path it usually has to cut loose from its train, turn off the road into the snow, then back up on to the road, turn, and connect up to the train again. Another type of snow road is where the tractor plows out the road each time it passes.

Roads with snow base and iced surface are made by watering the compacted snow. The entire width of road can be iced, but generally only the sleigh tracks are so treated. This type of road is usually rutted to the gauge of the sleighs, especially if the sleighs are of wider gauge than the tractor or trucks, which is a desirable feature. It is also advisable to build up solid ice shoulders to prevent the sleighs from slewing.

For icing the roads, water in sufficient quantities should be available at frequent intervals. The watering device consists of a wooden box water tank (capacity from 200 to 500 cu. ft.) mounted on sleighs, and equipped with a filling arrangement consisting of a water barrel sliding up and down an inclined skidway, the power being furnished by horse, truck, or tractor. It takes about thirty minutes to fill a 300 cu. ft. tank if a horse is used. Gasoline driven self priming pumps are also used for this purpose, and they should be housed and heated. It takes approximately 3,800 cu. ft. of water to cover one mile of roadway 8 ft. wide to a thickness of one inch.

Ruts are desirable when sleigh trains are used. These are made by pulling over the road a rutter which cuts two grooves to the gauge of the sleighs.

### Maintenance of Roads

Winter roads require continual care and attention if the surface is to be kept smooth, iced, and free from snow.

Snow should not be allowed to accumulate on either the iced or first class snow road. After every storm the road should be plowed and ruts cleaned and watered. In good weather the ruts should be cleaned, regrooved, and watered at least twice a week.

To keep the roads clear of snow, plows are either attached to the haulage units and operated when necessary, or regular plow units are sent over the road when required. Where traffic is heavy and continuous the former method is generally all that is necessary.

On the poorer snow roads usually little can be spent on maintenance, yet if pitch holes are allowed to develop the speed of the tractor trains is greatly reduced, and heavy maintenance equipment costs are incurred. In this case, about the only thing that can be done, is to haul a drag with an adjustable cutting edge behind each train to cut off the humps and fill in the hollows. These drags should be not less than 20 ft. long, and are used mainly when returning light. The drag should be built so that cross pieces between the skids have sleigh clearance.

Where sleigh trains are used on iced rutted roads the effectiveness of the icing is often greatly reduced by using sleighs of the same gauge as that of the haulage unit. The tractor treads or chained truck wheels are continually filling the ruts with chipped ice or snow, thereby increasing the frictional resistance. In the Lake States wider gauges are used to overcome this condition.

Maintaining and icing of winter roads is expensive, running as high as $350 per mile per season. Seventy miles of road, of which approximately 70 per cent was over lakes, averaged $310 per mile per season. The cost of icing and rutting will vary and may amount to half of that figure depending upon how much work is done. To counterbalance this latter charge it should be remembered that twice as much can be hauled over iced as over snow roads.

### Roads on Lakes and Rivers

While the freezing of the lakes, rivers and muskegs is a very real advantage to winter freighting yet it is accompanied by hazards and difficulties which must be guarded against and overcome.

As a general rule, heavy freighting on lakes and rivers should only be resorted to north of the Canadian National Transcontinental Railway, or where the temperature will stay at zero or below for a considerable portion of the winter.

(1) Some of the hazards of freighting on lakes and rivers are: Use of ice before it is sufficiently thick. It may be considered safe to put lightly loaded teams on ice when it has attained a thickness of 6 inches. It requires 18 in. to support a medium weight tractor and train and 24 in. for heavily loaded ones. To hasten the formation of ice on the roadbed the snow should be plowed off as soon as the ice is sufficiently strong to sustain a team of horses. The surface should be kept clear of snow for at least two and a half times the width of the roadway. Corduroy, twelve to sixteen feet long, frozen into the ice will help to distribute the load and is often used for short distances, such as across rivers or small lakes that are slow to freeze.

Fig. 5—A Tractor in difficulties having broken through the ice.

(2) Warm springs entering a lake or river from shore or underground. To avoid the former the road should be located sufficiently far from shore so as not to be affected by them. Underwater springs seldom occur,

but are a real danger unless known about from previous experience.

(3) Good thick ice is seldom found on shallow or muddy lakes. For this reason they should be avoided if possible.

(4) Expansion ridges. These are formed in milder weather when expansion is taking place, and cause the ice to be pushed up, forming a ridge which sometimes is several feet high. These can be cut down to permit the road to pass.

(5) Slush conditions. Slush is formed by the weight of snow causing the ice to sink so that water floods the surface and saturates the snow. This constitutes one of the greatest dangers, as a driver cannot see the actual surface he is driving over; also, the ice, while it does not melt under the water, deteriorates to a certain extent. Slush will not freeze if there is any snow on top of the water. If one must traverse such lakes and rivers, there are three methods of dealing with this difficult condition.

The first method is to plow a road through the slush with a tractor. This removes the snow and will permit the water to freeze. In this case the road should be plowed out to a width of at least 25 ft.

The second method is to keep compacting the snow from the beginning of the season by means of a roller or drag, so that a road is built up which will not be affected by the slush when it occurs.

The third method is to wade through it with light or medium weight tractors hauling a train of lightly loaded sleighs (not more than 6 to 7 tons for tractor or sleigh). When this method is adopted the trains usually operate in pairs, or several together, and are preceded by a plow. Generally, no cabs are placed on the tractors, so the driver has a clear opportunity to jump at the first sign of danger.

One of the difficulties of freighting on a wide expanse of open surface is to keep the road free from drifting snow. This may be minimized by locating the road near the shore from which the prevailing winds blow, and by plowing several deep and wide furrows to windward of the road. Plows, either as individual units, or attached to the haulage units, are a necessity, and are the chief means of keeping the road open.

Where the road enters and leaves the ice the approach should be bridged by stringers, one end resting well up on shore and the other extending out onto the ice. These stringers should be corduroyed and the whole frozen together.

At the beginning of the season it is advisable to load the trains lightly. They should not follow one another too closely, but rather a time interval should be allowed, so that any cracks formed by the passing of the first train may have an opportunity to freeze together.

Later in the season, when good thick ice exists (about 3 ft.) the sleighs may readily be loaded up to 20 tons each.

### Equipment

The character and amount of equipment required for any particular freighting job depends upon the following:

(1) The amount of freight.
(2) Length of time in which to handle it.
(3) Distance to be hauled.
(4) Characteristics of the road, that is, the grades, curves and road surface. Whether the road is over land, or lakes and rivers, or both.
(5) Whether the freight will be delivered at a uniform rate to the loading yard throughout the haulage period. If this cannot be done, then the maximum rate of delivery for a given time should be known.

The following is a list of equipment and buildings used on a large winter freighting job for the transportation of construction materials and supplies.

*Buildings and Equipment at rail head and loading yard.*

1 Bunkhouse fully equipped.
1 Cookery fully equipped.
1 Blacksmith shop fully equipped.
1 Repair shop, containing a small lathe, drill press, small shaper.
1 Garage.
1 Warehouse and platform.
1 Office and staff house.
1 Barn.
1 Power house containing:
  1-45 kw. electric generator direct connected to a gasoline engine.
1 Oil house with a 1,000 gallon gasoline tank outside.

**Fig. 6—Tractor Trains passing. The two Tractors breaking out a Siding. Note Caboose on Train.**

*Equipment for Transportation.*

12 100 hp. Linn tractors with snow plow attached.
2 30 hp. tractors for yarding purposes at the terminals.
1 60 hp. tractor for making up the loaded trains.
150 Heavy duty sleighs, 60 in. gauge with tractor hitch, 3½ in. by 9 in. by 9 in. double end runners. ⅝ in. cross chains. 2 poles. ½ in. by 3½ in. concave steel shoes. 8 ft. bolsters.
150 Racks for above sleighs.
4 10 ft. by 20 ft. cabooses.
10 8 ft. by 12 ft. cabooses.
7 Water tanks.
4 Horse drawn snow plows.
7 Tank sleighs. Same as above but without bolster.
2 ½ ton service trucks.
1 Snowmobile (runners in front—track on 4 rear wheels).
1 Automobile.
1 Gas-electric shovel fitted up as a crane.
15 Teams.

Camps, consisting of a small bunk-house, cookery and stable, were built at the longer portages, or where necessary for the men attending to the icing operations.

At the distant terminus there was a bunk-house, cookery, and garage, to provide for the switching and unloading crew.

During a season this equipment handled 22,500 tons of freight a distance of 68½ miles over iced roads, 20,000 tons of which were freighted in sixty days.

Sleigh maintenance is a heavy item of expense and the strongest and stoutest sleighs made are none too strong for use in mechanical haulage. During the past year an all steel sleigh has been placed on the market. As far as known, however, it has not been tested under the severe conditions of tractor train usage.

### Operation

Careful planning and scheduling, with competent supervision and a reliable organization, while essential to the success of any job, is particularly so in the case of freighting in undeveloped territories, owing to the shortness of the season and the many difficulties to be overcome.

Tractors are expensive and should, therefore, be kept working to near capacity as much of the time as possible. To accomplish this the following points should be closely watched:

(1) No time should be lost by the hauling unit having to wait for loading or unloading.
(2) The hauling unit should be kept in good running order. It should be greased and oil changed at regular intervals. Once a week it should be thawed out and thoroughly serviced in a warm garage.
(3) A reasonable stock of the more commonly required spare parts should be kept on hand.
(4) The roads should be maintained in as good condition as possible.
(5) A sufficient number of spare drivers should be employed to ensure continuity of service.
(6) To properly supervise the operation, and for emergency calls, snowmobiles should be provided.
(7) Means of communication from frequent points along the route should be provided, either by telephone, wireless, or aeroplane patrol.

### Loading and Unloading

The work of loading and unloading should go on continuously, or at least to the extent of always having a full load ready to be moved out. There should be a sufficient number of sleighs so that the haulage unit will not have to wait for them to be loaded, unloaded, or repaired. The sleighs are loaded by hand except for the heavier pieces which require the use of jacks or derricks. Where trucks are used, a method of loading should be devised which will cut the loading and unloading time to a minimum.

Upon arrival of a train at its destination, the tractor will either distribute the sleighs to their unloading point, or cut off from its train and leave the distributing to be done by a small unit. On return to headquarters the same procedure is carried out except that the tractor is thoroughly serviced and overhauled. On large jobs, small tractors usually distribute the sleighs and make up the trains ready for the big tractor to hook on.

A train is made up of a caboose and as many sleighs as the tractor can readily haul. The crew consists of two drivers and two helpers operating in pairs on either six or eight hour shifts. While en route the train is kept continuously on the move except for stops due to mishaps, oil changes, greasings, and meals if the road is rough. The men sleep and eat in the caboose, which is about eighteen feet long, eight feet wide, and eight feet high, contains two sets of double deck beds, a small cook stove, water barrel, wash basin, table, cupboard, and shelves to hold provisions, etc., and at the rear of the caboose is a meat box. The meals are cooked while the tractor is in motion, a railing is placed around the top of the stove to prevent the pots from sliding off. The routine inspection, greasing and oiling, are usually done at the morning and evening meal hours. Life on these tractor trains is not all that could be desired, and few men endure it for very long. For this reason, and on account of sickness, spare drivers should be always available.

The average speed of a heavily loaded tractor train on a good iced road may be between two to three miles per hour depending upon the load and the make and type of tractor. The return speed will be between 4 and 7 miles per hour. As for example, it took an average time of twenty-three hours hauling 75 tons per trip to make $68\frac{1}{2}$ miles. The return took fourteen and a quarter hours. Time at main depot reconditioning, etc. six hours. Time at distant terminus two and a quarter hours. A train consisted of between 4 and 6 sleighs, one of which was a caboose. The average load per sleigh was 15 tons with maximum of 38. The maximum load hauled on one train was 112 tons.

On good snow roads, about the same speed can be made, but the load will be reduced about 50 per cent.

On a poor snow road of the raised compacted path type, a speed of $1\frac{1}{2}$ to $1\frac{3}{4}$ miles per hour is considered good.

Where there is a heavy density of traffic, there is a distinct trend toward the use of trucks, either operating as an ordinary truck or used as a tractor to haul a train of sleighs, the body being loaded to give traction. This is especially so in the forestry industries, where they are being used extensively, and have in many cases displaced the horse and the tractor for the haulage of logs and pulpwood.

The motor truck was not originally intended to serve as a haulage unit for sleighs, and under the very severe conditions some weaknesses developed, chiefly in the rear end. These troubles are being overcome by increasing the gear ratios between engine and axle, and by the use of dual driven rear axles.

For trucks to operate effectively the roads must have a solid base, and be kept free from loose snow. If they are to haul sleighs the road should be iced, rutted, and have solid shoulders. Under such conditions trucks can operate at a much higher speed than tractors, and haul considerably more per dollar of purchase price. Their operating and maintenance costs are less and capital investment smaller. Besides, there is more ready employment for them during the rest of the year.

As an illustration of the above, take examples Nos. 14, 15 and 16 on the cost sheet (Table IV) which covers the hauling of logs by the same company. In example 14 the hauling was done by two 100 hp. gasoline Linn tractors, while in examples 15 and 16 the haulage was done by two Diesel Badger Leyland trucks. The daily hauling capacity of the trucks and tractors is almost exactly the same, the trucks being able to make twice as many trips as the tractors, but haul only one half the load per trip. The relative costs covering the haulage and maintenance of equipment are as 2.961 cents per ton mile for the tractor is to 1.835 cents for the first year truck operation and 1.522 cents for the second year's operation. If depreciation is taken into consideration there will be a greater difference in favour of the trucks, especially as they are used in summer.

**Fig. 7—Tractor Train transporting Generator Spider and other Equipment.**

An interesting comparison is given by the same company of the costs of hauling operations covering loading, hauling, tanking, road upkeep and rolling, over the same road by team, tractor and Diesel trucks.

| | |
|---|---|
| Horse teams | 9.07c per ton mile |
| Gasoline tractor | 7.3c per ton mile |
| Diesel trucks | 6.2c per ton mile |

In eastern Canada, logs and pulpwood are sometimes loaded directly on trucks for transportation, but owing to the low operating cost of the truck-sleigh train unit, this method is limited to special cases and depends for its success upon the speed of loading and unloading, and upon the character of the road.

To facilitate loading and unloading of pulpwood, an ingenious operator adopted the following scheme.

A rack consisting of two stringers of truck body length, with stakes at both ends, and supported by four hydraulic jacks, is loaded by hand. For loading, the jacks, which are controlled by four men, are lowered, and after loading, the rack is raised to sufficient height to allow the flat deck of a truck to back under the loaded rack and between the stringers. The front stakes of the rack are removed and the rear stakes of the truck replaced. The truck is fitted with a dumping platform. To unload, the rear stakes are removed and the deck tilted up. While the truck is away the rack is reloaded.

Loading on trucks has proved effective where the roads have many sharp curves and steep grades and where it would be impossible to successfully operate a train of sleighs. One such operation transported approximately 30,000 tons of logs, an average of 6½ miles over a very steep and crooked winter road of snow base and iced surface. The average load was approximately 8 tons, which greatly overloaded several of the trucks. The fleet of trucks consisted of Ford Warford 2 ton 157 in. W.B., G.M.C.'s Model T-90-C, International's Model C-40-F, and a Maple Leaf, all but the last equipped with two rear driving axles. The heavier grades against the load were 200 ft. of 13 per cent and 60 ft. of 16 per cent and with the load was a 17 per cent grade for 100 ft. Unfortunately no costs are available from this job.

In British Columbia and the Pacific States, where logging conditions are different to those of eastern Canada, transportation is being performed to an increasing extent by trucks which are displacing the logging railway. An excellent type of road is constructed over which is operated some of the largest trucks and trailers built. These trucks carry up to 50 tons and operate at speeds of 20 to 30 miles per hour.

Attached is a sheet giving the haulage costs, or portion of costs, of several freighting jobs, some done by tractor and some by truck. From the data obtained an endeavour has been made to classify the costs under the usual headings for a haulage operation. This information has been obtained from a number of sources, each of which has its own method of cost accounting and in consequence there may be wide variation. Also, the choice of the conversion unit for logs and cordwood into tons is largely based on judgment, and can only be considered approximately correct. A word of caution is therefore given regarding the use of any of the costs mentioned. It will be noticed that no depreciation of equipment has been shown. This is because nearly every firm depreciated it differently and in a number of cases no value was given.

**Fig. 8—A Ford-Warford Truck hauling a Train of six Sleighs.**

The following are a few cases where freighting has been done by contract—on a per ton, or ton mile basis:

(1) Freighting of 1,600 tons of mining machinery and supplies—a distance of 135 miles of which 117 was over lakes. Eighteen miles of winter road had to be cut. A considerable portion of the lake surface was covered with slush and the general ice condition was such that a 6 or 7 ton tractor was all it could safely carry. The tractors depending upon their capacity hauled 3 to 5 sleighs apiece. Six tons was considered a good load per sleigh. The contract was let for $60 per ton or 44½ cents per ton mile. This year the freighting is being done for 40¾c per ton mile.

(2) Freighting approximately 500 tons of mining supplies a distance of 138 miles over a winter land trail. The rate was 31.1c per ton mile.

(3) Freighting 900 tons miscellaneous mining supplies a distance of 26 miles over an already cut winter road. The rate was 33.7c per ton mile. The loading was contracted for at the rate of 60c per ton, with guaranteed minimum of 15 tons per day. Actual hauling time sixty days.

(4) Freighting 250 miles approximately 500 tons of supplies at a rate of 32c per ton mile. For approximately half of this distance the road is used by other parties.

### Aeroplane Freighting

Aviation has played a very important part in the development of our natural resources, not only in conveying men quickly to remote points, but also in carrying freight.

Last year approximately 13,500 tons of freight were carried by aeroplane and probably by far the greater amount of this was transported to the mines in the north country.

The largest single air freighting job in North America was carried out last year and consisted of transporting 800 tons a distance of approximately 70 miles.

Air rates will vary with the locality owing to changes in the price of gasoline and also with the intensity and type of operation. Aircraft are licensed by the government for a certain "all-up load." The difference between the empty weight and the licensed gross weight is known as the disposable load, and this is in turn divided between operating load and pay load. The former is made up of the weights of the crew, machine equipment, gas and oil; the pay load is the balance remaining after deducting the operating load from the disposable. It will thus be seen that, on operations where extra equipment, extra crew, or when abnormal quantities of gas must be carried, the pay load is correspondingly reduced and the cost per ton mile increased.

**Fig. 9—Logging in British Columbia. Heavy Diesel Truck and Trailer—Load 9,000 f.b.m. (approximately 36 tons). These Trucks handle up to 50 Tons.**

Intensity of flying operations is another important factor. The greatest part of the cost of aircraft operation under present day conditions consists of fixed charges, such as, insurance, depreciation, salaries and overhead. The more hours per month that a machine flies, the smaller are the fixed charges per hour. By having a heavy tonnage available for continuous and rapid handling, it is possible to considerably increase above the average the number of flying hours per month per machine, and thereby decrease the cost per mile flown. This is the reason for the considerable reduction in rates, as the freighting operations progress from occasional work to that of heavy tonnage, as shown by the following figures, kindly compiled by the Canadian Airways Limited. They do not relate to any specific job at present in hand, but are in line with current rates.

Table V

| Distance | 100 miles | 50 miles |
|---|---|---|
| (1) Straight charter basis, cost per trip.. | $100.00 | $60.00 |
| Pay load in pounds | 1,400 lb. | 1,500 lb. |
| (2) As soon as fairly frequent trips are warranted, the operation would be put on a poundage basis. Charges would then be approximately as follows: | | |
| Passengers—per trip | $25.00 | $15.00 |
| Freight per lb. and ton mile | 7c—$1.40 | 4c—$1.60 |
| Maximum charge per trip | $70.00 | $35.00 |
| (3) When traffic in the district became sufficient to warrant establishment of a regular schedule, the following rates could be expected: | | |
| Passengers—per trip | $20.00 | $10.00 |
| Less than plane load lots per lb. and per ton mile | 7c—$1.40 | 4c—$1.60 |
| Plane load lots | 6½c—$1.30 | 3½c—$1.40 |
| (4) On a basis of 500 tons to be available for continuous hauling, the rate per ton mile would be approximately | $1.00 | .90c. |

In certain districts where there is considerable competition, notably about Sioux Lookout or Hudson, the contract rate is 5½c per lb. for 135 miles, or 81½c per ton mile and $1.04 for small quantities. On another job covering about 69 miles, the rate was 94½c per ton mile for a large quantity.

In the undeveloped territories there are several new mines so situated that air freighting is the only practical means of transporting any materials required during the summer. For passenger and mails, it is the only means of transportation.

One of the reasons why aviation is playing such a big part in the development of our hinterlands is the very reason that makes it so hard to build good summer roads—namely, an abundance of water, most of which is in the form of lakes affording an excellent landing in either winter or summer.

Our aviators and the aviation companies are doing a splendid service in furthering the development of our natural resources in a country so difficult of access.

## Conclusions

With the increasing development of our natural resources, and as they extend deeper into the hinterlands, we may look for continued improvement in overland freighting methods. Today, with the adoption of mechanical haulage units, the engineer is playing an increasingly important part in the solution of these freighting problems.

Through the closer co-operation of the manufacturers' engineers with field engineers there is continual development of new equipment, or improving of old, more suited to our northern needs.

Roads are greatly improved and are being located and constructed according to engineering principles, being greatly assisted by aeroplane reconnaissance and surveys.

The telephone, wireless, and aeroplane are important links for the efficient transportation of goods into our undeveloped territories.

The cost of land freighting, whether for summer or winter, depends chiefly on the condition of the roads. Except possibly for small tonnages, the general statement that the better the road the cheaper the overall freighting costs, holds true.

For winter freighting, where there are large tonnages with short hauls, and in some cases, for the longer hauls, or where there is a heavy density of traffic, there is no doubt that trucks will be used to an increasing extent, either as sleigh hauling units, or to carry deck loads, or with semi-trailers.

The tractor, on account of its ability to operate on poor roads, will be used for low density traffic freighting. They haul a heavy load, are good for plowing snow, and general heavy work, and a certain number are a necessity on any winter freighting job. Their slow speed when travelling light is a great disadvantage. Under certain conditions a combination of tractor and truck might be worked out, whereby the tractor on the return trip is loaded on a sleigh and hauled back by truck.

For successful freighting a thoroughly competent and well organized field force is a necessity.

The heavier crawler type of tractor, when equipped with a bull-dozer or road builder, is an excellent machine for clearing and rough grading a road. It can also be used for hauling the heavier grading machines. These methods are helping cheapen the cost of road building.

The aeroplane will always be an important transportation unit for passengers and mail, also for freight, especially where speed is the main consideration.

## Acknowledgments

The author wishes to express his thanks and appreciation to Messrs. J. D. Gilmour, E. E. Johnson, A. M. Koroleff, V. H. Patriarche, J. W. Sutherland and R. R. Hennessy for information generously given, and to Mr. C. R. Townsend for his help and collaboration in the preparation of this paper, also, to the Woodlands Section of the Canadian Pulp and Paper Association and the many companies which were kind enough to allow the use of their cost data and other particulars.

## Notes Regarding Cost Units

Example 1—On account large tonnage to be handled, great attention paid to preparing roads over lakes and icing roads on portages. The road was kept in excellent condition during the season.

Example 2—Freighting to same destination as in Example 1. The material freighted consisted largely of heavy machinery, necessitating careful loading and in some cases special sleigh riggings.

The per mile road maintenance is about the same for both years, but the ton mile basis almost double.

Example 3—No break down given for the 12.9c per ton mile hauling operation.

Example 4—The $212 per mile is for 5½ miles of new portages.

Example 5—This example covers 3 winter months haul of a large freighting operation of 42,000 tons and extending over a period of 20 months. The tractor had a body load of 11 tons and hauled a trailer sleigh loaded with a like amount. The maximum grade against the load was 15%.

Example 8—Covers the fuel oil cost for a Diesel operated Linn tractor as compared with the gasoline tractors for the same seasons as Examples 6 and 7.

Example 9—Covers the hauling of supplies to several logging camps, varying from 22 to 52 mile haul. Both tractors are Diesels.

Example 10—Job started late in season—bad road—sharp curves and steep grades.

Examples 11 and 12—Number 11 gives the operating and maintenance costs of best tractor of the 6 included in example 12.

Example 14—Is for an intensive logging operation—operation carried on for 22 hours out of 24.

Examples 15 and 16—Intensive log hauling by same company as No. 14 but haulage unit changed to Diesel Leyland trucks.

Example 18—This company has been operating with the F.W.D. trucks for 5 years and have got their hauling down to a regular system.

Example 22—Is a summer operation over an excellent road.

Example 23—Is a logging company's trucking operations over an entire year and is not comparable to operations 15 to 21.

Example 24—Same logging company as in Example 23. Covering haulage of general supplies during months of September to February—by two trucks.

**Paper presented before the Semicentennial Meeting of The Engineering Institute of Canada, in Montreal, June, 1937.**

SUMMARY.—The Trail plant produces lead, zinc, silver, gold, cadmium, bismuth, sulphuric acid and also synthetic ammonia for fertilizer products. There is a continuous electric load of 100,000 kw., supplied to the plant at 60,000 volts and used at 13,200 volts, 2,200 volts and 600 volts. About 75 per cent is converted to d.c. for electrolytic work. Furnace and roaster gases are treated electrically for removal of metallic dust.

The use of electric power plays an important part in the various processes carried out at Trail in the production of metals, chemicals and fertilizer and covers a large field. It is not the purpose of this paper to cover all the problems and details involved, but rather to give a general picture of the layout and operations.

### The Plant

Trail smelter, the largest non-ferrous smelter in the world, is owned and operated by the Consolidated Mining and Smelting Company of Canada. It is located at Trail, British Columbia, on the Columbia river at a point near the International Boundary and is served by the Canadian Pacific Railway by means of a branch line which joins at Castlegar the line running through the Crow's Nest Pass to the coast.

The smelter was first constructed and put into operation in February 1896 by Mr. F. A. Heinze for the purpose of recovering gold from the rich ores in the Rossland area. The original plant had a capacity of 100 tons a day—which was rapidly increased to 250 tons—and covered an area of about two acres. A few years later the smelter was purchased by the Canadian Pacific Railway and with a number of mines in the district was put under the management of the present company in 1906. Lead and silver ores were smelted, but at first zinc could not be handled, in fact lead and silver ores containing over a certain percentage of zinc were penalized, or not accepted, as they interfered with the operations carried out. Eventually as a result of prolonged research, a flotation process of mineral separation was devised whereby lead and zinc in the ore could be separated in the form of concentrates. This, in conjunction with the electrolytic process of plating zinc onto aluminum cathode sheets, solved the problem of treating the complex lead and zinc bearing ores. The production of electrolytic copper was discontinued in 1925. The plant has been greatly enlarged from time to time and new processes added.

Custom ores are treated, but the major portion of the supply comes from the company's Sullivan mine at Kimberley. It is treated in the concentrator there and shipped to Trail in the form of lead and zinc concentrates.

The Trail plant consists of two main sections, the first, Tadanac, where the metal smelter and reduction plants are located as well as the sulphuric acid and $SO_2$ reduction plants, and the second, Warfield, where the various fertilizer departments are located.

The Tadanac plant covers 160 acres with about 30 acres of roofing on buildings. The buildings are nearly all steel with tile, gunite or transite siding. The Warfield plant covers 60 acres and the buildings are nearly all steel and brick. It is located on a higher bench of land about one mile from the Tadanac plant.

The two plants employ about thirty-seven hundred men and the daily capacity for the various products is: lead 550 tons, zinc 400 tons, sulphuric acid 450 tons, fertilizer products 300 to 400 tons, also elemental sulphur. There is

Fig. 1—The Tadanac and Warfield Plants.

a monthly production of approximately 750,000 oz. silver, 27,000 oz. gold, 20 tons of cadmium. Bismuth is recovered from the lead refinery by-products.

### Power Requirements

The power consumption for the year 1936 was 864,-223,827 kw.h. which is the equivalent of a continuous load of practically 100,000 kw. The plants operate twenty-four hours a day and every day in the year. The twenty-four-

**Fig. 2—High Tension Switching Station, Tadanac.**

hour load factor is nearly 95 per cent and the power factor about 95 per cent. For full load production in all departments there is a total load of 125,000 kw. in the plant which is divided approximately as follows:

| | |
|---|---|
| Zinc plant | 47 per cent |
| Chemical and fertilizer | 40 per cent |
| Lead smelting and refining | 8 per cent |
| Balance | 5 per cent |

Of the total 125,000 kw. load for both plants approximately 94,000 kw. is converted to d.c. by means of motor generator sets, rotary converters and mercury arc rectifiers, and is used for electrolytic processes in the production of metals and hydrogen gas. The balance of the power is used for various purposes as required. Except for special cases such as rotary converters and mercury arc rectifiers the general power voltages used in the plant for motors, etc., are 2,200 and 550 volts.

There are 2,612 motors installed having a total of 60,031 h.p. This figure does not include the large motor generator sets, rotary converters or mercury arc rectifiers. For lighting and miscellaneous 110 and 220 volt power requirements in the plant there are 141 transformers installed with a total capacity of 3,430 kva.

It may be of interest to note that before the ore reaches Trail in the form of concentrates from Kimberley the following amounts of electric power have been expended:

| | |
|---|---|
| Mining | 7.5 kw.h. per ton of ore mined. |
| Concentration | 22.2 kw.h. per ton of ore treated. |

### Power Supply

Power for the Trail plants is supplied by the West Kootenay Power and Light Company, a subsidiary company, from its four hydro-electric plants located on the Kootenay river some 30 miles away. These plants have a total installed generator capacity of 179,000 kva. consisting of:

| | |
|---|---|
| No. 1 Plant Lower Bonnington Falls | 52,500 kva. |
| No. 2 Plant Upper Bonnington Falls | 29,000 kva. |
| No. 3 Plant South Slocan | 52,500 kva. |
| No. 4 Plant Corra Linn | 45,000 kva. |

This power is delivered to a central high tension switching station in Tadanac at 60,000 volts, 3-phase, 60 cycles. There are four high tension transmission lines at present but this number is being increased to take care of the larger load which has built up the past few years. The original power supply to Rossland and Trail was at 20,000 volts and consisted of a double circuit line. These circuits were used for the past several years as a standby only but have now been discontinued.

The switching station shown in Fig. 2 is located about midway between Tadanac and Warfield and is equipped with high tension line and feeder oil circuit breakers. It has a duplicate set of main buses and lightning arresters are provided where required. High tension feeders run from this station to the various step-down stations. High tension tie lines are provided between the various step-down stations and are so inter-connected as to form a ring, or loop, which provides an alternative source of high tension power to each station when required.

### Distribution System—60,000 Volt Step-down Stations

There are nine high tension step-down stations, six in Tadanac and three at Warfield. These stations are located in different parts of the plants as near as possible to the load centre of the particular zone to be supplied with power. They are as follows:

*Tadanac Plant*

*No. 1 Sub-station:* Located in zinc plant. Indoor station rated 22,500 kva. consisting of 3 banks of three 2,500-kva. transformers 60,000 to 2,200 volts. The main 2,200-volt bus is carried in a concrete phase isolating structure and supplies twenty feeder circuits of which thirteen are 1,000 kw. motor generator sets.

*No. 2 Sub-station:* Located at refinery. Outdoor type consisting of three 5,000-kva. transformers 60,000 to 2,200

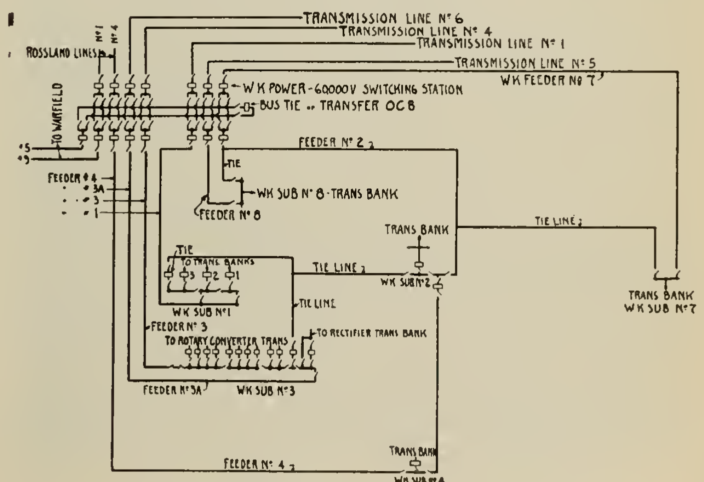

**Fig. 3—60,000-Volt Lines, Feeders and Tie Lines, Tadanac.**

volts. The 2,200-volt power is carried in a tunnel about 150 ft. from the transformers to the lead refinery generator room by means of ten 750,000-c.m. 3-phase P.I.L.C. cables into the distribution bus of a bank of metal clad switchgear consisting of eight feeder breakers.

*No. 3 Sub-station:* Located in zinc plant. Indoor type, rated capacity 51,500 kva. There are eleven 2,600-kva. transformers 3-phase, 60,000 volts to 6-phase 380 volts feeding ten 2,475-kw. rotary converters (one transformer being a spare) (see Fig. 4). Also a bank of three 8,500-kva.

single phase transformers 60,000 to 13,200 volts which feed three 5,600-kw. mercury arc rectifier units.

*No. 4 Sub-station:* Located at lead smelter. Outdoor type, consisting of three 5,000-kva. single-phase transformers 60,000 to 2,300 volts. The 2,300-volt power is distributed through metal clad switchgear to four circuits.

*No. 7 Sub-station:* Located at Stoney Creek pumping station. Outdoor type consisting of three 3,000-kva. single-phase transformers 60,000 to 2,200 volts. There are three 2,200-volt feeder breakers.

*No. 8 Sub-station:* Located at acid and $SO_2$ plants. Outdoor type consisting of three 5,000-kva. single-phase transformers 60,000 to 2,200 volts. There are two 2,200-volt feeder breakers.

*Warfield Plant*

*No. 5 Sub-station:* Supplies 2,200-volt power to the fertilizer plant. Originally this station consisted of three 5,000-kva. single-phase 60,000 to 2,300-volt transformers, but it was found that the insulators became coated with a dust deposit from the phosphate plant nearby which necessitated washing the insulators at frequent intervals. In order to do this without interrupting the service this station was changed to two banks of two 5,000-kva. single-phase transformers in open delta. A third transformer will be added to each bank when load conditions require it. The 2,200-volt power is distributed through metal clad switchgear to four main feeder circuits.

*No. 6 Sub-station:* Located at hydrogen plant. Outdoor type, capacity three 6,500-kw. mercury arc rectifier units, 60,000 to rectifier voltage.

*No. 9 Sub-station:* Located at hydrogen plant. Outdoor type, capacity two 8,300-kw. mercury arc rectifier units, 60,000 to rectifier voltage. A third 8,300-kw. unit is being added this year.

### Distribution System—2,200 to 600 Volt Sub-Stations

Some of the 2,200-volt power supplied by the above step-down stations is used at that voltage and some is stepped down again to supply the large number of 550-volt motors in the plant and also to voltages suitable for electric furnace work and special heating applications.

There are eight 2,200- to 600-volt sub-stations in the two plants. Tie lines are provided to form a 2,200-volt loop, or "secondary ring," such that any of these sub-stations can be fed from its regular step-down station, or if required fed from one of the other stations. The Warfield sub-station is not included in this arrangement, but, as mentioned previously, the step-down station supplying 2,200-volt power at Warfield has two separate banks of transformers.

These eight 2,200- to 600-volt sub-stations are also located in the plants as near as possible to the load centre of the particular zone which they supply and are arranged as follows:

*Smelter:* Old smelter sub-station. Two banks: one 3,000 kva., the other 4,500 kva. The 3,000-kva. bank is quite an old installation and is used chiefly as a standby.
New smelter substation—4,500 kva.
*Refinery:* 2,250 kva.
*Zinc Plant:* 4,500 kva.
*Acid Plant:* 1,200 kva.
*Concentrator:* 1,500 kva.
*Stoney Creek Pumping Station:* 1,500 kva.
*Warfield:* 4,500 kva.

The 600-volt power is distributed through oil circuit breakers to feeders each of which supplies one section of the plant as required.

Power is metered on the main 2,200-volt primary feeder panels and again on the 600-volt secondary feeder panels.

Lighting transformers as far as possible are tapped off the 2,200-volt primary feeders, although in a number of cases the 600-volt feeders are used where the higher voltage is not available.

All 60,000-volt feeders are aerial and in Tadanac the 2,200-volt and 600-volt are also aerial, but at Warfield all the secondary voltage distribution as well as lighting and telephones are carried underground in a duct system.

The present selection of oil circuit breakers for main feeders is based on the following rupturing capacities:

| | |
|---|---|
| 60,000-volt service........... | 1,000,000 to 1,500,000 kva. |
| 2,200-volt service........... | 300,000 kva. |
| 550-volt service........... | 55,000 kva. at 750 volts. |

As a general rule the feeder circuits are limited to the following maximum capacities:

| | |
|---|---|
| 60,000 volts............................. | 25,000 kva. |
| 2,200 volts............................. | 4,500 kva. |
| 550 volts............................. | 1,000 kva. |

A typical 2,200- or 550-volt feeder panel is equipped with the following instruments: watthour meter, indicating wattmeter (for large or important circuits), recording ammeter, one voltmeter per station, induction relays and calibrating studs for current and potential.

As far as possible motor controls in the plant are banked together at distribution centres. Remote, or push button, control for motors is used practically throughout, except for some of the larger and older installations.

Washed air plants are provided for all the generator and rectifier rooms to clean the air before it enters the room and also to cool it in the hot weather period.

### Electrolytic Plants

Approximately 75 per cent of the total power used in the plant is for electrolytic processes for the refining of metals or the production of hydrogen. In order to obtain the direct current required for this class of work three different types of conversion equipment are used, the installed d.c. capacities being:

**Fig. 4—No. 3, H.T. Step-down Station, Zinc Plant.**

| | |
|---|---|
| Motor-generator sets........................ | 18,250 kw. |
| Rotary converters........................ | 24,750 kw. |
| Mercury arc rectifiers........................ | 53,500 kw. |

This d.c. power is distributed in the following manner:

| | |
|---|---|
| Zinc plant............................... | 54,800 kw. |
| Lead refinery............................... | 5,000 kw. |
| Hydrogen plant............................... | 36,700 kw. |

As mentioned previously, another 8,300-kw. mercury arc rectifier is being installed in the hydrogen plant this year; this is not included in the figures just given.

### Zinc Plant

For the production of electrolytic zinc, the zinc arrives in the form of concentrates. These concentrates are roasted in the concentrate burning furnaces to drive off sulphur, then the zinc is put into solution in the leaching plant by dissolving it in acid, and after this solution is purified it is pumped to large storage tanks. From these tanks it is pumped to the electrolytic tank rooms where the zinc is plated on aluminum cathode sheets from which it is stripped every twenty-four hours, sent to the melting room to be melted down, and cast into 56-lb. bars for shipping. Some of the zinc is recovered at the lead smelter in the slag retreatment plant in the form of zinc oxide. This zinc oxide is dissolved and purified in a separate leaching plant from the roasted zinc concentrates and is then fed to the electrolytic tanks.

**Fig. 5—Zinc Refinery, Electrolytic Tank Room.**

The older electrolytic tanks are reinforced concrete tanks with a lining of rubber. All new tanks are now being made from Prodorite, which is an asphalt base material mixed with sand and crushed rock. These tanks are made up in the form of a double tank and are arranged for gravity flow of the solution and are connected electrically in series. The anodes are made of lead and are permanently attached in parallel to a copper bus bar which is lead covered and runs on one side at the top of the tank. The aluminum cathodes have two lugs attached at the top, one copper and one iron. The copper lugs make contact with the copper cathode bus also on the top of the tank, and the iron lugs rest on, but are insulated from, the anode bus. These cathodes are pulled out of the tanks one at a time while the unit is on load. The zinc is stripped off and the cathode replaced. The number of cathodes in a cell varies from 16 to 23 depending on the current density used. The size of the immersed area of the cathode is 2 ft. by 2 ft. 6 in. or ten square feet per cathode since both sides are used. There is always one more anode than cathode. The spacing is 3 or 4 in. depending on the number of cathodes per cell.

The maximum current density used is 52 amp. per sq. ft. For a current density of 40 amp. per sq. ft. the voltage per cell is approximately 3.5 volts which is made up as follows:

| | |
|---|---|
| Theoretical decomposition voltage of zinc sulphate ($ZnSO_4$) | 2.56 volts |
| Anode and cathode voltage plus polarization | 0.42 volts |
| Potential drop due to resistance of electrolyte | 0.52 volts |
| Total | 3.50 volts |

The cell efficiency obtained is 91-92 per cent.

The power consumed in producing one pound of electrolytic zinc is 1.62 kw.h.

### Direct Current Supply

In 1916-17 when the zinc plant first went into operation thirteen 1,000-kw. 125-volt motor generator sets were used. These sets have two 500-kw. generators, each of which supplies a group of 36 zinc cells with 4,000 amp. These generators are direct connected to a 2,200-volt motor.

When extensions were made to the zinc plant in 1925 and 1927, ten 2,475-kw. rotary converters were installed having a voltage range 470-550 volts. These machines are booster type with a.c. starting. They are fed from a 60,000-volt bus through individual transformers. Originally each rotary operated its own tank unit of 144 cells at 4,500 amp., but later it was decided to operate two rotaries in parallel at 9,000 amp. on each tank unit. Eight rotaries are now operated this way, one still operates singly on its tank group and one is used as a spare. Electrical interlocks on the d.c. side are provided for the units operating in parallel to protect these machines from severe overloads in case one unit drops off load.

A 10,000-amp. paralleling bus is run in the basement under the rotaries so that any group of machines can pick up any tank unit desired. This bus extends into the mercury arc rectifier section of the room.

In 1929 the zinc plant was extended again and this time three 5,600-kw. 10,000-amp. mercury arc rectifiers with d.c. voltage range of 460-560 volts were installed. Rectifiers at this time were coming into prominence in electric railway work as well as d.c. networks in cities and from their performance on these loads gave indications of being suitable also for electrolytic work, although few installations of any size were in operation at that time. It was found that, just as in the case of motor generator sets and rotary converters when they were first used for electrolytic work in various parts of the world, changes were necessary in the original rectifiers supplied in order to carry full load. These units have been operating at 9,000 amp. satisfactorily for some time now.

**Fig. 6—Rotary Converters, and Mercury Arc Rectifiers, Zinc Plant.**

The rectifiers are fed from a 13,200-volt bus in No. 3 step-down station and the d.c. voltage range of 460-560 is made in 24 steps by means of taps on the high tension winding of the rectifier transformers and an "on load" tap switch. There are two 5,000-amp. twelve anode cylinders (double six phase) per unit operating in parallel from one transformer. Air type reactors are provided on the d.c. side to smooth out the ripples. Closed circuit rectifier cooling, high speed d.c. circuit breakers and grid control for backfire or short circuit suppression are installed.

The power is metered on the high tension side of the rectifier transformer. Auxiliary 3-phase 110-volt power used for the rectifier is supplied by three 25-kva. oil insulated self cooled single-phase transformers fed from the 13,200-volt bus.

Fig. 7—Lead Refinery, Electrolytic Tank Room.

## Operating Data

The efficiencies of the various types of conversion equipment used in the zinc plant are:

| | |
|---|---|
| Motor generator sets | 86 per cent |
| Rotary converters | 96 per cent |
| Mercury arc rectifiers (including 1.3 per cent loss in the rectifier transformer) | 93.5 per cent |

The observed power factor of the rectifiers measured on the 13.2-kv. bus is 92.25 per cent. The motor generator sets and rotary converters operate at unity power factor.

A comparison of the percentage of time lost on these various units due to changes, maintenance and repairs to the total possible operating time for 1935 and 1936 is:

| | 1935 | 1936 |
|---|---|---|
| Motor generator sets | 5.55 per cent | 4.3 per cent |
| Rotaries | 7.08 per cent | 2.83 per cent |
| Rectifiers | 6.07 per cent | 1.1 per cent |

Outages for tank room or other causes are not included in the above figures. It should be noted also that the above outages do not necessarily mean loss of production in the plant, because quite a large percentage of the above time is made up from work done, such as complete general overhauls, etc., when the machines are down for other reasons. Also in No. 3 generator room there is one spare rotary converter which is used when one of the other units is off load for overhaul or repair.

## Lead Smelter and Refinery

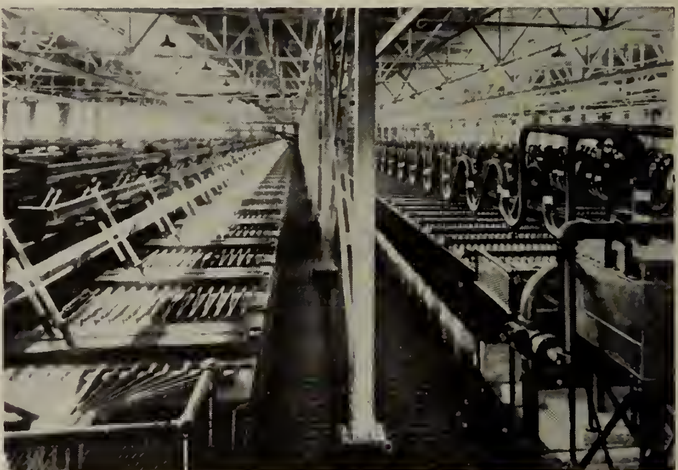
The bulk of the lead arrives in the form of concentrates which are mixed with flue dust and other ingredients, then "sintered" on Dwight and Lloyd machines to drive off the sulphur and some of the other impurities. After a double sintering process the sinter cake is fed to the lead blast furnaces along with various fluxes and coke. The metallic lead is tapped from the furnaces and taken to the drossing plant, where the dross is skimmed off and the lead cast in the form of anodes weighing about 370 pounds each, which are taken to the refinery and placed in the electrolytic tanks. The pure lead is plated onto lead starting sheets and every three days these are pulled, melted down and cast into 100-lb. pigs ready for shipping. The lead anodes are changed every six days.

Gold, silver and other metals are recovered from the slimes, or deposit left in the tanks after the lead has been plated out.

The electrolytic tanks are asphalt-lined reinforced-concrete tanks made up in the form of a double tank (see Fig. 7). These tanks are arranged for gravity flow of the electrolyte and are connected electrically in series. The lead anodes come from the drossing plant as mentioned above, and the cathodes or starting sheets are made from pure lead in the form of a thin sheet suspended from a copper bar. The cathodes are spaced 4⅛ in. apart. For 4,000-amp. operation there are 20 anodes and 21 cathodes. For 5,000 amp. there are 24 anodes and 25 cathodes. The area of the immersed section of each anode (both sides) is 11.8 sq. ft. The approximate current density is 17 amp. per sq. ft. The anodes and cathodes in each cell are connected in parallel respectively and in pulling the cathodes or anodes short circuiting bars are put across the bus bars on each end of the tanks thus cutting out this cell and then all the cathodes are pulled at one time by means of a crane. The voltage per cell is approximately 0.5 volts. The number of cells per unit varies from 240 to 300.

| | |
|---|---|
| The cell efficiency is | 90-93 per cent |
| Pounds of lead per kw.h | 10-12 |

To supply these electrolytic cells there are six motor generator sets consisting of one 1,200-kw. set 200 volts,



Figs. 8 and 9—Hydrogen Plant, Cell Rooms, Warfield.

three 1,000-kw. sets 200 volts, one 500-kw. set 120 volts and one 400-kw. set 110 volts. These last two sets are now used chiefly as spares. Bus bars are arranged to pick up the load on the spare machine if one of the other sets is down.

## Chemical and Fertilizer Plants

The company had been considering the question of utilizing the smoke from the zinc plant and lead smelter for some time and in 1929 started the construction of plants for this purpose. Smoke from the zinc plant was first to be used but a plant is now being constructed to treat the smelter smoke. A small sulphuric acid plant using the contact process was already in operation and three more plants of large capacity were built. At Warfield, where the acid is used in the production of fertilizer, the following were erected and put into operation, namely, hydrogen plant ammonia plant, phosphate plant and ammonia sulphate plant, as well as suitable storage bins, etc.

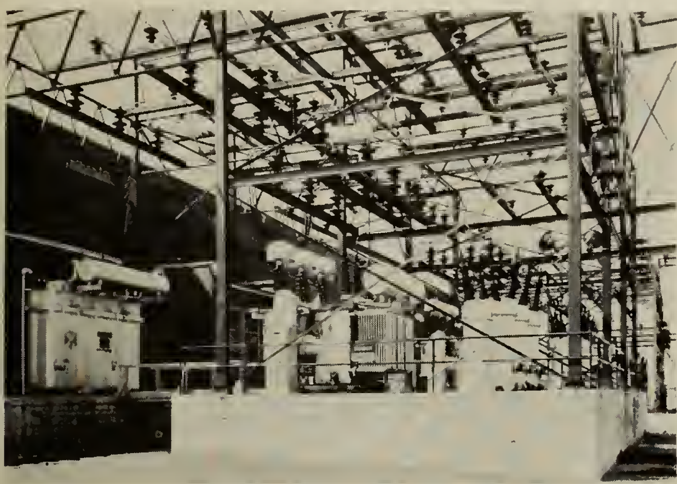


**Fig. 10—Hydrogen Plant, Rectifier Sub-station, Warfield.**

Of the total power used in these plants the hydrogen plant consumes approximately 80 per cent, ammonia plant 8 per cent and acid plant 6 per cent, the balance being distributed to other parts of the plant as required.

### Hydrogen Plant

Hydrogen is obtained by means of the electrolytic decomposition of water. In the original installation there were four types of cells used, namely, 306 Knowles (41 electrodes per cell), 312 Fauser (31 electrodes), 14 sections of Pechkranz and 24 Stuart. These cells were assembled into three 10,000-amp. 650-volt units.

Early in 1936 two more units of 360 Fauser cells (21 electrodes) were added. These operate at 10,000 amp. 830 volts. Another 10,000-amp. 830-volt unit is being installed this year which will consist of 336 Fauser cells (15 electrodes), while the original 312 Fauser unit is being changed to 270 cells (15 electrodes) but will still operate at 10,000 amp. 650 volts.

The majority of cells now installed are the Fauser type. They consist of a number of sheet iron electrodes suspended in an iron tank which is supported on porcelain insulators (see Fig. 8). The electrolyte used is either sodium hydroxide (NaOH) solution or potassium hydroxide (KOH). The electrodes are encased in an asbestos bag which traps the gas given off, it then enters a collector chamber at the top of the electrode and is fed into the gas mains by means of an insulating glass tube. The gas mains themselves are in sections insulated from each other at various points. Oxygen is collected at the anodes and hydrogen at the cathodes, there always being one more cathode than anode. The anodes are nickel-plated to protect the iron and also because the oxygen over-voltage to nickel is less than to iron. The cathodes are not plated. Provision is made automatically to keep the level of the electrolyte in the cell constant by feeding in distilled water, also means are provided for cooling the cells.

The cells are connected electrically in series. The current densities used vary from 36 amp. per sq. ft. for the 31 electrode cells to 67 amp. per sq. ft. for the 15 electrode cells. The voltage drop per cell also varies between 2 and 2.4 volts, depending on the current density used and the operating temperature of the cells, etc.

The Knowles and Stuart cells resemble the Fauser, but the Pechkranz cells are of the filter press type and operate in two groups in series, each group consisting of seven sections in parallel.

D.c. power for the above cell units is obtained by means of five mercury arc rectifiers; a sixth is being installed this year to feed the new cells. These are all 10,000-amp. units with two 5,000-amp. cylinders in parallel operating from one transformer. Three of the units are 600 to 670 volts d.c. and two 740 to 830 volts. The new unit will be 740 to 830 volts also. One of the 670-volt units is twelve-phase but all the others are double six phase and use d.c. reactors to smooth out the ripples.

The general arrangement of equipment is somewhat similar to the zinc plant layout, except that the transformers are outdoors, also there is a single step-down from 60,000 to rectifier voltage. The d.c. voltage range is obtained by means of voltage regulating transformers on the high tension bus just ahead of the main rectifier transformer. Each rectifier operates its own cell units and they are all operating satisfactorily at continuous full load.

A comparison of the percentage of time lost on these units due to changes, maintenance and repairs to the total possible operating time for 1935 and 1936 is:

| | |
|---|---|
| 1935 | 0.62 per cent |
| 1936 | 1.84 per cent |

The increase of lost time in 1936 was due largely to certain adjustments and changes made in the two new units put into operation early in the year. These figures do not include lost time due to tank room or other causes.

### Ammonia Plant

Ammonia is produced by combining hydrogen and nitrogen gas in a catalyst column under high pressure and at a high temperature. The nitrogen is produced by "boiling off" from liquid air. There are two units in this plant each capable of producing over forty tons of anhydrous ammonia a day (see Fig. 11). In the liquid air section a Burckhardt compressor is direct connected to a 450-hp. synchronous motor. The mixed gases are compressed by means of six-stage compressors which are driven by 2,250-hp. synchronous motors. Heaters on the four catalyst and one pre-catalyst columns are supplied by five 250-kva. transformers which have tap switches and a secondary

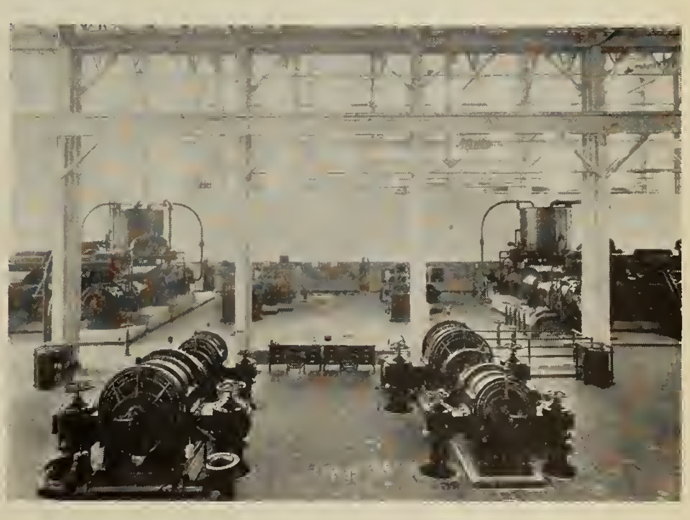

**Fig. 11—Ammonia Plant, Warfield.**

voltage range of 50 to 220 volts. There are four 125-hp. Breda gas circulating pumps as well as other smaller equipment installed.

The above descriptions cover the processes which consume the major portion of power used in the plant. Other processes in operation are relatively small consumers of power and will not be described, there are however a number of applications which while not involving large blocks of power may be of interest, a few of which are:—

### Dust Precipitation

There are several Cottrell treaters in the plant, used for the precipitation of metallic dust from the furnace and roaster gases on their way to the flue, as well as a "mist" precipitator in the acid plant.

The process requires a high potential uni-directional current at approximately 40,000 to 50,000 volts, which sets up an electrostatic field around wires which are suspended between metallic plates, or in some special cases are suspended in metal pipes.

Mechanical rectifiers are used to obtain this current. Some of the sets have the discs mounted on the same shaft as a small a.c. generator which supplies power to a transformer where it is stepped up to the required voltage. In others the disc is driven by a small synchronous motor while the 550-volt supply is stepped up by transformers. These sets are 25 kva. and several are used to supply a smoke treater which is divided into sections.

### Refinery Electric Evaporators

In the silver and gold refinery electric heating is used to evaporate solution for the recovery of blue-stone (copper sulphate). This is done by immersing electodes in two open type tanks of solution which are connected by having a small flow of solution between the tanks. This restricted area of solution makes a moderately high resistance path for the current flowing and is heated in this manner. These units are fed by 100-kva. transformers 2,200 to 110 volts.

The boiling point of the solution to be evaporated is 112 deg. C. If low pressure steam were used for this work the latent heat of evaporation could not be utilized, but only a small amount of the heat value above this point, which would give poor efficiency. The efficiency of the electric evaporation is about 85 per cent.

### Electric Steam Boilers

Three 1,500-kw., 2,200-volt, 3-phase electric steam boilers are installed at the refinery. They are placed together in a suitable location and feed steam into a common main for use in the plant to supplement the steam supplied from the waste heat boilers at the slag retreatment plant. These are used only intermittently.

### Electric Steel Furnace

A three-ton Greene electric steel furnace is used in the foundry for making steel and iron castings. Three 750-kva., 2,200/80-160-volt transformers are used and automatic control provided. The furnace operates at a little over 1,000 kw., taking about three hours for a full charge.

### Pumping Stations

The Stoney Creek pumping station pumps water from the Columbia river to a million gallon reservoir on the side of the hill above the Tadanac plant. It works against 400-ft. head and has a capacity of 38,000 gal. per min. with 5,775 installed horse power.

To supply the Warfield plant a second set of pumps is installed at the reservoir. The head is 517 ft. and capacity 15,000 gal. per min. with installed horse power of 3,050.

### Zinc Plant Bluepowder Electric Furnace

A ten-ton electric furnace for the production of zinc dust (bluepowder) from dross is used in the zinc plant, supplied by three 500-kva. 2,200/40-90 volts transformers. This furnace also has automatic control.

### Traction System, Cranes and Shops

The Tadanac plant is served by an 18-in. narrow gauge trolley system operating at 250 volts d.c. There are fifty-two 4- and 6-ton locomotives. Vee cars are used for transporting concentrates and similar materials, while special cars in the form of racks are used for carrying lead anodes; flat cars are used for general haulage.

A 500-kw. rotary converter supplies power to the system through feeders. Two 200-kw. motor generator sets are used as a standby.

The Warfield plant has no electric traction system, all the transportation of material being handled by motor trucks or conveyors. Warfield is also served by the Canadian Pacific Railway for shipping and heavy haulage.

There are over ninety hoists and cranes of different sizes in the plants. Some are 550 volts, 3-phase a.c. and others 250 and 125 volts d.c.

There are shops covering all kinds of work to be done in the plant. These are well equipped to handle any repair jobs which come up, as well as to make a large assortment of replacement parts and in some cases part of the equipment used in the plant.

# Modern Motive Power

*H. B. Bowen, M.E.I.C.,*

*Chief of Motive Power and Rolling Stock, Canadian Pacific Railway Company, Montreal.*

**Paper presented at the Semicentennial Meeting of The Engineering Institute of Canada in June 1937, in Montreal.**

**SUMMARY.—The author sketches the evolution of the various passenger and freight locomotive types, gives notes on modern light locomotives and trains, discusses the Diesel locomotive as applied to passenger and switching service, and is of opinion that the steam locomotive will predominate for some time to come in main line service on Canadian railways.**

It is fitting, as an introduction to a subject which so vitally influences our social, business and financial life, as does safe and rapid transportation, that we should, in the first instance, consider the evolution of the steam locomotive since its inception.

In particular, we may recall some of the steps by which the crude device which emerged upon the roads of France in 1769 became the present high speed, high capacity streamlined locomotive of to-day.

Despite the development of internal combustion engines, and their introduction into railway power units, the steam locomotive, with its flexibility, high capacity and ability to operate at high speeds, still holds as securely as ever the esteem which led every boy to wish to run a locomotive and every man to hear, in the musical note of an engine whistle, an invitation to seek surcease from his burdens by travel.

### Development of The Steam Locomotive

The first locomotive to actually operate by steam power over rails was built in 1803 by Richard Trevithick. Imagine the satisfaction of the builder when, hauling nine tons of iron, this locomotive attained a speed of five miles per hour. This machine definitely determined the two elementary facts which made to-day's locomotive possible; that sufficient adhesion for traction could be obtained by the use of smooth rails and smooth wheel treads, and that sufficient draft for maintaining steam pressures could be obtained by forcing exhaust steam from the cylinders through the smoke stack.

Early landmarks in the development of the locomotive were Hedley's "Puffing Billy" in 1813, with its complication of connecting rods, walking beams and gears; Blenkinsop's locomotive of 1814; several designs by Stephenson from 1815 to 1829, and in the latter year, the "Rocket." The successful performance of this locomotive upon the Liverpool & Manchester Railway led to the modern engine of to-day.

The first locomotive to be used in America was the "Stourbridge Lion" built in England for the Delaware & Hudson Canal Company. It arrived in America in 1829, making its initial trip at Honesdale, Pa., August 8th, 1829. The total weight of this engine was seven tons. Parts of the machinery and the boiler have been preserved in the National Museum, Washington, D.C.

In 1831 commenced the construction of several locomotives in the United States, including such well known engines as the "John Bull" of the Camden & Amboy; the "West Point" of the Charleston & Hamburgh; the "Dewitt Clinton" of the New York Central & Hudson River; the "York" of the Baltimore & Ohio.

The following year, 1832, saw the introduction of a four wheeled engine truck, embodied in the "Experiment" of the Mohawk & Hudson Railroad; also Baldwin's "Old Ironsides," the first successful locomotive built in America, was constructed.

### Evolution of Passenger Locomotive Types

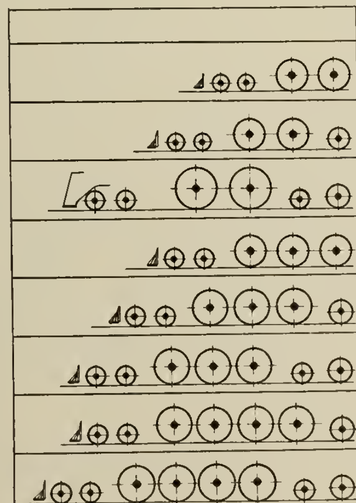
A type of locomotive which became almost universal upon American railroads was introduced in 1837 by Henry Brooks of Philadelphia. It had a four wheeled leading engine truck, horizontal cylinders, two pairs of coupled driving wheels and a tender for fuel and water. This wheel arrangement became known as the 4-4-0 or "American" type and was in general use in the United States and Canada for many years. Improved through the years, this type reached its peak performance on May 10th, 1893, when engine number 999 of the New York Central & Hudson River Railroad was credited with a speed of 112.5 miles per hour, while hauling the Empire State Express. This locomotive had cylinders 19 in. by 24 in., 86 in. dia. driving wheels, a boiler pressure of 180 lb. per sq. in., and a weight of sixty-two tons. The speed made by this little engine over the light track of the day has set a mark seldom exceeded even by modern motive power of any kind.

America was not alone in its appreciation of the 4-4-0 type locomotive. For many years the Midland Railway of England utilized this type of engine for most of their passenger train service.

At the present time, the "City" and "County" classes of the Great Western, the "Shire" class of the London and North Eastern and the "Schools" class of the Southern bear daily testimony upon English railways to the excellent qualities of engines using this wheel arrangement.

The evolution of various other wheel arrangements from this basic arrangement, by the introduction of additional driving wheels, of two-wheeled trailing trucks and more recently, of four-wheeled trailing trucks, is depicted by Fig. 1.

In 1895 the Baldwin Locomotive Works, Philadelphia, designed the first "Atlantic" or 4-4-2 type locomotive, by



| WHEEL ARR'G'T. | NAME OF TYPE | YEAR |
|---|---|---|
| 4-4-0 | AMERICAN | 1837 |
| 4-4-2 | ATLANTIC | 1895 |
| 4-4-4 | JUBILEE | 1935 |
| 4-6-0 | TEN WHEEL | 1847 |
| 4-6-2 | PACIFIC | 1901 |
| 4-6-4 | HUDSON | 1926 |
| 4-8-2 | MOUNTAIN | 1912 |
| 4-8-4 | NORTHERN | 1926 |

**Fig. 1—Development of Passenger Locomotives.**

adding a two-wheel trailing truck to the wheel arrangement of the 4-4-0 type. On account of its greater boiler capacity, better riding qualities and superior operation at high speeds, the Atlantic type superseded the American type for handling main line passenger service. To-day, relegated to local or branch line service, a few survivors still give satisfactory service.

Notable examples of the Atlantic type locomotive were engine 1027 of the Atlantic City Railroad, which made consistent records of speed and reliability between Camden and Atlantic City; the high wheeled Brooks engines of the Central Railroad of New Jersey; the 2900 class of the New York Central and others on the Harriman Lines, the Erie, the Burlington, Baltimore & Ohio and Mid-Western Lines. Some popular examples of compound locomotives were of this type.

In Canada at the turn of the century, on the Canada Atlantic Railway and Canadian Pacific Railway, the performance of the Atlantic type engines added to the laurels already earned, by records made in high speed passenger service between Montreal and Ottawa. A brief description of the locomotives built by the Canadian Pacific Railway Company at Montreal, in 1899 may be of interest. They had Vauclain compound cylinders of the following dimensions: cylinders, high pressure 13½ in. dia., low pressure 23 in. dia., stroke 26 in., boiler pressure 200 lb. per sq. in., diameter of driving wheels 84 in., tractive effort 18,000 lb. Weight of engine and tender—138 tons.

Successful examples of 4-4-2 Atlantic type engines also had an important place in the movement of passenger trains in England on such representative lines as the Great Northern, North Eastern, North British, Great Central and other railways.

It is a remarkable tribute to the Atlantic type locomotive that recent designs of locomotives for high speed passenger operation are based upon the 4-4-2 type locomotive, in some cases modified by the application of a four wheeled trailer truck.

In the design of the "Lady Baltimore" of the Baltimore & Ohio; of the "Hiawatha" of the Milwaukee, and of the "Jubilee" type of the Canadian Pacific, the experience accumulated in forty years operation of these successful locomotives has served as a foundation for the development of a most satisfactory new type of passenger motive power for the movement of light weight high speed trains. When the increasing weight of trains created a demand for more powerful locomotives, the adoption of new types followed. The ten-wheeled locomotive, evolved by adding an additional driving wheel to the 4-4-0 American type engine, was first built in 1847 by Septimus Morris.

The first Jubilee type locomotives on the Canadian Pacific were built for high speed operation and the 4-4-4 type was selected in preference to the 4-4-2, one of the principal reasons being to keep down the track stresses. The 4-4-2 type, with heavy wheel loads, would have given track stresses the equivalent of our heaviest type locomotives due to the wheel spacing. This year, when it was decided to build additional light weight equipment for operation on branch lines, it was necessary to modify the wheel arrangement slightly from the original Jubilee type This was arranged for by connecting the main rod to the rear driving wheel instead of the front driving wheel, thus allowing the driving wheels to be moved forward and decreasing the spacing between the leading engine truck and the leading driving wheel.

Notable speed records were made by high wheeled locomotives of the 4-6-0 type on the Lake Shore & Michigan Southern (now New York Central); on the "Royal Blue" trains of the Baltimore & Ohio and on other American railroads. The next phase of the progress of the ten wheeled type was the addition of a two wheeled trailing truck, thus bringing into existence the 4-6-2 "Pacific" type.

The first locomotive with this wheel arrangement was built in 1901 for the New Zealand Government Railways. The first group to be given the type name was built in 1903 for the Missouri Pacific from which the name originated. Many successful designs followed, until most of the main line trains of the United States and Canada were headed by Pacific type engines.

The Canadian Pacific, in 1906, built two groups, later extended by two more designs, all of which have produced most satisfactory records for efficiency and reliability. At the present time the Canadian Pacific operates 259 Pacific type locomotives in passenger and fast freight service.

The next development was the installation of a four-wheeled trailing truck, which, known as the 4-6-4 or "Hudson" type, has become very popular for high speed train handling. The best known early locomotives, from which the name was derived, were the 5200 class on the New York Central Railroad. Canadians are familiar with the 2800 class of the Canadian Pacific, and the 5700 class of the Canadian National, both of which are most efficient in meeting the difficult conditions of present day travel. The Hudson type possesses ample boiler capacity to ensure the maintenance of high sustained horsepower, large diameter driving wheels to permit of travelling at high speeds, and good riding and guiding qualities.

The addition of another driving wheel to the Pacific type, as first introduced by the Chesapeake & Ohio in 1912, resulted in a new arrangement, the 4-8-2 "Mountain" type locomotive. This was especially suited to the movement of heavy main line passenger trains and is also used to a considerable extent for fast freight work.

Canada was not behind in realizing the advantages of the type and in the same year, the Canadian Pacific built two Mountain type locomotives. The 6000 class of the Canadian National are of this wheel arrangement.

The four-wheeled trailing truck having proved its desirability, its inclusion in the place of the two-wheeled truck followed and thus was derived the 4-8-4 or "Northern" type. Built first in 1926, the 4-8-4 has become deservedly popular for heavy passenger and fast freight work. Canadian examples are the well known 3100 class of the Canadian Pacific and the 6100 class of the Canadian National.

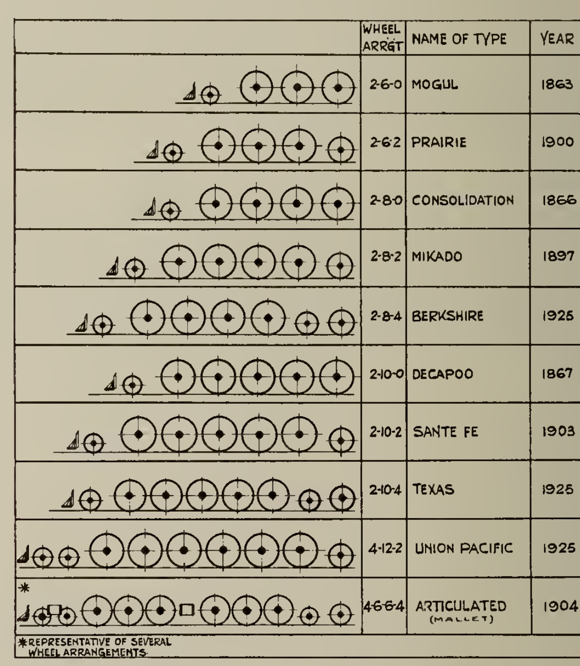


Fig. 2—Development of Freight Locomotives.

### Evolution of Freight Locomotive Types

The development of the types of freight locomotives was similar to that of passenger locomotives. In 1863, the 2-6-0 or "Mogul" type was introduced. It had such a popular appeal that even to-day the type name is wrongly used to signify a large massive locomotive. From this, the next step was the 2-6-2 and then the 2-8-2, and so on, up to the 4-12-2 used on the Union Pacific, as shown in Fig. 2. Figure 2 does not include the 4-14-4 type constructed for the Russian government in 1935, of which very little information regarding performance is available.

The story of the evolution of steam locomotive types is not complete without reference to the articulated type engine, where two complete engines are used under a single boiler to develop large tractive effort. This type of locomotive is used in both passenger and freight service, particularly in mountainous territory.

### Details of Steam Locomotive Construction

*Boiler:*

Locomotive boilers have changed considerably since the early days of the locomotive. Not only have they increased greatly in size, and in pressures used, but such auxiliaries as superheaters, brick arches, feedwater heaters and combustion chambers are practically standard on modern power. Alloy steels are now being used extensively in locomotive boilers, following the introduction of nickel steel boiler barrels by the Canadian Pacific on a comparatively large number of engines in 1926.

The following tabulation (see Table I), comparing the dimensions of early and recent boilers of Canadian Pacific locomotives may be of interest.

Table I

Boiler Dimensions

| | | | |
|---|---|---|---|
| Type of locomotive | 4-4-0 | 4-4-4 | 2-10-4* |
| Date built | 1882 | 1936 | 1929 |
| Tractive effort—lb | 13,160 | 26,500 | 89,200 |
| Boiler pressure—lb | 140 | 300 | 275 |
| Firebox, length | 5 ft. 11-13/16 in. | 9 ft. 6-1/16 in. | 11 ft. 8-3/16 in. |
| Firebox, width | 2 ft. 11 in. | 5 ft. 10-3/16 in. | 8 ft. 0 in. |
| Grate Area sq. ft | 17.4 | 55.6 | 93.5 |
| No. and dia. of tubes | 159-2 in. | 47-2¼ in. | 59-2¼ in. |
| No. and dia. of flues | Nil | 120-3½ in. | 203-3½ in. |
| Length of tubes and flues | 11 ft. 1¾ in. | 18 ft. 10-13/16 in. | 20 ft. 4⅞ in. |
| Superheater | Nil | With | With |
| Tube and flue heating surface—sq. ft | 928 | 2601 | 4509 |
| Arch tube heating surface—sq.ft. | Nil | 34 | 45 |
| Firebox heating surface—sq. ft. | 113 | 198 | 377 |
| Superheating heating surface—sq. ft | Nil | 1100 | 2112 |
| Combined heating surface—sq.ft. | 1041 | 3933 | 7043 |

*The boiler of the 2-10-4 class represents one of the largest boilers now in service on Canadian Pacific Railway locomotives operating in the Canadian Rockies.

There have been numerous experiments in boiler design with a view to utilizing higher steam pressures and eliminating stayed surfaces. Boilers with water tube fireboxes have had many sponsors, from the early designs of Brotan in France, to the multi-pressure designs of recent years. A few of these are still in service. Their comparative complication and maintenance difficulties have prevented their general adoption, although they have shown economies in operation.

At the present time the Union Pacific has under construction a turbo-electric steam locomotive with a novel type of automatic steam generator of the water tube design. This locomotive is to have two steam generating units; a capacity of 4,800 h.p., and a steam output of 40,000 lb. per hr. at 1,500 lb. pressure.

*Cylinders, Valves:*

The cast iron slide valve cylinders of early locomotives have been replaced by cast steel piston valve cylinders made either in halves, bolted together, or integrally cast with the engine bed or frame. The inside Stephenson valve motion has been superseded by outside, accessible motions of the Walschaert, Baker or Southern type.

For reversing the locomotives, screw and air operated gears are standard practice.

*Frames, Trucks, etc.:*

Modern locomotive frames are of cast steel, in one piece, including front bumper, cylinders, cross bracing, firebox supports, motion bearers and brackets for air pumps, brake hangers, etc. The trucks are of cast steel, usually equipped with roller bearings.

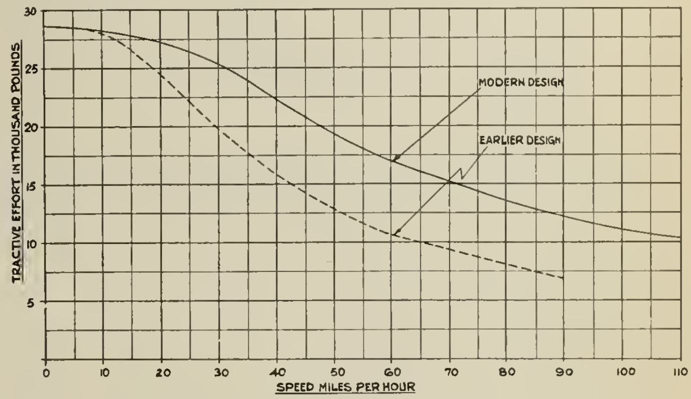

**Fig. 3—Speed-Tractive Effort Curves, Passenger Locomotives.**

Improved types of driving axle boxes reduce maintenance and permit less slack and wear to develop.

*Machinery, Rods:*

The use of alloy steels for valve motion parts and rods is general. By their use the weight of the details is decreased and difficulties encountered at high speeds materially reduced.

*Draft Appliances:*

Constant study and experimental work is being conducted with regard to draft appliances, not only by individual railway companies but also by committees of the Association of American Railroads. The result has been a steady improvement in fuel consumption. The record of Canadian railways in respect to fuel consumption has been most encouraging.

*Special Devices:*

The modern locomotive has many accessories which were unknown to locomotives of past years.

The superheater, which takes from the flue gases sufficient heat to raise the steam temperature to 700 deg. F. or higher, is standard practice to-day and is indeed the heart of the modern locomotive.

Feedwater heaters, deriving heat from a portion of the exhaust steam, raise the temperature of the feedwater before it enters the boiler, thus reducing fuel required and lessening boiler maintenance.

On account of the increase in firebox dimensions, stokers are applied to all large locomotives. It may be noted, in passing, that the type of stoker now in most general use, was first used in Canada on the Canadian Pacific Railway.

Small engines, known as boosters, increase the starting tractive effort of the locomotive by furnishing driving power to one of the trailing truck axles.

Lubrication of valves and cylinders is principally mechanical, while driving boxes, connecting rods and machinery use grease for lubrication.

Tender coal and water capacities have been increased to eliminate frequent stops for supply, and devices to improve the quality of water supplied to the boiler have been installed.

The changes which have been made in the steam locomotive over the past ten to twenty years have resulted in the production of a locomotive having a higher sustained capacity over a greater range of speed. Figure 3 shows the tractive effort curve of two locomotives having the same equivalent starting tractive effort, one for an early type locomotive and one of present day construction. It will be noted that in the older locomotive, the tractive effort drops off rapidly over the higher ranges of speed as compared to that of the modern locomotive. This accounts for the fact that the locomotive of to-day, if it can start the train satisfactorily, can handle a greater number of cars at higher rates of speed than the older locomotives.

### Modern Steam Locomotives and Trains

*Light Locomotives:*

Development of light weight trains powered by oil electric equipment has been paralleled by similar activities in the design of efficient high capacity steam locomotives specially purposed to operate in conjunction with trains of conventional type, but so constructed that the weight of the cars approximates 40 per cent less than that of cars previously considered standard. Such locomotives have demonstrated their ability to maintain schedules as fast as those operated by oil-electric units; have been more reasonable in initial cost; permit of flexibility in making up consist of trains; may be maintained by existing shop equipment and staff, and have indicated by their performance that changing operating demands may be successfully met by a modification of basic locomotive design ratios to meet a wide range of conditions.

Among the pioneers in the introduction of new, streamlined steam locomotives and of correspondingly light cars to be operated therewith, are the Baltimore & Ohio; Chicago, Milwaukee, St. Paul & Pacific and the Canadian Pacific. These lines have built locomotives which have given outstanding results, the characteristics of these being shown in Table II.

Table II

| Railroad | B. & O. | C.M.St.P. & P. | C.P.R. |
|---|---|---|---|
| Wheel arrangement...... | 4-4-4 | 4-4-2 | 4-4-4 |

| Oil capacity—gal....... | .... | 4000 | .... |
| Coal capacity—tons.... | 14 | .... | 12 |
| Water capacity—gal..... | 8,000 | 13,000 | 7,000 |

*Water tube firebox.

At the present time the Canadian Pacific has under construction twenty more light high speed locomotives of a slightly modified design.

*Baltimore & Ohio:*—The trains used in connection with the locomotives described in the table consist of eight cars. Exclusive of the locomotive, the total length is 557 ft. 10 in.; total weight, when constructed of special steel, 780,000 lb.; when constructed of aluminum, 699,540 lb. The seating capacity of the train is 325. The consist of the train is as follows:—

1—Baggage and mail
2, 3 and 4—Reclining chair cars
5—Dining and lunch
6 and 7—Parlor cars
8—Parlor and observation

All cars are carried upon four-wheel single equalizer type trucks equipped with roller bearings. Cars are not articulated.

*Milwaukee:*—The trains which make up the Hiawatha trains of the C. M. St. P. & P. Ry. consist of nine lightweight cars. Exclusive of the locomotive, the total length is 737 ft. 0 in.; total weight 860,400 lb. and seating capacity 464. As arranged for service, the consist is as follows:—

1—Express, tap room
2, 3, 4 and 5—Coaches
6—Dining
7—Parlor
8—Parlor—Drawing room.
9—Parlor—Observation

Trucks are of the four wheel type equipped with roller bearings. Cars are not articulated.

*Canadian Pacific:*—Light weight trains constructed by the Canadian Pacific are of the semi-streamlined type, mounted on four-wheel trucks which have roller bearings. Cars are not articulated.

The original trains designed for day operation consisted of the following units:

1—Mail and baggage
2—Baggage—Buffet
3 and 4—Coaches

Exclusive of the locomotive, the total length of train is 319 ft. 3½ in.; total weight 441,700 lb.; cars have a seating capacity of 130.

Four trains are now in operation between Montreal and Quebec; Toronto and Windsor; and between Calgary and Edmonton. The spacious accommodation, ample lounge room space, modern construction, air conditioning and improved schedules of these trains have brought instant recognition of their success in meeting modern transportation requirements. Thirty additional cars are now under construction.

*Heavy Locomotives:*

To adequately handle heavy passenger trains of conventional equipment, heavier locomotives than those referred to are required. The latest Canadian locomotives designed for this purpose are the well-known 2800 class of the Canadian Pacific and the 6400 class of the Canadian National. The dimensions of these locomotives are given in Table III.

Table III

| Railroad | C.P.R. | C.N.R. |
|---|---|---|
| Wheel arrangement.................. | 4-6-4 | 4-8-4 |
| Tractive effort—lb.................. | 45,250 | 52,000 |

| Water capacity—gal.................. | 12,000 | 11,700 |

*Under construction.

The Canadian Pacific locomotives are typical of the general trend to use 4-6-4 type locomotives for heavy passenger train service.

In England, where the weight of trains is normally much lighter than on American railways, streamlined steam locomotives are making enviable records for speed and reliability. The London & North Eastern Railway has announced that its new "Coronation" express will be scheduled to make the 392 mile run between London and Edinburgh in six hours.

The London, Midland & Scottish Railway recently covered 190 miles from London, St. Pancras Station, to Manchester in 202 minutes. On the return trip a speed of 91 miles per hour was attained, hauling a train of standard coaches.

The Great Western Railway and Southern Railway have kept abreast of the other lines in the operation of high speed schedules.

*Freight Locomotives:*

Freight train schedules have followed the trend of passenger train schedules. Increased speeds have changed the basis of operation from "gross tons handled" to "gross tons handled per train hour." The familiar freight locomotives, with small diameter driving wheels, moving "drag" tonnage slowly across the country, have been replaced by high wheeled locomotives either of the 4-8-4 type, or by articulated locomotives of new design. Representative of the latter development is the Union Pacific freight locomotive built in 1936. Its characteristics are as in Table IV.

Table IV

| | |
|---|---|
| Wheel arrangement | 4-6-6-4 |
| Tractive effort—lb | 97,400 |
| Cylinders | 4-22 by 32 in. |

Internal Combustion Motive Power

Twenty-five years ago, public interest was engrossed in weighty arguments, backed by formidable arrays of statistics, concerning the respective merits of electric and steam locomotives.

Several extensive electrifications, mainly constructed to meet specific local operating conditions, were pointed out as examples of the ultimate adoption of electricity by the railroads of America.

Steam still holds the supreme position as the prime mover of the world's transport. The contentions of proponents for the general adoption of internal combustion locomotives for railway service remind one of these early prophecies.

Encouraged by a fairly general utilization of rail motor cars, mainly for branch lines, a light weight unit train, powered by Diesel oil engines, with electric transmission, has been heralded by some as the ultimate form of railway motive power. The blaze of publicity which has accompanied the introduction into service of each of these light weight unit trains is apt to cause one to overlook the fact that their number compared with the thousands of passenger trains in daily operation is as yet insignificant. Specially designed, light weight unit trains number but twenty-one in service on the following railways:—

| | |
|---|---|
| Chicago, Burlington & Quincy | 8 |
| Union Pacific | 6 |
| Atchison, Topeka & Santa Fe | 2 |
| Gulf Mobile & Northern | 2 |
| Boston & Maine | 1 |
| Illinois Central | 1 |
| New York New Haven & Hartford | 1 |
| Total | 21* |

*Two more are ready for service on the Baltimore and Ohio Railroad.

As a comparison, a study of the Diesel powered locomotives constructed, paralleled by a list of steam locomotives purchased may also be of interest:

Table V

| | Steam Locomotives | Diesel Locomotives** |
|---|---|---|
| 1925 | 1065 | 3 |
| 1926 | 1362 | 8 |
| 1927 | 792 | 4 |
| 1928 | 701 | 8 |
| 1929 | 1289 | 2 |
| 1930 | 535 | 51 |
| 1931 | 178 | 11 |
| 1932 | 12 | 5 |
| 1933 | 42 | 21 |
| 1934 | 182 | 16 |
| 1935 | 110 | 9 |
| 1936 | 534 | 42 |
| 1937 to May 1st | 331 | 35 |
| | 7133 | 215 |

**Mostly for switching service, including those for industrial work.

The total number of Diesel locomotives ordered comprises three per cent of the number of steam locomotives ordered during the same period.

In 1935 the author expressed his conviction that the newly designed, smaller, lighter, low powered Diesel unit train would not prove adequate to meet the requirements of flexibility in consist, and interchangeability in operation; neither would it be sufficient in spaciousness or comfort to meet the demands which were being developed. All recently constructed unit trains have been increased in length, increased in cross section and increased in power. The latest examples have two power units, and in some cases the auxiliary lighting and heating equipment has been given space in a portion of a third car. In other words, recent practice abandons the construction of unit trains and reverts to the practice of separate locomotive units, either single or double, with single control.

Modern Diesel Powered Passenger Trains

*Denver Zephyr (Chicago Burlington & Quincy R.R.)*

The latest example of the line of "Zephyrs" placed in service consists of a double power unit, hauling ten passenger units, operated between Chicago and Denver. Some of the units are united by articulation, in order to reduce the number of trucks required. The first section of the power units is 56 ft. 9 in. long and houses two 900 h.p., 12-cylinder V-type two cycle Diesel engines direct connected to direct current generators. The second section of the power units, 55 ft. 0 in. long, houses a 1,200 h.p., 16-cylinder V-type two cycle Diesel engine, also direct connected to a direct current generator. In this section, also, are a mechanical air compressor driven from the main engine shaft and two automatic oil fired boilers for generating steam for train heating.

The first revenue car contains auxiliary power equipment to supply current for the operation of lighting, refrigeration, and air conditioning equipment. The revenue units are arranged for the accommodation of the following services:

1—Auxiliary power, mail and baggage
2—Baggage, crew's quarters, cocktail lounge
3 and 4—Coach passengers
5—Dining
6, 7 and 8—Open section sleeping cars
9—Drawing room, bedroom, compartment sleeper
10—Parlor, observation lounge

Units 3, 4 and 5; 6 and 7; also 8 and 9 are articulated.

The car sheathing and structure is of stainless steel fabricated by a welding process. The structure is designed so that the roof and under structure act as compression and tension members of a beam, being connected by sides making up a Pratt truss, modified as necessitated to allow for doors and windows. The car is insulated in roof, sides, ends and floor.

Car trucks are of the four-wheeled, double equalizer, swing bolster type and have 33 in. diameter wheels, spaced 8 ft. 0 in. apart. Truck framing is composed of nickel steel double annealed and drawn castings. Journals are equipped with roller bearings.

The total length of the train, including locomotive, is 883 ft. 9 in.; total weight is 1,269,470 lb. (634.7 tons); weight per horse power of main engines being 423.1 lb.

The passenger accommodation of the train, exclusive of dressing room seats is as follows:—

| | |
|---|---|
| Coach passenger seats | 100 |
| Berths, upper and lower | 93 |
| Parlor car | 10 |
| Lounge and dining room | 104 |
| Total | 307 |

The present time schedule of these trains may be of interest and is shown in Table VI.

Table VI

| No. 1 Westbound (read down) | Miles | Stations | No. 10 Eastbound (read up) |

| Average speed—m.p.h. | 66.5 | 68.0 |

*City of Denver* (*Union Pacific R.R.*)

The most recent services inaugurated by Union Pacific light weight unit trains are those operating between Chicago and Denver. These are similar in make-up to the Denver Zephyr of the Burlington, each train consists of a double power unit and ten passenger units. The two sections of the power unit are articulated by means of a bridge spanning from the rear truck of the front section to the front truck of the rear section. Each section of the power unit houses a 1,200 h.p., 16-cylinder, V-type, two cycle Diesel engine, direct connected to a direct current generator. Auxiliary current for lighting, etc. is furnished by two separate Diesel engined generator sets.

The arrangement of the revenue cars is as follows:—

1—Mail
2—Baggage
3—Baggage and tap room
4 and 5—Coaches
6—Dining
7, 8 and 9—Sleeping cars
10—Observation car

Units 4 and 5; 7 and 8; and 9 and 10 are articulated.

The locomotive units are sheathed with Cor-Ten steel plates. The revenue units have aluminum plate sheathing, attached to a strong framing, the parts of which are made of strong aluminum alloys; extruded aluminum sections are used for side sills and upper longitudinal members.

Trucks are of the four wheel type. The locomotive trucks are 8 ft. 4 in. wheel base and have 36 in. diameter wheels; car trucks are 8 ft. 0 in. wheelbase and have 34 in. diameter wheels.

The total length of the train is 864 ft. 0 in.; total weight is 1,250, 450 lb. (625.2 tons); weight per horse power of main engines is 521.0 lb.

The passenger accommodation furnishes seating capacity for 272 persons. The present schedule of the "City of Denver" trains appears in Table VII.

Table VII

| No. 111 Westbound (read down) | Miles | Station | No. 112 Eastbound (read up) |
|---|---|---|---|
| CT —6.20 p.m. | 0 | Chicago | CT—9.23 a.m. |

| Average speed-m.p.h. | 67.2 | 68.0 |

*Super Chief* (*Atchison, Topeka and Santa Fe R.R.*)

The latest Diesel powered unit train to be placed in service is the "Super Chief" operating between Chicago and Los Angeles on a 39-3/4 hour schedule, over the lines of the Atchison, Topeka and Santa Fe. This train, similar generally to the trains of the Burlington and Union Pacific, consists of a two section power unit of 3,600 h.p. with separate coaches, without articulation.

Each of the two sections of the locomotive contains two 900 h.p, 12 cylinder, V-type, two cycle engines direct connected to a d.c. generator. The consist of the revenue units is as follows:—

1—Mail, storage, post office
2—Mail, storage, baggage
3 and 4—Sections, compartments, drawing rooms
5—Bar, lounge, barbershop, crew
6—Dining
7 and 8—Bedrooms, compartments, drawing rooms
9—Bedroom, compartments, drawing room observation

The total length of the train, including locomotive is 856 ft. 11-3/4 in.; total weight is 1,419,000 lb., (704.5 tons); weight per horse power of main engines being 394.1 lb.

The passenger accommodations comprise:—

| | |
|---|---|
| Sleeping car berths | 104 |
| Dining car seats | 36 |
| Observation lounge, etc | 42 |
| | 182 |

The construction of the cars, arrangement of space and details of design are of the latest space and weight saving design.

This train embodies complete separation of motive power from the train units and also has been built without truck articulation, in order to obtain the same flexibility of consist which is found in steam operated practice.

### Modern Diesel Switching Locomotives

The typical modern Diesel electric switching locomotive consists of a 600 h.p. Diesel electric engine, usually having 6 vertical cylinders, direct connected to a d.c. generator.

The frame, of welded steel or cast steel construction, is mounted on two 4-wheel trucks. The engine and generator are enclosed within a steel weatherproof housing; the cab being located at one end of the locomotive.

A recent representative switching locomotive has the specifications in Table VIII.

Table VIII

| | |
|---|---|
| Weight on drivers, loaded | 212,000 lb. |
| Length | 39 ft. 6 in. |
| Height to top of cab | 14 ft. 3 in. |
| Rigid wheel base | 8 ft. 0 in. |
| Total wheel base | 26 ft. 0 in. |
| Tractive force (30 per cent adhesion) | 63,600 lb. |
| Tractive force (at continuous rating of motors) | 29,900 lb. |
| Speed (at continuous rating of motors) | 5.7 m.p.h. |
| Speed, maximum | 45.0 m.p.h. |

The development of the oil electric switching locomotive for American railway and industrial service commenced in 1923, the first successful locomotive weighing 55 tons, with a 6 cylinder, 300 h.p. Diesel engine direct connected to a d.c. generator.

While oil electric switching engines have, in some cases, been favoured over a steam locomotive, on account of ability to develop high tractive effort at low speeds, the oil electric lacks the flexibility in operation of the steam locomotive and must be carefully selected as to type and suitably assigned for service, if the benefits of its performance are to balance the high initial cost of the unit, and overcome other objectionable features. There has been a tendency, when making comparisons, to overlook the fact that the steam locomotives which have been replaced by oil electric switching locomotives have usually been obsolete engines of an uneconomic type.

### Modern Trends in Railway Motive Power

The trend of modern motive power is dependent largely upon local conditions and economic influence. On account of the small population of the Dominion, as compared with that of the United States; long distances through sparsely settled territory; need of furnishing adequate service to small communities along the line, and the severe winter weather conditions encountered, it is doubtful whether any other form of motive power can as successfully meet the range of limitations involved in Canadian railway service as can the steam locomotive.

A comparative study of the characteristics of an oil electric light weight unit train as compared with one operated by steam locomotives, must be based upon the following factors:—

(1)—Economical first cost
(2)—Economical maintenance
(3)—Adequate power
(4)—Safety
(5)—Comfort
(6)—Reliability, flexibility, speed, etc.

*Economical Cost and Maintenance:*

Admitting that the Diesel engine operates at a low fuel cost, and has high thermal efficiency, there are still many problems to be solved before its suitability for Canadian main line train service can be established.

The first cost of Diesel electric equipped locomotives must be materially reduced before they can be accepted. A comparison of costs follows in Table IX.

Table IX

| | Steam Train (including locomotive) | Gas Electric Rail Car | Light Weight Diesel Electric Train |
|---|---|---|---|
| Cost per pound | $0.30 | $0.48 | $0.95 |

These are actual Canadian prices except for the last item, which is based on conservative prices in the United States, which are approximately 45 per cent below Canadian prices for duplicate equipment. In this connection the latest trend is to the use of double unit Diesel locomotives for handling light weight trains. While this permits the installation of adequate power capacity, it doubles the initial cost, doubles the non-revenue weight, duplicates the mechanical and electric equipment and greatly increases maintenance costs. When in addition to devoting the entire space of the two first units of these trains to motive power equipment, the third unit is also partly taken up by the generating equipment for lighting, air conditioning and refrigerating, the revenue-producing space becomes unduly restricted. One recent example has less than 80 per cent of the train available for traffic accommodation.

When analysis is being made of fuel costs for Diesel operated light weight trains, it must be borne in mind that usual comparisons cited are not with those of a similar light weight steam train but with those of a heavy locomotive handling a train of heavier conventionally designed cars on an entirely different standard of service.

One of the chief points brought out to favour internal combustion power is the elimination of the locomotive boiler and its very high cost of repairs and maintenance, which may be saved by using the newer form of power. As actually these maintenance costs constitute only 19 per cent of the total cost of steam locomotive maintenance, they are not out of proportion to the total nor do they present a forceful reason for the abandonment of steam. Again, should figures purporting to show a striking reduction of fuel costs in favour of Diesel engines be placed upon a cost per ton-mile basis, the result is not so damning to the steam powered locomotive. The fuel cost of Diesel electric units is small because the tonnage moved is small. Comparative costs follow in Table X.

Table X

| | Diesel Electric Light Weight Train | Gas Elec. Car | Steam Passenger Train | Steam Freight Train |
|---|---|---|---|---|
| Cost of fuel per ton for one mile | $0.00114 | $0.001 | $0.00086 | $0.00004 |

If the cost of steam freight service represents unity, the comparison is as follows:—

28 25 21 1

*Note.*—Figures above are based on a gasoline cost of $0.15 per U.S. gallon; locomotive performance on cost of coal in U.S., Diesel electric costs on advertised performance of Union Pacific train; gas electric car on actual Canadian Pacific costs.

Fuel costs at best are indefinite. They are influenced by condition of engine, particularly worn cylinders, valves, pistons and rings, causing loss of compression; inaccurate fuel injection, inadequate scavenging, and weather conditions. Low temperature and heavy snow will increase fuel consumption. A general increase in demand for suitable fuel oil and a depletion in the available oil supply cannot fail to be reflected in increased fuel costs.

Maintenance costs for existing Diesel electric equipment are also very indefinite. The equipment has not yet been in service long enough to establish any standard of maintenance expense. Even successive individual units placed in service by the same railway have been radically changed in mechanical and electrical equipment, size of units, and length and weight of train. That the service of existing latest equipment can be perpetuated by means of modernization and rebuilding, as is the practice with

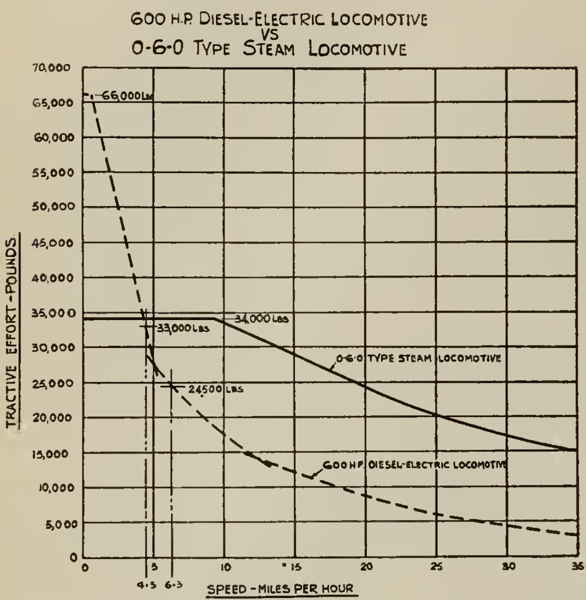

Fig. 4—Speed-Tractive Effort Curves, Switching Locomotives.

steam locomotives, has not yet been established. To maintain internal combustion engines and electrical equipment necessitates expensive installations of shop machinery, specially trained maintenance staff and probably the purchase of repair parts at high cost from the manufacturers. Obsolescence of the oil electric equipment through the development of weight reducing and fuel conserving designs, will make it probable that the cost of maintaining these units will always compare unfavourably with similar costs for steam locomotives.

*Adequate Power:*

The Diesel engine has no starting torque at zero speed, therefore its installation must include some means of converting a practical and economical engine speed to a low speed, high torque equivalent, at the driving wheel. Electric transmission involves a dual conversion, between engine and rail. It is, so far, the most successful transmission for locomotive use.

To equal the horse power output of a steam locomotive at high speeds, a very large, heavy Diesel installation is required at a cost approximately three times that of equivalent horse power in steam power.

Most of the Diesel electric locomotives are used in switching service. Figure 4 illustrates the comparative speed-tractive effort curve of a 600 h.p. Diesel electric locomotive compared with that of the steam locomotive which it replaced. Note the rapid decline in tractive effort of the oil electric locomotive at speeds between 5 and 10 m.p.h. This locomotive has two 300 h.p. engines, thus duplicating the number of parts to be maintained.

Dimensions of the two locomotives follow in Table XI.

Table XI

| | Steam | Diesel Electric |
|---|---|---|
| Weight on driving wheels—lb. | 169,000 | 215,650 |
| Dia. of driving wheels | 51 in. | 40 in. |
| Cylinders, dia. and stroke | 21 by 26 in. | 2 sets-6 cyl. 10 by 12 in. |
| Boiler pressure—lb. | 180 | .... |
| Tractive effort, max.—lb. | 34,000 | 66,000 |
| " " (1-hr. rating 4-5 m.p.h.) | .... | 33,000 |
| " " (continuous rating 6.3 m.p.h.) | .... | 24,500 |

Since the steam locomotive maintains a tractive effort of 34,000 lb. to approximately 9 miles per hour, it is 28 per cent more powerful than the Diesel electric within the range of switching speeds.

A striking example of the increased power which must be installed to overcome the tractive limitations of oil electric equipment is indicated by the use of 3,600 h.p. engines in the Super Chief of the A.T. and S.F. The trailing load behind the locomotive is 425.5 tons, being equivalent to one horsepower for each 236.4 lb. of revenue rolling stock. In steam practice one horsepower for each 500 lb. of train is ample for reliability of service.

*Safety:*

Reduction in weight lessens the impact when a light train suffers collision with another train or object but the damage sustained would probably be increased. Reduction in weight also increases the tendency for the lighter train to be derailed should an obstacle be encountered. Consideration for safety indicates that such reduction should be confined to a point where the hazards of operation should not be increased.

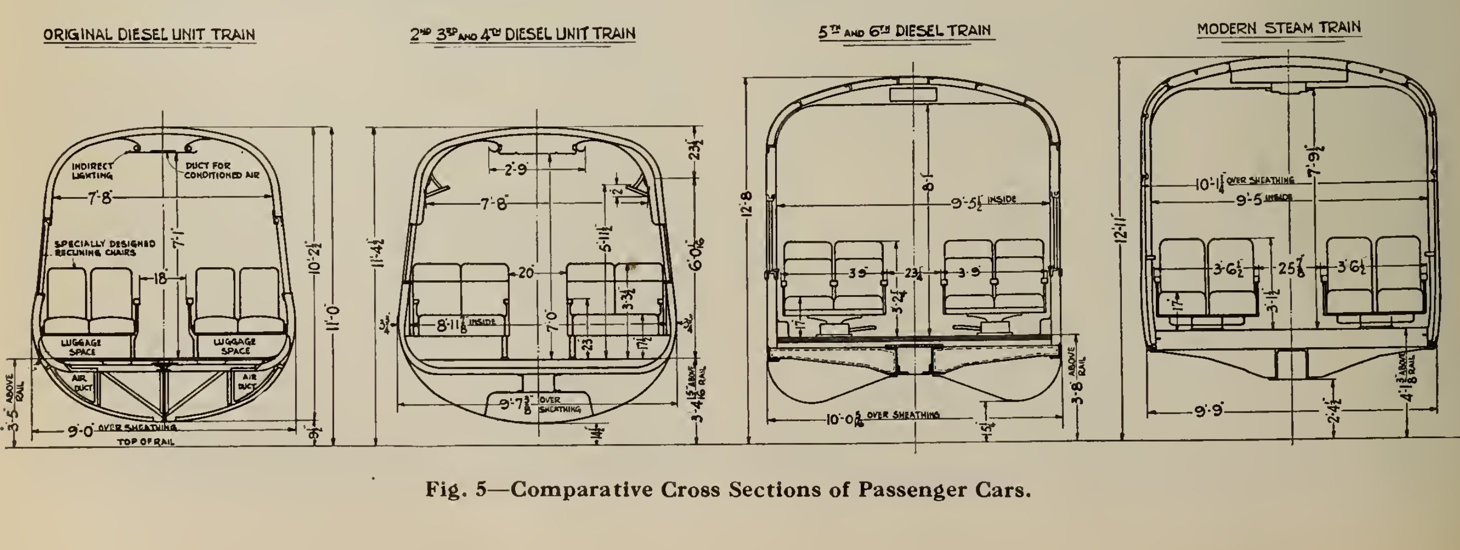

Fig. 5—Comparative Cross Sections of Passenger Cars.

*Comfort:*

Comfort in a railway train depends upon adequate space and accommodation coupled with good riding qualities. The diagrams of passenger equipment outlined in Fig. 5 indicate the modification of the cross section of cars of the first highly advertised light weight unit train, as later units were built, compared with the cross section of the latest Canadian Pacific coach at the extreme right. The original unit cars are low, narrow and restricted in seat and aisle space. The latest unit trains approach the dimensions and adequate air space per passenger of standard steam-train cars.

To overcome the disturbing forces of movement over inequalities of track surface, rail joints, crossovers, switches, etc. weight cannot be decreased to a point where resistance to such influences is inadequate. As speeds are increased this becomes more important.

In Canada, riding comfort is also materially affected by accumulations of snow and ice on the trucks and undergear of cars. To provide comfort in severe weather, adequate insulation and heating equipment is essential. In Canada auxiliary heating equipment, for use when steam is not available, is necessary. This equipment increases the weight of the cars and must be compensated for by additional motive power capacity.

*Reliability:*

There are few mechanical devices which have the proved reliability of a steam locomotive. Only the breakage of a major part can cause a complete failure. This reliability is not inherent in an oil electrically equipped unit having a multiplicity of moving and wearing parts, coupled with a probability of trouble with the electrical apparatus. In this connection, the most serious service failures of gas electric rail cars on the Canadian Pacific have been those of the electrical control and motive equipment.

For reliability an ample power reserve must be installed. To do so by duplicating Diesel engines increases cost, weight, maintenance and liability to failure.

*Flexibility:*

To provide for varying traffic demands, the standard practice on railways has been to increase or decrease the number of cars in the train. Unit trains, designed to be so operated, and powered with a capacity to suit, cannot adequately meet rapidly changing requirements for equipment. This is more definitely the case when cars of the unit have been articulated. In the latest trains this has led to the abandonment of articulation and to the separation of the power units from the revenue units. They do not have, however, the capacity of the steam locomotive to cope with increased tonnage due to increased number of cars in the train.

To install high speed trains, either oil electric or steam powered, involves increased maintenance of right of way, curves must be modified, grades reduced, bridges and culverts checked, protective devices installed or relocated and train operating rules revised. All this means increased maintenance costs, if high speeds may be undertaken with complete confidence. Whether the gain in time warrants such expenditures is problematical.

Streamlining has a strong popular appeal and has been prolifically advertised. At ordinary speeds its value is minimized and in no case does it effectively counteract the effect of heavy side or quartering winds against a moving train.

It is to be regretted from many angles that high pressure publicity has given the public the opinion that in Diesel powered light weight unit trains the acme of perfection in passenger travel has been reached and that such trains are an unqualified success. In reality, the modern steam locomotive and train offer more in comfort, safety and consistent speed than their newer rivals and accomplish this at less first cost, less mechanical complication and with more reliability.

While the thermal efficiency of the locomotive may be surpassed by that of some high pressure stationary installations, it is essentially efficient when considered as a concentrated, mobile power plant. It is capable of developing as much as 4,000 h.p.; receiving while in operation only the partial attention of a two man crew continually diverted by observing track, signals, etc.

It carries with it compactly all the necessities for rapid steam generation. A stationary plant of similar capacity would require nearly half an acre of ground space and would have a staff of at least five times as many men, devoting their complete attention to the functioning of the equipment.

### General Comments

The steam locomotive is over 100 years old. Adhering basically to its original design, it has met every evolution of transportation and is likely to continue as the world's supreme motive power. By gradual change in detail it has produced a constant improvement in fuel performance, horse power capacity and dependability. Thermal efficiencies have been improved by increasing boiler pressures. Boiler proportions have been altered to permit better heat transfer.

Riding qualities have been improved, giving greater stability at high speeds. Without increasing height and width clearance dimensions, locomotive power has been increased for the same weight on driving wheels as much as 50 per cent.

Long runs have demonstrated the reliability of steam locomotives, operated with little maintenance at intermediate points. Canadian Pacific passenger locomotives operate from Winnipeg to Calgary (831.7 miles) and from Calgary to Revelstoke (262.3 miles) without change. The latter run covers mountainous territory with severe grades.

It is certain that further research and experimentation will bring forth additional improvements in the design and performance of steam locomotives. There is as yet no definite general inclination in the direction of abandoning steam transport for other power instruments and it is doubtful whether as yet this is economically possible.

It is the opinion of the author that the steam locomotive will continue to predominate for some years to come; will haul our freight, transport our passengers and unite our communities by efficient, adequate service.

# THE ENGINEERING JOURNAL

## THE JOURNAL OF THE ENGINEERING INSTITUTE OF CANADA

VOLUME XX SEPTEMBER, 1937 No. 9

## Safety Features in Automobile Design

It is a commonplace to say that motor car design should be based on research. But what kind of research? As regards strength of construction, or the mechanical and electrical details of the power equipment, standard principles apply, and experimental data are available. There are, however, many features of design involving safety considerations which as yet cannot be studied by the engineer's regular methods of numerical analysis, since their effect depends on human nature as well as on the properties of materials.

The average automobile owner, in reply to the circulars sent out by the Customers' Research Departments of the great motor manufacturers, may be able to say whether he prefers maroon as a colour, or whether he would like his car to have hydraulic brakes, but his answers do not help to find out what features in existing automobile design should be changed to promote safety on the road, and if so, what the changes should be. For this purpose indeed the only source of useful information would seem to be the statistics and reports of such accidents as appear to be due to some characteristic of the car itself. No doubt the automobile of today has faults in design, but accident statistics as now collected throw no light on their relative importance as regards the occurrence or the severity of accidents.

Apparently only a small proportion, some six per cent, of automobile accidents are reported as being due to some fault in the vehicle itself. Further, in the majority of these comparatively few cases, lack of proper maintenance is the contributing cause, not the design of the car.

These facts indicate that so far as performance is concerned, present day automobile designers have given us a safe and reliable product, but that many of the automobile's limitations as regards safety arise from other factors, some of which are psychological, or physiological, and have to do with the effect of the car itself on such matters as the driver's vision, his liability to fatigue and his skill in controlling the car.

Automobile engineers are well aware of this situation and are devoting attention to it. The problems involved in the relation between automobile design and safety were featured at a recent meeting of the Society of Automotive Engineers. In a paper* by an officer of General Motors Corporation, the author presented an interesting summary of the ideas of the members of the Society on present day motor vehicle design viewed from the standpoint of safety on the highway. His analysis was based on opinions and data contributed by the various engineering organizations in the industry.

This discussion dealt only with passenger cars and covered in a general way such major topics as driver's vision, car control, and the "roadability" of the car.

In connection with the thorny question of headlights, it was noted that the problems of glare and insufficient road illumination have been complicated by attempts to comply with headlight specifications developed years ago by highway authorities when conditions were quite different, speeds were low, and only single beam lamps with narrow concentrated beams were available. The newer multiple beam systems, with better road-edge illumination, have done much to relieve the situation, by providing a driving beam for the open road and a diverted beam for meeting other cars, thus recognizing the fact that any adequate distant illumination of the road by the car headlights must glare the opposing driver.

Regarding schemes for using polarized light, or colour filters, the consensus of opinion seemed to be that these are impractical, not because they will not work, but because they require the uniform equipment of every car with two complete systems, one for projection and one for vision, plus the education of all drivers in their use. Some relief would be found in four-lane roads, in which the streams of traffic are more widely separated.

As for brakes, opinion varied as to the desirable distribution of braking power between front and rear wheels, especially having regard to the effect in cornering, since brakes must often be used on curves. The high speed and power of modern cars increase the difficulty of designing braking systems which will not become more sensitive as they wear, or will not "fade" during a single application.

On the whole it would seem that the brake designer has succeeded fairly well in meeting the requirements of increased car speed, even with the smaller space now available for his equipment.

In discussing the limitation of the driver's vision due to the construction of the car, it is considered that front road vision is reasonably good in the modern cars. Presumably however, the level of the passenger's eyes, or the roof over his head, will not be lowered further in the quest for reduced wind resistance and a lower centre of gravity.

Good wiper and defroster equipment is now available, though nobody has yet found out how to keep a windshield clear on a dirty road in heavy traffic when there is no rain to remove the mud splashes. Rear vision has been reduced rather than improved in recent passenger car models, but it is believed that such restrictions as have been made in driver vision have really been the result of improvements which have themselves contributed to safety.

The subject which seems to call most urgently for careful investigation is that of crash dangers. For this the experience of surgeons and hospitals is becoming increasingly available. The scope of such an enquiry would have to be very wide.

*Automobile Design and Safety, John H. Hunt, S.A.E. Journal August 1937.

The driver often escapes injury in minor crashes, but in more severe shocks is liable to damage by the cowl board or the steering wheel. An enquiry is suggested as regards safety glass, since the question has been raised whether in severe crashes, the fine splinters of safety glass may not cause more serious injury than the larger pieces of ordinary plate glass. Adequate information on this important point is needed. Similarly data are needed regarding injuries caused by bumpers, door handles and radiator ornaments. It must be remembered that these are matters affecting the equipment of millions of cars.

All motorists realize the great reduction in driving fatigue which has resulted from the quiet running, easy steering and adjustable seats of the modern car as compared with the type usual only five years ago. Improvements in car design however do not help the really tired driver to keep up the continuous attention to driving which is the first requisite for safety. The only proper remedy is for the tired driver to cease driving.

It appears from actual tests that the alleged effect of ventilating systems in drawing carbon monoxide into the car body is imaginary, unless there are openings in the car floor and a leaky exhaust line. Carbon monoxide in a car comes almost invariably from the exhaust of the car ahead.

The term "roadability" refers to those car characteristics which affect the handling of the car on the road. The response of the car to the driver's will, as regards speed and direction, should be such as to require no fatiguing mental or physical effort, and should call for the exercise of no unusual degree of skill on the driver's part. In the modern car the engine responds so readily and smoothly to sudden demands for power that the driver hardly thinks of it. There are occasions, however, as in overtaking another vehicle, when hesitation in the power supply might have serious results. This is why the introduction of speed-limiting governors on passenger cars is open to serious objection.

As regards steering, the discussion stresses the difficulty of adjusting the weights and proportional braking on front and rear wheels, and the amount of load transferred from the inner to the outer tires on a curve, so as to avoid "oversteer," by which is meant an unstable condition while cornering, in which the rear of the car tends to swing out farther than the front end. Actually a car with moderate "understeer" is desirable as giving good handling in the constantly changing conditions of road surface, road camber, and wind, met with in ordinary straight ahead driving.

On the whole the views expressed in Mr. Hunt's paper seem to present rather the disadvantages than the advantages of the various proposals considered. This is perhaps due to the method the engineer must follow in making his decisions. He must think of all possible objections to a piece of equipment, and then seek to avoid these objections when making his design.

A number of faults were pointed out during the discussion but the conclusions were in many cases not so definite as might be wished. Unfortunately no data are available to show whether cars which have more of these faults are involved in more accidents than cars having fewer of them, and, if so, whether this greater number of accidents is the result of the greater number of faults.

An investigation on this point would obviously present great difficulty. Actually it is only one of several subjects suggested as needing thorough enquiry, each involving a number of puzzling factors. It would seem that to make definite progress in these matters, the automobile designer will have to collaborate with safety engineers, public officials responsible for safety regulations, highway engineers and, in regard to certain questions, with surgical authorities and perhaps even psychologists.

## Guglielmo Marconi

By the death of the Marchese Marconi, the electrical engineering world has been deprived of one of its greatest pioneers. He died at his home in Rome on July 20th, at the age of sixty-three. He was born at Bologna on April 25th, 1874, and was of mixed parentage, his father being an Italian country gentleman who married an Irish lady.

Guglielmo Marconi, as a boy, took a keen interest in physical and electrical science. In 1895 he conceived the idea that a system of telegraphy through space could be provided by means of electric waves, the existence of which had been foreseen mathematically by Clerk Maxwell in 1864, and later investigated experimentally by Hertz, Oliver Lodge, Righi and others. Marconi, however, was the first of these pioneers to devise the practical means whereby they could be made to provide a new method of telegraphic communication.

In the early summer of 1895 Marconi conducted a number of experiments at his father's country house at Pontecchio, near Bologna. These experiments soon began to give remarkable results, communication being established in that year over distances in excess of one mile. In these early days Marconi also discovered that the distance of communication increased very rapidly if the height above ground of the elevated aerials was increased.

Coming to England in 1896, Marconi continued his experiments in London, and in that year demonstrated his invention before officials of the Post Office and foreign Government Departments. In 1897, at the invitation of the Italian Government, Marconi went to Spezia, where a land station was erected and communication with Italian warships was established up to a distance of 12 miles.

Wireless telegraphy was first used for commercial purposes in 1898, when the Kingstown Regatta races were reported by Marconi by means of wireless apparatus installed on a tug which followed the yachts on the Irish Sea. The utility of wireless in saving life at sea was demonstrated for the first time when, on March 3rd, 1899, a steamer collided with the East Goodwin lightship. Wireless apparatus had been installed on the lightship and on the shore at the South Foreland lighthouse. The accident was at once reported by wireless to the lighthouse and lifeboats were promptly despatched to the assistance of the light vessel. In March, 1898, Marconi established communication by wireless across the English Channel, between England and France. The wireless conquest of the Atlantic Ocean may be regarded as the culminating point of his pioneer work. On December 12th, 1901, he, on his first attempt, succeeded in transmitting and receiving signals from the long-distance wireless telegraph station at Poldhu, in Cornwall, to St. John's, Newfoundland. This achievement completely confirmed his opinion that electric waves would not be stopped by the curvature of the earth.

In 1905 he took out his patents for the horizontal directional aerial, which marked an advance in the design of long-distance stations. In 1916, during the war, experiments were commenced by Marconi in Italy with very short waves, with the object of devising a directive or beam system of wireless telegraphy. His anticipations were justified by the results obtained since that time by British and foreign experimenters. In 1924 he was the first to discover that short waves of the order of 30 m. in length could be transmitted and received over great distances during daylight.

The value of Marconi's work has been recognized by Governments, universities, and learned societies all over the world. In 1914 he was made a member of the Italian Senate, and in June, 1929, was created a hereditary marquis by the King of Italy.—*The Engineer* (abridged).

## OBITUARIES

### Colonel John Houliston, A.M.E.I.C.

We regret to announce the death in Ottawa on August 8, 1937 of Col. John Houliston, D.S.O., of the Royal Canadian Engineers (retired) and at one time District Officer Commanding, Military District No. 7, at Saint John, N.B.

Col. Houliston was born in 1868 at Three Rivers, Quebec, and graduated from the Royal Military College, Kingston, Ont., in 1890. Between graduation and 1904, when he received the appointment in the Royal Canadian Engineers, he was engaged in various engineering works and services in the vicinity of Three Rivers, principally in connection with the proposed improvements of the Three Rivers' Harbour Commission. During his career with the Royal Canadian Engineers he held the appointments of Director of Works and Buildings and Director of Engineer Services. Col. Houliston saw considerable service overseas during the war. In 1922 he was appointed as D.O.C. for Military District No. 7, retiring on pension two years later.

Colonel Houliston joined the Canadian Society of Civil Engineers as a Student in 1898, and transferred to the grade of Associate Member in 1899.

### Louis Philippe Roy, S.E.I.C.

The death of Mr. Louis Philippe Roy (aged 26) occurred July 16, 1937, as the result of a drowning accident. Mr. Roy joined The Institute as a Student in 1936 and graduated from the Ecole Polytechnique, Montreal, in 1937. At the time of his death at Chibougamau he was employed as a civil engineer with the Quebec Government.

### L. Ernest F. Fusey, A.M.E.I.C.

Members of The Institute will learn with regret of the death of Ernest Fusey, which occurred in Montreal on July 31, 1937. Mr. Fusey, prior to his retirement some five years ago was superintending engineer of the Sewerage Department, City of Montreal. He was born at St. Barthelemy, Que., in 1864, and was educated at the Ecole Polytechnique, Montreal, graduating in 1890. During the early part of his career, Mr. Fusey was employed as assistant engineer by the Department of Roads and Canals in Quebec and the Maritime Provinces and in 1906 became a member of the engineering staff of the City of Montreal. He joined the Canadian Society of Civil Engineers as an Associate Member in 1899 and became a Life Member in May 1931.

## PERSONALS

Captain N. J. W. Smith, R.C.E., S.E.I.C., has recently been transferred to Fort Canning, Singapore, Malaya. Capt. Smith is a graduate of Royal Military College at Kingston, Ontario and McGill University in 1932 and lately has been with the 1st Division Bridging Camp, Royal Engineers, Weymouth, England.

Eric C. Molke, A.M.E.I.C., formerly with H. G. Acres & Company, Niagara Falls, Ont., has accepted a position as structural engineer with Roberts and Schaefer Company, Chicago, Ill. Mr. Molke is a graduate of the Technische Hochschule, Vienna. Coming to Canada in 1922 he secured employment with the Trussed Concrete Steel Company of Canada, Walkerville, Ont. and from 1928 to 1932 was designing engineer in the Slave Falls division of the Hydro Electric System of the city of Winnipeg.

T. H. Doherty, A.M.E.I.C., has accepted an appointment on the engineering staff of the Coca-Cola Company, Toronto, Ont. Mr. Doherty graduated from McGill University in mechanical engineering in 1929 after which he joined the Riley Engineering and Supply Company, Toronto. From 1930 to 1932 he was with the Lima Locomotive Works, Lima, Ohio, then accepted a position as junior research engineer with the Fire Hazard Testing Laboratories of the National Research Council, Ottawa.

Cyril J. Carey, A.M.E.I.C., is now located in Halifax, N.S., where he is carrying on a practice as consulting engineer. Mr. Carey has been in private practice in St. John's, Newfoundland since 1931, engaged in general structural and survey work. He received his early education in Halifax, N.S., St. John's, Newfoundland and in England. From 1925-31 he was with the Engineering and Highroads Commission in Newfoundland, latterly as chief assistant to the chief engineer. His work included inspection, structural design and survey in connection with highways, harbours, water and sewerage supply systems and general building construction.

A. C. Herbert, S.E.I.C., has recently entered the engineering department of the Canadian National Telegraphs, Toronto, Ontario. Mr. Herbert graduated from the University of Alberta in electrical engineering in 1935 and entering the Royal Canadian Corps of Signals was located at Camp Borden, Ontario.

F. R. Killam, S.E.I.C., recently received an appointment with the Fraser Companies Limited at Edmundston, N.B. Mr. Killam graduated from McGill University in 1927, when he received the degree of B.Eng.

Howard Kennedy, M.C., M.E.I.C., formerly manager, Woodlands Department, E. B. Eddy Company Limited, has recently been appointed manager of the Quebec Forest Industries Association Limited. Mr. Kennedy graduated from McGill University in 1914 and joined The Institute in 1921 as an Associate Member. He served overseas for four years as Lieutenant and Captain in the 7th Field Company Canadian Engineers and on his return to Canada entered Lockwood Greene & Company. Later he became resident engineer with the Dominion Tire Company, Kitchener, Ont. and the Maple Leaf Rubber Factory, Port Dalhousie, Ontario.

D. Campbell Mackenzie, M.E.I.C., has relinquished his position as general manager of the Consolidated Alluvials of B.C. Limited, to resume his practice as consulting mining engineer; he has been retained, however, as consulting engineer for the above company. Mr. Mackenzie received his early technical education in Scotland and in 1907 was appointed Inspector of Mines and Machinery for the Department of Mines, New South Wales. He served overseas on active service as lieutenant with the 2nd Australian Tunnelling Company from 1915 to 1919, after which he resumed his duties in the Department of Mines. In 1922 he was appointed general manager for the Corrabin Coal Fields, New South Wales and later became manager of the Catamaran Collieries Limited, Tasmania. In 1926 he moved to Vancouver, B.C., where he set up practice as consulting mining engineer.

Victor Shanks, S.E.I.C., a graduate from the University of Toronto in 1935 is now located with the Sangamo Company Limited in Toronto. Mr. Shanks was previously with the Gutta Percha and Rubber Limited, Toronto.

# JOINT MEETING IN BOSTON, MASSACHUSETTS

## THE ENGINEERING INSTITUTE OF CANADA

and

## THE AMERICAN SOCIETY OF CIVIL ENGINEERS

Wednesday, Thursday and Friday, October 6th, 7th and 8th, 1937

HEADQUARTERS AT THE HOTEL STATLER

# Programme of Meetings, Entertainment and Trips

**WEDNESDAY—OCTOBER 6th—**

*Morning:*

**9.00** REGISTRATION—(Mezzanine Floor).

GENERAL MEETING—(Imperial Ballroom).

**10.00** **Joint Session** called to order by FRANK A. BARBOUR, M.E.I.C., M.Am.Soc.C.E., Chairman, Local Committee on Arrangements; Consulting Engineer, Boston, Mass.

**10.05** **Addresses of Welcome**

ALBERT HAERTLEIN, M.Am.Soc.C.E., President, Northeastern Section; Associate Professor of Civil Engineering, Harvard University, Cambridge, Mass.

HIS EXCELLENCY, THE GOVERNOR OF THE COMMONWEALTH OF MASSACHUSETTS.

HIS HONOUR, THE MAYOR OF THE CITY OF BOSTON.

**10.30** **Responses**

LOUIS C. HILL, M.Am.Soc.C.E., President, American Society of Civil Engineers.

GEORGE J. DESBARATS, Hon.M.E.I.C., President, The Engineering Institute of Canada.

**10.45** **Brief Addresses** by JAMES BRYANT CONANT, President of Harvard University.

KARL TAYLOR COMPTON, President of the Massachusetts Institute of Technology.

**11.00** **Address:—Culture and Technical Background of the "New Architecture"** by

WALTER GROPIUS, Professor of Architecture, Harvard University.

**12.00 to 2.00** STUDENTS' LUNCHEON—(Salle Moderne)

COLONEL CHARLES R. GOW, M.Am.Soc.C.E., presiding.

Speaker: COLONEL WILLARD T. CHEVALIER, Past Director, Am.Soc.C.E., Vice-President, McGraw-Hill Publishing Co., Inc., New York.

All Members of The Institute and the Society will be welcome. Tickets: $1.50.

*Afternoon:*

GENERAL MEETING—(Imperial Ballroom)

JOINT MEETING CONDUCTED BY THE ENGINEERING INSTITUTE OF CANADA.

*Chairman* — FRED NEWELL, Member of Council, E.I.C., Assistant Chief Engineer, Dominion Bridge Co., Ltd., Montreal.

**2.00** **Substructure of the New Highway Bridge over the Fraser River at New Westminster, British Columbia** by

MAJOR WILLIAM G. SWAN, M.E.I.C., Consulting Engineer, Vancouver, British Columbia.

Discussion opened by R. E. C. CHADWICK, M.E.I.C., President, The Foundation Co., of Canada Ltd. and LEWIS E. MOORE, M.Am.Soc.C.E., Consulting Engineer, Boston, Mass.

**3.00** **Recent Developments at the Port of Halifax, Nova Scotia** by

EDWARD H. JAMES, M.E.I.C., Consulting Engineer, Montreal, Quebec.

Discussion opened by JOHN B. STIRLING, M.E.I.C., Engineer, E. G. M. Cape & Co., Montreal,

(*Harvard Institute of Geographic Exploration*)

The State House and Boston Common

JOINT MEETING — (*Continued*)

RICHARD K. HALE, Assoc.M.Am.Soc.C.E., Associate Commissioner, Mass. Department of Public Works, Boston, Mass., and J. STUART CRANDALL, M.Am.Soc.C.E., President and Chief Engineer, Crandall Dry Dock Engineers, Cambridge, Mass.

4.00 **The Conception and Design of the Outardes Hydro-Electric Project** by
HENRY G. ACRES, M.E.I.C., Consulting Engineer, Niagara Falls, Ontario.
Discussion opened by
H. K. BARROWS, M.Am.Soc.C.E., Professor of Hydraulic Engineering, Mass. Institute of Technology; Consulting Engineer, Boston, Mass.

*Evening:*
**8.00** ENTERTAINMENT—(Imperial Ballroom)—
For Members and Guests including Ladies. Buffet Refreshments will be served. Informal.
Tickets are Free to Members. Each Member may apply for One Free Ticket for a Lady. Additional guest tickets may be purchased for $1.00 each.
*Tickets should be obtained by 2.00 p.m. on Wednesday.*

## THURSDAY—OCTOBER 7th—

### SOIL MECHANICS AND FOUNDATIONS DIVISION

*Morning and Afternoon*—(Georgian Room)—
*Chairman*—CARLTON S. PROCTOR, M.Am.Soc.C.E.

10.00 **The Objects of the Division and Work Proposed**
CARLTON S. PROCTOR, Director, Am.Soc.C.E., Chairman of Division; Consulting Engineer, New York.

10.15 **Applications of Soil Mechanics to Design of Levees in the Lower Mississippi Valley.**
SPENCER J. BUCHANAN, Assoc.M.Am.Soc.C.E., U. S. Waterways Experiment Station, Mississippi River Commission, Vicksburg, Miss.
Discussion opened by CHARLES SENOUR, Principal Engineer, Mississippi River Commission, Vicksburg, Miss.
THEODORE T. KNAPPEN, M.Am.Soc.C.E., Consulting Engineer, New York.

11.15 **An Investigation of the Stability of Embankment Foundations.**
BENJAMIN K. HOUGH JR., Jun.Am.Soc.C.E., U.S. Engineer Office, Ithaca, N.Y.
Discussion opened by S. C. HOLLISTER, M.Am.Soc.C.E., Associate Dean, College of Engineering, and Director, School of Civil Engineering, Cornell University, Ithaca, N.Y.; L. F. HARZA, M.Am.Soc.C.E., Consulting Engineer, Chicago, Ill.

*Recess for Luncheon*

2.00 **Application of Soil Mechanics to Building Foundations.**
ARTHUR CASAGRANDE, Assoc.M.Am.Soc.C.E., Assistant Professor of Soil Mechanics, Harvard University, Cambridge, Mass.
Discussion opened by DONALD W. TAYLOR, Assoc.M.Soc.C.E., Research Associate, Soil Mechanics, Department of Civil and Sanitary Engineering, Mass. Institute of Technology, Cambridge, Mass.; FRANK A. MARSTON, M.Am.Soc.C.E., Consulting Engineer, Boston, Mass.

3.00 **Review of the Science of Soil Mechanics,** Outlining Particularly Tests and Studies Now in General Use in Connection with Investigations of Soil Mechanics.
GLENNON GILBOY, Assoc.M.Soc.C.E., Associate Professor of Soil Mechanics, Mass. Institute of Technology, Cambridge, Mass.
Discussion opened by PHILIP C. RUTLEDGE, Associate Professor of Civil Engineering, Purdue University, Lafayette, Ind.; D. M. BURMISTER, Assoc.M.Soc.C.E., Assistant Professor, Civil Engineering, Columbia University, N.Y.

4.00 **General Technical Discussion—Methods of Boring and Sampling.**
*Chairman*—WM. P. KIMBALL, Assoc.M.AmSoc.C.E., Assistant Professor, Thayer School of Civil Engineering, Hanover, N.H.
Discussion opened by HENRY A. MOHR, Assoc.M.Am.Soc.C.E., Waban, Mass.

### SANITARY ENGINEERING DIVISION

*Morning*—(Parlor A)—
*Chairman*—ARTHUR D. WESTON, M.Am.Soc.C.E.

10.00 **Studies of the Pollution of Boston Harbour and Its Tributary Waters.**
ARTHUR D. WESTON, M.Am.Soc.C.E., Chief Engineer and Director, Division of Sanitary Engineering, Massachusetts Department of Public Health, and GAIL P. EDWARDS, Laboratory Co-ordinator, Massachusetts Department of Public Health, Boston, Mass.
Discussion opened by E. SHERMAN CHASE, M.Am.Soc.C.E., Consulting Engineer, Boston, Mass.; RAYMOND R. RIBAL, Assoc.M.Am.Soc.C.E., Office Engineer, City of Oakland, Calif.; RICHARD H. GOULD, M.Am.Soc.C.E., Engineer in Charge, Sewage Disposal and Intercepting Sewers, Department of Sanitation, N.Y.

11.00 **The Decomposition of River Deposits.**
GORDON M. FAIR, M.Am.Soc.C.E., Professor of Sanitary Engineering, Harvard University, Cambridge, Mass.
Discussion opened by LANGDON PEARSE, M.Am.Soc.C.E., Sanitary Engineer, Chicago, Ill.

### SURVEYING AND MAPPING DIVISION

*Morning*—(Parlor B)—
*Chairman*—WILLIAM BOWIE, M.Am.Soc.C.E.

10.00 **Land Registration in Massachusetts.**
CLARENCE B. HUMPHREY, Engineer, Massachusetts Land Court, Boston, Mass.
Discussion opened by RAYMOND C. ALLEN, M.Am.Soc.C.E., Civil Engineer, Manchester, Mass.

11.00 **The Establishment of the Massachusetts System of Rectangular Coordinates.**
E. C. HOUDLETTE, Engineer, Mass. Department of Public Works; Director, Mass. Geodetic Survey, Works Progress Administration, Boston, Mass.
Discussion opened by HERMAN J. SHEA, Instructor, Civil Engineering Department, Massachusetts Institute of Technology, Cambridge, Mass.

### 10.00 ENGINEERING-ECONOMICS AND FINANCE DIVISION

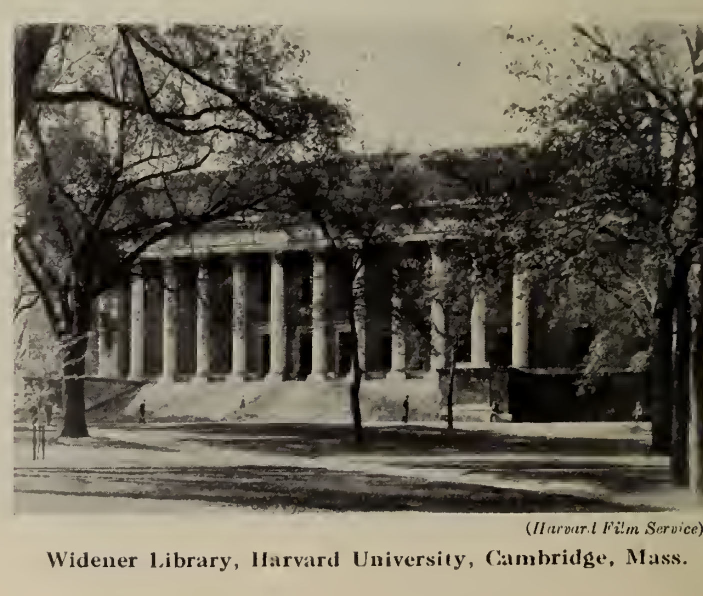
*Morning and Afternoon*—(Parlor C)—
*Chairman*—EDWIN F. WENDT, M.Am.Soc.C.E.

**Hazards of Uneconomic Public Works Construction.**
HENRY EARLE RIGGS, M.Am.Soc.C.E., Hon. Professor of Civil Engineering, University of Michigan, Ann Arbor, Mich.
Discussion opened by WILLIAM J. WILGUS, Hon.M.Am.Soc.C.E., Consulting Engineer, Ascutney, Vt.

*Recess for Luncheon*

2.00 **Engineering-Economics and Public Opinion.**
DANIEL W. MEAD, Past President, Hon.M.Am.Soc.C.E., Professor Emeritus, Hydraulic and Sanitary Engineering, University of Wisconsin; Consulting Engineer, Madison, Wis.

3.00 **Economic Advantages of Orderly Planning of Public Works.**
FREDERIC H. FAY, M.Am.Soc.C.E., Consulting Engineer, Boston, Mass.



(*Harvard Film Service*)

Widener Library, Harvard University, Cambridge, Mass.

(*Harvard Institute of Geographic Exploration*)

Mass. Institute of Technology, Cambridge, Mass.

**Waterways Division**

*Afternoon*—(Parlor B)—

*Chairman*—W. G. Atwood, M.Am.Soc.C.E.

**2.00 Recent Developments in Marine Borer Studies.**
Dr. William F. Clapp, Consulting Biologist, Duxbury, Mass.
Discussion opened by A. H. Morrill, M.Am.Soc.C.E., Chief Engineer, Boston & Maine and Maine Central Railroads, Chairman, New England Committee on Marine Piling Investigation; Francis L. Sellew, District Waterways Engineer, Mass. Department of Public Works; John N. Ferguson, M.Am.Soc.C.E., District Waterways Engineer, Mass. Department of Public Works, Boston, Mass.

**3.00 Repairs of Sub-Structure, Army Supply Base, Boston.**
Major Robert L. Miller, U.S.A., Construction Quartermaster.
Discussion opened by George L. Mirick, Senior Engineer, Construction Division, Quartermaster Corps, U.S.A.

**4.00 Reconstruction of the Deck and Footings of Commonwealth Pier 5, Boston, Mass.**
Charles M. Spofford, M.Am.Soc.C.E., Consulting Engineer, Boston, Mass.
Discussion opened by John Ayer, M.Am.Soc.C.E., Consulting Engineer, Boston, Mass.; C. J. O'Donnell, Resident Engineer, Mass. Department of Public Works., Boston, Mass.

**City Planning Division**

*Afternoon*—(Parlor A)—

*Chairman*—Harold M. Lewis, M.Am.Soc.C.E.

**2.00 The Value of a Thoroughfare Plan and Its Relation to Metropolitan Systems Serving Urban Areas.**
Frank H. Malley, Assoc.M.Am.Soc.C.E., Acting Secretary, Boston City Planning Board, Boston, Mass.
Discussion opened by A. B. Edwards, M.Am.Soc.C.E., Engineer, Mass. Division of Metropolitan Planning, Boston, Mass. The paper will be followed by a discussion on some phases of state planning of interest to civil engineers.

*Evening:*

**7.00** Dinner and Dance—(Imperial Ballroom)—
*Presiding*—Professor Edward L. Moreland, M.Am.Soc.C.E.; Head of Department of Electrical Engineering, Mass. Institute of Technology, Cambridge, Mass., and Consulting Engineer, Boston, Mass.
*Speaker*—Professor Robert Emmons Rogers of the Massachusetts Institute of Technology.
Dancing until 1.00 a.m. Music by Marshard's Orchestra.
Tickets for Dinner and Dance $3.00 each.
Dinner Dress.

## EXCURSIONS ON FRIDAY FOR MEMBERS AND GUESTS

*Several trips are planned for Friday Morning all ending with a "get-together" Shore Dinner at 1.30 p.m. at the New Ocean House at Swampscott where the afternoon will be devoted to recreation. In addition several optional all-day trips to visit engineering projects at a considerable distance from Boston will be arranged if a sufficient number wish to attend.*

**FRIDAY, OCTOBER 8th**—

*Morning and Afternoon:*

**9.00** Buses leave the Columbus Avenue entrance of the Hotel Statler for Harvard University and the Massachusetts Institute of Technology. (Buses for the alternate North Shore Trip leave at 10.30 a.m. from the same place.)

**9.30 to 11.15** **Inspection at Harvard University.**
Two trips are planned with competent guides, one for those wishing to inspect the engineering laboratories where methods of testing soils will be demonstrated in the Soil Mechanics Laboratory and the other for those who wish to visit the Widener Library, the Glass Flowers, and other points of interest.

**9.30 to 11.15** **Inspection at the Massachusetts Institute of Technology.**
The following laboratories of particular interest to civil engineers will be open for inspection: Sanitary Engineering, Seismology, Cement Research, Building Material Research, Soil Mechanics, and River Hydraulics (including an operating model of the Cape Cod Canal). Special arrangements can be made by those desiring to visit other features at M.I.T.

**10.30** **North Shore Trip.**
Buses leave the Columbus Avenue entrance of the Hotel Statler for a motor trip along the North Shore, visiting Revere Beach, Nahant, and Marblehead, terminating at New Ocean House at 1.30 p.m. for the Shore Dinner. This is an alternate trip planned for those who do not wish to visit Harvard or M.I.T.

**11.15** Bus leaves Harvard University (from gate at the Harvard Yard on Broadway opposite Memorial Hall) for M.I.T.

**11.30** Demonstration of "High-Speed" Motion Pictures by Prof. H. F. Edgerton in Eastman Lecture Hall (Room 6-120) M.I.T.

**12.30** Buses leave M.I.T. (from entrance directly outside Eastman Lecture Hall) for Swampscott, Mass.

**1.30** **"Get-Together" Shore Dinner at the New Ocean House, Swampscott.**

**4.30** Buses leave for the Hotel Statler. If a sufficient number desire to make an earlier return to Boston, arrangements will be made for one or more buses to leave the New Ocean House at 3.30 p.m.

*Tickets for the Shore Dinner, including transportation, are $3.00 each. These should be obtained at the Registration Desk not later than Thursday, October 7th.*

**Optional Trips on Friday, October 8th**

These will be arranged provided a sufficient number desire to attend.

Trip to the **Chelmsford Granite Quarries** and to the **Locks and Canals at Lowell, Mass.,** with **Shore Dinner at Swampscott.**
This trip will provide an opportunity to visit the granite quarries of the H. E. Fletcher Co. at West Chelmsford and the works of the Proprietors of Locks and Canals on the Merrimack River. At Chelmsford there will be an opportunity of viewing modern methods of quarrying granite using rotating core cutters, four feet in diameter, to release the pressure and place the material in a free state so that it may be split into sizes which can be handled by derricks. At Lowell may be seen the original drawings and models of apparatus designed by such early New England hydraulicians as James B. Francis and Uriah A. Boyden. Transportation will be by private automobiles, leaving the Hotel Statler (Columbus Ave. entrance) at 9.00 a.m. Tickets, including the Shore Dinner at Swampscott, $3.00. (This trip will be available only for those desiring to attend the Shore Dinner at Swampscott.)

Trip to **Cape Cod Canal.**
This will be an all-day trip. Items of interest are the three new bridges over the canal which have been completed recently, and the widening and straightening of the canal including dredging operations now under way.

Trip to **Quabbin Reservoir,** Boston Metropolitan District Water Supply Project.
This will be an all-day trip. Points to be visited will include the completed control works for the diversion of the Ware River water and the earth fill dam, now under construction by hydraulic sluicing methods, at the Quabbin Reservoir on the Swift River.

Note.—*These optional inspection trips will be arranged only if a sufficient number signify their desire to attend. Names should be left at the Registration Desk on Wednesday, October 6th.*

## ENTERTAINMENT FOR THE LADIES

**Ladies' Headquarters.**
The Library on the Mezzanine Floor of the Hotel Statler will be reserved for the exclusive use of the ladies attending the Meeting. Representatives of the Ladies Committees will be in attendance to be of service to the visitors.

*Morning:*

**10.00 WEDNESDAY, OCTOBER 6th—**

**Opening Session** in the Imperial Ballroom. Ladies will be welcome.

*Afternoon:*

**2.00 Visit to Isabella Stewart Gardner Museum.**
An Art Collection of unique interest. During the visit there will be a talk by the Director and music. Tea will be served. The party will leave the Columbus Avenue entrance of the Hotel Statler at 2.00 p.m.; transportation will be by buses. Tickets may be obtained at the Registration Desk, without charge.

*Evening:*

**8.00 Entertainment**—(Imperial Ballroom)—
Ladies are invited to attend the Entertainment for Members and Guests.

**THURSDAY, OCTOBER 7th—**

*Morning and Afternoon:*

**10.00 Motor Drive** to Lexington and Concord with Luncheon at the Wayside Inn, old-time hostelry made famous by Longfellow and restored and now owned by Henry Ford.
Transportation will be by buses, leaving the Columbus Avenue entrance of the Hotel Statler at 10.00 a.m. Buses returning from Wayside Inn will arrive at the Hotel Statler about 5.00 p.m. Free tickets for the trip and luncheon will be limited to one lady for each registered member of the Society and of The Engineering Institute of Canada. Additional tickets may be obtained at $2.00 each.
*Tickets for this trip should be secured at the Registration Desk before 5.00 p.m. on Wednesday, October 6th.*

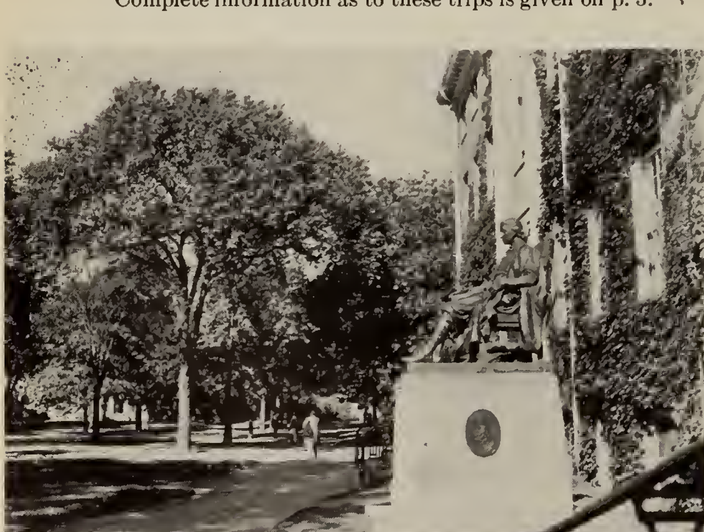
*Evening:*

**7.00 Dinner and Dance**—(Imperial Ballroom)—
Professor Robert Emmons Rogers of the Massachusetts Institute of Technology will be the after-dinner speaker. There will be dancing until 1.00 a.m. See p. 3.

**FRIDAY, OCTOBER 8th—**

*Morning and Afternoon:*

Ladies are invited to attend the **Trips** which are to take place on Friday. Several different trips are planned—terminating at the New Ocean House at Swampscott for a "Get-Together" Shore Dinner.
Complete information as to these trips is given on p. 3.



(*Harvard Film Service*)

**John Harvard Statue, Harvard University, Cambridge, Mass.**

## HOTEL ACCOMMODATIONS AND ANNOUNCEMENTS

In order to be certain of accommodations, members are *urged to make definite arrangements for rooms at least a week in advance* of the Fall Meeting, paying for the rooms in advance for at least a part of the period which they expect to be in Boston.

HOTEL RATES

| | Single Room | Double Room |
|---|---|---|
| Statler Hotel | $3.50 up | $5.00 up |
| Bellevue Hotel* | 3.00 up | 4.00 up |
| Bradford Hotel | 2.50 up | 4.00 up |
| Copley Hotel | 4.00 up | 6.00 up |
| Parker House | 3.00 up | 4.50 up |
| Ritz Carlton | 4.00 up | 7.00 up |
| Touraine Hotel* | 3.00 up | 4.50 up |
| Westminster Hotel* | 2.50 up | 3.50 up |

The rates quoted are the prices per day for a room with private bath. Hotels marked with an asterisk (*) also have rooms without private bath at lower rates.

The Hotel Statler is the meeting headquarters, and it is expected that it will be able to care for all who attend. This hotel is located at Arlington Street and Columbus Avenue, near Park Square.

*Reservations are to be made directly with the hotel.* Hotel will make acknowledgment of reservation direct to member.

All who attend the Fall Meeting are requested to register immediately upon arrival at meeting headquarters, Mezzanine Floor of Hotel Statler. Special badges and tickets will be obtained at the time of registration.

## RAILWAY ARRANGEMENTS

Special convention fares having been discontinued by the American railways, the following are the lowest first class round trip fares to Boston available in October from the Canadian points named; one-way sleeping car (lower berth) rates are also given.

| From: | Round-trip rail fares | Limit | One-way sleeping car charges |
|---|---|---|---|
| Winnipeg | $89.80 | 30 days | $13.75 |
| Windsor, Ont | 46.30 | 1 year | 7.15 |
| Toronto | 37.15 | 1 year | 5.50 |
| Peterboro | 36.80 | 6 months | 5.00 |
| Ottawa | 27.10 | 1 year | (seat) .70 to Montreal. (lower) 2.75 to Boston. |
| Montreal | 20.50 | 1 year | 2.75 |
| Quebec | 25.30 | 1 year | 3.30 via Sherbrooke. |

## INFORMATION

A registration Desk will be provided on the Mezzanine Floor of Hotel Statler to assist visiting members in securing any desired information.

## LOCAL COMMITTEES ON ARRANGEMENTS

**Executive Committee**

F. A. Barbour, General Chairman.
F. H. Kingsbury, Secretary.
A. W. Dean, Director, Am.Soc.C.E.
H. A. Gray, Past-President, Northeastern Section, Am.Soc.C.E.
W. R. Benford, representing Providence Section, Am.Soc.C.E.
J. P. Wadhams, representing Connecticut Section, Am.Soc.C.E.
F. A. Marston, Chairman, Sub-Committee on Technical Program.
F. M. Gunby, Chairman, Sub-Committee on Finance.
Albert Haertlein, President, Northeastern Section; Chairman, Sub-Committee on Hotel and Registration.
J. B. Babcock, Chairman, Sub-Committee on Entertainment and Service.

**Ladies Committee**

Mrs. F. E. Winsor, Chairman.

| | |
|---|---|
| Mrs. F. A. Barbour | Mrs. C. B. Breed |
| Mrs. A. W. Dean | Mrs. H. P. Eddy |
| Mrs. S. M. Ellsworth | Mrs. F. M. Gunby |
| Mrs. Albert Haertlein | Mrs. R. K. Hale |
| Mrs. E. H. Rogers | Mrs. C. M. Spofford |

**Engineering Institute Committee**

Detail arrangements for the participation of The Engineering Institute of Canada were placed by the Council in the hands of a committee consisting of

Past President J. M. R. Fairbairn, Convenor.
Past President E. A. Cleveland
and Past President F. P. Shearwood

These gentlemen co-operated with the Boston Executive Committee in respect to the arrangements for the Joint Meeting.

## The Future of the Airship

As a consequence of the tragic end of the famous German airship the *Hindenburg*, the attention of the public and that of every serious student of aeronautics has once more been directed to the yet undecided question of long-distance flight, whether the future lies with the airship or with the aeroplane. The disaster to the *Hindenburg* may or may not prove more than a temporary setback. Travel by airship will certainly lose popularity for the time being, but as concerns the future, much will depend upon the result of the investigation now taking place; for the present that aspect of the subject may be dismissed in a few words.

Whatever may have been the immediate cause of the disaster, the only fact so far disclosed is that it was due to fire and not to any structural defect. If helium had been used in place of hydrogen, it is fair to assume that the airship would not have been lost, although there might have been something in the way of an "incident"; but if the *Hindenburg* had been inflated with helium her buyoancy and her margin of lift would have been reduced by approximately 14 tons, which would represent the loss of a pay-load of the magnitude equivalent to 150 passengers and crew with an allowance of ½ cwt. each for luggage, etc. Bluntly stated, this means that the *Hindenburg* would, for all practical purposes, have ceased to possess any commercial value; and then it would become a question of weight saving, cheeseparing, a bit here and a bit there. The dilemma is the same as that which resulted in the loss of the R.101. In the design and construction of that airship everything possible was said to have been done with the object of making her *safe*. Diesel engines by Messrs. Beardmore were adopted to do away with the danger of petrol; special provision was made in the construction of the hull to enable her to resist bad-weather conditions and to ride out a storm at her mooring post. But these very precautions resulted in the buoyancy being cut too fine; the Diesel engines and some other components came out just a little heavier than expected. A lack of buoyancy in an airship is a fatal defect. It was one of the findings in that particular case that there had been a serious leakage of gas, but that merely exaggerated a defect that would probably have resulted in disaster in any case. When over the Channel there were already signs that the R.101 was deficient in buoyancy, and she should have been ordered back home. It is worthy of remark that had R.101 been filled with helium instead of hydrogen the disaster would not have occurred, because then she would never have left the ground at all; she would have remained safe and sound at Cardington.

In discussing the future of the airship *vis-à-vis* of the aeroplane it would be wrong to make too much of the disasters of the past; a great deal of experience has been accumulated, and doubtless there are many more lessons to be learnt.

On the score of safety, we may assume that the aeroplane of the future will be driven by not less than four engines of sufficient power to render the plane safe to fly with any one engine out of commission. Such machines exist to-day. On a large machine it is further possible to make provision for the rectification of minor defects while in the air; this means that a breakdown involving a forced landing would be a very rare occurrence. It is already recognized that the Diesel type of engine for flights of long duration has the advantage of the additional deadweight being more than compensated by the economy and saving of weight in fuel; thus the danger from fire is practically eliminated, or at least reduced to very small proportions. The stages flown over long stretches of water could be negotiated by flying boats, which if brought down could be navigated under favourable conditions or would remain afloat for a considerable time in bad or stormy weather. There is no necessity for the one type of machine to be used on the different stages of a long-distance flight. An aeroplane capable of making a passage at something over 200 m.p.h. would not be at the mercy of the wind as would an airship with less than half that flight speed; and there is no prospect that the speed of the airship can be increased beyond 100 m.p.h. unless its size be increased substantially beyond what it is to-day. And even as things stand, the possibility of total loss is a very considerable risk; an airship, if from any cause it is unable to remain in the air, is almost certain to meet with disaster unless by good fortune it is in the vicinity of a mooring post and able to call up the requisite crew to effect a safe landing.

In view of the above, the writer feels very doubtful whether the airship has any prospect of a commercial future at all.—Dr. F. W. Lanchester, F.R.S., in *Engineering.*

## Steel Wire for Bridge Cables

Although wire-drawing was already an established industry at Tintern in Elizabethan times, it was not until 1854, when James Horsfall discovered the effect of controlled rate of cooling and invented the process that is still known in the trade as "patenting," that cold-drawn steel wire came into general use for ropes. The "patenting" process produces in the steel an exceedingly fine sorbitic structure of remarkable ductility that facilitates cold-drawing and thereby enables great tensile strength to be gained in association with the toughness that is characteristic of roping wire. Nearly all the steel wire that is now used in ropes and in bridge cables is cold-drawn with a number of passes after some form of patenting process. A certain amount of bridge wire in recent years has been heat-treated still more drastically, by quenching in an oil-bath, to give the full tensile strength required without any subsequent reduction of cross-sectional area by cold-drawing. Wire that has been hardened in this manner, by oil-quenching instead of by cold drawing after patenting, is known as "heat-treated" and has been used to some extent in important suspension bridges in the United States.

Interesting cases of failure of heat-treated wire occurred in the cables of the Mount Hope Bay bridge between Bristol and Portsmouth, R.I., and also in the slightly longer Ambassador bridge which, about the same time, was under construction across the Detroit river. The cables of these two bridges were dismantled before the completion of the structures and were replaced by new cables of cold-drawn wire. The failure of heat-treated wire in the Mount Hope bridge in particular has been recently investigated in a characteristically thorough manner by the National Bureau of Standards, Washington; and a detailed description of this work and of the circumstances that led up to it is contained in a paper by W. H. Swanger and G. F. Wohlgemuth, now published by the American Society for Testing Materials. The paper has been awarded the Charles B. Dudley medal of the Society and is of outstanding interest to bridge builders and to all interested in wire ropes.

The authors give a detailed account of the failure of the heat-treated wires in the cable anchorages of the Mount Hope bridge. In February, 1929, several months after the completion of the spinning of the parallel wires in position in the cables, but before the completion of the bridge structure, fractures were discovered in the wires where they had been bent to form loops round the cast-steel shoes pin-jointed to the eye-bars of the anchorages. The wires were of 0.195 in. diameter and the shoes of 19½ in. diameter, and all the fractures occurred at or near to the points of tangency on the shoes. Attempts were made to replace the first few broken wires, but further fractures developed more rapidly than they could be replaced.

The cause of the brittleness was traced to the surface condition of the galvanized heat-treated wire. A large group of samples was assembled to contain those in which the proportion of brittle fractures was higher than usual, and it was found that the proportion could be much reduced by polishing the surface after the layer of zinc had been removed by acid. When the outer surface was removed mechanically to a depth of 0.015 in., all low-reduction breaks were eliminated. Further classification endorsed the conclusion that the brittleness was due to deeply-seated defects, occurring sporadically, but apparently throughout the whole of the heat-treated wire. The nature and origin of the deep-seated defects was investigated micrographically with reference to the process of manufacture.

The authors express the opinion that the defects originated from pits formed where mill-scale and other rolling defects had not been ironed out during the one or two draws that brought the wire to size before heat-treatment, these pits being possibly enlarged in the pickling bath that preceded the galvanizing. But if this were the only explanation, it seems difficult to understand why cold-drawn wire should be so consistently free from the same trouble. The profiles of the defects appear decidedly reminiscent of the grain structure, and it seems not unlikely that they formed as cracks during quenching or, alternatively, that they may have formed during the galvanizing process by the intrusion of zinc between the grains of metal subject to tension. In view of work that has been done in England, the point is one that seems to merit further investigation.—*Engineering.*

## Canadian Air Transport

According to statistics just received for 1936, the 43 companies engaged in air mail and freight transport in Canada showed a substantial increase in business over 1935; no less than 43 per cent in the case of ordinary commercial freight, namely 11,272 tons, while air mail reached a new high level of 1,153,812 lb. Canadian Airways is the largest operating company, with a freightage last year of 7,750,000 lb., followed by Starratt Airways with 3,600,000 lb., and Wings, Limited, with 2,232,000 lb. These three companies between them used 53 aircraft of seven different types. Much of the business is, of course, associated with Canada's leading industry of mining, and in one contract carried out by Wings, Limited, it involved the transport of an entire mining plant from a point 325 miles east of Lake Winnipeg to a new mining site just over the Ontario boundary—a distance of 145 miles. The total weight of cargo was more than 600,000 lb., and included a mine hoist, a mine cage, sinking buckets, rock drills and steel, eight ore cars, 60,000 lb. of dynamite, 70 workmen and their belongings, and some 35 tons of foodstuffs. Special air bases, with radio stations, were established at both ends of the run. Some of the machinery to be moved raised difficult problems owing to weight and bulkiness. The compressor when assembled weighed 14,000 lb., and the hoist 4,600 lb. The sub-base of the compressor was 15 ft. long; it was cut in two and reassembled at the new site, each piece weighing ½ ton. Two tractors weighing, respectively, 6,250 lb. and 5,700 lb. were also sent in sections. Canadian fisheries also find air transport of great value. One company alone—United Air Transport, with headquarters at Edmonton—conveyed more than 1,000,000 lb. of fish during the past winter. An interesting experiment is that of re-stocking small lakes with fish by means of aeroplanes; this is said to have proved successful.—*Engineering.*

## Ground-line Preservation of Wood Poles

Transmission problems, in connection with telegraph, telephone and electricity supply, call for constant maintenance, not the least of which is connected with the use of wooden poles for carrying wires and cables. The greatest trouble with these is experienced at or just below ground level. A method practised in Ontario of protecting this region with a view to prolonging the life of such poles was described in a paper read before the Association of Municipal Electrical Utilities at Toronto, early this year, and given in a recent issue of the *Bulletin* of the Hydro-Electric Power Commission of Ontario.

The preventive measures are the result of experience dating back to the year 1920, which fully establish the value of coal-tar creosote.

It is with a view to saving the hot and cold dipping, applied either at some central depot or *in situ*, that the bandage or collar method of treatment now favoured has been adopted for both new and old poles. The collars employed provide a setting equal in strength to the surrounding earth and also make for easy re-treatment, without excavation, when and if required. They also prevent loss of creosote by the pole treated and retard its absorption of moisture from the area of soil surrounding it. Capillary action within the sap wood is relied upon to carry the applied creosote in both directions vertically. Galvanized sheet iron is employed, loosely wrapped round the pole and secured by wire, then lowered into position and radially extended by means of wooden, tapered wedges. The sheet iron joint is secured by nails, at the overlap, to one of the wedges which is permanent. The annular space is then filled with sand and the temporary wedges are withdrawn. After the application and absorption of the creosote, the job is completed by filling up the collar to the brim with a mixture of sand saturated with creosote, to form a seal. Experiments have proved that the eighteen-inch column of sand holds, according to its fineness, 20 per cent to 25 per cent of its volume of creosote. Approximately three-quarters of this is absorbed, in the case of cedar, and the remainder is relied upon to inhibit fungus growth.

Wastage of creosote which might otherwise occur, due to its leakage pending absorption, is prevented by placing the tightening wire close to the bottom of the sheet and allowing the wooden wedges to exert their pressure against that portion of the sheet above it. About half a gallon of creosote per pole, of cedar, is a good allowance, and reliance is placed upon the crust formed by the finishing top layer of sand saturated with creosote to prevent loss of loose sand by wind or by rain.—*Engineering.*

## The Vibrations of Airscrew Blades

Engineers seldom have a good word to say for vibration. Decrease in the weight of material and a corresponding increase in the working stresses have, however, resulted in the subject becoming a matter of importance when factors of safety are comparatively low. Certain parts of aircraft present outstanding examples of this, since the need for economy of material has led to slender structures which are in this connection extremely sensitive to the periodic forces produced by aero engines in particular. The stress on the blades of an airscrew, for instance, may well be increased to four or even five times the normal value if the torsional deformation on the crankshaft amounts to a degree or so of arc, under conditions of resonance. Such an increase of stress calls for due consideration in view of the usual factors of safety employed in this class of construction. But there is more to be said on the point, for most objectionable noises can in general be caused when only small amplitudes of vibration are involved, and this adversely affects the measure of comfort of aerial transport. Though but different forms of periodic disturbance, vibration and noise require separate consideration with reference to the remedial measures to be taken. This is so because both the phenomena affect the passengers and pilots, but the former tends further to the development of undesirable stresses in the structure concerned, as already pointed out. While certain types of oscillation arise mainly from aerodynamical sources, others are induced by the mechanical effect of the unbalanced forces and couples associated with aero engines. This may or may not cause the principal parts of the system, such as the fuselage and airscrew, to execute large vibrations, since the motion depends partly on the conditions that make for resonance, and partly on the amount of energy involved in the disturbance.

The failure of propellers on this account is a comparatively rare occurrence in this country, but the few instances on record nevertheless suffice to emphasize the need for an examination of the contributory factors. The subject is of special interest to engineers on account of the fact that the engine is the principal source of disturbance in certain circumstances, due to variations in the driving torque being transmitted by way of the shaft to the airscrew. This is only one aspect of the problem presented by actual blades, for their form renders them liable to complicated oscillatory motion, even when the machine is making a straight course, as was demonstrated recently by Major B. C. Carter before the Royal Aeronautical Society, in a paper entitled "Airscrew Blade Vibration." The information contained in this contribution to the subject amplified our knowledge on an extremely difficult matter, in so far as the experimental work was based on the fact that the crankshaft and propeller vibrate as a structural unit.

# BULLETINS

*Turbine Pumps.*—A 6-page bulletin has been received from the Roots-Connersville Blower Corporation, Connersville, Indiana, describing the construction of their Type T turbine pump.

*Milling Machines.*—Brown & Sharpe Mfg. Co., Providence, R.I., in a 4-page bulletin give particulars of their No. 12 electrically controlled plain milling machine.

*Convection Heaters.*—A 6-page bulletin from Trane Company of Canada Limited, illustrate their floor and wall-hung cabinet type heaters.

*Expansion Joints.*—Stainless steel S type expansion joints are described in a 10-page booklet which has been received from the Foster Wheeler Corporation, St. Catherines, Ont. With suitable modifications these joints are good for operating pressures of 300 lb. per sq. in. and temperatures of 700 deg. F.

*Group-Operated Switches.*—General Electric Company of Canada, Toronto, in a 4-page bulletin describe their type TC group-operated switch, a moderate duty vertical-break switch for outdoor use, 7.5 to 46 kv.—200 amperes.

*Magnetic Clutches.*—The Northern Electric Company, Montreal, give particulars of their C-H magnetic clutches sizes 3 to 78 in. in a 4-page leaflet.

*Arc Welding.*—A 14-page booklet recently prepared by the Lincoln Electric Company gives particulars of the arc welding process as applied to the construction of pipe lines.

*Pipe Fittings.*—The Dresser Manufacturing Company, Toronto, Ont., have issued a catalogue announcing a standard line of style 65 fittings which eliminates the necessity of pipe threading. The complete line of these fittings includes: standard and extra-long couplings, ells (both 45° and 90°), and tees, all supplied in standard steel pipe sizes from ½ in. I.D. to 2 in. I.D., inclusive, black or galvanized.

# Preliminary Notice

## of Applications for Admission and for Transfer

August 20th, 1937

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

**Communications relating to applicants are considered by the Council as strictly confidential.**

---

The Council will consider the applications herein described in October, 1937.

R. J. Durley, Secretary.

---

*The professional requirements are as follows:—

**A Member** shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

**An Associate Member** shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

**A Junior** shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

**A Student** shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

**An Affiliate** shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

> The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

### FOR ADMISSION

BEAVER—HUGH EYRE CAMPBELL, of London, England., Born at Johannesburg, South Africa, May 4th, 1890; Educ., Wellington College, 1904-10; Member, Inst. Chem. Engrs.; Fellow, Royal Economic Society and Royal Statistical Society; 1910-21, in service of Punjab Govt., India; 1922-30, on the staff, and 1931 to date, partner in the firm of Sir Alexander Gibb and Partners, London, England. Work included: 1931, head of mission under Sir Alexander Gibb to report on Canadian national ports; reconstrn. of West Side of Saint John Harbour; layout and constrn. of Messrs. Guinness' brewery, factory and industrial estates; consulting engr. to Commissioner for Special Areas; also reports and preparation of various large industrial development schemes.

References: Sir Alex. Gibb, J. M. R. Fairbairn, C. H. Mitchell, A. G. L. McNaughton, E. A. Cleveland.

BRYCE—JOHN BEMISTER, of 2 Highview Crescent, Toronto, Ont., Born at Toronto, Jan. 1st, 1913; Educ., B.A.Sc., 1935, M.A.Sc., 1936, Univ. of Toronto; With the H.E.P.C. of Ontario as follows: Summers 1935-36, power house operator, and Aug. 1936 to date, junior engr., hydraulic dept.

References: O. Holden, R. W. Angus, J. J. Traill, S. W. B. Black, J. R. Montague.

McLAUGHLIN—WILLIAM GORDON, of Cumberland, Ont., Born at Cumberland, Sept. 16th, 1910; Educ., B.S.c. (Mech.), Queen's Univ., 1934; M.E. (Mech.), Rensselaer Polytech. Inst., 1936; 1934-35, demonstrator, dept. of mech'l. engrg., Queen's Univ.; 1936-37, technical dept., E. B. Eddy Co. Ltd., Hull, Que., and April 1937 to date, constrn. of bleach sulphite plant for same company.

## EMPLOYMENT SERVICE BUREAU

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.

*All correspondence should be addressed to*

**The Employment Service Bureau, The Engineering Institute of Canada**
2050 Mansfield Street, Montreal

### Situations Vacant

DRAUGHTSMAN, with knowledge of mechanical and electrical drawings. Also familiar with survey drawings. Apply to Box No. 1621-V.

DRAUGHTSMAN, experienced in pulp and paper mill operation and maintenance. Permanent position. Apply to Box No. 1625-V.

MECHANICAL ENGINEER, for plant layout and estimating work and some draughting. Location Montreal. Apply to Box No. 1626-V.

RECENT GRADUATE, for time study work with large industrial company in Montreal. Apply to Box No. 1627-V.

DRAUGHTSMAN, general engineering draughtsman for newsprint mill in Quebec, staff house accommodation. Single man preferred. Must be neat draughtsman and able to make raw material surveys. State age, experience and salary expected, and submit sample of work. Apply to Box No. 1628-V.

MECHANICAL SUPERINTENDENT. General contractor will shortly require mechanical superintendent to supervise mechanical and electrical sub-contract work to cost in excess of one million dollars on large city building construction contract. Man appointed will be expected to relieve office engineer and general superintendent of all details pertaining to mechanical and electrical work. Present contract will last about eighteen months, with possibility of further engagement thereafter. Interesting opportunity for right man. Apply to Box No. 1634-V.

ELECTRICAL AND CIVIL ENGINEER, with some experience, for a town in the province of Quebec. Apply to Box No. 1636-V.

RECENT GRADUATE, in mech. or civil engrg., with some experience in design and draughting. Location Ontario. Apply to Box No. 1637-V.

MECHANICAL ENGINEER, preferably with paper mill experience, but would consider training a young graduate. Apply to Box No. 1639-V.

ELECTRICAL OR MECHANICAL ENGINEER with sales experience, preferably of Swiss nationality, for British India. Apply to Box No. 1640-V.

CHEMICAL ENGINEERS. Young chemical engineer with one or two years experience in pulp and paper mill. Also a recent graduate in chemical engineering. Apply to Box No. 1641-V.

DRAUGHTSMEN. Experienced ship draughtsmen. Salary from $150 to $200 per month depending upon experience. Location Montreal. Apply to Box No. 1642-V.

CIVIL ENGINEER, with experience in connection with bush operations, particularly with reference to construction of dams and piers for holding grounds, small houses and logging equipment, including marine engines, tractors, trucks, saw mills, etc., for a pulp and paper mill in the province of Quebec. Apply to Box No. 1643-V.

MECHANICAL DRAUGHTSMEN. Situations vacant for experienced mechanical draughtsmen. Permanent employment for suitable men. Applications by letter only, giving full particulars of experience. Dominion Engineering Works Limited, P.O. Box 3150, Montreal, Que.

### Situations Wanted

PURCHASING ENGINEER, graduate mechanical engineer, Canadian. Married, with fifteen years experience covering construction and operation, principally having to do with specification and ordering of equipment and materials for new construction and maintenance. Details upon request. Apply to Box No. 161-W.

INDUSTRIAL ENGINEERING EXECUTIVE, with wide experience including fourteen years in design, construction, maintenance and operation of pulp and paper mills and power developments. Now employed, desires change of location. Apply to Box No. 320-W.

CIVIL ENGINEER, B.A.Sc., age 44, structural, harbour, executive. At present designing 32,000-h.p. development in Newfoundland. Available in near future. Apply to Box No. 536-W.

DOMINION LAND SURVEYOR, and graduate engineer with extensive experience on legal, topographic and plane-table surveys and field and office use of aerophotographs, desires employment either in Canada or abroad. Available at once. Apply to Box No. 589-W.

### Situations Wanted

ELECTRICAL ENGINEER, B.Sc., E.E., age 38. Married. Ten years electrical experience; including, one year operation, one year maintenance, and four years on construction of hydro-electric plants and sub-stations. Four years electric maintenance and construction in pulp and paper mill. Also experience on highway construction and Geological Survey. Available at once. Apply to Box No. 636-W.

ELECTRICAL ENGINEER, B.Sc. E.E. '28. Two years with large electrical manufacturing company including test course, about two years in supervisory operating office of a large electrical power utility, and considerable experience in electrical and mechanical draughting. Location in Ontario preferable. Apply to Box No. 660-W.

YOUNG CIVIL ENGINEER, B.Sc. (Univ. of N.B. '31), with experience as rodman and checker on railroad construction, is open for a position. Apply to Box No. 728-W.

CIVIL ENGINEER, B.Sc., M.Sc., R.P.E.; Lieut. C.E., R.O. 16 years municipal, highway and construction, 5 years overseas. Married. Read, write and talk French. Will go anywhere. Apply to Box No. 737-W.

RADIO AND ELECTRICAL ENGINEER, B.Sc., '31, Jr.E.I.C. Single. Age 30. One year and a half actual field experience in power and lighting equipment. Extensive work in telephone and radio layouts in switchboard and installation depts. Particularly interested and experienced in sales and traffic work in telephone and radio company. At present supervisor over sales and service of radio and electrical company. Available on short notice. Location immaterial. Apply to Box No. 740-W.

PLANT ENGINEER or SUPERINTENDEBT, capable of supervising all phases of industrial plant operation, graduate electrical, eleven years diversified industrial experience including test course, four years on large Quebec industrial development, on construction and operation, also six years with prominent consulting firm supervising electrical and mechanical engineering projects. Age 31, single. Apply to Box No. 795-W.

CIVIL ENGINEER, S.E.I.C., B.Sc. in C.E. (Sask. '32). Single. Age 27. Three years experience includes—instrumentman, compiling reports and draughting with a National Park; in charge of construction of water supply and sanitary sewer systems; assistant on city surveys. Excellent draughtsman. Available at once. Location immaterial. References. Apply to Box No. 818-W.

MECHANICAL ENGINEER, Jr.E.I.C., technical graduate, bilingual, age 35, married, experience includes five years with firm of consulting engineers, design of steam boiler plants, mechanical equipment of buildings, heating, ventilating, air conditioning, plumbing, writing specifications, etc. Five years with large company on sales and design of power plant, steam specialties and heating equipment. Available on short notice. Apply to Box No. 850-W.

STRUCTURAL ENGINEER, B.A.Sc., A.M.E.I.C. Twenty-two years experience in design of bridges and all types of buildings in structural steel and reinforced concrete. Three years experience in railway construction and land surveying. Apply to Box No. 856-W.

ELECTRICAL ENGINEER, B.Sc. (McGill '28), age 34. Experience includes transmission line and rural distribution construction and design. Some installation of motors and equipment, also house wiring. Available immediately. Apply to Box No. 940-W.

ENGINEER SUPERINTENDENT, age 44. Engineering and business training, executive ability, tactful, energetic. Had charge of several large projects. Intimate knowledge of costs and prices, reports and estimates. Available immediately. Any location. Apply to Box No. 1021-W.

ELECTRICAL ENGINEER AND GEOPHYSICIST, B.Sc. (Man. '23), A.M.E.I.C. Married. Ten years specialized experience in the practical use of magnetic, electrical and mechanical instruments for the prospecting, surveying and mapping of mineral, oil and gas lands. Five years experience with telegraph, telephone and radio equipment. Capable of giving instruction in theory and practice in these lines and in college physics. Available on short notice. Apply to Box No. 1063-W.

### Situations Wanted

CIVIL ENGINEER, A.M.E.I.C., with over twenty years experience in field and office on construction, maintenance, surveying, location, etc., desires position preferably of a permanent nature. At present near Montreal, but willing to locate anywhere. Apply to Box No. 1168-W.

ELECTRICAL ENGINEER, B.Sc. '34 (Univ. of N.B.), S.E.I.C. Age 24, single. Desires any kind of electrical work. Will consider any location. Apply to Box No. 1262-W.

ELECTRICAL AND RADIO ENGINEER, S.E.I.C., B.Sc. (Elec.) '32, M.Sc. '34. Experience includes four years part time operator for radio broadcast station, repairs to radio receivers and test equipment, design and construction of amplifiers and inter-office communication systems. Available on short notice. Apply to Box No. 1283-W.

CIVIL ENGINEER, B.Sc. 1910, A.M.E.I.C. Married. Twenty-six years experience on heavy construction work, both field and office; rails, roads, power house, hotels, bridges, etc. Location immaterial. Available at once. Apply to Box No. 1470-W.

CONSTRUCTION SUPERINTENDENT, M.E.I.C. Age 49. Married. Twenty-two years experience as engineer, superintendent and manager in charge of hydro-electric, mechanical production, structural steel erection, also considerable experience in steam plants, combustion, transmission lines, millwright work, complete mine installations, rock work, rock crushers and conveyors. Executive ability. Speaking French fluently. Location immaterial. Apply to Box No. 1482-W.

ELECTRICAL ENGINEER, B.Eng. (McGill '33). One and a half years experience in plant and production routine, and with considerable training in sales work. Bilingual, single, and available at once for any location. Apply to Box No. 1509-W.

ELECTRICAL ENGINEER, B.Sc. '31 (Univ. of Alta.), Jr.E.I.C. Age 28. Married. One year students' test course with C.G.E.Co. including testing and operation of transformers, meters, industrial control and switchgear apparatus. Two years as instrumentman on highway construction. Desires electrical utility, commercial lighting or air conditioning work. location immaterial and available at once. Apply to Box No. 1522-W.

CIVIL ENGINEER, B.Sc. '32, S.E.I.C., P.E.N.B., DY.L.S.N.B., age 32. Experience in mining, both coal and metals, private and legal surveys, railroad construction, geology and building construction. At present in private practice in coal mining district. Desirous of changing location for position either in mining field or construction in Canada. or abroad. Apply to Box No. 1562-W.

RESIDENT ENGINEER, familiar with all types of surveys and construction work including, railway, roads, irrigation, drainage, buildings and air ports. Executive ability. Had charge of several large projects. Intimate knowledge of reports and estimates. Available immediately. Any location. Apply to Box No. 1567-W.

CIVIL ENGINEER, B.Sc. '17, O.P.E. Married. Executive and administrative experience. Extensive office and field experience in harbour works, dredging; both steam and electric railways in location, construction and maintenance; telephone works in design, construction and maintenance of pole lines, wire, cable and conduit; highways in location, construction and paving; municipal works in roads, sidewalks, sewers and water mains. Intimate knowledge of estimating, unit costs, cost accounting and analysis. Some knowledge of air conditioning. Willing to locate anywhere. Available at once. Apply to Box No. 1587-W.

ELECTRICAL ENGINEER, B.Sc. '27 (McGill), A.M.E.I.C. Age 36. Married. Bilingual. Three years experience in telephone work (installation of manual and automatic exchanges). One year electrical prospecting. Nine years experience with electrical power company. Apply to Box No. 1601-W.

EXECUTIVE TOOL AND PRODUCTION ENGINEER, desires to make a permanent change, graduate in mechanical (Queen's '23), A.M.E.I.C., married. Well abreast with modern production methods and present competition. Competent supervisor of tool and die design and construction; operations and methods, plant layout, efficiency and time study, toll and production estimating, tooling development foundry, machine shop and designing experience. Best of references. Apply to Box No. 1653-W.

ENGINEER, age 44, seeks connection as chief or plant Engineer, with pulp and paper, or textile concern. Apply to Box No. 1662-W.

METALLURGICAL ENGINEER, graduate 1936. Experienced in gold smeltering and milling, also in stee and pig iron manufacturing. Desires new connection in eastern Canada or Great Britain. Apply to Box No. 1673-W.

# Recent Developments at the Port of Halifax

*E. H. James, M.E.I.C.,*
*Consulting Engineer, Montreal.*

**Paper presented at a joint meeting of The Institute and the American Society of Civil Engineers, Boston, October 6, 1937.**

SUMMARY.—The main Port facilities in Halifax Harbour are at two points some 1¼ miles apart. The construction of the various piers is described, with notes on the difficulties experienced, and the reconstruction or extensions carried out from time to time during the past twenty years.

The Port of Halifax is situated on the Atlantic coast of Nova Scotia about 7½ miles in from the open sea and is one of the two principal Eastern seaboard ports of Canada, the other one being Saint John, N.B.

Halifax has an exceptionally fine natural harbour with a useful water area of about 10 square miles. There is ample depth of water for all purposes, no dredging ever being required except for the shoreward parts of new construction, and there being no rivers of any size entering the harbour there is no trouble with any form of siltation. Foundation conditions are good; the tide range is only about 6.7 ft., while currents are negligible, never exceeding about one mile, and Halifax is still the only port in Canada which can dock any ship now afloat at any time of the year.

The business of the port is largely seasonal, being very much greater during the winter months than in the summer when the ports of Montreal and Quebec on the St. Lawrence river are operating. As a natural result of this situation much of the accommodation which is busy in the winter is often necessarily idle during the summer months.

The city of Halifax was originally founded in 1749 and in the early days most of the pier construction was carried out by the naval and military authorities. During the nineteenth century, however, extensive trading was carried out between Halifax and the West Indies and American ports and during this period a number of timber pile wharves were constructed by various private interests, mostly located in the section between the present Deep Water and Ocean Terminals, and most of these properties are still privately owned.

The first railway connection to Halifax was in 1858, this railway being taken over in 1876 by the Intercolonial Railway. From this time until 1928 the port, apart from privately owned docks, was under the control of the Government Railways. In 1928 the Halifax Harbour Commission was formed, consisting of three local Commissioners appointed by the Federal Government. This body remained the controlling authority until 1935 when in common with the other principal ports of Canada, viz., Montreal, Quebec, Vancouver, Three Rivers, Saint John and Chicoutimi, Halifax was taken over by a central body known as the National Harbours Board. This body consists of three Commissioners, with headquarters in Ottawa, who control all ports, appoint the local port managers and also carry out all new construction work, the work of the port chief engineers being now confined to maintenance work and minor new works.

Reference to the general plan shown in Fig. 2 will show that the main port facilities are divided into two sections, the inner portion known as Deep Water Terminals and the outer known as Ocean Terminals. The early development was at deep water in the neighbourhood of the naval dock yard, but in 1913 the facilities were becoming inadequate to handle the traffic and a very extensive new scheme of development was put in hand. This new development, instead of extending the existing facilities at Deep Water, was removed to an entirely new area some 1¼ miles nearer to the harbour entrance, and as no rail connection could be established along the water front between the two sites owing to lack of space and existing streets, the new scheme involved construction of a railroad around the back of the city and the removal of the railway terminals to the new site. At the time this work was put

(*Courtesy of R.C.A.F.*)

**Fig. 1—Aerial View of Halifax Harbour and Bedford Basin.**

in hand the Harbour Commission had not been formed, and the construction of the first units was carried out between 1913 and 1919 by the Government Railways.

There has been considerable difference of opinion regarding the wisdom of developing the new site, as this location is undoubtedly more exposed than the inner harbour and some berths are even now undesirable when the wind is in certain quarters. The new scheme involved also the construction of a protecting breakwater, the moving of the railway terminals, the construction of the new railway line, part of which was in heavy rock cut and requiring a number of over bridges and the building of a new passenger station and yards. From an operating point of view the port labours under the disadvantage of having two separate sections a considerable distance apart without direct rail connection, the time required for switching being very considerable. On the other hand the new location provided for almost unlimited expansion when needed and employed land which was cheap and not otherwise in use at the time, whereas the space available at Deep Water was limited towards the north and already occupied by numerous private interests and therefore involved expropriation towards the south.

It is not proposed to give any detailed description of facilities in existence up to this time as they have been dealt with exhaustively in other papers, though a general idea of the situation may be given here.

At Deep Water Terminals there is a pier known as Pier 2, about 780 ft. by 235 ft., built between 1912 and 1915. This pier was originally intended to be one of four to form part of an extensive new development, but no further units were ever proceeded with. The pier is supported on 24 in. square concrete piles with concrete deck and carries a two storey concrete shed about 200 ft. wide in five spans. Two railroad tracks run into the shed under cover on the lower floor and there is an outside track on each apron. This pier survived the disastrous explosion of 1917 and is still in good condition and handled a tremendous amount of business during the War. The concrete piles were recently inspected and were found to be all sound below water, but above low water, particularly in the case of those piles which were too short when driven and were extended *in situ*, considerable deterioration took place due to frost action, etc., and in 1929 and 1930 about $230,000 was spent repairing these upper portions and the under side of the deck system. All loose concrete was cut out and all exposed reinforcing sand blasted, after which the structure was re-surfaced with gunite impregnated with finely ground iron. This work is at the present time sound and the pier generally is in very good condition.

There are also two timber piers known as 3 and 4, about 160 ft. by 606 ft. and 82 ft. by 540 ft. with one storey timber sheds. These piers were built in 1898 and 1892 and are still in fair condition and in regular use, but they were practically rebuilt in 1917.

At Richmond, about 1¾ miles above Deep Water, there is an open wharf parallel to the shore line about 700 ft. long. This is an old timber structure and is not in very good condition though still serviceable. It is leased in sections to various industries requiring water front accommodation. There is also a large cattle shed and facilities for handling cattle by rail and water.

Richmond was the site of the earlier railroad developments and the accommodation was at one time much more extensive than at present. The greater part of the facilities, however, were destroyed in the 1917 explosion and were never rebuilt.

Accommodation at Ocean Terminals consists of a long wall 2,006 ft. in length, parallel to the shore line and providing 45 ft. depth at low water, capable of docking the largest ships afloat. (See Fig. 3.) There is a return wall

of about 1,200 ft. length at its southern end and also Pier A about 1,250 ft. by 300 ft.; altogether the development provided nine berths for large ships. The long wall is provided with two storey brick and steel transit sheds on two berths, Nos. 21 and 22, built between 1921 and 1926, and a single storey steel shed on one berth, No. 20, built in 1929, and accommodation is also provided for the port administrative offices and immigration quarters. The remaining berths have single storey timber sheds, four of which, Nos. 23, 24, 25 and 28, were built in 1917 to 1918, while one, No. 27, was built in 1929. Berth No. 26 is open, as it is occupied by the Dominion Coal Company's handling plant.

The substructure work in this section is of a very high grade type and all walls above low water are faced with granite blocks; the base of the wall consists of a number of reinforced concrete shells set one on top of the other to the required height, having the front pockets filled with concrete and the rear ones with rubble rock. The base course was set on carefully prepared foundations, this work being carried out in the dry inside a large diving bell. Towards the shore the work involved a large amount of rock excavation while for part of the outer sections a rubble mound was required to provide the foundation for the shells, as bed rock was lower than −45. At the southern end of the entire development a protecting breakwater was built from the largest pieces of rock excavated from the cut for the new railway approach, and as there was still a large surplus of rock this was dumped on what was intended to be the site of the next unit to be built under the scheme, to form its central core.

There is also a 2,200,000 bushel grain elevator with galleries making most berths available for grain shipments and a cold storage plant, this latter having originally been built as a private enterprise although it was taken over by the port.

This was the position of the port when the Harbour Commission was formed in 1928, no works of any size having then been carried out for some time. In this year it was decided to build an additional unit in the original Ocean Terminals scheme. In the ordinary course of events the existing core mentioned before would have been used as part of this new pier, but the location of the cold storage plant erected in the interval had made it practically impossible to provide suitable trackage to a pier on this site and the new Pier "B" was therefore built on the next site seawards, still however adhering to the original general plan.

### Construction of Pier B and Transit Sheds at Ocean Terminals

This pier is 1,250 ft. by 300 ft. and the type of construction adopted consisted generally of large concrete cribs filled with pumped sand with concrete superstructure

(*Courtesy of R.C.A.F.*)

Fig. 3—R.M.S. *Majestic* at Passenger Landing, Ocean Terminals.

wall and a central rock and sand fill. As additional yard space was needed by the railway a further large excavation was made immediately behind the pier and the spoil used as filling, the amount required over and above this being obtained near the harbour entrance by a sand sucker and pumped into the pier site.

A considerable amount of rock dredging was required at the shore end of the pier where the basins were dredged to 35 ft. at low water while at the outer end a rubble mound was dumped up to 45 ft. below low water, and the cribs set on this mound, after depositing a bed of crushed stone and carefully levelling it off by sweeping with a heavy beam suspended beneath a scow. There were therefore two types of cribs, those for the 35 ft. depth being 42 ft. wide and those for 45 ft. depth 52 ft. wide. All cribs were built of a height sufficient to bring them above high water when set. The cribs were constructed in a floating pontoon on the Tromenhauser system in which the crib floor is poured on the bottom of an open pontoon and the construction of the walls started with forms erected inside the pontoon. As work proceeds the increasing weight forces the pontoon lower into the water, but before it is submerged the crib is able to float itself and the pontoon is then removed and the bottom forced off by weighting its projecting edges, after which the crib is completed afloat, the pontoon being reassembled for the next crib. This method of construction has many advantages and can be used in almost any location but has the disadvantage common to most floating methods of starting concrete cribs, that it is almost impossible to make the pontoons so rigid that they will not distort somewhat during the pouring of the floor slab. As a result of this the crib floor is often not a plane and when the crib is set and filled very large and indeterminate stresses may be set up owing to its not bearing evenly in its bed. Moving forms of the grain elevator type were used for the walls of the cribs, lifted continuously by jacks. When the cribs were completed they were towed to the site and sunk in position by admitting water by siphons and were then filled with pumped sand. Aluminous cement was used throughout for the crib construction with a view to avoiding deterioration through sea water and frost action, and owing to the great heat developed by this cement when the concrete is setting it was necessary to install pipes on the lower edges of the moving forms to cool the concrete. The spaces between cribs were filled in with bag concrete to the underside of the superstructure wall, the bags being set in place by divers.

It was originally intended that the outer wall of the cribs should form the actual dock face, to a level just above high water, but in practice many of the cribs were not set to a perfect line and a number moved after setting as a result of settlement in the rock mound when the cribs were loaded. This situation was remedied by slightly increasing the width of the pier and bolting a timber waling to the cribs just above low water, shaped so that its outer edge was exactly to the new line. The superstructure wall on the cribs was then carried down to the timber waling, thus providing a finished wall to a perfect line, the irregularity of the cribs themselves not being visible. This wall was reinforced and was held to the crib walls by bolts passing through them and supporting a reinforcement system. The superstructure wall was partly built with aluminous cement and partly with Portland cement, and time should therefore show definitely whether aluminous cement is or is not superior to Portland cement for resisting frost and salt water action. The cement used was a European one known as Ciment Fondu which was developed in France and is now manufactured in England. Its price was however about twice that of Portland cement, so that its advantages need to be very considerable to make its use for this type of work economical.

After construction was started a change was made in the width of the pier, which was increased from 260 ft. to 300 ft. so as to provide additional trackage and permit of double banking cars at the back of the sheds, a proceeding usually adopted when shipping apples, the cars on the outer track being unloaded through those on the inner track. When the substructure was completed in 1932 money was not immediately available for sheds and the pier was used only for open storage until 1934 when arrangements were made for the construction of the sheds shown in Fig. 4.

The new shed was a one-storey steel structure about 94 ft. 6 in. wide, built continuously along both sides of the pier, and across the sea end, so that it is possible to travel completely round the pier inside the shed, thus providing four berths 600 ft. long and one 300 ft. long. There is a single railroad track on each apron at the water side of the sheds and four in the centre, two behind each wing of the steel shed with a truck roadway in the centre providing access to the outer part of the sheds without passing through the inner parts.

The first problem to be dealt with was the question of foundations for the sheds, no provision having been made therefor in the design of the substructure. As explained before, the central fill consisted of well consolidated rock up to a certain height which varied considerably but was generally below low water, and above this fine sand which had been placed hydraulically. This fill had been in place for some time and was well consolidated but it was evident that a considerable amount of leakage of the fine sand was taking place, partly through the bagwork in the spaces between the cribs and partly as a result of the very fine material gradually drifting into the interstices in the rock fill beneath, and it was decided for all rear columns to use piled footings taken through the sand down to the rock fill. For the front columns which were over the sand-filled cribs near the front it was not thought there could be any settlement and spread footings on the sand were provided. When the ground was opened up however a test load was put on the sand over the cribs and it was found that considerable settlement took place. Investigation showed the following reason:—

The sand filling in the concrete cribs was extremely fine and as the cribs were practically watertight the water

Fig. 4—General View of Sheds, Pier B.

pumped in with the sand was still present so that the contents of the cribs was practically a quicksand. Piles were driven into the cribs as an experiment and these went down about 4 or 5 ft. a blow until they met the crib bottom and if the hammer was then lifted the pile would come up about 3 or 4 ft., but if the hammer was left on the pile for about 10 to 15 minutes the pile would remain in position after lifting the hammer. After considering various alternatives and estimating their cost, it was eventually decided in the case of the large cribs to bridge the crib pockets from wall to wall by a continuous reinforced concrete beam and carry the footings for the steel columns on these beams and to use pile foundations driven to the bottom of the cribs in the case of the smaller cribs. This situation involved a large amount of excavation and additional concrete work and piling and increased the cost of the shed construction by a considerable amount and indicates the advisability of always providing for the foundations of future sheds when the substructure is built. There has however been no trouble with these foundations since the work was completed.

It is desirable for handling freight from ship to shed that the dock apron should be level with the shed floor on the water side but at the rear of the shed where the traffic is between shed and cars, the shed floor must be about car floor level, involving the necessity for depressed tracks. As the approach to the pier was already on a considerable grade, the shed floors were sloped upward from front to back so as to increase this grade as little as possible, thereby reducing the track depression by about 1 ft. 9 in. This grade on the floor has not been found any disadvantage, particularly as the outgoing traffic is greater than the incoming and towmotors are largely used. The retaining wall at the rear of the sheds has no foundation being a concrete curtain supported by the footings for the columns and only carried about 12 in. below ground level.

The shed floor is a 6 in. concrete slab reinforced with wire mesh and panelled to provide for expansion and contraction and is laid directly on the sand fill.

The steel shed structure is a single span, avoiding all obstruction on the floor by columns, and consists of steel trusses carried on built up steel columns with channel purlins to support the roof deck. The structure is closed in with galvanized corrugated steel siding, with a considerable window area supplied with ventilated steel sash.

Most of the older sheds at Halifax are provided with continuous sliding doors, permitting of any bay being opened. However Halifax is mainly a winter port and operation therefore has to be carried out under snow and ice conditions; further, its climate is such that thaws frequently occur when the sun is out in the day time followed by freezing temperatures at night, and sliding doors had proved very troublesome under these conditions owing to snow and ice collecting in the lower guides. It was therefore decided to use folding vertical lift type doors for the new shed. As the cost of these doors per opening greatly exceeds the sliding type, doors at the front of the sheds are only provided in each alternate bay. These doors are 14 ft. high and 18 ft. wide and are of two different types. On the north side they are 3-leaf doors and on the south 2-leaf doors. At the back of the shed doors are provided in every bay and are all of the single leaf vertical lift type by the Truscon Steel Company. These doors are 9 ft. high and 18 ft. wide, except for one opening in each shed section which is provided with a 14 ft. door similar to those on the water front side to provide for movement of any exceptionally large piece of freight. They are very rarely needed however.

All these doors have proved satisfactory after the adjustment of a few initial difficulties. All doors are operated by hand chain gear and those at the back of the sheds operated so easily that they could be closed by pulling the door down without using the chains. This caused the chains to travel so fast that they flew off the sprockets and jammed so that special guides had to be provided to prevent this trouble.

All doors are very carefully weatherstripped to prevent the ingress of driving snow and rain and have proved to be satisfactorily weathertight.

It was originally intended to use a mill type roof built up of 2 in. by 4 in. timber, but owing to the very high winds experienced at times at Halifax, trouble had been experienced as a result of air passing through the timber deck and tending to blow off the roofing; it was therefore decided to use a 1½ in. T. and G. deck, carried on 3 in. by 5 in. rafters. Nailing strips were omitted on the purlins and the rafters were attached directly to the steel by means of 1 in. by 1/8 in. cadmium-plated strips which passed round the purlins and were spiked to the sides of the rafters so that the nails are in shear. This method of fastening has proved perfectly satisfactory and the whole roof deck was actually considerably cheaper than the original mill type design. The roofing is a 5-ply felt, tar and gravel bonded roof and special care was taken with the nailing and mopping to avoid any tendency to lift. The eaves troughs are of timber on steel supports and are lined with copper. Eighteen copper ventilators are provided in the roof.

Each of the two long wings of the shed is divided at the mid point by a solid brick firewall carried 3 ft. above the roof, the external portion being completely sheathed in copper flashed down to the roofing. Connection between the sections through the walls is provided by sliding automatic fire doors.

At the shore end of each wing a brick office block is provided, each having two floors, the upper floors containing office space subdivided as required by tenants, while the lower floors contain heated rooms for perishable commodities or stores. The main entrances to the sheds pass through archways on the lower floor and under the office space. A heating plant is provided supplying both office blocks and there is also a transformer and switchboard room for the lighting installation.

The main sheds are lighted with Holophane reflectors which provide a diffused light without dark shadows, and the exterior is also similarly lighted from brackets on the roof, both on the water side and at the rear of the sheds; power connections for portable electric equipment are installed at intervals.

Water supply is provided with connections to fire hoses inside the sheds and to three hydrants located outside. Along the dock face connections are provided to boxes below floor level for supplying water to ships, portable meters being used to measure the quantity delivered.

Open type gear rooms are provided in each section built of heavy galvanized wire mesh on tubular supports, these being carried up to the underside of the roof trusses. With this type of room all gear can be seen but is protected from theft and is also well ventilated.

The concrete floors were finished with a wood float to provide a rough surface, as during the winter there is a lot of condensation on the floors and smooth or asphalt finish floors become extremely slippery.

There is a sewerage system running the entire length of the pier with an outfall at the outer end which picks up all down spouts from the roof, catchbasins on the roadway and sewage from the office buildings.

A complete sprinkler installation is provided, which since the shed interiors are often below freezing is of the dry pipe type. It is controlled by heat actuated devices which admit water to the system when the temperature rises at a greater rate than a certain pre-arranged speed. If these devices go into action an alarm is sounded but no water can escape unless a head goes, and after water is admitted the system practically becomes a wet pipe system.

This system avoids the necessity for a considerable air pressure in the pipes and avoids the release of water as a result of accidental breakage and consequent damage to cargo; it further gives an alarm some time before a head would go and therefore a small fire might be extinguished by hand equipment before a head went, thus avoiding water damage.

The water supply to the sprinkler system is derived from the city mains and also from an automatic fire pump with suction direct from the sea, which goes into action if the pressure drops below a pre-arranged figure. Thus the pump not only supplies the required water in the event of a failure of the city mains but also boosts the pressure if this should become too low.

The shed work included paving the approach roads and providing an independent stevedores rest room, provided with lavatory accommodation. The tracks were laid by the Canadian National Railways, but the paving of the aprons around them was part of the shed contract.

The cost of the entire work was approximately $965,000, and as no money was available at the time the sheds were required, the contractors financed the entire project, receiving payment after completion and acceptance of the whole work in 3 per cent bonds of the Commission redeemable at par 3 years after acceptance of the work. As a result of this arrangement the contractor had to bear all financing charges with the result that the cost was of course greater than if open competitive bids had been called. The general contractors were the Dominion Bridge Company and the J. W. Cumming Manufacturing Company jointly, and the work was entirely completed during the 1934 summer season.

### Reconstruction of Pier No. 2 at Deep Water Terminals

In September 1933 a disastrous fire started on the upper floor of Pier 2 at Deep Water. Some 7,000 tons of cargo, principally flour, were destroyed and the upper storey of the concrete shed was completely wrecked. As the winter season was due to start in three months and this shed was urgently needed, much of its space being already booked, it was necessary to rebuild at the earliest possible moment.

It was almost a week after the fire before the upper floor was cool enough for the damage to be inspected. The

Fig. 5—Clearing Up After Fire, Pier 2.

shed was entirely of reinforced concrete and the upper storey had completely collapsed leaving only a tangled mass of broken and disintegrated concrete and reinforcing steel. The only portion of the upper storey which was still standing was a few bays at the shore end, the only part which the fire department had been able to reach.

A contract was immediately placed on a force account basis for the removal of all wreckage amounting to some 7,000 tons (see Fig. 5). This work took three weeks and at the earliest possible moment an inspection was made of the floor slab to ascertain if it was still serviceable. For this purpose numerous test sections were cut out of the slab and crushed and it was found that the strength was generally not seriously reduced, though a few bays had to be removed and replaced owing to partial disintegration of the concrete. The original floor was a 6 in. concrete slab with a 1½ in. finish placed shortly after pouring. This had

Fig. 6—Reconstruction, Pier 2.

almost entirely separated from the slab proper and had to be completely removed, but there is no doubt that it had protected the main slab and prevented any serious damage.

In view of the time element and the early approach of freezing weather it was not considered practicable to rebuild in concrete and it was therefore decided to adopt a structural steel design. It was found impossible to drill holes for anchor bolts for the steel columns, owing to the mass of reinforcing steel in the floor system at these points, and therefore the old dowels for the upper floor concrete columns were left in place, bent over and concrete pedestals 18 in. high poured around them, the anchor bolts being set in these pedestals, which also provided protection for the light steel columns from damage by truck traffic on the floor. The steel framing was designed and a contract placed immediately, and as soon as the floor had been cleared its entire surface was covered with a 2 in. asphalt paving. For laying this floor a 10 ton roller was taken up and as this of necessity passed over every portion of the slab many times and its load concentrations were rather greater than those for which the slab had been originally designed, it provided incidentally a very good test for the slab. Concrete curbs were built round all floor openings for stairs, escalators, etc., and these temporarily covered with waterproof material so that the lower floor could be used as a transit shed while the work above proceeded. As this floor was quite flat the drainage was not very good and a certain amount of leakage took place on very wet days, but it was not sufficient to prevent the lower floor being kept in use, tarpaulins being kept handy to protect cargo when necessary.

The expansion during the fire was sufficient to cause severe cracking of the two concrete ends of the building and such cracks were all cut out and filled with gunite, while at the same time other needed repairs were carried out, the necessity for which had not been caused by the fire.

As the new steel structure (shown in Fig. 6) was in five spans the same as the original concrete sheds and the members were therefore all quite light, erection was carried out very rapidly by a small travelling derrick and presented no difficulty.

The roof deck was of timber 2 in. by 4 in. mill type laid on nailing strips bolted to the purlins and a new brick firewall was built at the mid point projecting through the roof.

A large part of this upper storey was often used for potato storage, for which purpose the shed had been insulated with a timber and fibre board lining backed by eel grass matting and heated. This lining was a fire hazard and had undoubtedly been responsible for the rapid spread of the fire and it was not considered desirable to repeat it. The main shed siding was corrugated galvanized iron throughout except for the shore end wall which was rebuilt in brick, and for the heated portion a 6 in. wall of hollow tile was built inside the sheeting between the steel columns leaving an air space, and the roof was covered with 1 in. of Donnacona board in two ½ in. layers over the timber deck and beneath the roofing. Insulated doors were also fitted to all wall openings and tile housings were built over the escalator and stair openings. This was not of course a very efficient method of insulation, but it was fireproof and was rapidly carried out at small cost and as it is only necessary to keep the temperature just above freezing it has proved quite satisfactory. Heating was accomplished by seven Dunham units fitted with automatic control, the temperature being maintained at about 35 deg. F. Roofing throughout was 5-ply tar and gravel. The outer half of the shed was not insulated in any way and was closed in by the siding only.

Ample large windows were provided in steel sash with ventilating sections, the windows in the insulated section being double and of smaller size. There are only eight outside doors in the upper floor opening on to projecting steel platforms and these were replaced in steel and wood in the unheated section and with refrigerator type doors in the insulated portion.

The paving contractor who laid the asphalt floor having no means of lifting his 10 ton roller on to the upper floor built a temporary ramp for this purpose and all asphalt from his plant was also trucked up this ramp. Another contractor took this over afterwards for his work and the arrangement was found so convenient that the Commission decided to make it a permanent feature. A new ramp was therefore built providing access for trucks to the upper floor. This ramp entered the shed at the side, and the opening was fitted with a refrigerator type door as it is in the insulated section. The arrangement has proved to be very useful and has saved its cost several times over in reduction of handling charges.

A sprinkler system of the same type as at Pier B was installed on the new upper floor. The question of installing a similar system on the lower floor was carefully considered but was decided against, as the design of the existing concrete structure is such as to make such an installation difficult and expensive.

The lower floor was originally equipped with continuous sliding type doors. These doors were old and already in need of extensive repair and were further considerably damaged as a result of the fire. Their operation had always been difficult in freezing weather and it was therefore decided to replace them.

A new installation of sliding doors would have involved new overhead track and new bottom guides, as these were badly corroded and in poor condition. In view of their difficult operation it was decided to replace these with 3-leaf vertical lift doors in each alternate opening, the blank openings being filled in with 8 in. interlocking tile panels, cement plastered outside, and containing a large steel sash. As the existing door openings were not rectangular, they were squared up by structural steel frames placed inside them which carried the new doors. Fitting these frames was a rather tedious operation as no two openings were of exactly the same dimensions and a lot of special fitting was necessary. The doors, however, since completion have operated very satisfactorily and the alternate opening arrangement has not caused any trouble with traffic handling.

The shed was fitted with four electric escalators and a freight elevator, all of which were considerably damaged, especially at their upper ends. A new elevator with push button control was installed and the escalators were taken out and shipped to their manufacturers who carried out the necessary repairs and replacements and re-erected them. It was also decided to install two additional escalators.

The concrete enclosures for stairways, etc., were badly cracked and otherwise damaged and where necessary these were taken down and replaced with 3 in. gunite partitions.

The shore and sea end walls of the shed which were of an ornamental character in reinforced concrete were seriously cracked and damaged as also were the offices contained in the first two bays of the shed. The upper part of the shore end wall was demolished and rebuilt in brick while the lower portion was repaired with gunite, all cracks being deeply cut out and refilled and all broken and detached portions of concrete built up again. New steel sash were required for many openings and sills and jambs needed reconstruction in gunite. New offices were built with tile partitions on the upper floor and the original lower floor ones were renovated, refloored and painted. The sea end wall was also repaired with gunite and was not replaced on the upper floor, the galvanized siding being carried round the end.

When all work was completed the entire shed presented a satisfactory appearance, the siding on the upper floor doors, etc., being painted harbour grey which harmonized with the concrete lower floor.

The whole work was completed by January 1934, but actually the lower floor went into use in December and the upper was largely used before actual entire completion, so that no serious delay was caused to traffic operations.

Throughout the design and construction close co-operation was maintained between the engineering and operating departments.

Owing to the urgency of this work time could not be taken to fully design the whole work and prepare plans on which tenders could be called for the whole work and therefore the engineers practically acted as general contractors, sub-letting the work in sections as the plans were prepared and carrying out some portions of the work with the Commissioners own forces.

### Construction of Fish Pier at Ocean Terminals

In 1934 it was decided to construct a small pier in front of the existing cold storage plant to provide accommodation for trawlers and fishing schooners that wish to land their catches for treatment in the plant; it was also proposed to provide space on this structure for the erection of fish processing plants. The pier was 290 ft. wide and 200 ft. long and use was made of the old rock fill in front of the cold storage plant which has been previously mentioned.

The large pier which was contemplated when this fill was originally placed was wider than the proposed fish pier and was also intended to provide a depth of water not less than 35 ft. at low tide, but for the purpose of the fishing vessels a depth of only 20 to 25 ft. of water was needed and it was therefore decided to use small concrete cribs about 70 ft. by 30 ft. and to set them on benches in the sides of the old rock fill, excavated in such a location that the required depth of water would be provided. The cribs carried a mass concrete superstructure wall and the centre was filled in with material obtained from steam shovel excavation and hydraulic dredging. The sea end of the structure was left open in view of the possibility of extension at some later date and the opening between the new wall and the central rock core was closed by small timber cribs to retain the earth portion of the fill. As the pumped material used for part of this fill was a very fine sand which erodes very rapidly, due to wind action in the summer when it is dry, it was specified that the upper two feet of the fill should be of some suitable heavy or compact material.

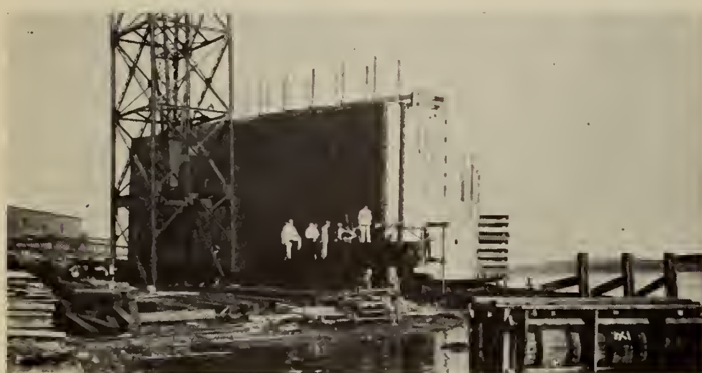

**Fig. 7—Launching Crib for Pier 9 (Richmond)**

**Fig. 8—Crib Launched, Pier 9 (Richmond).**

The formation of the benches on the side of the rock fill was carried out by a large drag line which travelled on the central core out of the water and had sufficient reach to cover practically the whole area. At the shore end of the basins a certain amount of rock excavation was necessary but as this only amounted to 2,215 cu. yd. it was carried out by a small two unit floating gasoline drill plant and the material after shooting was removed partly by the drag line and partly by a floating derrick and clam shell.

The concrete cribs were constructed on ways, as in the immediate neighbourhood a convenient piece of foreshore existed which was solid and almost at the grade required for launching. Panel forms were used for the concrete work and the pouring was carried out with the cribs in a sloping position at right angles to the ways, but as a very dry mix was used and the concrete vibrated no particular difficulty was encountered as a result of the slope.

Concrete was poured in these forms for a height of about 14 ft. after which they were removed, the cribs launched and completed to their full height while afloat. In all nine cribs were built and no difficulty was experienced either in launching or completing them afloat.

When the excavation was completed the bed for the cribs was levelled up by depositing approximately 12 in. of crushed stone and the cribs then sunk in their correct location by admitting water by means of portable gasoline driven pumps, pumping to a pipe header with valves on outlets to the different crib pockets. The spaces between the cribs were filled with bag concrete placed by divers, and brought up to the level of the under side of the superstructure wall. The cribs were filled partly with material obtained from shore and partly by gravel dredged by a clam shell near the entrance to the harbour. As these cribs were set upon an old rock fill which had had many years to consolidate, practically no settlement occurred when the cribs were loaded and they were therefore set very accurately. After the setting and filling of the cribs the superstructure wall was poured in place, the line being corrected by a slight overhang of the wall. Expansion joints were provided at 50 ft. intervals. The lower portion of the fill, in the V-shaped space between the back of the cribs and the old bank, was filled in with the loose rock previously excavated, after which the other material was placed. One crib was provided with a special valve chamber for the main water intake of the cold storage plant and provision also had to be made for extending a sewer and a small open stream which was collected by a culvert and carried beneath the filling to the outer end of the pier. The new work was connected up to the existing bulkhead cribs of Piers A and B, so that the superstructure wall is now continuous. The pier is now in use for the accommodation of fishing vessels, but up to the time of writing the work of constructing the proposed fish processing plants has not been proceeded with.

### Extension of Wharf at Richmond. (Pier 9)

At the same time as the above work was authorized it was also decided to extend the wharf at Richmond owing to the desire of the Commissioners to remove the plant of the Dominion Coal Company from Pier A to a new location. This coal plant is in the middle of the passenger terminals and when operating in a high wind is objectionable owing to the blowing of coal dust. In addition to this there were requests from certain industries to lease property with water front facilities who could not be accommodated unless further space was provided. The new work at Richmond, about 730 ft. long, connects with the existing wharf parallel to the shore but makes an angle therewith of about 150 degrees. As the old work was a timber crib structure it was decided to use timber crib work for the extension. The new cribs were approximately 100 ft. by 35 ft. and stepped at the back. They were built partly of 10 in. by 10 in. local hemlock and partly, for the longer timbers required, of 10 in. by 10 in. B.C. fir. The face timbers of the cribs were creosoted and protected by sheeting with 3 in. creosoted hard wood, as there is a certain amount of activity by limnoria in Halifax Harbour. (See Fig. 7.)

For the construction of the cribs the contractors decided to use one of the disused ways of the Halifax shipyards which was quite close to the site of the work. This involved launching the cribs in a longitudinal direction instead of the more usual broadside method. Further, instead of launching after a few courses had been completed and finishing the cribs afloat, they were entirely finished and partly ballasted on the ways.

The contractor made a number of experiments with a model before the first launch and the experiments worked out quite satisfactorily. When the first crib was launched, however, shortly after its mid point had passed the end of the ways the leading end plunged downwards suddenly, lifting the rear and throwing the greater part of the weight on to the supporting timbers near the end of the ways. These timbers failed under the increased load and the crib fouled the ways with about two-thirds of its length over the end and considerable difficulty was experienced in extricating it from this position. It was eventually necessary to excavate considerable material in the front of the ways and put new timbers beneath the crib when with the combined efforts of floating derricks and jacks at the rear, the crib was eventually successfully launched. Inspection showed that with the exception of the above mentioned broken timbers which were replaced, the crib had not suffered any serious damage and it was eventually set in place quite satisfactorily.

Trouble was also experienced with the second crib launched, although the difficulties in this case were not nearly so severe. It was finally decided to sheet the leading pockets with 1 in. timber to provide flotation for the front end of the crib when launching. This arrangement solved the difficulty and no further trouble was experienced. (See Fig. 8.) The light sheeting usually failed soon after the crib was clear of the ways and it then floated on an even keel. Owing to the two steps at the back of the cribs certain pockets had to be ballasted before launching so that the cribs would float level and to avoid any tendency to turn over. The weight of filling required for this ballasting was determined by experiments with the model and the results obtained turned out to be quite satisfactory.

While the cribs were being constructed the necessary dredging of the site to provide a bed on which to set the cribs was carried out. The soft material overlying the rock was removed by clam shell dredges and, when suitable, was deposited behind the line of the crib wall to form part of the fill. Rock excavation was carried out in the usual manner by means of drill boats and the broken rock afterwards removed by the dredges. In those portions of the site where the rock was below the level of the crib seats the ground was built up to the required height by a rubble mound formed from rock taken from dredging and from imported material. After the excavation and mound had been completed the beds were levelled up with about 12 in. of crushed stone and the cribs sunk in place.

Before bringing the cribs to the site it was necessary to add a considerable amount of ballast so that they would be floating sufficiently deeply in the water to enable them to be grounded in a comparatively short space of time. This operation, owing to the shape of the cribs, had to be carried out with considerable care, as at times the addition of a very small amount of weight on one side or the other would cause the cribs to tilt over suddenly to an angle of almost 45 degrees. The cribs were usually brought to their desired locations around high water and were provided with guides which held one end in its correct position relative to the last one set, while the free end was manoeuvred into place by means of lines handled from a spud derrick. The cribs were allowed to ground on the falling tide and additional ballast rapidly added to prevent their flotation on the following rising tide, after which they were entirely filled with stone and preparations made for the building of the concrete superstructure wall.

As these cribs could not be set to an absolutely exact line and several of them settled and moved somewhat after loading, the face was brought to the correct cope line by attaching a creosoted timber waling to the cribs, built continuously throughout the whole length of the wall and so shaped that its outer edge was on the correct line. The superstructure wall was poured from a temporary gantry constructed on top of the cribs, and was provided with construction joints at 50 ft. intervals. The lower portion between low and high water was sheathed with creosoted timber which acted as a form and remained permanently in place to protect that portion of the concrete wall within the tide range from deterioration due to frost action. The northernmost end of the crib wall was connected to shore by dumping a bank and the impounded area filled in with material partly obtained by hydraulic dredging and partly from shovel pits close to the site of the work.

It was necessary to provide for the extension of several sewers and surface water drains which had previously discharged along the shore. These were collected in culverts and carried to the face of the new wall.

### Reconstruction of Grain Galleries at Ocean Terminals

While these two larger projects were proceeding a number of smaller works were carried out, the principal of which was the reconstruction of certain grain galleries. The existing galleries carrying grain from the elevator to the various berths were constructed many years ago in timber and a large number of the posts had rotted at their lower ends and in other locations where water was able to collect. In addition, these high timber galleries, the legs of which passed through the timber transit sheds, presented a very considerable hazard should fire break out in any of the sheds. It was therefore decided, instead of undertaking repairs to the existing timber structures, to make a start on the eventual replacement of the whole gallery system in steel. The section put in hand at this time involved the reconstruction of the important tower "B," any accident to which would put practically the whole grain conveyor system out of action, and the galleries on berth No. 25.

In 1931 a steel marine leg for unloading grain from ships had been built on this berth and in the reconstruction of the galleries a double deck system was installed to provide more convenient working from this tower, provision being also made for future extension of the gallery along berth No. 26 which is at present occupied by the Dominion Coal Company, the intention being at some future date to remove the coal plant to another location and to construct a transit shed on this berth. The grain gallery work was carried out by the John S. Metcalf Company, of Montreal, and was completed with almost no interruption to grain traffic. All those portions of the steel work which passed through existing transit sheds were fireproofed with a coating of gunite to a height of some 20 ft. above the sheds to protect them in the event of any conflagration in the sheds. The timber loading platform in front of the transit shed, which was in bad condition, was removed and replaced in concrete, all concrete foundations being brought

Fig. 9—Building Cribs, Imperial Oil Company Pier.

up to the level of the platform and a new concrete apron was also laid at this berth and on berth No. 23 on the opposite side of the basin.

### Construction of Pier for Oil Shipment at Imperoyal

The Imperial Oil Company have a large refinery on the opposite side of the harbour to the city of Halifax where they have their own town known as "Imperoyal." All waterborne shipments of crude or refined products were shipped from a timber dock at this refinery which in 1934 was in poor condition, and about this time the Company decided to build a new pier. Construction on this work was started in the spring of 1935 and completed about January 1936. As shipments are handled from boat to shore or vice-versa by pumping, the main purpose of the pier was to carry the necessary pipe lines to a point at which the ships can lie with sufficient depth of water. As the vessels engaged in this business include the very large tanker, *C. O. Stillman*, the minimum depth of water

**Fig. 10—Launching Crib, Imperial Oil Company Pier.**

had to be not less than 35 ft. at low tide. The pier consisted of four concrete cribs 98 ft. long by 44 ft. wide, set about 2 ft. apart, with 18 in. exterior and 12 in. interior walls dividing the crib into 24 cells. These cribs were built on the Halifax side of the harbour at approximately the same location as those for the Fish Pier referred to before, where the foreshore is at a convenient slope for the construction of ways.

As the contractor for this work proposed to use the sliding type of forms for the crib construction and it was therefore not thought desirable to build these cribs on a slope, the ways were provided with a rocking device which enabled the bottom slab and first 14 ft. of the crib walls to be poured in a horizontal position. (See Fig. 9.) When the pouring had reached this point and the crib was ready to launch it was tilted on the rocking ways until the tilting platform was in the same line as the ways, this being accomplished by nine jack screws attached to a frame behind the platform. The process of tilting occupied from 2 to 3 hours after which the links which prevented the crib from sliding before the tilting was completed were released and the crib allowed to slide down the ways into the water. The tilting platform was built up of nine heavy timbers, one below each cross wall of the crib, and under about the centre of each timber there was a heavy steel box girder which ran on a curved steel plate set in concrete, so that the crib and its platform could roll from the horizontal to the inclined position. When the lower part of the crib was being poured the platform was blocked up solid, and was set slightly off centre on the curved plates to avoid any tendency to run away when the blocking was removed.

While the crib was being tilted it practically formed two cantilevers as it was only supported at the centre point, and to resist the heavy stresses set up at this time some additional steel was added to all cross walls near the top of the 14 ft. height poured before tilting.

It was usually necessary to start the crib moving by means of hydraulic jacks, but very little pressure was required for this purpose. All four cribs were successfully launched without any difficulty, as shown in Fig. 10, the forms being left on during the launch and the pouring subsequently completed afloat alongside the bulkhead of Pier "B" where there was the necessary depth of water at low tide. As the height of the cribs increased it was necessary to ballast them by admitting water to prevent them becoming unstable.

While the construction of the cribs was in progress the necessary dredging was carried out at the site of the pier. The bottom at this point was on a moderate downward slope seaward and to avoid extensive dredging a location was selected where the necessary 35 ft. of water could be provided by dredging a bench on the floor of the harbour, low portions of the foundation being raised by depositing rubble rock to bring the bed up to the correct elevation. When this work was completed 12 in. of crushed stone was laid over the foundation and carefully levelled off by means of sounding and sweeping.

The approach to the pier is by means of a creosoted pile trestle from the shore which carries the 14 pipe lines required for handling the oil. This trestle was also constructed while the concrete cribs were being built to provide access to the work and when everything was ready the first crib was set at the end of this trestle. The trestle itself provided means of holding one end of the crib in its correct position, while the other end was controlled by means of a large salvage derrick boat having the necessary winches and gear for handling a number of lines. When the crib was in the correct position it was sunk by admitting water through valves until it grounded, after which the position was checked and if correct the crib was allowed to fill to prevent flotation on the rising tide. After the first crib was set the second and subsequent cribs were placed in position in the same way, the previous crib providing the means of holding one end while the derrick boat, as before, controlled the other.

Owing to some difficulties in carrying out the dredging work the cribs were completed some time before it was possible to set them and owing to the risk of having these cribs afloat for long periods and the lack of availability of suitable berths for storing them the contractor decided to beach one of the cribs on a convenient piece of foreshore and to lift it again when required by pumping out water. The crib was successfully beached, but unfortunately some days after it slid down the foreshore into deep water,

**Fig. 11—Filling Cribs, Imperial Oil Company Pier.**

taking up a position such that at low water one corner of the crib only was visible, the remainder being totally submerged.

The cribs had been insured by the contractor and the insurance company decided to attempt the salvage of the crib, consequently a contract was placed with a salvage company to carry out the work. A cofferdam was built around the crib, the timber sheeting and strutting being placed by divers. When the cofferdam was completed it was made watertight by placing canvas over the exterior of the sheeting and the cofferdam and crib pumped out. On the first attempt the cofferdam unfortunately was not sufficiently strongly braced to withstand the head and a failure occurred, but on the second attempt the crib was successfully refloated and was found to be entirely undamaged. The tops of the cribs when set were just above high water (as shown in Fig. 11). They were filled with sand, gravel and other material obtained from outside sources and a superstructure wall built completely around the pier, the 2 ft. spaces between the cribs being bridged by concrete slabs which were not rigidly attached to either crib but were left free to move in the event of any settlement, although to date no visible settlement has occurred. The space over the cribs enclosed by the superstructure wall was then filled with gravel with the exception of a concrete pipe trench in which the various pipe lines were housed below deck level, this trench being bridged over by a removable timber cover.

To provide for slight inaccuracies in setting the cribs the superstructure wall projected over the cribs a theoretical 12 in. on all sides, though in practice this 12 in. varied from about 9 in. to 15 in., creosoted timber walings shaped to fit the cribs being first placed to bring the base of the wall to the correct line, these walings being attached to the crib by T-headed bolts in slots to provide for easy removal and replacement when required.

The whole of the deck of the pier with the exception of the pipe trench is paved with a 6 in. concrete slab laid on the fill and a timber coping runs completely around the structure. The approach trestle, in addition to carrying the pipes, also carries a 10 ft. truck roadway as it is sometimes necessary to run trucks out on to the pier for handling barrel shipments. The approach roadway to the pier was built by the Imperial Oil Company's own forces, and all pipe lines were also laid by them, the remainder of the work being carried out by the E. G. M. Cape Company of Montreal.

Of the work described in this paper, Pier "B" transit sheds and the reconstruction of Pier 2 were designed and supervised, under the direction of the author as consulting engineer, by the Harbour Commission staff with Mr. C. S. Bennett as chief engineer. The remainder of the Harbour Commission work was designed by the Commission staff, the author being consulting engineer in an advisory capacity during construction. In the case of the dock for the Imperial Oil Company the author was consulting engineer for the company, as this work did not come under the Commission.

# The Outardes Falls Power Development

*H. G. Acres, D.Sc., M.E.I.C.,*
*Consulting Engineer, Niagara Falls, Ontario.*

**Paper presented at a joint meeting of The Institute and the American Society of Civil Engineers in Boston, October 6th, 1937.**

**SUMMARY.—The paper describes a 65,000 hp. hydroelectric development with an 18 ft. pipe line 5,960 ft. long and two turbines working at 208 ft. normal head. The design had to meet somewhat unusual conditions as regards location and operation.**

Through the initiative of The Ontario Paper Company of Thorold, Ontario, Mr. A. A. Schmon, President and General Manager, there is now in process of creation, on the north shore of the Gulf of St. Lawrence, about 200 miles below the city of Quebec, an entirely new and modern industrial community, listed in the postal directory under the name of "Baie Comeau." This community will be supported by a newsprint mill, now under construction for an initial rated output of 320 tons per day, which will draw the bulk of its wood supply from The Ontario Paper Company's limits in the basin of the Manicouagan river. The Ontario Paper Company is a wholly owned subsidiary of the Chicago Tribune and the Daily News of New York, which newspapers it supplies with newsprint. The towering figure of Colonel Robert R. McCormick, publisher of the Chicago Tribune, stands behind the entire project.

The new mill being inaccessibly located with reference to existing electric utility systems, it was necessary for the Ontario Paper Company to locate and develop its own motive power supply as an integral element of the scheme. The site chosen for this purpose is about 14 miles westward of the mill-site at Outardes Falls. This site is on the Outardes river, immediately adjacent to tide-water, and appears to be the eastern terminus of a series of important natural water-powers, created by the final plunge of the Laurentian rivers over the hard southern edge of the Precambrian Shield, which extends westward across the Province of Quebec through Montmorency, Shawinigan, High Falls on the Lievre, Chelsea on the Gatineau, to Chats Falls on the Ottawa at the Ontario boundary.

The Outardes Falls itself exists as a reach of river something over a mile in length, through which, by way of one main and two subsidiary channels, the waters pass over a series of falls and heavy cascades, the lower ones discharging direct into tide-water. The natural fall over this reach is about 190 ft. at normal high tide.

Work on this project was commenced in 1926, by the company's own engineering staff at the home office in Thorold, under the direction of Mr. Jules T. Jaeger, chief engineer, and later with the Power Corporation of Canada as consultants. When active operations were temporarily suspended in 1932 all of the permanent elements of a concrete main dam and intake had been completed. During this period also there was built and used a small hydro-electric installation. This plant is located at one of the lower cascades, and is again being used as a source of power for construction purposes.

Active operations on the project as a whole were resumed in March of 1936 under the same auspices, so far as the engineering work was concerned, but with Mr. John Stadler of Montreal as general consultant. On account of an accelerated progress schedule, and space limitations in the Thorold engineering office, the engineering and designing staff of H. G. Acres and Company, at Niagara Falls, only seven miles distant, was incorporated for the time being as a unit of the Thorold organization, with Mr. Jaeger retaining the title of chief engineer in respect of both organizations. Under this arrangement, all of the economic and layout studies, all of the specifications and contract plans, and all phases of the subsequent engineering and design detailing relative to the Outardes power development were handled in the offices of H. G. Acres and Company, while all similar procedure relative to the mill, townsite and woods operations was handled in the company's engineering office at Thorold.

Actual construction work commenced at Baie Comeau and Outardes Falls with the opening of the 1936 working season, under the direction of the company's own field engineering staff, and with The Foundation Company of Canada in charge of construction operations.

The completed main dam being already in existence, as previously explained, the matter of conception, design

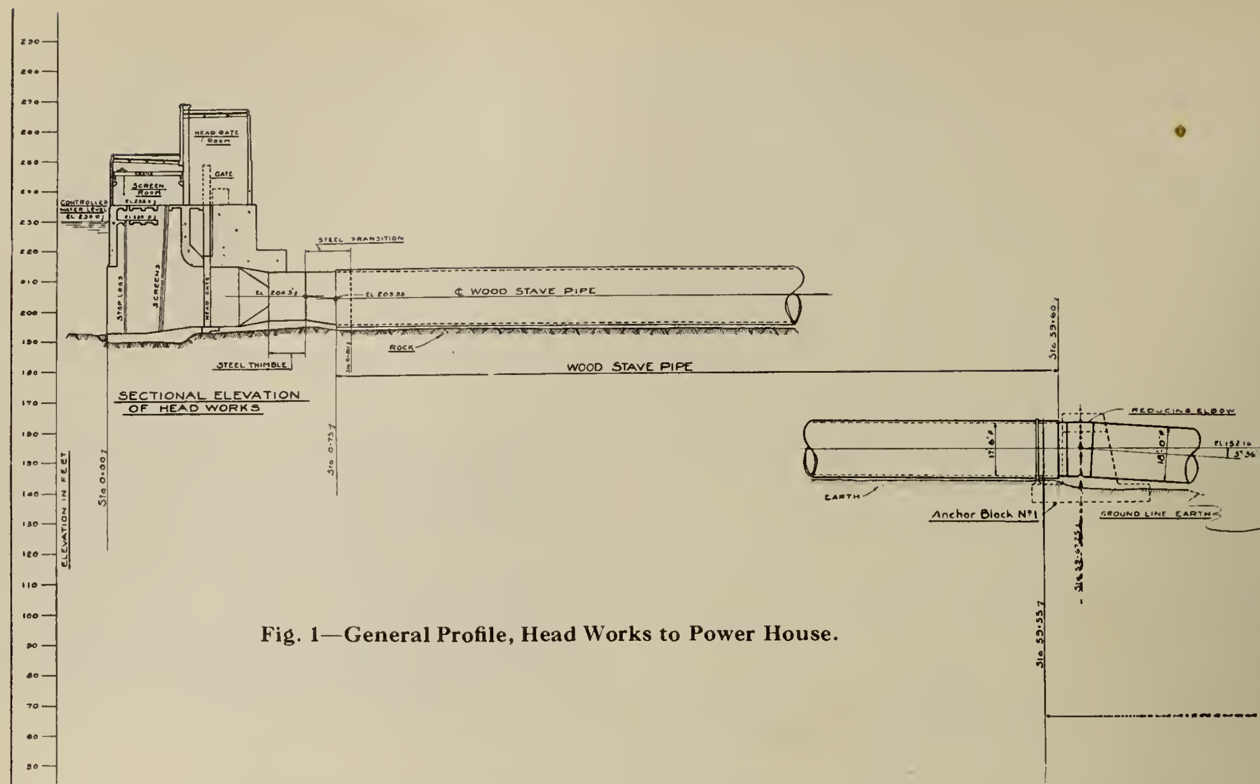

Fig. 1—General Profile, Head Works to Power House.

and construction involved the remaining major elements of water connections, power-house and tailrace, main and auxiliary machine installation, transmission line and step-up and step-down transformation.

The conception and design of the above elements of the scheme were governed by the following primary considerations:—

(1) The industry at Baie Comeau has an assured raw-material supply, and an assured and stable market for its total rated output, so that an adequate, dependable and continuous source of motive power was an outstanding consideration, by reason of its extraordinarily direct influence upon the fixed-charge and overhead elements of mill production cost.

(2) Owing to the fact that the operating system comprised an isolated and single source of power, supplying an isolated and single consumer with a large block of power to be applied almost wholly on industrial load, inherent hydraulic and electrical stability constituted the paramount consideration associated with the technical design.

(3) In order to make good the time schedule prescribed by the Ontario Paper Company, and in view of the fact that the site is only accessible for the delivery of equipment and construction material for the period May to November, inclusive, in each year, it was necessary to take into consideration and to study conditions, relative to conception and design, which are not ordinarily associated with a project of this type.

The general profile, Fig. 1, indicates the topographical features which fixed the general principle of the design. From the intake location down to station 59+60 the drop in adjusted gradient is 51.8 ft., indicating the economic advantage of an open pipe-line under a static head limitation which made it possible to consider wood-stave construction.

From station 59+60 to the power-house the increased gradient, and the necessity for a rather deep cut through the overburden at the crest of the hill, involved the consideration of some material other than wood for this section of the pipe-line.

The total length of pipe-line from intake to power-house is 6,580 ft., so that surge control was an unavoidable feature of the design. The surge-tank was located at station 63+76, for the primary reason that at this point occurred the most suitable and accessible outcrop of ledge for the tank foundations. The second advantage of this location is that it enables the surge-tank to exercise control over 96 per cent of the total length of the water column, with a proportionately large measure of relief to the duty on the turbine governors.

The above combination of economic and physical conditions constituted the basis upon which the details of layout and design had to be developed.

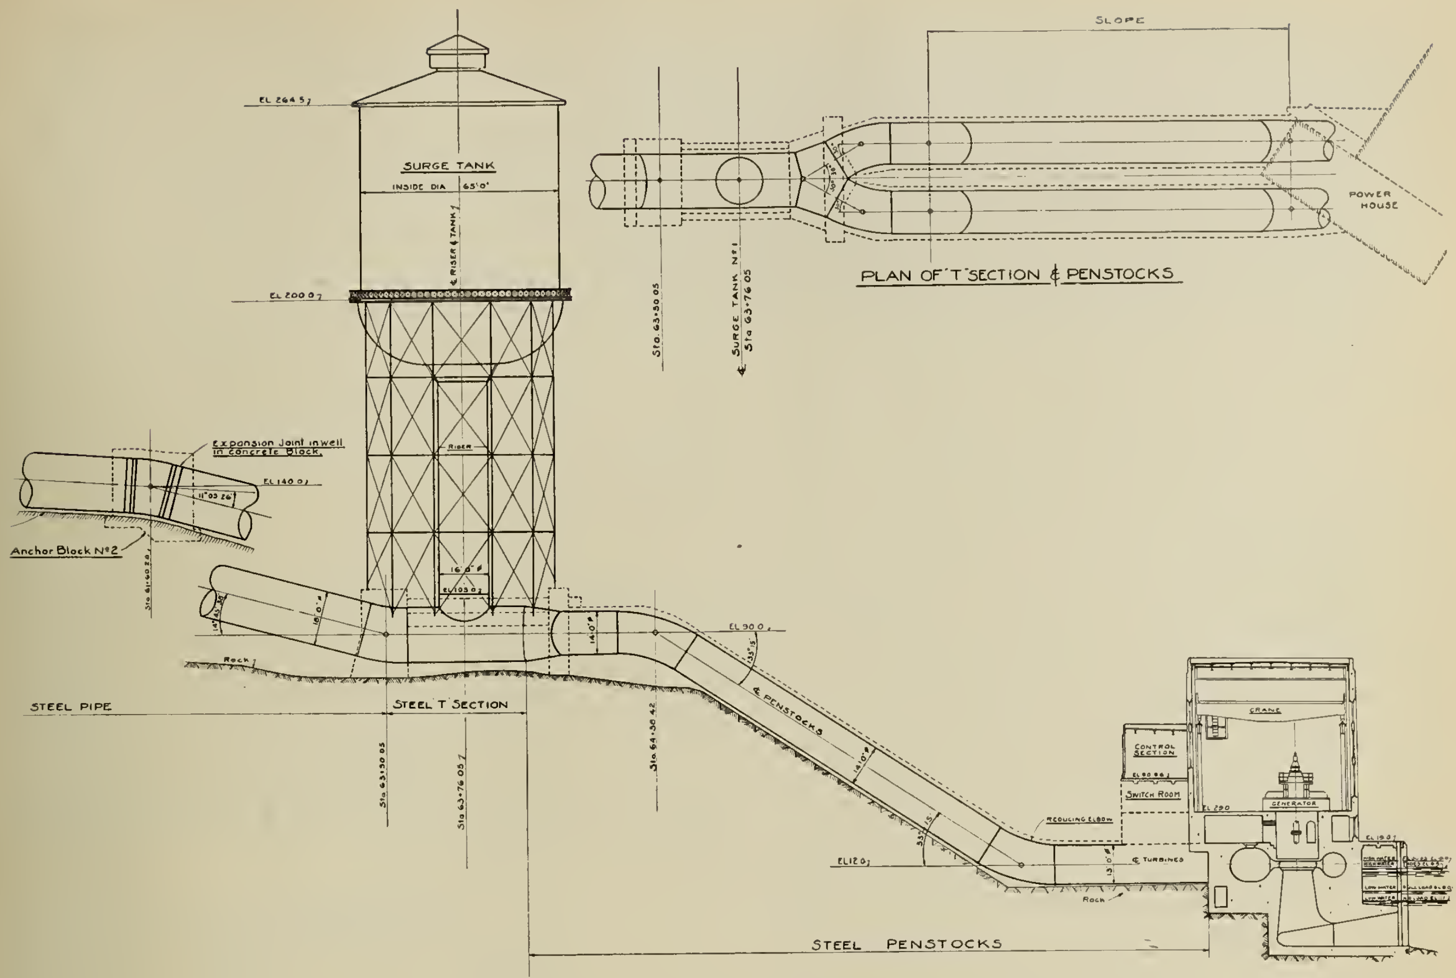
### Available Head

The gross head continuously available was of course fixed by the relationship between tailwater elevation at high tide and the regulated level in the headpond, as governed by the structural features of the main dam, already in place. The relationship as thus fixed made available a gross head of 222 ft.

It was found, after giving consideration to the various factors involved, one of which was the primary necessity of obtaining at all times an ample supply of motive power for the Baie Comeau mill, that the allowable economic sacrifice of gross head would be about 14 ft., so that the normal effective head on the wheels was fixed at 208 ft. at high tide.

### Available Flow

At the time the study of flow conditions was made, continuous records of the daily flow of the Outardes river at the power-site were available for an 11-year period, 1923-24 to 1928-29, and from 1930-31 to 1934-35, inclusive. These records are shown in condensed form on Fig. 2 in terms of average monthly flow for the period. This curve shows a minimum recorded monthly flow to have occurred in February of the year 1924, and that later, in March of



1926, there occurred a minimum which was substantially the same as that of February, 1924.

About 75 miles above the power-site there is a lake storage available, which could be developed for a gross capacity of not less than four billion cubic feet. The effect of this storage is also shown on Fig. 2 by the dotted lines subsidiary to the curve of natural flow.

A further and much larger increment of storage is also available at the head-waters of the river, which would make available a large additional block of primary power.

It is not necessary to elaborate on the flood flow conditions of the Outardes river, as the discharges within the flood range are beyond the limits of economic development, and are interesting only insofar as they are related to the ability of the main dam to safely control and dispose of them.

In this latter connection the records reveal two significant facts: the first being that the maximum recorded peak flow is 85,800 sec. ft., and the second being that the peak flow in every year of record does not occur for a considerable time after the initial winter break-up, the primary reason for this condition being that the Outardes river flows generally in a southerly direction.

### Available Power

Figure 3 is complementary to Fig. 2, and shows the power available from the recorded monthly and daily flows under a normal effective head of 208 ft. Here again the additional primary power obtainable from immediately available lake storage is shown by the dotted lines subsidiary to the curves derived from natural flow.

This figure indicates that 39,500 e.hp. is available from the minimum monthly run-of-river flow, and 52,100 e.hp. of primary power from run-of-river flow supplemented by the immediately available increment of storage, as above mentioned.

### Intake

The intake, the substructure of which was built with the main dam, consists simply of two main openings, each having three bays protected by a curtain-wall and three sets of removable steel racks. Only one of these main openings is being made use of at the present time, the other being temporarily bulkheaded by stop-logs, reinforced by a steel plate diaphragm laid on the rack supporting beams.

In the other main opening, and behind the racks, are placed two roller-mounted, steel head-gates, which are raised by a stationary motor-operated hoisting mechanism, and which in emergency can be tripped electrically from the control-room in the power-house and dropped by gravity.

A substantial superstructure building has been provided to house the hoisting mechanism of the gates, and to permit the effective use of artificial heat under low temperature conditions.

At the rear of the main opening, now being made use of, is an embedded steel thimble to which the pipe-line will be attached.

### Wood Stave Pipe-Line

This pipe-line is 5,960 ft. in length, and the subgrade consists mainly of a mixture of sand, loam and clay. In the upper half of the grade occur several outcroppings of ledge and two comparatively short filled embankments.

As the result of a series of soil bearing tests it was found that the natural soils along the subgrade had bearing values well within the limits of economical footing design,

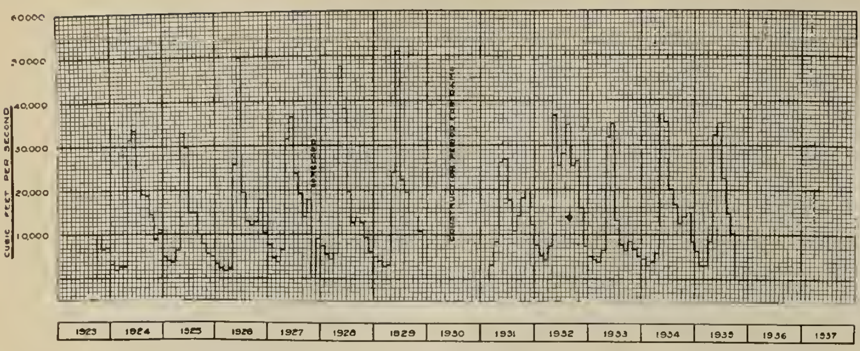


Fig. 2—Outardes River Average Monthly Flow.

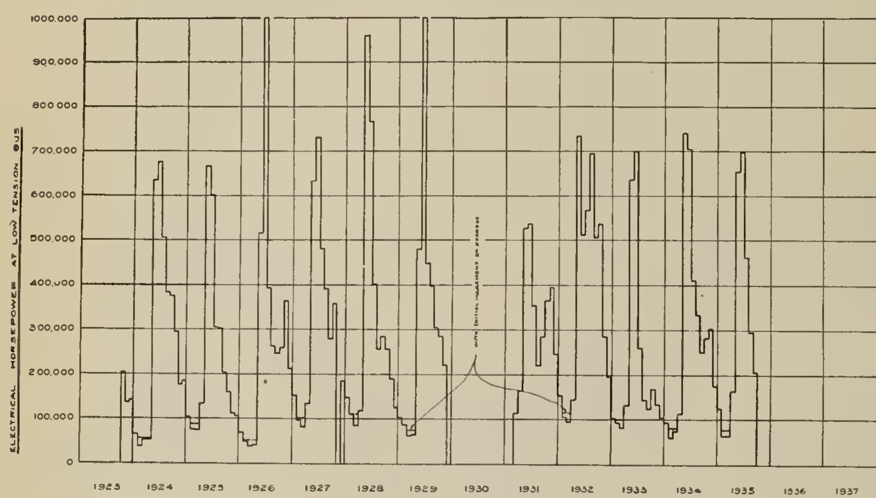

Fig. 3—Outardes River Available Power.

but that the filled embankments could not be relied upon without the help of piles. These piles were driven either to rock or sufficiently deep into the natural soil subgrade to assure the required bearing value. Tapered cast-in-place piles were used for this purpose, 258 in all being placed, in length ranging from 7 to 35½ ft.

The wood-stave pipe has an inside diameter of 17 ft. 6 in., and will be the largest diameter pipe of this type built up to the present time. The staves are special grade Douglas fir, $4\frac{11}{16}$ in. thick, with double-tenon butt joints, tongued and grooved edges, and faces milled to the radius of the pipe. The bands are of one inch diameter, medium grade structural quality steel, with malleable cast-iron shoes. The barrel of the pipe is supported on reinforced concrete spread footings and structural steel cradles spaced on 9 ft. centres. An assembled section of the pipe-line, saddle and footing is shown on Fig. 4.

The wood-stave section of the pipe-line terminates at station 59+60, as shown on Fig. 1, immediately upstream from a heavy concrete anchor block which constitutes an element of the junction between the wood-stave and the steel section of the pipe-line.

### Steel Pipe-Line

The steel pipe-line begins at the anchor block at station 59+55, and thence through the cut in the overburden at the crest of the hill down to station 64+07, where it terminates in a Y-branch immediately below the surge-tank tee.

This section of the pipe-line is supported in part on ledge and in part on spread footings, spaced at approximately 22½ ft. intervals, in combination with intervening reinforced concrete struts, which terminate in a combined thrust and anchor block located on solid ledge, and integral with the surge-tank foundations and the reinforced concrete structure enveloping the surge-tank tee.

The principle of design used for the steel pipe-line is that of the elastic theory of thin membranes or the so-called "shell theory." Analysis by this theory shows that the main stresses in the pipe plates are direct tensile and compressive stresses and shearing stresses, bending stresses being very small. The exemplification of this theory requires that the pipe be kept truly circular and this has been accomplished by providing ring-shaped steel plate girders, 18 in. deep at approximately 22½ ft. centres. Short posts at each end of the girder horizontal diameter provide a means of support whereby the load is taken to the footings.

Since only direct and shearing stresses govern the design of the pipe plates, and bending stresses are concentrated in the ring girders, metal can be used with great economy and a large saving in tonnage effected.

On each side of the anchor block, located at the central bend, a slip-type expansion joint has been provided. These expansion joints we considered essential in order to reduce thermal stresses in the pipe shell to a minimum and to relieve the central anchor of the large lifting forces which would otherwise obtain. Foundations for this anchor are on soil, since ledge rock was known to be at a depth of about 45 to 50 ft. below the natural grade.

For the joint purpose of frost protection and of stabilizing the slopes of the cut at this point, the lower-half circumference of this steel pipe will be given a protective coating and backfilled. The upper-half circumference will be protected by an insulated housing.

### Surge Tank

The surge tank is of the Johnson differential type, with an outside riser 16 ft. in diameter, and a tank 65 ft. in diameter. The main tank is supported on a 12-legged tower, and the completed structure will be 200 ft. 9 in. high from the horizontal centre-line of the surge-tank tee to the peak of the roof.

The whole of the outside riser and the dish bottom of the tank up to the gallery floor are to be insulated by a layer of rock wool with a weather-proof outer coating. The tank roof is to be similarly insulated.

A non-spilling tank of this type, correctly proportioned, affects in a positive and absolutely non-failing fashion those hydraulic changes in the water column, which, acting together with the turbine adjustment, are required to maintain equilibrium between power developed and system load demand. At the same time the tank affords the maximum of protection against dangerous water hammer pressures.

### Penstocks and Valves

The two penstocks now to be installed are 14 ft. in diameter, and, after entering the rear of the power-house substructure, each terminates in a 13 ft. diameter butterfly valve.

The subgrade of these penstocks is entirely in ledge, being at the grade of the natural surface at the Y-branch and in a cut about 55 ft. deep adjacent to the power-house. On this account the footing design was very simple, and involved nothing beyond supporting the pipe at its designed grade during the process of assembly.

As in the case of the steel pipe-line, the penstocks are of steel plate, welded throughout, but without expansion joints. Upon completion of assembly they will be encased in concrete and the rock cut will be backfilled.

The wickets of the butterfly valves are of annealed cast steel and are provided with horizontal trunnions. The seal is effected by renewable bronze segments fitted in an annular groove at the periphery of the wicket and seating on a stainless steel surface electrically deposited on the housing.

The housings are of one-piece construction, fabricated by electric arc welding from rolled plates and ribs, and after fabrication were stress-relieved in a furnace sufficiently large to accommodate the entire housing.

The operating cylinders are mounted vertically and are actuated by oil pressure, at 300 lb. per sq. in., which is controlled from two stations. One of these is a push-button in the control-room for closure only, and the other is a control stand located on the generator-room floor, from which point the valve can be either opened or closed by manual operation of an hydraulic valve. Suitable indicators, interlocks, and signal lamps have been provided.

### Turbines

The available net head at the Outardes site was such that the total motive power requirement of the Baie Comeau project could be concentrated in one main unit. This was obviously the most economical arrangement from the standpoint of subsequent operation as well as the first cost of that portion of the installation, as a whole, which included water connections below the surge-tank and the power-house structure with its contents.

Inasmuch as the already established market outlet for its products permitted the Baie Comeau mill to operate continuously at full rated capacity, the elimination of stand-

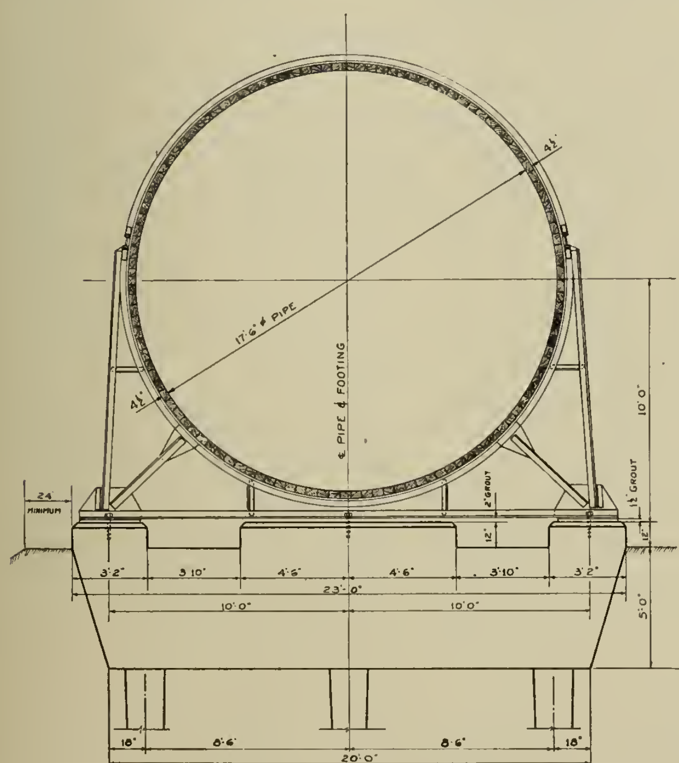

Fig. 4—Typical Section Wood Stave Pipe.

by losses resulting from interrupted operation and the realization of a maximum rate of return on invested capital became almost directly dependent upon an adequate and continuous supply of motive power. The imposition of this vital function upon the source of power supply was, in itself, sufficient justification for providing at the outset for the installation of a duplicate spare unit.

Associated with these primary considerations were two conditions peculiar to the site itself. During the winter the Outardes river, for a distance of approximately 200 miles above the power reach, is subject to ice blockages which temporarily obstruct the flow and result in short-period irregularities and deficiencies in the supply reaching the headpond.

The headpond, in turn, is small, having an area of only 1,750 acres, so that there will be a comparatively large and rapid headpond draw-down necessary in order to make good temporary deficiencies in flow due to ice blockage.

With the intake as now designed and built, a maximum draw-down of 15 ft. can be accommodated without exposing the lower line of the curtain-walls, and advantage was taken of this fact to specify a turbine so designed and dimensioned as to be capable of producing the total motive power requirements of the Baie Comeau mill under a temporary minimum net head of 193 ft.

The final consideration under this head arose out of the fact that the construction schedule made it necessary to have the power-house substructure completed up to the level of the turbine deck not later than August of 1936, and inasmuch as the work of layout and design did not get under way until March of that year, there was no time to wait for final layout drawings from the turbine contractor. It was therefore necessary to design the lower sections of the power-house substructure complete, and to require turbine manufacturers to bid and base their guarantees upon a definitely fixed draft-tube design.

Accordingly, the specifications called for two vertical, single runner, steel plate scroll-case units, turning at 180 r.p.m., each unit being so dimensioned and designed as to produce 32,600 hp. under the minimum net head of 193 ft. Under the normal net head of 208 ft., each of these turbines will deliver 35,300 hp. at the main coupling.

The turbines, as now being constructed, have a diameter of 11 ft. 2 in. at the scroll-case inlet, a shaft diameter of 24 in., and a maximum out-to-out diameter of 32 ft. The salient features of the turbine installation are shown on the cross-section, Fig. 5.

### Generators

The basic design of the generators was fixed by the simpler characteristics of the load. The six-day weekly load-factor was specified as not less than 90 per cent, and the synchronous load of the mill was such that operation could be maintained continuously at 95 per cent power-factor lagging at rated speed and voltage. As 25,000 kw. at the generator terminal were sufficient for the motive power requirements of the mill, the specifications called for a rated capacity of 26,315 kva.

Two water-wheel type generators were therefore provided for, each having the above specified capacity at 6,600 volts and 180 r.p.m. These generators were of the two-bearing type, with top mounted thrust bearing and direct-connected exciters, 3 phase, 60 cycles, star-connected. The estimated revolving weight of this unit, inclusive of turbine runner and shaft, is 135.5 tons. The general dimensions and outline are shown in Fig. 5.

### Electric Steam Generation

The process steam requirements of the Baie Comeau mill will be such that, under ordinary circumstances, it would be necessary to install three fuel-fired, steam generating units, any two of which would have sufficient capacity to carry the mill load. This would be necessary in order to give the process steam supply the same assurance of adequacy and continuity as was associated with the supply of motive power.

In this connection it was considered that the spare generating unit at the Outardes plant could properly assume the function of a steam generating unit without impairing its utility as a duplicate source of motive power supply, so that in place of a third fuel-fired steam generating unit at the Baie Comeau mill there was substituted for it an electric steam-boiler installation of sufficient capacity to take somewhat more than the total output of either one of the main units in the Outardes plant. So far as capital costs were concerned, this electric steam unit at Baie Comeau simply took the place of a third fuel-fired unit which would otherwise have been installed, while, as to annual cost, the economy of this scheme was measured by the annual saving in coal consumption which would result from the carrying, continuously, of something over half of the process steam requirements of the Baie Comeau mill, by the Outardes spare unit, while at the same time not interfering with the stand-by function of this unit as a source of motive power supply for the mill.

### Transformation and Switching

This element of the installation was, of course, not as vitally involved in the matter of an assured supply of motive power as the turbines and generators, but it was nevertheless a distinct advantage, as related to the short-period interruptions to which apparatus of this class is ordinarily subjected, to have it also installed in duplicate. Having in mind, however, as explained in the next preceding section, that the scheme of operation required both main units in the Outardes plant to be continuously under full load whenever they were in condition to operate, the installation of transformation and switching equipment in duplicate was not only advantageous but definitely necessary.

The transformation and switching at both the generating and delivery ends are of the outdoor type throughout.

The transformer installation at the power-house consists of two 3-phase, 60-cycle banks and a spare, stepping up from 6,600 to 66,000 volts. Each of these banks has a capacity of 25,000 kva. and each is connected to its own generator.

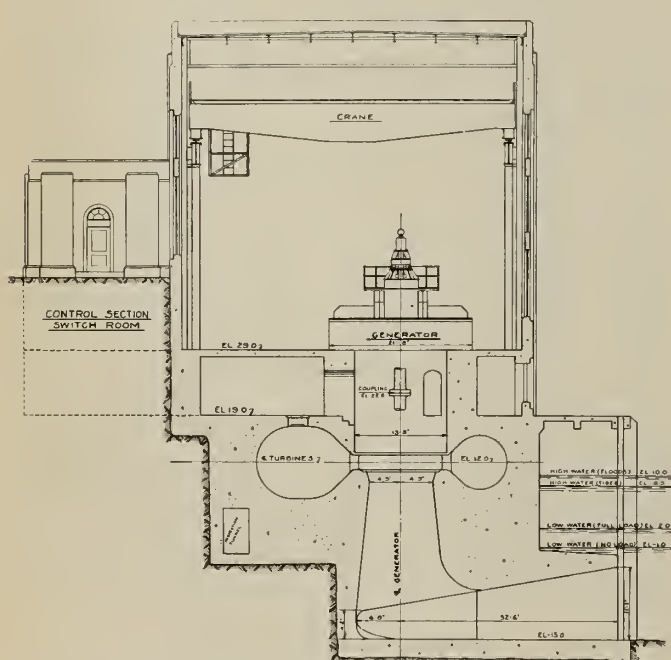

**Fig. 5—Cross Section of Power House Showing Arrangement of Main Unit.**

At the mill substation are installed three 3-phase, 60-cycle banks and two spares. One bank and spare steps down from line voltage to 4,600 volts for electric steam generator service, and one bank down to 2,300 volts for grinder-room service, and the third bank and spare down to 575 volts for general mill service, the 4,600 volt spare transformer being also available for 2,600 volt service if necessary.

All transformers are water-cooled and designed for a full load temperature rise of 50 deg. C. They have a reactance of 7 per cent, and are to be star-connected on the high, and delta on the low-voltage side, with neutrals solidly grounded. All are provided with four 2½ per cent taps on the high-voltage side, so that proper operating voltage may be available at the mill under all conditions of load.

To obtain the greatest economy and flexibility from the switching equipment, the stations at each end of the transmission line were designed as a ring bus system and all switching, except station service, is done on the high-voltage side of the transformers. Such an arrangement permits any one breaker in the ring to be removed for repairs without seriously affecting the operation of the station, but two breakers must be opened if any line or transformer bank is to be isolated.

The oil circuit breakers are of the high speed type, with a rupturing capacity of 500,000 kva., and oil-blast explosion chamber contacts. Each breaker consists of three single-phase tanks equipped with oil-filled bushings, and each tank is provided with two 500-watt heaters. They are solenoid operated by remote control from a control-room inside the power-house or paper mill, the power supply being obtained from a 125-volt storage battery. All breakers are interchangeable in the ring bus, and have bushing type current transformers of the same rating for metering and relaying.

Lightning arresters and impulse spark gaps are provided at each end of each transmission line to limit the potential rise to safe values during transmission line disturbances.

The buses and disconnecting switches are supported on galvanized steel structures, which were shop assembled before galvanizing so as to ensure ease of erection with a minimum of damage to the galvanizing.

Figure 6 shows, in half section, the general arrangement of the step-up transformer and switching layouts, respectively.

This structure is located at the south end of the power-house, with its floor about 12.75 ft. above the machine-room floor.

The high-tension ring-bus layout made it convenient to place one transformer bank, with its associated breakers, on either side of the transformer transfer track, and underneath this track there is space provided in the form of a tunnel, having a floor at the same elevation as the machine-room floor, for the power and control cables, water, oil piping, etc. The oil piping is so arranged that oil from the transformers or breakers will flow by gravity to the filter without in any way disturbing the apparatus.

A large door has been provided in the power-house south wall, through which the transfer track is extended to a gallery floor in the machine-room which is within reach of the main hook of the power-house crane. This arrangement provides convenient facilities for transformer substitutions and repairs. It is also thereby possible to store the spare transformer inside the building, thus eliminating the necessity of keeping it heated during the winter months.

As the low-tension cable leads to the generators are nearly all indoors, it was advisable to form the transformer delta near the generators instead of at the transformers. On account of the heavy low-voltage currents, six power cables per unit were required, and these were all placed inside the transformer delta connections, thereby dispensing with the usual transformer delta bus.

### Transmission Line

The route of the transmission line is, for the most part, through wet shallow muskeg with a sand bottom, and occasional ledge outcrops. Under such conditions the matter of footings for the line supporting structures became a problem of structural design, which, for simplification and standardization, required that the number of footing structures be reduced to a minimum. This consideration definitely eliminated wood pole construction and indicated an advantageous use of long spans supported on steel towers.

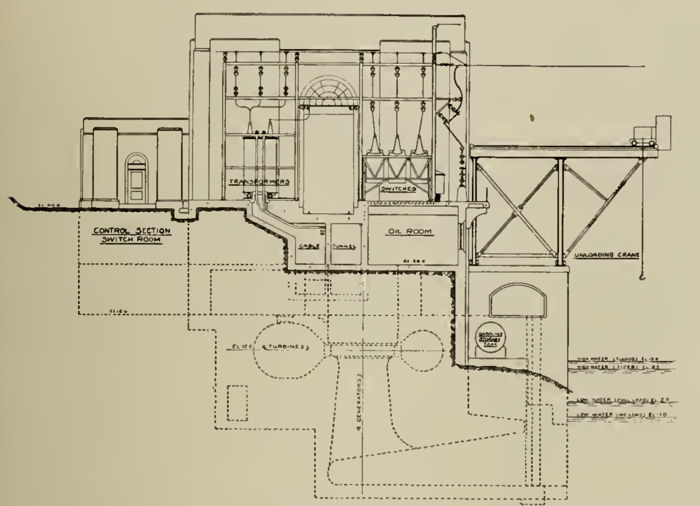

**Fig. 6—Sectional Elevation, Transformer and Switching Station.**

As the initial and future load conditions were closely defined, the line characteristics were susceptible of fairly precise determination, and an extensive comparative analysis was made of various voltages, conductor sizes and materials, etc., in order to derive a rational economic balance relative to capital cost, annual cost and line loss, assuming from the start the necessity of two 3-phase circuits to assure the continuity of service which the primary elements of the problem as a whole required.

This study resulted in the adoption of two circuits of 266,800 c.m., A.C.S.R. conductor, star-connected for 66,000 volts phase to phase and 38,100 volts phase to ground. The two circuits in parallel will carry the total station rated output of 52,360 kva. with a regulation of 3.25 per cent at 99.28 per cent power-factor, and one circuit will perform the same service with a regulation of 6.75 per cent.

The conductors are supported by suspension type insulators on double-circuit steel towers. The towers have a nominal spacing of 800 ft., and have a total height of about 80 ft. above the ground line. A 3/8-in. steel ground wire is carried on the tops of the towers, and there are a total of 82 towers of the various types required in the 13½ miles of line.

A graded highway is now under construction between Baie Comeau and Outardes Falls, which follows as closely as possible the transmission line route. This highway is being utilized for the erection of the line, the material for which was delivered in the fall of 1936 and distributed along the line during the following winter.

### Power-House

Rather unusual conditions were associated with the location and design of the power-house, relative to the position of underlying ledge, and the location of the pipe and penstock centre-line.

The only available location for the power-house was in the face of a practically vertical cliff, at the foot of which was a narrow parallel shelf of solid ledge dropping off vertically in turn into saturated sand and gravel of unknown depth. The obvious expedient under the circumstances was to minimize the heavy rock cut in the face of the cliff by laying out the nose-line of the tailrace piers parallel with and along the edge of this subsidiary shelf of ledge. The position of the power-house building was therefore fixed by the primary necessity of making use of solid ledge at the lowest natural elevation which the site afforded, and the secondary but important consideration of simplifying as much as possible a more-than-ordinarily expensive piece of rock work.

As previously mentioned, the rock cliff at the power-house location was surmounted by a steep slope of overburden consisting of a sub-stratum of blue clay, covered in turn by a thick layer of well-drained sand. The problem of supporting and holding an 18 ft. diameter steel pipe on this slope was governed by the following independent considerations, in order of their importance: first, the locating of accessible natural ledge to serve the double purpose of a solid foundation for the surge tank and a strong anchorage for the thrust-block at the terminal elbow of the steel pipe-line; second, a minimum of disturbance to the natural equilibrium of the overburden slope as a result of such excavation as might be necessary; and third, the confining of the excavation as much as possible to the sand overburden, with a consequent minimum of disturbance to the clay sub-stratum. The position of the steel section of the pipe-line was therefore fixed, as in the case of the power-house, by the joint influence of topographical conformation of the site and the foundation conditions.

The position of these two elements of the scheme having been thus fixed, the location of the penstock centre-line was also of necessity established, and instead of meeting the power-house rear wall at right angles, as is usually the case, it intersected the longitudinal centre-line at an angle of 34 degrees and 28 minutes. This complicated the basement layout to such an extent that it was necessary to make a ¼ in. scale model in order to properly visualize the valve-chamber clearances and the shape and volume of usable basement space which was required for piping, wiring and auxiliaries. Special provision had also to be made for bridging the wide skew opening in the northwest corner of the rear wall in order that the building con-

**Fig. 7—General View of Outardes Development.**

struction might proceed in advance of the erection and concreting-in of the penstocks.

The power-house building is of sufficient size to house the first two main units only, with auxiliaries. A temporary end wall is provided so that the north end of the building can be extended to accommodate any additional installation in the future.

The substructure is of reinforced concrete throughout, the foundation elevation being such that the draft-tube inverts are about 23 ft. below the level of ordinary high tide.

The frame of the superstructure is of structural steel with concrete encased columns supporting the crane girders, roof trusses and purlins. The walls are of reinforced concrete and the roof of Aerocrete slabs surmounted by a 20-year specification tar-and-gravel roof. Copper flashing is used throughout, and all construction joints are sealed with copper water-stops.

Apart from the complications arising from the entrance of the penstocks at an acute angle with the power-house centre-line, as already described, the only other unusual feature of the power-house structure arose from the fact that all heavy equipment had to be delivered on scows. In order to place this equipment within reach of the main hook it was necessary to provide for an opening in the power-house front wall, opposite the erection bay, and at the floor elevation of the machine-room main floor. The erection-bay floor was extended through this opening and out over the tailrace piers, which supported it, with flush rails at transformer gauge embedded in it. On this exterior platform there was erected a cantilevered steel framework supporting a 22½-ton motor-operated trolley hoist, by means of which loads were lifted from the scows, landed on the platform, and either trucked or skidded through the opening where they could be reached by the main hook. The general arrangement is shown in the section in Fig. 6.

### Auxiliary Equipment and Services

The most important items of auxiliary equipment are the turbine governors and the stop-log and sluice-gate hoists for the main dam.

Each main unit has its own individual oil pressure governing system, the actuator, oil pump and sump tank being designed as a unit and enclosed in a steel cabinet, on the face of which the controls and indicators are mounted.

The actuator flyball head is driven by a synchronous motor which receives its power supply from its own independent permanent magnet generator. This generator is mounted on the pilot exciter frame, and is driven through two flexible half couplings by the main unit generator shaft. The flyball head must therefore rotate in exact synchronism with the speed of the unit to which it is electrically connected, and will not be affected by any other electrical or mechanical condition.

The governor operating fluid is oil at a pressure of 300 lb. per sq. in., the pressure tanks being located immediately adjacent to their respective cabinets. The oil piping, however, will be interconnected so that in the event of trouble with one of the pumps it may be isolated and both governors will continue to operate under power pressure. No recourse need be had to the hand pump under such circumstances.

Each actuator is provided with the following manual controls located on the cabinet panel face: speed level, gate position limit, speed droop, generator air brake valve, and the transfer valve which permits operating the servomotors through either the auxiliary valve or the main relay valve. In addition, remote control of the speed may be accomplished from the bench-board in the control-room.

There is one pressure tank and one receiving tank only for both butterfly valves. As the demands on the valve oil pressure system are light, and are usually made at predetermined times, a separate oil pump for this service was dispensed with, and the butterfly valve oil pressure system was arranged for interconnection with either of the turbine governor pressure systems. A small transfer pump returns oil from the butterfly valve receiving tank to either of the governor oil sumps.

The main dam was provided with six roller-mounted steel crest gates operating in openings 10 ft. wide with sills 30 ft. below controlled water level. These are for headpond control, and are manipulated by a 16-ton electrically operated trolley hoist. There are, in addition, eight 30-ft. openings, with sills 10 ft. below regulated water level, which are to be closed by combination steel and timber stop-logs. These logs are to be placed or removed by a 25-ton electric stop-log machine of the rack and pinion operated spud type.

Two sluice and pier dams, known as "Dam A" and "Dam B," were built to close out neighbouring low rock contours. The former has thirteen, and the latter six 30-ft. openings. The stop-logs and stop-log machine are similar to those provided for the main dam, except that the latter has bogey trucks to negotiate the curve on Dam A and that between the two dams.

An auxiliary and emergency service unit was considered necessary on account of the isolated location and the low winter temperatures from which the plant, as a whole, must at all times be protected. A gasoline engine set offered the best combination of convenience, dependability and economy, and the installation consists of a 425 hp., 900 r.p.m. engine direct-connected to a 550-volt generator with its own individual exciter, rated 250 kva. at 80 per cent power-factor. This generator is connected through an automatic oil switch to the 550-volt station service bus, so that any station service load may be supplied from this unit, as well as from either of the main generators.

There has also been provided a stand-by M.G. exciter set, which consists of a 1,200 r.p.m., 500-volt, A.C., 250 hp. motor direct connected to a 150 kw. direct current generator and a 3 kw. pilot exciter. The generator and exciter circuits are arranged so that they can be connected at the control desk to either main generator and voltage regulator.

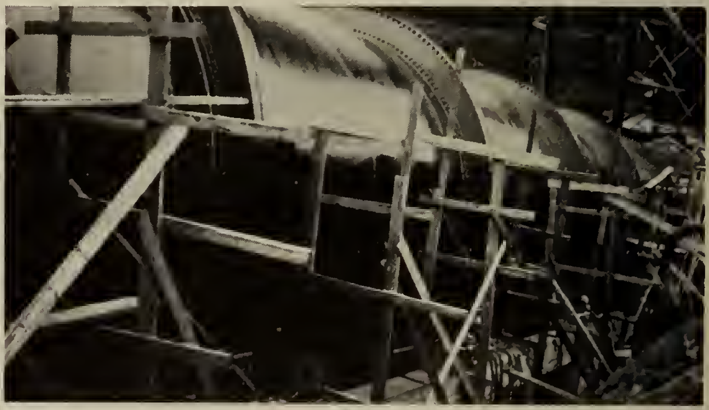

Fig. 8—18 ft. dia. Steel Pipe Showing Ring Girders and Struts.

The station service load is divided into two primary elements, and each element is served by its own transformers and control equipment. The more important of these is the station service supply to the governor pumps, cranes, spare M.G. exciter set and other auxiliary equipment in the power-house, and to the building heating and lighting. The other element, served by a 150 kva. bank of transformers, supplies power at 2,200 volts to the intake gate hoist and dams, which are located about 1 mile from the power-house.

Each generator bus is tapped by a separate feeder for this load, and the two breakers are interlocked electrically so that both feeder breakers cannot be closed at the same time, thus obviating the possibility of paralleling the generators on the low-voltage side of the transformers. The service high-voltage switching consists of a metal clad structure of four units, one unit for each generator feeder, and one unit for each element of the station service load. The breakers are rated 6,900 volts with a rupturing capacity of 250,000 kva. (sufficiently large to take care of the ultimate station generating capacity) and a short time current carrying capacity of 50,000 amp. The tanks and covers are of welded plate steel, and the contacts are of the oil blast principle, so as to reduce the arcing time to a minimum.

The power-house station service transformers consist of a bank of three 150 kva., single phase transformers, stepping the voltage down from 6,600 volts to 550 volts. The intake and dam station service transformers consist of three 50 kva. transformers stepping the voltage down from 6,600 to 2,200. Both banks are connected delta-delta so that if trouble develops in one transformer, the bank, connected in open delta, may carry on at reduced capacity. The transformers are of the standard distribution self-cooled type.

The 550-volt distribution switches are of the "Nofuz" breaker type for all of the motor and feeder circuits, except the stand-by exciter motor circuit, which switch, on account of its large capacity and infrequent service, is of the fused vacu-break type.

A storage battery has been installed for the primary purpose of controlling the oil circuit breakers, but also as a source of power for emergency lighting, and to supply power to a few small miscellaneous pieces of apparatus. It is the standard type of storage battery used for such purposes, consisting of 60 cells, and operating at a nominal potential of 129 volts.

Duplicate battery charging sets are provided, one as a stand-by to the other. They consist of a 5 hp., 60 cycle, 550-volt motor direct connected through a solid coupling to a 3 kw., D.C., shunt-wound generator. All signal lamps and certain emergency lighting circuits will be connected to the battery permanently, so as to provide sufficient load to hold the generator voltage steady.

As previously stated, a tunnel is located underneath the centre of the switching station for power cables, control conduit and oil and water piping for the transformers and breakers. Adjacent to this tunnel, at the south end of the building, is located an oil storage and filter room containing separate tanks for clean and dirty transformer and breaker oil.

A system of piping has been provided whereby oil may be transferred to or from the transformer or breakers to the proper tank or to the filter for purification, and thence back to either clean oil tank. This filter, with its centrifuge, is capable of handling 300 gal. per hr., and is equipped with a heater and motor-driven pump. Each transformer tank contains 1,280 gal., and each breaker tank contains 300 gal. of oil, thus making a total of 11,280 gal. of active oil to be served.

Combination steel and timber stop-logs have been provided for unwatering the turbine draft-tubes. They are manipulated by a gantry-type hoist travelling on the tail-race deck. The hoist is electrically operated and provided with a mechanical follower for engaging the logs.

During the normal operation it is expected that the interchange of water between pipe-line and surge tank, associated with the tank insulation previously described, will prevent ice forming on the water surface therein. During the first winter, however, the mill load will consist only of heating and town service, so that the above

Fig. 9—Concrete Encased Penstocks, Surge-tank and Steel Pipe Line.

condition could not safely be assumed. To take care of this condition an air bubbler system has therefore been provided for in the surge tank, which consists of two rings of pipe, drilled to form a series of nozzles. One of these rings is fastened to the interior of the lower part of the tank bowl, the other to the inside of the base of the internal riser, and both are connected to the station service air compressor receiver in the power-house. This air compressor is located at turbine deck elevation and is a single stage machine compressing 120 cu. ft. of free air per min. to 100 lb. per sq. in. gauge pressure.

An 8 in. connection to both penstocks just upstream from the butterfly valves makes an ample supply of water for station service available at all times. Because of the known fact that the river water carries large amounts of extremely fine silt in suspension, a complete filtering system has been installed in the basement of the control section.

For the coarser material, duplex strainers fitted with coarse and fine screens have been provided. To remove the extremely fine material, the water can be treated with suitable coagulants and passed through a series of mixing chambers and a settling tank.

No heating system has been provided which will heat the power-house completely during a shutdown period, but 5 kw. electric heaters have been distributed throughout the building at important points, such as near the governors, in the oil-room, etc., and these heaters will be supplied with power from the emergency gasoline generator set during any period of total shutdown.

Normally the building will be heated by circulating warm air from near the ceiling of the generator-room, through the control section and back to the generator pit. This is accomplished by means of a system of ducts leading from the ceiling of the generator-room to an exhaust fan located in the control section. This fan transfers the warm air, under pressure, to another duct system and distributes it to the various rooms of the control section. The air then passes downward to the turbine floor, whence it is drawn into the generator cooling system and re-heated. Regulation and tempering of the air are accomplished by the proper manipulation of doors within the building, and by a system of louvres in the south wall of the power-house.

### Speed Regulation and System Stability

The consideration of this problem was based primarily upon the following fixed elements of the general scheme:—

(1) A topographical conformation of the site which necessitated the inclusion in the development scheme of an active water-column 6,580 ft. long.

(2) A system load of the order of 65,000 hp. of maximum demand at 90 to 100 per cent working-day load-factor, divided approximately in the proportion of 30,000 hp. of steady non-inductive base load supply for electric steam, and the balance of 35,000 hp., inclusive of a negligible proportion of municipal load, for mill motive requirements, about 70 per cent of these latter requirements being synchronous.

(3) A close coupled self-contained system of production and use which will never have available to it the stabilizing influence of a transmission network connected to diversified sources of supply and varied classifications of consumer demand.

(4) A large single block of generated power supplying a single consumer with wholly industrial load over a short transmission line of low impedance.

Associated with the above fixed elements of the problem were the following desired operating conditions and requirements:—

1. A limiting speed variation of 2 per cent (1.2 cycles) up to a 10 per cent instantaneous swing in the motive power load.
2. Both main units and both high-tension lines in parallel on station and mill high-tension bus.
3. In the event of a disturbance on any one line, the functioning of relays and switches to be sufficiently fast and precise to effect the transfer of the total station load to the other line without serious disturbance to the machine drives in the mill, and without the necessity of dumping the electric boiler load.

As related to any one transmission circuit, it was recognized that by far the most frequent source of interruption would be single-line to ground faults; that line to line faults or double-line to ground faults would be a possible but relatively infrequent source of interruption; and that three-phase shorts were more of a station than a line hazard, and would in most cases cause an unavoidable system outage.

Fig. 10—Cinching and Spacing Bands on Wood Stave Pipe.

Fundamental to the realization of the above operating conditions and requirements was of course the control of the water-column. The means by which this was effected within the limits of feasible design has already been described.

Associated with this fundamental limitation, as to surge-control in the pipe-line, was the fact that the fastest breaker, in connection with which an acceptable guarantee is obtainable, is one which functions within 8 cycle limits.

It was therefore necessary to realize the desired operating conditions and requirements to the fullest extent possible within these two primary limitations.

Fig. 11—Completed Wood Stave Pipe.

As to speed control, it was found that with the surge-tank functioning as intended, the turbine governors would be able to regulate within the desired speed limits if each main generator had a fly-wheel effect of 10,000,000 "*WR* squared." This was accordingly called for and provided.

Principally in view of the large proportion of synchronous load to be handled, the realization of inherent system stability required:—

1. A high short-circuit ratio (low reactance) in the generators, associated with a high pull-out torque on the synchronous load.
2. High speed excitation as an adjunct to automatic voltage regulation.
3. Over-voltage control as an adjunct to high speed excitation.

The generator specifications called for a short-circuit ratio of not less than 1.25, and this value was incorporated in the accepted design. High speed excitation in this design took the form of a main exciter unit with a motor-operated bridge type field rheostat and a pilot exciter of 7½ kw. capacity with a back-of-board type of field rheostat. Over-voltage control and protection were effected by relaying across the pilot exciter terminals, and cutting in resistors in the shunt fields.

As an additional precaution under this head, each main generator was equipped with pole-face windings, which, while primarily affording lightning protection, have a beneficial influence on dynamic stability.

Thus designed and equipped, and with the system operating at full load with generators and lines in parallel at both ends, it was found that a condition of transient instability would be reached in 0.22 sec., or 13.2 cycles, in the event of a single-phase line to ground fault near the load end. This is well within the 8-cycle time element of the breaker plus the relay time, for the end nearest to the fault, but the clearing of the other end will be delayed until the first breaker has opened. This condition only applies to faults in the end zones, because if the fault is out on the line the high speed current and balanced power relays operate within one or two cycles to clear the line at each end.

The operating conditions to be anticipated under such circumstances are therefore:—

(*a*) That the system will ordinarily ride through a single-phase line to ground fault without the necessity of cutting motive load or dumping the electric boiler load.

(*b*) That the system may ride through line to line or double-line to ground faults and remain stable, this possibility being governed primarily by the distance of the fault from the generating end of the line and the amount of load being carried at the time.

(*c*) That three-phase faults anywhere on the system are to be treated as emergencies and not as normal incidents of operation, so that transient instability must be assumed as an unavoidable element of the situation thereby arising.

Relay functioning and protection were divided into four primary zones for study and design: namely, generators, transformer banks, station service, and transmission lines.

The split-phase armature windings of each main generator are protected with relays of the percentage ratio differential high speed type, for both split phase and overall protection, and a ground fault detector is also applied to the complete generator field and excitation system.

The transformers are provided with a differential relay protective scheme in which is included an overall back-up protection from the generator bus to the line side of the transformer high-tension breakers. For this scheme, relays with an operating time of 6 to 8 cycles were provided, which will give satisfactory clearing time to meet the stability requirements of the system.

For the station service transformer banks instantaneous induction overcurrent relays are used, while for the incoming feeders from the generators induction type overcurrent and instantaneous overcurrent relays are provided. These latter relays provide against the closing of these circuits on a bus short-circuit, and by the addition of an auxiliary relay will be rendered inoperative for a short time following energizing of the bus.

The functioning of the transmission-line relay system is dependent upon the potential obtained from potential transformers connected to the low-voltage side of the power transformers at each end of the line.

Ordinarily, both transmission lines are operated in parallel and therefore the current is divided equally between them. The first element of line protection and switch control therefore operates on a constant percentage current unbalance characteristic. This fixed characteristic is essential in order to eliminate unnecessary shutdowns on heavy external short-circuits. The second element of line protection is a combination of relays to protect against simultaneous faults on the same phases of both lines at the same location, in which case there might not be sufficient current unbalance to operate the current unbalance relays. This second combination of relays also provides for single-line operation, for operating two lines separately on the high-tension bus, and also for stand-by protection.

The relays are generally similar at each end of the line, except that balanced current relays are used at the power-house end, while at the mill end of the line balanced power relays are used, since at the mill end the relays must be independent of any back-feed of fault current from the synchronous motors in the mill.

### Grounding

A preliminary survey of both the mill and power-house sites indicated that suitable grounds might be difficult to obtain. At the power-house the sand in the bottom of the tailrace and the water itself were both of high resistance, but by driving ground rods 20 ft. long in the bottom of the tailrace a zone was reached which showed a ground resistance of about 4.5 ohms, which was considered satisfactory.

The mill site at Baie Comeau is predominantly ledge rock, but fortunately there were some mud flats situated about 500 yards from the mill substation, which at high tide are covered with brackish water. Ground rods driven in these flats showed a ground resistance of less than one ohm, and this site was therefore adopted as a permanent ground for the mill and station area.

Nests of ground rods were accordingly driven in the power-house tailrace and in the mud flats at the mill. These were tied together with heavy stranded copper wire and ground leads brought to all neutral points and all electrical apparatus in the stations.

Along the transmission line tower footing resistances are now being taken as the towers are erected. Some footings are known to have a very high resistance, being located on solid rock, and it is possible that part of the line at least will require a counterpoise in order to obtain a sufficiently large flow of fault current to ground to assure positive relay functioning.

### Personnel

The responsible personnel associated with this project is:—

The Ontario Paper Company, Limited:

A. A. Schmon, President and General Manager.
John Stadler, M.E.I.C., General Consultant.
R. W. Shaver, Manager, Comeau Bay Division.
Jules T. Jaeger, Chief Engineer.
W. L. Eliason, Electrical Engineer, Operation and Design.
Dan Anderson, A.M.E.I.C., Electrical Engineer, Operation and Design.
A. I. Cunningham, A.M.E.I.C., Resident Engineer.
R. V. H. Keating, A.M.E.I.C., Assistant Resident Engineer at Outardes.
J. B. Sims, Purchasing Agent.
F. J. Byington, Traffic Manager.
Chas. Warnock and Company, Limited—Inspection.
Allen Engineering Company, Limited—Inspection.

H. G. Acres & Company, Limited:

H. G. Acres, M.E.I.C., Consultant.
S. W. Andrews, A.M.E.I.C., Chief and Mechanical Engineer.
A. W. F. McQueen, A.M.E.I.C., Hydraulic Engineer.
D. L. Munro, Electrical Engineer.

The Foundation Company of Canada, Limited:

R. E. Chadwick, M.E.I.C., President.
V. G. Younghusband, Vice-President in Charge of Construction.
K. W. Bash, Plant Superintendent of Construction.
K. C. Weedin, Superintendent at Outardes.
L. H. Burpee, A.M.E.I.C., Engineer.

Of the above, the writer is indebted in particular to Messrs. Schmon, Andrews, McQueen and Munro for assistance and advice in the preparation of this paper.

# The Substructure of the New Highway Bridge Over the Fraser River at New Westminster, B.C.

*W. G. Swan, M.E.I.C.,*
*Consulting Engineer, Vancouver, B.C.*

**Paper presented at a Joint Meeting of The Institute and the American Society of Civil Engineers, Boston, October 6, 1937**

SUMMARY.—After describing the considerations governing the design of the substructure, the paper discusses the construction work, noting the difficulties encountered due to the heavy currents and nature of the site and foundation material.

The new Provincial Government bridge, now well advanced toward completion, will cross the Fraser river opposite the city of New Westminster, the oldest city on the mainland of British Columbia and its former capital. The new structure is to be known as the Pattullo bridge, so named after the present Premier of the Province, the Honourable T. D. Pattullo. The Fraser river at the point of crossing, which is situated twenty miles from the mouth, is about one-half mile in width. The depth of water varies from a maximum of seventy feet near the north bank to about half this depth for the larger portion of the river towards the south bank. The river bed is of alluvial formation, the deposit of sand towards the south bank exceeding one hundred and fifty feet in depth, while a hardpan ledge underlies the bed in the manner indicated by Fig. 2, a plan of the borings.

The current reaches a maximum velocity of eight and one-half miles per hour during the freshet season of June, while a reverse current having a maximum velocity of one and one-half miles per hour is encountered during the period of winter tides. The tidal range, except during the freshet period, is between five and six feet at the bridge site. Due to the heavy discharge of the river all the year around, the water is never brackish and no marine borer action occurs. At infrequent intervals the river freezes solidly at the new bridge site but never to a depth exceeding a few inches. Drift ice to a thickness of 15 ft., however, has been observed to choke the river at this location, and is a factor affecting pier design. The ground adjoining the river bank on the south shore is flat for at least a mile, being dyked to prevent flooding during the freshet season. On the north shore the ground rises abruptly from the river bank, attaining a height of 130 ft., sufficient for approach purposes, in a horizontal distance of about 500 ft. Muskeg formation from 20 to 40 ft. in depth overlies a sandy formation on the south shore, while a glacial deposit of hardpan and boulders outcrops on the north shore.

The bridge approaches are of reinforced concrete, the south approach being 1,400 ft. in length, reinforced by light welded truss construction, and the north approach consisting of two spans, each 70 ft. in length, with the usual bar type of reinforcement. Earthwork construction connects these approaches with the existing highway system. The bridge proper is shown in Fig. 1 and is of high level type consisting of a series of Warren deck trusses of two lengths, namely 200 and 250 ft. The main and central portion of the superstructure consists of three spans of continuous construction, the central span a tied arch 450 ft. in length with flanking spans 350 ft., similar to the Honore Mercier bridge at Montreal. The clearance under the central span for navigation purposes is 150 ft. above normal freshet level. The deck consists of a reinforced concrete slab 40 ft. of roadway width providing four lanes of traffic, while a six foot sidewalk is provided on the downstream side of the bridge. Welded steel handrails are provided both for approaches and bridge proper, and steel lamp standards will carry sodium vapour lighting. The bridge deck is designed for uniform live loading of 80 to 100 lb. per sq. ft. and concentrated loading of 20-ton trucks, with three-fourths of the load on the rear axle. As far as applicable, Canadian Engineering Standards Association specifications govern.

### Factors Governing Design

Before selecting the present site of the bridge, surveys and preliminary estimates were made of possible sites, between the mouth of the river twenty miles below and Port Mann, four miles above the final location. These sites were abandoned because of cost of approach roadway systems and the fact that the existing combination railway and highway bridge at New Westminster, which had established the main route south and east, had outlived its usefulness for highway traffic purposes. As the existing bridge at New Westminster has not heretofore been mentioned, it should be explained that it consists of a two-deck low level combination bridge, completed in 1904, from plans by Messrs. Waddell and Hedrick. The upper or highway deck was not designed for modern vehicular traffic, the width between curbs being slightly under sixteen feet. A proposal to strengthen the bridge as a whole and widen this traffic deck was considered but abandoned as it was felt that only a high level bridge would fill the needs of the very near future. As the old bridge is also owned by the province and is very necessary to the three railways who operate thereover, it was finally decided it should remain, but that the highway deck should be removed on completion of the new structure.

It will be seen that due to the proximity of the two bridges in a channel which carries a substantial deep sea traffic and a heavy tug, barge and tow boat movement, the selection of the location of the piers of the new bridge was greatly influenced by the position of those of the existing bridge. Under the direction of the District Engineer of the Public Works Department of the Federal Government, J. P. Forde, M.E.I.C., an enquiry was instituted as provided by the Navigable Waters Protection Act. A public hearing at New Westminster, at which all interests were represented and heard, resulted in the recommendation and selection of the present site, 200 ft. downstream from the old bridge. The authorization of the construction fixed the location of Piers 2, 3, 4 and 5 within such narrow limits as to practically determine their positions. At this point, namely in November 1935, the author was appointed by the Minister of Public Works for the Province, the Hon. F. M. Macpherson, to make surveys, obtain borings and test pile data and proceed with the preparation of plans and specifications and estimate the cost of the new project.

Borings in the river bed, as shown in Fig. 2, disclosed hard material available at practical depths for a distance of 350 ft. from the north bank. From this point southward to Pier 8 river sand of varying consistency was encountered to an indefinite depth. It was immediately apparent that Piers 3 to 8 inclusive must rely for their support on the bearing value of the sand plus friction on piles or caissons or both. Samples of the sand foundation disclosed a safe bearing value of 4 tons per sq. ft. and a frictional value of 600 lb. per sq. ft. The first studies were directed towards pneumatic caissons for Piers 1 and 2 and open caissons with pile pockets for the remaining piers. However, after the consideration of many factors, amongst the more

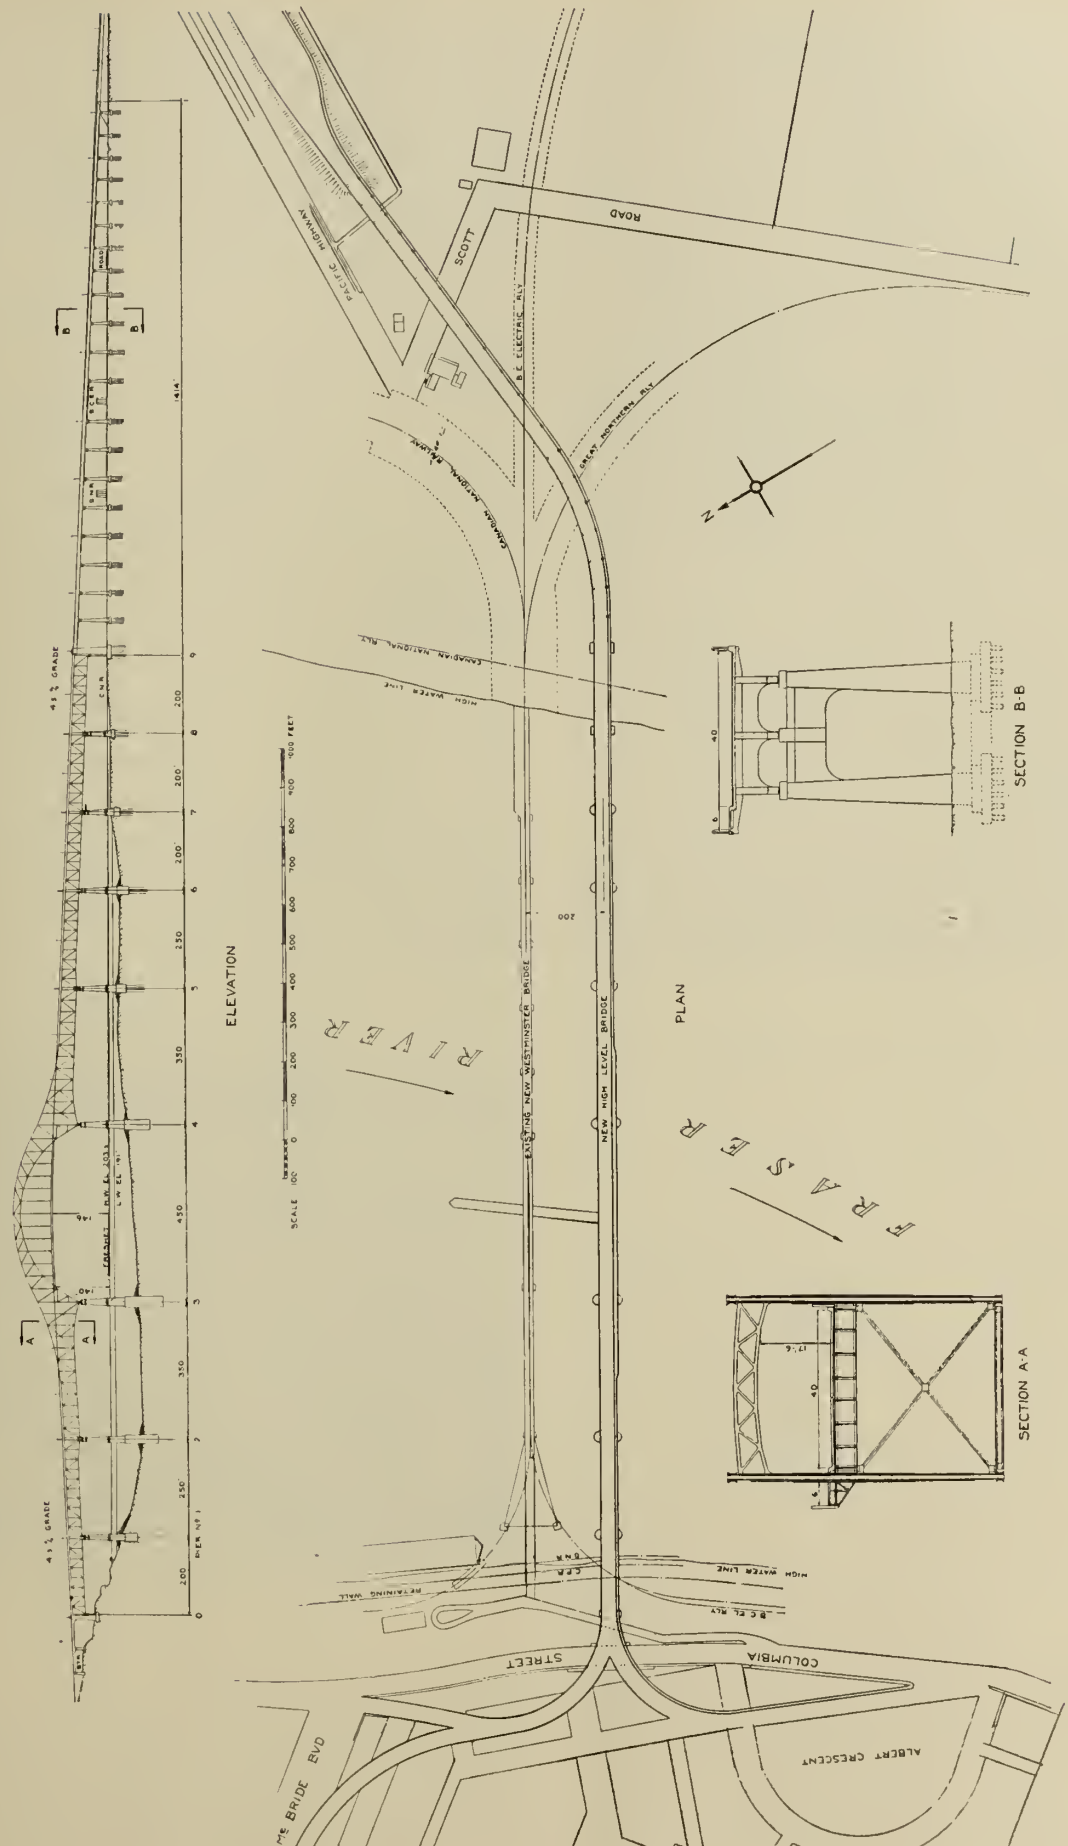

Fig. 1—General Plan of Bridge.

important being the practical depth at which bearing piles could be driven and figured with confidence, it was decided to adopt open caisson construction for Piers 2, 3 and 4, because of the excessive depth of water, and employ cofferdam construction on Piers 5, 6, 7 and 8 coupled with bearing piles for foundation purposes. Eventually the expense of air equipment for Pier 1 caused a decision to be reached providing for an open caisson job at this pier.

The firm of Messrs. Monsarrat and Pratley, bridge engineers, of Montreal, were employed by the author to advise on the foundation problem and their experience and advice were invaluable in the earlier studies and in the final designs adopted. A study of Pier 3 is covered by Mr. Pratley as follows (see Fig. 3):—

"The total weight of the pier with low water buoyancy reaches 24½ million lb., so that with the superimposed load of 6½ millions, about 31 million lb. is to be taken care of by bearing area and friction. The area of the base is 2,850 sq. ft. The friction on the outside surface only, at 400 lb. per sq. ft., amounts to between 5 and 5½ million lb. The friction on the inside surfaces of the wells A and C at 300 lb. amounts to about 3½ million lb. For these figures the unit pressure on the full bottom regardless of friction, is exactly 5½ tons per sq. ft. The outside friction reduces this to exactly 4½ tons. If the inside friction is also allowed, the unit is reduced to 7,770 lb. The punching load, therefore, on the bottom at the elevation of the cutting edge, −35, which is the total bearing unit, minus the natural pressure on the undisturbed sand at the same depth, is a very low and conservative figure. The design indicated on the sketch shows penetration down to −35 for the purpose of developing an ample friction and for presenting an amply large surface against the sand for resistance to horizontal moments. The figures on the latter question indicate that for longitudinal loads such as wind and friction at the bearings, but excluding ice and current, the pressures between the sand and the vertical surfaces of the caisson are sufficient at very low units to resist all horizontal moments. For horizontal forces in the other direction, transverse to the bridge, where ice and current pressure are included together with wind on the superstructure, the live load, and the pier, the vertical surfaces of the caisson submerged in sand will develop unit pressures against the natural sand which are well within permissible figures before any tilting effect can reach the cutting edge to increase the vertical punching units."

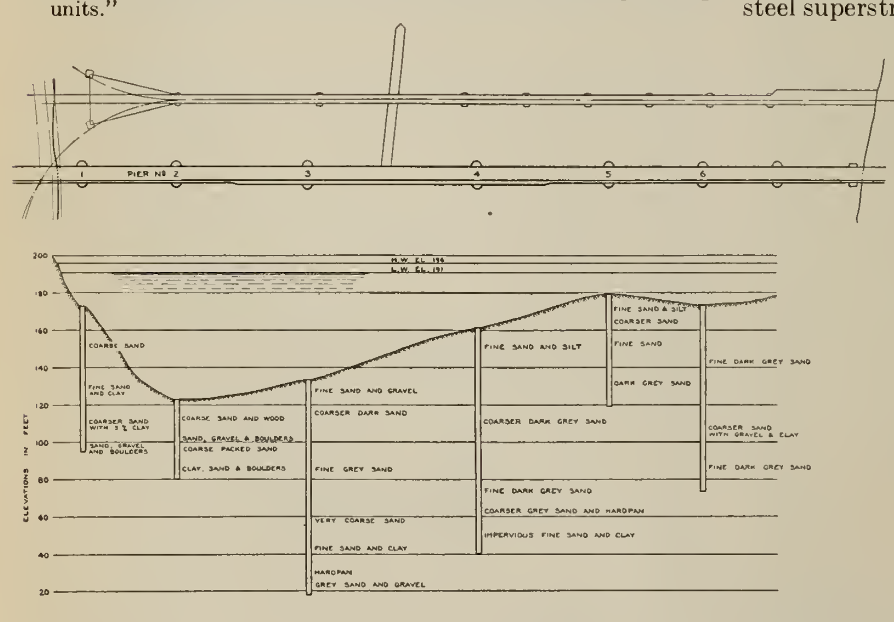

Fig. 2—Plan of Borings.

Alternative types of construction for the foundations which were studied and abandoned, covered the proposed use of large reinforced concrete cylinders for Piers 1 to 4 inclusive to be built in place with fixed forms and moving cylinders supported on false work piling during construction. The hazard of the heavy current alone caused this type to be discarded. Open cribs of horizontal courses with caulked joints and with cutting edge and pile pockets were also considered for Piers 5 to 8 inclusive. The sinking of these and probable scour during the sinking operations provided a problem that left doubt as to their successful use, and was the reason for their rejection.

As was to be expected from the nature of the foundation material, the north approach to the bridge is founded on hardpan with spread footings, while the south approach foundations are carried on wooden piling driven and cut-off well below ground water level. These portions of the work are dealt with later in some detail.

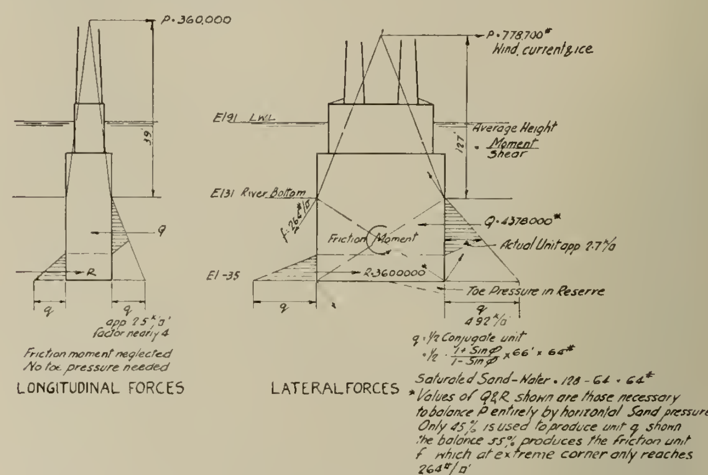

Fig. 3—Study of Pier No. 3, Lateral and Longitudinal Forces.

### Estimated Cost, Tenders and Contract

Final plans, specifications and estimates were submitted to the Chief Engineer of the Public Works Department on April 30th, 1935, and approved for tender. It was decided to call for tenders on a unit price basis for all foundation work, combined with a lump sum price for the steel superstructure. This list embraced nearly one hundred subdivisions for pricing and was felt by the Public Works Department to provide greater elasticity in ordering minor changes in the work during construction. The total estimated cost of the work was $4,000,000, which figure included right-of-way, property damage, legal and engineering expense. This sum was voted by the provincial parliament and funds made available accordingly. At this writing it would appear that the completed cost will be well within the statutory sum.

Tenders were called on April 30th, 1935, closing date being set June 10th, 1935. Two tenders were received, of which the lower from the Dominion Bridge Company Limited, amounting to approximately $3,250,000. was accepted. The successful bidder included in its figure that of the Northern Construction Company and J. W. Stewart Ltd., for the substructure and approaches, and the latter firm carried out this portion of the contract. The contract was signed August 21st, 1935.

### Piers 1, 2, 3, and 4

The contractor obtained a site for the construction of the caissons on the north bank of the river one mile above the bridge site. Here an old wharf existed which was repaired as a mooring wharf and adjoining a launching ways was constructed. The depth of water alongside was 30 ft. at low water and the channel to the bridge site provided a minimum of 30 ft. at high tide. The caissons could and accordingly were completed to a stage where they drew 29 ft. before towing to place. Steel cutting edges similar to that used for No. 1 caisson (and shown in Fig. 4) were erected on the launching ways and the caisson built to such a height as to provide a safe margin of stability in the launching operation. The sequence of caisson construction selected by the contractor was in the order 1, 4, 3, 2, beginning with the simplest operation and ending with the most difficult. This arrangement permitted experience to be gained by the contractor's personnel as the operations became more difficult. An outstanding example of how this worked out may be judged by the fact that the false bottoms of No. 1 caisson required ten days for removal, while in the case of No. 2, which is double in size, the same operation required but three days. Similar experience was observed in the rate of sinking after the cutting edges had entered into the river bed.

The construction of the caisson is depicted in Fig. 5, which is a plan and cross section of caisson No. 3. The framework is of the usual timber construction, sheeted with 3 by 12 in. fir planking with caulking groove, the joints butted for caulking. Concrete outside and partition walls are four feet in thickness less intrusions of timber brace frames. This concrete, designed for a strength of 2,500 lb. per sq. ft., was all poured in the dry. Caissons Nos. 2, 3 and 4 included a central longitudinal wall, while in No. 1 this was unnecessary and omitted. Dredging pockets in the larger caissons were 11 by 14 ft. and 11 by 12 ft. with triangular end pockets, the latter large enough to permit convenient operation of an orange peel bucket.

Concrete was poured in the cutting edge sections before launching and in every instance concreting was continued at the mooring wharf until a draft of 29 ft. had been reached. This provided a proper measure of stability necessary for towing to the pier sites. At the sites, pile enclosures strongly constructed, one end open and accurately located, were prepared to receive the caissons. Caisson No. 4 grounded in towing, without damage, was refloated at high tide and placed the following day. All other caissons

Fig. 4—Cutting Edge for No. 1 Caisson.

were towed to sites without mishap. In the case of caissons Nos. 1 and 4 these were completed including concreting at the mooring wharf, but due to the much greater depth of water, caissons Nos. 2 and 3 had to be completed at their respective sites before grounding. In each case the grounding was accompanied by scour at the upstream nose varying from three to five feet. Gravel was kept under load to deal with this situation and placed by sealing

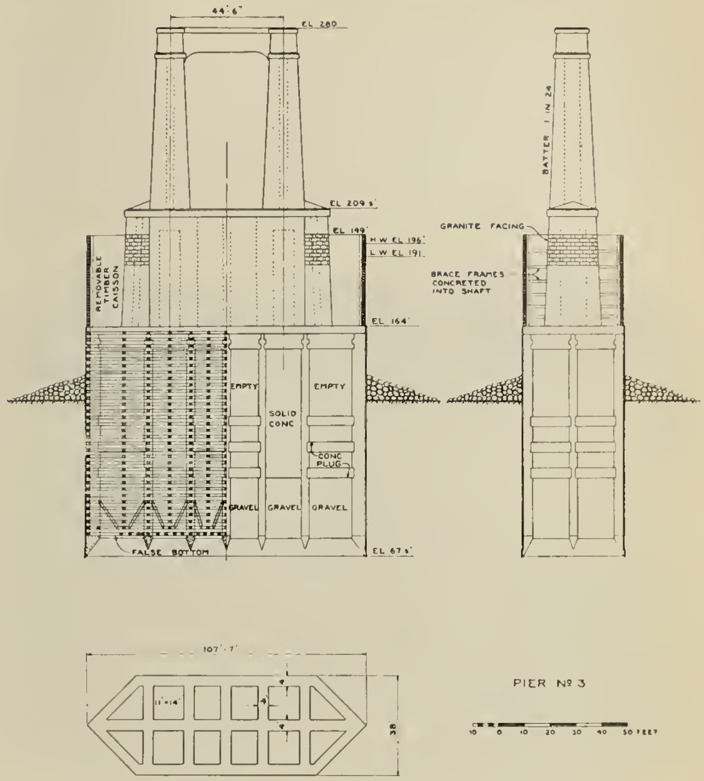

Fig. 5—Pier No. 3, Showing Caisson.

bucket as soon as the caisson was well grounded. Caisson No. 4 had to be raised and reset; all other caissons were accurately set at first grounding.

The following is a log of commencing the construction of, launching, placing and sinking caissons 1, 2, 3, and 4:—

| Caisson | Start Cutting Edge | Launched | Towed to Site | Grounded | Sunk to Finish Elev. |
|---|---|---|---|---|---|
| No. 1 ........ | 27 Dec. '35 | 28 Jan. '36 | 30 June '36 | 30 June '36 | 25 Sept. '36 |
| No. 2 ........ | 17 Aug. '36 | 16 Oct. '36 | Nov. '36 | 24 Dec. '36 | 17 Apr. '37 |
| No. 3 ........ | 30 May '36 | 15 July '36 | 3 Sept. '36 | 14 Oct. '36 | 3 Mar. '37 |
| No. 4 ........ | 10 Feb. '36 | 23 Mar. '36 | 17 Apr. '36 | 17 Apr. '36 | 20 Oct. '36 |

It will be noted that a considerable period of time elapsed between grounding and completing sinking No. 4 caisson. The reason for the delay was due to the extreme freshet conditions of the summer of 1936, which for a time seriously threatened the safety of the partly completed work on Piers 4 and 5. This situation will be dealt with later in some detail.

Sinking operations provided some interesting situations. Plans provided for sinking No. 1 caisson to cutting edge elevation of 135. At elevation 152 hard material was encountered and it required two months of continuous drilling and shooting to permit sinking to elevation 144, at which it was founded. Although considerably above desired level, selected as a safeguard against erosion of the north bank of the river, it was felt reasonable safety attended this decision. The bearing value of the foundation was at least eight tons per sq. ft. and accordingly all pockets were concreted in from the cutting edge level upwards. This caisson was finished with a maximum error in location of nine inches.

At a depth of 15 ft. below river bottom, caisson No. 2 brought up on a 30 in. cottonwood log, which appeared in four pockets parallel to and six feet inside the south side of the cutting edge. Almost a week was needed to shoot and chew away with orange peel bucket before this obstruction was removed. The entire operation at No. 3 caisson was the answer to a maiden's prayer. Grounding, removal of false bottoms and sinking proceeded without mishap. Figure 7 shows this caisson in place. It was never more than twelve inches out of level and on completion the maximum error in location was less than four inches. Caisson No. 4 had a rather hectic experience: it grounded in towing, suffered an extreme freshet and finished nineteen

**Fig. 6—No. 4 Caisson Before Grounding.**

inches from location as maximum error. All caissons were set within allowable tolerances of location, which were fixed at twelve inches for No. 1, eighteen inches for No. 2, and two feet for Nos. 3 and 4. With respect to correction of position of caissons by tilting during sinking operations, it was found that in the class of material encountered in the river bed, no correction worthy of consideration was obtainable after penetration had reached a depth of 20 ft.

It will be noted in the caisson design that solid pockets are constructed in the sections lying directly below the pier pylons, to better receive and distribute the superimposed load. Originally it was planned to fill these pockets with concrete to their base, but this arrangement was revised to ensure a more uniform compacting and bearing over the entire base of the caisson. Figure 5 indicates the nature of the pocket filling.

The manner of placing the gravel and sand filling and the concrete plugs and seals will be of interest. Sand, and gravel in the case of No. 3 caisson, were placed in all pockets by use of sealing bucket, to prevent segregation. The consistency adopted for this filling material was a 20 per cent excess of sand over gravel voids. The concreting followed immediately, a twelve-inch seamless steel tube with flange connections being the tremie pipe. In the case of No. 3 caisson this pipe was 94 ft. in length. It was, as will be judged, too long to permit plugging at the outlet to allow charging and lowering, both because of length and weight. A charge of excelsior was used to plug the tremie pipe immediately below the hopper. This is done by hand and must not be packed too tightly, otherwise it will not permit the flow of the charge. It worked out satisfactorily and it is interesting to note that in all tremie operations where concrete was poured under water covering the entire project, the charge was lost on only three occasions. Laitance to the depth of less than two inches was observable on completion of sealing Piers 1, 2 and 4, while in 3 about six inches was found. Hosing off the top of seals only was necessary and the concrete was of excellent quality and in appearance like a conglomerate formation.

The cofferdams for these piers were placed in three sections. They consisted of 12 by 12 in., 12 by 14 in., and 12 by 16 in. British Columbia fir timbers caulked and well braced with brace frames of similar dimensions. The brace frames were placed at intervals varying from three feet for the lower courses to seven feet for the top two sets of frames. The cofferdams gave no trouble from leakage excepting at the corner joints. To stop this leakage, cinders were fed into the joints from outside and canvas and wedging on the inside of the cofferdam combined in every case to reduce the total leakage to less than 400 gal. per min.

As referred to above, the three section construction was combined with holding down bolts which permitted the removal of the cofferdam in three operations. The specifications provided for the removal of brace frame timbers in courses, as the pier shafts were built. There were in all nine sets of brace frames. To carry out the specification meant at least seven separate breaks in pouring the shafts inasmuch as it provided for the removal of brace frame cross timbers as pouring proceeded. A revision of this clause of the specifications provided that seven of the nine cross frames might be concreted in the shaft construction and the ends of these timbers were cut off flush with the outer face of the shafts. No timber in shafts will occur above a horizontal plane within nine feet of low water level. This arrangement speeded up the operation very materially without detracting appreciably from the finished work.

PIERS 5, 6, 7 AND 8

These piers extending from the south bank of the river are, in the case of 7 and 8, sited practically on shore at ordinary stages of the water, while Piers 5 and 6 are in comparatively shallow water (see Fig. 8). The log of the borings (Fig. 2) indicated a material suitable for pile foundations. Test piles indicated that at 35 ft. of penetration a bearing load of 25 tons was quite safe. Actually

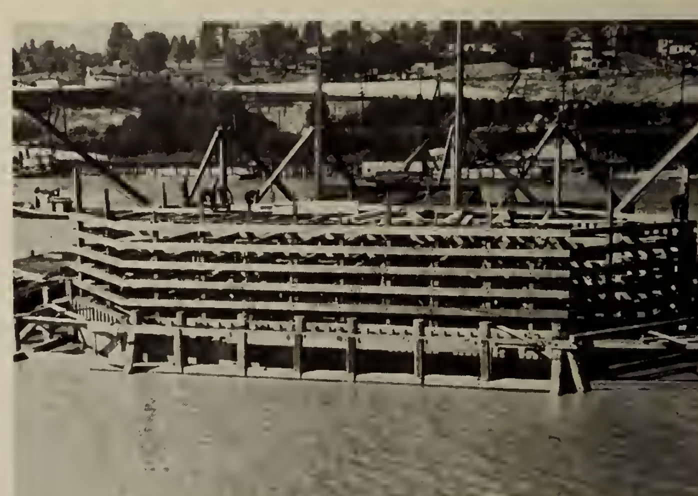

**Fig. 7—No. 3 Caisson at Site.**

the design provided average loading of from 19 tons at Pier 8 to 23 tons at Pier 5. Under extreme conditions of wind, live load and ice, a maximum load of 26 tons may be developed on the end piling, but as a precaution the larger piles were selected for these locations.

The pier sites were first levelled, and guide piles (in the case of Piers 5 and 6) driven, after which heavy brace frames were placed by counterweighting against buoyancy. The contractors elected to drive a single row of wooden sheet piling, twelve inches thick with a four inch tongue and groove, all of solid timber. The millwork was excellent and the fit exceptionally good. The engineering staff, including the author, were sceptical of the ability to satisfactorily unwater this design. Double timber waling at low water level and at the top of cofferdam level held the piling in line, steam hammer and water jet were used in driving. No caulking was resorted to, although cinders were fed into the outside joints during unwatering.

On completion of the cofferdam, excavation was carried down to the bottom of foundation slab level. Bearing piles were then driven with steam hammer and follower combined with water jetting. No difficulty was experienced in driving bearing piles accurately to place, except in the case of No. 7 Pier, where some logs were encountered at depth. The spacing of bearing piles was three feet centre to centre measured diagonally, possibly a trifle closer than usual practice but considered satisfactory because of the unusually large size of old growth B.C. fir, which was supplied. A twelve foot seal of eight-sack concrete was then poured by use of tremie. Eight days later unwatering began, and was found to be comparatively simple. Laitance was almost non-existent, the small amount being hosed off.

Six set-ups of tremie were used in Piers 7 and 8, eight in Pier 6 and ten in Pier 5. The seal was lost only twice in these operations. The concrete so deposited was about 18 in. high at tremie positions and the same amount below grade at the walls. High spots were picked or drilled down, piling cut off and a seven foot reinforced slab poured in the dry bringing it up to the base of pier shaft elevation. The balance of the operation, namely the construction of pier shafts and pylons, was comparatively simple, the only delay occurring when the granite masonry noses of pick faced finish were being built; this masonry extends from three feet below low water level to ordinary freshet level, a total height of 12 ft.

Instead of cutting off the cofferdam timbers above the level of the top of the foundation slab, specifications provided for driving this piling down to slab level. The object was to provide a skirt around the bearing piles which would give additional protection in case of unexpected scour. As the cofferdam of Pier 5 was lost during the 1936 freshet, other plans of a similar nature had to be developed here.

It will be noted that throughout the pier construction by cellular design, weight was reduced in pier shafts and pylons to the greatest possible extent commensurate with strength and loading requirements. In some cases this policy may seem to be carried to extremes but it should be noted that form lumber is cheap in British Columbia.

### Piers 0 and 9

These piers need little, if any, explanation. They are monumental in design and appearance, their purpose being to provide a suitable connection or break between the steel superstructure and the reinforced concrete viaducts. Pier 9 is shown in Fig. 9. Their construction is of the cellular type, voids comprising more than 60 per cent of the whole. In general the walls are but 18 in. in thickness with adequate reinforcement. Towards the river, their seeming large appearance is considerably screened by the superstructure steel, while away from the river they are reasonably moulded with the concrete bents and deck. No unusual problems were encountered in the design or construction of these piers. Pier 0 is founded on hardpan of glacial formations, having a bearing value of approximately eight tons per sq. ft., while Pier 9 is founded on fir piling cut off about six feet below ground water level.

### South Approach

The south approach to the bridge consists of a reinforced concrete viaduct 1,400 ft. in length. The soil formation is an overlying cover of muskeg varying in depth of from 20 ft. at the abutment to only a few feet at bent 10. Below the muskeg lies a bed of river sand of good consistency for foundation purposes and of unlimited depth. Piling was the natural form of foundation construction and consisted of untreated British Columbia fir driven generally 40 ft. into the sand, and cut off at least six feet below minimum ground water level. Piling was loaded not to exceed 25 tons per pile under extreme conditions of wind and live load. The general nature and type of construction is indicated by accompanying photographs.

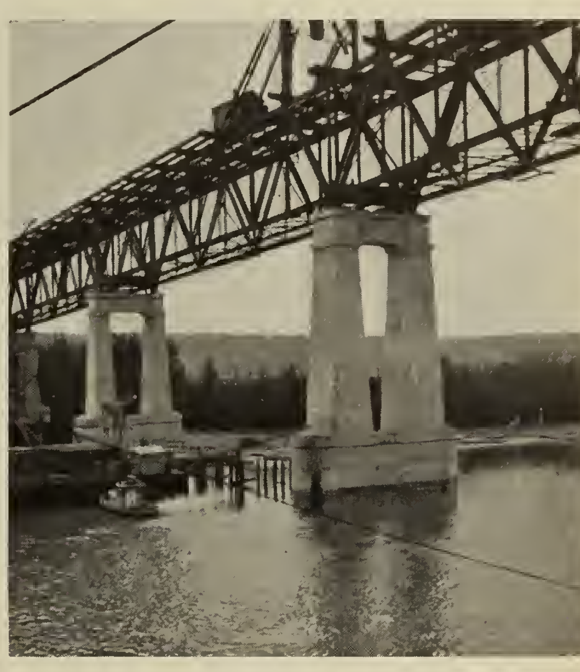

**Fig. 8—Piers Nos. 6, 7 and 8.**

Except in the case of the buried abutment, which was of solid concrete design, all of these bents are of cellular construction. Each bent consists of two cellular columns founded on separate concrete bases in turn supported by piling referred to above. The bases or footings were tied together with a heavy reinforced concrete cross-beam and in turn the tops of the columns combined to support a heavy concrete beam. The central girder of the deck system is carried on a cap built into the middle of the upper connecting beam while the main girders rest on caps which form the tops of columns.

The column walls have a thickness of 15 in., the inner wall being vertical while a batter of 1 in 24 is entirely in the outer wall; this arrangement, which was necessary for economy in design, differs from the pier pylons, which are battered on all faces. Both designs appear to be architecturally correct. The columns of these bents vary in height from 20 ft. at bent 29, to 80 ft. at bent 10. In consequence of the height, the concrete could not be poured continuously. The pouring was carried out as far as possible in lifts of 20 ft., the construction joint being carefully struck to a horizontal line which causes it to be almost indiscernible, due to the fact that form lumber around the columns was also erected in horizontal courses. Figure 9 clearly shows the nature of the forming.

Due to the inferior upper soil texture, considerable thought was given to the design of the abutment. It was felt that some movement in the header bank of the approach fill was inevitable. Solid buried abutment pedestals with broad bases were finally adopted. Filling operations, using sand and gravel, consisted of placing and compacting in layers from ground level upwards to maintain an approximate balance. The results were satisfactory until the autumn rains set in. A subsidence and thrust occurred two months after the abutments had been completed, resulting in a forward movement of nine inches in these pedestal piers, five inches in bent 28, and one-half inch in bent 27. The deck fortunately had not been placed. No movement has since occurred. No registered settlement of the foundations took place. In view of the foregoing, it was decided to extend the viaduct 60 ft. further south and add no further filling material, of which about six feet would have been required to restore the embankment to subgrade level. A composite structure was adopted, the roadway slab, similar to the viaduct, being carried on creosoted timber bents and stringers.

The original deck construction of the south approach viaduct was varied at the contractor's request to permit the use of light welded steel trusses and floor beams designed to carry the construction load without falsework support. This change necessitated the use of a third girder for which provision had to be made in the upper cross beam connecting the columns. The view of this approach (shown in Fig. 9) depicts this construction, which is known in Canada as the "Kane" system.

The specifications provided that all concrete work be given a wash coat of cement grout of proportions, one of cement to two of sand. With few exceptions the finish has been very good and the cement grout wash has been cancelled. The use of vibrators when placing concrete and intensive tamping has been chiefly responsible for a satisfactory finish. A harsh mix of too great a proportion of coarse aggregate has also been avoided at all times. Experience indicated that vibrators, while excellent for producing a dense concrete, were insufficient without adequate tamping to prevent gravel pockets in exterior faces. The slump used in this part of the work was four and one-half inches. Concrete was ready mixed from the contractor's floating plant, conveyed from wharf at river bank to site by light railway in one-yard buckets. The buckets were raised to work by use of dragline equipment, since a

Fig. 9—Pier No. 9 and End of South Approach.

portable tower was impracticable, due to numerous structures, power transmission and other pole lines on the route.

### North Approach

The north approach to the bridge, while less than 200 ft. in length, provided an awkward construction problem, due to highway, street railway, and other municipal services to be maintained. Columbia Street, the principal thoroughfare of the city of New Westminster, had to be re-located. This involved heavy retaining wall construction along the approach to the old bridge, a very busy section of highway. It also involved a partial re-location of the approach in question as Pier 0 was sited in the middle of the roadway. Intermediate bent "A" had to be located midway between Pier 0 and the north abutment in order to maintain width of Columbia Street diversion. This brought the bent "A" foundations on a steep sidehill of clay hardpan, which provides an excellent foundation when dry, but was made difficult by heavy seepage from the hillside. Considerable interceptor drainage was necessary. The footing was carried well into the foundation material, a five foot thick pad used for levelling

Fig. 10—No. 4 Caisson During Freshet.

up at the lower end. The bridge approach begins to flare to meet the two-way connection as soon as Pier 0 is passed. Intermediate bent "A" has, in consequence, an overall length of 70 ft. while the abutment has a length of 225 ft. including wing walls, which are in line with the abutment. Hardpan foundation was also available for the abutment and wing walls, suitable material being encountered from eight to ten feet below ground level.

### Foundation Damage at Piers 4 and 5 and Restoration Programme

The bridge contract was awarded to the Dominion Bridge Company in August 1935, subject to final approval of the structure by the Federal Government under the "Navigable Waters Protection Act." Some time elapsed before the contractor's work in the river was commenced, work on Piers 4 and 5 having been started about the middle of December. Pier 4 caisson was grounded on April 17th, 1936. By May 31st it had been sunk approximately 16 ft. into the river bed. By this date the second heaviest freshet in the history of the Fraser river was well under way, due to a late spring followed by three weeks of excessively warm weather in the interior. Pier 5 was scarcely as far advanced when the crest of the flood arrived. The seal course had been completed, unwatering accomplished and the base course placed. In the short period of ten days the river bottom surrounding the foundations of Piers 4 and 5 scoured to a depth of from 20 to 40 ft. below the original bed level. The cutting edge of Pier 4 caisson was exposed, and the caisson was barely prevented from overturning by placing hundreds of tons of rock under the lower side, which was eight feet out of level. One end of the cutting edge was three feet out of position. Figure 10 shows the condition of this caisson during this freshet.

Pier 5 foundation fared even worse. A pile and timber shearwater above the cofferdam broke loose and punctured the cofferdam. The latter was loosened and undermined, and flooding relieved the exterior pressure on the sheet piling, with the result that in a short time they began to break loose. Before the flood water had subsided, the river bed material surrounding this pier had scoured to bottom of the seal at the S.E. corner elevation 165. At the opposite corner the scouring carried down to elevation 129, only a few feet above the bottoms of the corner bearing piles. Scouring was unquestionably greatly increased due to the shape of the cofferdam itself, which was rectangular in form. It was provided by the plans and specifications to streamline the square ends of the concrete pier base as a part of its construction, but unfortunately the condition of the work at the time of the freshet had not reached this stage. Downstream from Pier 5 even deeper scour was found to have taken place, reaching elevation 122, about 75 ft. away. Although for a time it was feared that the work on Pier 5 would be destroyed, this did not happen, and actually no settlement took place.

Interesting observations were possible on the river currents during this exceptionally heavy freshet. During normal water, the current bears from south to north across the whole river, due to a heavy swing of the river to the southeast about one mile upstream, and to the existence of a broad sandbar at this bend in the river near the north bank. At the peak of the flood the sandbar was well covered and the current of the north half of the river was normal to the axis of the bridge, while although considerably straightened towards the south bank, still ran at an angle of about 10 degrees to the bridge axis. A heavy backwater was in evidence along the south bank. The depth of water at Pier 6, during the freshet, was reduced by 11 ft. The current in midstream reached a maximum velocity of eight and one-half miles per hour. Only the heavy upstream anchors held Pier 4 caisson from being pressed downstream. It was forced in that direction about two and one-half feet, of which one foot was recovered during subsequent sinking.

The problem of restoring No. 4 caisson was not difficult. The debris, consisting mainly of loosened forms, was removed. The caisson was partially righted for safety by jetting along the outside of the north portion of the cutting edge. Sinking operations were then continued, recovery of position taking place to the extent previously described. On completion of sinking, soundings indicated that the pier was sitting in a depression in the river bottom decreasing from 10 ft. alongside the caisson to nothing at a distance of 50 ft. This depression was back-filled with heavy sand and gravel, and rock riprap protection varying in thickness from 10 ft. alongside the caisson to three feet at the toe, was placed. The effect of this summer's freshet on the riprap protection will be checked and rock added if advisable. Figure 11 shows Piers 4 and 5 nearly completed.

The restoration plan for Pier 5 is shown in Fig. 12. The problem was primarily one embracing the following:

1. Restoration of bearing value of foundation piling.
2. Providing permanent protection against deep scouring action.
3. Streamlining the new work as far as practicable.

In the matter of restoring the bearing value of the pile foundation, particularly along the off-shore face of the pier, it was decided to backfill carefully around the exposed portions of the piles with suitable filling material. Pit run of sand and gravel, with 20 per cent excess of sand, was selected and placed carefully at first, to avoid side pressure on the piling. This filling was brought up to a level two feet below the bottom of the foundation slab and following this, fine sharp sand, selected to produce high frictional value, was jetted under the slab. Three exploration holes of four inch diameter were drilled on the centre line of the concrete slab longitudinally at the middle and quarter distances and by the use of sounding rods, the compacting of the supporting material was observable. Later, after steel sheet piling had been driven around the foundation, as shown in Fig. 12, additional jetting took place until the sand was forced well up the exploration holes.

Suitable filling material now having been deposited around the pier foundation, an outer steel sheet pile cofferdam consisting of Algoma Steel Company section B-6 —33 pounds per foot was driven at a distance of two and one-half feet from the sides of the concrete slab and with semi-circular ends, for stream line effect. The webs of the sheet piles were reversed in driving to give greater strength in cross bending and therefore provide greater resistance to unbalanced pressure of sand and gravel. The length of

**Fig. 11—Piers Nos. 4 and 5 Nearly Completed.**

sheet piling driven was 60 ft., the sections being driven by use of steam hammer and water-jet to a top elevation of 183, equivalent to eight feet below low tide level. This elevation also corresponds to the top of foundation slab which was finished at 183. Filling within the cofferdam was now carried up four feet to elevation 169. Wooden bearing piles were driven in the semi-circular ends to a top elevation of 171. Following this, four inch casing pipes, 44 in all, were placed at six foot centres in the end and side areas between cofferdam and foundation slab. Five feet of tremie concrete was now deposited between elevations 169 and 174 in the side and end sections, effectively sealing in the grouting casings.

Although it has not been indicated, it will be inferred that cement pressure grouting was being provided for. The object of this pressure grouting was two-fold, first to compact the sand and gravel foundation, and second to reduce interior pressure on the sheet piling in event of extreme scour from without. It will be noted that the sheet piling extended to elevation 123, the level of the bottom of the bearing piles. This, with protection now provided, appears to be sufficient for any contingency. Grouting operations were carried out by use of a pressure grouting machine and grout piping, the jet of which was driven down to average elevation of 153 before grouting. The operation was slow, as sand frequently blocked the jet, material was hard to penetrate with the jet points and freezing took place frequently. The average pressure used was 50 lb. per sq. in., as the jet could not be kept open with a lower pressure, which would have been desirable. In all, 4,000 sacks of cement were forced into the foundation material. Some escaped, as the bond between the sheet piling and the five foot concrete seal was frequently broken. The amount of grout forced into each location was governed by its appearance in adjoining casings and discontinued in any one location when this occurred. It was felt by the engineering staff that although the grouting operation did not result in entire consolidation, it had made a worth while contribution to the restoration plan.

In order to avoid undue disturbance of the water flowing around this pier, it was necessary to bring the level of the space between the sheet piling and the pier shaft up to base of shaft level, namely 183. This was accomplished by back filling with sand and gravel to a depth of seven feet on top of which two feet of coarse gravel, three inch to six inch, was placed. This finish appears to withstand any displacement by the current. Outside the cofferdam, over the sand and gravel filling which had previously been brought up to base of slab level, was now deposited rock riprap protection to an elevation four feet below the top of the steel sheet piling, namely to 179, placed carefully to a slope of one vertically to three horizontally.

A temporary crib cofferdam was employed to unwater the foundation slab for the purpose of constructing the pier shaft in the dry. This cofferdam was placed on top of the foundation slab, cement mortar grout being used to seal the contact between cofferdam and slab. The 10 by 10 in. cofferdam timbers were caulked between courses. No trouble was experienced in unwatering against the 14 ft. of head encountered.

### Contractor's Equipment

The contractor's equipment consisted of floating derricks, power scow, pump scow, floating pile drivers, floating concrete mixing plant, floating concrete hoist tower, tugs, scows, draglines, and light railway line and equipment.

Three floating derricks of 25, 30 and 35 tons capacity were available for handling lumber and timbers, excavation of foundations and similar work. Two of the derricks were equipped with compressors, and a two yard clam shell and a one and one-half yard orange peel bucket formed part of this equipment.

The power scow is a combined derrick and pump unit, having a 65 ft. boom, and capable of lifting 15 tons. Its hoisting engine is Lambert type 9 by 12 in., and the pumps are duplex reciprocating, one capable of supplying 700 gal. per min. at 125 ft. head, and the other 400 gal. at 125 ft. head. Auxiliary equipment is a 300 ft. per min. air compressor, and a one and one half kw. electric light generator. Steam is supplied by a locomotive type boiler and a donkey boiler. The power scow was used for water jetting, supplying air to the diver, and general purposes.

The pump scow is essentially a large capacity electrically driven pump mounted on a 43 by 120 ft. scow. The pumping unit is driven by a 650 hp. squirrel cage 2,200 volt induction motor and consists of two four-stage centrifugal pumps which can pump 3,800 gal. per min. at 400 ft. head. Four 10-ton derricks are located on the deck, for handling the hydraulic jacks, or other equipment. The power for this pumping unit is supplied by 500 ft. of three wire dredger submarine cable.

The floating driver was used for most of the pile driving on the river, the hammer being a 5,600 lb. drop hammer. It was also used for drilling and shooting the hardpan encountered at Pier 1.

The floating concrete mixer was designed and built for the particular needs of this job. It was built on a large scow 40 by 123 ft. and contains two one-yard Smith batch mixers capable of a maximum capacity of 80 cu. yd. per hr. when the concrete is mixed for one and one-half minutes per batch. The mixer was designed to be a compact flexible unit, easy handling and quick change from one mix to another. It contains 40 cu. yd. sand storage bunkers, 60 cu. yd. gravel storage bunkers, and cement storage of about 2,500 sacks. A conveyor belt carries the cement to the mixer room, and the sand and gravel are weighed in scales fed by gravity from the bunkers above. These scales are balanced to compensate for listing of the scow during weighing. Sand and gravel are fed to the bunkers by a two-yard clamshell bucket operated by a derrick on a 65 ft. boom. Power is supplied by two locomotive type and one donkey boilers and all equipment is steam operated. Driving and auxiliary equipment consists of two mixer engines, hoisting engines, pumps, a four and one half kw. generator, conveyor engine, etc.

The concrete after being mixed is dropped into a hopper and elevated by a hoist tower seventy feet high to a distributing hopper which feeds into a 50 ft. gravity spout.

Sand and gravel are taken from scows alongside, and continuous clamming is continued during pouring.

Cement is supplied from two storage scows, 102 by 32 ft. and the other 88 by 32 ft., with a total storage capacity of 1,500 sacks.

The floating concrete hoist tower was built on a 32 by 90 ft. scow with a 125 ft. tower. Its equipment consists of a donkey boiler, an American hoist engine 8¼ by 10 in. The concrete hoist bucket is fed from the mixer from a lower hopper and is elevated to an upper hopper discharging into a 35 ft. gravity shoot. A Chicago boom is fixed to the top of the tower for handling the shoot. This boom was also used for hoisting forms and reinforcing steel when the carpenters were erecting the forms. This tower was used principally to pour the concrete in the high river piers.

All of this floating equipment was towed and attended by three tug boats, one being a large steam tug, the *Fearful*, rated at 27.6 nominal hp. and 41.9 registered tonnage.

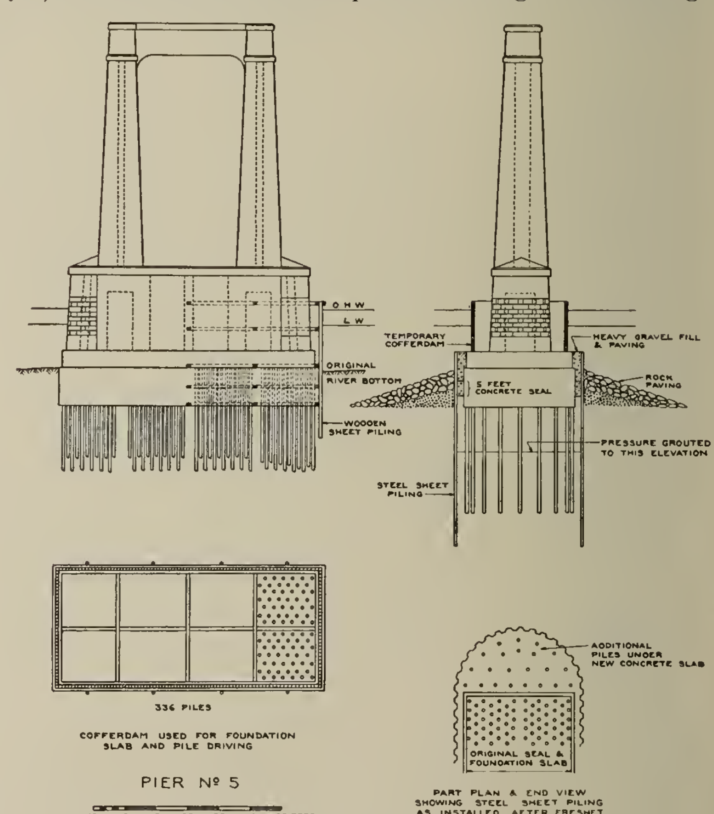

**Fig. 12—Pier No. 5, Showing Plan of Restoration.**

The other two, the *Harris* and the *Essangee*, are gas driven tugs 35 and 30 ft. in length respectively. The former is driven by a 45 hp. Buffalo engine and the latter by a 30 hp. Vivian engine.

In addition to the floating equipment described there are timber storage scows, sand and gravel scows, coal scow, a powder scow, and other miscellaneous scows.

Supplementary to the derrick equipment are two steam hammers used to drive timber and steel sheet piles and also some of the foundation piles driven under water;

also concrete and steel weights and anchors, buoys, divers' equipment, and 90 ft. of 12 in. tremie pipe.

Pumping of the caissons and cofferdams was accomplished by the pumps mentioned above and also several gas and electric pumps described below:—

1—200 hp. 2,200 volt electric centrifugal pump discharging 5,000 gal. per min. at 50 ft. head.
1—75 hp. 2,200 volt electric centrifugal pump discharging 3,000 gal. per min. at 50 ft. head.
2—20 hp. Ford gas 8 in. centrifugal pumps each discharging 1,500 gal. per min. at 50 ft. head.
1—125 hp. Waukesha 8 in. centrifugal pump discharging 2,000 gal. per min. at 50 ft. head.
1—20 hp. Jaegar 6 in. centrifugal pump discharging 1,000 gal. per min. at 100 ft. head.
2—6 hp. centrifugal pumps discharging 400 gal. per min. driven by a Sterling gas engine.

The land equipment consists of the items described below:—

A No. 14 Bucyrus dragline which was a five yard dragline converted to a 10-ten derrick. It has a 100 ft. steel boom and was used with a timber extension during part of the work making a total boom length of 120 ft. This machine weighs 90 tons and is steam driven. It is self propelled and the caterpillars occupy an area of 14 ft. by 27 ft. 6 in. It was used to hoist concrete and forms on the south viaduct.

A No. 20 B. Bucyrus shovel with a 45 hp. Atlas-Imperial Diesel engine was used on this job with a three quarter yard clamshell digging bucket, and was also used to hoist concrete and forms on the piers and viaduct on the south side of the river. The weight of this shovel is approximately 35 tons.

A speeder gasoline shovel which was a small shovel used early on the job for part of the pier excavations and for handling forms and hoisting concrete.

All pile driving on the land was done with a skid pile driver with 60 ft. leads. The hoisting engine was 8¼ by 10 in. A small air compressor capable of supplying 85 cu. ft. per min. was used for pneumatic drills.

Concrete was supplied to the south viaduct and piers on the south side from a narrow gauge track of about 2,000 ft. total length. Three gasoline driven locomotives 25 hp. weighing 6,000 lb. were used to haul the concrete and other materials. Nine one-cubic yard cone buckets on cars were used to deposit the concrete. These buckets discharged from a bottom ball valve operated from the Bucyrus.

The skid derrick on south concrete viaduct was a small stiff leg derrick operated by a 25 hp. Ford engine, and used to hoist forms on deck.

Water supply for the washing forms on the south side is supplied by a two-stage centrifugal pump operated by a 3 phase 220 volt 25 hp. motor; this motor feeds a 1,500 ft. water service pipe line.

In permitting this paper to be submitted, the courtesy is acknowledged of the Chief Engineer of the Provincial Public Works Department, Mr. Arthur Dixon, under whose direction and that of the Provincial Bridge Engineer, Mr. A. L. Carruthers, it has been a pleasure to serve, because of the spirit of efficient and friendly co-operation that has existed from the outset. The author begs to acknowledge also the excellent work and loyal support of his field staff under the direction of Mr. A. J. Leamy, who had served as assistant engineer on the construction of the original bridge in this location in 1902, and to his friend of many years, Major D. A. Graham, assistant resident engineer (now deceased,) and of his chief designing engineer, Mr. H. A. Rhodes. He is grateful also for the efficient work and fine co-operation of the officers of the contractor-in-chief, the Dominion Bridge Company, and of their sub-contractors, the Northern Construction Company and J. W. Stewart Limited.

The following engineering firms were employed by the author in a consulting capacity:—

Messrs. Monsarrat and Pratley of Montreal on the foundation work in the river.
Messrs. Sharp and Thompson, Consulting Architects, Vancouver.
Mr J Muirhead, Consulting Electrical Engineer, Vancouver.

# The Borden Bridge, Saskatchewan

## DISCUSSION[1]

J. F. Brett, A.M.E.I.C.[2]

The Borden bridge is the first concrete bow-string arch of over 200 ft. span built to date in Canada. As with concrete arches of all types, when the span exceeds some 150 ft., special attention must be paid to the stresses due to deformation or so-called parasitic stresses, which becomes the most important problem to be solved by the designer and the constructor as the span increases, in order to secure a rational and economical structure.

The authors are fully aware of the importance of this fact; the methods of design and construction they used have resulted in a structure which, in the writer's opinion, compares very favourably indeed with the best elsewhere.

In reading Part II, one cannot but feel that the authors have been very fortunate in being able to follow, during construction and after, by means of adequate observations, the coincidence of the theories on which their design is based and the actual behaviour of the structure.

We know that the shrinkage and other volume charges of concrete are closely related to the temperature and hydrometric state of the air, and since very little information on the matter concerning large monolithic structures under the peculiar conditions of Western Canada is available, the observations of elongation and deflection given in the paper are of great value to us.

The close agreement between computed and observed values is to the credit of the authors.

It may be said that the ideal conditions under which a concrete arch can act is the case where the work done results in the largest percentage of compressive stresses with the minimum amount of moments. For a given section and loads, the maximum fibre stress is lower, the more this principle is realized.

The authors have gone a considerable way towards this goal by using hinges for the arch and the tie, the provision

[1] Paper published in the Engineering Journal, May, 1937.
[2] Division Engineer, Montreal Water Board, Verdun, Que.

of roller bearing at one end and by the care taken of making the hangers as thin as possible in the longitudinal plane of the rib.

The girder approach spans resting on a compressible soil have also received careful attention, and are provided with split hinged columns and rocker bearing to provide for expansion and contraction and possible differential settlement. With these precautions it is possible and safe to construct continuous girder bridge spans on compressible soil foundations, a current practice abroad since many years, but which we are sometimes a bit timid in adopting.

The authors have been most candid in disclosing all their observations of the finished structure, pointing out where improvements should be attempted in the future under similar conditions. For this reason, the writer wishes to submit a few suggestions to those interested in this type of construction.

In the bridge under review, due to remote location, it was found quite expensive to weld the horizontal tie steel. The authors resorted to lapping after an experimental determination of the amount of concrete necessary to transfer the stress. If lapping is used, then the tie must be concreted first, which means that the tie concrete will be subjected to the full extension of the steel. If welding is out of the question, flat steel bars connected with turned bolts may be used; even if higher stresses occur at the connections, this would not affect the total elongation much.

It is also possible to pre-stress, so to speak, the tie steel; this will likely be the ultimate solution.

The only way to be absolutely sure to avoid small tension cracks in the tie concrete, if the latter is to bear the full elongation, would be to reduce the stress to somewhat about 13,000 lb. per sq. in.

The procedure of concreting the tie after the ribs also eliminates the possibility of the sag of the hangers. The latter may be put under some initial tension of letting them carry part of the weight of the tie bars. This results in a fairly uniform tension in the hangers which insures an even distribution of the deck load on the ribs at the time of decentring. If the tie is concreted first, the use of an I beam instead of bars as hangers is suggested. It is also possible to avoid hanger bars sagging by making them in two separate units to be welded together after the concreting of the ribs.

In connection with the hinges, the question arises as to where they may be located in the structure in order to obtain a maximum reduction of moment. The writer knows of a number of existing structures where the hinges were placed at the crown and at the junction of the terminal blocks with the ribs. The important point is to avoid any rotation of the terminal blocks so that a uniform pressure is exerted on the bearing seats. However, the authors have obtained a very satisfactory reduction of moment stresses with the lower hinges placed on the tie, a scheme which is new so far as the writer knows. This scheme deserves the close attention of designers since it permits the worthwhile saving of the extra reinforcing steel that would be required for a compression hinge located above the terminal blocks.

In connection with the bridge floor slab, the authors state that "one quarter of the negative moment steel was run through the top of the slab to care for tension which may be developed through the elastic extension of the tie." That the ties and the floor system work together as soon as the concrete hardens has been observed by several investigators including the present writer. Since the amount of extension that will occur depends largely upon the scheme of erection, hard and fast rules cannot be laid down. The writer believes that as a rule it is worth while to arrange the slab reinforcing with two separate layers of bars, top and bottom, the negative moment bars running the full length of structure.

The strain gauge readings taken at the crown hinge, together with the measurements of the tie elongation and the downward deflection of the rib during the decentring operations and in the early stages of loading, show the great difficulty of interpreting such data which represent the combined influence of rib shortening, tie elongation, temperature variation, the so-called plastic flow, etc. The interplay of these different factors is such that it may not be possible to assign definite value to any of them separately.

It is for this reason that the writer feels the method of pre-stressing can be applied to concrete bow string arches with great advantage. If the tie only is pre-stressed, it would be a very simple operation and could be carried out readily today without the necessity of much pioneering.

Using structural steel grade bars, the elastic limit of which has been raised by pre-stretching, a unit tensile stress of some 30,000 lb. per sq. in. or higher could be used with absolute safety since the elastic equilibrium of the structure as a whole is under control. Temporary hinges would not be required and the bow string would become a true two-hinged arch unaffected by tie elongation and deflection of the rib.

In reading Part III, one may appreciate the difficulties, due to extreme climatic conditions, faced by the authors and their associates during the construction of the substructure in the severe winter of 1935-1936. The fact that excellent workmanship was obtained in spite of it all is greatly to their credit.

In closing, the writer wishes to congratulate the authors in having created a splendid bridge, remarkable both for its technical excellence and for its artistic appearance.

E. M. Rensaa, A.M.E.I.C.[3]

The paper on the design and construction of the Borden bridge should be very welcome in that it deals with a subject about which comparatively little information is available in American technical literature. The authors are to be congratulated for the clear and detailed presentation, and especially for drawing attention to details which might be improved upon in future bridge construction.

The delay in elongation of the tie was probably due to continuing sliding of the tie bars as the tension in the steel increased and the bond resistance was overcome. This sliding would start at the cracks in the concrete and progress toward the middle of the 18 in. sections into which the tie concrete had cracked. The strength of the bond although probably somewhat impaired by the sliding would not reach a zero value and the concrete between the cracks would consequently still carry some tension with a corresponding reduction in the theoretical value of the elongation. The delay in the elongation would thus have little to do with plastic flow, especially since the effect of this would be counteracted by shrinkage.

It would be interesting to know what allowance, if any, was made for the tensile stress in the roadway, which could not be avoided with the method of construction used. It should be clear that the combined stress in the slab would be very different and less favourable than for the case of bending only. The shrinkage would add further to the tension in the concrete, and cracking of the slab under this condition could hardly have been prevented by the addition of some more reinforcement on the upper side. Besides the effect of cracking in weakening the slab against bending, it is also a question if the roadway will prove to be durable without the use of waterproof protection.

The problem of eliminating the tensile stress in the roadway cheaply and effectively has received much attention in Europe where reinforced concrete bow-string arch bridges have been much more frequently built than in

[3] Bonde and Company, Consulting Engineers, Oslo, Norway.

America. Several methods have been proposed and used which will either decrease or entirely remove this unwanted stress. It may be said in general that the tie should be the last member to be concreted, in order that it may be left free to elongate. As much dead load as possible should also be carried by the arch system before the tie and roadway are connected. The arches should therefore be built first in connection with steel ties which will allow that part of the structure to be released before the roadway is completed. The roadway may then be constructed by means of falsework suspended from the arches, and as the last operation the tie sections may be completed. It will also be beneficial to load the middle of the roadway in order to make up for the weight of the tie concrete before the connection is made by the last operation, and this load may then be removed as the concrete is placed.

The well-known German engineer Dr. Dischinger has proposed another method to achieve the elimination of roadway tension. The tie is placed in an open U-channel in the tie concrete, and hydraulic jacks introduced between the end of the tie and the terminal end of the arch. The tie may then be shortened by means of the jacks and as much compression as is desired introduced into the roadway, after which the tie is fixed to the arch and the channel concreted. Another advantage obtainable by this method is that the temporary crown hinge may be left out, as the bending stress introduced into the arch by axial deformation may be removed by shortening the span by means of the hydraulic jacks.

One reason why the tensile stress in short span bowstring arches has not caused more trouble is that the steel in the roadway which generally is not counted on as aiding the ties, will be such a large percentage of the total that the true average stress will be low enough to prevent serious cracking.

The temporary crown hinges seem to have worked satisfactorily, but it is the writer's opinion that higher working stresses might safely have been used for the 5,000 lb. concrete. It is essential that the stress in the hinge should be near the ultimate for unspiralled concrete as it is only under such condition that the concrete will be plastic enough for centring the thrust. The bending stress in the hinge calculated for that condition will, of course, be quite misleading. W. L. Scott, chief engineer, the Considère Construction Co., in England, stated in his book on concrete bridges that stresses in excess of the ordinary ultimate have been used successfully in Europe. He recommends as much as 8 per cent spiral steel in order to allow high stress and also says that it is not necessary to cut the arch reinforcement as the concrete core will shorten enough to prevent tensile stresses in the reinforcement. The steel is, of course, to be left uncovered for a sufficient length so that the part in compression will buckle. The angular movement in the hinge of a bow-string arch will of course be greater than for arches with immovable abutments and it is quite possible that cutting the steel was the safest in this case.

The authors' findings that no appreciable moments were induced into the arch ribs near the abutments due to deflection confirm an opinion earlier expressed by the writer. It would seem evident that the tie cannot have much restraining effect since it must deflect to about the same curve as the arch, neglecting the almost negligible effect of hanger elongation. The introduction of structural steel hinges at the junctions between the arch and the tie, as was done on an American bridge, would therefore seem to be an expensive and unnecessary detail, which really is apt to weaken the structure.

Perhaps the best method to avoid construction difficulty with the hangers would be to make each out of a single heavy bar, as is quite often done in Europe, and to leave out the concrete covering which in this case cannot be good for much else than rust protection. If the true cost of that concrete is counted including the excess steel required for the ties, it would probably be found that the hangers might have been much more cheaply protected by other means. The steel fence has to be painted now and then in any case, and it would not add much to the cost to maintain the hangers at the same time.

Whether or not the long span reinforced concrete bow-string arch bridge will be more frequently built in the future, will depend on its economic feasibility compared with steel spans. Its superior aesthetic value seems unquestionable, but its durability will depend to a large degree on careful construction. A more economical structure than the ordinary bow-string arch with vertical hangers is the arch with inclined hangers as invented by the Danish engineer Dr. O. F. Nielsen. This arch system combines the advantages of both the arch and the truss in that bending stresses are almost negligible. The great economic superiority of this structure both over the steel truss and the ordinary through reinforced concrete bow-string arch bridge for highway loadings and spans around 200 ft., has been confirmed by some investigations recently made by the writer.

P. B. Motley, M.E.I.C.[4]

Apparently the curves of the bows of the arches were of circular section. Why had they not been made parabolic?

C. R. Young, M.E.I.C.[5]

It would be helpful to know the circumstances that led the authors to use the Considère rather than the Mesnager type of hinge for the crown of the arch ribs. Considerable experimental data exist respecting the behaviour of the latter hinges, thanks to the researches of Mesnager himself and those of Parsons and Stang of the National Bureau of Standards, Washington. It might appear that some uncertainty of behaviour would have been avoided by using the Mesnager type with close transverse spacing of the converging rods.

The placing of a richer mix of concrete in the pier noses than in the adjacent portions suggests the inquiry as to whether any shrinkage cracks developed at or near the boundary of the differing mixes. Such cracks have been known to develop in other work to an extent indicating the need of special reinforcement in the region.

Forecasting of probable temperatures of mass concrete placed in cold weather is admittedly difficult, but it would be interesting to know if the authors could suggest any rough empirical rule for the resultant temperature at the side surfaces based on volume of the mass, form thickness and air temperature.

W. T. B. McCormack[6]

In moving a vote of thanks to the authors, comment should be made on the difficulties of pouring concrete during a Canadian winter. He had put in the concrete for a bridge at a temperature of 100 deg. F. Sometimes better work was done with inexperienced men, than with more experienced forces.

C. J. Mackenzie, M.C., M.C.E., M.E.I.C.[7] and
B. A. Evans, M.Sc., A.M.E.I.C.[8]

The authors appreciate very much the many complimentary remarks, criticisms and suggestions which have been expressed by those taking part in the discussion,

[4] Engineer of Bridges, Canadian Pacific Railways.
[5] Professor of Civil Engineering, University of Toronto.
[6] Chairman of the County Roads Board of Victoria, Australia.
[7] Dean of Engineering, University of Saskatchewan, Saskatoon, Sask.
[8] Designing Engineer, Borden Bridge, Saskatchewan.

particularly as all of the contributors have had extensive experience in this general field.

Both Messrs. Brett and Rensaa have drawn attention to very important considerations in connection with the design of the horizontal tie, which is a crucial feature of bow-string arches. A great deal of study was given to this aspect and designs were first prepared using flat eye-bars, and much consideration was given to welding, but, while both of these methods would have permitted the concrete envelope to be placed after the steel had elongated elastically, the former was ruled out due to excessive costs and difficulty of making the end connections, while the latter, as was stated, did not seem wise or economical under the existing conditions of remote location and doubtful availability of experienced and reliable welders. The discussion, therefore, must be considered in the light of the method adopted, although the authors would have preferred the welding of tension bars.

With regard to pre-stressing of the horizontal ties, there is the theoretical advantage that bending moments in the arch ring, due to elastic elongation of the tie may be thus practically eliminated and, as suggested by Mr. Rensaa, the necessity for a temporary crown hinge on that score avoided. In the particular case under consideration, however, where the piers did not have sufficient lateral stability to take up the necessary horizontal force of 2,000,000 lb. this method was not practicable. Even in the ideal case where pre-stressing would be feasible it is doubtful whether it would be advisable to go to the expense of pre-stressing in order to eliminate the crown hinge, which is much simpler and cheaper to construct and which in addition reduces potential bending moments due to factors other than elastic elongation of the tie.

There is little doubt that, if concreting of the tie could be left until the end, it would be a decided advantage; the cracks, which, incidentally, are very small and barely noticeable, would have been entirely eliminated, as the live load stresses and elongations are almost negligible as compared with the dead load effects, but what is more important the construction of the hangers would have been facilitated. The authors are inclined to agree with Mr. Rensaa that the vertical hangers, on economic and aesthetic grounds, might very well be made of an unprotected steel section.

The design of the floor system and its action under tie extension is another interesting feature referred to by both Messrs. Brett and Rensaa. In the design under consideration no allowance was made for any action of the floor system as a horizontal tie. If the pouring of the floor slab can be delayed until the horizontal tie has assumed its full elongation, due to arch ring, horizontal tie and floor beam dead weights, the extra elongation due to floor slab dead weight and live load would not introduce much longitudinal stress in the floor slab steel, and few cracks in the slab would appear. The suggestion that, instead of using the existing falsework, the floor system forms be suspended from the arches would, in our opinion, be quite expensive and the advantages of minor importance. The suggestions that more longitudinal steel be used in the floor system appears to be more practical.

There is little doubt, as laboratory tests carried out by the authors and many others have proved, that in the temporary hinges unit stresses well above the normal ultimate concrete strength could have been used, but there is little experimental data published on the increased flexibility that would have been obtained. When it is considered that nearly ninety per cent of the potential moment in the arch ring was relieved and that, if perfect articulation had been obtained, the actual stresses in the arch could not possibly have been relieved by more than twenty pounds per square inch, one may question whether, if very high hinge stresses were used in order to take advantage of a rather indefinite increase in flexibility, the loss in safety factor against unanticipated occurrences would not be too large a price to pay for a comparatively slight decrease in arch ring stresses.

Mr. Rensaa raises a pertinent point when he states that the future use of concrete bridges of long span will depend on their relative cost as compared with steel. It might be interesting to note that the superstructure on the Borden bridge cost no more than a steel span of similar span in a neighbouring location and, in the authors' opinion, where foundation conditions are good, long span concrete arches are competitive in cost with steel in Canada.

A design, after Dr. O. F. Neilsen's plan of inclined hangers for a bow-string, would be interesting. The only design of this type studied by the author was for a span where the major portion of the direct arch thrust was taken up by the abutments.

In reply to Mr. Motley, we would say that the axis of the arch was made to follow roughly the dead load string polygon and is more nearly parabolic than circular.

Professor Young very aptly inquires why, for the arch crown hinges, the Mesnager type, which has been subject to much study, was not used instead of the Considère type, for which there is less experimental data. The Mesnager type was preferred but it was found that the dimension of the arch ring indicated on other grounds did not provide a ring of sufficient width to use that type of hinge.

With regard to the method of strengthening the concrete in the pier noses, this was done by sprinkling dry cement over the concrete deposited at that location and tamping thoroughly; in this way there was no definite boundary between the mixes and no development of cracks.

The problem of forecasting probable temperatures of mass concrete placed in cold weather is, as Professor Young suggests, difficult and, while the authors have been interested in this problem for some time, they feel that, considering the number and uncertainty of the factors involved, any empirical rule might be more dangerous than helpful. It has been our practice to make liberal use of inexpensive resistance thermometers, as described in the paper, to follow concrete temperatures daily or hourly under severe temperature conditions, and then to provide temporary protection or heat if and where needed.

It was a novel and pleasant experience to have the vote of thanks tendered so sincerely by Mr. W. T. B. McCormack, a native of our sister Dominion of Australia, who contrasted in an interesting manner the effects of opposite temperature extremes which have to be met in our two countries, located as they are at opposite ends of a terrestrial diameter.

# A Study of Standard and Increment Methods of Measuring Stream Flow

**Paper presented at the Semicentennial Meeting of The Engineering Institute of Canada, in Montreal, June 16th, 1937.**

SUMMARY.—Compares two ways of developing a rating curve for the Bow river, Alberta, viz.:—The standard current-meter system and a new method based on known discharges through the power plant corresponding to certain increments of load.

In Alberta as in other provinces of Canada, stream flow studies are conducted by the Dominion Water and Power Bureau, Surveys and Engineering Branch, Department of Mines and Resources. These studies are carried on in co-operation with the provincial governments, and other private corporations or departments who have special problems relating to surface run-off, usually pertaining to a certain area.

The importance of an adequate supply of surface water cannot be over emphasized and it usually requires a water shortage to bring home the truth of this statement. The present drought conditions in western Canada have given abundant evidence of the value of surface water, and have proved that water is a resource of first importance.

Water is basic to the development and utilization of other resources such as mines, forests and lands, as well as to navigation, irrigation, water power and industry in general. The distribution of surface water, usually by stream flow, but by whatever means, therefore, becomes a very important matter. The accumulation of long-term records of stream-flow measurement data is the method adopted by the Dominion Government in analyzing the surface run-off for various streams throughout the country. Water Supply Papers issued annually contain this information and in Alberta, the flow data for a number of the important streams have been continuous for nearly thirty years. Experience has indicated that these stream flow records constitute the most reliable information of the water supply available from any drainage basin.

In the case of the Bow river in Alberta, the twenty-five years of these records show a great variability from year to year and from season to season. A flood stage for a short period may be over one hundred times greater than the minimum winter flow. Also, averages of the years or averages of the winter flow periods are not necessarily good guides to the probable water supply for the present year or for the next low water season. From a power viewpoint the dates of beginning and end of each low water season are subject to large and unpredictable variations. An early cold winter and late spring may necessitate many thousands of acre feet of storage water for power purposes more than would be indicated by forecasts based on the averages of past records.

A prolonged period of less than normal rainfall in the catchment basin results in a lower ground water table and less run-off may be expected during the next winter period. However, such general indications must always be supported by accurate records of stream flow, and the great variation in amount of run-off from year to year emphasizes the importance of daily records.

In many cases the average daily discharge can be obtained during the winter period by a hydro plant located on the river and in summer at a standard gauging station below the plant. The gauge height discharge relationship at a standard gauging station so located may be determined by current meter measurements or by use of the "increment method." Both of these methods will be described.

The study under consideration in this paper has only to do with the particular flow of the Bow river near Radnor. It has been made possible through the co-operative efforts of the engineers of the Calgary Power Company Limited and the engineers of the Dominion Water and Power Bureau, in the joint maintenance of this gauging station.

In the matter of the determination of the discharge of any surface water stream, several methods may be employed. As early as 1775 the famous French formula $V = C\sqrt{RS}$ was developed by the French engineer M. Chezy, and this formula has been very widely used even to the present day. Where stream stages are very high and velocity flow instruments cannot be lowered into the water due to floating debris, ice, etc., the Chezy formula is still commonly used. Where the stream flow is very small and suited to the installation of a weir, this method is preferable and often used. In general practice, however, in Alberta, stream flow measurements are made by the use of a current meter. During the history of the hydrometric survey in Alberta, as well as for all of Canada, various types of current meters have been used and extensive experiments have been conducted at the Dominion Government Rating Station at Calgary on different types of meters with a view to selecting from time to time the most suitable instrument for the work at hand.

TABLE I*

DOMINION WATER AND POWER BUREAU

Discharge Table for Bow River below Ghost Plant near Radnor, Alberta. Developed by the Dominion Water and Power Bureau by the standard method.

| Gauge height Feet | Discharge Sec.-ft. | Difference Sec.-ft. | Gauge height Feet | Discharge Sec.-ft. | Difference Sec.-ft. | Gauge height Feet | Discharge Sec.-ft. | Difference Sec.-ft. |

In water power operations various methods or combination of methods may be selected for determining the total stream flow past the plant and the Calgary Power Company has developed a new method which was used to rate the Bow river below their Ghost plant some 32 miles west of Calgary. The Ghost hydro-electric plant has a head of 110 ft. and an initial installation consisting of two vertical units of 18,000 hp. each with one station service unit of 1,450 hp. These units have been rated by the Gibson method and careful records are kept by the plant operators of the amount of water used by the plant each hour.

In conjunction with these measuring facilities at the power plant, the Dominion Water and Power Bureau maintains a gauging station about three miles below the plant. At this point an automatic gauge, housed in a shelter, provides continuous water stage records, and at

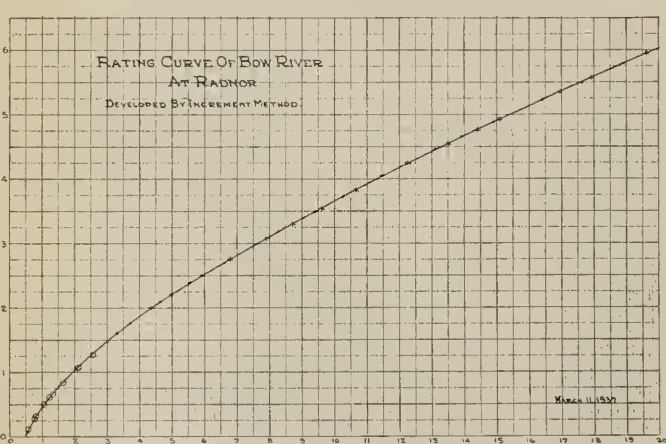

**Fig. 1—Rating Curve of Bow River Developed by Increment Method.**

a point about one mile below the plant, a cable is erected over the river from which current meter discharge measurements are secured.

All measurements at the above gauging station have been made with the standard equipment of the Dominion Water and Power Bureau including cable car, current meter, timing apparatus, sounding board, elliptical sounding weights, etc. The current meter and weights were suspended by 18 strand 1/16 in. diameter steel cable with a water return recording apparatus. Velocities in the vertical for each measurement were taken at 10-ft. intervals over a river width varying from 163 ft. at low water to 295 ft. at high water. The measurement experiments as conducted covered stages up to moderately high water comprising maximum sounding depths of 12.5 ft. Mean velocities for discharge measurements varied from 2.28 ft. per sec. at low water to 8.56 ft. per sec. at high water. Twenty current meter measurements in all have been secured and while the measuring section is not a perfect one, especially at low stages, owing to parts of the river bed being rough, yet the curve has been fairly well defined for all stages.

The use of the power plant for determining the daily winter flow of the river has many advantages. This method is free from the possible large inaccuracies in backwater estimates which comprise the major difficulty at gauging stations under varying ice conditions. However, during the open high water period the flow through the plant is small in relation to the total discharge of the river and the gauging station below the plant is necessary at this time.

The "increment method" used by the Calgary Power Company in developing the gauge height discharge curve at this gauging station, was to release known amounts of water by means of the Ghost power plant and to add this to the sluice dam discharge which was determined from the portion of rating curve already established.

The first step was to form the lower portion of the rating curve. This was done by the power plant alone from the lowest flow to high discharges which could be passed through the machines at times when no water was being spilled through the sluices. In order to do this a base load was carried by one or two machines at the Ghost plant to discharge a definite amount of water and this load was held until the graphic record of gauge height at the gauging station indicated a constant flow for at least one hour. The gauge height corresponding to this flow was read from the graph and the discharge was computed from the plant records. In this manner the rating curve was developed from 160 to 2,550 cu. ft. per sec.

The next step was to transfer all load from the Ghost plant to the other plants in the system and to operate the sluice dam to give a river flow at the gauging station somewhat less than the 2,550 cu. ft. per sec. previously determined. When the graphic record of gauge height indicated a constant flow, the sluice discharge was found to be 2,100 cu. ft. per sec. This was read from the portion

Table III

Percentage Difference between the two tables at half foot intervals of change in stage. Above two feet it will be noted that the results are remarkably close.

| Gauge height in feet | Dominion Water and Power Bureau Table used as Basis Table Sec.-ft. | Calgary Power Company Increment Table Sec.-ft. | Difference Sec.-ft. | Per cent difference |

of the rating curve which had been completed. The flow of 2,100 cu. ft. per sec. was maintained through the sluices and the plant then picked up enough load to give an additional discharge of 1,200 cu. ft. per sec. The total flow would then be 3,300 cu. ft. per sec. for which a gauge height would be recorded at the gauging station. This gave a new point for extension of the rating curve.

The plant was closed off again and the sluice discharge increased to 3,020 cu. ft. per sec. as shown by the rating

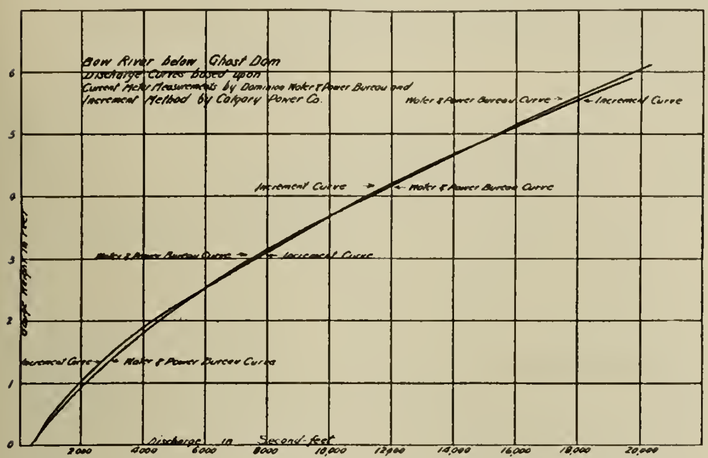

**Fig. 2—Current Meter Measurements of Bow River by (*a*) Dominion Water and Power Bureau and (*b*) Increment Method.**

curve. This flow was maintained at the sluices and the plant added another 1,340 cu. ft. per sec. which gave a total of 4,360 cu. ft. per sec. and another new point for extension of the rating curve.

In this manner the increasing spring flow was utilized to rate the river up to 20,000 cu. ft. per sec. by spilling through the sluices an amount which could be determined from the rating curve already established and adding a known amount through the power plant to give a further extension to the curve. A large number of check tests were made whenever river flow and load conditions were suitable and the manner in which these confirmed the original data indicated that confidence could be placed in the final result.

A brief description of the set-up necessary to follow this method may be of interest.

It is necessary to have an accurate means of determining the amount of water used each hour by a hydro plant and the fundamental information for this is obtained from recent overall ratings of each unit in the plant. Tables can then be compiled from these ratings to show the relation of kilowatt output to the water used for each machine under all conditions of head and load.

The Calgary Power Company's method of using this information was to select the greatest kilowatt output per second-foot which could be generated by the most efficient machine in the plant at its best load at full supply head. This was considered the maximum output for which there was no loss due to head or to unfavourable load apportionment. The output per cubic foot per second of water of this most efficient unit at any other load, or at less than full head, was of course less than the greatest possible output by a definite amount which could be expressed in kilowatts loss. Similarly all other units for the various loads and heads were compared to this highest possible output in kilowatts per cubic foot per second and their loss amounts listed in kilowatts below this amount. In this manner the ratings of all the machines were tabulated, showing a kilowatt loss amount below the maximum possible output of the most efficient machine in the plant. To determine the water used by any machine under the actual conditions of load and head the operator reads the kilowatt loss corresponding to the load and head conditions for each machine at the time, to which is added the load generated. This total kilowatt amount, when divided by the maximum kilowatts per second foot possible with the most efficient machine, will show the water used by the unit for the period. By this method the amount of water used by each machine is known and the total discharge below the plant, including leakage, may be determined.

This information served a double function, since it not only allowed a rapid determination of the amount of water used by each machine under any condition of load and head, but it also formed the basis of a plan for selecting the best combinations of machines and indicated the most efficient load for each machine for any required total load on the plant.

All leakage, including sluice dams, flashboards, headgates, turbine gates and other known percolation, is included in the total discharge recorded for the flow past the plant each hour. This provided the method of adding known increments of water by the power plant to determine the rating curve at the gauging station below the plant.

During the rating of the river discharge at the gauging station, the amounts of water spilled through the sluice dam were known, since the discharge was always held within the developed portion of the rating curve. The increment added by the plant to this gave the new point each time for the extension of the rating curve when used with the corresponding gauge heights shown at the gauging station. However, it was difficult to hold the sluice dam discharge constant which was a desirable condition for this method. The reservoir above the dam was always in a rising or falling stage during these operations and it was found necessary to rate the sluice openings in order to compensate for these changes in head. There are many variables and difficulties which arise in the rating of sluice dams when the openings are considered as broad crested weirs, and all test runs which showed a rise or fall of the reservoir exceeding one-tenth of a foot were discarded and corrections were computed for the minor changes in head. It was found that any single sluice opening, operated alone, could be rated quite accurately as a broad crested weir for the varying conditions of head and the height of stop logs in the opening. Also, the entire sluice dam could be rated satisfactorily with all stop logs removed from all of the openings, but difficulty was found in rating two or three adjacent openings together, as the ratings were never consistent with the sum of the individual discharges of the sluices. This is probably due to a combination of velocity of approach conditions above the sluices and the varying partial vacuum conditions below the crest. Spilling at the sluice dam during the tests, for the purpose of rating the gauging station, was carefully controlled and the required discharge obtained by operating single sluice openings with at least two closed openings on either side. The high amounts of sluice discharge were obtained when all stop logs were removed from all of the openings.

Figure 1 indicates the development of the rating curve derived by the "increment method." The circles represent discharges obtained from the plant alone, the dots show discharges through the sluice dam which were determined from the gauge heights shown at the gauging station and the crosses indicate the sum of the sluice dam discharge and the increment passed by the hydro plant. The crosses show the new points used for the projection of this rating curve. It will be noted from this method that sluice discharges should always show a lesser gauge height than the highest point determined at the time on the rating curve, since otherwise the projection of the curve would be dependent upon an estimate of slope and subject to possible inaccuracies which would influence the location of the balance of the rating curve.

The Calgary Power Company rates this station by the "increment method" each spring and takes many test points in the fall so that slight changes in the control below the gauging station or formation of gravel bars here will be compensated for by comparable changes in the rating curve.

The rating curve for this gauging station determined by the Dominion Water and Power Bureau by their standard practice is remarkably close to that developed by the "increment method" and it is believed that this latter method may be used to advantage in many locations where stream flow records are required and where such hydrometric records are not ordinarily taken by the Dominion Water and Power Bureau or other departments.

# Freight Hauling in Undeveloped Territories of Canada

*J. B. D'Aeth, M.E.I.C.*

## DISCUSSION[1]

C. R. Townsend, A.M.E.I.C.[2]

The author stresses the part that organization plays in any successful transportation scheme in undeveloped territory and we agree, and believe it is true of all transportation. The first census of the trucking industry in the United States reveals a great concentration of business in the hands of a few truckers. In 1935, 1.5 per cent of all concerns operating there received nearly half the total revenue, operated nearly 30 per cent of all trucks, and paid over 53 per cent of the total payroll of the industry. It seems likely that there is a connection between being able to pay close attention to details of organization and the concentration of the trucking business.

It is proposed to discuss a single but important phase of winter transportation in an undeveloped country where sleighs are used. During a study of the use of motor trucks in winter sleigh hauls it was found that there is often a considerable difference in truck performance under apparently similar conditions and this was so marked that it was considered worth while to attempt the determination of coefficients of sliding resistance of steel runners on ice and snow roads.

The only careful consideration of the use of runners on ice and snow surfaces which could be found is contained in Bulletin 13 of the School of Forestry, Yale University, and this was written before trucks had been used on sleigh hauls. The bulletin shows the sliding resistance of logging sleds on an iced road as being from 20 to 45 lb. per ton of gross load and says that "The sliding resistance during very cold weather (−30 deg. to −40 deg. F.) is about 20 per cent greater on an iced road and about 30 per cent greater on a snow road than when the temperature is just below the freezing point."

It is a generally accepted theory that steel shod runners slide easily on an ice surface because the pressure of the runners on the ice causes a film of water to form which lubricates the ice surface. This is an excellent theory but it does not explain fully variation in the coefficient of resistance or the action of the runners.

Tests were made with model sleds and due to lack of time and of cold weather they were comparatively few in number and results are shown to indicate a trend rather than to be all conclusive. The apparatus used was simple, consisting of a wooden frame work, erected on the frozen surface of a lake, with a pulley suspended near the top and another pulley attached near the base. A rope, attached to the sled under test, was passed through the two pulleys on the frame work and had a tray suspended from the end. The tray supported weights which gave a measure of the force necessary to move the sled under test. At below freezing temperatures it was found that when sufficient weight was put on the tray to start the load, this weight almost immediately gave the sled a considerable acceleration. It was then decided to get two values, one for a force which would not quite move the sled and a second for a force which would keep the sled moving after it had been given an initial low velocity. It should perhaps be stated that care was taken to have the runners dry for each test and in determining the first value the sled runners were tapped continuously while weights were being placed on the pan so that there was no "freezing down."

The results of the test were plotted on a graph (Fig. 1), with weight in pan divided by gross weight of sled, against temperature. Two points were plotted at each temperature below freezing at which tests were made. One point for zero velocity and the second for a velocity of 2 to 3 m.p.h. At above freezing temperature no difference between zero velocity and extremely low velocities could be found as with the apparatus used no practical way of closely determining velocity was available.

Results for 2 to 3 m.p.h. sliding resistance at below freezing temperatures showed agreement with the figures given in the bulletin previously referred to, but the resistance at zero velocity was about twice as high at a temperature just below freezing and about three times as high at a temperature below zero. At a temperature above freezing sliding resistance at low velocities gave results much below any on the opposite side of 32 deg. F. (see Fig. 2).

From the tests the following conclusions were drawn:

1. Sliding resistance of steel runners on an ice surface varies with temperature, but a large variation and probably most of the variation takes place through 32 deg. F.
2. Sliding resistance varies with velocity and with a great variation in low velocities at below freezing temperatures.

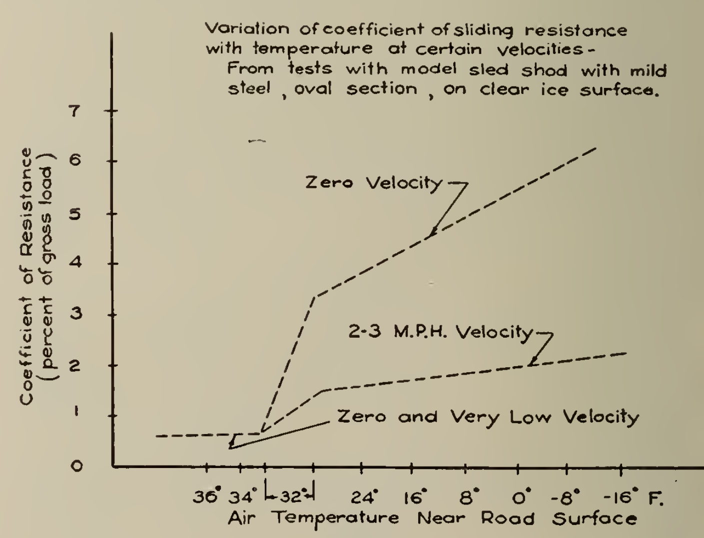

Fig. 1

3. Sliding resistance could be greatly reduced in below freezing temperatures by the application of water to the road, immediately before the runner passes.

There was no opportunity to try out "lubricating" a road in freezing temperatures but since the test was completed it has been found that one of the large paper companies practices this on at least one of its truck sleigh hauls by applying water to the road surface shortly before the trucks pass with loaded sleighs. An even more interesting case is that of a lumber company in Manitoba, where on a tractor sleigh haul, a water tank is drawn between

[1] Paper published in the Engineering Journal, September 1937.

[2] Canadian Pulp and Paper Association, Montreal.

tractor and loaded sleighs, with the water of the tank used to lubricate the road surface as necessary. Complete records of this operation are not available but it is known that a tractor with maximum draw-bar pull in low gear, of about 20,000 lb. (at 1.7 m.p.h.), has drawn loads of as much as 1,400 tons gross weight, indicating a sliding resistance of not more than about three-quarters of one

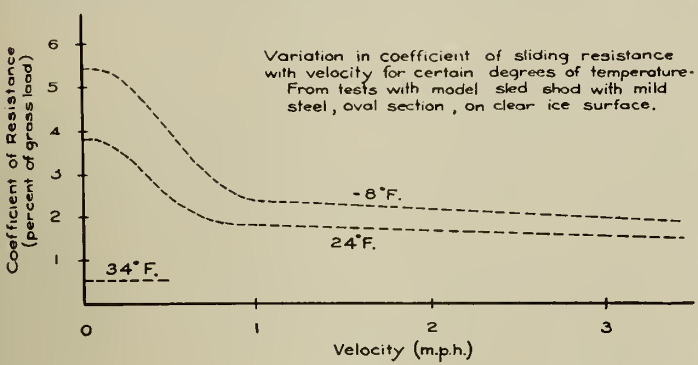

Fig. 2

per cent, and actually less as the tractor was able to work in higher gears over much of the road.

The lubrication of a winter road offers interesting possibilities. Using it a road might be deliberately located with a grade which would be insurmountable without lubrication. On a road in hilly country the "control" hill might be lubricated allowing greater loads to be hauled on each trip over all the road.

The low coefficient of friction at above freezing temperatures may seem to be of little interest in a winter hauling operation but on reflection, it will be found that there are numerous winter sleigh hauls which are carried on over short distances and with perhaps 5 to 10 round trips completed during the hours of daylight. On a sunny day even in the midst of winter the temperature of the air near the road surface is often above freezing and when this condition occurs sliding resistance will be at its lowest value. It seems possible that some practical use could be made of this and that loads on short hauls could be adjusted to the variations in sliding resistance.

The lowest possible value for rolling resistance of pneumatic tires, on the finest type of highway, is about one and one quarter per cent (25 lb. per ton), and on the usual dirt highway in undeveloped territory it is at least four per cent. It is of interest to know that it is possible to construct a temporary winter road, at comparatively low cost, over which loads can be hauled on sleighs with a resistance lower than the rolling resistance of the finest type of highway.

J. A. Freeland, A.M.E.I.C.[3]

Were bumping-poles used between the sleighs of the trains; the pictures did not indicate their presence.

W. J. Carson[4]

Further attention might be drawn to the heavy loads which it was possible to haul over winter roads. A load of 1,200 tons had been drawn at 6 m.p.h. with a draw-bar pull of only 6,000-7,000 lb. The difficulty lay in getting the load under way: once it was started, almost any load could be drawn.

John Chalmers, M.E.I.C.[5]

Was there any trouble experienced from side-sliding of the sleighs?

D. Forgan, A.M.E.I.C.[6]

The table of costs given in the paper was an eye-opener. On the Albany river near Pickle Crow, they had been unable to reduce the costs below forty cents per ton-mile: more usually it had been around sixty-five cents or higher. The value of well-made and well-protected roads should be stressed. It was often safer to use tractors without cabs, so that the drivers could jump clear in case the machine went through the ice.

O. Holden, A.M.E.I.C.[7]

The cost of transportation was a very vital matter. For example, in a 1,500 hp. power development on the Albany river the cost of transportation of materials from the railway represented no less than 20 per cent of the total cost of the work. Money was in general well-spent on improvements to navigation, and in one instance, by means of dams to drown rapids and marine railways and other improvements, the cost of transport was reduced from $60 to $20 per ton for a distance of about 160 miles.

J. B. D'Aeth, M.E.I.C.[8]

Special emphasis has been laid on the fact that a thoroughly good, competent and trustworthy organization must be employed. The reasons for this are:—

The winter freight hauling season is short—about three months.

The work is intermittent—that is, the organization generally cannot be held together during the entire year and one must know where good men are to be obtained when required.

While en route, the drivers are thrown on their own resources and have to get along the best they can with the equipment at their disposal. They are subjected to all sorts of weather and road conditions.

Mr. Townsend's experiments on winter road lubrication are extremely interesting and it is to be hoped that further experiments will be carried out along the lines already started. It will be noted that two haulage outfits have been making practical use of lubricating their roads to good advantage. One of these outfits has hauled 1,200 tons with a draw-bar pull of only 6,000 to 7,000 lb. In this particular case a second tractor had to help to get the load started.

In answer to Mr. Freeland, bumper poles were used between the sleighs. The usual connections between the sleighs are either cross chain connections with bumper pole or a pole connection of the T or the triangular type. There are usually cross chains or cross rods with bumper pole between the front and rear runners of a sleigh.

Trouble from side sliding or slewing as questioned by Mr. Chalmers is greatly reduced by rutting the road and by having solid shoulders. There is a tendency with fast truck-drawn sleighs to slew and the rear sleighs of the train to have a whipping action. This will occur where the road is wide and there are no ruts or shoulders to hold the runners in place.

On steep descending grades, there is a tendency for the train to buckle and become unmanageable. This is overcome by sanding the road, and if very steep, also by tying a chain around the last sleighs. This latter procedure is not desirable as it destroys the road.

The particular route mentioned by Mr. Forgan is known to be a bad one, being largely over lakes, which are very slushy and considered dangerous.

One of the troubles of freighting into the Red Lake and Pickle Crow districts is that the various concerns located there each lets a contract for its own needs. The result is that there are several hauling contractors operating in this district, none of whom can afford to build and maintain a good road. Each makes his own trail across the lakes with consequent high cost per ton mile.

# THE ENGINEERING JOURNAL

## THE JOURNAL OF THE ENGINEERING INSTITUTE OF CANADA

"To facilitate the acquirement and interchange of professional knowledge among its members, to promote their professional interests, to encourage original research, to develop and maintain high standards in the engineering profession and to enhance the usefulness of the profession to the public."

VOLUME XX OCTOBER, 1937 No. 10

## Visiting The Institute Branches

The visits to the branches, which the officers of The Institute are able to make from time to time, play an important part in the policies of our organization. The branch news, published in The Journal, serves to picture the interests and activities of each branch, and shows how its operations are carried out in conformity with the requirements of its members. Gatherings such as the Round Table Conference of Branch Representatives, which has just concluded, aid by giving an opportunity for the free interchange of information and for active debate on matters of branch policy and on branch activities. There is, however, a need for more than this. The problems which the branches have in common; the results of the deliberations of Council and its committees; the aims of The Institute as a Dominion-wide body of engineers, are topics of the kind which can best be dealt with by personal visitation of the branches by the officers of The Institute. It is also important that so far as is possible these officers should be personally known to the branch officers, executive committees and members, and that it should be possible for them to answer inquiries and make explanations which will clear up points on which branch members desire information. For these reasons the journeys which successive Presidents (and in many cases vice-presidents) of The Institute have found it possible to make, have constituted a most valuable service to The Institute. The branches recognize this, and have invariably voiced their appreciation of such visits by the heartiest welcome, and by almost overwhelming hospitality.

To this issue of the Journal President Desbarats contributes some notes of his recent tour of the western branches. Travelling some five thousand miles, he has come back with the impression, shared by his predecessors who have made similar journeys, of widespread activity on the part of the branches and of their keen interest in the affairs of The Institute as a whole. From the President's notes it will be evident that he was able not only to meet the officers and members of the various branches, discussing with them many of the problems which face The Institute at the present time, but also to prepare and present to the readers of The Journal a concise survey of existing industrial conditions, on which the engineer's work is so largely dependent.

Canada is a country of such wide extent, and its various zones possess such a diversity of geographical and racial characteristics, that the promotion and maintenance of a broad Dominion-wide outlook should be the mission of every good Canadian. Such journeys as that which the President has just completed cannot fail to have great influence in this direction. They certainly help Institute members to realize that the branch to which they may belong is only a part (though an essential part) of a much larger organization, whose recognized national, and indeed international, status, was so clearly evidenced at The Institute's recent Semicentennial Celebrations.

## Annual General Meeting 1938 to be held in London, Ont.

The Council has accepted with pleasure the proposal of the London Branch that the Annual General and General Professional Meeting for 1938 shall be held in London, Ontario, at the end of January. The headquarters for the meeting will be at the London Hotel, and an energetic local committee is at work on the preliminary arrangements. The actual dates will be announced shortly.

A full programme of technical papers is being planned to feature two subjects of special interest in Ontario, namely; The Engineer and Highway Safety, and Flood Control in Ontario.

The choice of London as a meeting place for The Institute is appropriate, first, because it is the seat of one of our most active and enthusiastic branches, and, secondly, because its central location makes it easy for members to attend from the principal industrial areas of the province.

## The E.I.C. Engineering Catalogue 1937

The 1937 edition of the E.I.C. Catalogue is now being distributed to corporate members of The Institute whose duties involve the selection or approval of engineering equipment. It is also sent to a number of executive officers of important industrial and engineering organizations and to engineers and architects in the construction field.

In the volume now published, it will be found that there is a considerable increase in the number of firms represented and in the number of products described. The list of index subject headings, which has been drawn up on a comprehensive basis, with reference to all branches of engineering, includes some 3,000 entries dealing with a variety of materials, equipment and products, ranging, for instance, from abrasive materials and battery charging equipment to ventilating systems and zinc. Information as to their products has been furnished by some 3,900 individual firms.

The primary object of such a comprehensive catalogue is to provide in a single volume information which will give a list of the available sources of supply of the various types of equipment, materials, etc., and at the same time furnish such data regarding these products as will assist the purchaser in determining that best suited to his requirements.

# Notes by the President on his Western Trip

During the month of August I had the pleasure of visiting the Western branches of The Institute from Sault Ste Marie to the Pacific Coast. I wish to thank the members for the kind reception I received and for the many courtesies extended to my wife and myself.

It was very gratifying to observe the spirit of optimism and cheerfulness which prevailed generally among the members of The Institute. Business throughout the country is improving. Engineers felt the first effects of the depression and resulting slackening of manufacturing and construction and they are now profiting from the better conditions prevalent throughout the country.

*Sault Ste Marie:* Each branch visited put forward some new project or some improved conditions to justify their optimism. At Sault Ste Marie the Algoma steel plant, after a long shut down, had resumed operations and was running full time. The Helen iron mine to the north is being re-opened, the port of Michipicoten nearby on Lake Superior is being equipped to handle the large shipments of iron ore which are anticipated, and the paper mill is running full time. The locks at the Sault are handling very heavy traffic this year.

*Lakehead:* At Fort William the works of the Canada Car and Foundry Company which have been closed for years are now being utilized by an aeroplane factory. The Great Lakes Paper Company is operating full time with a machine turning out a sheet 304 inches wide, the widest in the world until recently when a wider machine was manufactured for a Scandinavian firm. Shipments of grain through this port will be light this year owing to the small crop, but the dry dock at Port Arthur reports good business with a large amount of ship repair work. The mining development north of this section helps the Lakehead cities, which are feeling fairly well off.

*Regina:* Regina, in the middle of the drought district, does not present such an attractive picture. The surrounding plains are dried up after seven rainless summers and crops were light or non-existent. As a result business was poor, but the community refuses to be cast down. They base their hopes on forecasts issued both from Ottawa and Washington prophesying the end of the dry cycle and the return of the years of good rainfall, with resulting abundant crops and renewed prosperity for Saskatchewan and the West.

The engineers here are fairly well occupied on maintenance work, highway construction, water conservation projects and investigations and experimental work for relief of drought conditions.

At Regina through the courtesy of the "Leader Post" I was given the opportunity of addressing a radio audience over Station CKCK and saying a few words about the aims and doings of The Engineering Institute and the work of the engineer.

*Lethbridge:* After leaving the burnt up countryside at Regina and Medicine Hat it was very pleasant to see the green irrigated fields of the Lethbridge district. Dairy farming and coal mining are Lethbridge's chief industries and both are doing well. There is a strong community spirit in Lethbridge, one of the irrigation systems is a community venture and the main hotel is also a community enterprise.

Throughout Alberta engineers are mainly occupied on maintenance work, as owing to the political situation it is difficult to obtain capital for any new enterprise and construction work is therefore pretty much at a standstill. Crops in Alberta are fairly good, and with higher prices for grains and dairy products, general conditions have improved considerably.

*Calgary:* An interesting development is proceeding in the Turner Valley, some 40 miles southwest of Calgary. The early wells at the north end of the valley produced wet gas with a small percentage of oil. The later wells, further south, are giving a higher proportion of oil and it is expected that by this fall the production will be sufficient to supply the needs of Alberta in gasoline and possibly have some for Saskatchewan. The gas is piped to Calgary, High River and the surrounding districts and some has been pumped into exhausted gas fields, but a large quantity of gas goes to waste. The wells are now being drilled about 6,500 ft. to the limestone in which the gas and oil are found and the cost of drilling a well is about $150,000.

*Edmonton:* The prospecting and mining development work now being carried on in the valley of the Mackenzie and its connecting lakes brings business to Edmonton and provides employment for engineers.

While in Edmonton I presided at the unveiling of a memorial sundial erected on the power plant grounds as a tribute to the late W. J. Cunningham, M.E.I.C., former superintendent of the Edmonton power plant. The mayor, civic officials and members of The Institute took part in the ceremony, showing the esteem felt for Mr. Cunningham by his fellow citizens and fellow engineers.

*Victoria and Vancouver:* In British Columbia a good deal of government work was in progress. The Dominion Government is building the last link of the western half of the Trans-Canada highway around the big bend of the Columbia between Golden and Revelstoke. This is a heavy job and will not be completed for a couple of years. The Dominion Government is also completing the stations and landing fields of the Trans-Canada Airways. At New Westminister the new highway bridge over the Fraser is nearing completion; this will replace the present inadequate bridge leading to the highway system of the Western States. A British company is building a bridge over the First Narrows from Stanley Park to North Vancouver. The caissons for the piers are being built and work is proceeding on the approaches. The same interests are developing a large area on the north shore of the Inlet for residential purposes. The plans are on a lavish scale.

*Winnipeg:* Manitoba was rejoicing in a reasonable harvest and with government public works there was good demand for labour. Engineers in Winnipeg are faced with a foundation problem. Owing to the succession of dry seasons and as a result of city drainage, the clay subsoil has dried up and shrunk and the medium class of buildings are settling badly, necessitating expensive underpinning. The Winnipeg branch of The Institute have appointed a committee to study the question and, working with committees from other societies, have produced a valuable report on the causes of this trouble and have suggested means of avoiding it. Another committee has been appointed to study the related subject of ground water conditions in Winnipeg. The Winnipeg Branch is to be congratulated on the public spirit it shows in undertaking this work; other Branches could follow their example with profit.

At each Branch visited I gave a short talk about the work and aims of The Institute. I discussed the vote on the proposals put forward by the Committee on Consolidation and pointed out that while these proposals had been rejected, the discussion at the Plenary Meeting of Council showed that The Institute was anxious to have the greatest possible measure of co-operation with the Provincial Professional Associations. I described the recently appointed Committees on "Professional Interests" and "Membership and Management" with their personnel and their objects. I gave a description of the Semicentennial Meeting, mentioning its success and the high standing of the delegates from other engineering societies, stressing the high position held by The Institute in the scientific and engineering world, and the advantage to Canadian engineers of possessing a well-established national society. I also gave a statement of the finances of The Institute.

These talks seemed to be well received by the members. At three of the Branches ladies attended the meetings and I hope they were not bored by what must have been to them a rather dull talk.

At each Branch visited I found the friendliest relations existing between members of The Institute and members of the Professional Associations and a large measure of cooperation in existence. Marked interest was displayed in the work of the two committees appointed by Council and the belief was expressed that they would be of great benefit to The Institute.

Every Branch professed a desire for frequent relations with headquarters and visits from officers of The Institute. They urged that members of The Institute travelling through the west should arrange to stop over and give addresses to some of the Branches.

I wish again to express my appreciation of the kind way in which I was received by the Branches, of the attention given to my talks and of the trouble taken by the officers in arranging meetings and entertainments, and I trust these visits will be of some advantage to The Institute and to its Branches.

G. J. Desbarats,
*President.*

# OBITUARIES

## Charles Francois Xavier Chaloner, M.E.I.C.

The death of Charles Francois Xavier Chaloner occurred in October 1936 and will be noted with regret, particularly by the older members of The Institute.

Mr. Chaloner was born in Quebec on March 5th, 1861, and was educated at St. Anne de la Pocatière College and Laval University. He became a Member of The Engineering Institute in February 1887. In 1880 he was appointed to the engineering staff of the Public Works Department, with R. Steckel, as first assistant engineer in the inauguration of precise levelling in Canada. As assistant engineer he was on the first hydrographic survey made of the St. Lawrence river and as principal assistant engineer was on precise levelling during the years 1883 to 1904. From 1904 to 1908 he was in charge of the Georgian Bay precise levelling party. In 1910 he was appointed engineer-in-charge of this work and was actively engaged until his retirement in 1931, completing a stretch of over 50 years continuous service.

## Samuel Ernest McMillan Henderson, M.E.I.C.

It is with deep regret that members of The Institute, particularly those in Toronto, will note the death of Samuel Ernest McMillan Henderson, m.e.i.c., who died on September 2nd, 1937, after a short illness.

Mr. Henderson was born at London, Ontario, September 8th, 1879, and graduated from the University of Toronto (School of Practical Science) in 1900. He joined the General Electric Company at Schenectady, N.Y., in 1900, first in the drafting room; he then became a designing engineer and later engineer on the manufacture and inspection of the original Hydro-Electric Power Commission of Ontario installation. In 1910 he was placed in charge of the design and engineering on the meters, switchboards, etc., of the Canadian General Electric Company; in 1913 he was appointed electrical engineer for the above company,

S. E. McM. Henderson, M.E.I.C.

latterly becoming manager of the switchgear section apparatus sales department.

Mr. Henderson joined The Institute as a Member in 1929.

## Thomas James Fleming King, A.M.E.I.C.

It is with regret that we record the death of Thomas James Fleming King, a.m.e.i.c., which took place in Quebec on August 16th, 1937, after some months of illness.

Mr. King was born at Everton, England, in 1879 and graduated from the Glasgow and West of Scotland Technical College. He came to Canada in 1906 where his first position was on the design of smelter layout for the Mond Nickel Company, Victoria Mine, Ontario. He then entered railway work in Canada and in 1908 was appointed resident engineer on the construction of the Atlantic, Quebec and Western Railway. He was later with the Intercolonial Railway and from 1910 to 1912 was in the division engineer's office of the Canadian Pacific Railway at Montreal and North Bay, Ontario. In 1912 he joined the engineering

T. J. F. King, A.M.E.I.C.

staff of the Canadian Government Railways as assistant engineer on location, later becoming office engineer, then acting assistant engineer and finally assistant engineer of the Canadian National Railway for the Quebec District.

Mr. King at the time of his death was vice-chairman of the Quebec Branch of The Institute.

### William Frederick McLaren, M.E.I.C.

We announce with deep regret the sudden death of William Frederick McLaren, on Thursday, August 19th, 1937, at his home, "Balquhidder," Ancaster, Ontario.

Mr. McLaren, at the time of his death, held the position of chief draughtsman of the Canadian Westinghouse Company at their offices at Hamilton. He was born at Hamilton, Ontario, on May 21st, 1871, and was a graduate of the Royal Military College, Kingston, Ontario, and subsequently of Cornell University, graduating from the latter institution in 1894. Following this he took the engineering course of the Westinghouse Electric and Manufacturing Company for a period of eighteen months, after which he was engaged in power plant operation in Revelstoke and at Bonnington Falls, B.C. In 1901 he re-entered the service of the Westinghouse Company at East Pittsburgh and was then continuously in the service of that company until his death.

A highly skilled member of the engineering profession, he served in the Canadian Westinghouse not only as chief draughtsman but also as principal mechanical engineer.

Due to his modesty, only his close associates knew of his outstanding ability in engineering as applied to the mechanical construction of electrical apparatus, especially

W. F. McLaren, M.E.I.C.

large generators and motors. His quiet courtesy and tact won the respect of all those associated with him.

Mr. McLaren became a Member of The Engineering Institute of Canada in 1918 and played a large part in upholding the standard of the Hamilton Branch. He was secretary-treasurer of the Branch for six years, later becoming chairman.

He went overseas during the Great War with the 164th Halton and Dufferin Battalion with the rank of Captain.

### Stewart Sterling Oliver, M.E.I.C.

In the passing of Stewart Stirling Oliver in Quebec, on August 17th, 1937, Quebec city loses one of its oldest engineers and The Engineering Institute of Canada one of its oldest members.

Mr. Oliver was born in Quebec on April 9th, 1858, and was educated in that city, receiving a certificate as a Quebec Land Surveyor in 1880. In 1884 he became assistant engineer on surveys and location for the Quebec and Lake St. John Railway. In 1894 and 1895 he was engineer in charge of construction on the St. Juliane and St. Maurice sections of the Great Northern Railway. From 1896 to 1907 he acted as auditor for the Quebec and Lake St. John Railway and in 1908 and 1909 was engineer of maintenance of the Canadian Northern and Quebec and Lake St. John Railways. From 1910 to 1917 he was in private practice and also right of way engineer for the Quebec Railway Light and Power Company and for the Quebec and Saguenay Railway. In 1918 he became purchasing agent for the Quebec Light, Heat and Power Company, and retired in 1930.

Mr. Oliver joined The Institute as an Associate Member in 1887, becoming a Life Member in 1931. He acted as secretary of the Quebec Branch of The Institute in 1911 and chairman in 1912.

### Jeremiah James Macdonald. M.E.I.C.

We deeply regret to have to announce the death on September 4th, 1937, of Jeremiah James Macdonald, M.E.I.C., an outstanding Canadian engineer and at the time of his death chief engineer with Sir Alexander Gibb and Partners, London, England.

Mr. Macdonald was born at Vernon, P.E.I., on February 1st, 1882, and graduated with the degree of B.Sc. from McGill University in 1911. Prior to and during his university course, he was engaged on preliminary and location surveys on the Transcontinental and Canadian Northern Railways. In 1911 and 1912 he was with Waddell and Harrington, consulting bridge engineers, in Kansas City, Mo., engaged in the design of lift bridges and reinforced concrete structures, bridges and viaducts. In 1913 he acted as lecturer in mathematics and demonstrator in the civil engineering department of McGill University. From 1913 to 1916 he was office engineer for the Halifax Ocean Terminals in charge of structural design. From 1917 to 1918 he was assistant engineer for the Canadian Government Railways at Moncton and in 1918 and 1919 was resident engineer in charge of the installation of sewerage and water systems and the construction of reinforced concrete carshops in connection with the Halifax Ocean Terminals.

In 1919 Mr. Macdonald became chief engineer of design for W. Alban Richards, engineers and contractors, London and Paris, where his work included the construction of important works, notably the extension of the Royal Edward Dock at Avonmouth and large grain elevators for the same port. In 1923 he became construction engineer with the J. G. White and Company Limited, London, England, and had charge of the construction of the steam-electric power station for the London County Council at Barking. He also directed extensive sanitation and harbour works in South America for this company. In 1925 he was engaged on the difficult foundation work on the bridge across the River Tyne at Newcastle under Sir Douglas Fox and Partners for Dorman Long and Company.

In 1926 Mr. Macdonald returned to Canada and was appointed chief engineer of the Foundation Company of Canada Limited with headquarters in Montreal and in 1930 was appointed chief engineer of the Halifax Harbour Commission. While with this Commission he was called upon by the Federal Government to take charge of the reconstruction of the docks at Saint John, New Brunswick, after the disastrous fire, and did that work with great credit to himself and the organization with which he surrounded himself. The expenditure on the works in question amounted to over ten million dollars.

On completion of this work Mr. Macdonald returned to his duties with the Halifax Harbour Commission but a short time after was invited to join the staff of Sir Alexander Gibb and Partners, consulting engineers, London, England, where he was responsible for the design, supervision and construction of several large projects in England, Wales and other countries, most notably the rehabilitation of industries in Wales and the northeast coast of Great Britain.

Mr. Macdonald joined The Engineering Institute of Canada as a Student in 1911, became an Associate Member in 1914 and a Member in 1920.

## PERSONALS

W. Clyde Baggs, S.E.I.C., has recently received an appointment with the Bathurst Power and Paper Company Limited, Bathurst, New Brunswick. Mr. Baggs, whose home is in Curling, Newfoundland, graduated from Mount Allison University and subsequently from McGill University in 1936.

F. W. Bradshaw, A.M.E.I.C., has received an appointment as assistant to the chief engineer of the Consolidated Paper Corporation Limited, Grand'mère, Quebec. Mr. Bradshaw graduated with honours in chemical engineering from McGill University in 1925 and prior to and since graduation has had extensive experience in the pulp and paper industry. From 1925 to 1930 he acted as assistant to the mechanical superintendent of the Riverbend mill of Price Brothers and Company Limited, except for a six months period as assistant to their research engineer at Quebec. From 1930 to 1932 he was chemical engineer at the Jonquière mill of the same company. Between 1932 and 1934 Mr. Bradshaw was with the Carleton Mills Limited, Carleton Place, Ontario, and Beardmore Leathers Limited, Acton, Ontario. In 1934 he joined the Consolidated Paper Corporation as development engineer in their research and technical department at Three Rivers, Quebec.

Eric M. Coles, A.M.E.I.C., has been appointed assistant to the vice-president of the Canadian Westinghouse Company, Hamilton, Ontario. Mr. Coles graduated in mechanical engineering from the University of British Columbia in 1922. He then became instructor and later assistant professor of electrical engineering in the same University. Mr. Coles joined the Canadian Westinghouse Company as design engineer in the synchronous motor and generator section of the engineering department and in 1928 was placed in charge of all patent activities of the company. He served overseas during the War with the Royal Air Force and was awarded the Distinguished Flying Cross. Mr.

Eric M. Coles, A.M.E.I.C.

Coles has been active in the Hamilton Branch of The Institute for a number of years.

G. Sandford Davis, M.E.I.C., has been appointed assistant electrical engineer of the Department of National Defence in Ottawa. Prior to this appointment, Mr. Davis was electrical engineer with J. M. Robertson and Company, Montreal, with whom he has been connected since 1920. From 1905 to 1920 he was with the Canadian General Electric Company, as erecting and later design engineer.

P. C. Hamilton, S.E.I.C., has been appointed district engineer with the Gunite and Waterproofing Limited and Construction Equipment Company Limited with headquarters in Halifax, Nova Scotia. He was previously with the Avon River Power Company Limited, having graduated from the Nova Scotia Technical College in 1933.

W. G. Hamilton, S.E.I.C., recently severed his connection with the Tashota Gold Fields Limited, and is now mill superintendant and chief assayer at the Mine Apprentice Project, Lacey Gold Mine, Chester Basin, Nova Scotia. Mr. Hamilton graduated from the Nova Scotia Technical College with the degree of B.E. in Mining in 1935.

A. H. Pask, Jr.E.I.C., formerly with the Eagle Pencil Company Limited, Drummondville Quebec, is now located in Windsor, Ontario, where he is in the engineering department in the salt and general chemicals plant of the Canadian Industries Limited. Mr. Pask graduated from the University of Manitoba in electrical engineering in 1935.

M. E. Tregarthen, A.M.E.I.C., has recently received the appointment of assistant electrical engineer in the Department of Road Transport and Tramways, Sydney, Australia. This department controls the tramways and trolley bus system in New South Wales. Mr. Tregarthen was previously assistant engineer with the Department of Public Works of New South Wales. From 1927 to 1928 he was in Canada and associated with the Canadian Comstock Company. Mr. Tregarthen graduated from Sydney University in 1921 with the degree of B.E. in Mechanical and Electrical Engineering.

Keith B. Wallace, S.E.I.C., a graduate in mechanical engineering of McGill University in 1930, has left the Dominion Oilcloth and Linoleum Company, Montreal, where he has been employed since graduation, and is now with Barry and Staines Linoleum (Canada) Limited at Farnham, Quebec.

C. R. Young, M.E.I.C., Professor of Civil Engineering in the University of Toronto, has been appointed a member of the Royal Commission on Highway Transport recently named by the Ontario Government, the other members being Mr. Justice E. R. E. Chevrier, of the Supreme Court of Ontario (Chairman), and Mr. E. R. Sayles, publisher, of Renfrew, Ontario. This Commission is charged with the task of investigating and reporting on the operation of motor vehicles for gain in the transportation of freight and passengers in the Province, and the relation thereto of all competing forms of transport.

#### New Appointments, The Dominion Bridge Company, Limited

The Dominion Bridge Company, Limited announce a number of new appointments in Montreal effective October 1st, 1937:—

F. P. Shearwood, M.E.I.C., a past-president of The Institute, has been appointed consulting engineer of the company. He commenced his connection with the organization in August, 1887, as a draughtsman and was subsequently transferred to the Designing Department. He has held successively the positions of designing engineer, assistant chief engineer and chief engineer.

Mr. Shearwood is widely known in engineering circles for his association with the design and erection of many of the important bridges and other structures in Canada. He has been a member of The Engineering Institute for forty-five years; was treasurer for five years, president in 1934 and has served on the Council as vice-president and councillor for ten years.

Mr. Shearwood recently celebrated the fiftieth anniversary of his joining the company and much satisfaction is expressed that his wide experience is still available to the company in a consulting capacity.

Fred Newell, M.E.I.C., has been appointed chief engineer of the Dominion Bridge Company, Limited.

Mr. Newell was educated at the London and Woolwich Polytechnic School and received a Whitworth Exhibition in 1902. After several years' engineering experience in England he came to Canada and shortly after his arrival joined the Dominion Bridge Company, Limited, in 1908 as a designer in the Mechanical Department. Since that time he has held successively the positions of chief mechanical engineer and assistant chief engineer. He joined The Engineering Institute in 1916 as an Associate Member and has served on the Council for five years.

F. P. Shearwood, M.E.I.C.

F. Newell, M.E.I.C.

R. S. Eadie, M.Sc., M.E.I.C., has been appointed assistant chief engineer of the Dominion Bridge Company, Limited. On completion of his university course, Mr. Eadie lectured for four years in the Faculty of Applied Science of McGill University. He joined the Dominion Bridge Company, Limited, in 1924 and as a designer in the Bridge and Structural Department he has been intimately associated with many important structures built by the company during the past few years.

Mr. Eadie has been a member of The Institute since 1914, when he joined as a Student.

D. B. Armstrong, A.M.E.I.C., has been appointed Designing Engineer of the Dominion Bridge Company, Limited. He joined the company in 1909 as a draughtsman and has successively held the positions of designer, erection engineer and engineer in charge of special projects. He was closely associated with the design and erection of the Jacques Cartier bridge and latterly has occupied the position of engineer in charge of the Island of Orleans suspension bridge. He joined The Institute as an Associate Member in 1923.

## The Round Table Conference of Representatives of Branches of The Institute

### June 14th, 1937

One of the principal items of business at the meeting of the Council of The Institute held on September 24th, 1937, was the consideration of the report of the proceedings of the Round Table Conference which was held on June 14th, 1937; was attended by delegates from twenty-four of The Institute branches, and was called to afford an opportunity for the free discussion of questions of branch operation and management, including certain points affecting the membership as a whole.

The actual programme of this conference was based on suggestions received from branch committees, indicating matters of common interest, and covered a great variety of topics. During the three sessions of the conference there was a most instructive general interchange of views and information, a feature whose particular value will be appreciated in view of the great diversity of outlook and operating conditions which must characterize a series of branches extending from Cape Breton to Vancouver Island. Such discussions, or their equivalent, are indispensable if the widely spread membership of The Institute is to act collectively as a Dominion-wide organization.

In opening the proceedings, the chairman of the conference, Mr. Huet Massue welcomed the following delegates:

Representing the Branches:—

| | | |
|---|---|---|
| Cape Breton | Mr. M. R. Chappell | Chairman |
| Saint John | Mr. J. R. Freeman | Chairman |
| Moncton | Mr. H. J. Crudge | Member of Council |
| Saguenay | Mr. F. L. Lawton | Vice-Chairman |
| Quebec | Mr. Alex. Larivière | Chairman |
| St. Maurice Valley | Mr. C. H. Champion | Sec.-Treasurer |
| Montreal | Mr. C. K. McLeod | Ex-Sec.-Treasurer |
| Ottawa | Mr. Ephrem Viens | Ex-Officio |
| Peterborough | Mr. H. R. Sills | Chairman |
| Kingston | Mr. R. F. Legget | Executive |
| Toronto | Mr. A. U. Sanderson | Vice-Chairman |
| Hamilton | Mr. W. J. W. Reid | Vice-Chairman |
| London | Mr. A. O. Wolff | Chairman |
| Niagara | Mr. Walter Jackson | Member of Council |
| Border Cities | Mr. E. M. Krebser | Vice-Chairman |
| Sault Ste. Marie | Mr. J. Lang | Ex-Officio |
| Lakehead | Mr. G. R. Duncan | Vice-Chairman |
| Winnipeg | Mr. H. L. Briggs | Sec.-Treasurer |
| Saskatchewan | Mr. Stewart Young | Vice-Chairman |
| Lethbridge | Mr. P. M. Sauder | Chairman |
| Edmonton | Mr. W. E. Cornish | Executive |
| Calgary | Mr. Jas. McMillan | Sec.-Treasurer |
| Vancouver | Mr. H. N. Macpherson | Chairman |
| Victoria | Mr. I. C. Barltrop | Ex-Officio |

The Recording Secretary was Mr. E. R. Smallhorn, Secretary-Treasurer of the Montreal Branch.

There were also present by invitation:

| | | |
|---|---|---|
| Mr. J. B. Challies | Councillor | 1920-22 |
| | Vice-President | 1924-25 |
| | Treasurer | 1934-36 |
| Mr. P. L. Pratley | Councillor | 1927-29, 1932-34 |
| | Vice-President | 1935-36 |
| | Treasurer | part of 1932-33 |
| and Mr. E. A. Ryan | Councillor | 1935-36-37 |
| | Ex-Chairman, Montreal Branch | |
| | Chairman, Institute Membership Committee | |

These gentlemen, by their experience and knowledge of Institute affairs, were well equipped to give first hand information on many points which arose during the discussions.

Copies of the full report of the conference, prepared by Mr. Smallhorn, have been placed in the hands of all delegates, all branch secretaries, all branch chairmen, and all members of Council.

At the meeting of Council, the study of the twenty-six pages of this report with its appendices, occupied nearly the whole evening. Members present were unanimous in expressing appreciation of the excellent judgment with which the various topics had been selected, and the constructive nature of the discussions to which they gave rise.

The following brief notes on the various sections of the report and the views expressed thereon at the meeting of Council will be of interest to the membership:

1. *Uniformity in Dates of Branch Elections.*

Having noted the conference discussion on this point, Council strongly recommended that the branches should endeavour to have their fiscal years coincide with that of The Institute, and that the dates of election of branch officers should if possible agree with that of The Institute.

2. *Method of Election of Branch Secretaries and Officers.*

In Council's opinion the branches might well take action along the lines of the discussion, namely, that branch secretaries and committee chairmen should be appointed rather than elected.

3. *Term of Office of Officers.*

Council agreed with the feeling expressed at the conference, namely, that there should be no objection to the re-election of any branch officer, but also that as many members as possible should be encouraged to take an active part in the direction of branch affairs.

4 (*a*). *Rebates from Headquarters.*

In regard to a possible revision of the present scale of rebates, Council gathered that the present scale was not altogether satisfactory, particularly to the smaller branches, and it was decided that the question of its revision should be referred to the Committee on Membership and Management, which has recently been appointed.

4 (*b*). *Financial Years.*

With regard to the final statement of the rebates due to the branches at the end of the calendar year, it was pointed out that this figure could not be given by Headquarters until after December 31st, the end of The Institute's financial year, but the Secretary was directed to let the branches have this information as early as possible in January.

4 (*c*). *Classification of Branch Accounts*

Mr. McMillan (Calgary) having pointed out the difficulty of making any comparison of the accounts of the various branches, submitted to the conference a proposed standard method for classifying branch income and expenditure (Appendix B to the report of the conference). Council agreed with the conference that the adoption of a uniform method of classifying accounts would be very desirable, and referred the matter to the Finance Committee for consideration and consultation with Mr. McMillan, with a view of preparing definite recommendations.

4 (*d*). *Arrears of Fees.*

In order to facilitate branch co-operation in the collection of arrears of fees, the conference had recommended that copies of the General Secretary's letters to branch secretaries regarding this matter should be sent to the local councillors for their information. This suggestion was approved by Council.

5. *Membership Committees.*

Council noted the explanations given to the conference by Mr. Ryan, chairman of The Institute's Membership Committee, and fully agreed with the opinion expressed at the conference that the councillor of each branch should be an active member of the branch application and credentials committee so that he will be acquainted with the details of any unusual case coming before Council.

6. *Resignations and Admissions.*

In regard to the suggestion made at the conference that after a member has resigned he should surrender his certificate of membership, the Secretary explained to Council that although at the present time no request was made for the return of members' certificates, such requests had been made for a number of years in the past. It was found that the certificates were returned in very few cases, however, and the practice had therefore been discontinued. Council considered it advisable to retain the present practice of not asking for the return of the certificate.

7. *Speakers, Meetings and Publication of Papers.*

The Council was particularly interested in the discussion which had taken place at the conference regarding the securing of speakers and papers for the various branches of The Institute. It was pointed out that the principal difficulty in this connection was the impossibility of obtaining advance information as to members' intended movements. The President hoped that senior members of The Institute would make a point of addressing the members of the various branches through which they might pass when travelling on business, or, at all events, that they would get in touch with the officers of the local branch when visiting any branch centre.

It was suggested that possibly a questionnaire might be sent out at the beginning of each year to members of Council and senior members of The Institute asking to be informed of any journeys which they would probably make during the coming year. It was also considered most desirable that the vice-presidents should visit the branches in their respective zones.

Attention was drawn to the possibility of closer co-operation between the branches as regards the interchange of papers; an author presenting a paper before the Toronto Branch, for instance, might well be asked to give it also in Montreal or Ottawa.

After further discussion it was decided to draw the attention of the chairman of the Papers Committee to the discussion at the Round Table Conference and at the Council meeting, and to inform the Papers Committee and the branches that the Council is anxious to do everything possible to support the branches in their activities, particularly as regards speakers and technical papers.

8. *Membership on Executive Committees of Ex-Officio Officers.*

Council noted the request of the conference to consider a revision to Section 13 of the By-laws, under which councillors representing branches entitled to three councillors hold office for more than two years. Council was of opinion that this point should be considered by the Committee on Membership and Management.

9. *Elections.*

The question having been raised at the conference as to the signatures on ballot envelopes, Council agreed with the suggestion that the outer envelope should have space for the signature as well as for the printed or typed name of the voter.

10. *Relation between Council and Branch Executive Committees.*

Council noted that at the conference several speakers had referred to the desirability of having some officer of The Institute visit each of the branches each year. Council was in entire agreement with this idea, and it was pointed out that under Item 7 Council would encourage the vice-presidents to visit each year the branches in their respective zones.

It was noted that in the opinion of the conference the mark "Confidential" on minutes of Council was liable to misconstruction, and had, in some cases, prevented councillors from discussing Institute affairs with their branch executive committees. For this reason Council resolved that in future the sheets shall not be marked "Confidential" and that it should be left to the discretion of the councillors as to those items in Council minutes which should be treated confidentially.

11. *Provincial Divisions of The Institute.*

Following the discussion at the conference as to the desirability of forming Provincial Divisions of The Institute, Council resolved to refer this matter to the Committee on Membership and Management for consideration and report.

12. *Relations to Other Societies.*

It was decided by Council that the discussion on this subject should be referred to The Institute's Committee on Relations with National Societies.

13. *Employment Bureau.*

One of the suggestions made at the conference had been that The Institute should undertake a survey of industry's requirements for graduate engineers, and that the resulting information should be made available to undergraduates prior to their decision as to the branch of engineering they wish to study.

Considerable discussion took place on this point, and while it was felt that it would be impossible for The Institute to undertake a survey of this kind, it was decided that the Secretary should endeavour to secure from the various universities, at the beginning of each college year, information as to the registration in the various branches of engineering, such information to be published in The Journal.

14. *The Journal.*

It was noted with appreciation that considerable discussion had taken place at the conference regarding The Journal, and that Mr. R. F. Legget had prepared a written statement of his views, which had been attached to the report of the conference as Appendix A.

Following the resolution passed at the conference, recommending the study of the whole question of The Journal, it was suggested, after considerable discussion, that the whole subject of the publications of The Institute might with advantage be studied by a small active committee, and it was decided that all members of Council should be asked to submit their views on this point and on the personnel of this committee, for consideration by Council at its next meeting.

Attention was drawn to the elaborate inquiry on this matter made in 1928-29 and the report on the publications of The Institute which had been presented at the Fourth Plenary Meeting of Council in 1930, the present set up of The Journal being based as far as possible on this committee's recommendations.

Following this discussion, the Council resolved that a hearty vote of thanks and appreciation be extended to the committee in charge of the Round Table Conference in recognition of the valuable work which had been accomplished, as evidenced by the report of the proceedings of the conference.

Further, The Secretary was directed to inform the various branches, and the delegates who attended the meeting, as to the action taken by Council in regard to the points discussed at the conference.

## A New Membership List

It is intended to issue a new List of Members early in 1938. The utility and completeness of such a list depends on the extent to which individual members will assist by furnishing the information requested in the enquiry cards which have been sent out to members of all classes.

The Secretary begs that everyone will make a point of co-operating in this manner. It is especially desirable that the list shall contain, in *all* cases, the member's official position, the name of the organization employing him, and an indication of the branch of engineering with which he is concerned.

## Elections and Transfers

At the adjourned meeting of Council held on September 27th, 1937, the following elections and transfers were effected:—

*Members*

HARRINGTON, Arthur William, C.E. (Cornell Univ.), District, Engineer, U.S. Geological Survey, Albany, N.Y.

IZARD, Edward Whitaker (Glasgow Univ.), works manager, Yarrows Ltd., Victoria, B.C.

RELYEA, John DeWitte, B.A.Sc. (Univ. of Toronto), Department of Public Works, Toronto, Ont.

*Associate Members*

CONNOR, Gerald Russell, B.A.Sc. (Univ. of Toronto), instr'man., steam dept., Spruce Falls Power and Paper Co. Ltd., Kapuskasing, Ont.

HOOGSTRATEN, Jack, B.Sc. (Univ. of Man.), lecturer in civil engrg., Univ. of Manitoba, Winnipeg, Man.

MANLEY, Edward Hugh, B.Sc. (Syracuse Univ.), constrn. supt. Aluminum Company of Canada, Arvida, Que.

PEACHEY, Cyril Arthur, B.A. (Univ. of Toronto), mfg. engr., Northern Electric Co. Ltd., Montreal, Que.

*Juniors*

ADAMS, John DeWitt, B.Sc. (Univ. of Alta.), dftsman., Dept. of Highways of Ontario, London, Ont.

BORBEY, John Pierre, B.A.Sc. (Univ. of Toronto), designer, Dominion Bridge Co. Ltd., Montreal, Que.

BYERS, William Caryl, B.Sc. (E.E. and C.E.), (Univ. of Man.), Dept. of Public Works, Kenora, Ont.

DUBESKY, William, B.Sc. (Univ. of Man.), supt. and engr., Radio Oil Refineries Ltd., Winnipeg, Man.

GEORGE, Joseph David, B.E. (Univ. of Sask.), 1331 Henry St., North Battleford, Sask.

GRAY, Harry Alden, B.Sc. (Univ. of Man.), 1316 Dorchester St. West, Montreal, Que.

KERRY, Frank George, B.Eng. (McGill Univ.), service engr., Canadian Liquid Air Co., Montreal, Que.

LOVE, Herbert W., Lieut., R.C.E., B.Sc. (Queen's Univ.), engr. i/c Dominion Arsenal, Valcartier, Que.

McCAREY, Joseph Newell, B.Sc. (Queen's Univ.), technical staff, Canadian International Paper Co., Temiskaming, Que.

QUINN, Odoric Charles (McGill Univ.), engrg. secretarial work, Price Bros. & Co. Ltd., Riverbend, Que.

RYAN, Edward, B.Sc. (Queen's Univ.), 232 Sydenham St., Kingston, Ont.

SAMIS, George Roy, B.A.Sc. (Univ. of Toronto), designer, Dominion Bridge Co. Ltd., Montreal, Que.

SCRIVENER, Richard Harding, B.A.Sc. (Univ. of Toronto), designer, Dominion Bridge Co. Ltd., Montreal, Que.

WEIR, William Cecil, B.E. (Univ. of Sask.), mech. engr., Hudson Bay Mining and Smelting Co., Flin Flon, Man.

*Affiliate*

WESTOVER, Channing Spaulding, instr'man., Aluminum Company of Canada, Arvida, Que.

*Transferred from the class of Associate Member to that of Member*

BUNTING, William Russell, B.A.Sc. (Univ. of Toronto), power apparatus specialist, Northern Electric Co. Ltd., Montreal, Que.

LAWSON, Horace Hetherington, Major (Grad., R.M.C.), B.Sc. (Queen's Univ.), O.L.S., assoc. professor of engineering, Royal Military College, Kingston, Ont.

REID, William Joseph Walter, B.A.Sc. (Univ. of Toronto), works manager, The Otis-Fensom Elevator Co., Hamilton, Ont.

STUART, William Grey (Glasgow Univ.), power reconnaissance engr., 10335–117th St., Edmonton, Alta.

TOOVEY, Thomas William (R.P.E. of B.C.), technical adviser to chlorine sales dept., Pennsylvania Salt Manufacturing Company, Philadelphia, Pa.

*Transferred from the class of Junior to that of Associate Member*

DUNCAN, Conrad Munro, B.Sc. (Univ. of Man.), 28 Gilmour St., Ottawa, Ont.

EVANS, John Maurice, B.Sc. (McGill Univ.), engr., Dept. of Development, Shawinigan Water and Power Company, Montreal, Que.

*Transferred from the class of Student to that of Associate Member*

SAINT JACQUES, Jean, B.A.Sc., C.E. (Ecole Polytechnique, Montreal), B.Sc. (McGill Univ.), office engr., Quebec Power Company, Quebec, Que.

*Transferred from the class of Student to that of Junior*

BRIDGE, David E., B.A.Sc. (Univ. of Toronto), instructor in industrial maths., Hamilton Technical Institute, Hamilton, Ont.

FULLERTON, Roland McNutt, B.Sc. (N.S. Tech. Coll.), electrician, Canadian Malartic Gold Mines, Malartic, Que.

*VILLEMURE, J. Phileas, dftsman. and instr'man., City of Grand' Mère, Que.

*Students Admitted*

DOLAN, Michael Aloysius, B.Sc. (Queen's Univ.), 1 Aberdeen Ave., Kingston, Ont.

DUNN, John Thomas, B.A.Sc. (Univ. of Toronto), 131 King St. East, Ingersoll, Ont.

LEVINE, Samuel Dave (Univ. of Toronto), 62 Brunswick Ave., Toronto, Ont.

LOUTIT, John Alexander (Univ. of Man.), 51 Gloucester St., Ottawa, Ont.

VAN EVERY, Hugh Davidson, ap'tice dftsman., Dominion Bridge Co. Ltd., Montreal, Que.

*Has passed The Institute's examinations.

## BULLETINS

*Fuses.*—Two bulletins received from A. Reyrolle & Company, England (representatives: Northern Electric Company), discuss their lines of cartridge fuses for a.c. and d.c. circuits.

*Switchgear.*—A. Reyrolle & Company, England (representatives: Northern Electric Company), have issued an 8-page bulletin giving particulars of their metal clad switchgear, class B. up to 15,000 volts with compound-filled bus-bar chambers.

*Induction Motors.*—An 8-page bulletin from J. H. Holmes & Company, England (representatives: Northern Electric Company), contains details of their types L.C. slip-ring induction motors.

*Generators.*—An 8-page bulletin from J. H. Holmes & Company England (representatives: Northern Electric Company), deals with heavy-current low-voltage generators for electrical work.

*Printing Press Equipment.*—A number of bulletins issued by J. H. Holmes & Company, England (representatives: Northern Electric Company), describe electrical equipment used in printing offices. This includes unit and group drives, controls, web-breakage detectors and reel-stands.

*Steel Hard-Facing.*—An 8-page bulletin has been received from the Dominion Oxygen Company Limited, Toronto, outlining procedures and giving instructions for hard-facing steel with Haynes stellite.

*Rules.*—Lufkin Rule Company of Canada Limited, Windsor, Ont., have issued a 48-page booklet giving particulars of measuring tapes, tape-rules and rules for engineers and surveyors.

*Snow Removal.*—A 16-page bulletin of the Caterpillar Tractor Company, Peoria, Ill., illustrates various methods of snow removal utilizing tractors.

*Rotary Displacement Meters.*—A bulletin of 16 pages has been issued by the Roots-Connersville Blower Corporation, Connersville, Ind., describing general operating principles of meters. The standard meter may be utilized for line pressures up to 25 lb., the high pressure type up to 125 lb., and meters of special construction for pressures up to 300 lb.

*Drills and Breakers.*—The Independent Pneumatic Tool Company of Chicago describe, in a 6-page booklet, the Thor line of rock drills, paving breakers, clay diggers, sump pumps and accessories.

*Tractors.*—A 28-page booklet by the Cleveland Tractor Company, Cleveland, Ohio, illustrates some of the features of their tractors.

*Steel Sheet Piling.*—A circular of 4 pages has been received from the Canadian Sheet Piling Company Limited, Montreal. It gives design data used in the construction of cofferdams.

*Welded Piping.*—The Dominion Oxygen Company Limited, Toronto, in a 12-page circular, discuss some of the advantages of welded piping installations.

*Alloyed Cast Irons.*—A 20-page pamphlet of the International Nickel Company Inc., New York, gives data regarding the use of alloyed cast irons in petroleum refining equipment.

*Activities of the General Electric Company.*—An excellently illustrated 78-page brochure has been received from the General Electric Company, London, England. It contains a survey of the Company's organization and resources with some examples of recent installations.

### Errata

The following corrections should be made in the text of the paper on "The Characteristics and Quality of Nova Scotian Coals" by Dr. F. H. Sexton, published in the July number of The Journal, pages 524-532:

p. 529—Table IV—4th line—should read "4 Welsh anthracite 10.50 65.8 3.1"

p. 529—Table IV—8th line—should read "8 English coke 11.53 65.3 6.3"

p. 529—Table IV—9th line—should read "9 La Salle coke 10.08 75.8 7.1."

# BRANCH NEWS

## Niagara Peninsula Branch

*G. E. Griffiths, A.M.E.I.C., Secretary-Treasurer.*
*J. G. Welsh, S.E.I.C., Branch News Editor.*

On September 21st, 1937, the Niagara Peninsula Branch ushered in the 1937-38 season of activities with a highly instructive and entertaining dinner meeting at the Leonard hotel in St. Catharines. Following a few words by the Branch's new Chairman, L. C. McMurtry, A.M.E.I.C., in which the hearty co-operation of all was requested for the new Secretary-Treasurer, George E. Griffiths, A.M.E.I.C., A. McPhail, A.M.E.I.C., introduced Mr. P. B. MacEwen, combustion engineer of the Ethyl Gasoline Corporation.

Through the medium of motion pictures, Mr. MacEwen traced the research leading to the discovery of ethyl gasoline. First showing the development of the wheel, then the great discovery of potential energy of fire, resulting in the development of steam as a prime mover. Then came the internal combustion engine, and with the advent of the starter the automobile was deemed, by many, perfected. But in spite of all mechanical improvements, the engine retained its characteristic knock, so attention was turned to the fuel. It was almost immediately discovered that iodine bettered the condition, and finally tin and lead were found to be very effective in eliminating the knock as well as lowering the temperature on the cylinder walls. This led to the use of ethyl fluid. Ethyl fluid contains tetraethyl lead, ethylene dibromide, ethylene dichloride, and a dye for indication. Actual photographs were shown of the combustion in the cylinder head, having been secured by inserting a quartz window in the cylinder head. From these it was seen that under normal conditions the gas exploded with a blue flame travelling across the combustion chamber from the spark plug to the opposite cylinder wall, whereas under knocking conditions the flame was white, and there were two waves, one wave ignited by the spark plug, and another wave that shot back from the far cylinder wall, having been initiated by the high heat of compression generated by the primary wave. When these counter waves met, an explosion occurred resulting in the knock.

Mr. MacEwen then discussed the relationship of an engine to its fuel. Slides were shown comparing the properties of ethyl gasoline with ordinary gasoline, and with other explosive substances, the octane number being used to qualify the fuel. It was explained that the octane number was a measure of the anti-knock properties of the gasoline and that it was determined by matching the explosion pressures of a controlled mixture of iso octane and normal heptane to that of the gasoline, the percentage of iso octane being the octane number. The importance of the proper blending of the gasoline was emphasized. For starting, a light gasoline is required; for acceleration, a heavier grade, and for power, still heavier. Mr. MacEwen pointed out that there is no advantage in using a better fuel, if the spark is not advanced to permit the motorists to take advantage of the extra power available.

After a few remarks as to reduction in size of engines made possible by these improvements in fuel, the meeting resolved into a lively discussion. G. E. Hood, A.M.E.I.C., moved a vote of thanks to the speaker, which was heartily endorsed by those present.

## Saguenay Branch

*C. Miller, A.M.E.I.C., Secretary-Treasurer.*

The annual general meeting of the Saguenay Branch was held at Dolbeau on the afternoon of July 30th, 1937. About thirty members and guests were present.

After a very enjoyable luncheon at the Dolbeau Inn the meeting was called to order by F. L. Lawton, M.E.I.C., acting as chairman in the absence of S. J. Saunders, M.E.I.C.

The Secretary-Treasurer then presented the annual report. Moved by R. Rimmer, A.M.E.I.C., seconded by J. R. Hango, A.M.E.I.C., that the report be adopted as read.

The scrutineers' report on the election of officers for the Saguenay Branch Executive for the ensuing year was read; Chairman, F. L. Lawton, M.E.I.C., Vice-Chairman, M. G. Saunders, A.M.E.I.C., Secretary-Treasurer, C. Miller, A.M.E.I.C.

F. L. Lawton, M.E.I.C., then expressed the appreciation and thanks of the members of the Branch for the fine work done during the past season by the outgoing executive, and his appreciation of the honour bestowed in electing him Chairman for the coming year.

The Chairman then gave a brief resume of the Round Table Conference, and described the activities of the Semicentennial Meeting of The Engineering Institute of Canada held in Montreal. He stressed the importance of being able to speak with ease at such meetings and strongly urged the young men of the Branch to seize every opportunity of furthering their speaking ability.

G. H. Kirby, A.M.E.I.C., spoke briefly on the activities of The Institute, stressing the varied problems which are being dealt with day after day by engineers, and urging the younger members of the Branch to take an active interest in Branch affairs in order to benefit not only themselves but the engineering profession in general. Mr. Kirby then read a letter from Headquarters concerning the illuminated greetings sent to the Semicentennial celebrations by sister societies over the world, which were being passed from branch to branch to be displayed.

A. C. Johnston, A.M.E.I.C., suggested that the Secretary endeavour to obtain these greetings in order to display them at a future meeting.

Through the courtesy of A. G. Jacques, A.M.E.I.C., of the Lake St. John Power and Paper Company, Limited, the members were taken on an inspection tour of the mill, under the guidance of members of the staff who explained the process and operations step by step.

Following the trip through the mill, F. L. Lawton, M.E.I.C., expressed the thanks of all present for the courtesy shown the Branch by the Lake St. John Power and Paper Co., Limited, and for the very fine way in which the tour was conducted.

The meeting then adjourned to the Trappist Monastery where the members were conducted through the building and inspected the limestone quarry, following which the Chairman expressed the thanks of the members present to Father Samuel and Father Sebastien for their genial courtesy.

## Vancouver Branch

*T. V. Berry, A.M.E.I.C., Secretary-Treasurer.*

Forty-seven members and guests of the Vancouver Branch greeted President, G. J. Desbarats, C.M.G., Hon.M.E.I.C., at a luncheon held in his honour in the Georgian room of the Hudsons Bay Company's store on Wednesday, August 25th, 1937.

Seated at the head table with the President were Past-Presidents Hugh Walkem, M.E.I.C., and E. A. Cleveland, M.E.I.C., H. N. Macpherson, A.M.E.I.C., Chairman of the Vancouver Branch, P. H. Buchan, M.E.I.C., Councillor, A. Vilstrup, President of the Association of Professional Engineers of B.C., and E. A. Wheatley, M.E.I.C., Registrar of the Association, C. Arnett, President of the Vancouver Section of the A.I.E.E., and J. N. Finlayson, M.E.I.C., Dean of the Faculty of Applied Science of the University of British Columbia.

After luncheon Mr. Desbarats addressed the gathering on Institute matters. Speaking in a retrospective mood, he expressed the opinion that The Institute had accomplished much in its special sphere in its fifty years of activity. He was glad to observe, too, that The Institute was held in high regard by sister engineering societies in Great Britain, the United States and in other countries as was evidenced by the representation from these societies at the recent Semicentennial celebration and the expressions of goodwill and esteem received from them on that occasion.

Mr. Desbarats spoke of the relations of the Headquarters administration and the branches and outlined some of the difficulties which Council met due to the remoteness of some of the branches from Montreal. The speaker also referred to the recent ballot on the proposed amendments to The Institute's by-laws and commended the work of the Committee on Consolidation on their faithful work over many months prior to the ballot.

A vote of thanks to the speaker was proposed by Dean J. N. Finlayson and heartily endorsed by the meeting

## Victoria Branch

*Kenneth Reid, Jr.E.I.C., Secretary-Treasurer.*

An informal reception was held at the home of Mr. and Mrs. F. C. Reid, Victoria, B.C., on Friday evening, August 20th, 1937, in honour of G. J. Desbarats, Hon M.E.I.C., President of The Engineering Institute of Canada, and Mrs. Desbarats. This proved a most successful reception attended by over twenty-five members of the Victoria Branch and their wives. The President addressed the members briefly on Institute matters, outlining the work of the Committee on Consolidation, the results of the ballot, and the features of the recent Semicentennial celebration.

## Winnipeg Branch

*H. L. Briggs, A.M.E.I.C., Secretary-Treasurer.*

Summer activities of the Branch have included two luncheons to distinguished engineers from abroad who have been guests of The Institute at the Semicentennial celebrations, the first to Mr. Johnstone Wright, M.I.C.E., M.I.E.E., chief engineer of the Central Electricity Board, London, England, on June 8th, and the second to Brigadier-General Magnus Mowat, C.B.E., M.I.Mech.E., Secretary of the Institution of Mechanical Engineers, London, England., on July 12th.

Organized by Messrs. A. L. Cavanagh, A.M.E.I.C., and C. S. Landon, forty Winnipeg engineers and visitors took part in a golf tournament on August 9th at the Assiniboine Golf Club.

On August 30th, the Branch was honoured by the presence of President and Mrs. G. J. Desbarats at a dinner at the Motor Country Club, Lower Fort Garry.

President Desbarats addressed a general meeting of the membership on August 31st. He told of the outstanding success of the Semicentennial celebrations, outlined the steps which Council had taken to improve relationships with the Professional Associations by the formation of main and sub-committees on "Professional Interests," and described briefly his visits to the other western branches of The Institute.

## EMPLOYMENT SERVICE BUREAU

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.

*All correspondence should be addressed to*

**The Employment Service Bureau, The Engineering Institute of Canada**
**2050 Mansfield Street, Montreal**

### Situations Vacant

YOUNG MECHANICAL ENGINEER, for sales and service work, with a large industrial company, with at least five years experience, and some knowledge of power plants. Location Toronto. Apply to Box No. 1656-V.

ASSISTANT SUPTERINTENDENT, for machine shop and foundry employing up to three hundred men. Location Ontario. Must be familiar with latest shop practices, and be able to figure costs. Technical graduate with actual shop experience of heavy machinery preferred. Applicants should write giving details of age, experience, and salary expected to Box No. 1661-V.

CIVIL ENGINEER, graduate, with at least four years experience in engineering. Some experience in structural and concrete building and be adaptable to mechanical work. Location northern Ontario. Apply to Box No. 1662-V.

ELECTRICAL ENGINEER, preferably with physics trainingfor radio development work. Location Montreal. In reply give references and full details of education, experience and salary expected. Apply to Box No. 1663-V.

SENIOR CIVIL ENGINEER, for service in Colombia, South America. Position calls for a thoroughly competent man experienced in construction, road and railroad maintenance, with particular emphasis on new road construction work under difficult conditions. Single man preferred and one between the ages of 35 and 40. No one over 45 can be considered. Apply giving full details of experience and qualifications to Box No. 1667-V.

SALES ENGINEER. Young c vil engineer between the ages of 25 to 35, with construction experience to handle design problems, and sales, in connection with a product used extensively in the construction field. Apply to Box No. 1668-V.

YOUNG ELECTRICAL ENGINEER, for consulting engineer's office in the province of Quebec, with three or four years experience. Practical experience in steam plant construction or design would be an advantage. Apply to Box No. 1669-V.

SALES ENGINEER, with some paper mill experience for the sale of chemical products to paper mills in Canada. Apply to Box No. 1671-V.

CHEMICAL ENGINEER, with paper mill experience required by manufacturer of paper mill specialities. Should be competent to undertake the solving of mill problems and technical work in connection with the plant. Apply to Box No. 1672-V.

ELECTRICAL ENGINEER, for meter testing and installation department of power company in South America. Should be capable of taking charge of department if necessary. Actual experience with meters essential, also familiarity with the commercial aspects. Knowledge of Spanish desirable but not essential. Apply to Box No. 1676-V.

### Situations Wanted

PURCHASING ENGINEER, graduate mechanical engineer, Canadian. Married, with fifteen years experience covering construction and operation, principally having to do with specification and ordering of equipment and materials for new construction and maintenance. Details upon request. Apply to Box No. 161-W.

INDUSTRIAL ENGINEERING EXECUTIVE, with wide experience including fourteen years in design, construction, maintenance and operation of pulp and paper mills and power developments. Now employed, desires change of location. Apply to Box No. 320-W.

CIVIL ENGINEER, B.A.Sc., age 44, structural, harbour, executive. At present designing 32,000-h.p. development in Newfoundland. Available in near future. Apply to Box No. 536-W.

DOMINION LAND SURVEYOR, and graduate engineer with extensive experience on legal, topographic and plane-table surveys and field and office use of aero-photographs, desires employment either in Canada or abroad. Available at once. Apply to Box No. 589-W.

### Situations Wanted

ELECTRICAL ENGINEER, B.Sc., E.E., age 38. Married. Ten years electrical experience; including, one year operation, one year maintenance, and four years on construction of hydro-electric plants and sub-stations. Four years electric maintenance and construction in pulp and paper mill. Also experience on highway construction and Geological Survey Available at once. Apply to Box No. 636-W.

ELECTRICAL ENGINEER, B.Sc. E.E. '28. Two years with large electrical manufacturing company including test course, about two years in supervisory operating office of a large electrical power utility, and considerable experience in electrical and mechanical draughting. Location in Ontario preferable. Apply to Box No. 660-W.

YOUNG CIVIL ENGINEER, B.Sc. (Univ. of N.B. '31), with experience as rodman and checker on railroad construction, is open for a position. Apply to Box No. 728-W.

CIVIL ENGINEER, B.Sc., M.Sc., R.P.E.; Lieut. C.E., R.O. 16 years municipal, highway and construction, 5 years overseas. Married. Read, write and talk French. Will go anywhere. Apply to Box No. 737-W.

RADIO AND ELECTRICAL ENGINEER, B.Sc., '31, Jr.E.I.C. Single. Age 30. One year and a half actual field experience in power and lighting equipment. Extensive work in telephone and radio layouts in switchboard and installation depts. Particularly interested and experienced in sales and traffic work in telephone and radio company. At present supervisor over sales and service of radio and electrical company. Available on short notice. Location immaterial. Apply to Box No. 740-W.

ELECTRICAL ENGINEER. Graduate, age 34, single, with thirteen years experience in industrial electrical and mechanical work, also experienced in heating, ventilation, air conditioning and refrigeration. Now employed. Montreal preferred. Apply to Box No. 795-W.

CIVIL ENGINEER, S.E.I.C., B.Sc. in C.E. (Sask. '32). Single. Age 27. Three years experience includes—instrumentman. compiling reports and draughting with a National Park; in charge of construction of water supply and sanitary sewer systems; assistant on city surveys. Excellent draughtsman. Available at once. Location immaterial. References. Apply to Box No. 818-W.

MECHANICAL ENGINEER, Jr.E.I.C., technical graduate, bilingual, age 35, married, experience includes five years with firm of consulting engineers, design of steam boiler plants, mechanical equipment of buildings, heating, ventilating, air conditioning, plumbing, writing specifications, etc. Five years with large company on sales and design of power plant, steam specialties and heating equipment. Available on short notice. Apply to Box No. 850-W.

STRUCTURAL ENGINEER, B.A.Sc., A.M.E.I.C. Twenty-two years experience in design of bridges and all types of buildings in structural steel and reinforced concrete. Three years experience in railway construction and land surveying. Apply to Box No. 856-W.

ELECTRICAL ENGINEER, B.Sc. (McGill '28), age 34. Experience includes transmission line and rural distribution construction and design. Some installation of motors and equipment, also house wiring. Available immediately. Apply to Box No. 940-W.

ENGINEER SUPERINTENDENT, age 44. Engineering and business training, executive ability, tactful, energetic. Had charge of several large projects. Intimate knowledge of costs and prices, reports and estimates. Available immediately. Any location. Apply to Box No. 1021-W.

ELECTRICAL ENGINEER AND GEOPHYSICIST. B.Sc. (Man. '23), A.M.E.I.C. Married. Ten years specialized experience in the practical use of magnetic, electrical and mechanical instruments for the prospecting, surveying and mapping of mineral, oil and gas lands. Five years experience with telegraph, telephone and radio equipment. Capable of giving instruction in theory and practice in these lines and in college physics. Available on short notice. Apply to Box No. 1063-W.

### Situations Wanted

CIVIL ENGINEER, A.M.E.I.C., with over twenty years experience in field and office on construction, maintenance, surveying, location, etc., desires position preferably of a permanent nature. At present near Montreal, but willing to locate anywhere. Apply to Box No. 1168-W.

ELECTRICAL ENGINEER, B.Sc. '34 (Univ. of N.B.), S.E.I.C. Age 24, single. Desires any kind of electrical work. Will consider any location. Apply to Box No. 1262-W.

ELECTRICAL AND RADIO ENGINEER, S.E.I.C., B.Sc. (Elec.) '32, M.Sc. '34. Experience includes four years part time operator for radio broadcast station, repairs to radio receivers and test equipment, design and construction of amplifiers and inter-office communication systems. Available on short notice. Apply to Box No. 1283-W.

CIVIL ENGINEER, B.Sc. 1910, A.M.E.I.C. Married. Twenty-six years experience on heavy construction work, both field and office; rails, roads, power house, hotels, bridges, etc. Location immaterial. Available at once. Apply to Box No. 1470-W.

CONSTRUCTION SUPERINTENDENT, M.E.I.C. Age 49. Married. Twenty-two years experience as engineer, superintendent and manager in charge of hydro-electric, mechanical production, structural steel erection, also considerable experience in steam plants, combustion, transmission lines, millwright work, complete mine installstions, rock work, rock crushers and conveyors. Executive ability. Speaking French fluently. Location immaterial. Apply to Box No. 1482-W.

ELECTRICAL ENGINEER, B.Eng. (McGill '33). One and a half years experience in plant and production routine, and with considerable training in sales work. Bilingual, single, and available at once for any location. Apply to Box No. 1509-W.

ELECTRICAL ENGINEER, B.Sc. '31 (Univ. of Alta.), Jr.E.I.C. Age 28. Married. One year students' test course with C.G.E.Co. including testing and operation of transformers, meters, industrial control and switchgear apparatus. Two years as instrumentman on highway construction. Desires electrical utility, commercial lighting or air conditioning work. location immaterial and available at once. Apply to Box No. 1522-W.

CIVIL ENGINEER, B.Sc. '32, S.E.I.C., P.E.N.B., Dy.L.S.N.B., age 32. Experience in mining, both coal and metals, private and legal surveys, railroad construction, geology and building construction. At present in private practice in coal mining district. Desirous of changing location for position either in mining field or construction in Canada. or abroad. Apply to Box No. 1562-W.

RESIDENT ENGINEER, familiar with all types of surveys and construction work including, railway, roads, irrigation, drainage, buildings and air ports. Executive ability. Had charge of several large projects. Intimate knowledge of reports and estimates. Available immediately. Any location. Apply to Box No. 1567-W.

CIVIL ENGINEER, B.Sc. '17, O.P.E. Married. Executive and administrative experience. Extensive office and field experience in harbour works, dredging; both steam and electric railways in location, construction and maintenance; telephone works in design, construction and maintenance of pole lines, wire, cable and conduit; highways in location, construction and paving; municipal works in roads, sidewalks, sewers and water mains. Intimate knowledge of estimating, unit costs, cost accounting and analysis. Some knowledge of air conditioning. Willing to locate anywhere. Available at once. Apply to Box No. 1587-W.

ELECTRICAL ENGINEER, B.Sc. '27 (McGill), A.M.E.I.C. Age 36. Married. Bilingual. Three years experience in telephone work (installation of manual and automatic exchanges). One year electrical prospecting. Nine years experience with electrical power company. Apply to Box No. 1601-W.

CIVIL ENGINEER, B.Sc. in C.E., A.M.E.I.C. Age 32. Married. Three years of pulp and paper mill experience, draughting, instrumentman and maintenance. One year as instrumentman on highway construction. Five years checking and designing reinforced concrete and steel. Apply to Box No. 1658-W.

ENGINEER, age 44, seeks connection as chief or plant Engineer, with pulp and paper, or textile concern. Apply to Box No. 1662-W.

METALLURGICAL ENGINEER. graduate 1936. Experienced in gold smeltering and milling, also in stee and pig iron manufacturing. Desires new connection in eastern Canada or Great Britain. Apply to Box No. 1673-W.

# The Fatigue of Metals

*G. S. Farnham, Ph.D., M.Sc.,*
*Metallic Minerals Division, Department of Mines and Resources, Ottawa, Ont.*

**Paper presented before the Aeronautical Section of the Ottawa Branch of The Engineering Institute of Canada, April 6th, 1937.**

**SUMMARY:—A concise account of present knowledge as to the failure of metallic materials under alternating stresses, with notes on behaviour of crystals under stress, strain-hardening, and various methods of testing. Suggestions for routine tests on machine parts are given.**

Although "progressive failure" has been suggested as being a more truly descriptive phrase, custom has decreed that the somewhat vague and misleading term, "fatigue," should be used in describing the failure of materials under alternating stresses.

The endurance limit of a material is a measure of its ability to resist these alternating stresses and may be defined as the unit stress the material can stand for an indefinite number of stress cycles without failure resulting. The algebraic difference between the maximum and minimum stress in the cycle is referred to as the range of stress. The term "range ratio" is also used to indicate the range of stress. The range ratio is the algebraic ratio between the minimum and maximum stresses. A ratio of $-1$, for instance, indicates a completely reversed cycle through a mean stress of zero. The endurance limit varies with the type and range of stress and also with the temperature.

In designing structures, such as bridges, which are subject to fairly constant static stresses on which relatively unimportant cyclic stresses are superimposed, it is only necessary to know a material's ability to resist static stress. However, machine parts such as axles, shafts, gear teeth, connecting rods, etc., are subject mainly to alternating stresses and in these cases it is essential that the designer know what performance may be expected from his constructional materials under such alternating stresses. The high working stresses and speeds involved in aircraft parts make the problem of fatigue one of particular importance to the aeronautical engineer.

In spite of the importance of the subject, however, certain misconceptions as to the nature of the mechanism of fatigue failure still exist. Failure under alternating stresses is still referred to as failure by crystallization in spite of microscopic and X-ray evidence that the metal is just as definitely crystalline before being stressed as it is at the time of failure. There is also an impression, due to the unfortunate use of the word "fatigue," that a metal becomes "tired" and that the failure is associated with metal weariness, a weariness that can be cured by a resting of the material.

To obtain any understanding of the mechanics of fatigue failure the problem must be approached fundamentally, for the properties of metals and alloys must be related to their inner atomic structure. For this reason, no apology is given for introducing the subject of atomic physics.

In the final analysis, the strength of a material depends on the strength of its atomic bonds. Generally speaking, there are three types of atomic binding: the ionic, as in common salt, where electrons of opposite sign combine atoms; the homopolar, as in organic materials, where an electron is shared by atoms; and the metallic, where atoms are held together by positive electrons through what has been postulated as the interaction of electron gas. The problem of the nature of atomic cohesion is very complicated, however, and belongs to the field of the mathematical physicist. The metallurgist can only reduce the problem to a point where wave mechanics can be applied.

Metallic materials as a rule consist of a mass of very small irregularly oriented crystals separated by boundaries of irregular shape. Within the crystals the atoms are arranged in regular lattice forms. The crystal is made up of blocks of these perfectly formed atomic units, each block shifted slightly in relation to a neighbouring block. The nature of the material at the grain boundaries is debatable, for the various crystals are oriented differently and some adjustment must occur at these boundaries. It has been suggested that crystals are broken at the boundaries into small "crystallites" each oriented somewhat differently, the atomic bonds of the various crystallites being in a strained condition owing to this difference in orientation.

Most common metals have their atoms arranged in three definite orders: the body centred cubic, the face centred cubic, and the close-packed hexagonal.

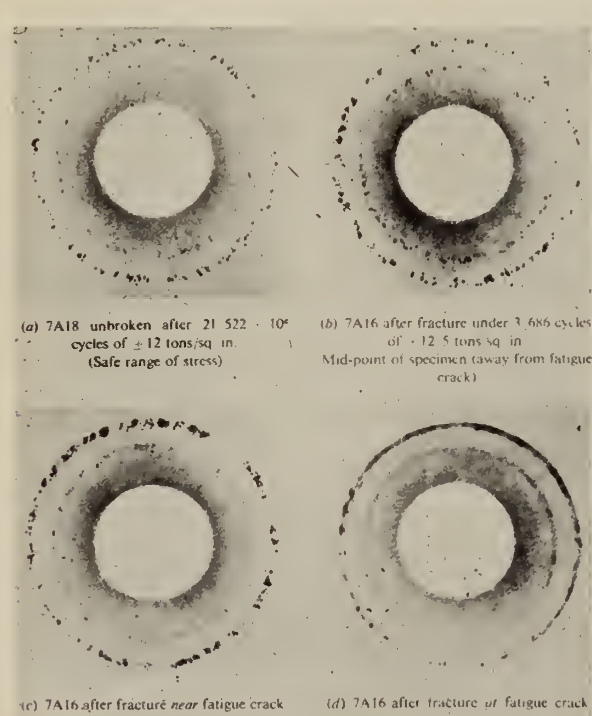
In order to correlate the physical properties of metals with crystal structure and so to reduce the problem to one of interatomic attraction, tests have been made on single crystals. Several methods can be employed in making single crystal test pieces. Test pieces containing two or more crystals can also be made, in which the effect of the crystal boundary may be studied. The research work of Dr. H. J. Gough, of the National Physical Laboratory, Teddington, England, on the fatigue properties of large crystals has been outstanding and he has added greatly to our understanding of fatigue failures.

Now it has been established, by an investigation of the behaviour of single crystals under static load, that deformation can occur either by what is known as slip, or by twinning, or by a combination of the two. "Slip" involves a shearing along certain crystallographic planes. In "twinning," two parts of a crystal are rotated about a common twinning axis. In general, these investigations showed that slip occurred along a direction containing the greatest number of atoms and on a plane parallel to planes having an equal or greater atomic density than any other plane containing the same slip direction.

Gough desired to obtain information on the mechanics of fatigue failure. His method of testing was as follows: The orientation of the longitudinal axis of the test specimen with respect to the crystallographic axes was first determined by the X-ray method. The specimen was then carefully polished and tested under reversed torsional stresses, a system of stressing which caused very little distortion at fracture and hence simulated fatigue failures encountered in service. At various intervals in the test, a microscopic examination of the surface of the test piece was made. It was discovered that slip bands formed on the surface of the metal.

These slip bands represent microscopic unevenness in the surface and can be removed by polishing. After each examination the specimens were repolished. By relating the position of these slip bands to the crystallographic axis of the fatigue specimen, Gough proved that the mechanism of slip was the same under alternating stresses as it was under static loading. Furthermore, he found that these slip bands formed rapidly at first, then less rapidly, and then finally ceased to form if no fracture occurred. Under an unsafe range of stress, however, these slip bands were still being produced when failure occurred. At loads very near the fatigue limit, fracture was found to occur after slip bands ceased to form. In every case the fatigue crack appeared at the most heavily formed slip band, although its subsequent propagation was influenced by the direction of the maximum nominal stress.

Additional tests by Gough on specimens containing two or more crystals revealed that crystal boundaries have very little effect on the fatigue mechanism, for each crystal



(*a*) 7A18 unbroken after 21 522 · 10⁶ cycles of ± 12 tons/sq in. (Safe range of stress)

(*b*) 7A16 after fracture under 3,686 cycles of ± 12.5 tons/sq in. Mid-point of specimen (away from fatigue crack)

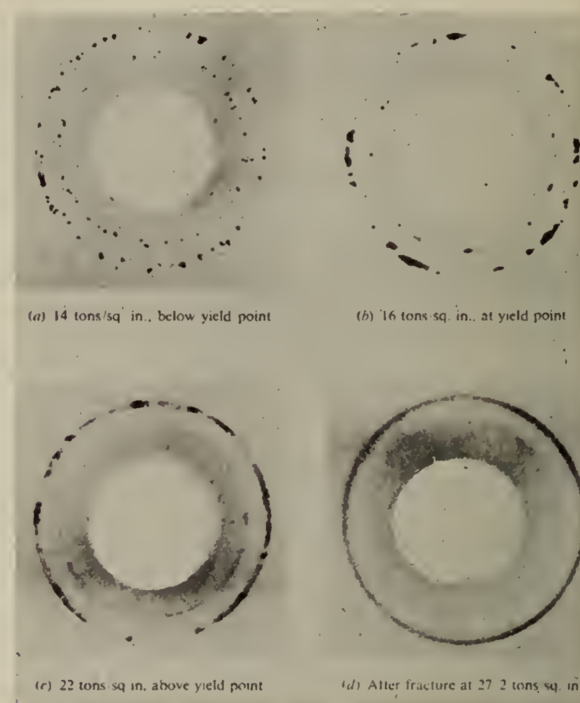
(*c*) 7A16 after fracture *near* fatigue crack

(*d*) 7A16 after fracture *at* fatigue crack

**Fig. 1—X-ray patterns showing crystal breakdown.**

acted as if it were a separate single crystal specimen, the slip bands changing direction at the boundary. In no case was intercrystalline failure found. It was concluded that the increased strength of a finer-grained aggregate was probably due to the fact that its crystals have a greater variety of orientation, with the result that deformation was more general. It was also thought possible that slip was restrained to some degree at the boundary.

Corrosive atmospheres lower the resistance of materials to alternating stress. Gough found that a specimen tested under corrosive conditions corroded very rapidly in the vicinity of the slip band, while specimens subjected to similar corrosion attack prior to being tested under atmospheric conditions pitted badly but exhibited practically the same fatigue resistance as did uncorroded test specimens. Gough therefore concluded that the low corrosion fatigue strength of materials was due to an accelerated corrosion action occurring locally in heavily strained regions.



(*a*) 14 tons/sq in., below yield point

(*b*) 16 tons sq. in., at yield point

(*c*) 22 tons sq in. above yield point

(*d*) After fracture at 27.2 tons sq. in.

**Fig. 2—X-ray patterns showing crystal breakdown.**

Gough, then, has shown that the nature of fatigue failure in specimens of more than one crystal is similar to that occurring in single-crystal specimens; that corrosion fatigue is merely a special type of fatigue failure; and that the mechanism of fatigue failure is similar to that involved in static failures, the only difference being that the action is one of local strain hardening produced by slip on favourably oriented planes in the first case and general strain hardening in the second. Strain hardening, it is thought, is brought about as a result of a straining of atomic bonds between small crystallites, the product of crystal breakdown, which are rotated with relation to one another. When this rotation of crystallites is sufficiently great a rupture of atomic bonds takes place and failure occurs. Stress alternation causes strain and hence rotation of the crystallites. It is assumed, when specimens are under a safe range of stress, that atoms in neighbouring crystallites are in equilibrium and reverse from one position to another without a straining of atomic bonds. Instead of being stored within the metal the energy of reversal is dissipated as heat.

Figures 1 and 2 offer experimental substantiation of this hypothesis.

These have been taken from a paper by Gough and Wood which appeared in Volume 154, Proceedings of the Royal Society, May 1936.

The spots on the rings represent reflections from individual crystals. Small crystallites produce solid rings; large crystals, spots. The breaking down of crystals can thus be followed by the changing nature of the X-ray pattern. The pattern in the upper left of Fig. 1 shows that the fatigue specimen is not greatly affected within a safe range of stress. The other three patterns illustrate the local nature of the fatigue fracture and show the extent of the crystal breakdown at the point of fracture.

Figure 2 shows spectrograms taken from a specimen submitted to static stress. It may be seen that the patterns are very similar to those obtained from a specimen broken by reversing stresses.

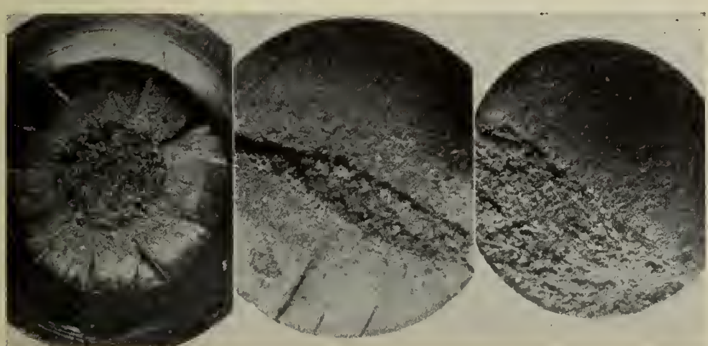
The real reason for slip and the nature of atomic bonds still remains to be solved. It is probably well said that the scientist solves problems by inventing bigger ones.

Machines have been designed for testing specimens under reversed axial, torsion and bending stresses, and under combinations of these stresses. The specimen is usually rotated or the stresses applied by means of an electric motor, an automatic count being kept of the number of rotations or reversals.

Machines are also used in which the test specimen is vibrated at its calculated natural frequency between the poles of a magnet. The vibrational speed is controlled by a radio valve, the frequency of vibration being measured by a stoboscope. Values given by these machines are 15 per cent below Wohler values but are claimed to be nearer the true result because of the use of a natural vibrational frequency.

The fatigue test specimens must be very carefully polished, for scratches result in stress concentration. It should also be remembered that the fatigue limit of a material varies with the type and range of stress. There is also reason to believe that the fatigue strength of large members is not proportionally as great as that of smaller parts. The testing method, then, should if possible approximate service conditions. However, valuable information can be obtained by the simple rotating beam test on small specimens.

The usual practice in making endurance tests is to load the specimen at about 60 per cent of its tensile strength and then progressively reduce the loading until a specimen runs for a large number of reversals without failure. A new test specimen is used for each load. The number of reversals of stress required before it can be concluded that no failure will occur after an infinite number of reversals is five million for wrought ferrous materials, ten million



(*a*) (*b*) (*c*)

**Fig. 3—Fractures produced by reversed bending.**

for cast ferrous materials, and fifty million for non-ferrous materials.

Various fast methods of endurance testing have been suggested. One of these methods measures the temperature changes in a specimen, another the strain. Although in some cases valuable results can be obtained, the general opinion appears to be that these methods are not to be relied upon. High speed machines have recently been made which reduce the time of testing. The speed appears to have little effect on the fatigue strength up to five thousand revolutions per minute. Above this limit, however, the endurance limit is somewhat raised.

The fatigue limit of ferrous material is from 40 to 50 per cent of the ultimate strength. No general relationship has been established for non-ferrous materials. An approximation can be obtained for the fatigue strength of ferrous material by multiplying the Brinell hardness by 250. The relationships stated, however, are only approximate, and for definite information fatigue tests should be conducted.

Fatigue failures can often be identified from the type of fracture. One of the features of fatigue failure is the

**Fig. 4—(above)—A fracture produced by static torsion. (below)—A fracture produced by reversed torsion.**

absence of distortion at the point of fracture, because under fatigue conditions a specimen is strained alternately through a mean position, while the strain under static conditions is in one direction. The result is an absence of distortion in the former case and marked distortion in the latter.

Failures by impact as a result of brittleness are also characterized by a lack of deformation. The fatigue fracture, however, has other peculiarities in addition to its freedom from marked distortion.

Three fractures are shown in Fig. 3 which occurred under reversed flexure. All are characterized by fine and coarse areas. The fine area represents the fatigue fracture and owes its fineness to the wearing caused by the repeated opening and closing of the crack. Failure occurred suddenly across the coarsely crystalline section. In (*a*) the fatigue crack worked in from all sides; in (*b*), from two directions; and in (*c*), from the top only. Under torsion the longitudinal shearing stress is as great as the transverse shearing stress, with the result sometimes that a star-shaped fracture is formed, failures occurring along different directions.

Figure 4 shows some torsion fractures, the upper produced by static torsion, the lower by alternating torsional stresses. The dark areas in the lower figure reveal the position of the fatigue crack. There are no coarsely crystalline areas in this instance, because the steel tested was a fine-grained material.

A failure under repeated axial stressing is shown in Fig. 5. Fine and coarse areas may be seen, but the fractur differs from that produced by bending in that these areas are not separated into distinct zones. The origin of the fatigue crack can sometimes be located by an examination of the fracture, as may be seen in Fig. 6 where the commencement of failure is outlined by a series of concentric circles.

In some cases an inspection may locate fatigue cracks before failure occurs. Fatigue cracks are usually too fine to be located by eye, and a microscopic examination is much too tedious. X-ray and gamma-ray detection methods are employed, but these are expensive and considerable experience is needed in interpreting the negatives. They are, however, valuable where members must be inspected in position. The surface to be examined is sometimes coated with oil. The excess oil is then removed and a coating of whiting and wood alcohol applied. Minute cracks retain oil which can be forced out by hitting the article with a hammer. The white coating shows up the oil streaks. A patented magnetic method of crack detection is also used. The articles are coated with a magnetic material, such as magnetic oxide of iron, and magnetized in two directions. Poles are formed where cracks occur and these collect the magnetic particles.

The National Carbon Company reports that cracks can be located by wetting the article in a solution of anthracene and carbon tetrachloride and then inspecting under ultra-violet light. The cracks are said to become phosphorescent.

The majority of machine part failures are undoubtedly of a fatigue nature. Some occur because designers do not make sufficient allowance for the effect of alternating stress, and some because the material is roughly handled and notched in fabrication. Before the days of high tensile steels, the custom was to design from the yield point, allowing a liberal factor of safety. Alternating stress was thus provided against, for the fatigue strength of the lower-strength materials bears nearly the same relationship to the alternate stress as does the yield point.

**Fig. 5—Fracture produced by reversed axial stress.**

This is not the case, however, for high-elastic-limit alloy material, and members made from this material must be designed from fatigue strength data.

Where such an expense is warranted, full-size specimens should be tested under stresses likely to be encountered in service. Failing this, the fatigue stress of the constructional material should be accurately determined from standard-size specimens and the values so obtained should be used in the designing of all parts likely to be subjected to alternating stresses. When using these data, however, it must be remembered that they have been obtained from highly polished specimens. The tests show up the effect of internal stress raisers, such as inclusions, etc., but do not take into consideration the effect of external imperfections which are sure to exist in machine parts. Some materials are more sensitive to these defects than others. In general, low-strength materials like mild steel are less "notch sensitive" than high-strength alloyed steels because they are more subject to plastic deformation which reduces stress concentration at the notches. The tendency

**Fig. 6—Showing origin of fatigue failure, outlined by concentric circles.**

toward plastic deformation also enables the weaker materials to better withstand occasional overstress. When notches are unavoidable, then, it is sometimes better to use the lower-fatigue-limit material rather than the high-elastic-limit high-fatigue-limit alloy steel. In any case, this latter material should always be given a good finish. A damping test developed by Dr. O. Foeppl, in Germany, for evaluating the property of notch sensitivity, would appear to deserve more attention than it has received to date.

The condition of the surface material is also important, especially when the member is subjected to reversed bending stresses. Carburizing and nitriding increase the fatigue strength, while a surface decarburization reduces the resistance to alternating stresses.

A well-designed part is useless, however, if made from poor material, consequently each metal shipment should be tested before being formed.

The following routine tests have been suggested: A tensile test, which reveals the ductility of the material; a single-blow impact test, which determines the shock-resisting properties of the material; and a proof stress fatigue test. In this last test the fatigue strength is estimated from the ultimate strength, for the relationship of the fatigue strength with the breaking stress is usually known. The specimen is then loaded at a ton per square inch below this limit and given five million reversals. If no fracture occurs the material can be passed. Even with a high speed rotating beam machine, however, this test would be fairly long and costly and would only be justified under special conditions.

Figures 3 and 5 of this paper were taken from the book, "Fatigue of Metals," by H. F. Moore and J. B. Kommers; Fig. 6 appeared in H. J. Gough's book, "Fatigue of Metals"; and Fig. 4 in a paper, "The Physical Properties of Axle Shafts," by H. B. Knowlton, which was published in the March 1937 number of the Transactions of the American Society for Metals.

# The Beet Sugar Factory at Picture Butte, Alberta

*F. H. Ballou,*
*Chief Engineer, Canadian Sugar Factories Ltd., and B.C. Sugar Refining Company, Ltd.*

**Paper presented before the Calgary Branch of The Engineering Institute of Canada, March 4th, 1937.**

**SUMMARY.—Includes reasons for choice of site, preliminary work and the construction of a beet sugar factory. A brief description is included of buildings, equipment and method of handling beets from the raw to the refined product.**

In building a beet sugar factory the first consideration is the selection of the site. The factory must be located on a railroad where the principal raw materials—beets, coal and limerock—are available at reasonable freight rates.

After the above requirements have been satisfied, it is desirable to select a site having the following characteristics:—

1. A good water supply.
2. Provision for waste water disposal.
3. Ground sloping in the right direction in reference to the railroad tracks and highways.
4. Soil suitable to sustain a load of 2 tons or more per square foot.
5. An economical supply of sand and gravel for concrete and for road building.
6. Size and shape suitable for the factory design and yard plans.

The selection of the site in this instance was quite simple as the Lethbridge Northern Irrigation District has a fund of reliable information such as aerial photographic surveys and topographic maps. The District also determined where reservoirs could be economically located. The site at Picture Butte was finally decided upon as best suited to meet all requirements.

### Preliminary Work

A topographic map was made by taking elevations at the intersection of parallel lines 25 ft. apart running north and south and east and west. From these data the exact location of the buildings, beet storage and pulp silo was decided upon. Plans were then made and the work started.

Temporary buildings consisting of bunk house, mess hall and office were started May 13th, 1935.

A gravel plant was built on the banks of the Old Man river three miles away and consisted of a belt conveyor, elevator, crusher, rotary screen, grizzly bar screen, sand washing box and bins. The capacity of the plant was 75 to 100 cu. yd. per day.

Soil tests were made in the usual manner by placing weight on a platform supported by a post exactly 12 in. square. Thirty-six hours after the application of 4,000 lb., equivalent to 2 tons per sq. ft., the post had settled 7/32 of an inch. This result was considered satisfactory for the load of 2 tons per sq. ft., and the foundations were designed accordingly.

To carry out a job of this nature in an economical manner, it is necessary to have a complete set of detailed plans and drawings. A considerable portion of this work was carried on in the Vancouver office which also acted as a clearing house for all information, and supervised all phases of the work. All plans, specifications and drawings were checked and approved before being sent to the field at Picture Butte for use in construction.

The Canadian Pacific Railway spur track was started about June 1st, 1935, and sufficiently completed so that six cars of lumber and piles could be received on June 8th.

### General Methods of Construction

Tracks were run through and alongside the locations for the buildings. A ramp was built along side a construction track for dumping the sand and gravel trucks into stock piles. The locomotive crane filled the elevated gravel and sand bins direct from these stock piles. These bins discharged direct to the concrete mixers.

The use of locomotive cranes permits economical construction. Two were used: one 25 ton crane with a 75 ft. boom and one 20 ton crane with a 50 ft. boom. Practically all of the structural steel and machinery were set in place by these cranes. The crystallizers, constituting one of the heaviest pieces and weighing 15 tons each, were lifted into position on the third floor by the large crane. A wooden pole was lashed to the end of the 75 ft. boom of the large crane and used for the erection of the highest structural steel and tanks.

In order to properly carry out the erection with one of the crane tracks going down the centre of the building, it was necessary to carefully schedule the delivery of the structural steel and machinery. We started at the east or beet end of the main building and backed up as erection progressed. Permanent tracks along the west side of the warehouse and east side of the boiler house and lime house, and the construction track south of the main building permitted access for locomotive crane work to practically all parts of the main building group.

Most of the work of excavation and moving of earth for the pulp silo, beet sheds, foundations, main water line and waste water tile line was either done with our locomotive cranes or carried out on a rental or contract basis employing such equipment as the Le Tourneau 10 yd. dirt mover, or power Fresno, crawler shovels, hoe and drag line.

### Type of Buildings

A reinforced concrete structure similar to concrete grain elevators was built for the bulk storage of sugar. This structure consists of six bins 33 ft. inside diameter by 85 ft. high inside arranged in two rows of three bins each.

The space between the large bins forms two additional bins called star bins.

On account of the heavy load, the bin foundations are carried on 752 piles, each pile being good for a load of 15 to 20 tons.

The six bin cylinders are all carried up simultaneously by means of moving forms, the pouring operation being carried on continuously 24 hours per day until finished. In our case the bin walls were carried up the 85 ft. from floor slab to roof in 161 hours. The cylindrical bins are lined with two layers of 7/16 by 3½ in. fir on 1¾ in. square studding, thus an air space is formed between the concrete and wood lining. The fir lining is laid in a horizontal position and fastened to the studding with galvanized nails. A waxed paper lining is placed between the two layers of fir. The sugar to and from the bins is all handled mechanically and is not touched by hand. The total capacity of these bins is about 240,000 one hundred pound bags, or 24,000,000 lb.

The other buildings, consisting of the main building, office, packing house, boiler house, power house, machine shop and storeroom, and warehouse, are built of concrete, steel and brick. The kiln house has corrugated galvanized iron siding above the second floor.

From the second floor up all brick walls are supported on steel.

As previously mentioned, foundations and column footings are designed for a soil pressure of two tons per square foot.

The steel is designed for a maximum stress of 16,000 lb. per sq. in. to allow ample strength for future changes or additions to the load.

Copper bearing steel sash was used throughout and that portion subject to moist air was galvanized. One-quarter inch wired glass was used throughout to reduce the fire hazard and maintenance.

Roofing is made of compressed asbestos, and Portland cement was also used for ultimate economy and for its fireproof qualities. As this type of roof sweats readily in cold climates, it was laid over 2 in. wood planks in locations where the air is moist.

All floors were treated with two coats of silicate of soda to reduce wear and particularly deterioration where subject to the acid action of sugar liquors.

The grouping of the buildings was carefully studied and plans made so that all buildings are connected together. At the same time provision is made for expansion, if ever necessary. A novel feature in the design is a gravel road encircling the main building group, giving truck as well as rail service wherever required.

### Boiler Plant

Two 707 hp. Stirling type boilers of the latest design were installed in the boiler house. These boilers are equipped with forced draft chain grate stokers, forced and induced draft fans, automatic soot blowers, superheaters, water cooled bridge walls, side wall cooling boxes, feed water regulators, boiler meters giving the steam flow, air flow and flue gas temperature, and automatic balanced draft and steam pressure control. The boilers produce steam at 250 lb. gauge and 140 deg. F. superheat. About one rated boiler horse power is installed per ton of beets sliced per 24 hours.

During a typical week the boilers operated at 174.5 per cent of rating which is equivalent to developing an average of 2,470 boiler hp. The boiler horse power developed this week per ton of beets sliced per 24 hours is 1.82, and per 100 lb. bag of sugar is 0.574.

**Fig. 1—Front of sugar factory with a sugar beet field in the foreground.**

The two steel stacks are supported directly on top of the two induced draft fans.

A novel feature of the design is the arrangement for operating one boiler at 300 per cent of rating in case the other boiler is out of service. When operating up to 200 per cent of rating the forced draft fan motors operate at 870 r.p.m. For ratings above 200 per cent the same motor operates at 1,160 r.p.m. The two induced draft fans are provided with three motors. Two of the motors will operate the two fans at 570 r.p.m. and the other motor can be used to operate either fan at 870 r.p.m. for ratings above 200 per cent.

The automatic boiler control maintains a slight vacuum in the combustion chamber at all times and controls the steam pressure. This instrument also maintains an equal distribution of the load between the two boilers. Electric motors operated through relays operate the dampers in this control system.

**Fig. 2—Rear of factory, in foreground edge of pulp silo with pipe supply line and beet piler.**

The overall continuous efficiency of the boilers is about 73 per cent. On account of the reasonable fuel cost due to our proximity to the coal mines, air pre-heaters would not pay a reasonable return on the investment.

The chain grate stokers discharge the ash continuously into a flume at the back of the boilers. A manganese steel lined pump connected to the flume discharges the ashes through a six inch pipe line into the waste water system.

The coal is elevated from a railroad car to the coal bunkers above the stoker hoppers with our locomotive crane. Each bin holds about one car of coal. The coal is continuously fed into the stoker hoppers through an oscillating chute equipped with magnets. These magnets are essential as they daily remove several pieces of tramp iron which might damage the stokers.

### Power Plant and Electrification

A 1,250 kilowatt steam turbine provides electric power at 480 volts, 3 phase, 60 cycles suitable for our 440 volt motors. The lighting system is 230-115 volt, 3 wire.

The entire plant is electrified except for the $CO_2$ compressor which is direct connected to a steam turbine. There are no steam cylinders, therefore no oil is present in the condensate or boiler feed water.

The actual load on the generator is about 750 kw. or 0.55 kw. per ton of beets sliced per 24 hours.

High speed motors carefully selected as to size resulted in a power factor of 82 per cent.

Flat belting has been nearly eliminated. Most of the machinery is either direct connected or driven through worm gear reducers which in turn are direct connected to the machine or drive the machine through roller chain drives. All pumps are direct connected except the sand pump. The balance of the drives are through V belts. This design permits the use of high speed motors with resulting economy in first cost and low maintenance.

### Beet Sugar Machinery

Most of the machinery is of the conventional design and standard in up-to-date plants. Some of the novel features in the design are as follows:

A beet feeder in main flume which regulates the flow of beets at the desired rate. This feature permits the use of a smaller beet wheel and beet elevator and increases the efficiency of the beet washer, roller table and picking table. The power requirements are also reduced. The following motors will easily handle the machines at a 1,500 ton slicing rate:

| | | |
|---|---|---|
| Beet wheel | 5 | hp. |
| Beet washer | 15 | hp. |
| Beet elevator | 7½ | hp. |

*Weightometer:* The sliced beets or cossettes are weighed on a weightometer as they travel on a belt from the cutters to the chute to the diffusion battery.

*Diffusion Battery Control:* The battery draft is controlled by a meter operated indicating dial. The meter is on the battery water supply line. This system is similar to that developed by the Swedish engineer, Mr. Nils Weibull.

*Calandria Pans:* All sugar is boiled in calandria pans of special design with low pressure steam, either first vapour at a pressure of 10 lb. per sq. in. (gauge) or exhaust steam at 22 lb. per sq. in.

*Thermo Compressor:* This machine is used to increase the steam economy and reduce the capital cost of evaporators. This device uses 292 lb. of live steam per minute at a pressure of 225 lb. per sq. in (gauge), and 140 deg. F. superheat to compress 243 lb. of first vapour at 10 lb. per sq. in. (gauge) into exhaust steam at 22 lb. per sq. in. (gauge).

*Bulk Storage Bins:* Four beet sugar factories in North America at this writing are using this method for storing sugar in concrete bins similar to grain elevators. The method was developed by the Great Western Sugar Company.

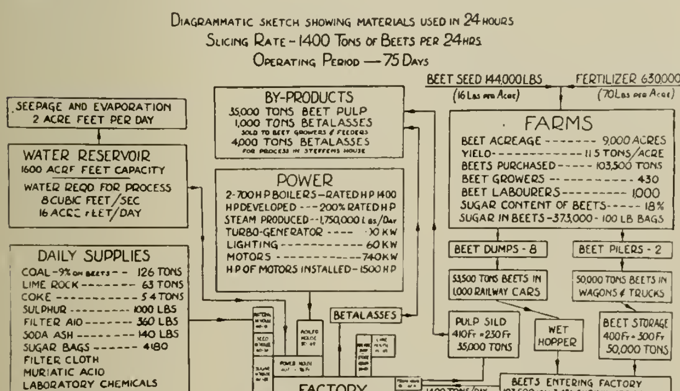


**Fig. 3—Materials used in 24 hours in beet sugar factory.**

*Pipe Design:* All piping 3 in. and larger have welded joints. Steel welding tees, ells, flanges, etc., are used in this design. The high pressure steam line has the Vanstone type of joint with cast steel fittings.

*Pumps:* The plant is equipped with 35 pumps which operate at 3,500 r.p.m., out of a total of 62 centrifugal pumps.

### Water Supply

The plant is supplied with water from a reservoir having 1,300 acre feet capacity, built for the use of the plant by the Lethbridge Northern Irrigation District. The reservoir is filled from Keho Lake through an irrigation canal.

The water is conveyed from the reservoir to the main water pumps in the power plant through a 20 in. i.d. wood stave pipe 3,224 ft. long. This pipe is double wrapped with asphalt impregnated burlap. As the pipe is buried six feet deep and kept full of water the year round, a long life is expected. There is a stand pipe at the lower end of the line to take the surge when the flow of water is interrupted.

**Fig. 4—View from top of bulk storage bins showing 42,000 tons storage pile of beets.**

The plant uses about 3,100 U.S. gal. per min. A like amount of water may easily disappear from the reservoir when strong west winds are blowing.

The water is pumped by centrifugal pumps to the main water tank on the fifth floor, sugar end, and distributed from there principally to barometric condensers. The warm water from the condensers is used for fluming beets and in the different processes.

### Beet Storage and Transporting System

About 42,000 tons of beets are stored on the storage ground over flumes on 45 ft. centres. This pile of beets is about 300 by 400 by 18 ft. deep. The beets are put into storage by means of two Hartburg pilers built at the Vancouver refinery shops of the company. These two pilers move parallel to the flumes, and handle up to 2,400 tons or more per 12 hour day.

Car beets are received over the wet hopper. The car of beets is dumped into this hopper and water flumes them into the plant as required. When the beets are frozen in the car a series of hoses distribute warm water over them to thaw them out before dumping. If not frozen too hard, 45 per cent of the beets in storage are worked into the flumes by two men. The balance is transferred from the pile to the flumes by a gas shovel. The flumes are all built on a grade of 1⅛ per cent on tangents and 1¼ per cent on curves. All flumes are equipped with overflow flumes or a space screened off from the beets where water can flow without obstruction, and turn back into the flume when past the blockade of beets. No beet signal whistle is provided as it is only necessary to dump beets into the flume as fast as taken away by the water.

The flumes under the beets in storage are built of cedar, the balance of the flumes being of reinforced concrete. The bottom of the concrete flumes are built on an 8 in. radius and are 20 in. wide at the top. The wood flumes have a flat bottom 16 in. wide and are also 20 in. wide at the top. All flumes under the storage pile are equipped with water tight gates to prevent warm water from backing up under the beets and causing deterioration in storage. A waste water connection and valve assures that all water can be drained out of the flumes above the gates.

After the beets are flumed into the factory a beet wheel lifts them out of the flume allowing the water alone to pass to the 24 in. tile line. The water from the flumes accounts for about 80 per cent of the total waste water. This 24 in. tile line runs a distance of 1,250 ft. and discharges into a coulee. The tile is laid on a grade of 3 ft. per 1,000.

The exhausted cossettes known as pulp are pumped out through an 8 in. overhead line 800 ft. long to the pulp silo. The silo is 300 ft. long by 200 ft. wide and will take care of 35,000 tons of pulp.

General Remarks

The plant was finished October 5th, 1936, and started manufacturing sugar on that date.

The total cost of the project is approximately $1,500,000, including 12 brick residences for employees.

Some $500,000 worth of machinery and supplies were purchased in Alberta, of which over $200,000 worth of machinery and steel was manufactured or fabricated in Calgary. About $300,000 was distributed in Picture Butte, Alberta, for labour.

On account of the difficulty of carrying out construction work during the Alberta winters, construction extended over a period of 17 months from May 1935 through September 1936. Up to April 1936 the number of employees employed on construction averaged 90. From that date to September 26th, 1936, the average was 240. The peak of activity extended for a period of five weeks from July 4th to August 8th, 1936, when the number of employees averaged 308.

One cannot emphasize too strongly that the success attained in building a project of this kind depends largely on the team work of the various units rather than on any grandstand plays. The purchasing, engineering, accounting and executive departments, the construction superintendent and the construction engineer were all members of that team. The construction superintendent and the construction engineer who were in charge of the work in the field carried on their part of the job in a very efficient manner.

The president of the company is keenly interested in having modern plants of the highest efficiency and his constructive attitude on the most modern equipment was an important factor in the up-to-date design adopted for Picture Butte.

The Company's total sugar production in Alberta during the past season was 652,996 one hundred pound bags.

The yearly consumption of the entire province is about 580,000 one hundred pound bags. The city of Calgary still uses about 40 per cent cane sugar, and as sugar producing capacity in this province is not justified unless the sugar can be sold, why not use more beet sugar and help a home industry?

# Development of Radio Communication in the Bush

*D. R. Taylor, S.E.I.C.,*
*The Canadian International Paper Company, Maniwaki, P.Q.*

**Paper presented at a meeting of the Junior Section, Montreal Branch of The Engineering Institute of Canada, November 16th, 1936.**

**SUMMARY.—Describes the development of communication in the bush with reference to fire protection, the advantages of radio, the improvements in equipment since 1929, some of the operating difficulties encountered and the desirability of employing a competent technical staff.**

The forests of Canada are one of the country's largest natural resources and the protection of these forests is a large and important business. Fire protection service calls for a reliable means of communication since it is only by rapid delivery of information concerning fires and orders for directing fire-fighting that the service can operate efficiently. In undeveloped country, the single-wire grounded-type telephone line has always been used since it is only necessary to string one wire through the bush, the ground serving as the return lead.

The Laurentian Forest Protection Association handles a considerable amount of fire-ranging in the Province of Quebec. Their largest limits, located on the North Shore of the St. Lawrence river, in the county of Saguenay, are entirely unsettled except for small lumber towns located along the shore of the St. Lawrence. This land is leased by the pulp and paper companies where wood is cut for pulp. At first, cutting took place along the coast, no company penetrating very far inland, during which time the L.F.P.A. operated towers and patrols along the coast and used telephone lines as their means of communication. As new limits were taken and cutting activities began to extend farther inland, it was found necessary to extend the telephone lines. This was inadequate since the grounded type line is very unsatisfactory over distances of forty or fifty miles. The noise level in the line becomes very high and makes conversation difficult and the maintenance costs, in a country where the only means of transportation is by canoe and portage, becomes excessive. By 1929 the demand for a better means of communication had become so great that the company decided to investigate the possibilities of radio communication.

Radio involved equipment which was much more complicated technically than that used in a telephone system. The equipment involves three units, a receiver for receiving intelligence, a transmitter for sending intelligence and a power supply for these first two units. The capital cost of the equipment itself is much higher. (This is not true today. The capital cost of low power radio equipment is lower than that of a 45 mile telephone line.) But the installation costs are much lower than those of an equivalent telephone line. Maintenance of a radio station is also very low compared with the almost prohibitive maintenance costs previously mentioned with a long telephone line. Hence it was decided to install two stations in 1929, a base station at Manicouagan (see Fig. 1) and a look-out tower and station about seventy miles inland (Tower Taboret). A third station (Tower Bellevue), to be installed in 1930, involved a 125-mile trip by canoe and portage in which there were twenty-three portages.

The requirements first demanded of the equipment were simplicity and good mechanical construction. Operating conditions demanded a transmitting range of 150 miles during daylight on a wavelength of 180 meters. The self-excited oscillator circuit was at this time a popular simple circuit and one that would give a fair degree of frequency stability if properly tuned and handled. Power in this type of circuit is limited only by the power of the tube available for the oscillator. The first transmitters installed were, therefore, ones using the Hartley oscillator circuit with a type 211 tube.

Radio telephony was also desirable since the type of work and traffic was more adaptable to telephone than to telegraphy. Also, using radio telegraphy meant employing telegraph operators which would increase the cost of operating the station. The system of modulation chosen was the Heising or plate system of modulation. This is also a simple circuit, and if the power used is not too high, speech amplifiers are not always necessary.

Hence the complete transmitter consisted of a type 211 tube as oscillator, a pair of type 845 tubes as modulators and a type 210 tube as speech amplifier. The speech amplifier was not used in all stations at first but was later found to increase volume, making about 90 per cent modulation possible. With these tubes, an output of between 75 and 100 watts was obtainable. Complete circuit diagram of the original transmitters is shown in Fig. 2.

The power supply for these transmitters was furnished by a three horse-power gasoline engine, belt connected to a 600 watt, 1,000-12 volt direct current generator, the 1,000 volts being used for the tube plate power supply and the 12 volts for the filament power supply.

The best battery tubes for receivers available at this time were the 5-volt filament type. Consequently, the receivers employed these tubes. The receiver consisted of a stage of tuned radio frequency, a detector, and two stages of audio. This meant the use of storage batteries for filament power supply since the life of dry cells is too short for use on such receivers.

Two such stations were installed in the two towers built in 1929. Communication proved quite satisfactory and in the following year three more stations were installed, one in the tower previously mentioned and two others in another division in another part of the province. These latter two worked independently of the other three. Communication between headquarters and the station located 125 miles inland did not turn out very well. Reception was very weak and quite often traffic had to be relayed by the third station. However, previous experiments with this type of transmitter had shown that the reliable transmitting range was about 100 to 150 miles. This seemed to point to the receivers as the source of trouble.

The type of receiving tube used was not economical. Battery drain was fairly high from the "B" batteries and the filament drain from the storage battery was 1.0 amp. for the receiver. The storage battery had to be charged with the gas-engine generator set used to supply power to the transmitter, and since batteries and gasoline had to be taken into the stations by canoe and portage, a larger and more powerful receiver was not desirable.

The next step was taken when the 2-volt type tubes were introduced. Four such tubes drew 0.24 amp. on the filaments as compared with 1.0 amp. for the old tubes, resulting in a saving on batteries. The "B" battery current was also lower. The triode of the series, the type 30 tube, had an amplification factor of 9.3 as compared with 8.0 with the corresponding type 5-volt tube. The type 32 screen-grid tube, used in the radio frequency stage, had an amplification factor of 610. It also made a more efficient detector. At the same time that these tubes were introduced the air cell battery was also brought into use as a filament supply for the tubes.

This was just what the forestry people wanted. The receivers were remodelled using a type 32 tube in the radio frequency stage and detector stage and a type 30 tube in the two audio stages. The performance of this receiver was much better than the old one and no difficulty was encountered in direct communication with all stations. In addition, costs were reduced by the lower "B" battery consumption, and by the fact that the air cell had taken the place of the storage battery and therefore extra gasoline for the gas engine generator set was not needed. This last was a considerable saving as gasoline costs a minimum of $1.00 per gallon delivered at the stations in the bush.

It now became necessary to install more stations. The same type of transmitter was not chosen, however, as it had been found that the frequency stability of these was not good enough. Sagging or swaying of the antenna in

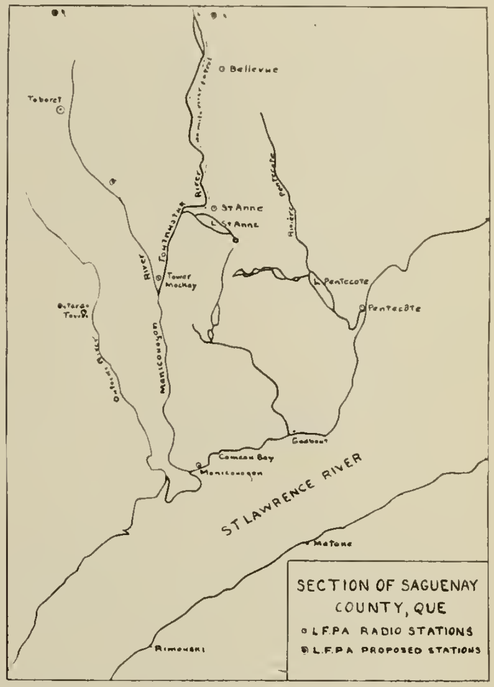

**Fig. 1—Map showing location of towers and the patrol on which the portable was put into service.**

the wind caused slight changes in frequency. Modulation of a self-excited oscillator is also not a good system since frequency modulation is liable to occur unless care is taken. Therefore, the next type of transmitter installed was the oscillator-amplifier type which uses an oscillator tube to generate the radio frequency desired and then a number of radio frequency amplifiers, the number of amplifiers depending on the power desired. The oscillator circuit in this type of transmitter is isolated from the antenna and other outside sources which might affect the frequency and therefore the frequency stability is very good. It is true that this type is more difficult to tune, neutralizing being necessary, but by this time the company had a technical staff of their own and simplicity was not as essential as previously. The two transmitters installed employed a 210 tube as oscillator and a pair of 210 tubes in parallel as amplifier, giving an output of twenty-five to thirty watts. These stations were nearer headquarters and hence the lower power was satisfactory.

The 6.3-volt type heater tubes were now becoming quite popular for battery receiving sets. They are a much more rugged type of tube and of slightly higher power than the 2-volt series. The filaments were designed to operate from storage batteries, which was not desirable as previously explained. However, a new piece of apparatus was on the market, namely, a "Wincharger," which was a wind-driven 6-volt generator with a propeller about six feet in length. This windmill was intended to go with receivers using the 6.3-volt tubes for battery charging purposes and seemed to solve the charging problem as all stations were located on tops of high mountains and a good clean sweep of wind was available.

Higher power receivers were now considered desirable since there was some talk of adopting a system of continuous listening, which meant the use of loudspeakers, and it was decided to install new receivers and Winchargers.

The receiver chosen was a three-tube model, using a type 39/44 tube in a tuned radio frequency stage and the detector stage and a type 38 pentode tube in the audio stage. The receiver was designed to operate on a plate voltage of 90 volts. At this voltage the 39/44 tube has an

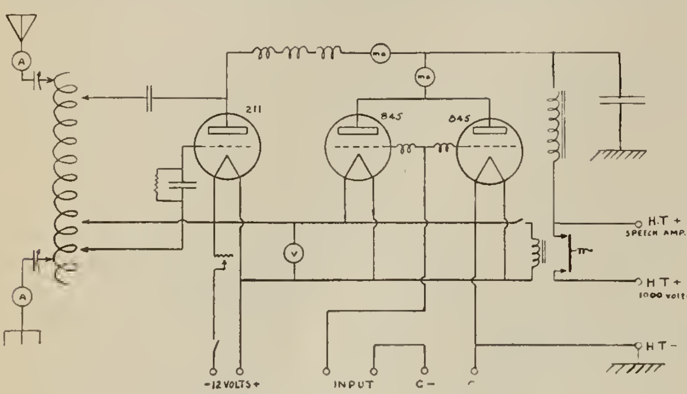

**Fig. 2—Original transmitter installed for forestry communication.**

amplification factor of 960 as compared with 610 for the type 32 tube. The 38 pentode tube has an amplification factor of 120 as compared with 9.3 for the type 30 tube, and it has an output of 0.27 watts which is ample to operate a loudspeaker. With the heater type tubes, resistor bias may be used which dispenses with the use of "C" batteries.

These receivers were installed in all stations during the summer of 1935 along with the Winchargers, and the outfit worked excellently. The Wincharger supplied ample power for charging the batteries and effected an estimated saving of six gallons of gasoline per station per season. Two 45-volt "B" batteries (heavy duty) were found to be good for one season's operation, the total receiver "B" battery drain being only about 16 milliamperes. This was a big improvement in receiver operation, loudspeaker operation being possible with low battery power consumption.

Another type of transmitter was tested in 1935 and installed in 1936. With the introduction of multi-grid tubes, a new method of modulation was also introduced, namely suppressor grid modulation. Modulation is obtained by impressing the modulating voltage on the suppressor grid of the tube. This method is very simple and requires little driving power from the modulator. A pair of type RK-20 tubes were used in an electron-coupled push-pull circuit and a type 210 tube was used as modulator. The electron-coupled circuit gives the advantages of the oscillator-amplifier circuit, but uses the same tube for a double purpose. The cathode, control grid and screen grid are used as a triode in the oscillator part of the circuit while the plate is wired in, in the amplifier part of the circuit. The pair of RK-20 tubes in such a circuit give an output of approximately 45 watts. This type of transmitter is very simple and easy to tune and yet offers the frequency stability of the oscillator-amplifier and a simpler system of modulation. This transmitter worked successfully and was eventually installed at headquarters in place of the original Hartley transmitter.

There was one other problem with which the company were having trouble—that is, dampness. It is not always convenient or possible to keep the stations heated at all times and when this is not done the humidity in the log-cabin-type buildings is very high. Quite often in rainy weather, water would drip from the transmitter racks and panels due to heavy condensation. This was very bad for transformers and other such pieces of apparatus using fine wire for windings, as an electrolytic action is set up which corrodes the wire. Therefore, whenever possible, resistance coupled circuits were used in place of transformer coupled circuits. The speech amplifiers were all remodelled, using the circuit shown in Fig. 4 in place of the original circuit shown in Fig. 3. This did away with transformer T and the chance of breakdown due to humidity was greatly reduced. Also, a great saving was effected in replacements since the price of resistors is about one-tenth that of transformers.

There are now eight stations in operation on the one network. This network is rather large and slightly unwieldy with which to run regular schedules as gas engine generator sets are used for power for the transmitters and these sets must be started and stopped each time a call is made. This takes time and slows up traffic and conversation. Therefore, the next step proposed was to have headquarters listening in at all times and the stations reporting only when there was traffic to send through. Regular listening periods could be established for the stations in the bush so that in-going traffic might be sent when necessary. This system was tried out for several weeks during the summer of 1936 and was found to work quite successfully. However, for a system operated in this manner, the frequency of all stations must be exactly the same and the frequency stability must be very good so that station calls will be heard at headquarters, where the receiver is tuned to the allotted wavelength. Trouble was noticed occasionally during the trials. Slackening of the antenna with the self-excited oscillator units or some

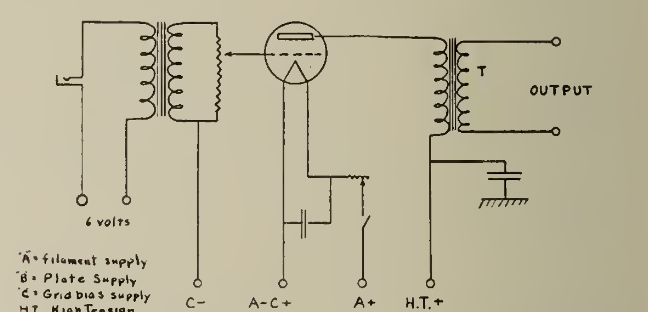

**Fig. 3—Diagram of speech amplifier using transformer coupling.**

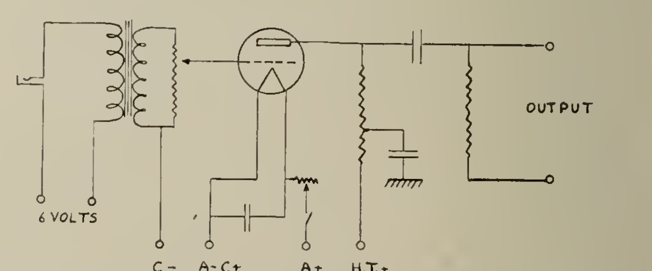

**Fig. 4—Diagram of speech amplifier changed to resistance coupling.**

other similar cause, would cause a shift in frequency and the station would not be heard, or if heard, it would be necessary to retune the receiver in order to bring in the station properly. This is not satisfactory and use of crystal-controlled transmitters is recommended as this type offers about the best frequency stability that can be obtained and assures that a station will always be on the same frequency.

A new branch of the forestry service is just developing, namely, the use of portable radio equipment. The first portable transmitter and receiver was tested during the summer of 1935 and this set consisted of a pair of type 802 tubes in an electron coupled circuit. The transmitter is identical with that previously described using the RK-20 tubes and is shown in Fig. 7, except that the 802 tube is a lower power tube, and gave an output of 2.0 watts on telephony. Microphone and microphone transformer were all that were used for modulation, the output of the transformer being fed directly to the suppressor grids of the tubes. The equipment was highly successful and found to be extremely useful for patrol work and for temporary set-ups where work was being carried on and communication was necessary.

In 1936, a portable set was put into actual service on a hundred-mile patrol. This set did not use the same type of transmitter, but a simple oscillator-modulator set. It was satisfactory provided a technical man was on hand to tune it up, since it had to be retuned each time it was set up and difficulty was encountered in setting the frequency correctly with only the receiver as a means of checking the frequency. However, while in operation it proved invaluable and future plans include a number of portable outfits equipped with emergency battery supplies, good for about eight to ten hours operation, and standard battery supplies, good for a summer's operation. The emergency power supply is to be used in case of fire when it is necessary to travel rapidly and weight must be minimized.

It is unfortunate that complete records of operating data are not available. Before 1934 records were not kept and the only information that is available is that obtained from employees working in the district at the time. During the first two or three years of operation, the percentage of successful calls was quite low. The company did not employ a technical staff but depended upon the manufacturer of their equipment for servicing. In the event of a breakdown, of which there was a considerable number, it took a man at least ten days to get to the stations in the bush, and then not knowing what the trouble was, he might not go prepared. Therefore, though the system of communication was in itself satisfactory, breakdowns in equipment caused long delays in routine communication which greatly lowered the percentage of successful calls. In 1932, the company began to employ a technical staff and from this time on the radio organization began to develop and increase in efficiency. Improvements in equipment and proper and continuous servicing kept the stations in first class condition.

There are some interesting figures available from 1934 to date. In 1934 the percentage successful calls for Bellevue tower was 93.7 per cent while in 1936 it rose to 97.6 per cent. This rise was attributed mostly to the installation of the 6.3-volt type receivers. The total traffic handled rose from 243 messages in 1934 to 601 messages in 1936, and of these, about 65 per cent were routine messages such as weather reports, etc. A new transmitter at St. Anne tower in 1936 increased the efficiency from 86 per cent for 1935 to 98.6 per cent. These figures are for an operating season of about three and a half months.

Some very interesting information was obtained during 1936 when the portable equipment was put into service. A fire broke out about thirty-five miles above Bellevue tower (see Fig. 1). The patrol immediately rushed to the scene of the fire, taking the portable with them. Travelling is not easy in this part of the country and it took two days to reach the scene of the fire from St. Anne tower. The portable was immediately set up and messages sent to Bellevue tower reporting the condition of the fire, the extent and what men and equipment would be necessary to fight it. Under ordinary conditions, it would have taken five days before these men could have investigated the fire and reported back to Bellevue tower with information. The portable stayed at the scene of the fire for eight days and during this time sixteen messages were sent giving details and progress of the fire and ten messages were received with instructions for the fire-fighters. The transmitter operated a total of seven and one-half hours and the receiver a total of ten hours. Not only did this portable equipment save time but it kept headquarters in constant contact with the fire-fighters, thus saving considerable concern and anxiety on the part of many people.

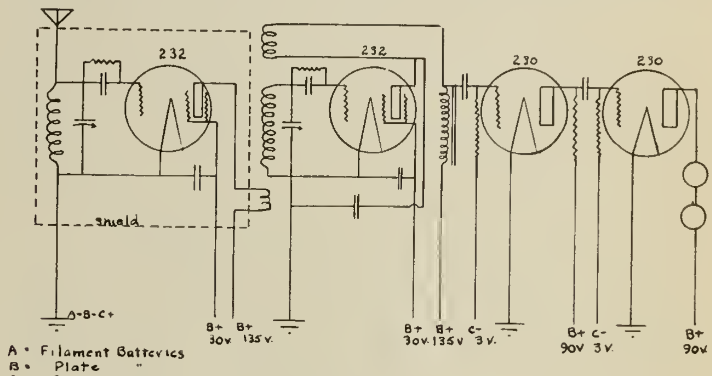

**Fig. 5—Diagram of receiver remodelled for 2-volt tubes. The audio stages were changed to resistance coupling, as shown, at the same time.**

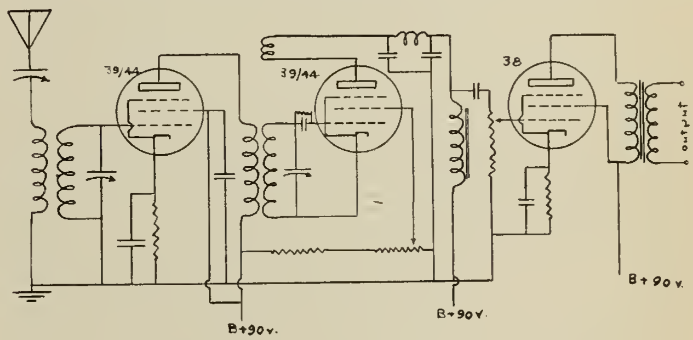

**Fig. 6—Diagram of 6.3-volt type receivers installed in 1935.**

The weight of equipment is an important factor, particularly with respect to the portable equipment. As previously mentioned, all travel in this country is done by canoe and portage, therefore, all equipment and supplies must be transported on the backs of men when travelling on the portages. The average load a man can carry is about one hundred pounds and hence all units sent into the bush must not exceed this weight and they must be of a size which can be carried easily and safely in a canoe. Any equipment weighing over this amount must be partially dismantled and packed in units of proper weight and size, transported, and then reassembled at the station. This has been done in the case of the gasoline engines. Hence light weight, compactness and good mechanical construction are essential. The radio equipment itself is comparatively light, the power supply unit being the one which contributes the major part of the weight. In the portable transmitter previously described, that using 802 tubes, the transmitter-receiver unit weighs only thirty-five pounds whereas the power supply unit (storage batteries and genemotor) weighs fifty-five pounds. Hence there is a total weight of ninety pounds to portage, which is about a full load. This type of equipment is rather heavy for a patrol covering a number of portages but is ideally suited to a river patrol where no portaging is necessary. Experiments have shown that 1.5-watt transmitter, operating under average weather conditions, is reliable for a range of twenty miles and a dry battery power supply weighing about fifty pounds will provide about twenty-five hours operation. For trips of short duration, or where considerable portaging is encountered, lighter weight battery units could be used, weighing about fifteen pounds and supplying about eight hours operation.

Radio has certainly proved itself the best means of communication in this type of country but this does not

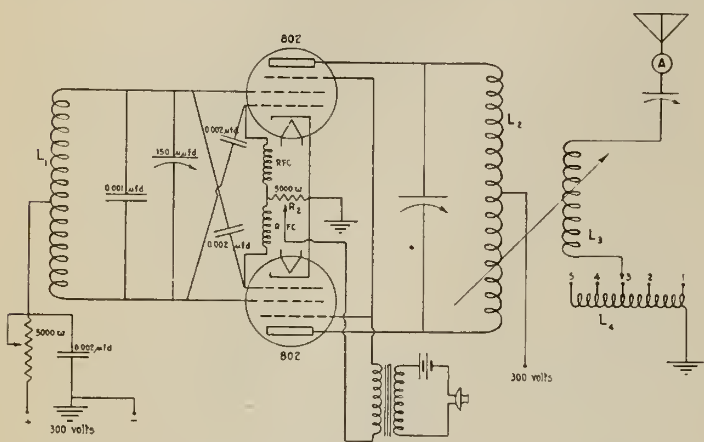

**Fig. 7—Circuit diagram of Marconi portable transmitter, type 48030.**

mean that all telephone lines should be abandoned. The telephone is very satisfactory over short distances or in a well developed country where a two-wire line may be strung on poles along a road. In heavy bush country, the radio is the only solution to the communication problem and it provides a system of communication approaching 100 per cent efficiency whereas a forty-mile telephone line seldom averages better than 75 per cent efficiency. Maintenance costs are very low for radio, the only requirements being gasoline (about three gallons per month per station in the system described) and one set of receiving batteries per season. Another big advantage of the radio system is its flexibility. In the event of fire, portable sets can be taken to the fire and communication provided at the scene of activities. This cannot be done with a telephone line and there is always the possibility of the line being burned and communication completely severed.

There are, of course, disadvantages to the radio system as two-way communication (i.e. conversation as carried on by telephone) is rather costly and has not yet been used for this service and one station must have his say and then close down and listen for the other station. The simplex system has greatly overcome this drawback, as it is only necessary to press a button to speak and release the button to listen for a reply. Another factor entering into the problem is the fact that a technical staff is required to install and supervise these stations whereas the telephone lines can easily be installed and maintained by anyone provided with the necessary instructions.

With the rapid advances in tube design and radio equipment in the past few years, the radio system has proven itself not only practical, but more efficient and easier and less expensive to maintain. It is still a new field and future developments will no doubt bring forth many improvements to provide a still better and more efficient system.

The information contained in the following essay was obtained during the summers of 1934 and 1935 while the author was employed as radio operator at Tower Bellevue and during the summer of 1936 while employed as radio inspector, Division F, for the Laurentian Forest Protective Association.

Figures on operating data were furnished through courtesy of K. G. Chisholm, radio engineer, Laurentian Forest Protective Association.

## APPENDIX I

### History of North Shore Stations

| Station | Date | Transmitter | Receiver |
|---|---|---|---|
| Manicouagan (Headquarters) | 1929 | 211 oscillator, 2–845 modulators, 210 speech amplifier. | 4 tube, 5-volt type. |
| | 1932 | | Receiver remodelled, using 2-volt tubes. |
| | 1934 | | 3 tube, 6-volt type receiver installed. |
| | 1936 | 2–RK-20's, electron coupled circuit, suppressor grid mod. | |
| Tower Taboret | 1929 | 211 oscillator, 2–845 modulators, no speech amplifier. | 4 tube, 5-volt type. |
| | 1932 | | Receiver remodelled, using 2-volt tubes. |
| | 1935 | | 6-volt type receivers installed and Wincharger. |
| | 1936 | 210 speech amplifier added, resistance coupled circuit. | |
| Tower Bellevue | 1930 | 211 oscillator, 2–845 modulators, 210 speech amplifier. | 5-volt type receiver. |
| | 1932 | | Receiver remodelled, using 2-volt tubes. |
| | 1935 | | 6-volt receivers installed and Wincharger. |
| | 1936 | Speech amplifier remodelled to resistance coupled circuit. | |
| Tower St. Anne | 1933 | 2–230 oscillators, telegraphy. | 4 tube 2-volt receiver, all type 230 tubes. |
| | 1934 | 2–210 oscillators, 2–250 modulators. | |
| | 1935 | | 6-volt type receiver and Wincharger installed. |
| | 1936 | 210 oscillator, 210 buffer, 2–801 power amplifiers, 2–59 class "B" modulators, 59 speech amplifier. | |
| Tower Mackay | 1934 | 210 oscillator, 2–210 amplifiers, 2–2A3 modulators. Run from 110 volt A.C. generator and using rectifier unit. | 2.5 volt type, run from generator. |
| | 1935 | | Receiver changed to 6.3 volt type. |
| | 1936 | 2–6L6 modulators. | |
| Pentecote (2nd Headquarters) | 1936 | First Manicouagan transmitter installed here. | 6.3 volt type. |
| Motorship "Lewis L" | 1931 | 2–210 oscillators, 2–250 modulators. This transmitter transferred to St. Anne Tower 1934. | 2 volt type. |
| | 1934 | 210 oscillator, 2–210 amplifiers, 2–2A3 modulators. | 6 volt type receiver. |
| | 1936 | 2–250 modulators. | |
| Outarde Tower | 1936 | Temporary installation. Portable transmitter, 2–802 tubes, electron coupled circuit, suppressor grid modulated. Storage battery and genemotor as power supply. | 6.3 volt type receiver, using a 6D6 tube in detector and R.F. stages and 6F7 tube in audio stage. Wincharger installed. |

# The British Grid System

*Johnstone Wright*

## DISCUSSION[1]

J. B. Challies, M.E.I.C.[2]

The author has furnished a brief and a comprehensive statement of both the historic and the technical highlights of the electrical utility industry of the motherland.

Not only is the paper a valuable contribution to technical knowledge, but it is timely because in this country there has been a good deal of loose talk about the British Grid. For instance, a few of the would-be power savants in the political world on both sides of the International Boundary have been telling an electricity-conscious public, already surfeited with power propaganda of the most misleading character, that some of the growing pains of the electrical industry on this continent would be relieved if something akin to the British Grid were established here. The writer is confident that the author will agree that one of the distinguished leaders of the British delegation to the Third World Power Conference was right when he stated at Ottawa last September that the British Grid was evolving for England precisely what the private power companies of Quebec and the Hydro-Electric Power Commission of Ontario have already secured for the territories they are privileged to serve, namely, a co-ordinated, standardized high-tension network spread over the whole country, fed from the cheapest and most reliable power-producing sources, and having as a primary purpose not only the conservation of natural resources, but a power system that will furnish the best electrical services to all classes of users everywhere at the lowest practicable cost.

A few pertinent facts about the British Grid should be emphasized. It is free from the least semblance of political control; it is not a state-owned enterprise; it was built with private capital subscribed by the general public. It was designed, constructed and is being operated under the supervision of a board of outstandingly successful professional experts who are in no way whatever subject either to governmental direction or political intervention.

It is exceedingly difficult for a Canadian or an American who has not actually studied the electrical generating and distributing facilities of England to understand the great national importance of the Central Electricity Board, of which our guest speaker today is the distinguished Chief Engineer.

Those who were privileged to be in London in 1924 for the First World Power Conference had an opportunity to appreciate the great difficulties which at that time faced the Central Electricity Board. That these difficulties are even now well on the way to a satisfactory solution is evidenced by this paper. Having done so much for the supply phase of the electrical industry, the author is now facing what is perhaps his most difficult task—the standardizing and modernizing of the distribution phase of the industry in England, and concurrently therewith the establishment of uniform rates for electrical services.

Despatches from London during the last few days indicate that the new British Prime Minister, the Right Honourable Neville Chamberlain, is keenly alive to the fine accomplishments of the Central Electricity Board in the generation and transmission fields and that his Government is determined to support the Board in carrying its fine work to its logical conclusion—the distribution field.

From what has already been told us about the British Grid System, we know that in respect of the Central Electricity Board, past performance is but a guarantee of still more notable results in the future. Of these results the author will be able to say with Virgil, "All of these things I saw, and a great part of them I was."

We in Canada, who are concerned with seeing that all classes of the public are furnished electrical services economically and efficiently, will profit from the experiences of the Central Electricity Board and are therefore grateful to the author for his informative paper. We particularly appreciate his coming all the way from London to present it in person.

Dr. R. W. Boyle, M.E.I.C.[3]

Has any trouble been experienced with high voltage cable after it has been placed in service underground? A cable might pass a rigid inspection satisfactorily, also tests at the factory, and then troubles might be experienced in service. Is there any likelihood that nitrogen gas filled cable will displace oil filled type?

E. V. Buchanan[4]

Enquired if existing stations were selected in constructing the Grid system.

The Chairman[5]

Have any tests been made to determine if nitrogen is a more satisfactory gas to use in cables than carbon dioxide?

C. V. Christie, M.E.I.C.[6]

Could the author say something of the problems and troubles inherent to the operation of the Grid system. Have any troubles been caused by surges due to lightning which might cause a shut-down over a large area with a system tied together such as the Grid?

P. T. Davies, M.E.I.C.[7]

What is the best operating efficiency obtained in B.t.u.'s per kw.h.? An efficiency of 10,000 B.t.u. per kw.h. has been obtained in the U.S.A.

Dr. F. A. Gaby, M.E.I.C.[8]

The paper which has been so ably presented is a brief historical outline of the development of the transmission and distribution of electrical energy in England, known as the Grid system, which system is a result of the improvement in the art and the demand for economy in industrial operations along with the desire for improved standards of living.

The writer recalls the visits of Sir Andrew Duncan and Sir Archibald Page to Canada about the year 1924, and discussing with them the principles and economics of the Hydro-Electrical Power Commission undertaking prior to the establishment of this authority and commencement of work on the Grid system in England.

The advent of power in its various forms has revolutionized our industrial operations and changed our social economy. In a large measure it has been responsible for the distribution and re-arrangement of world trade by the rapid advance in its use in industry, transportation and communication, with which our political economy has not

been able to keep pace in the regulation, adjustment, and co-ordination of the necessary advancements which have resulted in benefits to the industry and improved standard of living.

The present undertaking of the hydro-electric systems of Ontario is the ultimate attainment of such a scheme in which the whole territory to be served is under the control of one administration. The Grid system is the application of such a work to the conditions existing in England, with the fundamental difference in that the source of the supply is from coal in England and water power in Canada. This difference in the source does necessarily require a variance in the rate schedules, but there is a similarity in form. The economy in the application of the principle of high load factors is more evident in Canada with the source of the supply from water power.

One can appreciate the many difficulties that have been encountered in the co-ordination of so many diverse systems, with characteristics so different, and practical problems within a country of old settlements and conservative policies. Although the problem in Canada is different it lends itself more quickly of solution, due to the less density of population and lesser developments at the time of attack, which was twenty years prior to the establishment of the Grid, when transmission and distribution systems had not established themselves to the same extent.

In the United States there is not the same necessity for universal control and units can be established in economic zones within the vast territory to be served. Companies serving areas much larger than those under consideration in England, have made contractual arrangements for interchange of power utilizing both the surplus capacity and energy. Those that are interested will find the Reports of the Super Power Corporation of much interest.

The financial savings are of importance, and form the main considerations in the development of such a work, in addition to the handicaps through lack of economy in manufacture and utilization resulting from the multiplication of equipment and systems with characteristics so different. This same consideration led Ontario to work towards the elimination of duplicate systems, although in view of the very large capital commitments, it was obliged to standardize on two frequencies, twenty-five and sixty cycle.

The lowering of the costs by such economies, by improved load factor, by properly designed rates and through a greater density of customers is of the utmost importance in the extension of the benefits of electrical energy to the community as a whole, including the rural areas.

In Canada, rural use is further encouraged by properly designed Government subsidies.

Would the author state if the voltage is 132,000 between phases and whether radio is used for communication between control centres? Has any interference to telephone communication systems been caused by the operation of transmission lines? In Canada extra precautions are taken to ensure no interference to existing communication systems.

The author is to be congratulated on the comprehensive way in which he has presented the paper covering all features of the Grid development.

The Author[9]

The Central Electricity Board is not a government department and is not subject to political control. Its successful operation depends upon co-operation and understanding between municipalities and companies with the decision of the engineers on the Central Electricity Board. Advisory committees set up in areas are free to make appraisals treating companies and municipalities alike. The Central Electricity Board is not responsible for distribution.

Dr. Boyle's feeling of fear with reference to cable faults can not be appreciated. As an example, a 132,000-volt cable was placed underground for four years without faults aside from small oil trouble. Inspection at the factory was very severe and no real trouble was experienced after the cable was installed. A nitrogen-filled lead-sheathed cable manufactured for the Grid was placed in service for twelve months and when taken out and opened up for inspection was found entirely satisfactory. A cable filled with nitrogen gas is preferable, as carbon dioxide gas is dangerous to men.

The existing efficient stations used in conjunction with the Grid remain in their original ownership but their operation is directed by the Central Electricity Board. Small stations are used to supply peak load only. This should answer Mr. Buchanan.

With reference to Professor C. V. Christie's question regarding the use of lightning arresters, none of these were installed at first but an expenditure of £7,000 per year has been made for the past three years to discover everything possible regarding surge phenomena and this investigation will continue during the next three years. So far, results have proved that a great many lightning arresters which are sold as such do no good at all. The British Grid System has no comprehensive lightning arrester scheme.

The Grid has been designed on the ring system and two feeders are always available. Whenever faults occur they can be cleared as soon as possible. A few interruptions have occurred but they were not serious.

Mr. P. T. Davies' question may best be answered by citing the steam plant at Battersea which is the most efficient, at 12,250 B.t.u.'s per unit sent out, an efficiency of 28 per cent.

In reply to Dr. Gaby, 132,000 volts between phases is correct. The capital required for frequency changes is repaid by levies on the whole supply industry proportionate to the revenue received from the sale of electricity. The Central Electricity Board is financially self-supporting but is not allowed to make any profit. Capital for the conversion of non-standard systems, by their owners, to the 50-cycle frequency basis, adopted as the British standard, is advanced by the board, who are recouped for the interest and sinking fund charges on the money by the levy on industries as already mentioned.

# Pre-Cast Concrete Units in Engineering Construction

*R. E. Chadwick, M.E.I.C.*

## DISCUSSION[1]

J. F. Brett, A.M.E.I.C.[2]

The author's paper is very stimulating and all those engaged upon the design of engineering structures cannot fail to benefit by a careful study of it.

Pre-cast construction is especially suitable for Canadian conditions by reducing the hazards of pouring in cold weather or in water. A detailed description has been given of many structures such as wharfs, bridge piers and bridges, tunnels, pipes, etc., where the method has been used and his organization has laid some twenty-five miles of pre-cast concrete high pressure water mains from 36 to 72 in. in diameter in the streets of Montreal with complete satisfaction.

Attention of those interested in pre-cast work should be called to a new method of pre-casting realized recently, by the French engineer E. Freyssinet. This method consists of submitting the concrete, as soon as the moulds are closed, to a combination of pressure, heat and vibration. The result is a material which is very different from the usual conception of concrete. Its compressive strength can readily attain 8,000 lb. when taken out of the mould or 14,000 lb. at the age of twelve hours. When the concrete is used as reinforced concrete with pre-stressed steel reinforcing, it is possible to utilize fully the properties of this material.

The method has so far been applied to bridge girders, deep piling, caisson foundations in water, pipes, poles, building frames, floors, etc. It is claimed that it can be applied both to objects moulded in one operation and to works carried out *in situ*. The most important example of the latter is the underpinning of the marine station at Havre.

This new utilization of concrete, which has been called treated concrete, will tend to increase the use of pre-cast members very materially.

E. H. James, M.E.I.C.[3]

The writer agrees with the author as to the superior durability of pre-cast concrete over cast-in-place concrete when subject to the action of salt water and of alternate freezing and thawing. Pier No. 2 at Halifax, built about twenty years ago, was supported on pre-cast concrete piles. When examining this structure a diver looked at the piles, which were found to be in perfect condition below low-water level, although there was a certain amount of deterioration of the concrete between low and high-water levels. Of particular interest was the fact that a number of the piles had been cast too short and had been extended by concrete cast-in-place. In every case the cast-in-place concrete was in worse condition than the pre-cast work.

In the Ballantyne Pier at Vancouver all the concrete exposed to tidal action was pre-cast, with the exception of the small spaces between the pre-cast trusses and the slots in the tops of the caissons into which they fit, and according to Major W. G. Swan[4] this is the only place where any deterioration has taken place in the substructure. The central fill was retained by pre-cast concrete sheet-piles. The only cast-in-place part of the pier was the deck slab.

The author seems to regard concrete cribs with suspicion on account of the small thickness of their walls, which was necessary for flotation. In the two sea-water crib piers at Halifax the only exposed part of the crib wall was entirely below low-water and, therefore, not likely to cause trouble. In both structures there was a waling at low-water level, and a concrete apron-slab, comparatively easy to replace, protected the crib wall in the vulnerable part between low and high-water levels.

A similar method of construction to that mentioned by the author as having been used at Newark Bay was used for the original Second Narrows bridge at Vancouver. There, instead of a pre-cast base resting on piles, however, there was a pre-cast working-chamber built on launchways. After this was sunk, the pier was built inside a cofferdam, which cofferdam was not salved but was left in place.

There seems to be a considerable future for pre-cast concrete in marine work, particularly in cases where it is possible for some time to elapse between the time of casting and the date of placing. This method would be valuable when the pouring could be carried out in the summertime and the placing of the pre-cast units done in the ensuing winter months.

J. P. Leclaire, M.E.I.C.[5]

The author claims to be amazed at the reluctance on the part of many Canadian engineers to adopt the pre-cast method of construction used extensively in Europe for many years. Certain climatical, economical and political conditions, so to speak, prevailing in the eastern part of Canada, and particularly at Montreal, are possibly the cause of such reluctance. The following instance will illustrate this condition:—

When, as chief engineer of the Harbour Commissioners of Montreal, instructions were received to recondition the King Edward Pier, very much dilapidated by age, in order to permit the deepening of its berths to 37 ft. 6 in. below the low water datum (that was, to practically 7 ft. 6 in. below the base of its crib work), it was concluded that the best scheme would be the provision of a series of vertical beams or girders, topped with a reinforced concrete girder, acting as a cope wall in which the mooring bollards were to be incorporated. This cope wall would also act as a distributor of all loads between a group of vertical members, anchored in the rock at their base by means of steel dowels and, near their top, by means of tie rods fastened to reinforced concrete anchor blocks of suitable sizes. It must be remembered that the reconditioning undertaking was to be put in hand at the end of the month of November and completed not later than the 15th of the following April (that is, to be carried out during the winter months while the rising river surface is covered with a sheet of ice over 3 ft. thick) without disturbing the existing sheds and conveyor galleries.

At first, these vertical members were designed as pre-cast structures in the form of a hollow square column, two side walls to act as web members, one as a tension flange, the other as a compression one. These structures over 50 ft. in length, eventually to be filled with a lean concrete, were to be cast horizontally on the lower decks of the sheds and raised to a vertical position for the purpose

[5] Chief Engineer, National Harbours Board, Port of Montreal.

of their placing in their individual locations. Their bulk and weight, however, called for handling by special floating equipment, to be manoeuvred in ice, of size and power which was not immediately available to all tendering parties and whose time of construction would have prohibited the reconditioning of the pier in the time specified. A cast-in-place method was therefore selected for this particular reason.

At the Windmill Point Wharf, where conditions were different from that of the King Edward Pier, a compressed air caisson method was resorted to, also at the Alexandra Pier.

The circumstances described are generally prevalent at Montreal.

The author has mentioned the danger of the reinforcing steel in the pre-cast concrete cribs rusting due to its proximity to the exposed face of the cribs, and it might be pointed out that in Montreal, for that particular reason, the steel bars are so located as not to be closer than 6 in. from the exposed faces, and the concrete is vibrated in order to attain the greatest possible density.

He mentions also the pre-cast concrete blocks used on the Great Lakes over wooden cribs for the narrow band between the high and low water marks. In Montreal, at the time when wooden cribs topped with a mass concrete retaining or quay wall were the standard practice of wharf construction, the cribs were sunk to about 2 ft. below the then lowest recorded water level. On top of the filled cribs, pre-cast reinforced concrete boxes 15 ft. wide, 20 ft. long and 4 ft. high were provided. Concrete was then poured inside these topless and bottomless boxes, and the balance of the wall poured thereon. In order to take advantage of the protection afforded against the deleterious effect of the water on concrete poured in place even with a wooden form, the concrete work was started only when the water was at a convenient level. The fully set concrete of these reinforced concrete forms has proved to resist the action of the water very satisfactorily, while concrete poured behind submerged forms, particularly at the summer levels of the water, was, in many instances, disappointing.

R. F. Legget, A.M.E.I.C.[6]

The author of this interesting paper has presented many statements of a somewhat sweeping nature regarding the use of pre-cast concrete units. This was probably done intentionally, in order to provoke discussion, as his experience is warrant enough for the validity of these statements when applied to unusually large construction work. As the scope of the paper has been widened beyond a consideration of large pre-cast units, it may perhaps be suggested that some of the statements require qualification in respect to the size of job, and of unit, under consideration, and also with respect to local details. For example, it is suggested that "the cost of transporting a given tonnage in the form of completed units from a well located casting yard to the work, is likely to be less than the transportation of the same tonnage of separate ingredients from the point of delivery . . ." This may be true under the "appropriate conditions" mentioned in the paper, but is not the existence of such conditions, considering construction as a whole, more likely to be the exception rather than the rule?

That there are many cases where conditions are appropriate for pre-cast unity will surely be admitted by the most ardent advocate of cast-in-place work. One general type of concrete work not specifically considered in the paper is the building of small isolated structures, such as retaining walls, by means of interlocking pre-cast units of reinforced concrete. European practice in this direction has advanced far in recent years, notably for the miscellaneous structures found along railway lines, where freight handling, from a central casting yard of the railway company, is relatively easy. It would be enlightening to have the author's views on the possible development of this class of work in Canada, obviating as it does transport of plant for small jobs, dubious local workmanship, unskilled inspection, etc.

Although the paper deals essentially with pre-cast concrete units, the author's advocacy of "caisson foundations" raises some intreesting questions in another field of civil engineering. If one such question may be cited, relative to the statements in the first paragraph on page 699, surely the success, or otherwise, of a foundation, and all questions of settlement depend essentially upon a correct appraisal of the nature of the foundation bed material and on its fundamental properties, and the application of this information to design rather than on the adoption of a caisson foundation in preference to any other convenient construction method.

D. W. McLachlan, M.E.I.C.[7]

The author and Mr. James appear to be approaching the problem of justifying the pre-casting of concrete from a wrong direction. The pre-casting of concrete alone is not an insurance against disintegration.

At Sault Ste. Marie there is a 900 ft. lock with 20 ft. lift which is built out of cut stone. When it was built no precautions were taken to prevent the water from the upper level travelling along the back of the south wall and as a consequence 20 ft. of this 900 ft. wall was wet or damp at all times. In winter it is customary to leave the lower gates of the lock open and thus cold air comes in contact with the wet stone surface. In the thirty-five years since the lock was built about ten inches of material has been spalled off a face 900 by 20 ft.

The above is a case where limestone or dolomite of good quality has disintegrated. Many cases in which pre-cast concrete cribs, blocks and piles have disintegrated can be given.

The tops of concrete piles at Halifax, the pre-cast cribs at Carleton Point or Port Borden, P.E.I., and block work around Toronto Harbour are instances. In the above instances pre-casting did not prevent disintegration.

Chemists state that there cannot be any difference between pre-cast and cast-in-place concrete so long as the outside water is kept out of the concrete. Twenty-five years ago when the writer was examining plans for approval at Halifax, the idea of using a protective coating of creosoted lumber around concrete at the water line was considered to be effective and experience has proved nothing else can be done except keep the water content low. According to chemists, 20 per cent of the water used in mixing concrete is required for hydration; the other 80 per cent remains as globules in the mass or in spaces which later refill with water.

The globules when they freeze exert strong explosive forces and cause the disintegration with which all are familiar. Concrete and stone even of good quality will both disintegrate on the exposed sides of spillways of dams if the water content is not kept low. How low the content should be is not known. From experience on the Trent canal lean concrete placed relatively dry has stood the test of time while concrete with at least as great a proportion of cement placed wet has failed to stand against the elements. If the author and Mr. James could show that pre-casting reduced the water content in mixing and placing then they would be making a case for such methods, otherwise, they are not doing so.

[7] Engineer, Design and Capital Construction, Department of Transport, Ottawa.

P. B. Motley, M.E.I.C.[8]

A few years ago a railway bridge built in 1912 came to the notice of the writer. This consisted of two plate-girder spans, 120 ft. and 60 ft. long respectively, both resting on a common river-pier. Subsequently a power-development had been installed above the bridge, and the tail-race discharged at some 25 m.p.h. through the opening of the longer span. Not long ago that pier had fallen under suspicion, as it was noticed to have changed in colour to a dirty brown. No certain evidence of disintegration, however, was discovered by a close examination of the surface of the concrete by hammering and picking. Eventually a hole was drilled from the bridge-seat down to the bottom pier, and the core was found to consist to a large extent of material that had a consistency no better than mud. The interesting experiment was tried of introducing air (under 30 lb. pressure) into the hole, when it was found that the water all around the pier bubbled and frothed, leaving no doubt as to the porosity and disintegration of the concrete.

The weathering of concrete structures in the range between low and high-water constitutes a well-known and very serious problem. There was a device adopted in 1871 by the late Mr. H. J. Cambie, an honoured member of this Institute, who covered many piers and caissons—built of the concrete of those days—with 3 in. vertical staves of yellow pine throughout the tidal range. Concrete protected in this simple manner had lasted to the writer's knowledge at least 40 years when in 1912 they were superseded by a new bridge or a bridge in a new location and he continued the use of wood staves. That was twenty-five years ago, and there is no sign to date of deterioration under the staves.

The author is to be congratulated on his exhaustive account of many notable examples of pre-cast concrete work not only in Canada, but in other portions of the world. In his characteristic way, he has clearly, and accurately, recorded many examples of such work, which will be useful to other engineers who may have similar problems.

As a contribution to this discussion it might be suggested that dates be attached to all the examples cited, so as to record the progress of this kind of work. Further, no reference has been made to a very important example of pre-cast work in the field of engineering, and that is, the reinforced concrete pile. The year and place in which the first concrete pile was used is not known, but it was probably in England or France, perhaps under the direction of that famous French engineer, Hennebique.

Most of the structures to which reference has been made are subaqueous, but attention should be drawn to the reinforced concrete pre-cast girders which were used on the Canadian Pacific Railway in Toronto and Montreal between the years 1917 and 1919. These were of T section, 5 ft. deep and 37 ft. long, the top flanges being 6 ft. 6 in. wide, which, when paired with another similar reinforced girder, provided a structure suitable for a single track railway and ballast.

The Toronto structures consisted of two reinforced concrete trestles, the larger of which was 100 ft. high and 400 ft. long, and carried three tracks, while in Montreal the structure in question was the overhead bridge at Atwater Avenue; in each case the pre-cast T beams were 37 ft. long and weighed 58½ tons apiece.

The method of erection of the reinforced concrete girders was the same in all cases. After the substructure, whether it were abutments, piers or towers, had been built at the correct centres the reinforced concrete girders were lowered in by a bridge erection derrick car in the usual manner, working ahead, panel by panel, to completion.

These structures considering their magnitude, span lengths and date, were, as far as known, epoch making.

Their cost was only slightly higher than what steel structures would have cost at that time, steel being at war-time prices, otherwise they might not have been built. They did, however, provide permanent structures with ballasted floors, and have not cost a penny in maintenance, during the 20 years of their existence—which is saying a great deal.

Other members, who have personal knowledge of such structures, would be doing good service if they contributed such details as would complete the reliable record which the author has given in his most interesting paper.

[8] Engineer of Bridges (Retired), Canadian Pacific Railway, Montreal.

The Author[9]

Mr. Brett's brief description of the Freyssinet system of pre-casting, in which a combination of pressure, heat and vibration is used, is exceedingly interesting. Apparently there has been a good deal of research and experimental work along these lines all with the view in general of improving the density and strength of concrete, and with considerable success. All are familiar with the very superior quality of concrete contained in spun concrete pipe where centrifugal force is utilized to remove the excess mixing water and to subject the concrete to pressure while it is setting. It is obvious also that in any centrifugal process there must be certain amount of vibration, on the ground that it would hardly be possible to devise a spinning device that would be perfectly balanced, and perfection in balance would not be a desirable feature even if it could be obtained.

The writer is of the opinion that one will see in the future a great many more pre-cast concrete articles than are available today, and undoubtedly advantage will be taken of the superior facilities afforded in what might be termed factory production to obtain a much stronger concrete than that which we are now producing in the field.

Based on experience as a contractor the writer cannot help feeling that the cost of the various methods of improving the quality of concrete as, for example, by vibrating, is perhaps greater than one thinks it is, and cannot help feeling that there are many cases where the same expenditure in the form of additional cement would produce better results. This is with reference to the average structure in which vibrating is specified. One is inclined to charge to the cost of vibrating certain direct charges comprising the specific items, but is inclined to lose sight of a great many indirect charges and additional overhead expenses that should really be included. In factory production this would not apply to anything like the same extent, as all of the capital cost and installation charges would be applied over the entire useful life of the equipment employed.

Mr. James has brought out some very interesting points of which he is particularly well qualified to speak, such as the reference to the piles in Pier No. 2 in Halifax, and the pre-cast concrete cribs, also in Halifax.

It will be recalled that in Pier No. 2 in Halifax very large pre-cast piles were used, and that these were protected between high and low water with a covering of creosoted timber. As Mr. James mentions, a number of these pre-cast piles which were found to be too short were extended with cast-in-place concrete. It is understood that quite recently Mr. James reported on this pier and, as he mentions in his discussion, he found that in every case the cast-in-place concrete was in a worse condition than the pre-cast work. It is quite interesting to note that below the low water

[9] President, Foundation Company of Canada Limited, Montreal.

mark the piles were found to be in excellent condition after many years of service, and that the surface deterioration was confined to the concrete within the tidal range. This, it is believed, is the usual state of affairs, both in the case of pre-cast and cast-in-place work.

In connection with the cribs in Halifax, he mentions that the only exposed part of the crib was entirely below the low water mark. In this case the argument for thicker walls in these cribs brought out in the writer's paper might very well be modified, as undoubtedly the place where increased thickness and body might be considered advisable, is that band between high and low water level that is exposed to the elements.

Mr. Leclaire mentions the reconstruction of the King Edward Pier as a case where pre-cast concrete had been originally proposed but cast-in-place concrete had to be substituted. Presumably the substitution was made because, owing to the lateness of the season and the fact that the work had to be carried on throughout the winter, it was felt that floating equipment for handling these large pre-cast units might not be available and possibly could not be manoeuvred in the ice. Actually the work was done with floating equipment and was completed within the scheduled time, that is, the opening of navigation in the following spring, but the equipment used might possibly not have had sufficient capacity to handle the pre-cast vertical girders which were apparently originally contemplated and which he referred to as being the better scheme.

The reconstruction of the King Edward Pier was carried out in two sections under two separate contracts, and it so happens that the company with which the writer was associated did both jobs. Tenders for the first contract, consisting of the south side, were called for in the fall of 1928 and the work was completed by the opening of navigation in the following spring. Tenders for the second contract were called in the fall of 1930 and the work was again completed ready for the opening of navigation in the following spring. The scheme consisted of a continuous line of 7 ft. diameter steel caissons sunk to rock in front of the old crib wall, doweled into the rock at their lower ends, filled with concrete placed under water and surmounted with a cast-in-place concrete copewall tied back with heavy anchor rods. The arrangement has proved quite satisfactory but it is agreed that a system of using pre-cast vertical girders might have been better still.

Mr. Leclaire mentions Windmill Point in Montreal which was also a crib wharf that was faced up with more permanent construction. Here the conditions were quite different owing to the fact that it was necessary to carry the new work some considerable distance into the rock to permit of the dredged depth being increased. Obviously it would have been impracticable to have carried open caissons to the required depth and the pneumatic process was used, the new work consisting of a series of rectangular caissons sunk end to end to form a continuous wall. The caissons themselves were of steel, filled with concrete in the usual way. In this particular case a substantial saving in cost could have been effected by using steel for the working chambers only and framing the cofferdam, that is, the portion of the caisson above the working chamber, in timber sheeting with structural steel interior bracing. With this last type of caisson a small saving in cost might be effected by making the timber sheeting removable, but in the writer's opinion any such saving would be quite insignificant compared with the value of the sheeting as a protection against surface deterioration. In this connection it is interesting to note that in New York, where a continuous line of caissons is commonly used in deep foundation work, the practice in regard to the removal of the forms appears to vary, some contractors preferring to remove them, others preferring to leave them in place. This is a clear indication that there is no appreciable saving in cost through the removal of the forms, as caisson work in New York is a highly competitive business in which the contractors bidding are very proficient in their trade. Experience, both as an engineer and as a contractor, leads the writer to believe that the forms should invariably be left in place and form part of the permanent work and be so specified unless there is some particular reason for removing them.

Mr. Leclaire mentions the timber crib wharves in Montreal which are topped with a concrete retaining wall with the timber crib work generally terminating slightly below water level at the time the cribs were built. In certain of these wharves the bottom section of the concrete wall was, as he states, built in the form of large pre-cast reinforced concrete boxes, or hollow blocks, filled inside with cast-in-place concrete, the latter being continued up to the cope level to form the retaining wall proper. Some years ago the writer had occasion to examine these wharves in connection with some proposed repairs and was greatly impressed with the superiority of the pre-cast work in comparison with other similar work in which the concrete at the water level had been cast in place.

There is one remark in Mr. Leclaire's discussion that brings up a rather interesting point in connection with the calling of tenders for public works. He mentions in connection with the King Edward Pier, as one of the reasons for using a system that involved placing the concrete under water, the fact that the bulk and weight of the pre-cast units called for special equipment of a size and power not immediately available to all tendering parties. While this point of view might be dictated by political considerations it is, in the writer's opinion, hardly sound from the economic standpoint. Surely it is not good business or good engineering to forego the use of equipment that might permit of a better type of construction or might result in a lower cost, simply because all contractors who might desire to bid do not happen to have that particular type of plant. This policy carried to its logical conclusion would relegate us to the most primitive conditions and would presumably eliminate the use of any machinery at all. In other words, one would forgo the use of a steam shovel and would mix concrete by hand, on the ground that someone who did not happen to own a shovel or a concrete mixer might desire to submit a tender. Actually the plant that is available to one contractor is usually available to all as, generally speaking, contractors are quite ready to rent equipment to each other or, as an alternative, take a subcontract for any part of a work for which their equipment is particularly well suited. There has been a typical example of this in Montreal during the last two years in the building of concrete cribs in Montreal harbour. The arrangement was presumably advantageous from a financial standpoint to everyone concerned, including the Government.

In reply to Mr. Legget it was the intention to limit the paper to pre-cast units of fairly large size and it is admitted that it is rather difficult to draw a line between what might be considered as comparatively small. In short, the writer would not want to get into a realm of ordinary concrete blocks, pre-cast sills and lintels and pre-cast pipe and similar units of a size that can be ordinarily handled without the aid of machinery.

Remarks in regard to the comparative cost of transporting a given tonnage in the form of completed units and the cost of transporting the same tonnage of separate ingredients refers obviously to a fairly large operation of a type appropriate to the pre-casting method. There are a great many types of work in which the pre-casting system could not be used to advantage, and the statement regarding transportation could not of course apply to these. During the time this paper was being prepared the writers' company was engaged in pouring a concrete deck for a wharf founded in part on caissons and in part on piles. This deck was over the water in a place where one had to contend with a great tidal range. The forms on this particular job were exceedingly costly and the placing of the concrete was also quite costly. This deck could have been pre-cast in a manner that would have given a much better final result at a very substantial saving in cost. The principal saving would have been in the forms and it certainly would have been more convenient to have transported finished units than it would have been to have transported the concrete from a central mixing plant which was located at a site that was convenient to the supply of aggregate rather than convenient to the site of the actual placing.

Mr. Legget's remarks in regard to the smaller pre-cast units and particularly to practice abroad are noted and the writer is inclined to believe that in Europe they are well in advance of us in the use of pre-cast work. There should be a great future for this sort of work in Canada and that in the future one will see a great deal of concrete work cast in central yards located probably close to a satisfactory source of raw material. This would simply be following the change that has already occurred with many other building materials as, for example, cut stone, mill work, etc., which were once completely fabricated at the site of the work but which are now almost invariably completely formed or fabricated in centralized plants often located quite far from the actual work.

As mentioned in the paper, a caisson has been considered as a type of pre-cast work and, as such, a subject that might be properly included in the paper. The writer has been engaged in the caisson business for about twenty-five years and cannot recall from his own practice any instance of a caisson foundation having given any trouble after having been completed. There have been instances of caissons having upset and of caissons which for some reason or other have proved troublesome in sinking, but there are many more instances of cofferdams having given trouble and having completely failed to perform their function of insuring the work being carried out in the dry rather than, for example, of placing concrete under water. It is agreed that there are conditions under which the caisson could not have been used to advantage but in Canada the caisson has not been used to anything like the extent it has been used elsewhere, presupposing of course in both instances that the conditions are appropriate.

Mr. McLachlan appears to take the stand that all masonry, whether it be concrete, stone or a natural rock face, is subject to surface deterioration when exposed to conditions under which it is alternately wet and dry. The writer is in complete agreement on this point but one must recognize that the durability of concrete and of natural stone varies between wide limits. Granite has an exceedingly long life under the conditions referred to. A good grade of limestone also has a very long life, far exceeding that of the mortar in the joints. Certain classes of sandstone have an exceedingly short life. The natural rock at Sault Ste. Marie, which contains numerous horizontal seams, would, as Mr. McLachlan states, erode considerably over a period of years. As regards the relative life of concrete, experience convinces one that the best concrete that can be made today might be expected to have a useful life about equal to that of the poorest grade of stone that would be used as masonry.

Mr. McLachlan states that there is no difference between pre-cast and cast-in-place concrete as long as water is prevented from entering the concrete. This is agreed but it should be pointed out that the structures which have been considered are principally those that are exposed to water and in which it is difficult and perhaps impossible to prevent water from entering the concrete.

All know that in mixing concrete one gets a better result if the water content is kept as low as possible consistent with a workable mix. This, it is believed, is more readily accomplished than in pre-cast work than in cast-in-place work.

Mr. Motley mentions a rather interesting point in connection with concrete deterioration, this being the case of a bridge pier in a tailrace of a power plant which is exposed to a very swift current and in which it was noticed that the concrete had changed in colour to a dirty brown. A closer examination, apparently including the use of hammering and picking, disclosed no certain evidence of disintegration. The change in colour described is in itself conclusive evidence of disintegration in the centre of the pier and, it is understood that this characteristic brown stain is the residue from the passing into solution of certain of the more soluble constituents of the Portland cement, and is a sure sign of disintegration, not so much on the surface as within the body of the structure. This is found in dams and other structures exposed to water under pressure from one side, and it is not surprising to find it in a concrete bridge pier exposed to a very high velocity. It is expected that this concrete would be found to be quite porous.

Mr. Motley mentions the value of pine sheathing as a protection to concrete within the tidal range. He cites the case of certain bridge piers protected in this manner having lasted from 1871 until 1912. The writer happens to be familiar with the piers in question and has always considered them as a most remarkable example of the value of this form of protection. Mr. Motley will agree that when some of these piers were replaced in 1912 and 1913 the reason for their replacement was not that the concrete had lived its natural life but rather that the railway wanted to increase the permissible loading of the bridges.

Mr. Motley mentions a number of bridges on the C.P.R. in which pre-cast girders were used with great success. That at Atwater Avenue in Montreal was, it is believed, at the time it was built the longest span in which this type of construction had been used. The two reinforced concrete trestles with pre-cast decks located just outside Toronto are excellent examples of concrete construction and it is interesting to note that although they are now over twenty years old they have not cost a penny in maintenance.

# Growth and Spread of Arc Welding in Canada

*A. S. Wall, M.E.I.C.*

## DISCUSSION[1]

DAVID BOYD, A.M.E.I.C.[2]

This paper has been interesting and informative and the following are points of particular importance: namely, the details of the various types of joints, the training of operators and the shortage of skilled welding operators at the present time.

Recognized standards are urgently required. Inspectors are frequently appointed by customers and they come with all varieties of specifications. Standards are required to remedy this condition. Finally industries should cooperate and organize a welding school.

GORDON CAPE[3]

The author has dealt with shop technique. Design begins in the office and the co-operation of both office and shop is essential to produce the best product.

The following are a few points which should receive particular attention in the shop:

Make a number of small sub-assemblies and assemble these units. This makes it easier to allow for distortion. Prepare joint edges as accurately as possible; machining is preferable. Avoid clamping members together as clamping is likely to result in cracks. Start at the centre and weld outwards as this makes it easier to control distortion. Make butt welds first. Limit the size of weld, as far as possible, consistent with the strength required. Preheating reduces stresses in the finished assembly.

A. M. MACCUTCHEON[4]

Welding is used in our shops for such work as motor parts.

When welding was first used, about 1920-22, one of our engineers took a small welding set home and proceeded to play with it. It is a most usual occurrence to have the shop report back to the design engineer that a particular design is impracticable and it is impossible to weld it. In our company there is a ready answer. The engineer previously referred to goes down to the shop and completes the welds in question.

W. T. B. MCCORMACK[5]

Welding is used considerably for bridge construction in Australia. A 750 ft. welded bridge over the Snowy river was wrecked by flood waters and many weaknesses were discovered which it was possible to correct in later structures.

In Australia an engineer is always placed in charge of work on welded structures. He is trained in the shop beforehand and is thoroughly familiar with all phases of the work.

MAJ.-GEN. A. G. L. MCNAUGHTON, M.E.I.C.[6]

A 600,000 volt X-ray apparatus is being installed by the National Research Council and it is hoped that use will be made of it for inspecting welded structures.

F. P. SHEARWOOD, M.E.I.C.[7]

This paper has touched on a most important subject, particularly in structural work.

Welding has been a constant education and has shown among other things that structural steel may be distorted very considerably and still stand up. It has shown that the engineer cannot stop at design but must follow the work through welding and assembly. The writer would like to move a hearty vote of thanks to the author for a paper on a subject of such importance.

H. GERRISH SMITH[8]

Welding is extensively used in ship building. Barges are now usually welded and welding is very common for ship forms up to 300 ft.

The largest task to date has been a 15,000 ton oil tanker which is to be entirely welded except for a short distance at each end. The ends are not welded as a convenience in construction.

Practically all yards are welding most of the interior and the outside ends. Each yard conducts its welding school. A considerable amount of mechanical welding is being done. This is more difficult than structural welding on account of the complexity of the assemblies.

## The Joint Meeting with the American Society of Civil Engineers

### Boston, 1937

Three years ago the Annual Convention of the American Society of Civil Engineers took place in Vancouver jointly with the Western Professional Meeting of The Institute. This most enjoyable joint meeting gave our western members an opportunity of greeting one of the Founder Societies of the United States, and led to the formation of many new friendships and the renewal of many old ones.

On October 6th to 8th this year, on a cordial invitation received from the Board of Direction of the American Society of Civil Engineers, an equally successful joint meeting has been held in Boston, Massachusetts, on the occasion of the Society's Fall Meeting. The scenes of the two events are some three thousand miles apart, but this year's assembly, held in the dignified surroundings of the eastern city, was characterized by the same mutual cordiality and goodwill which were so evident in 1934 in the capital of British Columbia. From the beginning, The Institute and its members have received from American engineering societies many evidences of kind consideration, and the American Society of Civil Engineers has been one of the most generous in this respect.

Friendly relations between Canadian and New England engineers are of long standing. Our older members will recall that nearly forty years ago members of the Canadian Society of Civil Engineers journeyed to Boston as the guests of the Boston Society of Civil Engineers, visiting many points of engineering interest and holding joint technical sessions. Boston and its surroundings form an admirable setting for an engineering society's meeting. The historic background of New England, the commerce and industry of Boston and the surrounding district, the educational and cultural features of the cities which face each other across the Charles river, all build up the interest of the gathering. When the traditional hospitality of our American friends is added, the resulting mixture is a very agreeable one.

In accordance with the custom of the Society, its Board of Direction and certain of its committees met on the two days preceding the joint meeting. The officers of The Engineering Institute and their ladies were invited to attend the social functions on these days, which included an excursion to Plymouth for the ladies, and a New England dinner given by the Northeastern Section of the American Society of Civil Engineers in Faneuil Hall, that venerable building which has for so many years been the headquarters of the Ancient and Honourable Artillery Company of Boston.

Local arrangements were in the hands of an executive committee with F. A. Barbour, M.E.I.C., M.Am.Soc.C.E., as general chairman. This body consulted with a co-operating committee appointed by the Council of The Engineering Institute of Canada and consisting of Past-Presidents Fairbairn, Shearwood and Cleveland. The results of the meeting indicate that the Boston executive committee, and the ladies committee—of which Mrs. F. E. Winsor was chairman—are certainly to be congratulated on the manner in which all the events were carried out, and particularly on the smooth working of their arrangements for registration, information and transportation.

After registration at the Statler Hotel on the morning of Wednesday, October 6th, the joint meeting was called to order by Mr. Barbour. He was followed by Professor Albert Haertlein, the President of the Northeastern Section of the Am.Soc.C.E., who expressed the section's welcome to the assembled delegates. The good wishes of the Commonwealth of Massachusetts and of the City of Boston were voiced by the Governor of the Commonwealth and the Mayor of the City respectively.

In the unavoidable absence of President Louis C. Hill, these welcomes were gracefully acknowledged on behalf of the Society by E. P. Lupfer, vice-president, American Society of Civil Engineers, and by President George J. Desbarats on behalf of The Engineering Institute of Canada.

The meeting greatly appreciated the addresses by two outstanding educational authorities, which formed the next item of business. The President of Harvard University, Dr. J. B. Conant, spoke briefly on the policies of the University and the opportunities for engineering and scientific education which are available at the two great institutions in Cambridge. Dr. K. T. Compton, the President of the Massachusetts Institute of Technology, in his address, urged the more extensive application of engineering knowledge to problems of business and public affairs, and pointed out that clear explanations of the economic conditions under which public engineering projects are undertaken are due to the public, but are not always given. He referred to Benjamin Franklin's famous design for a sundial capable of making the time known by firing guns, and quoted the philosopher's conclusion "that many a private and many a public project is like this striking dial—great cost for little profit."

The concluding feature of the morning session was a lecture on The Cultural and Technical Background of the New Architecture by the professor of architecture at Harvard University. Dr. Gropius, who has been a leading figure in the development of new architectural forms in Europe, believes that the present movement towards new methods of expression in architecture affords a favourable opportunity for the rise of a new and distinctively American style.

One of the most interesting characteristics of the meeting was the prominent part assigned to student activities.

The first of these took the form of a luncheon on October 6th, at which some three hundred were present, and which was addressed by Colonel Willard Chevalier, a past director of the Society and one of the principal officers of the McGraw Hill Publishing Company.

The afternoon of Wednesday was devoted to a joint general session conducted by The Engineering Institute of Canada, the chairman being Fred Newell, M.E.I.C. At this session three Canadian papers were presented, dealing respectively with bridge construction, harbour development, and hydro-electric practice. A large audience, including many of our American friends, was greatly interested in this presentation, and the papers gave rise to active discussion which was only limited by the time available.

**Prominent Figures of the Opening Session**

Left to right (Standing)—Mayor Frederick W. Mansfield of Boston; James Bryant Conant, President of Harvard University; Edward P. Lupfer, Vice-President, American Society of Civil Engineers; George T. Seabury, National Secretary of the American Society of Civil Engineers. (Seated)—George J. Desbarats, President, Engineering Institute of Canada; Karl T. Compton, President, Massachusetts Institute of Technology; Walter Gropius, Professor of Architecture, Harvard University.

An important feature of Major Swan's paper was his description of the difficulties encountered at New Westminster through the damage, caused by violent freshets in the Fraser river, to two of the piers of the new highway bridge under construction there; the discussion on his paper centred around the methods adopted for dealing with this situation, which proved entirely successful.

The paper by Mr. James sketched the successive stages in the development of the wharf facilities in Halifax harbour. The discussion indicated that a feature of major interest to members present was the information given concerning pre-cast cribs of the permanent concrete type and the data as to recent improved methods of launching them.

Dr. Acres, the author of the third paper, on the Outardes Hydro-electric Project, was unavoidably absent, but was ably represented by A. W. F. McQueen, A.M.E.I.C., whose remarks on the hydraulic and structural features of the scheme were well supplemented by an account of the electrical features of the power installation given by F. M. Hamilton, M.A.I.E.E.

At the entertainment for members and ladies on Wednesday evening, the proceedings commenced with an excellent variety show, followed by buffet refreshments, and terminated with an informal dance, at which the many students present seemed to take the leading part.

Returning to more serious pursuits on Thursday morning, a multitude of important subjects were dealt with at the sittings of the six Technical Divisions of the American Society of Civil Engineers. So many were they, in fact, that a number of members found difficulty in deciding which sessions to attend. The work of the Soil Mechanics and Foundations Division attracted many, dealing as it did with problems in a field of very recent development. Our members from the Maritime provinces were anxious to hear about the latest researches in the study of marine borers. A strong contingent heard the papers and discussions of the Engineering Economics and Finance Division. These were concerned with a subject of primary importance at the present time, namely, the necessity for the better economic planning of public works. The discussion stressed the necessity in the United States for the careful analysis of every proposal to spend money raised by taxation, and for the rejection of every one not economically sound. Incidentally, it may be remarked that this point was not without interest to Canadian members.

At the dinner on Friday evening the chair was occupied by Professor E. T. Moreland, of the Massachusetts Institute of Technology, and the after-dinner speaker was Professor R. E. Rogers of the same institution. His remarks, while apparently somewhat rambling, were greatly appreciated. He touched on many topics of the day, including the retirement of Professor Leacock and the non-retirement of Mr. Aberhart. Passing on to the subject of the engineer and his work, he took as an example the professional activities of James Brindley, as commented upon by Thomas Carlyle, expressing appreciation of the methods of a man who, when planning a great aqueduct or a tunnel for one of his canals, did not require a large staff of assistants armed with slide rules, but retired to his bed and produced his plans by meditation therein. After Professor Rogers' departure, the room was cleared and an excellent orchestra provided music for the dancers.

The closing day of the meeting, Friday, October 8th, was devoted to excursions, which included visits to the engineering laboratories at Harvard, where a demonstration of testing methods was given in the Soil Mechanics Laboratory, and to the Massachusetts Institute of Technology, where the tidal model of the Cape Cod Canal was inspected, and where Professor Edgerton gave a remarkable exhibition of high speed motion pictures. Other parties made longer journeys to Lowell, the Cape Cod Canal and the Quabbin Reservoir. The final event of the day was a "shore dinner" at Swampscott, which gave just the right finish to a most enjoyable and interesting meeting.

*Courtesy of Civil Engineering.*

**Tidal Model of Cape Cod Canal.**

A word must be added as to the arrangements made for the ladies attending the meeting. They included a special visit to the Art Collections at the unrivalled Gardner Museum, at which the Director gave a talk, and a motor drive to Lexington and Concord, with luncheon at the Wayside Inn at South Sudbury. The Canadian ladies particularly appreciated the many kindnesses and the whole-hearted hospitality which they received from the Boston ladies committee.

All The Institute members who took part in the events of the Boston meeting will look back upon it with pleasure, and will look forward to other similar international gatherings as opportunities for further developing the cordial relations between Canadian and American engineers.

## Visit of M. Jacques Rabut, Hon.M.E.I.C.

It will be remembered that an honorary membership in The Institute was awarded at the Semicentennial celebrations to M. Jacques Rabut, an eminent French consulting engineer, who has an international reputation as an authority on reinforced concrete structures. Although unable to be present in June to receive this award in person, M. Rabut has recently paid a visit to the United States and Canada, during which he has delivered a series of lectures at the Ecole Polytechnique, Montreal, on French engineering construction, dealing largely with the works with which his firm has been associated as consultants. M. Rabut is one of the French engineers whose remarkable designs in reinforced concrete seem so daring to engineers accustomed only to North American practice in that material. Among such structures may be mentioned two reinforced concrete arch-rib bridges of 330 ft. span recently completed over the Meuse, and a number of reinforced concrete airplane hangars of 170 ft. span at Cherbourg and Querqueville.

After distinguished service at the front as an engineer officer during the War, he was sent to the United States with the French High Commission, and later served with the French mission in the United States for the purchase

Jacques Rabut, Hon.M.E.I.C.

of equipment for the rehabilitation of the devastated regions in France. He then went to China with an International Commission assembled by the Chinese Government to deal with the reconstruction of the bridge over the Yellow river. On several other occasions he has been retained by the French Government, notably in connection with a large cold storage plant erected in 1919 at Saint Pierre-Miquelon.

While in Montreal, at a luncheon given by a number of members of The Institute Council, M. Rabut took the opportunity of expressing his sincere appreciation of the honour which The Institute had done him in conferring its honorary membership upon him. This he gratefully acknowledged as a compliment to the engineering profession in France. In return Dr. Lefebvre, the chairman, was able to assure M. Rabut that his status is now that of an honoured member of the engineering fraternity in Canada.

## List of Nominees for Officers

The report of the Nominating Committee was presented to and accepted by Council at the meeting held on September 24th, 1937. The following is the list of nominees for officers as prepared by the Nominating Committee and published for the information of all corporate members as provided by Sections 68 and 74 of the By-laws.

List of Nominees for Officers for 1938 as Proposed by the Nominating Committee

| | | |
|---|---|---|
| President: | J. B. Challies, M.E.I.C. | Montreal |
| Vice-Presidents: | | |
| *Zone "B" (Province of Ontario)* | W. P. Wilgar, M.E.I.C. | Kingston |
| | E. V. Buchanan, M.E.I.C. | London |
| *Zone "C" (Province of Quebec)* | H. O. Keay, M.E.I.C. | Three Rivers |
| | Hector Cimon, M.E.I.C. | Quebec |
| *Zone "D" (Maritime Provinces)* | R. L. Dunsmore, A.M.E.I.C. | Dartmouth, N.S. |
| Councillors: | | |
| †*Cape Breton Branch* | A. P. Theuerkauf, M.E.I.C. | Sydney, N.S. |
| †*Moncton Branch* | B. E. Bayne, A.M.E.I.C. | Moncton |
| †*Quebec Branch* | A. Larivière, M.E.I.C. | Quebec |
| ††*Montreal Branch* | J. L. Busfield, M.E.I.C. | Montreal |
| | R. H. Findlay, M.E.I.C. | Montreal |
| | J. W. McCammon, A.M.E.I.C. | Montreal |
| | H. Massue, A.M.E.I.C. | Montreal |
| †*Ottawa Branch* | E. Viens, M.E.I.C. | Ottawa |
| †*Peterborough Branch* | A. B. Gates, A.M.E.I.C. | Peterborough |
| †*Toronto Branch* | Otto Holden, A.M.E.I.C. | Toronto |
| †*Hamilton Branch* | H. A. Lumsden, M.E.I.C. | Hamilton |
| †*Niagara Peninsula Branch* | W. R. Manock, A.M.E.I.C. | Fort Erie, Ont. |
| †*Sault Ste. Marie Branch* | J. L. Lang, M.E.I.C. | Sault Ste. Marie |
| †*Lethbridge Branch* | J. T. Watson, A.M.E.I.C. | Lethbridge |
| †*Winnipeg Branch* | A. J. Taunton, M.E.I.C. | Winnipeg |
| †*Calgary Branch* | J. Haddin, M.E.I.C. | Calgary |
| | G. P. F. Boese, A.M.E.I.C. | Calgary |
| †*Victoria Branch* | I. C. Barltrop, A.M.E.I.C. | Victoria |

*One Vice-President to be elected for two years.
†One Councillor to be elected for two years.
††Two Councillors to be elected for three years each.

*Additional Nominations*

Section 68 provides also that "Additional nominations for the list of nominees for officers signed by ten or more corporate members and accompanied by written acceptances of those nominated, if received by the Secretary on or before the first day of December, shall be accepted by the Council and shall be placed on the officers' ballot."

## Discontinuance of the Non-Active List

It will be remembered that a non-active list was established by Council in 1932 to meet the case of those members who in consequence of the depression were unable to pay their annual fees to The Institute. At one time the list included over seven hundred names. To-day the number remaining is so small that Council has felt justified in discontinuing the list as of January 1st, 1938, on which date the names of the non-active members will be restored to the regular roll.

It is possible that this will affect a few members for whom the situation has not materially improved. In such cases Council would appreciate a confidential communication to the Secretary explaining the member's difficulties, so that on application, such cases may receive further consideration by Council.

# OBITUARIES

## William Gregory Chace, M.E.I.C.

William G. Chace, M.E.I.C., consulting engineer, died suddenly on July 12th, 1937, at his home in Toronto at the age of sixty-two, his death closing an active career in engineering extending over a period of thirty-five years.

He was born on May 16th, 1875, in the county of Lincoln, Ontario, and was educated at St. Catharines Collegiate Institute and the School of Practical Science, Toronto, graduating from the latter with honours in 1903.

William Gregory Chace, M.E.I.C.

After a short time teaching he joined the staff of the Canadian Niagara Power Company, which was then busy with the construction of the first hydro-electric power plant to be built on the Canadian side of the river at Niagara Falls. In 1904 Mr. Chace was appointed engineer-in-charge of construction on the hydro-electric power plant of the International Railway Company at Niagara Falls and in 1905 and 1906 was engaged on preliminary studies for the electrification of Temiskaming and Northern Ontario Railway and on reports for the first Hydro-Electric Power Commission of Ontario.

In 1907 he became a member of the firm of Smith, Kerry & Chace, consulting engineers, Toronto, and took charge of the preparation of a report to the city of Toronto which resulted in the establishment of the Toronto Hydro-Electric System. From 1908 to 1911 Mr. Chace was chief engineer on the construction of the Municipal Hydro-Electric Power System of Winnipeg with generating plant at Pointe-du-Bois. In 1912 he was appointed assistant general manager of the Mount Hood Railway, Light and Power Company, Portland, Oregon, and in 1913 as president and chief engineer of the Crane Falls Power and Irrigation Company, Boise, Idaho, constructed an irrigation system serving 30,000 acres of land.

Late in 1913 Mr. Chace was appointed chief engineer for the Shoal Lake Aqueduct of the Greater Winnipeg Water District where he remained until the completion of that undertaking in 1920. From 1920 to 1924 he occupied the position of President of the Canada Lock Joint Pipe, Limited. Later, his time up to 1928 was devoted mainly to the study of the properties and utilization of reinforced concrete pipe.

In 1928 Mr. Chace became a member of the firm of Sullivan, Kipp and Chace, consulting engineers, Winnipeg, and prepared special reports for the Government of Saskatchewan dealing with the general electric power supply system in that Province and later taking charge of the construction of two extensive plants for central steam heating in the city of Winnipeg, for the Northern Public Service Corporation.

Mr. Chace returned to Toronto in 1932 and working in conjunction with his old firm Kerry & Chace, Limited, made, in 1933, reports on the supply of hydro-electric power to the gold mines in Northern Quebec. In 1934 he prepared preliminary designs for a hydro-electric power development on the Upper Ottawa river for Noranda Mines Limited and in 1935 designed and built a hydro-electric power plant for God's Lake Gold Mines, Manitoba. In 1936 Mr. Chace had charge of the construction of a 48-inch supply pipe and storage dams for the Quesnel Mining Company, Limited, British Columbia.

Mr. Chace joined The Institute as an Associate Member in 1906, became a Member in 1912, served as chairman of the Winnipeg Branch in 1915 and 1916, as a councillor of The Institute from 1915 to 1917 and as a Vice-President in 1920 and 1921. He was awarded the Gzowski Medal in 1911.

## Clyde Barber Joy, A.M.E.I.C.

It is with deep regret that we record the death of Clyde Barber Joy, A.M.E.I.C., in Hamilton, Ont., on April 27th, 1937, after an illness of eight months. Mr. Joy was born in Hamilton, North Dakota, in March 1896 and moved to Toronto when a boy. In 1917 he joined the Canadian Flying Corps and after the war entered Toronto University graduating in 1924 with the degree of B.A.Sc. in Civil Engineering. In 1924 he was employed as draftsman by the Canadian National Electric Lines, Toronto, and in 1925 by the American Bridge Company, Pencoyd, Penn. In the latter part of 1925 he joined the Austin Company in their estimating and architectural department in Philadelphia. He returned to Canada in 1930 as designer and estimator with the London Structural Steel Company, London, Ont., later being employed by James, Proctor & Redfern, Limited, Toronto. Mr. Joy joined The Institute as a Student in 1920, transferring to the grade of Junior in 1925 and became an Associate Member in 1931.

## Claude Wilson Morrison, S.E.I.C.

It is with regret that we record the passing of Flight-Lieut. Claude Wilson Morrison, S.E.I.C., who died in Belleville, September 15th, as a result of injuries received in a motor accident. Flight-Lieut. Morrison was born in Montreal in May 1908, receiving his technical education at McGill University from which he graduated with the degree of B.Sc. in Mechanical Engineering in 1931. He joined the Royal Canadian Air Force in 1932 and had been stationed at Camp Borden, Trenton and Ottawa. At the time of his death he was at the air station at Trenton, Ontario.

## Harold Rolf, M.E.I.C.

In the passing of Harold Rolf, M.E.I.C., at his home in Lachine, Quebec, on September 19th, Canada lost one of her outstanding engineers. Mr. Rolf at the time of his death was President of the J. S. Metcalf Company, having joined the firm in 1904 as inspecting engineer and reached the position of President by 1917. His company was well known as designers and builders of grain elevators in United States, Great Britain, South America and all parts of Canada. Mr. Rolf was born in Toronto, Ont., February 1872 and graduated from the School of Practical Science, Toronto, in 1894. From 1895 to 1897 he was engaged in drafting and design with the Pacific Rolling Mills, San Francisco, and from 1897 to 1902 in mining and surveying in British Columbia and the Yukon Territories. He joined The Engineering Institute of Canada as an Associate Member in 1909, becoming a Member in 1920.

### Harry George Rogers, A.M.E.I.C.

The death of Harry George Rogers, A.M.E.I.C., in Toronto in June 1937 will be noted with regret. Mr. Rogers was born in Peterborough in November 1884 and received his education at Trinity College School, Port Hope, Ont., and McGill University. He acted as field inspector for the Canadian Inspection Company from 1908 to 1910 and bridge inspector for the Canadian Pacific Railway from 1910 to 1914 and again from 1928 to 1931. From 1925 to 1928 he was on the construction and design for the Toronto Terminals Railway station. In 1932 Mr. Rogers moved to Toronto where he resided at 118 Howard Park Avenue.

### Andrew Douglas Stalker, A.M.E.I.C.

We regret to announce the death in Ottawa on September 30th, 1937, of Andrew Douglas Stalker, A.M.E.I.C. While Mr. Stalker only recently joined The Institute as an Associate Member, he has been engaged in engineering for the past twenty-five years. He was born in Ottawa in November 1892, receiving his education at the Ottawa Public Schools and Queens University from which he graduated in 1916. From 1916 to 1919 he served in Canada and overseas as works officer of the 38th Battalion, C.E.F. From 1919 to the time of his death he was in the employ of the waterworks department of the city of Ottawa, first of all in the construction of the overland pipe extension and distribution system Eastview, and the low lift pumping station, Lemieux Island. From 1929 to 1930 he acted as resident engineer on the construction of the Ottawa water purification plant and pumping station extension. In 1933 he became assistant waterworks engineer, which position he held until the time of his death.

## PERSONALS

R. G. Barbour, S.E.I.C., has been appointed industrial engineer with T. Pringle and Son, Limited, Montreal. He is a graduate of the University of New Brunswick, receiving his degree in B.Sc. in 1924 and M.Sc. in 1927. From 1926 to 1929 he was electrical engineer on construction with the Aluminum Company of Canada at Arvida, Quebec, and since 1929 has been electrical engineer with Messrs. McDougall and Friedman, consulting engineers, Montreal.

K. Y. Lockhead, Jr.E.I.C., has recently been appointed building superintendent of the Hudson's Bay Company's retail store at Winnipeg. Mr. Lockhead graduated from McGill University in 1932, acted as demonstrator in the mechanical engineering laboratory of the same university until 1933 when he joined the Hudson's Bay Company at Winnipeg as assistant to the power plant engineer.

H. G. Conn, A.M.E.I.C., has joined the Mechanical Engineering Staff of Queens University. Mr. Conn graduated from Queens University with the degree of B.Sc. in Mechanical Engineering in 1931, receiving an appointment as demonstrator in the Physics Department of the same university. In 1932 he joined the staff of the Proctor and Gamble Company, Hamilton, Ont., and since 1935 has been plant engineer at their Hamilton plant.

E. J. Davies, A.M.E.I.C., has been transferred from the Peterborough Collegiate and Vocational School, where he has been acting as instructor, and has been appointed director of industrial arts in the new Vocational School at Cornwall, Ont., which will open in September 1935. He graduated from the Nova Scotia Technical College in 1923 with the degree of B.Sc. in Mining Engineering. From 1924 to 1929 Mr. Davies was with the Babcock-Wilcox and Goldie-McCulloch, Ltd. Galt, Ont., and in the latter year received the appointment which he now vacates.

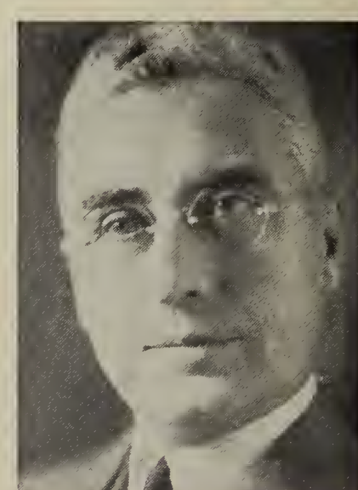
J. T. Williams, S.E.I.C., has accepted a position with the Imperial Oil Company at Sarnia, Ont. Mr. Williams graduated in mechanical engineering from Queens University in May 1937.

W. A. Dawson, A.M.E.I.C., has resigned from the staff of the Algoma Steel Corporation, Sault Ste. Marie, Ont., to accept the position of mechanical superintendent of the new motor plant of the Chrysler Corporation of Canada, Windsor, Ont. He graduated in mechanical engineering from Queens University in 1923 but prior to graduation had considerable experience as a tool and die maker and inspector of tools and gauges. Mr. Dawson was associated with the Ford Motor Company of Canada, Windsor, Ont., for a number of years and advanced to the position of chief of the department of machine and tool design. In 1935 he received the appointment from which he has just resigned, that of assistant superientendent of the Algoma Steel Corporation.

P. L. O'Shaughnessy, A.M.E.I.C., has accepted a position as field engineer with Messrs. Robinson and Steinman, consulting engineers, on the Thousand Islands Bridge. Since 1934 he has been construction engineer with the Canada Cement Company and prior to that was highway engineer to the Ontario Government. From 1928 to 1933 he was plant engineer with the Canada Cement Company, Belleville, Ont. He graduated from McGill University in 1923 and later became a qualified Dominion Land Surveyor in New Brunswick.

C. D. Meals, M.E.I.C., has been appointed chief engineer of the Wire Rope Division, Bethlehem Steel Corporation, Williamstown, Penn., thus terminating his connection with B. Greening Wire Company Ltd., Hamilton, Ont., where he has been since 1931. Mr. Meals has had extensive experience in the wire rope and cable industries and will be remembered for his numerous technical papers on these subjects. His connection with this industry started in 1911 when he became draftsman with the John Roebling's Sons Company, Trenton, N.J. This appointment was followed by others with the Bethlehem Steel Corporation and the American Cable Company, with whom he was chief engineer from 1927 to 1930. From 1930 to 1931 Mr. Meals was president and general manager of the Wire Rope Corporation of America, New Haven, Conn.

#### Shawinigan Appoints Assistant General Managers



J. B. Challies, M.E.I.C.

The following promotions to the executive staff of The Shawinigan Water and Power Company were announced recently by the president of the company, Dr. Julian C. Smith, past president of The Institute: Messrs. J. B. Challies, P. S. Gregory and John Morse, all Members of the Institute, also Mr. R. J. Beaumont, to be assistant general managers.

Mr. Challies began his professional career in 1903 as engineering clerk in Topographical Surveys of Canada. Successively, chief hydraulic engineer, Department of Interior; superintendent of Water Power; director and chief engineer, Water Power and Reclamation Service; director, Dominion Hydrometric Survey; member, Dominion Power Board; member, Dominion Fuel Board; consulting engineer to Department of External Affairs regarding International Waterway matters; liaison officer for the Federal Departments on the Research Council of Canada. He represented the Government of Canada in 1915 at the International Engineering Congress in San Francisco, and in 1924 at the World Water Power Conference in London. Resigning from the Federal Government Service in 1924 he became a departmental manager of Shawinigan, Montreal.

P. S. Gregory, M.E.I.C.

John Morse, M.E.I.C.

Mr. Gregory began his professional career in Hamilton with the Canadian Westinghouse Company; he was then with the Montreal Tramways Company and the Electrical Commission of Montreal. After two years on construction of the street-lighting system for the City of Montreal, he, in 1918, joined Shawinigan. In addition to his duties as assistant general manager, Mr. Gregory is assistant to the president of the Quebec Power Company.

Mr. Morse graduated in electrical engineering from Chalmers Technical Institute, Gothenburg, Sweden, in 1906, and started his professional career as a draughtsman with the Otis-Fensom Elevator Company, Yonkers, N.Y. There followed some time with the Maxwell Briscoe Motor Company, Tarrytown, N.Y., and the General Electric Company at Schenectady, N.Y. In 1907 he joined Shawinigan and four years afterwards became superintendent of operation. In 1916 he was made general superintendent, a position he has held until his recent appointment as assistant general manager.

## 17th World Congress of Industrial Chemistry

At the request of the Seventeenth Congress of Industrial Chemistry, Major D. C. Unwin Simson, R.C.E., A.M.E.I.C., was appointed by the Council to represent The Institute at the meetings of the Congress which were held in Paris, France, from September 26th to October 3rd, 1937. Major Simson is resident engineer of the Canadian Battlefields Memorial Commission, St. Laurent Blangy (P. de C.), France, and submits the following report of the proceedings of the Congress:

On Sunday the 26th the delegates were received by the President, Sir Robert Mond, and M. M. G. Painvin, President of the Committee of Organization, M. Gerard, Vice-President of the Society of Industrial Chemistry, and other notabilities, in their magnificent building, 28 bis Rue St-Dominique, on the left bank of the Seine.

After the presentations, all the delegates repaired to the main hall, where dancing and attractions alternated for the entertainment of the visitors, coupled with an excellent buffet.

On Monday morning, after being photographed in the court-yard of the Maison de Chimie Industrielle, at ten o'clock about 200 delegates assembled in the hall of the building and the Congress was declared open by M. Max Hymans, Under-Secretary of State for Commerce and Industry.

This was followed by a conference conducted by Sir Robert Mond, member of The Institute of France and President of the Society of Industrial Chemistry, on the "Growth of the Nickel Industry." This brought Canada very much before all the delegates as practically the whole of his speech dealt with the growth of the Canadian nickel industry, only passing mention being made of that of New Caledonia and Finland.

This was followed by a reunion of the presidents, vice-presidents and secretaries of the various sections of which there were 17. These were as follows: Section 1—Analytical chemistry; 2—(*a*) Factory lay out and installation, (*b*) Water treatment; 3—Combustible solids; 4—Combustible liquids; 5—Minerals; 6—Electro-chemistry; 7—Lime, cements, etc.; 8—Glass; 9—Industrial organic products; 10—Fats; 11—Resin and rubber, etc.; 12—Cellulose, paper, artificial textiles; 13—Tannery; 14—Fermentation, beers, sugar; 15—Primary foods, bakery, fruit preserving, etc.; 16—Technical agricultural chemistry; 17—Scientific organization.

From this moment until Thursday, September 30th, these sections of the Congress were in almost continual session from 9 a.m. until 5 p.m. with a break for lunch.

On the afternoon of the 27th was opened, in another part of the building, an exhibition of the latest laboratory equipment. Exhibits from French and German firms predominated and the machinery varied from scales designed to weigh infinitesimal particles to crushers for analytical purposes. This was followed at 6 p.m. by a full conference of the Congress on "The Importance and Development of Artificial Fibre in Germany." This paper was given by Dr. W. Eller, head of the Central Office of the Artificial Silk Industry.

On September 28th, a full conference was given on "The Action of Silicates on Modern Life," by S. A. Artigas, director of High Studies at the Polytechnique of Madrid. At 5 p.m. the delegates were received at the Chamber of Commerce of Paris, where the band of the Republican Guard were in attendance.

On the 29th, conferences were held by W. S. Muller, professor of the Technical School of Vienna, on the "Corrosion of Metals in Solution Considered as an Electro Chemical Phenomenon," by L. M. Heilbrown D.S.O., D.S.C., Ph.D., F.R.S., director of the chemical laboratories of Manchester University, on "Ten Years of Research on Vitamin 'D'"; and a further conference at the Sorbonne, in the amphitheatre, on "Liquid Air," by Georges Claude.

The following day all sections wound up their business, and in the afternoon the President of the French Republic, M. Lebrun, arrived and was greeted by Sir Robert Mond as President of the Society. After the presidential party had taken their seats, the business of the closing of the Congress commenced under the leadership of M. Jean Perrin, Nobel Prize winner, member of the Institute of France and late Under-Secretary of State for Scientific Research. Speeches were made commemorating the foundation of the Society of Industrial Chemistry, under the Presidency of M. Jules Jullien, Under-Secretary of State for Technical Science. Later a visit was made to the Exposition of International Art and Science, at the pavilion of the Corporative Union of French Art, followed by an official banquet presided over by M. Paul Ramadier, Under-Secretary of State for Public Works, at the restaurant Roi Georges V.

This concluded the theoretical and business side of the Congress which now split into four different groups for a three day trip to visit different objects of interest. This started on Friday, October 1st, and Group 1 visited the Goodrich factory, at Colombes; 2—The Laboratories of Dr. Roussel, at Romainville; 3—The factory of "Pain Vibor," at Paris; 4—The studios of Pathé Cinéma, at Joinville.

On Saturday, Group 1 visited the new Chemical Laboratories of the Ecole Normale Supérieure and the new Laboratories of the City of Paris.

The other groups left on a visit to Alsace to inspect the potash mines and chemical products of Thann and Mulhouse, also the power installation on the Rhine, at Kembs. On Sunday, after an excursion through the picturesque country of the Vosges around Mulhouse and Colmar, the delegates returned to Mulhouse where they took train for Paris, after a most successful and interesting Congress.

Great credit is due to the organizers for the efficient method in which the delegates were looked after and the business of the Congress carried through.

## The Engineering Journal 1930-1936

An interesting classification of the technical papers published in the Engineering Journal during the years 1930 to 1936 inclusive has been made recently and a summary of this is given here for the information of the members.

The first line of the table gives the number of technical papers included in each classification, the total amounting to three hundred and twelve. The second line gives the approximate percentage which each group is of the total.

| Mechanical and Aviation | Civil and Structural | Electrical including Radio | Mining, Metallurgical and Chemical | Various |
|---|---|---|---|---|
| 80 | 85 | 64 | 29 | 54 |
| 25% | 27% | 21% | 9% | 18% |

## ELECTIONS AND TRANSFERS

At the adjourned meeting of Council held on October 25th, 1937, the following elections and transfers were effected:

*Member*

BEAVER, Hugh Eyre Campbell, consltg. engr., partner in firm of Sir Alexander Gibb and Partners, Queen Anne's Lodge, Westminster, England.

*Associate Members*

MUNRO, George Neil, B.Sc. (Univ. of Sask.), inspr., Dept. Public Works Canada, North Battleford, Sask.

PATRIARCHE, Valance Heath, B.Sc. (Univ. of Man.), general traffic manager, Canadian Airways Limited, Winnipeg, Man.

SEELY, Harold Chipman, B.Sc., (Univ. of N.B.), 1197 Crawford Bridge Road, Verdun, Que.

THEOBALDS, Thomas Reynold, B.Sc., (McGill Univ.), town engineer to the Castries Town Board, St. Lucia, B.W.I.

*Juniors*

McLAUGHLIN, William Gordon, B.Sc. (Queen's Univ.), M.E. (Mech.), (Rensselaer Polytechnic Inst.), asst. constrn. engr., E. B. Eddy Co. Ltd., Hull, Que.

RAMSAY, William Wallace, B.Sc. (Univ. of Man.), res. engr., Century Mining Corpn. Ltd., Elbow Lake, Man.

WALSTON, Timothy Cragg, B.Sc. (Univ. of Man.), archt'l. dftsman., Green, Blankstein, Russell & Ham, Winnipeg, Man.

*Transferred from the class of Junior to that of Associate Member*

GILCHRIST, John, B.Sc. (Univ. of Man.), district plant engr., The Barrett Company, Montreal, Que.

THOMPSON, Frank Lawrence, B.Sc. (N.S. Tech. Coll.), technical service engr., Imperial Oil Limited, Dartmouth, N.S.

*Transferred from the class of Student to that of Associate Member*

HAWKE, Charles Edison, B.A.Sc. (Univ. of Toronto), asst. engr., Dept. Public Works Canada, Toronto, Ont.

*Transferred from the class of Student to that of Junior*

MACREDIE, John Robert Calderwood, B.Sc. (Univ. of N.B.), instr'man., Dept. of Highways of N.B., Fredericton, N.B.

*Students Admitted*

ASPLIN, Albert Grant, (McGill Univ.), 3592 University St., Montreal, Que.

BAKER, Rogerson Albert, B.A.Sc. (Univ. of Toronto), 264 Hunter St., Peterborough, Ont.

FERGUSON, David H., (McGill Univ.), 3637 Oxenden Ave., Montreal, Que.

FERGUSON, Robert Norman, (McGill Univ.), 3637 Oxenden Ave., Montreal, Que.

JOYCE, William Anderson, (R.M.C.), Royal Military College, Kingston, Ont.

MENDELSOHN, Albert, (McGill Univ.), Ste Agathe des Monts, Que.

MULLINS, Harrison Alexander, B.Sc. (Univ. of Man.), 524 Dominion St., Winnipeg, Man.

McLEOD, Arthur Malcolm, B.Sc. (Univ. of Alta.), 18 Harvey St., Hamilton, Ont.

OATWAY, Harold Calahan, (McGill Univ.), 2059 Stanley St., Montreal, Que.

POLSON, Jack Ambrose, B.A.Sc. (Univ. of B.C.), 194 Reid St., Peterborough, Ont.

RUBIN, Leon Julius, (Univ. of Toronto), 539 Palmerston Blvd., Toronto, Ont.

SNYDER, William Garrett, (McGill Univ.), 2063 Stanley St., Montreal, Que.

WHITELEY, Eric, B.A.Sc. (Univ. of Toronto), 301 Reid St., Peterborough, Ont.

# Committee on Foundations in Winnipeg, Manitoba

**Interim Report as presented to the Executive Committee of the Winnipeg Branch of The Institute, August 5th, 1937**

During the summer a committee of engineers and other technical men investigated the problem of soil conditions in the Winnipeg district with particular reference to foundations. As there seems to be a widespread interest in the subject of foundation engineering and soil mechanics at the present time, it is believed that the publication of their report will be of interest.

After amending Recommendation 3, as shown at the end of the report, this report was adopted by the Technical Bureau of the Winnipeg Board of Trade. It was then submitted to the Council of the Board on September 27th, adopted and released to the City Council, Winnipeg Builders Exchange, Winnipeg Real Estate Board, Home and Property Owners Association, Provincial Department of Public Works (Architects Branch), Mortgage Loans Association, the Press and other interested parties.

A further report may possibly be forthcoming but this will depend largely whether sufficient funds are raised to carry on investigation work.

To The Executive Committee,
Winnipeg Branch, E.I.C.,
Winnipeg, Manitoba.

Gentlemen:

At your executive meeting of April 23 last, the following resolution was moved, seconded, and carried: "That Professor A. E. Macdonald as chairman, assisted by Professor W. F. Riddell, form a co-ordinating committee on the study of foundation conditions in Winnipeg and that they contact other interested bodies in this respect."

Following these instructions an organization meeting was held on May 10. This was attended by representatives of The Engineering Institute of Canada, Winnipeg Branch; the Association of Professional Engineers of the Province of Manitoba; the Manitoba Association of Architects, and the Manitoba Branch of the Canadian Institute of Chemistry. Further meetings were held on June 24, July 8, and July 29, 1937.

Your instructions to this committee were to report on this subject under the following three headings:—

1. Why difficulties are experienced with foundations.
2. How best to repair faulty construction.
3. Proper design for new foundations.

The correct answers to these three questions are matters of considerable importance to all citizens of Greater Winnipeg. Your Committee finds that there are a great deal of data available which, if compiled and made use of, would be of value in explaining many foundation failures and would assist technical men to design new foundations and repair construction satisfactorily.

On the other hand, to answer definitely the three questions asked, a considerable amount of research, observation and experimentation will be necessary over a period of several years. Such a study will naturally require financing and, until your Committee is provided with funds, the suggested study is out of the question.

Your Committee has therefore compiled certain information which is readily available and has condensed it into this Interim Report.

A criticism of this report may be that obtaining a consultant to design and inspect all ordinary house foundations is only adding to the cost of house construction. It is pointed out, however, that the small additional cost of a proper design with adequate inspection during construction of the foundation of the average dwelling is money well spent.

The economic angle of the problem is one which should be given very careful consideration by the general public. Frequently, the owner of a residence or apartment block will hesitate or will absolutely refuse to spend a little extra money to ensure a proper foundation. It is believed that ninety-odd percent of the dwellings in Greater Winnipeg have been built without benefit of technical advice from architect or engineer. The contractor's function is to construct, not to design, so he should not be blamed for faults of design.

In this Interim Report no attempt has been made to formulate general rules which may be applied to all cases. *This cannot be done as every foundation is a problem in itself and must be dealt with as local conditions warrant.*

### Formation of Winnipeg Soils and Sub-Soils

1. The supporting value of soils in different large areas is influenced by their geological formations.

The Winnipeg area is part of the bed of old Lake Agassiz, the great glacial lake which many thousand years ago covered the greater part of Manitoba. There is evidence that this great sheet of water at one time stood at a depth of over five hundred feet above the present city of Winnipeg. Great masses of clay or powdered rock settled to the bottom of this lake and with the melting of the ice barrier and consequent release of the impounded water the site for the future city of Winnipeg was provided.

2. Winnipeg, then, is built on the bed of an old lake. We find between prairie grade and limestone bed rock (which is approximately sixty to seventy feet below) the following typical layers of soil (see Fig. 1), which, however, will vary considerably even over a limited area.

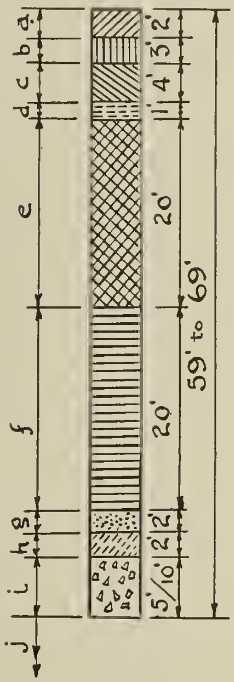

Fig. 1.

(*a*) Roughly two feet of loam with a clay sub-soil, very sticky and plastic when wet. This is the material which appears on the surface of our mud roads.

(*b*) Three feet of material which might be classified as silty clay. This provides a fair foundation for very light structures so long as it retains its moisture. When dried out by drainage or evaporation, however, it becomes brittle and unstable. On the other hand, if saturated with water it becomes plastic and subject to flow and under given conditions it may even be eroded.

(*c*) Four feet or so of brown clay. In its normal state, this is dense and firm, fine grained and practically impervious to the passage of water. Under pressure it is subject to compression and flow and such compression and flow may cause a bulge beyond the limit of the footing. It dries slowly but in the process of dehydration it cracks and shrinks to a considerable degree, and becomes pervious.

(*d*) The so-called "yellow-strip" This is a mixture of clay and silt, bright yellow in colour, which varies in thickness from a few inches to three or four feet. Twelve to eighteen inches is a fair average. It is greatly affected by changes in moisture content. When dehydrated shrinkage is high and the material becomes hard and more or less laminated. If saturated with water it swells and becomes very soft and greasy. In passing it may be stated that this yellow strip has been at least a contributing factor to much of the foundation trouble which has developed in Winnipeg.

(*e*) Approximately twenty feet of dense chocolate-coloured clay. Many buildings in the business area of Winnipeg have foundations in this stratum. Where they have been rationally designed and conservatively loaded and where there has been no undue variation in moisture content of the clay such foundations have, in general, been highly satisfactory.

(*f*) Some twenty feet of dense clay of the type usually known as blue clay. Remarks applicable to (*e*) apply equally to this stratum.

(*g*) Two feet or so of sandy grey material containing a fairly large percentage of ground up limestone and some boulders. Usually this stratum carries water in greater or less degree but rarely in sufficient volume to cause trouble. The bottom of this material is the limit to which an auger boring can be carried.

(*h*) Two feet or more of material somewhat similar to (*g*) but containing a greater percentage of crushed limestone and as a rule embedded boulders ranging in size from ten inches to thirty inches or larger. For want of a better name this material may be classed as semi hard-pan.

(*i*) Five to ten feet or more of hard-pan. This is a very dense material, sometimes described as boulder clay, containing a high percentage of crushed limestone and boulders. It can be excavated with a pick only with considerable difficulty and has about the hardness and consistency of a poor quality concrete. In contact with water, it disintegrates readily.

(*j*) As a general rule limestone bed rock is encountered immediately below hard-pan. Sometimes a layer of water bearing sand, gravel, and decomposed limestone is found. This may provide a heavy flow of water under pressure which in turn may lead to a considerable expense for installation and operation of pumping equipment.

### Foundations for New Buildings

3. There is a feeling, more or less wide spread, that really satisfactory foundations cannot be provided in Winnipeg. *This is not a fact. Satisfactory foundations have been and can be built.* However, the man on the street must face the fact that he, in the final analysis, will get just exactly what he pays for and if he wishes to build a house or an apartment block, he must be prepared to expend a reasonable sum to ensure a foundation which will not cause trouble by uneven or excessive settlement.

4. Very heavy buildings present no particular problem. The best and most economical foundation is a concrete pier (commonly known as

a "caisson") of the requisite size carried to solid bed rock. Examples of such foundations are the Hudson's Bay Store, the Winnipeg Auditorium and the Dominion Public Building.

5. Relatively heavy buildings where foundation loads are not sufficiently great to justify the use of caissons to bed rock have been successfully carried on spread footings in chocolate or blue clay. Such footings must be constructed at a depth sufficient to prevent or minimize dehydration and consequent shrinkage of the supporting clays. Buildings of this type are Canadian General Electric Building, Manitoba Cartage Warehouse, and the Security Storage Building.

6. Another type of foundation suitable for this class of building may be provided by the use of wooden piles driven to refusal at semi hard-pan. As examples may be cited the Wheat Pool Building, and the Nurses Home at St. Boniface Hospital.

7. (*a*) Medium weight buildings such as apartment blocks, schools, etc. have been satisfactorily supported by the deep spread footing as outlined in Paragraph 5. Examples are the Balfouria Apartments, Unit No. 1, River Heights Apartments, and the Royal Canadian Mounted Police Headquarters on Portage Avenue.

(*b*) Wooden piles driven to refusal at semi-hard-pan as described in Paragraph 4 have been also used. Riverbend School is an illustration of this type of foundation.

(*c*) Reinforced concrete piles, auger bored to refusal at semi hard-pan have been used with apparent success on the Dufferin School, Mordue Funeral Home and several structures erected by the Greater Winnipeg Sanitary District.

8. Another type of foundation for such buildings which has considerable possibilities is the thirty-inch caisson, auger bored to or near semi hard-pan and hand excavated and belled out through the semi hard-pan to and into firm hard-pan.

9. The greatest problem of all is encountered in residence construction. The more expensive houses where a little extra money is available can be supported by means of the deep spread footing, the concrete or wooden pile and the small caisson to hard-pan. With few exceptions, however, these methods have not been used for the medium and low cost house. Practically all of such buildings are constructed with spread footings located from four to six feet below prairie level. In other words, the foundations are in brown clay (see Paragraph 2, sub-section (*c*)) or are in or above the so-called yellow strip (see Paragraph 2, sub-section (*d*)). The clays upon which the foundations are supported have within recent years become dried out and laminated to such an extent that immediate settlement takes place. As the drying out process continues, settlement is increased. Further, when the building is completed, the interior foundations are no longer subjected to the direct rays of the sun and the drying out process at this point is retarded. It continues unabated, however, at the exterior walls, particularly those with south and west exposures. The result is a differential settlement which can only end in damaged foundation walls, shattered plaster and partitions, distorted doors and windows and a very appreciable decrease in value.

10. Some improvement has been made by stiffening foundation walls with steel reinforcement, also by stiffening the entire structure by the use of reinforced concrete beams and slabs at the ground floor level. For smaller houses having dimensions up to about 30 ft., beams may span from wall to wall and all interior columns and footings may be eliminated. This transfers the load to the exterior foundation and automatically does away with one of the most potent causes of differential settlement.

11. The stiffening of foundations, however, does not eliminate the fundamental cause of settlement damage, namely, the location of foundations in unstable clay. It may minimize subsequent damage and make for an even settlement but it certainly will not do away with all movement. It would seem, therefore, that the day is not far distant when a better type of residence foundation must be provided either by the use of deep foundations, piles or otherwise. This condition will not come about until the average home buyer realizes that additional foundation security means additional financial outlay.

12. Finally, for all yielding foundations (such as those constructed in clay must of necessity be) the outstanding considerations in design must be the provision of footing units so proportioned that the load per square foot on the supporting clays is uniform and conservative, that the clay itself is uniform and that the live load used in arriving at such proportions is one which may reasonably be expected to apply at all times and not an extreme load which may be in effect for short periods only.

## Causes of Settlement

13. The causes of settlement in buildings are many and varied. Any foundations supported by a compressible material such as clay must of necessity settle to a certain extent. However, if the settlement is not excessive and if it is uniform, no appreciable damage is done. Material settlements due to overloading of the supporting soils and differential settlement due to improper proportioning of footing units and to lack of uniformity in the character of the underlying clay or its moisture content, are those which must be guarded against.

14. The primary cause of settlement in the Winnipeg area is the location of foundations at shallow depths. So long as our clays retained their moisture and so long as non-uniform and excessive soil pressures were avoided, little or no trouble was encountered. During the recent dry years, however, our soils have lost a very great proportion of their moisture. This, in turn, has led to a very material decrease in their volume with accompanying formation of vertical cracks and horizontal laminations. Chocolate or blue clay in its normal condition contains moisture to the extent of 35 to 40 per cent. Today this has in many cases been reduced by more than half, at depths much greater than the average residence or apartment block foundation. The effect of the withdrawal of this amount of moisture and the consequent shrinkage of the clay may readily be imagined.

15. Soil pressures under the average residence are less than a thousand pounds per square foot and under the average apartment block they rarely exceed two thousand pounds per square foot. These pressures are certainly not excessive for clays in their normal state. It has been shown, however, that our clays and particularly their upper layers are today in an abnormal state. It has been further shown that the foundation of the average residence or apartment block is only four to six feet below prairie grade, a depth even less than that of the fatal yellow strip. Settlement of such foundations has therefore been very rapid during the last four or five years.

16. It might be argued that a number of wet years following the recent dry period would restore the clays underlying our foundations to their normal condition. It is submitted that this will not be so. The construction of buildings, pavements, sewers, etc. leads to nearly 100 per cent run-off of rainfall. Even in wet years therefore little moisture finds its way into the sub-soil and the clays are not restored to their former conditions.

17. Certain settlements may be caused by an excess of moisture in localized areas with consequent softening of the upper clays. A defective eaves trough or downspout, a heavy bank of melting snow, or a variety of other factors, may allow water to reach a foundation causing a saturation and softening of the underlying soils, with subsequent differential settlement. This is particularly true if the footing is located in or above the yellow strip or if previous dehydration and shrinkage has provided channels for the inflow of water.

## Repairs to Existing Damaged Construction

18. In the Winnipeg area, underpinning, that is, the addition of new permanent supports to existing foundations, has been on the increase during the last few years. In general, the methods used locally are:—

(*a*) To excavate under existing defective foundations and to build a larger footing at a greater depth; supporting the existing footing on the new one through an additional foundation wall constructed between the old and new footings. This might be defined as under-mining rather than underpinning. When the load of the building is transferred to the clay under the new footing such clay is subject to immediate compression and further settlement takes place. This type of underpinning may therefore serve to accentuate the previous settlement.

(*b*) The method outlined in (*a*) in addition to "pretesting," that is, the use of jacks between the existing building and the new footing to force the latter downward, thereby compressing the underlying soil. Supporting walls or piers are constructed between old and new footings before removal of jacks. The jacking action removes the objection outlined for (*a*) but a considerable period must elapse to permit a proper compression of the newly loaded clay. This system is therefore slow in its construction.

(*c*) To bore under the existing footing to semi hard-pan by means of an auger thirteen inches to twenty-two inches in diameter or larger and to fill the resulting shafts with concrete, reinforced with steel rods. This method is usually described as the cast-in-place concrete pile system.

(*d*) The method outlined in (*c*) but making use of an auger thirty inches in diameter or larger. Boring is stopped at or slightly above semi hard-pan, after which excavation is carried further by hand labour until the solid hard-pan is reached. The bottom of the shaft may be belled out to provide additional bearing area on hard-pan. After completion of excavation, shafts are filled with concrete.

(*e*) Hand excavated concrete filled caissons to hard-pan or rock. If stopped at hard-pan the bottom may be belled to carry the required load at seven or eight tons pressure on the hard-pan. If carried through to bed rock, a pressure of thirty tons per square foot may be used.

(*f*) Methods (*a*) and (*b*) have today been largely superseded by (*c*) and (*d*) and occasionally (*e*).

## Field Tests and Other Work Suggested for the Consideration of The Institute

19. It has been shown that satisfactory foundations can be secured in clays if the information now at the disposal of the engineering, architectural, and construction fraternities is utilized. It is considered therefore that tests of bearing capacities of clays will serve no useful purpose at this stage. It is suggested, however, that valuable data can be obtained by setting up an organization to make periodic check levels on existing and new buildings with a view to determining the rate and extent of their settlement. Some work of this nature is now being done by certain firms and individuals but this of necessity can be of a very limited nature.

20. Few loading tests have been performed on concrete or wooden piles and none at all on caissons to hard-pan. Further, there is a certain amount of controversy amongst engineers and others as to the interpretation of data available on the allowable loads for various sizes of piles, also as to the means whereby a pile sustains a load, whether by skin friction, by point bearing, by bulb of pressure, etc. Another question on which no data are available is the relation between the carrying capacity of a single pile and that of a group of piles. It is suggested therefore that a really comprehensive series of tests be carried out on single piles, on groups of piles and on caissons to hard-pan and that such be made in various parts of the Greater Winnipeg area.

21. Various firms and individuals have considerable data on file regarding the depth and character of the soil formation over the Winnipeg area. This should be collected and compiled.

22. Much valuable information could be obtained by excavating a number of test pits in various parts of the city. A study should be made and a record compiled of the character of the excavated materials, their moisture content, etc.

23. Another question worthy of attention is the cause and prevention of heaving or upward movements of concrete basement floors.

24. Laboratory studies might be made at the University of Manitoba and in other laboratories suitably equipped for such work. Such studies would provide data regarding mechanical, physical, and chemical characteristics of our soils.

### Summary

Summarizing the foregoing it may be stated that:—

1. Excellent foundations can be obtained for heavy buildings by the use of caissons to bed rock.

2. Extending foundations to such depths for dwellings and moderate weight buildings is not economically practicable.

3. The upper soil strata in Greater Winnipeg are unstable and great care should be exercised in designing foundations, even for ordinary dwellings.

4. Sufficient information is already available for reasonable security in designing foundations for dwellings and moderate weight buildings.

5. Experience and technical knowledge is imperative for such designs.

6. Due to variations in soil formation each foundation is a separate problem.

7. It is desirable to make the cost of technical advice on dwelling foundations as small as possible so that construction costs will not be prohibitive.

8. Much is already known about how piling of wood or concrete can be used successfully in foundation work.

9. Less is known as to the *sustained* carrying capacity of individual piles and groups of piles, particularly in Winnipeg soils.

10. Other factors among many worthy of further investigation are:—

(*a*) The effect of ground water or the lack of it, on piling of wood or concrete.

(*b*) The effect on foundations of raising and lowering the water level of our two rivers.

(*c*) The possibilities of stabilizing soils by saturation chemical action, etc.

### Recommendations

The following recommendations are made:—

1. That the public be given more information on foundation problems in the Greater Winnipeg area.

2. That even those intending to build dwellings or other relatively low cost structures, be advised to employ technical consultants on the design and supervision of construction of foundations.

3. That research work on foundation problems both in the field and laboratory be carried on and that funds be raised for this purpose.

Recommendation 3 has been amended to read:—

That research work on foundation problems both in the field and in the laboratory be carried on and that the raising of the necessary funds (estimated at $40,000) for this purpose be investigated.

### Committee on Foundations in Winnipeg—1937

## Handbook of Chemistry

*Compiled and edited by Norbert Adolph Lange, Ph.D., Handbook Publishers, Inc., Sandusky, Ohio, 1937. 1,802 pages, 5⅝ by 7¾ inches, fabrikoid, $6.00.*

A complete and handy reference volume for those requiring chemical and physical data and while principally of value to the chemist or student of chemistry it should also prove most useful to physicists, mineralogists, engineers and librarians.

The book contains some 1,800 pages including 250 pages of mathematical data and tables and an index of more than 2,700 entries.

This second edition while following the same pattern as the first contains new tables and changes to a large number of others to bring them up to date. New material includes sections on organic ring systems, formula index and melting points of organic compounds, 160 pages on refractive indices, formulae of denatured alcohols and authorized uses and 6 pages in the appendix on probability functions and factors.

The binding is of durable fabrikoid and the size, style of type and arrangement of tables makes reference work easy and reading accurate.

## Man in a Chemical World

*By A. Cressy Morrison, Charles Scribner's Sons, New York, 1937. 292 pages, 9 by 6½ inches, cloth, $3.00.*

In this book, which was written in connection with the American Chemical Industries Tercentenary, the 300th anniversary of the founding of chemical industries in America, the author presents a fascinating account of the usefulness of the chemical industry to the people of the United States.

It is intended to be educational, its object to impress the man in the street with the fact that the chemical industries render a service that touches practically all activities and to what extent he is dependent upon these industries.

Mr. Morrison in this volume has departed from the story that has been told for the last twenty years, that chemistry is the key to modern civilization and the hope of the future, and the reader will find an informative story of how this industry contributes to life's necessities such as food, clothing, medicine, transportation, communication, shelter, social security and luxuries.

There is little of historical matter or of the future and both the engineer and the non-technical man will find this book full of practical informative and worthwhile reading.

## How to Make Alignment Charts

*By Merrill G. Van Voorhis, McGraw-Hill Book Company, New York, 1937. 114 pages, 9 by 6, cloth, $2.50.*

The author who has had experience in presenting a course of nomography to technical men has drawn up and presented his material for this text to suit the requirements he has found most necessary.

The purpose of the volume is to provide instruction on how to make nomographic or alignment charts for the solution of engineering and other formulae. Stress has been placed on how to handle various types of equations. Graphical construction methods are described when practical along the mathematical method. Of the two theoretical approaches to the subject in general use, the author favours that by plane and analytical geometry in preference to that by the determinants.

A list of general type equations, nineteen in number, is included and some forty-four formulae have been charted. The theory of construction, which is in not essential to the making of the charts, is confined to the appendix where it is briefly outlined for reference purposes.

The text of this work is well treated, the simplest formulae being treated first and as groups of equations are described, their relation to each other and to certain type forms become obvious.

# BULLETINS

*Tractors.*—A 16-page pictorial bulletin by the Cleveland Tractor Company, Cleveland, Ohio, shows their crawler tractors in operation in every corner of the world. (Form No. 822.)

*Groov-Pins.*—Groov-Pin Corporation, Union City, N.J., describe their groov-pins and drive-studs in a 16-page illustrated catalogue.

*High-Pressure Pumps.*—Worthington Pump and Machinery Corporation, Harrison, N.J., announces, in a 6-page bulletin, the development of a new pump designed for high-pressure boiler feed and gathering service in the oil fields. (Bulletin W-103-B3.)

*Flat-Rolled Steel.*—The American Institute of Steel Construction has published a 35-page illustrated booklet of an address, "Light-Gage Flat-Rolled Steel in Housing," by F. T. Llewellyn, research engineer, United States Steel Corporation, October 1937.

*Excavators.*—Priestman Brothers Limited, London, Eng., show photographs of their excavators, dredgers and grabs in a 6-page bulletin.

*Water Heaters.*—A. Reyrolle and Company, England (representatives: Northern Electric Company), have issued a 12-page circular on medium voltage electrode water-heaters and an 8-page circular on metal-clad medium-voltage immersion-heater banks with totally-enclosed connectors for thermal-storage building-warming domestic hot-water supplies and other industrial applications.

## Expansion Programmes of Canadian Power Firms

Capital outlay by the major Canadian power systems for 1937-38 will aggregate about $20,000,000 while work planned to be completed in the next year totals another $25,000,000. A further outlay of $10,000,000 is anticipated on transmission and distribution line work. These returns from 17 major power systems in all parts of the country indicate their expansion to meet the demand for electrical service.

These returns, by provinces, represent 80 per cent of the new capital expenditure:

| | |
|---|---|
| Nova Soctia | $ 1,727,000 |
| New Brunswick | 350,000 |
| Quebec | 28,575,000 |
| Ontario | 11,745,000 |
| B.C. | 1,500,000 |
| Prairies | 129,000 |

A large proportion of the planned outlay covers new developments. Shawinigan Water and Power Company and Brown Corporation are carrying out, over a period of two years, a $15,000,000 plant development at La Tuque, P.Q. The Quebec Power Board have $10,000,000 to spend for the supply of power in districts at present without electrical energy. With hardly an exception all the companies listed below are expanding their systems in order to open up new territories.

| Company | Capital Outlay | Remarks |
|---|---|---|
| Shawinigan | $ 750,000 | Sub station at Three Rivers. |
| St. Maurice Power* | 15,000,000 | Plant of 150,000 hp. at La Tuque, P.Q. |
| Quebec Power Board | 10,000,000 | Not allocated; to be used in setting up Provincial Hydro. |
| Saguenay Power | 450,000 | Isle of Maligne Unit. |
| Seaboard Power | 300,000 | Steam generator 7,500 kw. |
| B.C. Power | 1,500,000 | 47,000 hp. unit. |
| Montreal Power | 300,000 | Sub station; distribution lines. |
| N.S. Power Board | 1,360,000 | 5,200 hp. unit on Mersey river. |
| Ontario Paper | 2,000,000 | Balance of expenditure on power plant at Outardes Falls. |
| Canada Northern | 1,145,000 | Distribution lines. |
| Ontario Hydro | 1,600,000 | New plant developments. |
| | 2,500,000 | Transmission lines. |
| | 3,500,000 | Rural and distribution feeders. |
| | 3,000,000 | Transformer stations. |
| Gatineau Power | 75,000 | Distribution lines. |
| N.B. Power Board | 350,000 | $75,000 on plant; balance distribution. |
| Eastern Light | 67,000 | Distribution lines. |
| Dominion Electric | 42,000 | Distribution and plant. |
| National Light | 87,000 | Transmission lines. |
| West Kootenay | | Maintenance; charged to current income; no capital outlay. |

*Joint undertaking at Shawinigan and Brown Corp. at La Tuque.

—*Financial Post.*

*The Canadian General Electric Company Limited* have just issued a new 572-page Wiring Materials Catalogue which includes a forty-page introductory section added to help electrical contractors sell adequate wiring. Complete up-to-date listings of wiring materials and accessories, and a bilingual introductory section in catalogues for the province of Quebec, makes this catalogue one that will be extremely interesting to electrical contractors and electrical departments of mines and industrial plants.

Copies may be obtained on request to the C-G-E office nearest you.

# BRANCH NEWS

## Edmonton Branch

*M. L. Gale, A.M.E.I.C., Secretary-Treasurer.*
*F. A. Brownie, Jr.E.I.C., Branch News Editor.*

Members of the Edmonton Branch of The Institute met at a luncheon in the Jasper room of the Macdonald hotel on Saturday, August 28th, 1937. The guest speaker on this occasion was G. J. Desbarats, C.M.G., Hon.M.E.I.C., President of The Institute, who spoke briefly on Institute matters.

He referred to the splendid success of the semicentennial meeting held this year and outlined briefly the present state of the negotiations with regard to the relationships between The Institute and the provincial associations. Mr. Desbarats spoke emphatically of the necessity of more active participation by members in Institute affairs and also suggested that members make greater use of head office facilities.

On the meeting being adjourned by the chairman, Mr. J. D. Baker, there followed an informal period in which members had an opportunity of meeting the President personally.

At 4 o'clock the members drove to a newly developed park at the city power plant where they joined with other engineers and civic officials in a brief, impressive ceremony in which Mr. Desbarats dedicated a memorial sundial to the late William John Cunningham, A.M.E.I.C.

Mr. Cunningham was superintendent of the Edmonton Power Plant for many years and during that time had left no doubt as to his skill as an engineer and his fine qualities as a citizen and friend.

To many of those present, as the President unveiled this beautiful little memorial of stone and brass, there was recalled the deep sense of personal loss they had experienced in the passing of this brother engineer.

## Montreal Branch

*E. R. Smallhorn, M.E.I.C., Secretary-Treasurer.*

JUNIOR SECTION BRANCH VISIT

On Saturday afternoon, October 2nd, 1937, the Junior Section of the Montreal Branch were permitted, through the kindness of the officials of the company, to visit the plant of the Noorduyn Aircraft Limited at St. Laurent, P.Q.

This was a particularly interesting inspection trip as the company manufactures the Norseman and Beechcraft lines of aircraft and employs some one hundred and fifty men. Technical information was provided by the company's engineering staff and some one hundred and twenty-five members of the Junior Section attended.

FOREST INDUSTRIES IN THE ECONOMIC LIFE OF QUEBEC:

At the first fall meeting of the Montreal Branch, held on October 7th, Lt.-Col. L. J. D. Marquis, chief of the Department of Forest Products with the Department of Land and Forest of the Province of Quebec, gave an address on the part played by the forest industries in the economic life of the Province of Quebec.

An interesting discussion followed, which was led by Mr. G. C. Piché, formerly chief of the forest service of Quebec.

The evening's entertainment was terminated by the showing of motion pictures of lumbering operations in British Columbia. These were presented by Mr. Archie Moore, manager of the British Columbia Lumberman.

Refreshments were served at the conclusion of the meeting. Prior to the meeting an informal dinner was held at the Windsor hotel.

Huet Massue, A.M.E.I.C., acted as chairman.

JUNIOR SECTION

"The Engineer as the Citizen" was the subject of an address given before the Junior Section on October 13th by David Boyd, A.M.E.I.C., who is on the engineering staff of the Canadian Car and Foundry Company Limited, Montreal. Mr. Boyd's address was an excellent and thought-provoking discussion which pictured the engineer as a private citizen and the part he should take in public and private life and also in his relations with government, labour and the public generally.

Refreshments were served at the close of the meeting.

C. E. Frost, A.M.E.I.C., was in the chair.

INDUSTRIAL RESEARCH

On October 14th, Dr. L. W. Chubb, Director of Research of the Westinghouse Electric and Manufacturing Company at East Pittsburgh, discussed the part that research plays in engineering achievement. His address was an excellent presentation of some of the more dramatic engineering developments and scientific improvements. Exceedingly interesting demonstrations were made during Dr. Chubb's discussion.

Members of the Institute of Radio Engineers were guests of the Branch. Prior to the meeting an informal dinner was held at the Windsor hotel.

Chairman: C. J. DesBaillets, M.E.I.C.

## Peterborough Branch

*W. T. Fanjoy, A.M.E.I.C., Secretary-Treasurer.*
*J. L. McKeever, Jr.E.I.C., Branch News Editor.*

The Peterborough Branch of The Institute held their annual outing on Saturday, September 25th, 1937, at the Kawartha Boys, Camp on Clear Lake. A programme of sports had been arranged by a committee under Mr. B. I. Burgess, the main item of which was a softball game. This game, and particularly the prowess exhibited by "Babe Ruth" Cruthers and "Dizzy Dean" Fanjoy, proved to be of such interest to the horses and cattle for miles around that the game had to be halted to drive them (the horses and cattle) off the diamond. After six innings, one side gave up the struggle, so after a brief respite the teams were again pitted against each other in a nail driving contest which ended in a riot upon the discovery that someone had "driven" a nail into an open knot-hole. The final sport event was a buck-saw

Members of the Peterborough Branch at Clear Lake, Ont.

contest which showed up the degeneracy of the modern youth who has learned only to turn a switch on the electric range instead of to cut wood for a fire.

By this time all were ready to enjoy the very satisfying supper set out in the camp dining hall, after which the camp director, Mr. McClenaghan, led the party in some action songs. The Branch chairman, Mr. V. R. Currie, then called upon our oldest member, Mr. W. A. Logan, who was celebrating his 86th birthday the next day, to tell one of his baseball stories. Before telling his story, Mr. Logan gave an interesting account of a survey of the Clear Lake and Stoney Lake regions in which he took part some fifty years ago. Finally, Mr. Currie moved a very hearty vote of thanks to Mr. McClenaghan and his staff, and the outing was brought to a conclusion by the singing of the National Anthem.

## Design of Elevated Highways Competition

Traffic accidents and congestion constitute one of the most serious problems confronting the United States today. An annual toll of 37,000 fatalities, 125,000 permanent disabilities and 1,200,000 personal injuries creates a social situation demanding solution. Rapidly growing congestion, especially in cities, is an obstacle to efficient production and distribution, in general, and greatly depreciates the tremendous investment in automotive equipment of all kinds.

Leading traffic authorities have been forced to the conclusion that the only permanent solution of this joint problem of accidents and congestion is through the construction of major traffic routes particularly adapted to the operating characteristics and potentials of the automobile. Thus, they have projected a type of highway design to have the following physical and operating features:

1. It provides for a complete physical separation of streams of traffic moving in opposite directions.
2. It eliminates any direct access to abutting property.
3. It provides for an elimination of all intersections through a complete and continuous separation of grades.
4. It provides decelerating lanes for vehicles slowing to leave the highway at specially provided exits and accelerating lanes for vehicles entering from specially provided entries.

Traffic routes of this type of construction have already demonstrated their ability to carry safely large volumes of traffic through congested districts at open highway speeds. Several cities are now projecting comprehensive systems of this type and many others will undoubtedly follow.

An analysis of physical and fiscal elements leads to the conclusion that the essential functions of this special highway design can be achieved most practically and economically through elevated construction. To stimulate interest in this programme, which holds such great promise for the permanent solution of urban traffic problems, the American Institute of Steel Construction is sponsoring a competition for design of a structure of this type.

### Eligibility

Any person, persons or firm, with the exception of staff members of the American Institute of Steel Construction, may enter the competition and submit designs. The competition is open to persons of all nationalities and to amateur as well as to professional designers and architects. Those intending to enter the competition should notify the American Institute of Steel Construction immediately. There are no entry fees, and competitors may submit one or more designs. Each design will be considered a separate entry.

The competition will continue until March 31st, 1938, by which date all designs submitted by competitors must be in the hands of the American Institute of Steel Construction.

### Awards

Sole authority for the making of awards shall rest in a Jury of Award consisting of seven members as follows: Harland Bartholomew, City Planner, St. Louis; Col. Willard Chavalier, President, American Road Builders Association, Vice-President, McGraw-Hill Publishing Company, Inc., New York; Paul P. Cret, Architect, Philadelphia; Loran D. Gayton, City Engineer, Bureau of Engineering, Department of Public Works, Chicago; Paul G. Hoffman, President, The Studebaker Corporation, South Bend, Ind.; Albert Kahn, Architect, Detroit, and C. M. Pinckney, Chief Engineer, Borough of Manhattan, New York.

In submitting designs competitors must agree to abide by the decision of this Jury of Award.

The awards shall be as follows: First prize, $5,000; second prize, $2,000; third prize, $1,000; and ten honourable mention awards, each $100.

### Conditions

Each competitor shall submit drawings showing both structural and architectural treatment of an elevated highway structure. Two or more persons may jointly be a competitor. The designs shall be of such a character and of such detail as to be readily interpretable by a person normally familiar with structural and architectural design and may or may not be accompanied by a description.

The object of this competition is to develop a technique of design suitable to elevated highways. The competition will be judged on the originality of design, practicability of construction, the economical use and arrangement of materials, adaptability to actual conditions, and beauty. Designers may feel free to use new methods of design, new materials, and colour if they so elect.

Each design must incorporate all of the physical and operating features of elevated highway construction as previously set forth in this announcement.

The following technical conditions shall control the designs:

1. The structure shall be designed for an "H-20" loading, as a maximum, but any competitor may design for the exclusive use of passenger automobiles based upon such load factors as he may propose, provided that one "H-20" truck shall be assumed to be on any one span, with a congested load of passenger automobiles. The actual size of steel members need not be given. The loadings are given merely as a guide for proportioning materials and fixing construction limits.

2. The design shall provide for two eleven-foot operating lanes in each direction, physically separated and with adequate outer guard rails, but any competitor may submit additional designs providing for three or more operating lanes in each direction.

3. The structure shall be designed to be built over existing thoroughfares. Any type of support may be used, provided, however, that if supports are placed in existing roadways they must not interfere with the free flow of surface traffic. The competitor may pick out some actual site in his own community and develop a design to meet actual conditions.

4. Structures designed to pass over existing surface traffic shall provide for a free and unobstructed clearance of fifteen feet between the bottom of the elevated structure and the pavement of the street below.

All structural members shall be of steel. Other parts may be of any material suitable to the design.

Each competitor shall submit two drawings for each separate entry. Each drawing is to be 20 in. by 32 in., which shall include a half inch margin on all sides. The drawings are to be mounted on stiff board.

The first drawing shall be used for a perspective sketch or a plain elevation drawing of the proposed structure. There shall be no figures, dimensions, or written descriptive matter on this drawing other than the title.

The second drawing shall consist of an elevation covering at least one span and a cross section showing the supports and showing the provisions for ingress and egress drawn at a scale of one-eighth inch to the foot. There shall also be drawn at the same scale a cross section at the centre of the span to describe the construction. Such details as may be necessary are to be drawn at a scale of three-quarters of an inch to the foot. Dimensions, design data, size and kinds of material and other written descriptive matter may be used on this drawing.

Signatures will be concealed by the Institute until the jury has completed its selections.

Drawings must be sent to the American Institute of Steel Construction, V. G. Iden, Secretary, 200 Madison Avenue, New York City, not later than March 31st, 1938.

# EMPLOYMENT SERVICE BUREAU

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.

*All correspondence should be addressed to*

**The Employment Service Bureau, The Engineering Institute of Canada**
**2050 Mansfield Street, Montreal**

## Situations Vacant

YOUNG MECHANICAL ENGINEER, for sales and service work, for an established company selling specialized product. Location Montreal. Apply to Box No 1681-V.

YOUNG ELECTRICAL ENGINEER, with some experience in electrical design and draughting. Location Montreal. Apply to Box No. 1683-V.

MECHANICAL DESIGNER, experienced in machine design. Must also be a good draughtsman, for manufacturing plant in Montreal. Permanent position. Apply at once to Box No. 1684-V.

YOUNG ELECTRICAL ENGINEER, for sales position in Montreal and vicinity. Must speak French and English. Apply to Box No. 1485-V.

THE NATIONAL RESEARCH COUNCIL OF CANADA, announces two vacancies in the division of chemistry. One for a Junior Research Chemist at a salary of $2,100 a year, and the other for a Senior Research Assistant at a salary of $1,620 a year. Full information may be secured through the Employment Service Bureau of The Institute.

## Situations Wanted

PURCHASING ENGINEER, graduate mechanical engineer, Canadian. Married, with fifteen years experience covering construction and operation, principally having to do with specification and ordering of equipment and materials for new construction and maintenance. Details upon request. Apply to Box No. 161-W.

INDUSTRIAL ENGINEERING EXECUTIVE, with wide experience including fourteen years in design, construction, maintenance and operation of pulp and paper mills and power developments. Now employed, desires change of location. Apply to Box No 320-W.

STEAM POWER PLANT DESIGNER, with wide experience will be available after Dec. 1st. next, on completion of a six hundred and fifty pound pressure steam-electric plant now going into service. Apply to Box No. 525-W.

CIVIL ENGINEER, B.A.Sc., age 44, structural, harbour, executive. At present designing 32,000-h.p. development in Newfoundland. Available in near future. Apply to Box No. 536-W.

DOMINION LAND SURVEYOR, and graduate engineer with extensive experience on legal, topographic and plane-table surveys and field and office use of aero-photographs, desires employment either in Canada or abroad. Available at once. Apply to Box No. 589-W.

ELECTRICAL ENGINEER, B.Sc., E.E., age 38. Married. Ten years electrical experience; including, one year operation, one year maintenance, and four years on construction of hydro-electric plants and sub-stations. Four years electric maintenance and construction in pulp and paper mill. Also experience on highway construction and Geological Survey. Available at once. Apply to Box No. 636-W.

ELECTRICAL ENGINEER, B.Sc. E.E. '28. Two years with large electrical manufacturing company including test course, about two years in supervisory operating office of a large electrical power utility, and considerable experience in electrical and mechanical draughting. Location in Ontario preferable. Apply to Box No. 660-W.

YOUNG CIVIL ENGINEER, B.Sc. (Univ. of N.B. '31), with experience as rodman and checker on railroad construction, is open for a position. Apply to Box No. 728-W.

CIVIL ENGINEER, B.Sc., M.Sc., R.P.E.; Lieut. C.E., R.O. 16 years municipal, highway and construction, 5 years overseas. Married. Read, write and talk French. Will go anywhere. Apply to Box No. 737-W.

ELECTRICAL ENGINEER, B.Sc. '31, Jr.E.I.C. Single. One and a half years with contracting firm installing power and lighting equipment. Four years supervision over service and sales staff of electrical and radio company. Draughting and designing experience in power and compressed air layouts. Estimating and designing for electrical and mechanical layouts desired. Available on short notice. Apply to Box No 740-W.

## Situations Wanted

CIVIL ENGINEER, S.E.I.C., B.Sc. in C.E. (Sask. '32). Single. Age 27. Three years experience includes—instrumentman, compiling reports and draughting with a National Park; in charge of construction of water supply and sanitary sewer systems; assistant on city surveys. Excellent draughtsman. Available at once. Location immaterial. References. Apply to Box No. 818-W.

MECHANICAL ENGINEER, Jr.E.I.C., technical graduate, bilingual, age 35, married, experience includes five years with firm of consulting engineers, design of steam boiler plants, mechanical equipment of buildings, heating, ventilating, air conditioning, plumbing, writing specifications, etc. Five years with large company on sales and design of power plant, steam specialties and heating equipment. Available on short notice. Apply to Box No. 850-W.

STRUCTURAL ENGINEER, B.A.Sc., A.M.E.I.C. Twenty-two years experience in design of bridges and all types of buildings in structural steel and reinforced concrete. Three years experience in railway construction and land surveying. Apply to Box No. 856-W.

ELECTRICAL ENGINEER, B.Sc. (McGill '28), age 34. Experience includes transmission line and rural distribution construction and design. Some installation of motors and equipment, also house wiring. Available immediately. Apply to Box No. 940-W.

ENGINEER SUPERINTENDENT, age 44. Engineering and business training, executive ability, tactful, energetic. Had charge of several large projects. Intimate knowledge of costs and prices, reports and estimates. Available immediately. Any location. Apply to Box No 1021-W.

ELECTRICAL ENGINEER AND GEOPHYSICIST, B.Sc. (Man. '23), A.M.E.I.C. Married. Ten years specialized experience in the practical use of magnetic, electrical and mechanical instruments for the prospecting, surveying and mapping of mineral, oil and gas lands. Five years experience with telegraph, telephone and radio equipment. Capable of giving instruction in theory and practice in these lines and in college physics. Available on short notice. Apply to Box No. 1063-W.

CIVIL ENGINEER, A.M.E.I.C., with over twenty years experience in field and office on construction, maintenance, surveying, location, etc., desires position preferably of a permanent nature. At present near Montreal, but willing to locate anywhere. Apply to Box No 1168-W.

ELECTRICAL ENGINEER, B.Sc. '34 (Univ. of N.B.), S.E.I.C. Age 24, single. Desires any kind of electrical work. Will consider any location. Apply to Box No 1262-W.

ELECTRICAL AND RADIO ENGINEER, S.E.I.C., B.Sc. (Elec.) '32, M.Sc. '34. Experience includes four years part time operator for radio broadcast station, repairs to radio receivers and test equipment, design and construction of amplifiers and inter-office communication systems. Available on short notice. Apply to Box No. 1283-W.

CIVIL ENGINEER, M.E.I.C., R.P.E., married, age 40. Twenty-two years experience in detail, design, estimating and cost accounting of buildings, bridges, tanks and all types of structures; organization and management. Apply to Box No 1367-W.

CIVIL ENGINEER, B.Sc. 1910, A.M.E.I.C. Married. Twenty-six years experience on heavy construction work, both field and office; rails, roads, power house, hotels, bridges, etc. Location immaterial. Available at once. Apply to Box No 1470-W.

## Situations Wanted

CONSTRUCTION SUPERINTENDENT, M.E.I.C. Age 49. Married. Twenty-two years experience as engineer, superintendent and manager in charge of hydro-electric, mechanical production, structural steel erection, also considerable experience in steam plants, combustion, transmission lines, millwright work, complete mine installations, rock work, rock crushers and conveyors. Executive ability. Speaking French fluently. Location immaterial. Apply to Box No. 1482-W.

ELECTRICAL ENGINEER, B.Eng. (McGill '33). One and a half years experience in plant and production routine, and with considerable training in sales work. Bilingual, single, and available at once for any location. Apply to Box No. 1509-W.

ELECTRICAL ENGINEER, B.Sc. '31 (Univ. of Alta.), Jr.E.I.C. Age 28. Married. One year students' test course with C.G.E.Co. including testing and operation of transformers, meters, industrial control and switch-gear apparatus. Two years as instrumentman on highway construction. Desires electrical utility, commercial lighting or air conditioning work, location immaterial and available at once. Apply to Box No 1522-W.

CIVIL ENGINEER, B.Sc. '32, S.E.I.C., P.E.N.B., D.L.S.N.B., age 32. Experience in mining, both coal and metals, private and legal surveys, railroad construction, geology and building construction. At present in private practice in coal mining district. Desirous of changing location for position either in mining field or construction in Canada or abroad. Apply to Box No. 1562-W.

RESIDENT ENGINEER, familiar with all types of surveys and construction work including, railway, roads, irrigation, drainage, buildings and air ports. Executive ability. Had charge of several large projects. Intimate knowledge of reports and estimates. Available immediately. Any location. Apply to Box No 1567-W.

CIVIL ENGINEER, B.Sc. '17, O.L.S. Married. Executive and administrative experience. Extensive office and field experience in harbour works, dredging; both steam and electric railways in location, construction and maintenance; telephone works in design, construction and maintenance of pole lines, wire, cable and conduit; highways in location, construction and paving; municipal works in roads, sidewalks, sewers and water mains. Intimate knowledge of estimating, unit costs, cost accounting and analysis. Some knowledge of air conditioning. Willing to locate anywhere. Available at once. Apply to Box No 1587-W.

ELECTRICAL ENGINEER, B.Sc '27 (McGill), A.M.E.I.C. Age 36. Married. Bilingual. Three years experience in telephone work (installation of manual and automatic exchanges). One year electrical prospecting. Nine years experience with electrical power company. Apply to Box No. 1601-W.

CHEMICAL ENGINEER, graduate McGill '36. Eight months experience in commercial laboratory of large industrial plant. Knowledge of coal chemistry and boiler water treatment. Also some experience in pulp and paper control work. Location immaterial. Apply to Box No. 1617-W.

CIVIL ENGINEER, B.Sc. in C.E., A.M.E.I.C. Age 32. Married. Three years of pulp and paper mill experience, draughting, instrumentman and maintenance. One year as instrumentman on highway construction. Five years checking and designing reinforced concrete and steel. Apply to Box No. 1658-W.

ENGINEER, age 44, seeks connection as chief or plant Engineer, with pulp and paper, or textile concern. Apply to Box No. 1662-W.

METALLURGICAL ENGINEER, graduate 1936. Experienced in gold smeltering and milling, also in steel and pig iron manufacturing. Desires new connection in eastern Canada or Great Britain. Apply to Box No 1673-W.

ELECTRICAL ENGINEER, B.A.Sc., U. of T. '24, A.M.E.I.C., single, age 44. Ten years in supervisory operating office and two years in construction division (office and field) of large city electrical utility commission. One year factory supervision and tool design in manufacture of small electrical equipment. Wide experience with internal combustion engines. Experience handling heavy machinery. Private pilot's license for light aircraft. Full details on request. Available on short notice. Apply to Box No. 1693-V.

MECHANICAL AND ELECTRICAL ENGINEER, age 47, graduate University of Toronto, 1911. Machinist's trade. Two years tool design and quantity production in the U.S.A. Twelve years Canadian shop experience design and producing heavy equipment. Twelve years as chief sales engineer and field man for one of the largest Canadian national concerns. Experience in manufacturing and sales of pumps, engines, paper mill equipment, power plant equipment and specialties, electrical machinery, etc. Clean record, excellent connection. Apply to Box No. 1699-V.

ELECTRICAL ENGINEER, B.Sc., E.E. (Univ. of Man. '37). Experience in highway construction as inspector. Available at once. Apply to Box No. 1703-W.

# Preliminary Notice

## of Applications for Admission and for Transfer

October 27th, 1937

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

**Communications relating to applicants are considered by the Council as strictly confidential.**

The Council will consider the applications herein described in December, 1937.

R. J. Durley, Secretary.

*The professional requirements are as follows:—

**A Member** shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

**An Associate Member** shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

**A Junior** shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

**A Student** shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

**An Affiliate** shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

### FOR ADMISSION

BALLOU—FREDERICK H., of Vancouver, B.C., Born at Independence, Iowa, U.S.A., July 30th, 1884; Educ., Mech. Engr., Stevens Institute of Technology, Hoboken, N.J., 1908. R.P.E. of Alta.; 1908-16, ap'tice, dftsman. and engr., and 1916-20, asst. chief engr., i/c of Montana Divn. at Billings, Mont., for Greater Western Sugar Co., Denver, Colorado; 1920-22, chief engr., The Amalgamated Sugar Co., Utah; 1922-24, chief engr., W. J. McCahan Sugar Refining & Molasses Co., Philadelphia, Pa.; 1924-30, chief engr., American Beet Sugar Co. (now the American Crystal Sugar Co.), Denver, Colo.; 1931 to date, chief engr., B.C. Sugar Refining Co. Ltd., Vancouver, B.C., and Canadian Sugar Factories Ltd., Raymond, Alta.

## FOR TRANSFER FROM THE CLASS OF STUDENT

ANTENBRING—CLARENCE V., of 417 Machray Ave., Winnipeg, Man., Born at Winnipeg, Man., May 11th, 1903; Educ., B.Sc. (C.E.), Univ. of Man., 1926; 1925 (summer), instr'man. on constrn., Chicago, North Shore & Milwaukee R.R.; 1926 (summer), dfting., inspecting, designing on municipal engrg. works for town of Mundelin, also instr'man. on base line survey for Chicago subway system, for Kelker & DeLeew, Chicago; 1927 to date, designer of reinforced concrete structures for Cowin & Co. Ltd., Winnipeg, Man. (*St. 1934.*)
References: H. B. Henderson, E. S. Kent, A. E. Macdonald, G. H. Herriot, A. J. Taunton.

BACKLER—IRVING SAUL, of 1577 Van Horne Ave., Montreal, Que., Born at Manchester, England, Dec. 14th, 1907; Educ., B.Eng., McGill Univ., 1932. R.P.E. of Que.; Summers 1929-31, dftsman., Northern Elec. Co. Ltd., drilling machine, Noranda Mines, dftsman., Meagher Bros., Montreal, and asst. supt. on constrn. of apt. house, Montreal; 1932-33, designing engr., Allied Engineers, Montreal; 1933-35, designing engr., Backler & Gersovitz, Montreal; 1935 to date, consltg. engr., specializing in reinforced concrete and structl. steel design. (*St. 1930.*)
References: E. Kugel, E. Brown, R. DeL. French, J. Weir, G. J. Dodd.

BAILEY—LORING WITHALL, of Grand Falls, N.B., Born at Quebec, Que., July 30th, 1903; Educ., B.Sc. (E.E.), McGill Univ., 1925; 1923 (summer), operator, British American Nickel Corpn., Deschenes, Que.; 1925-27, students' course, and 1927, test foreman and dftsman., Canadian Westinghouse Co., Hamilton, Ont.; With the Gatineau Power Company as follows: 1927-28, res. engr. at St. Jerome, Que. i/c of constrn. of substation and installn. of equipment, also supervision of equipment installn. at Rawdon power house; 1928-34, designing engr. at Ottawa, and from Nov. 1934 to date, station supt., Grand Falls Station, and in charge of company property in New Brunswick. (*St. 1922.*)
References: W. G. C. Gliddon, G. G. Gale, W. E. Blue, A. V. Gale, R. F. Howard, J. Woodside, G. Stead, J. S. Parker.

BARBOUR—RONALD GRANVILLE, of Montreal, Que., Born at Saint John, N.B., Aug. 6th, 1903; Educ., B.Sc., 1924, M.Sc., 1927, Univ. of N.B.; 1924-26, engrg. course, Can. Gen. Elec. Co. Ltd., Peterborough and Toronto; with the Aluminum Co. of Canada Ltd., as follows: 1926-27, technical asst. on generating plant constrn., Arvida, Que.; 1927-28, asst. chief operator, generating plant; 1928-29, electl. engr. for constrn. and subsequent operation of electric slag ore reduction plant; 1929 to date, electl. engr., with McDougall & Friedman, Consltg. Engrs., Montreal, Que. (*St. 1924.*)
References: G. K. McDougall, E. A. Ryan, F. J. Friedman, M. S. Macgillivray, J. D. Fry, C. P. Creighton.

BARR—FREDERICK GORDON FORDYCE, of 43 Admiral Road, Toronto, Ont., Born at Toronto, Nov. 11th, 1904; Educ., B.A.Sc., Univ. of Toronto, 1927; With the Bell Telephone Company of Canada as follows: 1927-28, student engr., and 1928-30, asst. to toll line engr., gen. traffic dept.; 1931 to date, asst. to equipment engr. (western area), traffic engrg. of central office equipment, principally dial equipment. (*St. 1926.*)
References: T. R. Loudon, C. L. Brooks, D. G. Geiger, A. M. Reid, A. S. Poe.

BERRINGER—ORMUS BENJAMIN, of Lunenburg, N.S., Born at Lunenburg, Nov. 19th, 1907; Educ., B.Sc. (Mech.), 1932, B.Eng. (Civil), 1935, B.Eng. (Elec.), 1935, N.S. Tech. Coll.; 1930 (summer), asst. mech. inspr., Aluminum Co. of Canada; 1935 (summer), road inspr., Milton Hersey Co. Ltd.; 1935, constrn. supt., Standard Paving Co.; 1936 (May-Nov.) and 1937 (May-Oct.), plant inspr., Milton Hersey Co. Ltd.; at present paving inspr., Lunenburg, N.S. (*St. 1933.*)
References: S. Ball, M. F. Macnaughton, H. W. L. Doane, G. J. Currie.

BILLETTE—ROGER, of 549 Bonaventure St., Three Rivers, Que., Born at Valleyfield, Que., Dec. 23rd, 1909; Educ., B.Sc. (E.E.), McGill Univ., 1931. R.P.E. of Que.; Summers 1928-29, surveying and dfting.; 1931 (3 mos.), sheet steel and ornamental iron salesman; 1932 (Jan.-Apr.), heating layouts, Gurney Massey Co.; 1932 (Apr.-Oct.), electl. constrn., Beauharnois Constrn. Co.; 1933, gen. dfting., City of Valleyfield; with the Shawinigan Water & Power Company as follows: 1933-36, junior distribution engr., 1936 (Feb.-June), meter shop asst., and June 1936, to date, designer and tester, electl. repair dept. (*St. 1931.*)
References: R. H. Mather, A. C. Abbott, C. R. Reid, A. S. Runciman, J. H. Fregeau, L. McGillis.

BOUTILIER—FREDERICK THOMAS, of Arvida, Que., Born at Sydney, N.S., April 5th, 1904; Educ., B.Sc. (Mech.), 1928; 1928 (June-Nov.), asst. to steam engr., Dom. Steel and Coal Corpn., Sydney, N.S., and Nov. 1928 to Dec. 1929, dfting and designing for same company; 1930-31, technical asst., mechl. dept., Aluminum Co. of Canada, Arvida, and with same company to date as follows: 1931-32, technical asst. in aluminum plant; 1932-35, gen. foreman, remelting and alloy dept., and Sept. 1935 to date, asst. to Aluminum Plant Supt. (*St. 1928.*)
References: A. P. Theuerkauf, W. S. Wilson, H. R. Wake, A. W. Whitaker, Jr., M. G. Saunders, A. C. Johnston, R. H. Rimmer.

BRADDELL—EBERHARD SYLVESTER, of 1441 Drummond St., Montreal, Que., Born at East Bay, Man., Dec. 16th, 1910; Educ., B.Sc. (E.E.), Univ. of Man., 1932; 1929 (summer), gen. mech., C.P.R., Sask. and Alta.; 1930 (summer), asst. steel inspr., also i/c production of galvanizing dept., Manitoba Bridge and Iron Works Ltd.; with the Winnipeg Electric Company as follows: 1931 (summer), engrg. asst. on (underground) electrolysis survey; 1932-34, engrg. asst. on electrolysis survey, investigation and research; 1934-36, asst. in distribution engr.'s dept., voltage testing and inspection on constrn.; 1937 (Mar.-Apr.), dftsman. in engrg. dept.; 1936 (Jan.-Oct.), asst. in apparatus sales dept., English Electric Co. of Canada Ltd., commercial phases of manufacture of power apparatus; at present, power apparatus sales engr., Northern Electric Co. Ltd., Montreal, Que. (*St. 1931.*)
References: E. V. Caton, E. P. Fetherstonhaugh, J. N. Finlayson, T. C. Main, W. R. Bunting.

BRITTAIN—NORMAN WESTAWAY, of Minto, N.B., Born at Welsford, N.B., June 4th, 1905; Educ., B.Sc. (C.E.), Univ. of N.B., 1932. R.P.E. of N.B.; 1925-28, dftsman., appraising, switchboard installn. and line constrn., N.B. Telephone Co. Ltd., Saint John, N.B.; 1929 (summer), Provisional Pilot Officer, R.C.A.F., Camp Borden; 1930 (summer), instr'man. i/c surveys, Lake George Mines Ltd.; 1931 (summer), engr. i/c surveys for Miramichi Lumber Co. Ltd., in coal mines at Minto, N.B.; 1932 to date, private practice in civil engrg., mining, surveying, railroad constrn. etc. (*St. 1932.*)
References: J. Stephens, E. O. Turner, A. A. Turnbull.

BURRI—HENRY WILLIAM, of Port Hope, Ont., Born at New York, March 4th, 1909; Educ., B.Eng. (Mech,), McGill Univ., 1935; 1926 (6 mos.), installer, Bell Telephone Co. of Canada; 1926-28, telephone circuit dftsman., also checker, Northern Electric Co. Ltd.; 1928-30, mech. dftsman., Crane Limited; 1935-37, with Warden King Ltd. (subsidiary of Crane Ltd.), i/c plant drawing office, designing new machy., conveying systems, product, layouts, etc.; at present, with Mathews Conveyer Co. Ltd., Port Hope, Ont., proposition mech'l. engr., designing and drawing up proposed conveying systems to data, etc. (*St. 1934.*)
References: E. Brown, C. M. McKergow, L. R. McCurdy, A. R. Roberts, J. F. Plow.

CAMPLONG—LLOYD W., of Shawinigan Falls, Que., Born at Hudson, Que., Feb. 13th, 1906; Educ., 1925-27, McGill Univ., completed first year engrg.; 1927-28, layout engr., A. F. Byers & Co.; 1928-29, asst. field engr., Bell Telephone Co. of Canada; with Fraser Brace Engrg. Co. Ltd., as follows: 1925, reinforced steel checker; 1926, special cost clerk; 1927, asst. to constrn. engr.; 1929-30, quantity engr., and at present, quantity engr. at Shawinigan Falls, Que. (*St. 1930.*)
References: W. M. Mitchell, P. C. Kirkpatrick, A. F. Byers, J. A. Loy, W. J. S. Dormer, G. R. Stephen.

CAPELLE—WILLIAM ABRAM, of 418 Broadway Court, Winnipeg, Man., Born at Winnipeg, Dec. 8th, 1910; Educ., B.Sc. (C.E.), Univ. of Man., 1932; 1926-31 (summers), chainman, rodman and instr'man., C.N.R.; 1935-37, design and layout of store alterations, T. Eaton Co. Ltd., Winnipeg, and at present, purchasing agent, engrs. dept., of same company. (*St. 1929.*)
References: H. A. Dixon, J. H. Edgar, E. P. Fetherstonhaugh, J. N. Finlayson, J. L. Charles, A. E. Macdonald, N. M. Hall.

CARSON—MERVYN SHANNON, of 204 Wineva Ave., Toronto, Ont., Born at Landis, Sask., June 29th, 1909; Educ., B.Sc. (Civil), Univ. of Sask. 1930; 1929-30 (summers), estimating and dfting. on paving projects, instr'man. on sewer and water constrn. work, town planning, dfting and surveys; 1930-31, design of storm sewerage system, and field engr., City of Saskatoon; 1931-33, field engr., i/c prelim. survey, layout, etc., on a reinforced concrete bridge over the Saskatchewan River; Dec. 1935 to date, production engr.. Link-Belt Ltd., Toronto, Ont. (*St. 1931.*)
References: C. J. Mackenzie, R. A. Spencer, R. E. Smythe, A. R. Greig, I. M. Fraser.

CARTER—JOHN RUSSELL, of Asbestos, Que., Born at Kagawong, Ont., Sept. 17th, 1904; Educ., B.A.Sc., Univ. of Toronto, 1931; 1925-26, carpentering, installing machy. and machine tender in pulp mill; 1927-28-29 (summers), lumber mill work, instr'man., Welland Ship Canal, res. engr., highway constrn.; 1930-33, with H.E.P.C. of Ontario, on steel and reinforced concrete design on generating stations at Alexander, Chats Falls; transmission stations at Leaside, Woodstock and Guelph; 1935-36, Dept. of Northern Development of Ontario, res. engr. on highway constrn., location, dfting, estimating quantities, setting grades and general supervision; 1936 (June-Dec.), development and prospecting with mining companies in Northern Ontario; April 1937 to date, designer, engrg. dept., Canadian Johns-Manville Co. Ltd., Asbestos, Que. (*St. 1931.*)
References: E. B. Dustan, R. C. McMordie, H. R. Cleveland, C. R. Young, R. E. Smythe.

CLARKE—OWEN MAWBEY, of Ewarton, Jamaica, B.W.I., Born at Westmoreland, Jamaica, June 8th, 1908; Educ., B.Sc., McGill Univ., 1931; 1928 (summer), asst. chemist, La Salle Montreal Coke Company; 1930 (summer), dftsman., Anglo-Canadian Pulp and Paper Mills, Quebec; 1931-32, inspr. of sub-assembly, Victor Radio of Canada; 1932-34, engr., and 1934-37, chief engr. and chief chemist, Worthey Park Sugar Factory, Ewarton, and at present, asst. manager, Worthey Park Estate. (*St. 1929.*)
References: C. M. McKergow, J. O'Halloran, H. W. Lea, E. Brown, L. R. McCurdy.

CLARKE—STEPHEN HERBERT, of Montreal, Que., Born at Hinckley, Leicester, England, Oct. 6th, 1903; Educ., 1920-24, Faraday House Electrical Engrg. College. Diploma, 1924; 2 years ap'ticeship with elect'l. mfg. companies under supervision of Faraday House; 1924-25, dfting office ap'tice, 1925-26, junior dftsman., W. H. Allen Sons and Co., Bedford, England; 1926-27, junior dftsman., Electric Constrn. Co., Wolverhampton; 1927-28, dftsman., Can. Gen. Elec. Co. Ltd., Peterborough, Ont.; 1929-31, elect'l. layout and dfting., Power Corporation of Canada, Montreal; 1931-32, with F. B. Brown, M.E.I.C., consltg. engr., i/c design and installn. for street lighting system for Town of Mount Royal; 1936 to date, i/c layout and constrn. of electrical plants for gold mines in Northern Quebec; at present, elect'l. engr., for Sladen Malartic Mines Ltd. (*St. 1933.*)
References: S. S. Colle, G. Kearney, H. S. Grove, J. H. McLaren, J. T. Farmer.

COOPER—LAWRENCE O'TOOLE, of 95 John St., Sudbury, Ont., Born at New Liskeard, Ont., Jan. 14th, 1909; Educ., B.Sc., 1930, M.Sc., 1931, McGill Univ., 1925-27, (summers), surveying, McIntyre Mine; 1928-30 (summers), R.C.A.F. Training course; 1931-34, lecturer, McGill Univ.; 1934 (summer), i/c triangulation party, 1934 to Aug. 1937, mine mechl. dept., and at present, asst. to master mechanic of mines, International Nickel Company, Sudbury, Ont. (*St. 1928.*)
References:—E. Brown, F. M. Wood, C. M. McKergow.

CRAIG—CARLETON, of Montreal, Que., Born at Ottawa, Ont., April 25th, 1909; Educ., B.Eng., 1933, M.Eng., 1934, McGill Univ.; Summers—1926-29, rodman, C.N.R., 1930, inspr., C.N.R., 1931, clerk, Bureau of Economics, C.N.R., 1937, instr'man. and inspr., C.N.R.; 1934 to date, lecturer, dept. of civil engrg. and applied mechanics and dept. of mathematics, McGill University, Montreal, Que. (*St. 1931.*)

## Business Management and the Scientific Point of View*

*Harry Arthur Hopf, M.C.S., M.B.A., M.S.,*
*Managing Partner, Hopf, Kent, Willard and Company, New York.*

**An Address delivered before the Montreal Branch of The Engineering Institute of Canada on April 29th, 1937.**

SUMMARY.—The address discusses the application of scientific methods to the direction of business enterprises, more particularly as regards the four principal activities, planning, organizing, co-ordination and control. A number of specific problems are mentioned as coming under the four major headings. The qualifications necessary for a scientific business executive are indicated and attention is drawn to the scope and importance of possible economies in management which should result from a scientific attitude on the part of executives.

In his book, "The Last Puritan," which he describes as a memoir in the form of a novel, George Santayana, the philosopher, makes a young German governess express her opinion of American business men in the following terms, which she employs in a letter written to her sister:

> ". . . they hate to think. They are too busy, too tired: or if they half form an opinion in spite of themselves, they won't take the trouble to express it accurately, or to defend it. They laugh at what people *think*, even at what they think themselves, and respect only what people *do*. Yes, my dear, and beneath that horrid cynical scepticism, there is something deeper still. They are *afraid of the truth*."

Certainly this is not a flattering picture of American business men. Doubtless the young governess, in penning her delineation, was not conscious that, although she might perhaps with propriety single out American business men for special emphasis in this connection, she had made an observation which is well-nigh universal in its application.

After long experience in dealing with business men in a number of countries, it has been borne in upon me that they do not, generally speaking, think in fundamental terms. Most of them are technicians, familiar with the traditions, procedures and problems of the functions within which their experience has been generated. In other words, all their thinking has been vertical, and they have not acquired the habit of thinking horizontally, which is a pre-requisite to successful exercise of the responsibilities associated with the direction of a business enterprise.

Under present-day economic conditions, when business appears to be ground between the upper mill-stone of the demand of labour for an increasing return upon its effort, and the nether mill-stone of the need for lowering prices to the consumer—the only way in which greater distribution of goods can be achieved—the necessity for thinking in fundamental terms about the internal and external problems of business is more urgent than ever.

When those in charge of this programme requested me to suggest a subject that would prove fitting for discussion on this occasion, reflections such as these convinced me that it would be appropriate to select "business management" as the broad, general background of my address, and to stress in that connection the validity and importance of the scientific point of view.

During the past two or three decades, business management has gradually become exposed to the influences emanating from the application of the rule of science. In the rapidly changing world of today, all fields of human endeavour are more and more experiencing the impact upon existing conditions of the concrete results produced by the genius of the scientific mind; wherever we turn, we are faced with the dynamics of a new and unprecedented order of things which demands both readjustment and control. In the business world, progress can be made only by so plotting a course through a sea of uncertainties as to avoid the Scylla of ignorance, extravagance, prejudice, discord, incompetence and vacillation, on the one hand, and, on the other, to steer clear of the Charybdis of over-organization, greed for profit, ruthless competition, economic illiteracy, unparalleled size and autocratic dominance.

While it must be recognized that science can be of benefit to mankind only if the discoveries it makes available are exploited in behalf of advancement of the common good, we may postulate that the scientific point of view—the habit of thought that scorns to employ in the solution of problems any process except the scientific method—should be an important, if not indispensable, part of the mental equipment of all persons truly desirous of making contributions of permanent value to the advancement of business management.

May I add to these introductory remarks two statements which seem apposite to me? First, I wish to point out that the implications of the theme which I have chosen are constantly pervading my professional and avocational activities; I am, therefore, happy to have the opportunity of sharing with this audience the product of my experience, thought and study with respect to them. Secondly, it is my considered judgment that in her development toward higher planes of economic and social accomplishment, Canada occupies a position of importance in which she is able to make a contribution of marked value to the advancement of management, and, *per contra*, to benefit from further application of the art and science in the cause of her industrial, commercial, financial and technical progress.

### WHAT IS THE SCIENTIFIC POINT OF VIEW?

I have previously indicated that science and the scientific method are entering gradually into the field of business management. A business executive who does his work scientifically is more valuable to his company than one who, however well he may be natively endowed, allows rule-of-thumb methods and unsupported thinking to permeate his activities.

What is the scientific point of view? In order to answer this question, we must first define the word "science."

---

* Delivered at a joint meeting of the Montreal Branch of The Engineering Institute of Canada, Montreal Personnel Association, Chartered Institute of Secretaries, Society of Chartered Accountants of the Province of Quebec, and the Canadian Society of Cost Accountants and Industrial Engineers.

In his scholarly work, "The Organization of Knowledge,"[1] Bliss describes science as "verified and organized knowledge, analytic and synthetic, rationally and methodically proceeding from experiential data and perceptual relations to generalizations, theories, laws, and principles, and to conceptual systems."

If we turn to some of the great mathematicians of the past, men whose genius of intellect enabled them to penetrate the mysteries of science and to reveal them to the astounded gaze of mankind, we find in their writings illuminating sidelights on the meaning and basis of science. So, for example, Sir Francis Galton, who expressed the firm belief that "until the phenomena of any branch of knowledge have been submitted to measurement and number, it cannot assume the dignity of a science."[2] And this statement, made and often repeated by Adolphe Quetelet, Belgian astronomer and statistician, is of similar import: "The more advanced the sciences have become, the more they have tended to enter the domain of mathematics, which is a sort of centre towards which they converge. We can judge of the perfection to which a science has come by the facility, more or less great, with which it may be approached by calculation."[3]

Science, then, is organized knowledge which has been submitted to the acid test of measurement and verification. It is not a hodge-podge of facts brought together in more or less related order; it is knowledge acquired through research, supported by utilization of the scientific method, i.e., observation, experimentation and formulation of verifiable law.

In his great work, "An Introduction to the Study of Experimental Medicine," Claude Bernard, the famous French physiologist, contemporary of Pasteur and member of the Académie Française, put the case for science in this fashion:

> "By simply noting facts, we can never succeed in establishing a science. Pile up facts or observations, we shall be none the wiser. To learn, we must necessarily reason about what we have observed, compare the facts and judge them by other facts used as controls. But one observation may serve as control for another observation, so that a science of observation is simply a science made up of observations, i.e., a science in which we reason about facts observed in their natural state, as we have already defined them. An experimental science, or science of experimentation, is a science made up of experiments, i.e., one in which we reason on experimental facts found in conditions created and determined by the experimenter himself."[4]

With these interpretations of the significance of science before us, we are better prepared to analyze the meaning of the scientific point of view; in fact, the quotations given have assisted in answering, at least partly, our query on that subject. It is evident that a point of view, to be characterized as scientific, must be dominated by the desire to discover the truth, or, as we are apt to say in every-day parlance, to get at the facts. Unfortunately, however, for the cause of science in business, much of what passes for fact is produced by methods which, to say the least, are open to grave question, because quantitative analysis, based on measurement, has played no part in them. "Until measurement is possible in a science," writes Mills, "it is unavoidable that its observations and findings should lack precision, no matter how brilliant the flashes of intuition or how painstaking the labours of its students may be."[5]

The scientific point of view, then, rests firmly upon the foundation of research, supported by the scientific method; in approaching the solution of problems in a chosen field of investigation, it rigorously excludes from consideration, and scorns to employ, any method which is not in harmony with the tenets of science. At the risk of quoting unduly from Bernard, whose "Experimental Medicine" constitutes an illuminating revelation of the mental processes of a great scientific investigator, permit me to read these additional paragraphs:

"The true scientist is one whose work includes both experimental theory and experimental practice. (1) He notes a fact; (2) apropos of this fact, an idea is born in his mind; (3) in the light of this idea, he reasons, devises an experiment, imagines and brings to pass its material conditions; (4) from this experiment, new phenomena result which must be observed, and so on and so forth. The mind of a scientist is always placed, as it were, between two observations; one which serves as a starting point for reasoning, and the other which serves as conclusion."[6] Finally, Bernard holds that "scientific generalization must proceed from particular facts to principles; and the principles are the more stable as they rest on deeper details, just as a stake is the firmer, the farther it is driven into the ground."[7]

Without wishing to extend this discussion of the scientific point of view, I cannot resist the temptation of referring to certain lofty thoughts and eternal truths which have been eloquently expressed by great leaders in different departments of human knowledge when endeavouring to interpret the spirit of science and the real meaning of the scientific approach to the solution of fundamental problems.

Ruskin once said that "the work of science is to substitute facts for appearances and demonstrations for impressions." Goethe asserted, with that calm, clear vision which characterized the poet-philosopher, that "we see only what we know." Huxley expressed the belief that science is nothing but trained and organized common sense. On one occasion he also spoke of "the great tragedy of science—the slaying of a beautiful hypothesis by an ugly fact." Whitehead alleged that "it is no paradox to say that in our most theoretical moods we may be nearest to our most practical applications." Marcus Aurelius concluded that "nothing is so productive of elevation of mind as to be able to examine methodically and truly every object which is presented to thee in life."

And last, Poincaré, perhaps the greatest mathematical philosopher of modern times. In an essay on "Science and Reality," he reveals one of those brilliant flashes of intellect of which only a genius of the first order is capable. In stressing the value of devotion to science for its own sake, he concludes with this profound observation:

> "All that is not thought is pure nothingness; since we can think only thoughts and all the words we use to speak of things can express only thoughts, to say there is something other than thought, is therefore an affirmation which can have no meaning. And yet—strange contradiction for those who believe in time—geologic history shows us that life is only a short episode between two eternities of death, and that, even in this episode, conscious thought has lasted and will last only a moment. Thought is only a gleam in the midst of a long night. But it is this gleam which is everything."[8]

Much as we may admire the scientific point of view and acknowledge it as one of the chief causative factors in the advancement of civilization throughout the ages, we are forced to recognize the comparatively limited extent to which, after all, it pervades business today. Unlike the college professor who in a burst of scientific

fervour expressed the hope that his subject might never become practical, we should regard it as greatly to be desired that the bond between science and business be strengthened as time passes, so that ultimately business men, discerning the wisdom of this union, will never fail to explore in truly scientific fashion the foundations upon which all sound accomplishment must inevitably rest.

### WHAT IS BUSINESS MANAGEMENT?

In order to facilitate understanding of what is to follow, it is desirable to set forth initially a definition of the term, "business management."

Despite the many definitions advanced by others, I have elected to define management as "the direction of a business enterprise, through the planning, organizing, co-ordinating and controlling of its human and material resources, toward the achievement of a predetermined objective." This definition, it will be seen, places the emphasis upon the dynamic aspects of management; in other words, it views management as an art, but, it should be added, with complete acceptance of the scientific foundations upon which the art must rest.

It will be observed from the definition that the master-function of direction sub-divides itself into the four functions of planning, organizing, co-ordinating and controlling. Broadly speaking, the first of these functions concerns itself with the formulation of a programme of action, based upon present and probable future requirements and conditions; the second involves combination, development and adaptation of all appropriate structural elements; the third addresses itself to the establishment of sound integration, co-operation and motivation, and the fourth is concerned with the measurement of performance, supervision and maintenance of standards.

Within the compass of the activities of a single enterprise, planning, organizing, co-ordinating and controlling, which are the *sine qua non* of management, must be applied first to the master objective of the enterprise, then to the major divisions of finance, production, distribution and facilitation, and then through the greater and lesser organization sub-divisions to the last worker on the smallest operation.

When formulating a concept of planning, mental processes concern themselves readily and naturally with the establishment of the best methods, the creation of standards of work and cost, and the scheduling of operations. To give practical expression to this concept, it is usual to apply it primarily to the discovery and introduction of the most effective methods of performance, and to utilize in this connection such quantitative measures of volume, cost and time as will lead to increasingly effective and economical operating results.

Much thought and study have been devoted to the problems involved in the discovery of the best or most effective methods. In fact, many proponents of improvement in the art of management have allowed their advocacy thereof to crystallize in the statement that a controlling consideration is the determination of the "one best way." As a contention, this statement is entitled to weight, but in practice it must always be surrounded by marked qualifications. Under the dynamic conditions amid which the art of management is exercised, the one best way must constantly be modified by an enormous number of variables, of which there need be emphasized only the elements of organization, personnel, equipment, volume, cost and time. Determination of the one best way resolves itself, then, into a constant readjustment of such elements to changing conditions, which becomes, in almost every instance, a continuous process. It is this aspect of planning with respect to methods that must be stressed, for only too frequently the fallacy involved in adherence to a supposedly best way is not discerned until long after methods have crystallized into a routine which gradually and persistently departs more and more from correct requirements.

Quantitative measures of volume, cost and time are tools which, when properly employed, constitute great aids in advancing the art and science of management. From the point of view of planning, the element of volume presents a most important and difficult problem. Material fluctuations are present even in normal times; during periods of depression, they are either supplemented or altogether replaced by marked downward trends. In either case, planning implies the most effective readjustment of operating conditions to the current and prospective volumes of work, as expressed quantitatively in appropriate units of measurement. With regard to the elements of cost and time, these are in some respects fixed and in other respects variable, and because of this fact they must be given constant attention. Planning has for its objective the attainment of that level of performance which is in harmony with valid standards in terms of volume, cost and time.

Within the limits here discussed, planning may be described, broadly, as a function which leans heavily on the processes of analysis, simplification and standardization. The first of these, scientifically undertaken, constitutes the correct approach to investigation of existing conditions; the second frankly recognizes and adjusts itself to the constant need for elimination, revision and improvement of steps in the procedures, and for modifications in the equipment necessary to achieve the objectives involved; the third represents the constant striving for perfection which is so ancient a characteristic of human endeavour. Analysis, simplification and standardization, in effect, set the stage for purposeful planning as applied to the erection of adequate foundations required by other divisions of the function of direction.

When formulating a concept of organizing, it should first of all be recognized that underlying every form of business enterprise there will be found an organization structure, or framework, which is designed to provide the necessary foundation for the activities to be carried on. In comparatively rare instances will the structure be well adapted to the attainment of the objectives it is intended to promote. More often it will turn out to be fixed or rigid in character, and lagging far behind current conditions and requirements. Indeed, in numerous instances the structure will be so poorly devised that it will constitute a formidable interference with constructive accomplishment.

Now, it cannot be too often emphasized that organization is but a means to an end, and not the end in itself. It is a continuous process that depends for its success upon the maintenance of such degrees of combination, development and adaptation of the structural elements as will keep the business machine moving swiftly, surely, and without frictional losses, toward its appointed objective. Sound organization expresses recognition of the fact that purpose and conditions are controlling considerations, and that the design of the structure must be adapted to them.

Analysis of the influence of organizing upon accomplishment at first leads to the conclusion that at all stages of size of a business enterprise a plan of organization can be devised that will adapt itself effectively to existing requirements. But when one probes farther into the question, it often becomes apparent that where adaptation to requirements exists, it has been the resultant, not of a conscious process of organizing, but mainly of fortuitous circumstances. It will be recognized that the influence of the factor of personnel in shaping the process is great; where one encounters instances of sound conditions of organization, it frequently turns out that they are referable to a welding of the human elements that has proceeded without the assistance of a well-ordered plan, and has been dominated by psychological adjustments of varied character.

Study of the organization structures of hundreds of business enterprises, both in America and abroad, has convinced me that in many instances they reflect the forces of personality and power rather than the logic and strength of proper structural relationships. In this fact lies the explanation for the ultimate arrival of such enterprises at a plateau of progress from which emergence more often follows a downward than an upward curve. That a business cannot permanently occupy levels of effectiveness higher than those clearly determined by the capacity of its executives is self-evident, but it is not generally understood that the influence of superior organization upon the accomplishments of mediocre executives can raise the enterprise to heights not otherwise attainable.

Experience has shown that such organization faults as over-elaboration, unwarranted subdivision of activities, unjustifiable extremes of functionalization, excessive departmentalization, and others that could be cited, are important contributing factors to the failure of many businesses to achieve sound conditions of development. Their influence is subtle and not easily discerned; it is made more compelling by the fact that even where there is the will to organize soundly, this is often frustrated by a clash between the points of view of ownership and management—especially when the two roles are merged in one and the same person or group—with ownership usually dominant, and scant regard accorded to such abstract considerations as sound principles of organization.

Co-ordinating, as already stated, has to do with the establishment of sound integration, co-operation and motivation. Perhaps the most important aspect of the problems involved in co-ordinating the activities of a business enterprise is the integration of line and staff functions, or, in other words, integrating the work of the persons responsible for operating results with that of the persons who act in an advisory capacity.

The interaction of line and staff often produces situations of extremely delicate character, requiring skilful handling and experience in the art of intelligent compromise. Regardless of how clearly defined are the lines of demarcation between functions and individual spheres of activity, there is unfortunately a widespread tendency in business institutions for executives gradually to depart from any scheme of organization laid down. Moreover, conflicts of personality, which are of frequent occurrence, tend in the long run to lead to a blurring of functions, to competing jurisdiction over the same subject matter, and to the forcing of the organization pattern into distortions which correspond roughly to the degree of aggressiveness, or lack of it, displayed by executives in various important positions. Dealing successfully with situations of this kind involves utilizing every factor adaptable to integration and to the advancement of the interests of the organization as a whole.

Every attempt at co-ordination through proper integration and adjustment, brings the opportunity, indeed the necessity, for co-operation. Co-operation is a binding process which should pervade every activity of the organization. Practically every act of management requires for its consummation that co-operative relationships be maintained between two or more persons. Here arises, however, the need for determining just what co-operation involves. It is not difficult to secure general agreement to the statement that management should so perform its function as to be sure that adequate co-operation will exist. The problem is to determine the best methods of bringing about these relationships.

The existence of co-operation depends primarily upon the setting by top executives of an example which may be found worthy of emulation by other members of the organization. It is, of course, true that business organizations cannot be kept moving forward at the requisite rate of speed by maintaining the town-hall meeting brand of management, or by attempting to secure universal agreement to a proposition before it is adopted. Particularly in disturbed times, it is essential that management keep a firm hand on the helm and demonstrate its ability to issue specific orders and exact prompt and willing obedience thereto. It is not, however, inconsistent with this need that a decent regard be had for the points of view of all whose opinions may contribute something worthwhile to the progress of the institution.

The acid test of the existence of true co-operation is the presence of a twofold relationship of loyalty—loyalty to his superior on the part of the subordinate and loyalty to his subordinate on the part of the superior. If this relation of mutual confidence exists, the result, in practical terms, spells the finest type of co-operation.

The preceding statements lead naturally to a brief consideration of the subject of motivation. Effective stimulation of human beings is among the most powerful agencies which may be utilized to further the aims of a business enterprise, or any other human undertaking. Executives and employees alike respond readily to the right stimuli. An understanding and alert management will easily discover practical methods of motivating its subordinates so that their desire for worthwhile accomplishment will express itself dynamically.

The essentials of co-ordinating, it may be said, consist of a process of adjusting material and human resources to a soundly integrated organization structure, a process which is dependent for effective operating results upon methods of co-operation and motivation that denote morale, esprit de corps and leadership.

Finally, what can be said by way of interpretation of the function of controlling, the fourth and last to be considered? There is hardly a word in the terminology of management which is used with so many and such widely differing applications. The owners of a business possess *control* over its material and human resources; when bankers step into the picture, *control* is said to pass into their hands; administration and management usually have the power to exercise *control* over operations; the financial affairs of an organization are *controlled* through the budget; *control* over production is largely a function of the planning department; the activities of salesmen are *controlled* by the sales manager; *control* over office operations is the responsibility of the office manager.

For present purposes, a restricted interpretation of the concept of control will in no sense detract from its importance; hence, it is postulated that we are here dealing with a terminal function which concerns itself, as previously indicated, with measurement of performance, supervision, and maintenance of standards. Thus it will be seen that control is a dynamic concept, and that in operation it tends to keep the enterprise upon the appointed course, to provide it with the proper momentum, to determine its rate of progress, and to evaluate the operating results produced.

The onward march of industry, from small beginnings to great size, has been accompanied at all stages by perplexing questions of control. Indeed, in the period which has elapsed since the turn of the century, such questions have assumed particular prominence in view of the magnitude and complexity of the great corporations which have become characteristic of the economic order in which we live. It is widely recognized by students of the problem that human development has not kept pace with corporate size, and that, therefore, even the most finely conceived processes of control as yet made available are inadequate for the purpose of determining, achieving, and maintaining optimal conditions. While the last word has not yet been said upon this subject, it is certainly demonstrable that when institutions such as banks, life insurance companies, public utilities, mail order houses, department stores, and great concerns in industrial fields pass a certain stage in their development, something seems to happen to them that is in the nature of decreasing success, if not, indeed, of pronounced loss.

It is impossible to generalize with respect to the causes responsible for such reversals, but we do know that supervision often breaks down because it is placed in the hands of technicians whose ability to deal with *things* far outweighs their capacity for controlling the *human beings* for whose success they are responsible. Moreover, we are aware that, despite the era of science in which we are living, comparatively little has been done in the field of measuring performance in general, and practically nothing in evaluating scientifically the results produced by comparable groups of executives. As for maintenance of standards, rarely are executives furnished with valid norms, qualitatively and quantitatively expressed, and hardly ever is recognition given to the need for differentiating adequately between controllable and non-controllable conditions affecting performance. It is a regrettable fact that these shortcomings exist; to a great extent they are preventable, but I question whether much progress will be made with their eradication until a new generation of executives appears upon the scene, endowed with sufficient intelligence and scientific training to understand, accept, and practice the principles underlying sound methods of control.

### WHAT ARE SOME OF THE SPECIFIC PROBLEMS TO BE SOLVED?

The first step in the application of the scientific viewpoint to business management, consists of realization of the fact that only through controlled investigation, experimentation and the building up of a body of verified principles, can management emerge from the trial and error stage to the attainment of certain and effective results. If management is to be intelligently and purposefully exercised, it must visualize the area with which it has to deal, must isolate all of the forces within that area which are operating for or against the attainment of the desired results, and must, above all, learn to cope with many specific problems whose existence and nature can be discerned only by penetrating scientific analysis.

What are the problems which confront business management in seeking to achieve a predetermined objective? Bearing in mind the four functions previously stated, namely, planning, organizing, co-ordinating, and controlling, let me call attention briefly, under these headings, to some of the problems with which management is bound to concern itself, even in progressive and apparently well organized institutions:

A. *With Respect to Planning*

Analysis

1. To what extent does useless work exist and how can it be eliminated?
2. What is the most effective manner of reducing peak loads?
3. Has each position in the organization been analyzed as to work performed and qualifications of worker?
4. Do space arrangements obstruct or promote the proper flow of work?

Simplification

5. What policy should govern the destruction of old records?
6. Has "paper" work been reduced to a minimum?
7. Can any operations be combined to advantage with others?
8. Can any operations be more advantageously performed by outside organizations?

Standardization

9. Are there any limits to the value of mechanization?
10. Have all forms and records in use been properly standardized?
11. Is there in existence an effective system of control over the origin, revision and elimination of printed forms?
12. Is uniformity of equipment carried throughout the organization?

B. *With Respect to Organizing*

Combination

13. To what extent are service functions centralized?
14. Is ultimate control centralized?
15. Is a centralized personnel department in existence?
16. Is a centralized planning department in existence?

Development

17. How far can work be advantageously subdivided?
18. Have changes in size been accompanied by the necessary fundamental changes in organization?
19. Has development of the organization structure been warped or restricted to conform to individual attributes of the executive personnel?
20. How many levels of authority are present in the organization structure?

Adaptation

21. To what extent is it advisable to change operations from a sequential to a simultaneous basis of performance?
22. Do the duties assigned to each executive call forth his best ability and engage his entire time?
23. Is any executive overburdened with duties?
24. Is authority placed as closely as possible to the point where action originates?

C. *With Respect to Co-ordinating*

Integration

25. Are the relations between staff and operating departments promotive of superior operating results?
26. Is authority clearly defined and allocated?
27. Is authority to make important decisions placed in competent hands?
28. Are all activities effectively co-ordinated?

Co-operation

29. Have executives and supervisors an organization viewpoint, rather than a departmental viewpoint?
30. Are systematic training procedures employed?
31. Are adequate measures taken to maintain high standards of health among employees?
32. Are suitable and comfortable working conditions provided?

Motivation

33. What is the most effective type of financial or non-financial incentive to be utilized in a given situation?
34. To what extent is it advisable to invite suggestions from employees?
35. How can the fetish of seniority be abolished?
36. What is the relation between remuneration and length of service?

D. *With Respect to Controlling*

Measurement

37. What is a fair day's work in given occupations?
38. What should be the elapsed time for given cycles of work?

39. How can this period, once established, be controlled?
40. Is each department measured on a profit and loss basis?
41. Is the performance of each individual executive measured?

Supervision

42. What is the relation of supervision to increased production?
43. How can the optimal degree of supervision be ascertained?
44. How many levels of supervision are in effect?
45. Is planning separated from performance?

Maintenance of Standards

46. What is the best method of checking given types of work?
47. How far should the checking process be carried?
48. How can detailed information best be transformed into control information?
49. Are satisfactory standards developed for measuring financial results?
50. Is the cost of compiling statistics and reports kept within justifiable bounds?

Comparatively simple as many of these questions seem to be, there will be found lurking in their implications vast areas for the application of intelligent investigation by means of the scientific method. Questions such as those that I have posed, and literally scores of others that can be cited, comprise the dynamics that attach to the performance of the task of management under present-day conditions.

The fact that I have cited the foregoing problems is not to be construed as an indication of the belief on my part that they have not, to some extent, been made the subject of scientific inquiry, or that gratifying results have not often followed such individual researches. From broad experience in dealing with the problems of business management during the past two or three decades, however, the opinion may be ventured that, generally speaking, application of the scientific method to that field still lags far behind by comparison with such developments as have occurred in the sciences.

The reasons for this condition are not far to seek. In the realm of management, planning and performance have been constantly intermingled, with the result that the former has been obliged to suffer because of the current claims of the latter. In the second place, adjustment to the impact of hostile economic conditions has claimed so much of the time and effort of major executives, especially in recent years, that, strange as it may seem, the activities comprised in management have not been able successfully to vie with them for attention. Moreover, until recently the view has been widespread that management is not susceptible of measurement. This view is happily being dissipated, largely through increased awareness of the need for operating successfully in ever narrower margins set by economic conditions.

In order to raise management to the level of progress attained by other arts and sciences, and to introduce conditions which will lend themselves to effective control, we are forced to the conclusion that a scientific approach to the solution of its problems must be undertaken in an organized manner. From the practical point of view, this means that the task of management must be entrusted to individuals who have a thorough knowledge and appreciation of the scientific point of view, together with the capacity to translate these into effective action.

## WHAT QUALIFICATIONS MUST THE SCIENTIFIC BUSINESS EXECUTIVE POSSESS?

It will readily be deduced from what has been said that, in the last analysis, the problem involved in introducing the scientific point of view into management becomes, apart from certain impersonal aspects, an individual one, and that the attributes of the executives concerned constitute important, if not controlling, elements in its solution.

Some individuals are possessed of the scientific point of view; others are not. Some have the ability and inclination to acquire it; others could never conform to its rigorous demands. The type of executive who dismisses science with a snort of contempt and boasts of the possession of so-called "practical" qualities, is still far from rare in business.

Since the application of the scientific point of view to management seems to depend so much upon personal temperament and capacity, it may prove interesting, if not useful, at this point to describe some of the more important qualifications which, in my judgment, in addition to technical capacity, enter into the make-up of what may be termed the scientific business executive. I submit these qualifications as representing purely my personal viewpoint, and I surmise that there may be many in this audience who will disagree; that is their privilege.

The scientific business executive is he who possesses, among other characteristics, the following:

1. A strictly impersonal viewpoint;
2. The ability to think in terms of management;
3. A passion for truth as revealed by the methods of science and research;
4. Adequate training in sound methodology and thorough grasp of modern statistical methods;
5. An ample cultural background;
6. An attitude of philosophic doubt;
7. Devotion to bibliochresis, i.e., the scientific use of literature;
8. A spirit of co-operation with other workers in the field, as well as with members of his own organization;
9. Success in the art of self-interpretation;
10. The saving grace of humour.

"True science," it has been said, "has no fetishes that it clings to in the face of evidence."[9] Therefore, in the application of his energies to the solution of the problems confronting him, the scientific business executive may always feel confident that faithful pursuit of his objectives will lead inevitably to enduring satisfaction through sound accomplishment.

What opportunities are available to executives and to those who aspire to such positions, to prepare themselves for serious work of lasting value in their chosen field of vocational effort? There are, first of all, the courses of formal training given by schools of business and similar institutions whose aim it is to equip their students with technical knowledge, joined to a firm grasp of principles, in the fields covered by their curricula. Most of the older schools of business do excellent work of high grade; those who are fortunate enough to be so situated as to be able to enrol as students and to complete the courses offered, usually secure a training which proves a decided asset throughout their business careers. Next in line are the institutions which aim by means of the correspondence method to teach students who for various reasons cannot arrange to attend residence schools of instruction. There are at least two so-called "correspondence" schools with whose text books and methods of instruction I am sufficiently familiar to be able to say that the courses in management offered by them are comprehensive and thorough and, if faithfully pursued, are bound to equip the student with

[9] Kelley, Truman L., The Scientific versus the Philosophic Approach to the Novel Problem; Science, Vol. LXXI, No. 1838. The Science Press, New York, March 21, 1930.

knowledge of practical value in fitting himself for an executive position.

But what of the executive, or junior aspiring to such a position, who devotes his entire time to the performance of his business duties and finds an extended course of training incompatible with the demands made upon him by his daily work? To such a man who is ambitious to explore his chosen field of effort and to equip himself for greater responsibilities, an avocational interest of major consequence and lasting value is presented through membership in organizations such as those represented here tonight. Many questions of importance to executives are discussed at the forums which these organizations regularly provide; in fact, I doubt not that a search through the published proceedings of these professional bodies would disclose that a number of the questions which I have propounded have been made the subject of careful inquiry and report.

Perhaps the greatest benefit of membership comes, however, in the opportunities afforded for personal mingling with men and women of similar experiences and interests, and for participation in the discussions that constitute so vital and practical a feature of the meetings. The pooled knowledge of the entire group is always at the disposal of the individual member; on occasion eminent authorities appear to discuss the burning questions of the moment; the records of their presentations and of the ensuing discussions, form an indispensable part of the source material which every aspiring business executive will wish to preserve.

A distinguished American statesman once said in effect that every man owes of his time and effort to the profession to which he belongs. If I have made any progress at all in my profession of management engineer, it is primarily and chiefly because for over a generation I have consciously elected to expose myself to the constructive and stimulating influences that pervade the scientific organizations, both here and abroad, in which I am privileged to hold membership. I have come to attach so great a degree of importance to such membership as a criterion of the capacity, standing and worth of an individual, that whenever it becomes my responsibility to judge persons who offer themselves for consideration as candidates for high executive positions, this test is invariably among the first to be applied.

## CONCLUSION

Before bringing this address to a close, it may be appropriate to visualize for a moment the great and growing importance of the field of business management, in order to give point to the observation that effective management is among the objectives to the achievement of which business and government should purposefully and persistently address themselves. Let us look at just one branch of management for illustrative material.

While exact figures unfortunately are not available, I venture to express the belief that approximately five millions of office workers are at present employed in the States. Of these, several hundreds of thousands are in governmental service. Assuming an average salary of $1,000 per annum (a conservative estimate, I feel sure), the total annual payroll would amount to five billions of dollars. Statement of this figure leads to keen speculation as to the justification for so large a disbursement of money for what is often inelegantly, but not altogether inappropriately, described as "paper work."

With great regard and entire sympathy for the human values involved, I am of the opinion that a horizontal saving of at least 10 per cent of this amount, or $500,000,000 per annum, is easily within the realm of accomplishment, through the application of sound principles and techniques of management. In addition to such a saving, there are of course uncounted millions of dollars of collateral economies that would flow from items such as rent, equipment, supplies, etc., which would be scaled down in proportion.

Unless the time honoured point of view of the engineer is to be wholly subordinated to the onward sweep of the new doctrines enunciated by the sociologist, the politician and the labour leader, it seems reasonable to assume that something should be done to take advantage of the unparalleled opportunity which the figures just recited apparently make available. There must of course be developed as a prerequisite to accomplishment, a sane appreciation of the worthwhileness of securing the savings, for until current tendencies to extravagance in the expenditure of money, which have been so flagrantly displayed in public affairs, have been brought under control, it is hardly to be expected that private business will develop the urge, or the will to do, which must be the precursor of effective action.

Perhaps a beginning might be made by inducing some of the independent agencies of research to survey the field and, in particular, to gather concrete information as to the cost to the tax-payer of the clerical activities that have been instituted as an apparently minor phase in the administration of the various governmental organizations which have been established at the Federal capital. My own observations lead me to conclude that if present developments along these lines are continued on a permanent basis, the time will ultimately arrive when many of these organizations will be threatened with the danger of stifling in a morass of paper work.

As for the factor of space, not alone is it impossible under present conditions in Washington to find housing facilities, however inferior, in which to accommodate clerical activities incident to the administration of such undertakings as the Social Security Board, but what is quite as much to the point is the fact that governmental buildings recently erected leave much to be desired when the need for intelligent planning and arrangement of clerical staffs and equipment is taken into account.

Following an inspection made a short time ago of one of these buildings, I was asked to appraise it from the planning point of view. My answer, made with what was interpreted by my interrogators as brutal frankness, was that those responsible for the planning of the building had succeeded brilliantly in providing everything but adequate and well-arranged space.

I revert, finally, to the all-pervading influence of science. Its status in business today constitutes a challenge to every forward-looking executive, whether his interests be in the office or the plant, in production, sales or finance, to gauge his own mental processes and ability to understand and apply the scientific method to his daily activities. In what spirit shall this challenge be met? The answer to this query, it seems to me, can be given in no more effective manner than by relating in a few words the story of Dr. William Beaumont, whose name and fame are enshrined forever in the annals of medicine.

A little over a hundred years ago, Beaumont was a young and obscure army surgeon, stationed at the military barracks at Ft. Plattsburg, New York. One day there was brought to him for treatment a French Canadian woodsman, St. Martin by name, who had been horribly torn in the abdominal region by the accidental discharge of his gun. After applying heroic measures and devoting unremitting care to the injured man, Beaumont managed to save his life. But even his great skill was unequal to the task of closing the hole in the abdominal wall occasioned by the penetration of the shot. Thus it was vouchsafed to Beaumont, first among all men since the very dawn of life upon earth, to observe through the opening provided, the activities of the vital organs of a living human being.

In the skilled surgeon there at once developed the determination (fortified no doubt by a long held passion for research, joined to eager intellectual curiosity) to make the most of the unparalleled opportunity so miraculously presented to him. Securing the consent of St. Martin to share his modest quarters with him and to submit to experiments which he proposed personally to undertake, Beaumont during the course of the next two or three years actually performed over one hundred experiments to determine the conditions controlling the processes of digestion. St. Martin, being fed up in more ways than one with these intimate interferences with his physical integrity, ran away, but was induced by the promise of a bounty to return and to submit himself to further experimentation.

What Beaumont learned as the result of his tests and observations constituted an astounding and epoch making contribution to the advancement of the medical knowledge of the day. In fact, many of the beliefs then held by scientific men were completely overturned and much of what is now accepted fact is derived from the discoveries then made by Beaumont.

By nature cautious and of great modesty, as well as imbued with a thorough appreciation of ethical procedure, Beaumont reduced his findings to written form and, under the title, "Experiments and Observations of the Gastric Juice and Physiology of Digestion," submitted them to his medical society in Boston for review and critical comment. Because of the revolutionary character of his findings, he found it expedient to write a preface to the report; in this a sentence occurs which will for all time be an inspiration and an example to conscientious devotees of research. This is what he wrote: "I submit a body of facts which cannot be invalidated. My opinions may be doubted, denied, or approved, according as they conflict or agree with the opinions of each individual who may read them; but their worth will be best determined by the foundation on which they rest—the incontrovertible facts."[10]

Thus did a great scientist take his stand and nail his colours to the mast!

# Preservative Treatment of Structural Timbers

## with Special Reference to Creosoting

*J. F. Harkom, A.M.E.I.C.,*

*Forest Products Laboratories of Canada, Department of Interior, Ottawa, Ont.*

**Paper presented before the Ottawa Branch of The Institute, November 5th, 1936.**

SUMMARY.—**Discusses the principal causes of decay in wood and the methods of treatment designed to prevent the action of these agencies or to render wood fire-resistant. Methods of testing preservatives, the preparation of timber for treatment, and the application of preservatives to Canadian timber products are described.**

In order that forests should not become choked with fallen trees, nature provided various destructive agents to clear away the timber lying on the ground, and these destructive agents sometimes interfere with the use man desires to make of wood when the conditions of service are similar to the damp ground of the forest. When conditions of service are changed by maintaining the timber in a dry, or water-soaked condition, wood-destroying fungi and most insects do not flourish, and, therefore, maintaining wood in an air-dry condition is the simplest form of wood preservation. Although wood submerged in fresh water will remain sound indefinitely, sea water is sometimes infested with "marine borers" which will rapidly destroy it. Wood in service is also, of course, subject to destruction by weathering, fire, and mechanical wear

### Decay

The decay of wood is due to the growth in the wood of low forms of plant life known as fungi. Fungi will grow readily in untreated wood provided the conditions of moisture, air supply, temperature, and food are suitable. The food is supplied by the wood substance, and it is only necessary for conditions of moisture, air supply and temperature to be favourable to bring about the decay of timber in service. The moisture conditions required for growth vary over a wide range. Wood which is maintained below a moisture content of from 20 to 25 per cent will not be attacked by fungi owing to insufficient moisture, and wood which is stored under water will not be attacked, owing to the cells of the wood being so filled with water that the air supply is insufficient. When timber is buried in the ground the air supply varies with the nature of the soil. In heavy clay soils the air supply is diminished at a short distance beneath the surface, while in light sandy soils decay can progress up to a depth of four to five feet below the surface. The upper and lower temperature limits for fungus growth are about 110 and 32 deg. F. respectively, and the best temperature is between 65 and 95 deg. F.

Since the above requirements for the growth of fungi are found in the living tree, it is not surprising that there is a considerable loss of merchantable timber due to decay in standing trees. The question as to whether decay in standing trees will continue after the timber is cut is of considerable importance. Tests carried out at the Forest Products Laboratories, Dominion Forest Service, Department of Mines and Resources, indicate that the fungus, *Trametes pini*, which causes the red heart rot in jack pine, does not appreciably affect the life of railway ties, provided the attack is confined to small pockets of incipient decay so located that the strength of the tie is not reduced.

During the air-seasoning of green lumber, what are known as staining fungi are sometimes very troublesome, and cause a considerable loss owing to degrade of the lumber. An example is blue-stain in the sapwood of white pine. The strength of the wood is usually not reduced by the staining fungi, which feed on the food stored in the wood cells and seldom attack the cell walls. The discolouration of the wood is caused by the coloured mycelium of the fungi, and is sometimes augmented by infiltration into the cell walls of the wood of substances produced by the fungi during growth.

The terms "wet rot" and "dry rot" are sometimes rather loosely used. Wet rot might be considered to describe the large group of fungi which bring about the decay of ordinary timbers such as fence posts, telephone poles, railway ties, and similar products. Dry rot can be used to describe a limited group of fungi, one of which is known as *Merulius lachrymans*. These fungi possess the property of conducting water through their mycelia. When the decay starts in a wet spot the mycelia can spread over brick or stone work and, on reaching dry wood, can destroy it although the timber was too dry for decay to start at that point.

The service life of untreated timber is largely governed by the fact that optimum conditions of temperature, moisture, and air supply seldom occur. When all these three conditions are at the optimum point, the decay of wood is very rapid. Obviously, little or nothing can be done to control the temperature, or air supply, but a great deal can be done to insure that the moisture content of the timber is below that favourable to fungus growth, that is to say below 20-25 per cent.

The toadstools that appear on the surface of wood which is in an advanced stage of decay, are a convenient point at which to start a description of the life cycle of a fungus. These toadstools are known as fruiting bodies, and at maturity shed minute seeds or spores. Each tiny spore that settles on wood, where conditions are favourable to decay, can germinate and start the formation of tiny cells, which possess the property of releasing secretions, or enzymes, that break down the wood structure and reduce it to a soluble form. A plant cell consists of an outer wall, within which is a layer of living protoplasm, which appears to function as a semi-permeable membrane, and within the semi-permeable membrane are the cell sap and other substances. By "semi-permeable" is meant that certain substances in solution may pass through the membrane while others cannot. In wood-destroying fungi, the cells absorb the wood substance brought into solution by the secretions released by the cells, and this food promotes growth, and the formation of new cells, which multiply in the form of slender filaments or hyphae, which spread like the branches of the tree, and then form a mass known as mycelia in the broken down and disintegrated wood. The mycelia eventually form fruiting bodies on the surface of the timber, and the life cycle is thus repeated. Decay can also spread by the growth of mycelia from decayed timber into adjacent sound timbers.

In order to protect timber from decay it may be impregnated with chemicals which poison the wood substance on which the fungi grow. It is now known that wood preservatives must be toxic to, or at least inhibit, the growth of fungi, but it is interesting to note that the preservatives most commonly used in Canada and the United States, creosote and zinc chloride, were in use in England as early as 1838, while it was not until 1874 that it was shown by Hartig that the decay of wood is caused by fungi, and is not, as previously believed, a case of slow combustion.

It is a well established fact that the presence of a sufficient quantity of creosote, or of some water-soluble salts such as zinc chloride or sodium fluoride, will prevent the growth and cause the death of wood-destroying fungi. If it were only the water-soluble salts which were toxic it would be possible to explain the action by saying that the salts in solution could pass through the semi-permeable membrane of the cells and interfere with the life processes of the fungus. However, since creosote oil is also very toxic, it is necessary to find some other explanation. E. Bateman of the Forest Products Laboratory, Madison, Wisconsin, U.S.A., has advanced an interesting theory that creosote may be considered as consisting of two groups of compounds, one of which is sufficiently soluble in water to produce a toxic solution, which, being water soluble, can be absorbed by the body organisms of the fungus. The non-toxic group of compounds in the creosote act as a reservoir, in which the toxic oils are completely soluble, as well as being slightly soluble in water. A state of partial solubility of the toxic oils then exists between the non-toxic oils and the adjacent moisture in the wood. As the moisture in the wood changes, fresh toxic solution is drawn from the creosote. Since creosote has been known to protect timber from decay for periods of forty years and over, it is evident that the withdrawal of the toxic solution from the creosote, as outlined above, is very gradual.

### Insects

Very fortunately timber in service in Canada is comparatively free from destruction by insects. Unpeeled logs left on the ground in the bush will be degraded by the action of insects, but attacks on fence posts, poles or structural timbers are so infrequent that there is little or no demand in Canada for lumber treated to resist insect attack. In other countries, where termites are prevalent, it is necessary to provide adequate measures of protection. Fortunately, the chemicals used to protect timber from decay will usually provide protection from insect attack.

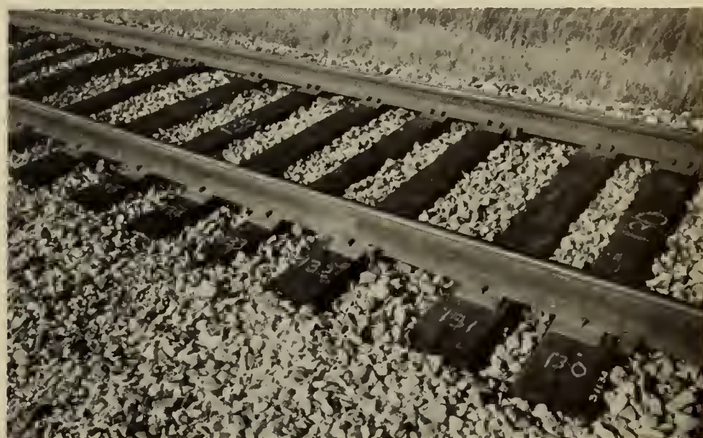

**Fig. 1—Creosoted jack pine ties, incised and not incised, after 14 years' service in main line.**

### Marine Borers

Wood, submerged in fresh water, will last indefinitely, but sea water, in many parts of the world, including the Atlantic and Pacific Coasts of Canada, is infested with marine borers, which burrow in the wood for shelter and food and eventually totally destroy it. Marine borers may be divided into two classes, the *Mollusca* commonly known as "Teredo" or "ship-worms," and the *Crustacea* which are known as "Limnoria" or "wood lice." Teredo attack starts from a small embryo floating in the water, which attaches itself to the wood and bores a minute hole. When once the teredo penetrates beneath the surface, the hole is extended and enlarged to accommodate the rapidly growing body, and eventually the timber is honeycombed with longitudinal galleries or burrows, usually, in Canadian waters, 6 to 12 inches in length, and about ¼ of an inch in diameter. The original entrance hole is not enlarged, so that what is in appearance a sound pile, may be nothing but a weakened, honeycombed shell. The attack of limnoria is quite different from that of teredo, inasmuch as the timber is eaten away on the surface, and the damage is apparent to the eye. Limnoria are about the size of a grain of rice, and excavate little galleries, side by side, extending about half an inch below the surface. The burrows are so numerous, and so close together, that the partitions of wood between the tunnels are soon worn away by the action of the waves, whereupon the limnoria make fresh burrows, which are in turn disintegrated. The piling attacked is consequently eaten away until it resembles an hour glass.

### Weathering

When unpainted wood is exposed to the weather the moisture content of the outer fibres fluctuates with changes in atmospheric conditions. The repeated swelling and shrinking, caused by the changes in moisture content, gradually loosens the outer fibres, and the wood acquires the well-known weathered appearance. Weathering can be prevented by paint specially prepared for use on exterior woodwork.

### Fire-Retardant Treatment of Wood

Wood can be impregnated with certain chemicals which render it comparatively inert to fire, that is to say, if a piece of the treated wood is placed in a fire it will slowly char, since it is an organic material, but if it is removed from the fire, or if the surrounding fire dies out, the wood will not continue to burn. Some of the most effective fire-retardant chemicals are phosphoric acid, ammonium phosphate, ammonium borate, ammonium sulphate, ammonium chloride, magnesium chloride, zinc chloride, boric acid, and borax. Mixtures of these and a few other chemicals form the base of most of the fire-retardant treatments which are used. On the whole, ammonium phosphate and ammonium sulphate are probably the most important commercial fire-retardant chemicals. Ammonium phosphate is by far the most effective, but costs two to three times as much as ammonium sulphate. An effective fire-retardant treatment is a mixture of ammonium phosphate and ammonium sulphate. The proportions can be varied from 70/30 to 30/70 without any very noticeable difference in the fire-retardant effect. The ammonium sulphate is hygroscopic and the limiting factor in the percentage that can be used, and consequently the cost of the treatment, is the humidity to which the treated wood is exposed in service. It is advisable to add a small percentage of a toxic salt to control moulds and wood-destroying fungi. Two to three per cent of boric acid is sometimes used.

**Fig. 2—Creosoted hardwood culvert.**

At present wood treated with fire-retardant chemicals is not produced commercially in Canada. This is easily explained by the high cost of fire-retardant treated wood as marketed in New York where the building by-laws call for the fire-retardant treatment of all wood used in buildings over 150 ft. in height. The prices range from $50 to $75 per M., in addition to the original cost of the wood. This is for timber which has been treated to refusal, under pressure, with water solutions of fire-retardant chemicals. At first thought the price may seem excessive, but when it is remembered that the timber must be air-dried before treatment, then treated in a cylinder under pressure, and again dried after treatment, it will be found that an estimated cost in Canada of $40 per M. is not unreasonable. In order to reduce the high cost of fire-retardant treated wood, it will be advisable to try to determine just what degree of fire-resistance should be imparted to wood in order that it will survive the fire hazards found in service. Under present standards, it is necessary to impregnate timber with from 4 to 5 lb. of chemicals per cu. ft. of wood. It is known that larger timbers are very fire-resistant. This has been demonstrated in many fires, and is recognized in the design of what is known as the slow-burning type of mill construction. Certainly this would seem to indicate that it should not be difficult to add a high degree of fire-resistance to larger sizes of timbers with less expensive treatments. Compared to other available construction materials, wood compares favourably when the following factors are taken into consideration:

(1) Ease of ignition or inflammability.
(2) Rate or intensity of burning, which is largely a question of the air supply, and this can be reduced by the use of fire-stops.
(3) Resistance to change of shape on heating.
(4) Conductivity.
(5) The effect of water applied to hot members during a fire.

After considering all the above factors, it would seem reasonable to suppose that present laboratory tests, which indicate the necessity of using 4 to 5 lb. of chemical per cu. ft. of wood, should be much more closely co-ordinated with actual service requirements. Until this is done, there is a danger of penalizing wood by insisting on heavy and expensive treatments, whereas for many uses, lighter treatments may be all that is actually required, and, in some types of construction, untreated wood is sufficiently resistant to fire to provide all the protection that is necessary.

### Preservatives

Preservatives in general use may be divided into two classes:

(1) Oils such as creosote or mixtures of creosote and coal tar, creosote and crude oil. (Crude oil is not a preservative.)
(2) Water-soluble salts such as zinc chloride.

### Creosote

The wood preserving industry has little or no control over the production of creosote, which is a by-product from the distillation of coal tar, and the tar is a by-product from the distillation of coal, for the purpose of obtaining illuminating gas or metallurgical coke. This situation has existed for nearly a century, and it will be readily understood that during this period many different grades of creosote have been used for the preservation of timber, owing to the many types of coal used, and continual changes and improvements in the methods of distilling coal and tar. Owing to the complex and varying constituents of creosote, it is difficult to determine which are the essential fractions, since up to date so many types of creosote have provided adequate protection from decay when properly used. If there had been failures in service, due to the creosote alone, the problem would be easier to solve. Although no definite results have been obtained, a great deal of work has been done in Europe and the United States in the endeavour to determine which fractions of creosote protect timber for long periods of service from decay, marine borers, and insects.

The specifications for creosote for use as a wood preservative require that certain physical tests be complied with in order to insure that a pure coal-tar product is supplied. The specifications such as those issued by the American Wood Preservers' Association, the American Railway Engineering Association, and the Bureau of Standards, U.S.A., are a commercial compromise. On the one hand are consumers asking for types of creosote that they have successfully used for many years, and on the other hand are the producers of creosote forced to market the type of creosote that developments in distillation processes make available. As long as only limited quantities of new types of tar or creosote are produced, some distillation plants can blend different types of tar or creosote to produce a creosote to meet the specifications. When the quantity produced by the new method becomes larger, it is necessary to amend the specifications.

The first retorts for distilling coal for the production of illuminating gas were of cast iron, and operated at temperatures of about 800 deg. C. In order to increase the yield of gas, horizontal retorts lined with fire clay, so that the temperature could be raised to 1300 deg. C., were developed. Up to this point the retort was charged intermittently, and the next development was the vertical retort which could be operated continuously. The wish to recover by-products in the manufacture of metallurgical coke led to the development of the by-product coke oven. All the above methods for distilling coal affect the type of tar produced, and the type of tar produced is also dependent on the type of coal used. Cast iron retorts operated at low temperatures produce a tar rich in tar acids and comparatively low in naphthalene. Horizontal retorts, operating at higher temperatures, increase the naphthalene content and also the free carbon. Vertical retorts produce a tar higher in tar acids and lower in naphthalene than the horizontal retorts. Coke oven tars are intermediate between vertical retort tars and horizontal retort tars. Water-gas tar is of a different character. It is not a coal tar product inasmuch as the raw materials are coke and petroleum oil. A large body of coke is placed in a retort and heated to incandescence by an air blast. The air blast is shut off and steam then blown through the coke. The steam is decomposed and reacts with the carbon with the resulting production of carbon monoxide

Fig. 3—Highway overhead crossing at Haig, B.C. Composite concrete creosoted timber deck on creosoted timber bents.

and hydrogen. The water gas thus produced does not meet most standards for city gas, and has to be enriched by carburetting, that is by spraying petroleum oil into the gas in chambers containing hot refractory brick-work. The high temperature volatilizes the oil and fixes it as a gas. Some heavy vapours formed in oil carburetting are not permanent gases, but condense out of the gas on cooling. The liquid so condensed is known as water-gas tar. There is some doubt as to whether or not creosote, distilled from water-gas tar, is as effective as pure coal-tar creosote as a wood preservative, although it is quite certain that it has a marked protective value.

In the distillation of tar the market for pitch is often the controlling factor, and the distillation is cut to produce, as for instance in the early days in America, a soft roofing pitch and, consequently, a light, low-boiling creosote, while in Europe, a hard briquetting pitch was in demand, and resulted in the production of a heavier creosote. In the early days, the wood preserving industry in the United States was trying to obtain a heavier creosote than was generally produced in that country, but was forced to include in its specifications Grades 2 and 3 creosote, in order to admit the use of available creosote with 35 and 40 per cent distilling up to 235 deg. C. The industry urged tar distillers to increase the supply of heavier domestic creosote. This was done by developing the markets for harder pitches and the manufacture of pitch coke, thus permitting the distillation to be carried further and increasing the production of higher-boiling oils. The more general production of heavier creosote has now permitted the elimination of Grades 2 and 3 from the specifications. For the distillation of tar and starting with the simple batch still, steam agitated stills, vacuum stills, gas recirculation stills, pipe stills, coke stills, and later coke oven stills have been developed, and the percentage of creosote recovered raised from about 40 per cent in the batch still to about 70 per cent in the coke-oven still.

The situation today is that the producers of creosote are now marketing considerable quantities of what is known as high residue creosote oil. In a sense they have gone beyond the demand of the wood preservation industry. A typical so-called high residue creosote is one of which 60 per cent is distilled below 355 deg. C. and the remaining 40 per cent is called the residue. In the period between 1914 and 1929 the percentage of creosote and creosote coal-tar solution produced and used in the United States, and having a residue of less than 20 per cent, fell from 27 to 5 per cent. The question that is troubling many people at the moment is whether the lighter but more toxic oils, such as have been used in the past, should be regarded as being the most efficient, or whether the heavier, high residue oils, which contain less of the low-boiling fractions, are the suitable types. The fraction of creosote distilling below 270 deg. C. is more toxic and also more volatile than the remainder. There is a conflict between toxicity tests, which emphasize the advisability of using a considerable percentage of creosote distilling below 270 deg. C., and reports on the analysis of creosote extracted from timber after various periods of service, which show that the creosote distilling below 270 deg. C. has largely disappeared. However, just because the lower fractions have disappeared in service is not to say that these lower fractions have not played a part in protecting the timber, and it is not possible to say definitely that creosote, similar to that extracted from timber after a long period of service, would protect timber for as long a period as the original mixture of high and low boiling oils. Fortunately, it is possible to use an additional 2 to 3 lb. of creosote per cu. ft. of wood when there is any question as to the length of life that will be obtained from any coal-tar creosote.

The amount of creosote required to protect wood varies with the species and with the conditions of service. In general, it will usually be more economical in the end to use the maximum amount of creosote specified instead of the minimum. For marine piling, complete saturation of the sapwood rings is required, and in species having a sapwood ring of 3 to 3½ in., an absorption of 16 to 18 lb. of creosote per cu. ft. of wood will be necessary, while for other species with 1 to 1½ in. of sapwood, 14 to 16 lb. will be sufficient. For structural timbers of approximately 6 by 8 in. in cross section, 6 to 8 lb. per cu. ft. for empty cell treatment, and 8 to 10 for full cell-treatment will be suitable. For larger and smaller timbers, the absorption should be decreased and increased respectively in order to compensate for the change in ratio of surface area to volume.

### Zinc Chloride

Zinc chloride is a water-soluble salt, and for the treatment of timber is used in water solutions up to 5 per cent in strength. From ½ to ¾ lb. of dry salt per cu. ft. should be used to protect timber from decay.

Mercuric chloride, copper suphate, and sodium fluoride are also water-soluble salts and are used in much the same manner as zinc chloride. They are, however, with the exception of sodium fluoride, corrosive to metals, so cannot be used in the ordinary steel treating cylinders in use at commercial treating plants.

### Testing of Preservatives

Unfortunately, a reliable estimate of the service life of a preservative cannot be based on data obtained solely from accelerated laboratory tests. However, although the conclusions to be drawn from laboratory tests are very often a matter of individual opinion, and there is no guarantee that the conclusions will be confirmed by service tests, it is still possible to obtain a fair idea as to whether a new preservative is worthy of serious consideration. In the first place, the preservative must be cheap. Secondly, it must be toxic to, or at least inhibit, the growth of fungi. Thirdly, the question of permanency must be considered, and the less volatile and the more resistant to leaching by water the better. The fact that preservatives may be exposed to water that is slightly acid, or slightly alkaline, must also be considered. Information on these points can be obtained by laboratory tests, and it is thus possible to limit service tests, which will require anywhere from ten to twenty years, to compounds that show satisfactory results in preliminary laboratory tests.

The toxicity of a preservative, as determined in a laboratory, is often quoted, and while it is essential that a preservative be toxic, the extent of the experimental error in toxicity determinations is not always realized, and undue weight is sometimes given to small differences in toxicity. Also, it should be remembered that toxicity tests give little or no information regarding permanency, or the length of time the portion of the preservative remaining in the treated timber will be toxic.

In order to study the different types of fungi, pathologists developed a technique of growing fungi on an artificial food or media placed in glass containers. One of the mixtures on which fungi will grow readily is made up of malt extract, agar agar and water. A small piece of decayed wood, which need only be 1/8 in. or so in thickness, and long enough to be held in forceps, is placed in the media in the glass container, and the fungus will spread from the decayed wood into the media. Of course, there is often more than one fungus present in the decayed wood, and also moulds and bacteria may be present. However, by transferring selected pieces of the media containing the desired fungus, it is possible to obtain a pure culture. This strain of the fungus, as it is called, can be maintained for years by subsequent transferring to fresh flasks.

For toxicity tests it was, therefore, quite simple to go one step further and add different percentages by weight of a preservative to the media placed in a set of glass flasks. When the flasks were inoculated with the same strain of fungus, growth was not prevented by the low concentration of preservative, but higher percentages killed the inoculum. The toxicity was taken as the percentage between the flasks showing growth and no growth. In order to obtain the same figures for the toxicity of a preservative, different workers must use the same strain of the same fungus, similar media, and store the flasks in boxes maintained at the same temperature and humidity. The use of different fungi and different strains of the same fungus will change the percentage of preservative required, so that the toxicity may be 0.05 for one fungus and 0.10 for another. In a very toxic fraction of low-boiling creosote only one or two drops mixed with the medium are required to bring the percentage of the preservative by weight up to the killing point.

Toxicity tests can also be carried out by growing mats of fungus on agar agar, and then placing small blocks of wood approximately ½ by ⅝ by 2 in., treated with different concentrations of preservative, in a set of flasks. The toxic concentration, as determined by the wood block test, usually differs considerably from tests on artificial media. The difficulty with the wood block test is that it is not possible to control the moisture content of the wood in the flasks, and obtaining the optimum moisture content for fungus growth is more or less a case of hit or miss. Wood block tests require from six to eight months' exposure.

It will be noted that toxicity tests, as outlined above, are simply empirical tests. A true understanding of the action of preservatives will involve a proper conception of the life processes of fungi as mentioned under the heading "Decay."

Laboratory tests to determine the permanency, or resistance to evaporation and leaching, of preservatives are not as standardized as toxicity tests. Obviously, a large number of tests can be developed in which small wooden blocks, treated with a preservative, can be passed through cycles of heating and cooling in air, and leaching in hot or cold water. A comparison of the properties of different preservatives under the conditions of the test can be obtained, and by including preservatives that have been used extensively in the past, such as creosote and zinc-chloride, some information can be obtained regarding the possibilities of a proposed preservative, and those that cannot pass a few simple comparative tests can be eliminated and extravagant claims regarding proposed wood preservatives can be checked.

As a rule, laboratory tests can easily be made too drastic, but this has the advantage that the error is on the side of safety, if the tests are carefully carried out. When reliable preservatives are available, it is not necessary to take chances on untried or questionable methods of treatment.

As mentioned before, service records are the final test of a preservative. However, to be of value, service tests require details of the preservative used and the method of treatment, and reports on yearly inspections, so that all renewals for decay, mechanical wear or other causes can be taken into consideration when calculating the average life. This continuity of interest over a period of years is seldom obtained, and it is not surprising, therefore, that the number of completed service tests which fulfil these requirements is surprisingly limited. There are an embarrassing number of half recorded service test results which fully demonstrate the value of preservative treatments, but cannot be used to determine the results of minor differences in preservatives, or improvements in processing, owing to lack of details. Of recent years much more attention has been paid to the proper recording of service tests, and the detailed information collected will in time provide a much closer co-ordination between service tests and laboratory tests, so that eventually it should be possible to develop laboratory tests to a point where service tests will not be as essential as at present.

### Preparation of Timber for Treatment

Careful preparation of timber for treatment is necessary, in order to obtain an adequate penetration of the preservative to a depth of one-half to one inch, and to ensure that the timber does not check after treatment, and expose untreated wood to the action of fungi. The preferred method is to air-season the timber before treatment and, by removing the free water, provide space for the penetration of the preservative and, if checking cannot be prevented, it is preferable that it should occur before and not after treatment. In the early days of the wood preserving industry, indiscriminate treatment of different species of green timber resulted in short life, due to checking after treatment, and led to emphatic statements regarding the necessity of only treating thoroughly air-seasoned timber. However, in order to benefit by the advantages of air-seasoning, consumers have to foresee their requirements sufficiently in advance to allow time for the timber to air-season before treatment. Also, in order to air-season large quantities of timber at a reasonable cost, it is necessary to purchase land for seasoning yards at a reasonable price, and climatic conditions have to be such that the timber can be air-seasoned with little or no loss from decay. In the Southern States decay during seasoning was a problem, due to climatic conditions, and led to the extensive use of conditioning green southern yellow pine by steaming in the treating cylinder followed by a vacuum. On the Pacific Coast of Canada and the United States, possibly due to the necessity of locating treating plants on more expensive water front property, with rail and dock facilities, the treatment of green timber was favoured, and as steaming was not effective in the case of Douglas fir, the Boulton process of conditioning by boiling timber in oil under a vacuum was adopted. In Canada, with the exception of Douglas fir, little or no timber is treated in the green condition. The Laboratories have carried out experimental treatments on green yellow birch, hard maple, and beech ties, and on green jack pine and red pine poles in order to obtain information on the penetration of creosote and the checking of the timber during and after treatment. The only indication of success has been in the case of green yellow birch ties, where a good penetration was secured and the checking after treatment was much less than in the case of hard maple and beech. Jack pine and red pine poles, creosoted after preliminary steaming and vacuum in the cylinder, showed poor results. The penetration of creosote was poor, and there was a considerable amount of checking in the heartwood, extending along the length of the pole. The steam seasoning of red pine and jack pine structural timbers should present less difficulty, but in the case of the heartwood of the pines, the lower the moisture content the better the penetration of creosote.

Fig. 4—Untreated drift timbers in a mine.

In Canada, softwoods require from five to twelve months and hardwoods from five to six months seasoning depending on climatic conditions and the season of the year.

### Cutting and Framing Before Treatment

Since the penetration of preservatives into wood is not complete, it is necessary to depend on the maintenance of an exterior treated shell of from one-half to one inch in depth. In order to secure this it is essential that all cutting and framing should be carried out before treatment. There has been a remarkable development in recent years in pre-framing bridge and other construction timbers at the treating plants before treatment. It has been found that quite intricate timber structures can be shaped and fitted, and erected in the field after treatment, with little or no disturbance of the exterior treated shell.

### Incising

The incising process consists of passing the timber through a series of studded rolls which punch incisions spaced 6 in. apart longitudinally and staggered one-quarter inch in the faces of the timber. The penetration of preservative is greater longitudinally than radially, and a uniform penetration to the depth of the incisions is obtained. This process is extensively used in Canada, and nearly all the large commercial pressure-treating plants are equipped with incising machines.

### Treating Processes and Equipment

The object of all treating processes is to apply the selected preservative in such a manner that the increase in service life will pay for the cost of treatment and also return a dividend or profit on the money invested in the treatment. The selection of the preservative to be used and the decision as to how it should be applied are governed by the conditions of service and the facilities available for carrying out the treatment. There are several methods of applying preservatives, some of which are undoubtedly superior to others, but each method possesses certain advantages which render it suitable for use under particular conditions. The different methods may be grouped into two divisions, namely, superficial and pressure treatments. Superficial treatments cover only the surface of the wood with the preservative and are not as reliable as pressure treatments, where the preservative is forced beneath the surface to a depth of one-half inch or more. Superficial treatments are cheaper than pressure treatments and a minimum of equipment is required, so that their use is justified under conditions where a short period of service life is required or where transportation costs prohibit the use of timber treated by a pressure process. Descriptions of the various methods of treatment follow.

### Brush Treatment

This is a superficial treatment with a creosote oil preservative. As the name implies, the process consists of applying the oil to the surface of the wood with a brush. The wood to be treated should be well air-seasoned and its surface should be perfectly dry. The oil should be heated to about 190 deg. F. before being applied, and care should be taken to brush the preservative thoroughly into all checks, cracks, and joints. For best results, a second treatment after an interval of several hours is recommended. This method of treating wood is cheap and requires no outlay for apparatus or any skill in its application. But the protection against decay afforded by the creosote does not extend beyond the surface of the wood, and this surface, therefore, should not be broken through or worn away and expose the untreated interior. Should any such exposure occur, either through checking of the wood or from mechanical abrasion, the fresh surfaces should again be well brushed with hot creosote. Of course, if the timber is even slightly infected with decay, a surface coating is useless. Thus a brush treatment on timbers containing sapwood, which is very susceptible to decay, will, as a rule, be less effective than a brush treatment applied to timbers that are 100 per cent heartwood. In general, a brush treatment may not be expected to afford protection against decay for more than a few years. It has, therefore, limitations, although in some instances the life of timber so treated may be extended by a yearly or semi-yearly brush treating of the wood in place, with a creosote oil.

### Dipping

This is also a superficial treatment consisting of dipping or submerging the wood for a short period in a creosote oil. As in the brush treatment, the wood should be dry and well seasoned, and the temperature of the oil should be maintained at about 190 deg. F. during the treatment. This process requires a container or vat large enough to permit submersion of the wood and also a means for heating the oil in the container. For these reasons the method is not always suitable for the treatment of small lots of timber. For large quantities of timber, however, it is more economical than a brush treatment, since dipping can be carried out much more quickly than brushing. Further, owing to the greater certainty of the preservative flowing into checks and cracks during the submersion of the wood, the dipping treatment is safer and in general gives better results than brush treatments in prolonging the life of the timber. Any checks or abrasions that may occur during or after the placing of the treated wood in service should be well brushed with hot creosote.

### Open Tank Treatment

This method of treatment derives its name from the character of the equipment required, namely, two open tanks of any convenient size and shape. It is used chiefly for the butt treatment of cedar telephone poles and for the butt or full length treatment of fence posts.

**Fig. 5—Incised timber and chisel point knife.**

The poles or posts are placed upright in the creosote to a depth of 6 to 12 in. above the ground-line and allowed to stand for from one to several hours, during which time the temperature of the creosote is maintained at about 220 deg. F.* This hot bath partly volatilizes the moisture in the wood and expands and forces out of the wood-cells a certain amount of air and moisture. The posts are then removed from the hot tank and quickly submerged in a tank of cold oil. This cools and contracts the air and moisture in the wood and draws in the creosote. Instead of using a separate cold tank the posts may be kept in the hot tank, which is allowed to cool. The duration of the hot and cold baths depends on the species of timber and the dimensions of the posts under treatment. The air-seasoned sapwood of some species of timber, such as red pine, will readily absorb creosote during the cold bath, and more difficulty will be experienced in preventing excessive consumption of creosote than in obtaining complete penetration of the sapwood. With the exception of spruce, hemlock, and a few other species, sufficient penetration of creosote in the sapwood can be obtained, in round posts, to increase the average service life from five years untreated to twenty years treated.

*It is advisable to use a creosote in which the distillate does not exceed 25 per cent up to 235 deg. C.

Open tank treatments can also be used for the treatment of round posts or poles with water-soluble preservatives, such as zinc chloride or sodium fluoride.

Open tank treatments have not been extensively used for the treatment of heartwood timbers, since the heartwood is much more refractory, in nearly all species, than the sapwood.

### Full-Cell Process

This method of treatment is a pressure process often referred to as the "Bethell" process, after John Bethell, who patented it in England in 1838. Either green or seasoned material may be treated by this process, although best practice recommends that the wood be well air-seasoned before treatment. The timber is loaded on to small steel cars, or "buggies," which are then run into a long horizontal steel cylinder. This cylinder or retort is equipped with steam coils for heating the preservative, and has a cast-steel door fitted to a cast-steel flange, which is riveted to the shell of the retort. The retort varies from 6 to 8 ft. in diameter and from 80 to 150 ft. in length. After the retort door is closed and bolted, the timber, if green, is subjected to a bath of live steam—usually not exceeding 20 lb. per sq. in.—for several hours. With air-seasoned material the steam bath is omitted. A vacuum is then drawn on the cylinder by means of a vacuum pump and maintained for one or more hours. Without breaking the vacuum the preservative, which has already been heated by steam coils in the working tank, is drawn or pumped into the cylinder until the latter is full. Pressure is then built up and maintained in the cylinder by means of a pressure pump which forces the preservative from the working-tank into the cylinder. The pressure used varies between 100 and 180 lb. per sq. in., and is maintained until the gauges or scales show that a pre-determined amount of preservative has been forced into the wood, or until the wood has been treated to refusal. During this pressure period the temperature of the preservative in the cylinder is maintained at approximately 190 deg. F. The pressure is then released and the oil is pumped from the cylinder back to the working tank. The charge of timber is then allowed to drip for a short period (many operators apply a final vacuum to hasten the drip and dry the timber) after which it is removed from the cylinder.

The full-cell process may be used to treat timber with creosote or with mixtures of creosote and other oils, or with solutions of water-soluble preservatives. If the treatment is carried out with the water-soluble salt, zinc chloride, the process is known as the Burnett process, from a patent granted to William Burnett in England in 1838 for the preservation of timber with zinc chloride. The full-cell process has proved to be very effective in prolonging the life of timbers used for different purposes. With creosote oil, however, the process is relatively expensive, owing to the amount of oil that is absorbed by the timbers. For the protection of timbers against marine borers this heavy absorption is both desirable and necessary, but for other purposes a diminution of the amount of creosote retained by the timbers would still give satisfactory results, although there is a relation between the amount of creosote absorbed and the life obtained in service. A reduction in the amount of creosote used may be secured by empty-cell treatments, which are described below.

**Fig. 6—Teredo attack on untreated pile, Iona, C.B.**

LOWRY PROCESS

This process is named after C. B. Lowry, to whom was granted in 1906 a United States patent covering the process. This is also a pressure process and it differs from the full-cell process in the order of application of pressure and vacuum. Air-seasoned timber is loaded on trams or buggies and run into the treating cylinder, which is then closed and filled with hot oil from the working tank. A pressure of from 100 to 180 lb. per sq. in. is applied and maintained until a certain absorption of preservative by the wood is secured. During this pressure period the oil in the cylinder is maintained at a temperature of about 190 deg. F. After the pressure is released the oil is pumped back to the working tank and a vacuum of 24 to 26 in. of mercury is then drawn on the cylinder by a vacuum pump. After the vacuum is broken, the recovered oil is pumped back to the working tank, the cylinder door is opened, and the charge of timber removed. The Lowry process, which recovers some of the free oil from the wood-cells, thus leaves the cells to some extent empty of creosote and is, therefore, often described as an empty-cell process. The process is extensively used for the treatment of railway ties, and the ratio of oil absorbed to the depth of penetration is smaller than in the Bethell full-cell process.

RUEPING PROCESS

This is also a pressure process used for the treatment of timber. It was developed in Germany and patented in the United States in 1902. The object of this process is to obtain a deep penetration of creosote oil in timber, and then to withdraw a percentage of this oil before the timber is removed from the cylinder. Therefore, it is essentially an empty-cell process. The timber to be treated should, preferably, be air-seasoned, though green timber may be treated after it has been subjected to a steaming-and-vacuum conditioning in the cylinder, or has been seasoned by boiling-under-vacuum in oil in the cylinder. The pressure of the air in the cylinder is raised to about 50 lb. per sq. in., after which hot creosote from the working tank is pumped into the cylinder from which (the original pressure still being maintained) the compressed air is allowed to escape. When the cylinder is filled with creosote the pressure is raised to 125 to 200 lb. per sq. in. During this oil-pressure period the temperature of the oil is maintained at about 190 deg. F. When the predetermined absorption of oil, known as the gross absorption, has been secured, or when the wood will absorb no more oil, the pressure on the cylinder is released and the oil is pumped back to the working-tank. With the release of the pressure there occurs a "kick-back" of oil from the wood, caused by expansion of the air compressed in the wood cells during the "initial air pressure" period. This kick-back may expel from the timber as much as 50 per cent of the gross absorption of oil, which the oil pump returns to the working tank. A final vacuum of at least 20 in. is then drawn on the cylinder. This increases the expansive force of any compressed air remaining in the wood, and thus withdraws still more of the oil that was forced into the wood during the pressure period. The vacuum is continued until the drip of oil from the wood ceases and the surface of the timbers is fairly dry. The vacuum is then broken, the cylinder door is opened, and the charge of wood withdrawn. The amount of oil now actually remaining in the treated timbers is known as the net absorption.

From the foregoing description of the Rueping process, it is evident that penetration of the wood is accomplished with a minimum consumption of creosote oil. With round timbers of non-refractory species a recovery, from kick-back and vacuum drip, of 70 per cent of the gross absorption may be secured by certain manipulations of the initial air and oil pressures. The process is quite extensively used, but whether it is equal to the full-cell process in the degree of protection afforded timber against decay is a debatable question that must be considered in conjunction with the cost of the oil, the proposed uses of the treated material, salvage value, and other points.

BOILING-UNDER-VACUUM

This is not exactly a treating process, but is a method of preparing green timber for treatment by artificially seasoning the timber in the treating cylinder. It is generally recognized that it is not possible to force a preservative into wood, the cells of which are already full of water. Green wood contains a considerable quantity of water, sometimes amounting to over 50 per cent of the weight of the green wood, or over 100 per cent of the weight of the oven-dry wood. Before a preservative oil can be injected into green timber a large portion of this contained water must first be removed; in other words, the moisture content of the wood must be reduced. Some species of timber suffer a considerable reduction in strength when processed at high temperatures, and, in order to vaporize and remove the moisture in the wood (that is, to give it an artificial seasoning) and to do this without having recourse to high temperatures, the wood is boiled in oil under a vacuum as follows:

The green wood is run into the cylinder, which is then closed and filled to about two-thirds of its height with oil heated to about 200 deg. F. in the working tank. This temperature will drop to about 180 deg. F., or lower, when the oil comes into contact with the wood in the cylinder. A vacuum is then drawn on the cylinder, and this vacuum is maintained throughout the seasoning period, during which time the temperature in the cylinder is held between 180 and 220 deg. F. As the timber becomes heated by the oil, the moisture in the wood vaporizes under the reduced pressure and is drawn off through a condenser by the vacuum pump. This vaporization of the water causes foaming within the cylinder, and to prevent this foam (a mixture of water vapour and liquid oil) from being carried into, and quickly filling the condenser, the vapours are led through a tall goose-neck piping mounted vertically on the cylinder and extending to a height of about 30 ft.*

The seasoning continues until the condensate removed from the timber is approximately 1/10 lb. per cu. ft. of

*An experimental device for breaking up the foam, developed at the Forest Products Laboratories, permits the cylinder to be filled to within a few inches of the top, the vapours only being allowed to pass into the condenser.

timber per hour. This point may not be reached until after a long period—often 20 hours—and it is determined by examination at intervals of the amount of condensate in the drip tank. The foaming in the cylinder, which is violent at the beginning of the operation subsides after a few hours and permits more oil to be drawn into the cylinder to cover the wood completely. After the timber has been seasoned, the cylinder is completely filled with oil without breaking the vacuum. Pressure is then applied and the treatment is carried out at an average pressure of 175 lb., and an average temperature of 180 deg. F., as already described in the description of the full-cell process. If the timbers are to be treated by the Rueping process the cylinder is emptied of preservative after the boiling-under-vacuum period. The timbers are then subjected to air pressure of sufficient intensity and duration, to provide, under a final vacuum, for the ejection of surplus preservative and to ensure the retention and proper distribution of the stipulated amount of preservative to be left in the timbers. The preservative is then introduced into the cylinder and the treatment carried out as in the Rueping process.

Seasoning by boiling-under-vacuum is practised extensively in plants on the Pacific Coast engaged in the treatment of green Douglas fir ties, timbers, and piling. It is not often resorted to in plant operations in Central or Eastern Canada, where all material is generally air-seasoned before treatment.

## TREATED CANADIAN TIMBER PRODUCTS

### Railway Ties

The following species are used for ties in Canada, both treated and untreated; jack pine, lodgepole pine, red pine, white pine, spruce, eastern and western hemlock, Douglas fir, and oak. Tamarack and cedar are used untreated. Yellow birch, hard maple and beech are used when treated.

With the exception of the treatment of a limited number of ties with zinc chloride, for use in Alberta and Saskatchewan, creosote has been the preservative in general use for the treatment of ties. In the east, 20 per cent of tar was mixed with creosote for several years, and this has been increased to 30 per cent in recent years. In the west, crude oil could be purchased more advantageously than tar, and from 30 to 50 per cent has been mixed with creosote to provide a cheaper treating mixture. In the period from 1913 to 1924, a net absorption of 8 to 10 lb. per cu. ft. was used. The rising price of creosote and the adoption of the incising process, caused and permitted respectively, a reduction of the net absorption to 6 lb. per cu. ft. It has recently been possible to increase the preservative to 8 lb. at some plants. When using a 50/50 creosote crude oil mixture instead of a 70/30 creosote coal-tar mixture, it has been customary to increase the net absorption by at least one pound.

It is difficult to obtain records of the service life of different species of ties in Canada, since renewals are made individually as the ties wear out in service, and a very intensive system of inspection is required, since a section of track may contain ties of different species, treated and untreated, and installed in different years. It is only since 1920 and 1921 that tie treatments have attained any volume in Canada. Consequently, the majority of the treated ties in use have not been in service long enough to obtain extensive data on the service life, but it is sometimes considered that the average life will be about 25 years, judging by the present condition of some of the older ties. This compares with an untreated life of 5 to 9 years for softwoods and 4 to 11 years for hardwoods.

The percentage of railway ties treated in Canada from 1922 to 1932 inclusive is as follows: 16.7, 24.4, 18.9, 16.5, 28.0, 33.1, 30.6, 30.1, 27.5, 38.7, 33.1. Average for 11 years—27.7.

### Telegraph and Telephone Poles

The chief advantage to be derived from the preservative treatment of telephone poles is that species with suitable taper, high strength value, but lacking in natural durability, can be utilized when treated. In Canada, untreated eastern and western cedar have been used extensively for poles, and of recent years a considerable number have been butt-treated with creosote. In Canada, for many years, untreated cedar poles proved quite satisfactory, and the average service life often exceeded the average plant life, that is the poles were changed by reason of increasing loads calling for larger poles, or moved on account of street or highway widening, or for similar reasons, before they failed from decay. In future, a larger percentage of poles will be placed under more stabilized conditions and the 35-year life of creosoted poles used to advantage. The question of continuity of service is now of great importance, and the freedom from failure during sleet storms shown by the stronger treated pine poles is very advantageous.

### Marine Piling

Timber construction is very suitable for port and harbour structures, the chief advantage being that as conditions change and larger wharves are required, wooden wharves can be altered and enlarged. The greater resiliency of wood as compared with stone or concrete is also of definite value in connection with the berthing of ships. With regard to permanency, most structures are out of date before treated timber has reached the end of its useful service life of about 35 years. In sea-water timber must be protected from marine borers, and since water-soluble preservatives will, of course, be rapidly leached from the woods, the choice of preservatives is more limited than in the case of protecting wood from decay. Creosote, however, has been found to be quite satisfactory provided an adequate quantity is used. 14 to 18 lb. per cu. ft. is required for round piling.

### Foundation Piling

Formerly the use of untreated wooden foundation piles necessitated cutting the piles off below low water mark in order that they would always be saturated with water, and thus be immune to decay. Trouble sometimes occurs due to a lowering of the water table, and the consequent failure of untreated piling. Creosoted piles buried in the earth and capped with concrete footing are protected from decay, and are being used increasingly for permanent construction irrespective of the water level.

### Mine Timbers

The rapid development of the mining industry in Canada, in particular the metal mines, has been accompanied by increasing consumption of timber products, and in 1935 about $5,000,000 worth of lumber was utilized by the mining industry. The tendency in mining operations is to utilize the cheapest and most available timber situated near to the mine, and probably the greatest advantage to be derived from the preservative treatment of mine timbers, is the resulting conservation of timber supplies, which are situated close to the mines, and, of equal importance, is the fact that species of low natural durability can be utilized when treated. In nearly every mine there are certain permanent or semi-permanent timbers that can be treated to advantage such as shaft and slope timbers, entry timbers, drift timbers and ties.

The preservatives most commonly used for the treatment of mine timbers are zinc chloride and creosote. Others that have been used are sodium chromate, arsenic, mercuric chloride and zinc sulphate.

Table I. Average Treating Schedules

| Species | Treating mixture | Boiling under vacuum | | | Oil bath | | Initial air | | Oil pressure | | | Gross absorption | Final vacuum | | Net absorption | Total time treatment |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | Hours | Temp. deg. F. | Inches | Hours | Temp. deg. F. | Lb./sq. in. | Hours | Lb./sq. in. | Hours | Temp. deg. F. | Lb./cu. ft. | Inches | Hours | Lb./cu. ft. | Hours |
| Douglas Fir No. 1 Green | 50/50 creosote crude oil | 12½ | 200 | 17-21 | | | 70 | ½ | 150 | 1 | 155 | | 24 | 1½ | 8 | 15½ |
| Douglas Fir No. 1 Seasoned | 70/30 creosote crude oil | | | | 3-6 | 190 | 75 | ½ | 150 | 4-7 | 180 | 10.9 | 24 | 1½ | 8 | 11 aver. |
| Jack Pine No. 1 Seasoned | 70/30 creosote coal tar | | | | | | 65 | ½ | 190 | 3 | 195 | 14.6 | 24 | 1 | 7 | 4½ |
| Birch, Beech, Maple No. 2 Seasoned | 70/30 creosote coal tar | | | | | | 50 | ½ | 175 | 2½ | 195 | 13.4 | 24 | 1 | 7 | 4 |

LUMBER AND STRUCTURAL TIMBERS

The preservative treatment of structural timbers has been increasing each year, the most important item probably being the treatment of bridge timbers. The railway companies have made extensive use of treated timber for bridges and trestles, and the highway departments are following their example. In the construction of highways a great advantage of treated timber is that, when a bridge requires widening or strengthening, it can readily be carried out, when constructed of treated timber, or, if the site is abandoned, the treated timber has a higher salvage value than any other material.

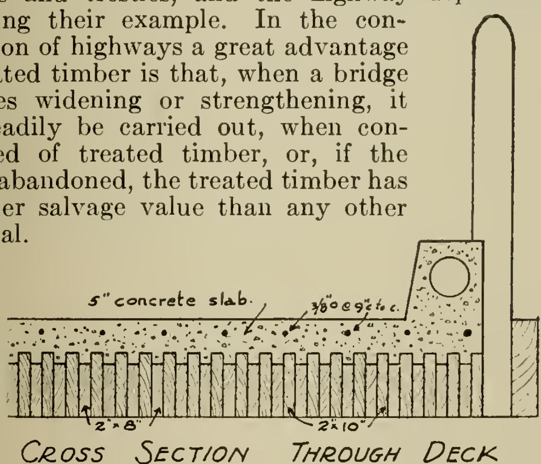

**Fig. 7—Construction of roadway for composite bridge illustrated in Fig. 3.**

The treatment of component parts of buildings such as sills, joists, sub-flooring, nailing strips, rafters and roofing planks has increased steadily. In amusement parks many structures can be constructed of treated wood such as stadium seats and bleachers. On farms, small outbuildings, chicken houses, fences and gates will present a neat and tidy appearance during long years of service, if constructed of treated wood. For irrigation projects, creosoted flumes, wood stave pipe, gates and diversion boxes are serviceable and economical. There are also numerous miscellaneous uses for treated wood such as retaining walls and cribbing, septic tanks, ice-houses, loading platforms, water tanks, scows, etc.

TREATING SPECIFICATIONS

The pressure treatment of timber is quite simple, and the only problem is to leave exactly the specified quantity of preservative in the timber, and to distribute the preservative so that a deep and uniform penetration is obtained.

Specifications for the purchase of pressure-treated timber should stipulate the process, the net retention of preservative, the maximum and minimum temperatures, and the maximum and minimum pressures to which the particular species of timber should be subjected in the treating cylinder.

Table I gives some representative treating schedules used in Canada.

The penetration requirements should call for the treatment of all of the sapwood and as much of the heartwood as practicable. Owing to the erratic nature of the penetration of preservatives in heartwood, it is very difficult to state what the average penetration should be for a particular size and species of timber treated with a given quantity of preservative. A very great deal of work would be required to determine the number of borings for penetration and the number of pieces to be bored per charge in each size of timber product, so that the average penetration required could be safely specified without leading to the unwarranted rejection of treated timber. The incising process helps to secure a more uniform penetration of preservative, and should be specified for square timber whenever possible.

To date treating specifications for Canadian timbers have not been issued by any association, but the Canadian Engineering Standards Association will shortly publish a specification for wood piling, which will include a treating specification, and it is hoped that this will be followed by other specifications dealing with treated Canadian timber products.

Until such time as Canadian specifications are available, the "Manual of Recommended Practice," issued by the American Wood Preservers Association, will be found very useful.

# Synthetic Plastics in Aircraft Construction

*C. Y. Hopkins, Ph.D.,*
*Division of Chemistry, National Research Council, Ottawa.*

**Paper presented to the Aeronautical Section of the Ottawa Branch of The Engineering Institute of Canada, on March 4th, 1937.**

The synthetic plastics have a unique combination of properties which makes them exceedingly interesting as materials for aircraft construction. In comparison with wood, they are almost fireproof, much less susceptible to deterioration by water and weather, and are prepared in the desired shape by moulding.

In comparison with metal, they are lighter and non-corroding. They damp vibration and they are electrical insulators. Their surface is naturally smooth and requires no protective coating.

### Types of Resins Available

The synthetic resins are simply materials which have the appearance and characteristics of natural resins but are produced synthetically.

While the natural resins are usually marketed in the form of lumps or flakes, the synthetic materials are more often ground and mixed with filler and sold as moulding powder.

Nearly all of the synthetic resins have the property of becoming plastic at elevated temperatures. Those which have this characteristic are properly known as plastics. In the process of moulding, a mass of plastic material is subjected to simultaneous heat and pressure whereby it takes the desired shape and is then termed a moulded product.

There is an unfortunate tendency to apply the term "plastic" to both the moulding powder and the finished product. In most cases the moulded article is permanently hard and it is misleading to refer to it as a plastic.

The world production of synthetic resins is said to be about 70,000 tons each year. Of this amount 30,000 tons or nearly half is used in varnishes. The remaining 40,000 tons is used for the manufacture of moulded products.[1]

Synthetic resin varnishes are used extensively on airplanes and might well be included under this title. The average airplane today probably carries more synthetic resin in the form of varnish than in the form of moulded products. The introduction of this material into varnish constitutes the greatest advance in the paint and varnish industry in the last decade. The hardness, flexibility and durability of these varnishes places them far above the old type in quality.

Mention should be made of the cellulose derivatives although these cannot be called strictly synthetic. The cellulose part of the molecule comes from wood or cotton and is the essential part of the material. The chemical modification of it is a secondary feature.

The available types may be classed as follows:

*Class I, Natural Polymers*

(*a*) Cellulose derivatives (acetate, nitrate, ethyl, benzyl);
(*b*) Casein;
(*c*) Shellac.

As far as moulded products are concerned, cellulose nitrate is too inflammable for airplane use. It also deteriorates under the action of light.

Ethyl and benzyl cellulose are relatively new and show promise. Cellulose acetate is the important material in Class I.

Both casein and shellac are affected by moisture and are inferior to the true synthetic resins in other respects.

[1] Fonrobert, British Plastics, Jan. 1937, p. 375.

*Class II, True Synthetic Resins*

(*a*) Phenolic type, e.g. phenol-formaldehyde;
(*b*) Urea type, e.g. urea-formaldehyde;
(*c*) Alkyd type, e.g. glycerine-phthalic anhydride.

The phenolic type has probably the widest use and is regarded as the most promising in this class for aircraft use. The urea resins have poorer moisture resistance and display no advantage in strength. The alkyds are not primarily moulding resins. They may be cast, sheeted or extruded. Their greatest use is probably in varnishes and enamels.

*Class III, Synthetic Polymers*

(*a*) Acrylic type, e.g. polymethyl methacrylate;
(*b*) Vinyl type, e.g. polyvinyl acetate;
(*c*) Styrene type, e.g. polystyrene;
(*d*) Synthetic rubbers.

The distinction between resins and polymers is chemical and refers to the mechanism of their formation. The resinous materials are generally coloured and are thermosetting while the polymeric materials are more often obtained colourless and transparent; most of them are permanently thermoplastic.

In practice both classes are usually referred to as resins.

The acrylic type is not only the newest but probably the most important of this group. It appeared on the market in England and the United States only within the last year or two and is sold under such names as Perspex, Luglas, Plexiglas, Acryloid and Lucite.

The vinyl type has good properties in general but has a tendency to cold flow and is not entirely unaffected by light.

Polystyrenes have exceptionally good electrical properties and are useful wherever such characteristics are especially important. They are probably too expensive for ordinary moulding. Their water absorption is zero.

The synthetic rubbers do not come within the scope of this survey. They may become important in aircraft on account of their resistance to sunlight and to oil.

### Propellers

During the war propellers were used in the United States which were made of a phenolic resin product called Micarta. This is a laminated phenolic material and is still on the market in the form of sheets for wall coverings and counter tops. It is made up by saturating sheets of cloth or paper in the soft resin and bonding a number of layers together in a heated hydraulic press. These propellers were apparently satisfactory but have not come into general use.

A more recent development is the coating of a wood propeller with a thick layer of resin. This is the Schwarz process, which is used in Europe. After a preliminary treatment of the wood, a sheath of cellulose acetate is placed over it and is then bonded securely to the wood by heat and pressure. The result is a smooth, moisture resistant and abrasion resistant surface. The member has the tensile strength of wood and the durability of a synthetic resin.

It has been proposed to manufacture a controllable pitch propeller having moulded blades attached to a metal hub.

A possible development is the impregnation of wood propellers with a resin by a recently developed process.

The result of impregnation is to increase the strength and weight in about the same ratio but water resistance and durability are greatly improved.

The production of a moulded propeller from pure resin is technically possible but is open to a number of objections. In the first place, it would be twice as heavy as wood with little or no advantage in strength. In comparison with duralumin the moulded propeller would have much poorer strength characteristics. On the other hand it would be lighter, less subject to fatigue and non-corroding.

### Engine Parts and Accessories

Moulded products may not be used where they are exposed to the full heat of the engine. Like all organic materials, they will burn at temperatures higher than about 200-300 deg. C. (400-500 deg. F.). The phenolic resins are the most resistant to heat. However, many of the accessory parts may be made of moulded products for lightness and cheapness. Distributor caps have long been moulded of phenolic resin, hard rubber having been abandoned during the war.

Other parts which can be made from plastics include water pump impellers, timing gears, insulators, washers, bushings and small housings.

The use of moulded instrument panels, instrument cases and of translucent dials is now quite common. Even if weight were not a factor, they have many advantages over wood, metal and glass. Control knobs, switches and radio parts made from plastics are also standard. Control levers can be made of plastics moulded on a metal core.

The most common materials for these purposes are cellulose acetate and phenolic resins. Cellulose acetate is somewhat more expensive but is tougher and more pleasing in appearance. The larger parts (instrument panels and cases) are more likely to be made of phenolic resins.

### Structural Parts

The tensile strength and transverse breaking strength of the moulded products is inadequate for parts such as spars, ribs and struts which are subject to severe stresses in use.

| Material | Specific[2] Gravity | Tensile[2] Strength lb. per sq. in. |
|---|---|---|
| Phenolic | 1.35 | 7,000 |
| Acrylic | 1.2 | 8,000 |
| Phenolic (laminated) | 1.37 | 10,000 |
| Duralumin | 2.85 | 50,000 |
| Steel | 7.8 | 100,000 |
| Spruce | 0.4 | 10,000 |
| Birch plywood | 0.8 | 15,000 |

The laminated phenolic products can compete with cast aluminum alloy for parts requiring relatively low tensile strength, i.e. up to 30,000 lb., when the saving in weight is taken into consideration. They are not suitable for places where the highest structural strength is needed.

Laminated phenolic products in sheet form have been suggested for cowling and covering of wings and fuselage. The acrylic ester resins have not yet been offered in laminated sheets and it is likely that they will be more serviceable than the phenolics, being lighter and tougher.

This form of covering has two advantages which may not be immediately apparent. One is the natural smooth surface which results in a minimum skin friction drag. The second is the property of absorbing or deadening vibration.

The laminated board would appear to be eminently suitable for wall covering in cabins and freight compartments.

A possibility which has not been explored is the manufacture of resins in a sponge structure for wings. It is quite simple to prepare a resinous mass with a great number of voids and having a specific gravity as low as 0.3 with reasonable strength. Even lighter grades can be made for sound or heat insulation.

[2] Average figures from various sources.

### Organic Glasses

One of the earliest uses of plastics on airplanes was in the preparation of safety glass. It is now generally used in laminated glass in cabin windows of transport planes. Originally cellulose nitrate, this material gave way almost entirely to cellulose acetate and the latter is yielding in turn to vinyl and acrylic products.

Sheet resins without glass are now used for windshields and cockpit enclosures. Cellulose acetate is preferable for this purpose, the nitrate being too inflammable. When plasticized with triphenyl phosphate, cellulose acetate is practically fireproof.

The vinyls and acrylic esters may replace cellulose acetate sheet for this purpose also.

These products are known as organic glasses and are likely to come into wide use not only in aircraft but for ordinary building purposes. The windows in the airship Hindenburg were of acrylic resin sheet.

The organic glasses are about one quarter the weight of glass, the visibility is as good and ultraviolet transmission is much higher. While they are subject to scratching and wear, replacement is simple. Their light transmission is over 85 per cent. The acrylic glasses are the most resistant to scratching while the polystyrenes have the greatest hardness.

Transparent Sheet[3]

| | Scratch resistance | Indentation hardness |
|---|---|---|
| Cellulose acetate | 9 | 7 |
| Cellulose nitrate | 10 | 11 |
| Ethyl cellulose | 6 | 6 |
| Acrylic resin | 15 | 14 |
| Vinyl resin | 10 | 15 |
| Styrene resin | 11 | 20 |

The recently formed Plastics Division of the Bureau of Standards at Washington has devoted considerable attention to the organic glasses.

### Conclusion

Miscellaneous uses for plastics include the manufacture of heavy duty bearings. These have been very successful in industrial use and might be used to a limited extent on aircraft, with a resultant saving in weight. A phenolic resin glue is now used for making waterproof plywood. The material has remarkably good water resistance.

General methods of testing moulded products have been well developed and are in everyday use. A specification for phenolic resins and moulded products is shortly to be issued by the British Standards Institution. It will contain complete details of the methods of test.

The trend is therefore toward the use of plastics for making small parts, for transparent sheets to replace glass, in laminated sheets for covering large areas, and for incidental use in various places.

The moulding of large shapes is difficult and their strength is not high enough to warrant their use in structural parts. The discovery of high strength plastics and of simplified moulding methods may occur in the future. If such a development does come, it will be a gradual process and one will probably find moulded products becoming larger and larger until the construction of a complete wing from moulded shapes may conceivably be accomplished. As a commercial possibility this is some distance away.

The use of plastics for the purposes mentioned is, however, a large and increasing one and represents a considerable advance in the technology of aircraft.

DISCUSSION ON

# The Characteristics and Application of Modern Electric Relaying

*Paper by E. M. Wood[1] published in The Engineering Journal, May 1937*

P. ACKERMAN, A.M.E.I.C.[2]

In the opinion of the writer, stepped distance protection represents for our conditions the most universal principle for line protection, satisfying, for most power systems, practically all requirements for selectivity and speed of clearance.

The pilot principle, as far as its application to overhead systems, covering wide areas, is concerned, will remain a refinement, applied only in case of short tie lines which may be beyond the stepped distance principle; or in special cases, where extra clearing speed may prove particularly desirable. The ultimate form of high speed pilot protection will not necessarily be the one described by the author. Such pilot protection will probably be rather superimposed on an ordinary distance protective system, using for this purpose the standard distance relay equipment for the a.c. function, and for the pilot circuit whatever communication circuit will best fit into the specific case. Where speed of clearing is the main motive of the pilot protection, schemes which will transfer a trip impulse, rather than a blocking impulse, should prove advantageous.

The writer fully concurs with the author that high speed protection, coupled with re-closing feature, has many open fields for development.

A warning should be sounded regarding the use of special pilot protection to prevent trip-out on wide swings, or out-of-phase conditions between power sources. This is a risky way of tackling this problem. The only basic solution is to speed up the fault clearance, or to arrange the system layout so as to avoid serious voltage dips between synchronous systems parts, so that no instability or wide swings will occur at all.

As has been pointed out, most of the characteristic methods of high speed relaying, as described in this paper, have been applied extensively on the system of the Shawinigan Water and Power Company since 1920. By 1930 the main system of this company was almost entirely equipped with instantaneous system protection, at a time when other systems only started to make some timid attempts in this direction. True, what was called in those days "instantaneous," represented a total clearing time of approximately 5/10 of a second, whereas today total clearing times of 5/100 of a second can be obtained. This is 1/10 of what was considered quick clearance in 1930.

Except for stability reasons, no such extreme high speeds, however, are actually required to assure the full benefit of avoiding power arc damage and station oil fires. This is best proved by the records of the Shawinigan system, where instantaneous clearing times still range approximately between 0.2 to 0.5 seconds. The following extracts from records for the five-year period 1931-35, as published in a Bulletin on Shawinigan Engineering Features (September 1936), show the beneficial effect obtainable from such instantaneous protection, even at these slower instantaneous clearing speeds:

1. Of 1,400 circuits, cleared by relay protection during the five-year period from lightning flashovers, only 32 circuits were permanently damaged, that is, slightly over 2 per cent, whereas in the other 98 per cent of outages, the circuits went back immediately into service.

2. Of 145 station troubles, cleared by instantaneous zone protection during the five-year period, one-half of these troubles were momentary flashovers, where the instantaneous protection prevented power arc damage, permitting immediate resumption of service on the respective apparatus. During that period there were no cases of a serious oil fire.

Such records as mentioned indicate how, by persistent efforts, full control over a hazardous situation can be attained. The significance of such progress can best be appreciated by power house operators and line maintenance gangs of former days who used to be called out at any time of the night into severe storms to try to locate a damaged transmission line in utter darkness, or to fight a pernicious station oil fire.

This progress in speeding up the power system protection is particularly gratifying as it represents the final goal, for the attainment of which the writer has been fighting for the past twenty-five years.

F. F. AMBUHL[3]

The author has covered the subject in a very able and interesting manner. The extensive development during the past eight years in producing suitable relays to meet the many requirements imposed by the varied applications and operating conditions is something for which the operating engineer is truly grateful. This development is due in a large measure to the close co-operation of the engineers of both the operating and manufacturing companies. The improvement seems to have been fairly general in all types of equipment where relays are employed. Of the many supervisory and control systems which were placed in service eight or ten years ago only a few of these are now supplied in their original form. Considerable trouble was experienced with most of the early supervisory equipment though very little difficulty is experienced at present in obtaining equipment which may be considered quite satisfactory.

In the field of electric power generation and distribution, the benefits derived from the high speed clearance of a faulty section or element through the employment of high speed relays in conjunction with high speed cirucit breakers, cannot be easily over-estimated. Studies of system stability have shown that in general, the most effective method of accomplishing this result is the high speed clearance of the faulty section or element. Other methods may be and have been employed to increase the limit of stability though in any case the maximum results cannot be obtained unless high speed clearance is employed. While the clearing time depends on the type or nature of the fault, the allowable variation in clearing time is very small. Taking the worst condition, that of a three phase short circuit, the clearing time should be from 0.1 to 0.2 seconds, whereas with a single-phase-to-ground fault a clearing time of from 0.2 to 0.4 seconds would probably be found satisfactory.

[2] Consulting Electrical Engineer, Montreal.

[3] Assistant to Chief Engineer, Toronto Hydro-Electric System, Toronto, Ont.

Selective high speed clearance of faulty lines and equipment on large low voltage systems (12,000 volts and under) is also of the utmost importance as the failure to isolate a faulty section or element before it involves other equipment has in many cases resulted in the destruction of a large amount of equipment. Even on the low voltage networks where the entire secondary network is connected solidly together, continuity of service is dependent on high speed clearance of any faulty transformer or primary feeder supplying the network.

F. C. Barnes[4]

The field of protective relaying has become so extensive in the last few years that it is practically impossible to cover in one paper even a résumé of the certain problems which are common to most relay applications and until recently the difficulties involved in relaying under certain conditions have not been very thoroughly analyzed. The author indicates in his paper some of these difficulties and suggests various methods which have been used to overcome these troubles successfully.

In connection with very high speed differential protection for transformer banks, there are available on the market, relays capable of operating in one cycle or less, but experience in recent years with high speed transformer protection does not substantiate the increased benefits to be derived in the light of other factors. It has been proved in the field, that with relays operating at such high speeds, extreme care must be taken in choosing current transformers with suitable characteristics, so as not to cause false operation during heavy through short circuits, in which offset current waves are involved. Unless both the high tension and the low tension current transformers transform the offset waves nearly identically, false relay operation may result when using relays which operate in less than six to eight cycles. In the case of power transformers, where the current transformers on either side are of different types, such matching of characteristics is an expensive if not an almost impossible job.

In most cases, the difference in cost of repairing a transformer in which a fault persists for nine or ten cycles (assuming a breaker time of eight cycles and one or two cycles of relay time) is not materially different from that required where the fault lasts for fifteen cycles. With a synchronous machine it is different for here the repair may involve replacing iron which is generally not necessary in transformer repairs.

On some recent installations, high speed relays have been used on the generator circuit, where current transformers could be very carefully matched on both sides of the winding, due to the fact that they are of the same type, rating and design. Very high speed relays have been used on the transmission line but, on the transformer bank, relays operating in six to eight cycles have been used without any detrimental effect due to increased damage in the transformer because of the longer clearing time for a fault and without any danger of instability due to the slower tripping.

In some cases where high speed transformer differential relay applications have been made and where the bank is to be energized from the high tension side, the use of a potential transformer and undervoltage relay has been recommended. The contacts of the undervoltage relay are used to apply voltage restraint to the high speed relay raising its operating point from, say two to to eight amperes only for a second or two during the period of energizing the transformer. As soon as voltage appears on the secondary side the voltage relay picks up and removes the restraint from the relay. The only disadvantage of this scheme appears to lie in the fact that the sensitivity of the relay is decreased at a time when a fault is most likely to become apparent, although other engineers have indicated that if the transformer is sound when taken out of service it is unlikely to be faulty when put back into service.

G. R. Davis, A.M.E.I.C.[5]

The author's remarks on the improvement of present relay schemes are particularly interesting and timely in that there are many systems where the relaying has become too slow for most efficient operation and it is imperative that either the present relaying be improved or that complete new relaying be installed. As the improvement is the less costly it is the method that will usually be tried before scrapping present relaying.

Ten or twelve years ago on the smaller systems protected with inverse definite time relays of the induction disc type it was common practice to have minimum definite time settings of several seconds. As generating station capacities increased and the systems became interconnected with other systems it became necessary to shorten these times to at least one second wherever possible.

The benefit of clearing faulty lines in a comparatively short time was seen immediately insofar as system stability was concerned and the only thing that prevented even shorter time settings being used with induction disc relays was the matter of selectivity of one line section with another.

On systems with many small generating stations comparatively far apart and connected by transmission lines, numerous loops were formed by these lines and by lines to load centres. It can readily be seen that on such a system it was impossible to make relays selective on a time basis only and as the current available to operate a line relay depended on the number of generators connected to the system at the time of the fault it was not always possible to depend on the relay reaching a minimum definite time value. The relay settings finally used were more a result of experience than of calculations because so many different system connections were possible and experience only could determine the settings that gave the least faulty operations and unnecessary interruptions.

In laying out new relay schemes for this style of system layout it would seem impracticable to determine all new current and time settings by calculations only and disregard the old settings that had been determined largely by years of experience. The better method would be to superimpose instantaneous overcurrent or impedance features on the present relaying and gradually adjust settings to give more efficient results. With system generating capacity other than normal the present relaying would not be affected in any way and with system capacity normal the added features would clear the faulted sections instantaneously and system stability would be decidedly improved.

From a stability viewpoint pilot wire relaying on short lines has proved most satisfactory but as mentioned by the author the cost is usually prohibitive.

E. W. Knapp, A.M.E.I.C.[6]

The author has managed with considerable success to cover his subject in a condensed but nevertheless thorough manner but the writer would like to review the protection problem from a somewhat different angle.

In the not-very-distant past, protection relays were accepted by the engineering staff as a necessary evil and welcomed as an operating convenience by the operating personnel. At that time all protective gear, including relaying and switch-gear, was slow in operation and not

[4] Canadian General Electric Company, Limited, Toronto, Ont.

[5] Hydro-Electric Power Commission of Ontario, Ottawa, Ont.

[6] Shawinigan Water and Power Company, Montreal.

always effective or selective in action. The obvious result was extensive power arc damage, costly repairs and extended service interruptions.

As the power systems grew, power equipment became larger and more costly, transmission systems developed into networks and system interconnections became quite common. It then became apparent that effective and selective relaying was no longer a necessary evil, but an urgent necessity. In order to cope with the growth of the power system, the protection engineer was obliged to develop adequate protection schemes for each element of the power system, so designed that a faulted element could be isolated with a minimum of damage to itself as well as a minimum of disturbance to the interconnected system. Needless to say, this was a situation requiring a thorough understanding of the various elements of the problem and considerable initiative on the part of those responsible for relaying. This was particularly true in view of the limited amount of information readily available on the subject at that time, and the inadequacy of relays then available.

During this development period many experiments were tried with varied success. Some of these were successful and are still in use; others required considerable modification and still others proved unsatisfactory in practice and had to be abandoned. Considerable progress has been made during the past few years, not only in the development of new schemes of protection, but also in improved instruments to use in these schemes.

Relay protection is today an integral part of the power system. No system planning organization is complete without a representative of the Protection Department. Each element of the power system must be studied carefully in its relation to every other section, including the necessity or ability of providing an adequate relay protection. The design of the relay protection must be carefully correlated with the power system plan and available protective gear, including relays and switch-gear. If fast isolation of faults is required, then it is important that both switch-gear and relays have fast operating characteristics. The choice of relays is of paramount importance in any relay scheme, particularly on the network systems where system stability, selectivity and service continuity are important factors.

After the protection has been installed, it is necessary to have a maintenance organization to insure that all protective gear is kept in good condition. It must not be overlooked that this equipment is normally inactive, but when called upon, it must be ready to complete its job within a small fraction of a second.

Training of the operating and maintenance personnel is also an important section of the relaying organization. This is particularly true on those extended systems where outlying stations may be several hundred miles from the relaying organization. In this case preference is often given to simple and rugged schemes and instruments, requiring the minimum of attention. It has been found that supervisory and indicating lights, control switches and other conveniently arranged devices are of considerable assistance to the local station or district personnel, and these features very often form an important part of the protection design.

The author has mentioned such features as primary tests, automatic recording instruments, relay indicators, symmetrical components and instantaneous automatic reclosing and the writer is in agreement with the expressed opinions on these features. The Shawinigan Water and Power Company have adapted these features to their system and have found them helpful. They also correlate and analyze all data pertaining to each automatic operation on the power system. This procedure has proved of considerable value in locating and permitting the removal of defects on the power system, including protective gear.

In conclusion, the importance of the protective gear from a service viewpoint should be stressed and to emphasize the serious consequences from a damage and service viewpoint if this feature of the power system is not effective in every important function.

F. L. Lawton, m.e.i.c.[7]

This excellent paper has been read with considerable interest, as it presents a comprehensive survey of relay practice. However it would be appreciated if the author would discuss the following questions;

(*a*) What is the relative reliability of high-speed carrier pilot relay schemes, particularly of the component equipment?

(*b*) How does the cost of such relaying on, say, a 100-mile transmission line compare with conventional high-speed impedance relaying?

(*c*) Has it been possible to eliminate all faulty operations of current-differential protection schemes on low-voltage, 15 kv. and under, zones where through fault, currents of high value occur?

D. J. McDonald, Jr.e.i.c.[8]

The author has discussed the advantages which accrue to the power company which uses modern relaying systems.

When trouble occurs on a power system induced voltages appear on communication circuits which are in the vicinity of the power circuits affected. The magnitude of the induced voltage and its effects depend on the amount and duration of the residual current flowing in the power circuit. Anything which is done to reduce the duration and extent of the power system disturbance is therefore a direct benefit to communication systems, which operate circuits adjacent to the power circuits, as well as to the power company.

E. G. Ratz[9]

The author has pointed out the characteristics and advantageous features of induction types of relays. In discussing the protection for important transmission circuits there has been some tendency to criticize the induction type of relay unjustifiably when, as a matter of fact, it is the application of the relay which is in error rather than the relay itself.

It is true that the characteristics of the induction type relay can no longer be considered adequate for important main transmission circuits. Nevertheless the rugged, accurate and reliable characteristics of this form of relay make it ideal for the tremendous number of applications on branch feeder circuits, apparatus protection, etc., on which it is still used, without any real equal in regard to ease of setting for both current and time, these features all being combined in the one piece of equipment.

The induction type relay was first made in 1902 and has been used in continually increasing quantities ever since that time.

Induction type overcurrent relays can now be made with burdens of less than 1 VA at the tripping current and to operate in less than 2 cycles (60 cycle basis). When used as differential relays these induction relays have the great advantage that they largely ignore the troublesome transient currents which are the result of current transformer characteristics and are described fully on page 246 of the author's paper. Other types of relays which take cognizance of these current transformer secondary currents must be

[7] Electrical Engineer, Saguenay Power Company, Arvida, P.Q.

[8] Bell Telephone Company of Canada, Montreal.

[9] Canadian Westinghouse Company Limited, Hamilton, Ont.

set with higher currents to avoid them—and therefore with less sensitivity.

The fast induction type overcurrent relay just mentioned can also be made practically free from chattering and rebounding at the contacts—a feature of importance in high speed relay design brought out by the author.

In the case of high speed distance relays a fault within the range of the instantaneous zone should cause the corresponding relay element to operate in a cycle or two, and the arc resistance for the instantaneous range is therefore hardly of any consequence—because it has not had the opportunity to rise and lengthen. For the instantaneous zone the impedance relay therefore is the equal of the reactance relay in accuracy and has the great additional advantages of simplicity, ease of setting, and low cost. Further, where the lines are long the arc resistance, if any, adds at right angles to the reactance of the line and has therefore comparatively little effect on the "impedance" measured. In the case of the second or time zones a high degree of accuracy in the measurement of the distance to the fault is usually not necessary.

The form of carrier protection described by the author, when controlled by distance relays at each terminal, greatly facilitates the adequate protection of lines with branch circuits, or main line networks of the Y type when three or more main terminals are used. These are types of lines that have been very difficult to adequately protect heretofore, particularly when the branches of the lines have widely different lengths.

Ralph C. Silver, s.e.i.c.[10]

The author has covered his subject so well that it is difficult to offer much discussion. The following may, however, be of some interest.

In certain cases instantaneous overcurrent relays may be applied as a supplement to directional impedance relays or other protection employing directional relays. In case of a three-phase metallic short circuit just outside a line O.C.B. there will be no voltage on the directional relays and they cannot operate.

It is interesting to note that some of the restrictions which a few years ago were imposed on a system arrangement by the requirements of selective relaying and stability considerations are being removed by the development of high speed breakers, carrier current relaying and automatic reclosure. It should, however, be kept in mind that the system layout is still one of the most important factors in producing a stable system with simple and effective relaying.

The importance of various design details and accurate operating data has rightly been stressed. In dealing with high speed relaying even seemingly unimportant details may completely upset the correct working of a protection scheme.

The combination of high speed relaying and automatic reclosure will undoubtedly prove to be one of the major advances in modern relaying. There will also be a tendency to bring the advantages of high speed protection to the lower voltage and small capacity feeders through the use of instantaneous overcurrent relays. An induction type relay is now under development which will operate in $1\frac{1}{2}$ to 2 cycles at high currents, but which will have the normal inverse time characteristic at smaller currents. There should also be further simplifying of the relays themselves and of certain relay circuits. The use of electron tubes has rapidly increased during the last few years and although they have not been employed to any great extent in power system relaying, except for carrier current installations, they should be considered as a possible means of providing simplified and better relay systems.

Is it correct to assume that Curve $A$ in Fig. 5 is for slightly different circuit or load conditions than curves $B$, $C$ and $D$?

[10] Gatineau Power Company, Ottawa, Ont.

The Author[11]

In looking over the discussion one is impressed by the value of the information and opinions brought forward by the various contributors. Each has added something that was not treated at length in the paper but which was pertinent to the subject. The author concurs, without important reservations, in the opinions expressed and wishes to thank the contributors.

There remains only to reply to the questions asked.

Replying to Mr. Ralph Silver, curve $A$ of Fig. 5 on page 247 differs from curves $B$, $C$, and $D$ in that the fault location is 15 per cent of the line length away from the point shown, which accounts for the different shape of the initial part of the curve.

Replying to questions raised by Mr. F. L. Lawton.

(*a*) Regarding the reliability of the component equipment of high-speed carrier relaying, up to very recently there have been no installations in service in Canada. There are, however, a very considerable number in service in the United States and the author has reason to believe that they are operating successfully. Some early trouble with loss of adjustment of timing of the carrier sets has, we are advised, been overcome.

(*b*) The cost of relaying on a 100 mile line by carrier-pilot would be of the order of two to three times that of conventional high speed impedance relaying, not taking into account potential or current sources for the relays.

(*c*) In current differential protective schemes such as bus zones at 15 kv. or less, where there is very heavy through fault current, but where sensitive settings are necessary, the author has used a two-stage scheme consisting of one set of differential current relays of the maximum required sensitivity, timed at one-half second and supplemented by a set of high speed relays which are set above the transient unbalance but which are effective for all heavy faults. This combination has proved effective in stopping improper operations wherever used on zone protections which had given trouble. Mr. Ratz in discussing the paper mentions a high speed low-energy induction relay which might be useful in such cases.

# THE ENGINEERING JOURNAL

## THE JOURNAL OF THE ENGINEERING INSTITUTE OF CANADA

"To facilitate the acquirement and interchange of professional knowledge among its members, to promote their professional interests, to encourage original research, to develop and maintain high standards in the engineering profession and to enhance the usefulness of the profession to the public."

VOLUME XX DECEMBER, 1937 No. 12

## The Council and the By-Laws

The ever present question of amendments to The Institute by-laws is one to which Council has devoted a great deal of attention both at its regular meetings during the past year, and at the Special Plenary Meeting of the 14th June last. In this connection the principal points involved have been the character of our future relations with the various Professional Associations, the extent and manner of co-operation with them and the nature and breadth of the necessary by-laws providing for such co-operation.

The events which have led up to the present situation regarding by-law revision are thus of great interest to the membership. Their importance in relation to the future of The Institute is such that Council has directed the publication in The Journal of a statement informing members as to the action taken by Council in respect to them on various occasions during the past twelve months.

Such a resumé will be found in another column. It will be remembered that the results of the ballot on the proposals of the Committee on Consolidation were published in May 1937. Following this, at its meeting on May 28th, Council appointed representatives to confer with a local committee in Nova Scotia which was already studying the possibilities of co-operation between The Institute and the Provincial Professional Association there. Since that time the subject of our relations with the Associations has come up at practically every Council meeting, and it has developed that in certain provinces such as Nova Scotia, New Brunswick, Manitoba, Saskatchewan and Alberta, the problem might be regarded as comparatively simple. The number of members involved is not large, and it may well be that working arrangements for co-operation can be established with some of these bodies as soon as the Council is authorized to enter into agreements with the Associations concerned. But as regards the three larger Associations, the situation is essentially different. Their membership is larger and contains a greater proportion of Association members who are not in The Institute. There are also a considerable number of members of The Institute who do not belong to those Associations. For these and other reasons, the desirable objects, such as common membership, or uniform standards of admission as between the Associations themselves and with The Institute, seem more difficult of attainment in these cases.

At the present moment a point has been reached where the Council finds itself unable to support a series of proposed amendments which were put forward on October 1st by thirty-one corporate members. It is felt that under present conditions the interests of The Institute would be better served by a simple amendment giving Council the legal power to enter into an agreement with any of the Professional Associations. This decision was taken at the Council meeting which has just been held in Toronto, at which, after noting the marked diversity of interests, membership, and working conditions that characterizes the various Professional Associations, Council did not think it advisable to approve a series of by-laws which prescribe in detail a single scheme intended to be applicable in all cases.

The steps which Council has now taken as to agreements in Nova Scotia and New Brunswick, and which it is desired to legalize by the membership's approval of Council's proposal for a new by-law providing for the conclusion of agreements with the Associations, are however, in Council's opinion, an indispensable preliminary to further progress. On this account it is urged that Council's proposal, which will shortly be mailed to members and will be submitted for discussion at the Annual General Meeting, should receive the support of every member of The Institute.

## Committee on the Publications of The Institute

One of the recommendations of the Round Table Conference of Branch Delegates held at the time of the Semicentennial was that Council should give its early consideration to the publications of The Institute, and the Conference also submitted some definite suggestions with regard to The Engineering Journal. Council was of the opinion that the subject was too important to be dealt with without the fullest consideration, and therefore appointed a Committee to make a comprehensive study of the Publications of The Institute, and to report on any improvements or changes which may be found possible.

The personnel of the Committee is as follows:—

| | |
|---|---|
| R. W. Boyle, M.E.I.C., | National Research Council, Ottawa, |
| A. Duperron, M.E.I.C., | Chief Engineer, Montreal Tramways Co., |
| R. H. Findlay, M.E.I.C., | Mechanical Engineer, Dominion Bridge Co., Montreal, |
| F. S. B. Heward, A.M.E.I.C., | F. S. B. Heward and Company, Montreal, |
| J. L. Busfield, M.E.I.C. | (Treasurer of The Institute), Chairman. |

The Committee has held an organization meeting, and appreciating that the opinions of the membership are of fundamental importance in the development of The Institute's Publications, it has been decided to issue a questionnaire to the membership at large asking for specific information with regard to each member's preferences. After the replies have been received and studied, and the whole subject thereby brought to a focus, it is expected that a second questionnaire will be submitted dealing with proposals for the future.

Members will appreciate that the Committee's work will be facilitated by a prompt and universal reply to the questionnaire, so they are earnestly requested to take the few minutes necessary just as soon as the questionnaire is received.

## The Fifty-Second Annual General Meeting

Notice is hereby given in accordance with the By-Laws, that the Annual General Meeting of The Engineering Institute of Canada for 1938 will begin at Headquarters at eight o'clock p.m. on Thursday, January 20th, 1938, for the transaction of the necessary formal business including the appointment of scrutineers for the Officers' Ballot, and will then be adjourned to reconvene at the London Hotel, London, Ontario, at twelve o'clock noon on Monday, January 31st, 1938.

R. J. Durley,
*Secretary*

## The Late Lord Rutherford of Nelson

The news of the death of Lord Rutherford on October 19th, at the age of sixty-six, will greatly affect the many Canadians who knew him as Macdonald Professor of Physics at McGill University during the years 1898 to 1907. It was at this time that he made the first of the discoveries which were later to serve as the foundation of much of our present knowledge of radioactivity and the structure of the atom.

Born in Nelson, New Zealand, and a graduate of the University of New Zealand, Ernest Rutherford came to England and entered Trinity College, Cambridge, in 1894. There he worked in the Cavendish Laboratory, under Sir J. J. Thomson, investigating the newly discovered properties of ionized gases. He became interested in the problems of radioactivity which arose from the investigations of Becquerel and Curie, and soon after his appointment at McGill, and in conjunction with Frederick Soddy, obtained experimental results which provided an explanation of the disruption of the atoms of the radioactive elements. It was found that these unstable elements are being continually transmuted into other elements, as, for example, the change of the unstable uranium into the more stable element lead. This work led to his election as a Fellow of the Royal Society in 1903.

Leaving Montreal in 1907, he was appointed Langworthy Professor of Physics at Manchester University, and was awarded the Nobel Prize for Chemistry in 1908. Three years later, having established the existence of the atomic nucleus, he advanced a theory of atomic structure which aroused the interest of many other workers and has resulted in the development of the present ideas of atomic physics. He was knighted in 1914, and in 1919 returned to Cambridge, where he succeeded his old chief, J. J. Thomson, as Cavendish Professor and Director of the Cavendish Laboratories. From that date until his death he continued his work on radioactivity and the artificial disintegration of the elements, his services to science and the State having been recognized by the award of the Order of Merit in 1925 and by a peerage in 1931. He was the recipient of other degrees, prizes, medals and honours too numerous to mention here.

In addition to his engrossing occupation with radioactivity, Lord Rutherford found time for a considerable amount of public work, serving, for example, for seven years as chairman of the Advisory Council of the Department of Scientific and Industrial Research. He was an ardent advocate of research as an aid to the application of science in industry.

His leading personal characteristics were modesty, friendliness, remarkable skill as an experimental physicist, and striking ability to awaken in those who worked with him an enthusiasm comparable to his own.

The story of his life closes with his burial in Westminster Abbey, near the graves of Newton, Kelvin and Faraday.

## Fifty-Second Annual and General Professional Meeting London, Ontario

### January 31st to February 2nd, 1938

It was with pleasure that the Council accepted the suggestion from the London Branch that the Annual Meeting for 1938 should be held in that city. The event is a happy one, for while the large contingent of Institute members who live in South Western Ontario will no doubt furnish the main body of participants, London is such a pleasant rendezvous, and access by road and rail is so convenient, that a very substantial pilgrimage from more distant points may be confidently expected.

An active local committee, under the chairmanship of E. V. Buchanan, M.E.I.C., is working out the detail arrangements for a three-day meeting, of which the leading technical features will be the discussion of two questions of vital present day interest; namely, Safety on the Highways, and Flood Control and Water Conservation in South-Western Ontario.

The following is an outline of the programme as at present arranged. It is of course subject to minor changes.

**Monday, January 31st**

Registration, Luncheon, Annual General Meeting.

**Tuesday, February 1st**

Professional Session: Papers on "Engineering the Highways for Safety" and "Engineering Efficiency into the Highways."
Annual Dinner of The Institute.

**Wednesday, February 2nd**

Professional Session: A Symposium on Flood Control in South-Western Ontario with papers on: "Flood Control and Water Conservation in South-Western Ontario," "Agricultural Drainage in South-Western Ontario and its Effects on Stream Discharge," "Precipitation in South-Western Ontario" and "Stream Discharge and Run-off in the Thames and Grand Rivers."

Also, "Canadian Steam-Electric Power Plants" and "Large Pipe-Lines with Supporting Stiffeners."

Official Luncheon.

Special entertainment for ladies is being arranged by the Ladies Committee.

Visits to industrial establishments and public institutions in the vicinity of London are planned.

**New Dominion Public Building, London, Ont.**

Relief from the hard work of the professional sessions will be afforded by judiciously planned social functions, and by the hearty welcome which the London Branch will extend to all visiting members and ladies. The headquarters for the meeting will be at the **London Hotel.**

## The Institute's Relations with the Professional Associations

### Resumé of Recent Events

*January 29th, 1937.* The proposals of the Committee on Consolidation were discussed at the Annual General Meeting, and the proposed revisions to the by-laws were sent forward to ballot by the membership. A difference of opinion between Council and the Committee on Consolidation led to the submission of an alternative proposal by Council in respect to one section of the proposed amendments.

*April 30th, 1937.* The proposed amendments were rejected on ballot, with the exception of those not directly concerned with the consolidation scheme.

*May 28th, 1937.* Council was informed that a local committee in Nova Scotia was studying the possibilities of co-operation there between The Institute and the Professional Association. Discussions along similar lines were taking place in Saskatchewan and Manitoba. The President reported in regard to a visit to Winnipeg, made at the request of Council, to meet the members of the Winnipeg Branch and the members of the Manitoba Professional Association. He outlined the proposals for co-operation between The Institute and the Association in Winnipeg which had been under consideration there.

Mr. Busfield also reported as to his recent visit to the Maritime Provinces, made at Council's request, and stated that the Council of the Association of Professional Engineers of New Brunswick was also considering the matter. In compliance with a suggestion from Halifax, conveyed in Mr. Busfield's report, Professor H. W. McKiel and Mr. C. A. Fowler were appointed to represent the Council in the Nova Scotia discussions.

At the same meeting Professor R. A. Spencer and Messrs. J. L. Busfield and F. S. B. Heward were appointed a committee to make suggestions at the Plenary Meeting of Council as to the best method of dealing with problems relating to professional interests and the management of The Institute.

*June 14th, 1937.* The Plenary Meeting of Council and the Round Table Conference of Branch Representatives were held. At the Plenary Meeting, Council discussed the relations of The Institute with the Professional Associations in Nova Scotia, New Brunswick, Manitoba and Saskatchewan, and a resolution was unanimously passed expressing Council's desire to co-operate with all of the Associations. Professor Spencer presented the report of his committee, and, after discussion, it was decided to appoint a Committee on Professional Interests, and also a Committee on Membership and Management of The Institute. The former Committee, under the chairmanship of Past-President F. A. Gaby, with Past-President O. O. Lefebvre and Councillor F. Newell as members, is to deal *inter alia* with matters involving negotiations with the Professional Associations, without prejudice, however, to the negotiations in Nova Scotia, and is to work by the aid of provincial sub-committees. The latter Committee will investigate problems connected with the internal organization and functioning of The Institute, under the chairmanship of Professor R. A. Spencer, councillor from Saskatchewan.

*October 1st, 1937.* On this day proposals for the amendment of The Institute by-laws were received from thirty-one corporate members for submission to Council. These proposals comprise modifications of some of the important provisions submitted by the Committee on Consolidation in 1936, and propose the retention of the class of Associate Member; the automatic admission of corporate members of the Professional Associations, subject to classification by Council; the establishment of Component Associations, and of a Committee on Association Affairs; the payment by a Component Association annually to The Institute of a fee of 50 cents for each member of a Component Association licensed to practise; the payment by a Component Association whose corporate members are admitted as members of The Institute of a per capita annual fee to be determined by the Council, which shall include the per capita fee of 50 cents referred to, and an annual subscription to The Journal; the recognition of a new class of non-corporate membership to be called "Provincial Associates" and to comprise those members of an Association who do not become members of The Institute; the compulsory investigation by Council of the conduct of any member who may be expelled from a Component Association; the fixing of the entrance fee of The Institute for all corporate members at $15.00.

On a separate ballot two proposals are provided for—one to raise the quorum of Council from 5 to 11, and the other to limit the number of *ex-officio* members upon Branch Executive Committees to 4 (the latter provision affects the Montreal Branch only).

*October 8th, 1937.* The first draft of their report on the proposals for co-operation with the Professional Association in Nova Scotia was received from Messrs. McKiel and Fowler. This report had been prepared in conference with the representatives of the Association of Professional Engineers in Nova Scotia and of The Institute branches in Nova Scotia. A resumé of the report was sent out to members of Council.

*October 22nd, 1937.* Messrs. McKiel and Fowler attended the Council meeting and presented their report on the situation in Nova Scotia, outlining a scheme for co-operation between The Institute and the Professional Association which had been endorsed by the Council of that body and by The Institute branches in Nova Scotia. They recommended that Council express its willingness to enter into an agreement with the Association whereby The Institute would accept all members of the Association as corporate members of The Institute, while the Association would collect a single fee from all of its members, covering the annual fee to The Institute, a sum for the operation of The Institute Branches in Nova Scotia, and the annual fee to the Association. This arrangement would be conditional on all members of the Association joining The Institute.

After discussion, the meeting approved the scheme in principle, and it was directed that a letter ballot of Council should be taken as to Council's willingness to enter into such an agreement. It was noted that as the proposal would involve a change in the schedule of fees for Nova Scotia members, it would be necessary to obtain an amendment to the by-laws empowering Council to enter into an agreement of this kind.

At the same Council meeting, the proposals of thirty-one corporate members for the amendment of The Institute by-laws, which had been sent in on October 1st, were submitted for Council's consideration in accordance with Section 75 of the By-laws. It was noted that the proposers had authorized Messrs. Hector Cimon, Brian R. Perry and E. Viens to act for them in regard to any suggestions for the change or withdrawal of these proposals.

After discussion, it was the opinion of Council that in view of the report just received from Nova Scotia and the activities of the Committee on Professional Interests, it would be desirable to suggest to the representatives of the thirty-one proposers either the withdrawal of their proposals and the substitution of an amendment legalizing Council's action regarding the Nova Scotia agreement, or some modification of their proposals which would bring them more in line with Council's views as developed during the year. With this in mind a committee consisting of the President, Past-President Shearwood, and the Presidential Nominee, Mr. Challies, was appointed to confer with Messrs. Cimon, Perry and Viens.

In Council's view, the length and apparent complexity of the proposals of the thirty-one members, as well as the retention of many points of similarity with the consolidation proposals rejected on ballot, would make it very difficult to secure their acceptance by vote of the general membership, whereas a briefer and broader proposal would have a much better chance of obtaining the necessary majority. Further, Council felt that these proposals would be contentious and would tend to confuse the promising negotiations presently in hand with several of the Associations.

*October 29th, 1937.* The three representatives of Council conferred with Messrs. Cimon, Perry and Viens, and it was arranged that Messrs. Challies and Perry should endeavour to prepare briefer proposals (eliminating all unessential features), which would be acceptable to both parties, and could be submitted to Council at its next meeting on November 19th.

*November 16th, 1937.* At a second conference Messrs. Challies and Perry presented a compromise draft consisting of three sections additional to the existing by-laws, covering respectively the formation of Component Associations, with whom Council would be empowered to enter into agreements as to admission and members' fees; the representation of such Associations on Council; and the establishment of a special Standing Committee on Association Affairs.

After prolonged discussion, the representatives of the thirty-one proposers felt that, without consulting their principals, they could not express approval of the substitution of these three sections for the original proposals. Such consultation would take place as quickly as possible.

*November 19th, 1937.* At the Council meeting in Toronto held on this date, it was reported that on letter ballot a majority of councillors thought that Council should express willingness to enter into an agreement with the Nova Scotia Association. No negative votes were cast.

A similar request having been received from New Brunswick it was decided to take similar action in that case and to notify our representatives in both provinces of Council's favourable decision in both cases.

The President undertook to confer further with the parties concerned during his forthcoming visit to the Maritime Provinces.

In regard to by-law amendment, the President submitted the three sections drafted as a compromise and reported that they had not been acceptable to the representatives of the thirty-one proposers.

After full discussion, Council also felt unable to accept the suggested new sections and directed that the representatives of the proposers should be notified of this fact.

The members of Council present then agreed on the draft of a new section merely enabling Council to cooperate with any of the Professional Associations and enter into agreements with them in furtherance of the mutual interests of the members of The Institute and of the Associations, and in particular respecting the admission of their members to The Institute and the amount and method of collection of fees. It was directed that this draft should be submitted to all members of Council for approval by letter ballot before being put forward as a definite proposal of Council.

## OBITUARIES

### Harry William Dudley Armstrong, M.E.I.C.

Members of The Institute will learn with the deepest regret of the death of Harry William Dudley Armstrong, M.E.I.C., on August 2nd, at his residence in Toronto. He was 85 years of age and one of the first Members of the Canadian Society of Civil Engineers, having joined in January 1887.

Mr. Armstrong will be remembered for his regular attendance at annual meetings at The Institute and for having spoken during the business sessions of the last meetings in Hamilton and Toronto.

He attented private school in Ottawa and then became an articled pupil of Sir Sandford Fleming, then chief engineer of the Intercolonial Railway, in 1889. He was later with the Great Western Railway in the chief engineer's office on location and also on the surveys for the Detroit River bridge. In 1874 he was appointed assistant engineer with the Toronto Water Works, leaving in 1875 to become assistant engineer on location and construction for the Pacific Railway between Selkirk and Rat Portage.

From 1881 to the end of his active career he held numerous responsible appointments on the engineering staff of the Canadian Pacific Railway Company and other Canadian railways.

Mr. Armstrong played an important part in quelling the Riel Rebellion as the man directly in charge of the transportation of troops around Lake Superior at the point where there were gaps in the railway construction.

### Charles Warnock, A.M.E.I.C.

It is with great regret that we announce the death of Charles Warnock, A.M.E.I.C., president of Charles Warnock and Company Limited, Montreal, who passed away on November 4th, 1937, at his residence in Montreal. Mr. Warnock was born at Prince Albert's Landing, now the city of Fort William, Ont., on November 9th 1873.

He was educated at Lake Forest University, Forest, Ill., and subsequently was employed with the Illinois Steel

Charles Warnock, A.M.E.I.C.

Company and other metallurgical firms for a period of eight years. In 1902 he joined the staff of Robert W. Hunt and Company in the United States and in the following year was sent to Montreal as the company's Canadian representative, opening an office for the company in Montreal and becoming manager. He later became vice-president and general manager of Robert W. Hunt and Company Limited and in 1923 he was elected president of this company. In 1926 Mr. Warnock severed his connection with Robert W. Hunt and Company Limited and became president of his own firm under the name of Charles Warnock and Company Limited.

He was elected as an Associate Member of The Institute in 1911.

### Thomas Robert Henderson, M.E.I.C.

The death of Thomas Robert Henderson, M.E.I.C., in Edinburgh, Scotland, in February 1937, will be noted with regret. Born in Montreal, Mr. Henderson received his early education here and attended McGill University. His first engineering appointment was that of rodman on the Ottawa, St. Lawrence and New York Railway in 1885.

During the early part of his career he was connected with the construction of railroads and bridges in Eastern Canada. Mr. Henderson was for a number of years connected with Dobell Coal Company in Western Canada and a greatly esteemed member of the Edmonton Branch of The Institute. He was then residing at Tofield, Alberta.

About 1919 or 1920 he unfortunately suffered severe disabilities as a result of an accident which incapacitated him from doing further engineering work. He went to Scotland to reside in 1927.

Mr. Henderson became an Associate Member in 1892, Member 1905 and Life Member in 1926.

### Rolfe Leigh Doucet, S.E.I.C.

We regret to record the death of Pilot Officer Rolfe Leigh Doucet, R.C.A.F., who was killed in an aeroplane crash, in which three fliers met their death, at Trenton, Ont., on October 19th, 1937. Mr. Doucet was born at Shediac, N.B., June 18th, 1912. He received his education at Acadia University and at the Nova Scotia Technical College, from which he graduated in 1935 with the degree of B.Eng.

In 1935 and 1936 Mr. Doucet was employed by the Milton Hersey Company Limited as an inspector on highways construction in the Maritime Provinces. He obtained his commission as Pilot Officer in the Royal Canadian Air Force last July.

## PERSONALS

H. A. Gibault, A.M.E.I.C., formerly assistant director of Public Works for the City of Montreal, has recently received the appointment of assistant chief engineer for the city.

W. G. MacIntosh, S.E.I.C., has been appointed to the engineering department of the Trans-Canada Air Lines. He graduated from the University of Manitoba in 1936 and prior to accepting his present appointment was a draftsman in the Boeing School of Aeronautics, at the Oakland Airport, California.

M. S. MacGillivray, A.M.E.I.C., is now on the engineering staff of Canadian Industries Limited, Montreal, having left the employ of Messrs. T. Pringle and Sons Limited where he has been since 1929. Mr. MacGillivray is a graduate of Queen's University of the year 1923, after which he took an apprenticeship course with the Canadian Westinghouse Company Limited at Hamilton, Ont. In 1925 and 1926 he was demonstrator in the Electrical Engineering Department of the University of Toronto, and from 1926 to 1929 was assistant electrical superintendent with the Aluminum Company of Canada Limited, Arvida, Que.

C. D. Wight, A.M.E.I.C., until recently assistant roadway engineer and city surveyor for the city of Ottawa, has been appointed assistant waterworks engineer. Mr. Wight graduated from Queen's University in 1928 and was for some time partner in the firm of MacRostie and Wight, consulting engineers, Ottawa.

Leo Roy, Jr.E.I.C., is now sales engineer with the Quebec Power Company in Quebec, having recently been transferred from the Commercial and Distribution Department of the Shawinigan Water and Power Company. Mr. Roy is a graduate of both the Ecole Polytechnique, Montreal, and McGill University, leaving the latter institution in 1932 with the degree of B.Eng. in electrical engineering.

Bruno Grandmont, A.M.E.I.C., until recently district engineer, Department of Public Works, Canada, at Three Rivers, has been appointed to a similar post in Quebec city. Mr. Grandmont, who is councillor for the St. Maurice Valley Branch, graduated from Laval University in 1914. Since that time he has been engaged in engineering work in various capacities in the above department, principally in the vicinity of Three Rivers.

J. H. Landry, A.M.E.I.C., is now district engineer, department of Public Works, with headquarters in Montreal. He for a number of years prior to this appointment assistant to the district engineer in Montreal. He graduated from Laval University in 1913.

A. G. Sabourin, A.M.E.I.C., until recently district engineer with the Department of Public Works, Canada, at Quebec, is now superintending engineer with the department at Ottawa. He graduated from the Ecole Polytechnique, Montreal, in 1902.

J. E. St. Laurent, M.E.I.C., has been made chief engineer, River St. Lawrence Ship Channel, Department of Transport, Montreal. He was previously with the Department of Public Works in Ottawa. Mr. St. Laurent graduated from the Ecole Polytechnique, Montreal, in 1909 and since then has been employed in various capacities throughout Canada with the above department. He was for a time district engineer at Port Arthur and also at Winnipeg. He has been in Ottawa since 1925.

J. B. DeHart, M.E.I.C., has accepted a position with the Provincial Institute of Technology and Art, Calgary, Alberta, where he will be in charge of the coal mining courses. Since 1923 he has been district inspector of mines for the government of the Province of Alberta and located at Lethbridge. Mr. DeHart is a graduate of McGill University in both civil and mining engineering, receiving his M.Sc. in the latter faculty in 1912. Since that time he has had extensive experience in coal mining, having held a number of positions as manager or general superintendent of coal mines between 1914 and 1923.

H. W. B. Swabey, M.E.I.C., has recently been appointed to the staff of the Industrial Investigation Committee, Department of National Defence, Ottawa. He was previously associated with the J. T. Donald and Company and Donald Hunt Limited, Montreal, with whom he had been since 1926. Mr. Swabey received his engineering education at the Crystal Palace Engineering School, London, and his experience since coming to Canada has included that of supervising engineer on the construction of the Atlantic, Quebec and Western Railway, resident engineer for a time on the construction of the Quebec and Western Railway, resident engineer for a time on the construction of the Quebec and Saguenay Railway, and with the Canadian Pacific Railway Company as resident engineer on construction of the Campbellford-Lake Ontario and Western Railway. During the War, as chief inspector of steel, he had charge of the inspection of all steel and forgings for shells manufactured in Canada for the British government.

Brigadier J. L. H. Bogart, R.C.E., D.S.O., A.M.E.I.C., has recently been retired from his appointment as Officer Commanding Military District 13 at Calgary, Alberta, and will reside in Pembroke, Ont. Brigadier Bogart graduated from the Royal Military College with honours in Civil Engineering and in 1897 was appointed to the Reconnaissance Survey of the Militia of Canada. In 1904 he obtained his commission in the Corps of Royal Canadian Engineers, becoming a colonel in 1930. During the War he served in England and France, was awarded a D.S.O. and was mentioned three times in dispatches. In 1918 he acted as staff officer to the C.R.E. Canadian Corps in France and from 1919 to 1923 as senior engineer officer in Military District 2. From 1923 to 1929 he was camp engineer at Petawawa, Ont, and from 1930 to 1934 was director of engineer services, Department of National Defence, Ottawa. From 1934 to 1936 he was again in Petawawa in charge of Department of National Defence relief camps in that area, after which he received the appointment which he is now vacating.

## T. H. Hogg, D.Sc., M.E.I.C.,

**Chairman, Hydro-Electric Power Commission of Ontario**

Dr. Thomas Hogg, M.E.I.C., has been appointed chairman and chief engineer of the Ontario Hydro-Electric Power Commission. Dr. Hogg graduated from the University of Toronto in 1907 after which he accepted a position with the Ontario Power Company at Niagara Falls, resigning in 1911 to become editor of The Canadian Engineer. In 1912 he was appointed assistant hydraulic engineer of the Hydro-Electric Power Commission of Ontario, subsequently being made acting hydraulic engineer and in 1925 chief hydraulic engineer. In 1934 he became acting chief engineer and chief operating engineer, then later chief engineer.

Dr. Hogg has an international reputation as a hydraulic engineer and has been largely responsible for the design for many of the Commission's power plants. He has also

T. H. Hogg, D.Sc., M.E.I.C.

served as consulting engineer for the Dominion and a number of the provincial governments. He represented the Ontario Government in the preparation of the report of the International Joint Commission on the St. Lawrence waterways project and for a number of years past he has been a member of the Lake of the Woods Control Board.

Dr. Hogg has actively participated at meetings of the World Power Conferences and in 1926 presented a paper on "Recent Trends of Water Power Development in Canada" before the Second Conference in Berlin. At the Third World Power Conference in Washington in 1936 he was a member of the Canadian National Committee and also an official Canadian delegate.

Dr. Hogg received the honorary degree of Doctor of Engineering from the University of Toronto in 1927.

## ELECTIONS AND TRANSFERS

At the meeting of Council held on November 19th, 1937, the following elections and transfer were effected:

*Juniors*

*CHAREST, Pierre Antoine, dftsman., Fraser Companies Limited, Edmundston, N.B.

*HOVEY, Charles Mansur, (Univ. of Man.), laboratory technician, civil and mechanical engrg. depts., University of Manitoba, Winnipeg, Man.

*Transferred from the class of Junior to Associate Member*

RUSSELL, John Arthur, chief engr., Dominion Coal Company Limited, Sydney, N.S.

*Students Admitted*

COURTNEY, Ernest Cleveland, B.A.Sc., (Univ. of B.C.), 3637 Oxenden Ave., Montreal, Que.

DeMAIO, Alexander, B.A.Sc., (Univ. of Toronto), 149 Rubidge St., Peterborough, Ont.

FINDLAY, Allan Cameron, ap'tice dftsman., Dominion Bridge Co. Ltd., Montreal, Que.

FROMSON, Sam, (McGill Univ.), 524 Prince Arthur St. W., Montreal, Que.

GODDARD, Albert Reginald, (Univ. of Man.), 696 Strathcona St., Winnipeg, Man.

HARVEY, Ernest Allen, B.Sc. (Univ. of Sask.), (Univ. of Man.), 379 Broadway Ave., Winnipeg, Man.

KORCHESKI, William B., (Univ. of Man.), 460 Kennedy St., Winnipeg, Man.

LEMAISTRE, Edward Benjamin Aycrigge, (McGill Univ.), Central Y.M.C.A., Montreal, Que.

MORRISON, John Davis, (McGill Univ.), 68 Bruce Ave., Westmount, Que.

NORTHOVER, Arthur B. Clinton, B.A.Sc. (Univ. of Toronto), Cawesco Club, Hamilton, Ont.

PALMER, Kenneth Winfield, B.Sc. (Metal.), (Univ. of Birmingham), 1321 Sherbrooke St. W., Montreal, Que.

PHOMIN, Barney Louis, (Univ. of Man.), 395 Union Ave., Winnipeg, Man.

WILLIAMS, Donald D., (McGill Univ.), 359 Laurier Ave. W., Montreal, Que.

**Students at the Ecole Polytechnique, Montreal, Que.**

ASSELIN, Hector, 118 Maplewood Ave., Outremont, Que.
BEIQUE, Freddy Paul, 550 Davaar Ave., Outremont, Que.
BERNIER, Hubert, 3695 St. Andre St., Montreal, Que.
CHADILLON, Francois, 2343 St. Antoine St., Montreal, Que.
COUPIENNE, Gilbert, 2091 Union Ave., Montreal, Que.
FRIGON, Raymond A., 125 Pagnuelo Ave., Outremont, Que.
HALLE, Paul, 1470 Ontario St. East, Montreal, Que.
HAMELIN, Roger, 7609 de Gaspe, Montreal, Que.
LACROIX, Jean, 1785 Van Horne Ave., Outremont, Que.
LALONDE, Jean A., 958 Dunlop Avenue, Outremont, Que.
LAMARCHE, Marcel, 1891 Sherbrooke St. East, Montreal, Que.
LECAVALIER, Fernand, 6280 St. Denis St., Montreal, Que.
LEROUX, Jacques Pierre, 3686 St. Hubert St., Montreal, Que.
L'HOMME, Louis Philippe, 50 Yamaska Ave., Farnham, Que.
MARCHAND, Fernand, 8202 St. Denis St., Montreal, Que.
MARTEL, Pierre, 2006 St. Denis St., Montreal, Que.

### Errata

The following corrections should be made in the text of the paper "The Beet Sugar Factory at Picture Butte, Alberta" by F. H. Ballou, published in the November number of The Journal, pages 802-806:—

Page 805—first column—lines 42-44—should read "*Pumps:* The plant is equipped with 62 centrifugal pumps of which 35 operate at 3,500 r.p.m. No reciprocating pumps are used."

Page 806—second column—Omit last two paragraphs substituting the following paragraphs:

The total production of Alberta sugar from the sugar beet crop of 1936 was 652,996 one hundred pound bags.

The latest figures on yearly consumption in Alberta show about 620,000 one hundred pound bags of which Alberta sugar supplied in 1936 around 290,000 one hundred pound bags or less than 50 per cent. In the city and district around Calgary, sales of Alberta sugar reach over 70 per cent, but a large proportion of Alberta grown sugar must be sold elsewhere than in Alberta.

The beet sugar industry of Alberta has supplied producing capacity, to furnish all the sugar required in Alberta. Estimates for 1937 crop are over 700,000 one hundred pound bags.

## Addresses Wanted

Any information regarding the following members for whom we are without addresses, would be much appreciated:—

Members
*A. H. Blanchard*
*J. Hardy Devey*
*C. P. Dunn*
*Harry Kay*
*Geo. Scott*

Associate Members
*John G. M. Baxter*
*H. R. Bissell*
*Chas. K. Brown*
*D. L. Carr*

## CORRESPONDENCE

The Editor,
The Engineering Journal.

Dear Sir:—

In his paper, "The Fatigue of Metals,"* Dr. Farnham has attempted, quite successfully, to give a very brief survey of what is known to date concerning the fatigue type of failure of metals. The writer agrees with the author that "progressive failure" is the proper term to be used in describing the type of failure under discussion, though "creeping fracture" might also be employed. He cannot agree, however, that the term "fatigue failure" should continue to be used as synonymous with "progressive failure," for the latter term describes the process by which failure takes place, whereas the former refers to the process by which the initiation of the fracture, which subsequently develops by the progressive process, occurs. Progressive failures may occur which are not initiated by the fatigue process, if one limits the concept of fatigue as being directly and uniquely related to cyclic stressing. In a sense, all fractures are progressive. Cyclic stressing produces a slowly progressing fracture—on the other hand, static stresses produce a rapidly progressing fracture and there are certain cases which lie between these extremes.

Attention should be especially directed to the author's statement concerning the failure of metals due to "crystallization in service." It has been known for a long time that no such process can occur in metals at temperatures below their respective critical ranges but it is remarkable how this false notion has persisted so long in the engineering mind. Anything which can be done to eliminate this erroneous idea is worthy of commendation.

Too much emphasis cannot be placed on the value of Dr. Gough's important work in which he has shown for the first time that failure of metals initiated by fatigue is identical, macroscopically at least, with that initiated by static stressing. That is to say, the mechanism by which the crystal grains break up initially is the same in all cases so far observed regardless of the type of stressing. These changes have been described by Dr. Gough as a "dislocation of the initially perfect grains into large components...", with the subsequent formation of crystallites, i.e., small submicroscopic blocks of crystal having a definite lower limit as to size. This process is accompanied by internal stressing of these fragments. The full impact of these important discoveries is only just beginning to be felt in the field of the science of metals.

The photograph, Fig. 1, illustrates a fracture of a plain carbon steel street-car axle. All of the features on the photograph show the fracture to be of the progressive type. The writer does not believe this to be a fatigue failure, however, for the following reasons: The stresses on the metal were not particularly high even when the car was under full load. From the records of distance travelled by the car, it was estimated that the number of stress cycles was of the order of $300 \times 10^6$. The fracture became complete a few days after a period of very low atmospheric temperatures and records show that failures of axles seldom occur in the warm weather. It seems probable that the correct explanation of such failures—without going into a detailed discussion—is that small cracks are started by impact during the period of low temperature of the metal and while the frogs in the track are rigidly held in frozen ground. Once started, the progressive failure develops in precisely the same manner as if the initial cracking had been produced by fatigue stressing. The result is the same in both cases. The cause, however, is different.

**Fig. 1—Low Temperature fracture in a street car axle.**

I. F. Morrison,
Professor of Applied Mechanics,
University of Alberta.

## BULLETINS

*Tractors.*—A 24-page bulletin by the Caterpillar Tractor Company Peoria, Ill., deals with the adoption of Diesel power for highway construction and maintenance equipment. Various types of equipment are illustrated in operation throughout the United States.

*Pumps.*—A 6-page leaflet by the Roots-Connersville Blower Corporation, Connersville, Ind., gives details of their automatic boiler service units and the sizes in which they are manufactured. These units are particularly adaptable for all plants using steam for processing.

*Snow Ploughs.*—The Cleveland Tractor Company have published a group of 4 leaflets illustrating their snow removal equipment including snow ploughs and bulldozer combinations.

*Insulating Materials.*—Insulating products of the Canadian Johns-Manville Company, Montreal, are described in a 64-page booklet recently received and covers among other things roofs, floors, friction and insulating materials generally, also packings, gaskets, refactory cement and transite.

*Time Switches.*—The Canadian General Electric Company, in an 8-page bulletin, give details of their general purpose automatic time switch, type T-17.

*Jaw Crushers.*—A 12-page pamphlet received from the Dominion Engineering Company, Montreal, describe their jaw crushers, a complete range from 10 by 20 in. to 48 by 72 in. in 9 standard sizes.

*Air Filter.*—A 4-page circular from the Northern Blower Company, Cleveland, Ohio, describes their Norblow, a square type air filter for automatic and continuous service.

*Monel, Nickel and Inconel.*—The International Nickel Company, in a 28-page booklet, list 400 practical applications for monel, nickel and inconel, under corrosive conditions, tabulating data of definitely established uses of these materials in a concise form.

## Index to Volume XX

The Index to Volume XX of The Engineering Journal, covering the twelve issues, January to December 1937, appears in the back of this number of the Journal.

This has been made as complete as possible in the space available and all articles and important items have been included.

In many cases references appear under two or more headings in order to facilitate any search for information.

## New Zealand Institution of Engineers

At a special general meeting on September 15th, 1937, in Wellington, the rules of the New Zealand Society of Civil Engineers were amended so as to change the name of this Society to the New Zealand Institution of Engineers.

This step is of interest to members of The Institute as it may be remembered that the Canadian Society of Civil Engineers took a similar step in 1918 in changing the name of our Society to The Engineering Institute of Canada.

# BOOK REVIEW

## The Motor Truck in Woods Operation

*By C. R. Townsend, Woodlands Section, Canadian Pulp and Paper Association, Montreal, 1937. 82 pp. 9 by 12 inches.*

Reviewed by J. B. D'Aeth, M.E.I.C.*

This book is based upon the findings of Mr. C. R. Townsend, who was employed by the Woodlands Section of the Canadian Pulp and Paper Association to investigate the use of motor trucks for the transportation of logs in Canadian woods operations. Mr. Townsend had previously had extensive experience in woods operations with the Consolidated Paper Corporation.

The publication is the result of ten months of study and investigation of the subject, which is comparatively new and to a great extent in the experimental stage.

The book is divided into two parts. Part one covers the different phases of a woods operation such as:

The methods employed in the pre-haul or the delivery of logs to the main truck road from the stump.

Methods of loading trucks or sleighs; also tables showing various rates of loading in cords per man hour.

Types of winter truck roads with description of methods and equipment required for making and maintaining same.

The different types of hauling equipment used, such as trucks, trucks with semi-trailer, and trucks hauling sleighs. A table is given showing the Provincial truck regulations governing the length, width, height, and loading of trucks for each province.

Methods and arrangements for unloading wood.

There is a list of 13 typical woods trucking operations with partial hauling costs. These operations are well described and the basic data given for each case. Twenty-two diagrams and three hundred and thirty-six small photographs are used to illustrate the descriptions and show details of the various phases of the work described.

Part two covers the theory and mechanics of the haulage equipment and covers such questions as:

Truck power and the relationship of gear ratios. This becomes extremely important when the truck is acting as a haulage unit for a train of sleighs.

Sliding resistance of sleighs, and some interesting experiments conducted by the author to show the advantage of water lubrication on iced or snow roads immediately preceding the passage of loaded sleighs.

The author presents results of experiments to show that rubber does not follow the ordinarilly accepted laws pertaining to the coefficient of friction as follows:—

That the coefficient of friction in the case of rubber increases with the area in contact, that it increases with the load applied, that it increases with velocity at low velocities, and that the kinetic value is greater than the static.

Rolling resistance is discussed in relationship to road surfaces and tire chains.

Diagrams and formulae are given to show the effect of sleighs attached to trucks and the resulting distribution of load on the front and rear axles of the truck.

There is a good discussion on truck tires, and the question of overloading them, also the proper use of chains.

Discussion of grades and curves and the necessity of grade compensation when they occur together.

As far as the reviewer is aware, this is the first time that such extensive data on the subject has been collected and made available in a unified form. To anyone interested in the transportation of logs or winter truck freighting this book should prove extremely valuable.

* *Engineer, Fraser, Brace Company Limited, Montreal.*

# The Profession's Current Problems

*An address, by Willard Chevalier**

*Vice-President of the McGraw-Hill Publishing Co., New York.*

**(Abridged from a report in the Engineering News-Record, November 18, 1937)**

This word "profession" is bandied about very glibly but there are not many people who will agree on a clear-cut and convincing definition of what the term means.

Does it mean any calling that, in the public interest, is closed by a statute to all except those duly licensed to practise it? Does that make a professional man of a barber or a bar-keeper? Obviously our conception of a profession and a professional man cannot be expressed accurately by a term that is used so loosely; neither can we create the profession that we have in mind merely by the enactment of a statute or the technical definition of a term.

Even in medicine and law, with all their statutory regulation, the public still must rely in large measure upon the moral influence of a professional spirit to make this thing effective and make it work. In other words, the point I am trying to make is that there is something bigger, more vital, and more fundamental in a professional relationship than anything you can write into a statute.

Unless we have in the profession of engineering some vital influence above and beyond the mere statute itself, it will be but a question of time before those of minimum technical qualifications will demand and be accorded the right to practise, regardless of what you and I may think of their other professional qualifications.

And these other qualifications are of the very essence of what I understand to be a profession. Certainly they mean a great deal in law and medicine. Why? Because of the confidential relationships with uninformed laymen who are not in a position to protect themselves or guard themselves against the charlatan. Shall we be able to maintain and enforce similar standards in the case of the engineer, or shall we be forced to rule those out? Are we in danger of facing a ruling one of these days that any one who can meet the minimum technical requirements has the right to be licensed and practise his calling? That is when we shall find out whether we have a profession or just another licensed trade.

When we start drawing this analogy between the engineer and the doctor and the lawyer, we find another false note. We find that it is the intent and the ambition of the young doctor and the young lawyer sooner or later to go into practice for themselves. They may for a time work for someone else; they may be a part of a professional organization as subordinates. But either they are going to become partners in a firm or they are going to have their own practice. That is true of the bulk of them. It is not true of the great bulk of young engineers who must look forward—and I say this in no invidious sense—to being employees on someone's payroll—that of the public, some corporation, or an individual.

You will have a very great difference in the ultimate responsibilities of the men who call themselves engineers by virtue of a definition in a statute or on a diploma. One man may have almost no ultimate technical responsibility. He is hired by other engineers who take full professional responsibility for his work, and his ultimate client—the layman—may never know of his existence. Let us face that fact.

On the other hand, we have at the top men who will carry the ultimate technical responsibility to their clients. The chief engineer of a railroad, the consulting engineer for a city, the chief engineer of an industrial plant or a city department who reports to a lay board of directors or a lay city council—that man must take the ultimate technical responsibility for his decisions. There is no technical man above him who will modify his decisions or take responsibility for his failures. There is an *ultimate technical responsibility* and to me it is that relationship which constitutes the core of a professional relationship.

Many of these engineers who have no ultimate responsibility always will regard the other engineers, not as their professional brethren, but as their bosses. A very eminent engineer once told me that he considered it a definite part of his responsibility to his employer to hire his staff on the lowest terms consistent with competent service. This instance, although not typical, shows that we have a very definite problem in the relation between employer-engineer and employee-engineer, *insofar as their current relationship* is concerned.

We thus have the employer and employee relationship among engineers, all of whom have the same words on their diploma, all of whom can qualify under the same statutes. That is another reason why I do not believe that we ever are going to solve these problems by statutes alone. That is why I believe that the several professional engineering societies today have an even broader field of usefulness and a more important function to perform than they ever had before the statutory licensing of engineers. If we are going to give spiritual effect to the bare flesh and bones of our engineering legislation, we must have these professional societies which, entirely apart from statutory requirements, will take into account everything else about a man in addition to his educational and technical attainments.

That is the reason why I do not want to see any formal relationship between these two. I do not want to see our long-established professional bodies made tails to any statutory kite, neither do I want to see those societies involved in the operation of a licensing statute. The national engineering society's function today has become even more vital than before. It is they, with their tradition of disinterested and voluntary association for purely professional concerns, who must be in a position to establish and enforce those standards of professional responsibility and ethics that cannot be written into a statute.

Therefore, I hope that our professional societies, both old and new, will recognize today their responsibility for the less sharply definable concepts of what constitutes a profession and that they will guard them more closely than ever before.

What shall we say to the employed engineer when he asks, "Shall I join the union or not?" I would say: "My boy, you have your own way to make in the world. You must earn the best living that your energy, skill and intelligence will make available to you. You are carving out your own career, so make up your own mind. When you have done so, go the way you have chosen without complaint, if it does not work out the way you expected. If you are primarily interested in what a labour union offers, if you want to cast in your lot with organized labour, that course is open to you."

On the other hand, if you feel that there is something of real value in what we call the engineering profession, the chances are that the labour union will not give you what you want. You have a right to make your own decisions as to what road you will take, but when a certain point is passed there can be no turning back.

I have great sympathy for the young men who are being paid less than the mechanics with whom they must work every day. There are many thousands of these young men, who never will have the opportunity to do any more responsible work than they are doing. They will acquire experience but will remain employee-engineers, responsible to some employer-engineer. To such men, who know they are close to the limit of their earning capacity, there is little use of talk of professional future. If they are to remain at that kind of work and are willing to cast their lot in with that of the manual worker, why should the professional engineers try to take them in?

Probably out of all this will come a natural separation. Some individuals will align themselves with labour organizations. They will consider the material interests of today. If they have any professional heritage, they will be willing to sell it for the pottage of immediate benefits. If they decide that that is the road that they want to follow, they have a perfect right to follow it, just as does any craftsman who organizes to better his condition.

On the other hand, if the professional group makes the profession seem worthwhile and stimulates these men's interest in things not concerned exclusively with material interests, many will follow the professional standard and later will fill positions of responsibility in the profession.

The destiny of the engineering profession cannot be shaped by legislation, nor can the problems of engineering employment be solved by denouncing this movement or that organization. Regardless of present difficulties, the long term welfare of the profession and its members will be worked out by individuals, each pursuing a course which seems to him to be sound.

The instruments that must be used to shape our profession include the work of the engineering examiners, the professional engineering societies and the engineering schools. Through all of these it is possible to create a profession that will measure up to its responsibilities. Each of these contributes its part: technical and intellectual fitness, a professional conscience that assumes a responsibility to the community for the standards of its members, an attitude toward the day's work that is distinct from that of the time-server, and the power of the state to safeguard the people against injury at the hands of the unworthy..

Let us then organize our societies and enact our statutes; let us organize our schools to educate the young men on the threshold of the profession and let us do our best to establish working conditions that will recognize sound relationships between employers and employed. Let us do all we can to inform these young men as to what a profession is, what it stands for, and what it offers to them in return for what it demands.

*Before the National Council of State Boards of Engineering Examiners at their annual meeting in Scranton, October 11-13, 1937.

## World Power Conference

By invitation of the Austrian National Committee, a sectional meeting of the World Power Conference will be held in Vienna from August 25 to September 2, 1938. The meeting will deal with "The Supply of Energy for Agriculture, Small-Scale Industries, Household Purposes, Public Lighting, and Electric Railways." The technical programme of the Conference, which has just been published from the offices of the Weltkraftkonferenz, Teiltagung Wien, 1938, Lothringerstrasse, 20 (Konzerthaus), Wien, III, Austria, is accordingly arranged in five sections, and it is emphasized that, within each of these sections, the question of the energy requirements should be dealt with solely from the point of view of the consumer. Apart from the last section relating to electric railways, the scope of the first four sections is to cover all forms of energy available and in actual use, including solid and liquid fuels, gas, water power, wind power, steam, electricity, and human and animal drives. In order to allow sufficient time for the printing and distribution of the papers and general reports, the Austrian National Committee requests that papers be in their hands not later than March 1, 1938.—*Engineering.*

## Discussion on Lubrication and Lubricants

The Institution of Mechanical Engineers with the co-operation of other Societies and Institutions held a general discussion on lubrication and lubricants from October 13th to 15th, 1937. At this meeting a series of some 100 papers were presented by leading authorities throughout the world. An exhibition was held in connection with this meeting. The papers presented were grouped under four heads: 1. Journal and thrust bearings, including general and practical aspects, bearing materials, tilting-pad bearings and collar and related types. 2. Engine lubrication for internal combustion and reciprocating steam engines. 3. Industrial applications, including lubrication of anti-friction bearings and gear lubrication. 4. Properties and testing.

Bound volumes of these proceedings may be obtained from the Institution.

## Symposium on Propellers

North East Coast Institution of Engineers and Shipbuilders, Newcastle upon Tyne, announce a "Symposium on Propellers" which is to take place on March 31st and April 1st next. The authors are almost entirely outstanding tank experimenters in connection with the design of propellers in England and on the continent. There will possibly be additional papers later. It is hoped by bringing together so many of the leading tank experimenters dealing with subjects upon which each is a specialist that up-to-date information valuable to engineers and naval architects will be provided by the symposium, and that the discussion on the papers may, on the other hand, be helpful to the experimenters represented by the authors. A list of the papers follows:—

- "Qualities Required in Propellers," by Dr. G. S. Baker, O.B.E., Honorary Fellow, Superintendent of the William Froude Laboratory.
- "Measurement of Wake," by Prof. Dr. Ing. F. G. A. Horn, Technische Hochschule, Charlottenburg.
- "Aerofoil Sections and Their Adoption in Propeller Design," by James F. Allan, B.Sc., Experiment Tank, Messrs. Wm. Denny and Bros. Limited.
- "Open-Water Test Series with Modern Propeller Forms," by Ir. L. Troost, Member, Superintendent, Experiment Tank, Wageningen, Holland.
- "Effect of Rough Water on the Performance of Propellers," by J. L. Kent, the William Froude Laboratory.
- "Immersion of Propellers," by Dr. Ing. G. Kempf, Director of Hamburg Tank.
- "Effect of Shaft Brackets on Propeller Performance," by R. W. L. Gawn, R.C.N.C., of Admiralty Experiment Works, Haslar.
- "Propellers for Tug-Boats," by Frank W. Benson, Member, Scotts' Shipbuilding and Engineering Company.
- 'Experiments on the Optimum Diameter of Propellers of Single-screw Ships," by Dr. Masao Yamagata, Director, Teishinsho Experiment Tank, Tokyo.
- "Torsion and Torsional Oscillation of Blades," by Dr. W. J. Duncan.

## November Journals Required

Copies of the November, 1937, issue of The Engineering Journal are required for binding, and it would be appreciated if members having no further use for this issue would forward copies available to Headquarters at 2050 Mansfield Street, Montreal.

## Memorial Sun-Dial to the late W. J. Cunningham, A.M.E.I.C.*

A feature of the President's visit to Edmonton on August 28th, 1937, on his recent tour of the Western Branches was a ceremony which took place at the City Power Plant, and at which he presided. This ceremony was the unveiling and dedicating of a sun-dial to the memory of W. J. Cunningham, A.M.E.I.C., for some years preceding his death superintendent of Edmonton's power plant.

Mr. Cunningham's untimely passing in 1934 was a matter of such regret to his many friends that the idea was conceived of preserving his memory in a material way. A memorial sun-dial was decided upon as the means of doing this and a committee was formed with A. W. Haddow, M.E.I.C., Edmonton's City Engineer, as chairman, to carry out the plan.

A site for the memorial was provided by the city in front of the power plant office. The city also bore the expense of constructing the foundation and of beautifying with lawns and flowers beds the area thus set aside. The monument itself was paid for from contributions by Mr. Cunningham's personal friends in the engineering profession in various parts of Canada.

The sun-dial was designed by Prof. Burgess of the University of Alberta and consists of a Tyndall stone shaft surmounted by a brass dial bearing the inscription. Also affixed to the shaft is a small brass plate bearing suitable symbols and so placed by the Wardens of Camp VI, "The Ritual of the Calling of an Engineer."

Others taking part in the ceremony who spoke briefly or placed sprays of flowers on the memorial besides President Desbarats and Mr. Haddow, were J. D. Baker, M.E.I.C., for the Wardens of Camp VI, C. E. Garnett, M.E.I.C., for the Association of Professional Engineers of Alberta, R. G. Watson, A.M.E.I.C., for the power station staff and Mayor Clarke, who assumed permanent custody of the memorial on behalf of the City of Edmonton.

The eulogistic nature of the references to the late Mr. Cunningham were significant as to the calibre of the man and significant too were the simple but impressive words on the dial of the dignified little monument.

**William John Cunningham**

**Superintendent of Edmonton City Power Plant, 1920-1934, intended to place a sun-dial on this spot. In respect for his devotion to duty and for his desire to create beauty around him, his friends now fulfil this intention.**

---

*Submitted by F. A. Brownie, Jr.E.I.C., Edmonton Branch News Editor.

## Second Symposium on Water Hammer

A Second Symposium on Water Hammer is being held under the auspices of the American Society of Mechanical Engineers in New York on December 8th and 9th, 1937. Signor Lorenzo Allievi has been appointed Honorary Chairman, and the American Society of Mechanical Engineers is to confer an Honorary Membership in the Society on him on that occasion in recognition of his contributions to the advancement of knowledge on the subject.

The Engineering Institute of Canada will be represented by a number of members including Messrs. Norman R. Gibson, M.E.I.C., S. Logan Kerr, M.E.I.C., Professor Robert W. Angus, Hon.M.E.I.C., and Professor F. M. Wood, A.M.E.I.C.

# BRANCH NEWS

## Border Cities Branch

*J. F. Bridge, A.M.E.I.C., Secretary-Treasurer.*
*F. J. Ryder, Jr. E.I.C., Branch News Editor.*

The first dinner meeting of this Branch for the 1937-38 season was held at the Prince Edward hotel, Friday evening, October 15th. There were thirty-seven persons present to hear and see sound pictures on "Heat Insulation." Mr. William G. Bright, of the Canadian Johns-Manville Company Limited, discussed the paper as presented by the sound reels and answered questions.

### Heat Insulation

Heat is nature's most powerful force and without heat man cannot live. Heat is defined as molecular motion. Various scientists have discarded old theories and promulgated new ones as more and more has been learned about heat and its actions. Heat being a form of energy follows the law of conservation of energy, namely, "That energy can neither be created or destroyed. Any type of energy can be transformed into any other type of energy." There are three methods of transferring heat which are: convection, conduction and radiation. A popular belief in the so-called "dead-air space," which is supposed to insulate our homes, has been proven a fallacy as the moving picture camera has been able to photograph convection currents set up in "dead-air space" due to differences of inside and outside temperatures.

After discussing the theory of heat and the problems presented in order to conserve it, the methods that the Canadian Johns-Manville Company used in their laboratories to provide the best means of controlling and overcoming these problems were outlined.

Mr. Krebser thanked the speaker on behalf of the Branch.

## Calgary Branch

*James McMillan A.M.E.I.C., Secretary-Treasurer.*

The Branch started the new season's activities by staging the annual golf tournament at Strathmore on the finest afternoon experienced this September. The enjoyment of the afternoon was greatly enhanced by the hospitality extended by Mr. and Mrs. G. H. Patrick to those who took part in the outing.

### The World Oil Situation

On the evening of September 17th, the first technical address of the season was presented by Dr. G. S. Hume, Dominion Government Geologist, on "The World Oil Situation." He began by describing the potential and producing oil fields of the United States in which 60 per cent of the world production is centred. The East Texas field, the world's largest, has wells which produce as much as 12,000 barrels per day. From a peak production of 750,000 barrels per day in 1933 the production has been reduced to 450,000 barrels by means of proration. The ultimate surface yield of this field is estimated at four and one-half billion barrels. The greatest reserve in the United States is in the State of Kansas where 54 new fields were discovered last year. Approximately only 10 per cent of the country's potential production is now being taken due to market conditions. The Near East fields are next in importance to those in the United States due to their proximity to the great oil consuming countries of the world. The most important of these are in Baku, Irak and Iran. In Germany, France, Italy, Japan and Britain hydrogenation of coal and oil shales is becoming a serious competitor of crude oil as a source of fuel. Dr. Hume drew attention to the ever increasing importance of fuel oil as opposed to gasoline in domestic, industrial, commercial and shipping operations.

### Dinner Meeting

At the meeting on October 20th, the members of the Branch were entertained as guests of the Canadian Western Natural Gas, Light, Heat, and Power Co. Ltd. at an informal dinner in the company's new demonstration auditorium. Following the dinner Mr. E. W. Bowness showed a series of motion pictures of his trip to Europe, which included scenes of the coronation and gave his impressions of the political and economic situation in each country which he visited.

## Hamilton Branch

*A. R. Hannaford, A.M.E.I.C., Secretary-Treasurer.*
*W. W. Preston, S.E.I.C., Branch News Editor.*

The opening Fall meeting of the Branch, held October 5th, 1937, in McMaster University, will stand out in the members' minds for a long time. Following an informal dinner in McMaster Refectory, the distinguished visitor, Major-General A. G. L. McNaughton, C.B., C.M.G., D.S.O., LL.D., President of the National Research Council, Ottawa, and formerly Chief of Staff for the Department of National Defence, addressed an audience of 97. General McNaughton, who was introduced by his one time class mate, Major H. A. Lumsden, M.E.I.C., spoke on "The Work of the National Research Council."

### The National Research Council

The speaker drew an analogy from the present rearmament race in Britain to warn industrialists of the dangers in skimping research development. Just as the pending international crisis has spurred Britain to rearm suddenly at great cost to the taxpayers for generations to come, so, sooner or later, perils may affront Canadian industry both in our own and the markets of the world compelling enormous sums to be spent on research in a short period. A considerable proportion of Britain's expenditure could have been avoided if those who held the purse strings in the years since the war could have been persuaded to allow research, experiment and development, as the army authorities wished, at a moderate rate. The speaker believed that industrial research is not being carried out in Canada on a scale needed for adequate protection, and pleaded that industry gradually expand its research activities and avoid possible crises.

The work of the National Research Council is conducted in aid of industry and on request. The Council endeavours to provide information through its accumulation of technical literature, by precise measurements, by co-operative measures with outside sources and through collections in its museums. Beneficiaries and not the state are the Council's chief source of revenue.

The accuracy of results obtained in these laboratories must be superior to the results of other investigators in Canada and must agree with the results obtained at foreign laboratories.

Giving brief descriptions with lantern views, General McNaughton outlined the facilities of the laboratories and their work, citing numerous examples.

Several achievements of the Council have not previously been made public because patents had not been granted, but device has been designed to aid aeroplane pilots trace forest fires to their source by means of sound; and a windmill has been perfected to enable farmers to charge radio batteries. Weather forecasting by the use of cathode ray direction finders is being developed so that operators at distant points can synchronize their apparatus at a given signal, and by a system of triangulation and co-relation of meteorological information will, it is hoped, be able to forcast the weather with a greater degree of accuracy than is done at present.

In an attempt to solve the problem of transporting perishable foods to Britain, physicists and biologists are working on a new system of refrigeration where it will be possible to control humidity at forty degrees below zero.

A rust resisting wheat will be ready for the Western farmers next spring and work is progressing on a new type of barley for the use of British maltsters.

Colonel E. G. MacKay, Chairman of the Hamilton Branch, presided at the dinner and also at the Professional meeting.

The vote of thanks, which was very heartily endorsed by all present, was proposed by W. Hollingworth, M.E.I.C., and seconded by E. T. Sterne.

Chancellor Whidden and Dr. Burke of McMaster University were present at the dinner and meeting and spoke to the gathering.

After the lecture an enjoyable half-hour was spent while refreshments were served to all.

### Recent Achievements in Colour Photography

On October 21st, Mr. Herbert Johnson, of the Eastman Kodak Company Rochester, N.Y., addressed the Branch on "Recent Achievements in Colour Photography." Visiting ladies were the guests of the members of the Branch and after the lecture 187 members and ladies, together with a large delegation from the Hamilton Camera Club, enjoyed refreshments in the library of McMaster University.

Mr. Johnson spoke of the progress of photography from its early stages, showing many interesting slides.

The visible spectrum, he explained, is a narrow band compared to the range of invisible light; infra red having a longer wave length and ultra-violet a shorter wave length than that of visible light. With infra red it is possible to photograph scenes not visible to the naked eye at 200 miles distance. Ultra-violet will penetrate eleven inches of steel and will make old, faded documents legible.

Introducing his explanation of colour photography, the speaker showed a beautiful coloured slide of flowers, then the same photograph was shown in black and white and a sigh of disappointment came from the spectators. Colour photography is based on a blending of the three primary colours of white light, blue, red and green or their complementaries, yellow, magenta and blue-green. When white light shines on a red transparent medium, only red light passes through, and blue and green are absorbed. Similarly blue absorbs all but blue light, and green passes only green light. Based on these principles photographic films have been made with three, separated, sensitive layers each of which reacts to one of the colours. The developing of a coloured film requires twenty-seven processes and takes three hours.

There are two systems of colour photography, the Additive and Subtractive systems, and their relation can be illustrated by picturing a triangle whose sides are the colours yellow, blue-green and magenta; whose apices are the combination of the adjacent sides and whose centre is the combination of all three colours. When yellow and blue-green overlap, that is, when they shine independently on the same area or are added, the resultant is green. Similarly, blue-green and magenta produce blue, and magenta and yellow give red. The centre of the triangle where all colours overlap is black and such overlapping of colours is known as the Additive system. In taking a colour photo by this system it is necessary to make three shots, each with a different filter. The colour reproduction is good, but dense, and requires so much light for projection that special cooling arrangements must be provided. In the Subtractive system the process is reversed. Instead of the primary colours, the complementary colours are used. For example, when white light shines on blue-green, each of the primary colours in the combination, namely, blue and green, are passed and red, the colour wanted, is absorbed. Following the address Mr. Johnson showed a reel of coloured motion pictures depicting "The Growth of Transportation on the American Continent Through 150 Years," as depicted in the pageant performed at the recent exposition at Cleveland.

The speaker was introduced by W. J. W. Reid, A.M.E.I.C., vice-chairman of the Branch, and G. Moes, A.M.E.I.C., proposed a vote thanks. Colonel E. G. MacKay, A.M.E.I.C., presided at the meeting.

## Kingston Branch

*R. A. Low, A.M.E.I.C., Secretary-Treasurer.*

The annual meeting of the Kingston Branch was held on October 25th, 1937, and the following were elected officers: Chairman, Major H. H. Lawson, M.E.I.C.; Vice-Chairman, Prof. W. L. Malcolm, M.E.I.C.; Sec.-Treas., R. A. Low, A.M.E.I.C.; Executive, J. B. Wilkinson, A.M.E.I.C., R. F. Legget, A.M.E.I.C.; (ex-officio), Lt.-Col. L. F. Grant, M.E.I.C., Lt.-Col. N. C. Sherman, M.E.I.C., J. E. Goodman, A.M.E.I.C.

A report of the Branch activities during the season 1936-37 was presented. The Branch had met on five occasions and a statement of membership at the present time showed an increase of 13 over the previous year. A bank balance of $50.65 was carried forward in comparison with a balance of $63.54 of the previous year.

Regret was expressed at the determination of Lt.-Col. L. F. Grant to resign as Branch Secretary, a position which he has so ably filled for the past nine years.

### The Boulder Dam

At the first public meeting of the Branch this season, an interesting lecture on "Boulder Dam" was given by S. C. Hollister, Dean of the School of Engineering, Cornell University, in Convocation Hall, Queens University, on Friday, November 12th.

The lecture was largely attended by both the staff and students of Queens University and the Royal Military College.

Prior to the lecture, a complimentary dinner was given for Dean Hollister at the Badminton Club, other guests including Principal Wallace and Dr. McNeil of Queens University, Brigadier Matthews, Prof. Richardson of the Royal Military College and several members of the Peterborough Branch.

The speaker, who was consulting engineer for Babcock and Wilcox on the Boulder Dam project, has been responsible for much of the development in concrete design and practice on this continent in recent years.

Introduced by Prof. W. L. Malcolm, under the chairmanship of Major H. H. Lawson, Dean Hollister commented on the magnitude of the project, and the impossibility of covering the subject with the short time at his disposal. He justified the project for three reasons other than power development, stating that its primary purpose was to provide adequate flood control for the Colorado river, provide irrigation for the Imperial Valley in Southern California, as well as provide a domestic water supply for Los Angeles and irrigation for the citrus fruit growing region near that city.

Illustrating his lecture with both slides and moving pictures, he outlined the development of the project from its inception, laying particular stress on the design of the dam and the penstocks. While keeping general features in the foreground, he described many interesting problems in research and design which were encountered in this vast undertaking.

The lecture was followed by a series of motion pictures showing general construction features during the progress of the work, and the interest evoked was clearly indicated by the numerous questions.

A hearty vote of thanks, moved by Dean A. L. Clark, Hon.M.E.I.C., of Queen's University, was tendered the speaker for his excellent lecture.

## Lethbridge Branch

*E. A. Lawrence, S.E.I.C., Secretary-Treasurer.*
*R. F. P. Bowman, A.M.E.I.C., Branch News Editor.*

The regular dinner meeting was held on Saturday evening, October 9th, with 24 members and guests present. Music was supplied by Mr. Geo. Brown and his quartette, and community singing was enjoyed. A much appreciated solo was also rendered by Mr. Stott.

A feature of the dinner hour was the presentation to the club of a gavel, by Messrs. Cross, DeHart and Bowman, the gavel having been made by these gentlemen from a part of the first wrecking car on the Alberta Railway and Irrigation Company's line.

The minutes of the last meeting were then read and approved, and the report of the Chairman of the Programme Committee received. The speaker of the evening, J. T. Watson, A.M.E.I.C., City Manager, was then introduced by Mr. Wm. Meldrum.

Mr. Watson said that the original power plant in the City was owned by the Lethbridge Water and Electric Co. and was located at the west end of 1st Ave. S. This was rather small and the service poor, but with the building of a new plant in 1906 service was improved. This plant was taken over by the municipal authorities in 1908, but was burned down on New Year's Eve, 1909, and a new plant at the present site rushed to completion in 1910. Mr. Watson came here himself in 1916, and it is interesting to note that there are now only two pieces of the equipment of the 1916 plant remaining.

The speaker quoted a number of figures to show the past and present state of the finances of the plant, and the present high efficiency. In 1915 the plant used 5.37 lb of coal to produce one kilowatt hour, in 1936 it used 2.55 lb. of coal to produce a kilowatt hour.

He then showed a number of slides of the boilers, generators, etc., in use before the present equipment was installed, the present boilers, and their accessory equipment, the present generator and standby units, switchboards, and sub-stations, and the pumping and filtration plants.

At the conclusion of the address, Mr. Arthur Reid, also a former city power plant superintendent, moved a hearty vote of thanks to the speaker, and the meeting closed with "God Save the King."

### November Dinner Meeting

A dinner meeting and Ladies Night was held at the Marquis hotel, November 6th, 1937, with 60 members and ladies present. During the dinner, music was supplied by George Brown's instrumental quartette, following which vocal solos by Miss Jean Gibson and Mr. Terrence Horne, piano duets by Jack DeHart and Ross Robinson, and monologues by Mr. Alex Branch were enjoyed. Community singing was led by Mr. Bob Lawrence.

The speaker of the evening was Mr. Jack DeHart, son of J. B. DeHart, M.E.I.C., whow as one of the Canadian student representatives at the coronation of His Majesty King George VI, and gave an interesting account of his trip. There were 168 boys and 150 girls in the Canadian contingent. The boys sailed from Montreal at the end of April and landed at Southampton, going to London, where quarters were provided.

On coronation day the students were in place at their stands opposite Buckingham Palace Gate at 7.30 a.m. and from there watched the grand and impressive procession from the Palace to Westminster Abbey.

During the next few days numerous gatherings were held for the students. Stanley Baldwin addressed them at the Royal Albert Hall, and the Archbishop of Canterbury preached at a special service in Westminster Abbey.

Following the address, the chairman, J. M. Campbell, A.M.E.I.C., DeHart, M.E.I.C., who was one of the Canadian student representatives paid a glowing tribute to J. D. DeHart, who is leaving Lethbridge to reside in Calgary. Mr. DeHart's enthusiastic and conscientious work in connection with the Branch has largely contributed to the success of its activities. Mr. Campbell then presented Mr. and Mrs. DeHart with travelling bags as a token of appreciation and friendship from the Branch. Both Mr. and Mrs. DeHart spoke briefly in acknowledgement.

## London Branch

*D. S. Scrymgeour, A.M.E.I.C., Secretary-Treasurer.*
*Jno. R. Rostron, A.M.E.I.C., Branch News Editor.*

The October meeting of the Branch was held on the 20th at Wong's Cafe and took the form of a dinner meeting to welcome Mr. Durley.

After a substantial repast which all enjoyed, A. O. Wolff, M.E.I.C., chairman of the Branch, presided, and after the reading of the minutes called attention to the fact that Headquarters had agreed to the request of the London Branch Executive that the next Annual General Meeting of The Institute be held in London. After consultation with Headquarters, the dates upon which the meeting would be held have been fixed for January 31st, 1937, and February, 1st and 2nd, 1938 (Monday, Tuesday and Wednesday), at the Hotel London.

The evening was devoted to making preliminary arrangements for the next Annual Meeting and much helpful advice was given by Mr. Durley, drawn from his long experience in such matters.

At the conclusion, a hearty vote of thanks was expressed by J. A. Vance, A.M.E.I.C., seconded by H. F. Bennett, M.E.I.C., and unanimously carried.

About 20 members were present.

## Montreal Branch

*E. R. Smallhorn, A.M.E.I.C., Secretary-Treasurer.*

### The Isle of Orleans Suspension Bridge

On October 21st, 1937, D. B. Armstrong, A.M.E.I.C., of the Dominion Bridge Company, presented a paper on "Pre-stressing and Erection of Isle of Orleans Suspension Bridge." The speaker was supervising engineer of the construction of this bridge and was therefore well qualified to describe the problems which were met and overcome in fabricating and erecting this bridge. He also discussed the methods used in pre-stressing the suspension cables and erecting them at the site.

P. L. Pratley, M.E.I.C., was in the chair.

Technical Men in Industry

"Technical Men in Industry" was the subject under discussion at the meeting on October 8th, when Messrs. C. A. Peachey, Northern Electric Co., and Dr. H. G. Littler, Canadian Industries Limited, were the speakers. The first paper outlined the functions of the technical man, his present resposibilities, and future possibilities. The engineer's place under modern conditions and his responsibility in the reduction of costs were the principal points stressed.

Dr. Littler believed that unless a drastic change took place in the viewpoint of the technical man his voice was not likely to be heard in the planning of new industrial organizations in the future, as the engineer was lacking in proper training and experience in economics.

The chairman was Dean Ernest Brown, M.E.I.C.

Canadian Air Transportation

Mr. G. A. Thompson, General Manager of the Canadian Airways, Ltd., Winnipeg, on November 4th gave a most interesting address covering the history of commercial flying in Canada and other countries, the development of types of planes for Canadian use, and the present requirements of a general purpose aircraft for northern transportation. The economics of the operation of the commercial planes were also discussed.

Prior to the meeting an informal dinner was held at the Windsor hotel.

Chairman: G. G. Ommanney, M.E.I.C.

Junior Section

On November 8th an interesting visit was made to the hydraulics laboratories of the Ecole Polytechnique.

These laboratories, the most modern in Canada, were designed and built under the supervision of Professor Armand Circé. They are primarily equipped for teaching purposes but are also suitable for research work and studies on models of spillways with various profiles are at present being made.

The laboratories are equipped with a hydraulic turbine, small models of turbines and a 120 ft. channel with a spillway 4 ft. wide.

Mr. Raymond Boucher, M.Sc., C.E., Jr.E.I.C., Professor of Hydraulics at the Ecole Polytechnique and a graduate of Massachusetts Institute of Technology, gave a short description of the laboratory and particulars of the research work recently undertaken.

Electrical Operating Problems

Four short papers dealing with operating problems in the electrical industry were presented before the Branch on November 11th. It is understood that these are the first of the series which will discuss operating problems of the main Canadian industries. The subjects and authors were as follows:

"Operating Difficulties in Maintaining Service," by R. N. Coke, A.M.E.I.C.; "66 k.v. Cable Operation in Montreal," by A. Benjamin, A.M.E.I.C.; "Load Trends on the Island of Montreal and Vicinity," by G. C. Read, these three speakers all being from the Montreal Light, Heat and Power Consolidated; "Ground Resistance Measurements for Large Substations," by J. M. Crawford, A.M.E.I.C., Shawinigan Water and Power Company.

Chairman: G. R. Hale, A.M.E.I.C.

Junior Section

Montreal Locomotive Works, Montreal, received an inspection by the members of the Junior Section on Saturday afternoon, November 13th. Work in progress in the shops of the company included several locomotives of the Canadian Pacific Railway, 2800 class. These and other features proved of great interest.

## Niagara Peninsula Branch

*G. E. Griffiths, A.M.E.I.C., Secretary-Treasurer.*
*J. G. Welsh, S.E.I.C., Branch News Editor.*

On October 28th the Niagara Peninsula Branch was the guest of the Engineering Society of Buffalo for an instructive and enlightening afternoon and evening.

Members of the two organizations met at 1.30 o'clock in the afternoon in the Statler hotel, Buffalo, and divided into two groups one of which was taken on a conducted tour of the new "Strip Mill" of the Bethlehem Steel Company at Lackawanna. It was an excellent time to see this plant since at this season the production rate for the light gauge steel which they roll is quite high. This product now being used in large quantities for the making of car bodies and fenders.

The second group made an inspection trip of the treatment plant of the new Buffalo Sewage System. The original plans had been that the trip would be an inspection of the main works of the whole system but owing to wet underground conditions this part of the trip was impossible.

At 7 o'clock the groups reunited in the Statler Hotel to join in an enjoyable dinner. Mr. J. G. Ullmann, chairman of the Engineering Society of Buffalo, made a short speech of welcome to members of the Niagara Branch which was followed by a toast to the King. L. C. McMurtry, A.M.E.I.C., chairman of the Niagara Peninsula Branch, extended the good wishes and thanks of the Canadian group and hoped that the two organizations would again be able to get together in the form of a meeting on this side of the border.

Following the dinner, the meeting adjourned to the assembly hall of the hotel for moving pictures with sound descriptions of the construction of the new Golden Gate bridge. The first picture presented by John A. Roebling's Sons Company proved to be most interesting in that it depicted practically every phase of the erection of the suspension cables. One of the most instructive parts of the picture was the showing of the principles of spinning cables for a suspension bridge and how the rate of spinning cables has increased in the latest bridges of this type. This has been done by both increasing the number of cable carrying wheels and by increasing their speed of travel.

The second picture showed the construction of the towers and stiffening trusses of the suspended span of the same bridge and was presented by the Bethlehem Steel Company.

## Ottawa Branch

*R. K. Odell, A.M.E.I.C., Secretary-Treasurer.*

Some Recent Developments in Aircraft Fuels

At the first noon lucheon of the new fall and winter season held at the Chateau Laurier on October 14th, M. S. Kuhring, Mechanical Engineering Division, National Research Laboratories, gave an address on "Some Recent Developments in Aircraft Fuels." His address dealt largely with three general problems at present facing the refiners and the manufacturers and users of aircraft engines. These relate to vapour pressure, distillation range and octane number, three considerations closely interconnected and of relatively equal importance.

Vapour pressure the speaker defined as the property which controls vapour lock or interference of the metering of the fuel by the carburettor due to evaporation before passing through the carburettor jet. The vapour lock may result in either excessively lean or excessively rich mixtures which of course may not be tolerated. In most of the specifications today for aircraft engine fuels the maximum permissible vapour pressure is seven pounds per square inch.

Aeroplanes today are capable of climbing so rapidly that quite often the fuel in the tanks is actually boiling when the ceiling is reached, due to a lag in the drop of the fuel temperature combined with the reduced atmospheric pressure to which the fuel is subjected. Very volatile fractions in fuels of the future, therefore, may have to be somewhat restricted, though on the other hand such fractions have good anti-knock value and starting properties.

The distillation range is related to the starting possibilities of the fuel when used in an engine, to its tendency toward vapour lock and to its power of distribution and acceleration. Certain refiners believe that volatility plays a part in motor fuels as great as lead in regard to anti-knock quality.

This, stated Mr. Kuhring, may be true to a large extent for those used in automobile engines—butane has been added to some fuels so used with success—but for aircraft engines there is always the vapour pressure to be taken into account. This whole question, according to the speaker, is one of great complexity and well worthy of a paper by itself.

The greater portion of the address was devoted to the octane number or anti-knock quality of the fuel which the speaker characterized as "by far the most interesting single property of aircraft fuels today."

Shortly after the Great War the phenomenon of detonation was first observed in connection with engines. Damaged pistons, cylinders and valves due to this cause had, of course, previously been encountered. Quite properly, they were ascribed to overheating and remedial efforts were usually directed toward trying out new types of cowling. But there was more than this to the question.

With the efficiency of an internal combustion engine depending upon the density of the charge in the combustion chamber before ignition the natural thing was to attempt to increase the specific power output by increasing the compression pressure. But such attempts soon resulted in sudden and unnatural temperature increases generally accompanied by knocking or pinking sounds. This discovery has led to a vast amount of investigational work, which is still being carried on.

For carrying on such investigations the single-cylinder CFR engine has been developed to test the resistance of fuels to detonation, and two chemically pure hydrocarbons have been selected which may be mixed in any definite proportion to match the anti-knock value of whatever fuel may be under test. After much experimentation, iso-octane and normal heptane have been selected for this purpose as basic reference standards, the former having a much higher resistance to detonation than the latter. In comparative tests as carried out with the CFR engine under certain rigidly controlled operating conditions the percentage of iso-octane in the blend of iso-octane and normal heptane which just matches the unknown fuel in anti-knock value is known as the "octane number." In other words, if 87 per cent of iso-octane is required in the blend of iso-octane and normal heptane to match the anti-knock value of an aviation fuel, then that fuel will have an octane number of 87.

Mr. Kuhring then described some of the rigidly controlled conditions under which the engine must be operated in carrying on the tests. Some years ago, he stated, the aircraft fuels in use ranged from

66 to 73 octane number. They then moved up to 80 and then to the 87 which is in use at the present time. Fuels of much greater octane number, even to those greater than 100, are now being considered; and while it may be a little time before they are in general use they will no doubt be produced commercially to meet the demand. The usual practice in rating the very high test fuels is to report them as being "iso-octane plus so many c.c.'s of lead," since the octane scale does not go above 100.

To give an idea of what the increase in octane number may mean to the engine manufacturer and the operator, Mr. Kuhring instanced the case of an engine which started out with a horsepower under 600 but which, thanks to the fuel now available, is capable of over 1,200 h.p. without any increase in speed of the engine.

#### Canadian Hydrographic Service on the Pacific Coast

Henri Delpe Parizeau, District Hydrographer of the Canadian Pacific Coast, gave a talk at the luncheon, October 28th, on the "Canadian Hydrographic Service on the Pacific Coast." J. G. Macphail, chairman of the Ottawa Branch, presided and other head table guests included: G. J. Desbarats, president of The Institute; J. B. Challies of Montreal, F. H. Peters, S. J. Chapleau, G. B. Dodge, and R. J. Fraser.

Mr. Parizeau first of all traced the history of the Canadian Pacific coast with particular reference to exploration, coast line and hydrographic surveys from the early days to the present. Captain Cook, who brought the first British ship into these waters in 1778, he stated, "had done more for North America than any general, admiral, scientist or hydrographer." He was the father of the hydrographic service of the British Isles and the grandfather of the hydrographic service of Canada; and it was distinctly unfortunate that his memory was not commemorated by a monument in Canada.

With a coast line five times as long as the distance from Halifax to Vancouver, with 1,150 miles of open water and 4,500 miles of inland channels, some of them extending back as much as 75 miles from the open sea, with high hills and mountains lining the coast, the tops of which were frequently in the clouds, and with periods of extended rainfall, there are plenty of natural difficulties to be encountered on the hydrographic survey.

The speaker described some of the methods and equipment used and gave details regarding the survey ship the *W. J. Stewart*, which was named after the late chief hydrographer.

As an instance of the manner in which methods have progressed, whereas formerly many hours were required to take individual sounding in deep water now the same thing can be done by modern methods in a few seconds.

## Peterborough Branch

*W. T. Fanjoy, A.M.E.I.C., Branch Secretary.*
*J. L. McKeever, Jr.E.I.C., Branch News Editor.*

The first technical meeting of the season was held on October 28th, 1937, at which the speaker was John Grieve, A.M.E.I.C., Promotion Manager, Imperial Varnish and Colour Co., Toronto, on the subject of "The Manufacture of Paints and Varnish with relation to Weathering, Durability, and Insulating Properties."

Mr. Grieve started his talk by describing the basic materials used in paint manufacture, the oils, pigments, pigment bases etc., and was able to show samples of most of the materials he mentioned. He made mention of the sources of the various materials and the amount of work that is being done to find substitutes for imported material, as for example china-wood oil, the trade in which has practically been stopped by the present Sino-Japanese War.

The speaker next went on to describe the various types of paints and their uses, pointing out cases where the older standard preparations were now being replaced by better modern substitutes, a case in point being the supplanting of red lead by lead chromate as a primer for steelwork.

He gave some interesting demonstrations of the precipitation of various pigments and of the different properties of various commonly used oils. He stressed the necessity of the paint manufacturer being informed of the various conditions to be met with in any large job so that the correct paint might be applied and deprecated the common assumption that one paint would cover a multitude of different requirements.

Mr. Grieve proved to be a pleasant speaker, well versed on his subject and his talk was greatly enjoyed by the Branch. Attendance, 47.

#### Junior and Student Section

An interesting development in the activities of the Branch was the first meeting of the Discussion Club recently formed by the Junior and Student Section, held on October 21st, Mr. A. L. Malby was Chairman of the meeting, and the two speakers were: Mr. D. A. Drynan on "Lightning and Lightning Protection" and Mr. W. F. McMullen on "Single Phase Revolving Fields."

From the amount of discussion which took place it was evident that the first meeting of this kind was a distinct success and it is hoped that future meetings will evoke an equal amount of enthusiasm. Attendance, 25.

## Saint John Branch

*L. G. Lilley, Jr.E.I.C., Secretary-Treasurer.*
*H. P. Lingley, Jr.E.I.C., Branch News Editor.*

The regular monthly meetings of the Saint John Branch started on October 22nd, 1937, when about 30 members gathered in the Admiral Beatty hotel to hear Mr. W. R. McCaffrey, Secretary of the Canadian Engineering Standards Association, speak on the work of the association.

Mr. McCaffrey discussed briefly the set-up of the C.E.S.A. and explained how a specification was voted on before it became a standard.

He was followed by Mr. W. P. Dobson, Chief Testing Engineer of the Ontario Hydro-Electric Power Commission, who spoke at some length on "Laboratory Approval and Research Work."

Mr. Dobson gave a very interesting account of the Laboratory Branch of the Hydro Commission and went on to explain that there were three functions of the laboratory, namely, testing, research and approvals.

Mr. Dobson, who is Chairman of the Eastern Division of the Canadian Electrical Code Commission, and Mr. McCaffrey had just returned from a meeting in Amherst, N.S., of the Eastern Committee of the Code Commission, and this Branch was very fortunate in having them address us.

The chair was occupied by the chairman of the Branch, Mr. Sidney Hogg, who tendered a very hearty vote of thanks to the speakers, on the completion of their addresses.

#### Mineral Resources and World Politics

On Thursday, November 18th, 1937, the Saint John Branch held a regular meeting in the Admiral Beatty hotel with thirty members present. Sidney Hogg, A.M.E.I.C., presided, and the speaker was Professor H. W. McKiel, Dean of the Faculty of Engineering at Mount Allison University.

Professor McKiel's subject, "Mineral Resources and World Politics," gave the Branch a very interesting picture of the effect and importance of a country's mineral deposits, both in peace and war.

He discussed the use of metals from early times, and pointed out that all large industries were situated in certain areas depending on their mineral deposits. Conditions now, however, are different than before, as the present deposits are practically all used up, necessitating a move towards discovery of new deposits or importation from other countries.

Professor McKiel than gave a list of the countries in the order of their mineral importance, the countries of North and South America leading, with the United States at the head, owning or producing about 40 per cent of the world's supply. Canada has what amounts to a virtual monopoly in nickel, but is lacking in iron, importing an amount nearly equal to its other mineral productions.

On the whole, the mineral deposits of the various countries of Europe are on the decline, although little is known about Russia's future due to its large little known areas. Germany was deprived of nearly all her supplies of iron after the war, although there is no other so large an industrial country having such a poor supply of minerals. Much of Germany's unrest today is due to her loss of mineral resources.

In time of war, possession of important minerals is of supreme importance, as minerals mean munitions. A union of the United States and Great Britain would mean a practically undefeatable combination as the two countries together control more than 75 per cent of the world's supply.

After his address, Professor McKiel discussed the proposals for a scheme of union similar to Nova Scotia, and the meeting went on record as approving in principle the scheme as put forth by Professor McKiel.

## St. Maurice Valley Branch

*C. H. Champion, A.M.E.I.C., Secretary-Treasurer.*

#### Farewell Dinner to Bruno Grandmont, A.M.E.I.C.

A farewell dinner in honour of M. Bruno Grandmont was held on October 8th at the Chateau de Blois in Three Rivers. Members of the St. Maurice Valley Branch and of the Association of Professional Engineers gathered to say farewell to a fellow engineer who had been active in affairs for that region for many years past.

M. Grandmont, a past chairman of the Branch and a councillor of The Institute, has occupied the position of district engineer, Public Works of Canada, at Three Rivers for the past 16 years and is now being moved to Quebec.

John Wickenden, A.M.E.I.C., chairman of the Branch, presided at the dinner and mentioned, as did several other speakers, how much the Branch regretted losing M. Grandmont. M. Grandmont, in reply, thanked those present for offering their best wishes and for the honour done him. Messrs. Bonaventure and St. Cyr assisted in the organization of the dinner.

#### Grand'Mère Meeting

The Saint Maurice Valley Branch held their last meeting of the fall season in Grand'Mère, on Friday, November 5th, 1937, with some fifty members and visitors present. This meeting took the form of a dinner meeting prior to which cocktails were served in the Men's Club. The party then adjourned to the Laurentide Inn for an excellent dinner.

The chairman of the Branch, Mr. John Wickenden, A.M.E.I.C., was in the chair. The guests present were Messrs. D. O. Robinson, A.M.E.I.C., and R. A. Crysler, A.M.E.I.C., of Toronto; E. A. Smallhorn, A.M.E.I.C., Secretary of the Montreal Branch, and J. F. Plow, A.M.E.I.C., Assistant Secretary of The Institute, Montreal.

At the conclusion of the dinner there was a short business meeting at which the Branch Nominating Committee for the naming of officers for the next year was elected. These were Messrs. H. O. Keay, M.E.I.C., W. B. Scott, A.M.E.I.C., and C. H. Champion, A.M.E.I.C.

Mr. Champion then gave a short résumé of the recommendations which resulted from the Round Table Conference of the Branch representatives which took place in Montreal at the time of the Semi-centennial Meeting of The Institute. Mr. Plow gave a short talk on The Institute and its work, stressing particularly what it was able to do for members of the Saint Maurice Valley Branch.

Professor Keay then introduced the speakers, Messrs. D. O. Robinson and Mr. R. A. Crysler of the Canada Cement Company of Toronto.

Mr. Robinson, who undertook to give a general talk on Portland cement and concrete, referred particularly to recent developments in highway and bridge construction. Mr. Crysler, who followed, carried the subject on to include many types of reinforced concrete structures in United States, Canada and Europe. Some very excellent slides were shown and the general consensus of opinion was that they did not believe that a discussion on concrete could have been made so interesting.

The speakers were thanked by E. B. Wardle, M.E.I.C., heartily supported by those present.

## Toronto Branch

*J. J. Spence, A.M.E.I.C., Secretary-Treasurer.*
*A. E. Berry, M.E.I.C., Branch News Editor.*

The opening meeting of the Toronto Branch was held on October 21st, 1937. A. U. Sanderson, A.M.E.I.C., chairman of the Branch, occupied the chair. The speaker was Professor C. R. Young, M.E.I.C., of the University of Toronto, and his subject "Modern University Training for Civil Engineers."

The speaker described the development of engineering education in this and in other countries. Perronnet, who instituted in 1747, in France, a scheme of instruction for designers of bridges and highways may be considered to be the father of engineering education. Early civil engineers in Britain received their training through articled pupilage to practising engineers, and engineering schools as we now know them were slow in arriving.

On this continent, the first engineering college to have a continuous existence, and the first of its kind to be established in any English speaking country, was the Rensselaer Polytechnic Institute at Troy, N.Y., founded in 1824.

Modern engineering education in Ontario began in 1878 with the founding of the Ontario School of Practical Science, now the Faculty of Applied Science and Engineering of the University of Toronto. In each of the three Departments of Civil, Mechanical and Mining Engineering, then announced, the avowed object was to afford a thorough education in physical science with a direct bearing on the occupation which students might wish to follow.

Professor Young stated that the choice of subjects at that time was excellent, and that whatever changes have been made in the past 60 years have for the most part pertained to the extension of the field and intensity of each subject, or the subdividing of it to conform to the astounding growth of scientific knowledge. Realizing that the work of the engineer is that of a co-ordinator of many sciences to the end that he may achieve a desired result, the university has added to the curricula numbers of subjects of a business, economic, or cultural character, such as Business, Technical English, Economics and Finance, Commercial Law, Engineering Law, Management, Engineering Economics, Contracts and Specifications, Municipal Administration, and Public Speaking.

An interesting phase of the address was the statement that during recent years the trend has been away from marked specialization within the long-established engineering departments. Thus, in Civil Engineering, election of subjects is limited to about 15 per cent of the time in the fourth or final year. A broad, fundamental training has been found best having regard to the employability of graduates.

Students entering the university have ample opportunity of specialization in the choice of the department in which they register.

For the average student of engineering, four years is the maximum practicable length of time to spend in college, but others find it advantageous to return for graduate work, and to take up subjects of an advanced character. Only three schools on the continent have engineering courses longer than four years; one of three years arts and three years engineering; and two others of five straight years of engineering.

The meeting was well attended, and the discussion which followed was broad and of considerable interest.

## Winnipeg Branch

*A. E. Macdonald, M.E.I.C., Chairman.*
*H. L. Briggs, A.M.E.I.C., Branch News Editor.*

### Acoustics

On October 21st, 1937, Dr. W. J. Hodge, Chief Acoustical Engineer, Johns-Manville Company, New York City, gave the members of the branch an instructive and interesting evening on the above subject. Commencing with a sound film which set forth the principles of sound production and propagation, reflection, refraction, and the manner in which the human ear is influenced, he proceeded to demonstrate sound level, absorption, reverberation, echoes, and the focusing of sound by curved surfaces to produce local areas in auditoria where the acoustics were particularly poor. Means were shown whereby rooms were soundproofed by producing "discontinuities" across which vibration did not carry. In special cases floors, walls and ceilings were carried on sound isolators consisting of saddles supported on hair felt pads.

J. W. Porter M.E.I.C., expressed the appreciation of the large audience to the speaker.

The chairman noted with much regret the departure of F. G. Goodspeed M.E.I.C., from Winnipeg, and assured him of the good wishes of the Branch on the occasion of his appointment to the Board of Engineers, Department of Public Works, Ottawa.

### The Cyanide Process

In an interesting paper on November 4th, G. E. Cole, A.M.E.I.C., Director of Mines, Department of Natural Resources, Province of Manitoba, described the history and improvement of the cyanide process for the extraction particularly of gold from its ore. The years 1886 to 1900 marked the birth and success of the cyanide method, 1900 to 1912 the consolidation of the process and progress in grinding the ore, while from 1912 until the present has witnessed the intense development of special machinery.

The steps in the process as used at present are:

(1) Preparation of the ore for cyaniding.
(2) Dissolving of the gold from the finely ground rock to form a pregnant solution.
(3) Separation of the finely ground rock from the pregnant solution.
(4) Precipitation of the gold.
(5) Separation of the gold from the barren solution.
(6) Conversion of the gold sludge to gold.

After a number of slides and considerable discussion, Professor N. M. Hall, M.E.I.C., expressed the thanks of those present to the speaker.

## List of New and Revised British Standards

(Issued during July, August and September)

*B.S. No.*

37—1937. *Electricity Meters.* (*Revision*).
Extended to include "long-range" meters, and meters of sizes up to 6,000 amperes. The permissible limits of error have been reduced wherever possible.

153—Pts 3, 4, and 5—1937.
*Girder Bridges.* (*Revision*): *Part 3, Loads and Stresses*; *Part 4, Details of Construction*; *Part 5, Erection.*
Revision of portions of the B.S. Specification for Girder Bridges issued in 1923, and additions made to Parts 3, and 4.

209—1937. *Fuel Oils for Diesel Engines* (*Petroleum and Shale Oils*) *including Methods of test.* (*Revision*).
Issued as a result of the development of the modern high speed diesel engine. It deals with oils of petroleum and/or shale origin and includes a grade of oil suitable for engines for automotive and allied purposes of speeds in excess of 800 r.p.m., together with other grades for medium and slow running engines.

240—1937. *Method and Tables for Brinell Hardness Testing.* (*Revision*).
Revision of 1926 issue incorporates amendments relating to the manner of carrying out the test, principally in regard to the thickness of the test specimen, the appropriate $\frac{P}{D^2}$ ratio, and the time of application of the load.

742—1937. *Fuel Oils for Burners* (*Petroleum and Shale Oils*) *including Methods of Test.*
Deals with hydro-carbon oils of petroleum and/or shale origin. There are two schedules for fuels for domestic purposes, two for marine purposes and four for industrial purposes.

---

*Canadian Car and Foundry Company Limited* have issued an interesting and useful catalogue of mining equipment. The book has been prepared in loose-leaf form and the present contents includes various types of mine cars, narrow gauge track work for light industrial railways, car wheels, wheel and axle mountings, crusher and grinding parts, mill liners, etc.

In addition to a large number of photographic illustrations, dimensional drawings and detail specifications are included.

# Preliminary Notice

### of Applications for Admission and for Transfer

November 24th, 1937

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

**Communications relating to applicants are considered by the Council as strictly confidential.**

The Council will consider the applications herein described in January, 1938

R. J. Durley, Secretary.

*The professional requirements are as follows:—

**A Member** shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

**An Associate Member** shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

**A Junior** shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

**A Student** shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

**An Affiliate** shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

## FOR ADMISSION

BINNS—FRANK, of Sackville, N.B., Born at Bradford, England, Dec. 9th, 1885; Educ., B.S., Tufts College, 1909. M.S. in Engrg., Purdue Univ., 1935; 1902-05, ap'tice, Lawrence Machine Co., Lawrence, Mass.; 1910-18, dftsman., Hamblet Machine Co., Lawrence; 1918-19, dftsman., Peter Cooper Hewitt, New York; 1919, detailer, Baldwin Locomotive Works, Philadelphia; 1925-27 (2 periods), 1928, designer of heavy machy., Cameron Machine Co., Brooklyn, N.Y.; 1927, designer of special machy., Wall Rope Works, Beverly, N.J.; 1929, designer of special machy., Brown-Bridge Mills, Troy, Ohio; 1919-24, instructor in mech. drawing, Univ. of Pennsylvania; 1924-25, instructor in mechanics, Pennsylvania State College; 1928, instructor in engrg. drawing, Texas Technological College; 1929-33, instructor in practical mechanics, Purdue Univ.; 1936 to date, instructor in engrg. drawing, Mount Allison University, Sackville, N.B.
References: H. W. McKiel, F. L. West, H. W. Read, J. F. F. Mackenzie, C. A. Fowler.

BURLTON—GEORGE ARNOLD, of 26 Union St., Halifax, N.S., Born at Halifax, April 28th, 1912; Educ., B.Eng. (Mech.), N.S. Tech. Coll., 1935; 1935-37, summers, paving inspr. on highways, and winters, asst. in engrg. dept., St. Mary's College, Halifax, N.S.
References: S. Ball, L. B. Feetham, J. J. Sears, A. F. Dyer.

CARLEY—FOREST CECIL, of Montreal, Que., Born at Consecon, Ont., June 17th, 1895; Educ., B.A.Sc., Univ. of Toronto, 1923; 1923-24, meter calculation and calibration, and 1924-27, sales and service engr., Bailey Meter Co.; 1928-33, with Chambers & Carley, Toronto. Air conditioning, automatic control for heating, calibrations in liquid measures; 1933 to date, manager, Montreal office, Affiliated Engineering Corps. Ltd., Montreal, Que.
References: W. L. Yack, N. E. D. Sheppard, O. Biedermann, W. W. Timmins, G. L. Wiggs.

CHAPLIN—HERBERT ELLIOTT, of Montreal, Que., Born at St. John's, Nfld., Sept. 2nd, 1910; Educ., B.Eng. (E.E.), McGill Univ., 1934; With the Imperial Tobacco Co. Ltd., Montreal, as follows: 1933, machine shop; 1933-34, dfting. office; 1934-36, factory engrg. dept., 1936 to date, asst. factory engr.
References: C. V. Christie, E. Brown, J. T. R. Steeves, N. C. Cameron, C. M. McKergow.

DYSON—VINCENT SEDDON, of 229 Maple Ave., Welland, Ont., Born at Sheffield, Yorks., England, March 30th, 1879; Educ., private study; 1900-04, mgr. and underground mgr., Stannington Wood Colliery; at present, supt., heavy forging plant, Canada Foundries & Forgings Ltd., Welland, Ont.
References: C. H. M. Burns, H. A. Ricker, W. R. Manock, M. B. Atkinson, P. E. Buss.

GODFREY—WILLIAM ROBERT, of Chatham, N.B., Born at Chatham, Apr. 10th, 1914; Educ., B.Sc., Univ. of N.B., 1935; 1934-35, survey foreman, Public Works of Canada; 1936, dftsman., Ross Realty Co.; at present, dftsman., cost keeper and engr.'s helper with Highway Divn., Dept. of Public Works of N.B., Chatham, N.B.

## FOR TRANSFER FROM THE CLASS OF JUNIOR

DesBRISAY, ARETAS WILLIAM YOUNG, Capt., R.C.S., of 102 Bagot St., Kingston, Ont., Born at Petit Rocher, N.B., June 4th, 1904; Educ., Grad., R.M.C., 1925. B.Sc., McGill Univ., 1927; Ph.D., Univ. of London, 1937; With the Bathurst Company, Bathurst, N.B., as follows: 1925 (summer), asst. operator, hydro-electric plant, 1926 (summer), instr'man., hydro investigation survey, 1927, instr'man. on prelim. rly. survey, 1928, block line survey, 1928, dftsman; 1928-31, transmission engrg., Northern Electric Co. Ltd., Montreal; 1931 to date, Officer, Royal Canadian Signals, Dept. of National Defence, at present, chief technical instructor, Canadian Signal Training Centre, Barriefield, Ont. (*St. 1926, Jr. 1931.*)
References: D. M. Jemmett, W. L. Laurie, C. Vokes, L. F. Grant, H. H. Lawson.

FARRELL—ALFRED JAMES, of 5088 Cote St. Antoine Road, Montreal, Que., Born at Montreal, May 15th, 1900; B.Sc., McGill Univ., 1924; 1924-26, installn. of rubber flooring, Dominion Rubber Company, Montreal; 1926-28, inspr., Canadian Fire Underwriters Assn., Montreal; 1928 to date, with the Royal Trust Company, Montreal, on repairs and mtce. of rented properties. (*St. 1924, Jr. 1926.*)
References: C. M. McKergow, J. M. Fairbairn, H. W. Lea, A. J. Foy. E. R. Smallhorn, H. J. Leitch, R. S. Logan.

GRANT—ALEXANDER GEORGE, of Red Rock, Ont., Born at Glasgow, Scotland, Dec. 10th, 1903; Educ., B.A.Sc., Univ. of Toronto, 1927; 1925-26 (summers), dftsman., John T. Hepburn Co., Toronto, and Can. International Paper Co. Ltd.; 1927 (7 mos.), dftsman., Roger Miller & Sons, Toronto, 1927-28, dfting, designing, surveying, G. W. Rayner, M.E.I.C., Toronto; 1928-29, asst. engr., Shell Co. of Canada Ltd.; 1929, quantity surveyor and field engr., Russell Construction Co. Ltd., Toronto; 1929-30, field engr., Can. International Paper Co. Ltd., Temiskaming, Que.; 1930-32, dftsman., Ontario Power Service Corpn., Fraserdale, Ont.; 1934-35, designing dftsman., Howard Smith Paper Mills, Cornwall, Ont.; 1935-36, dftsman., struct'l. design and dtting. (4 mos.), asst. engr., rehabilitation of houses (10 mos.), Anglo-Newfoundland Development Co. Ltd., Grand Falls, Nfld.; at present, field engr., mill constrn., Lake Sulphite Pulp Co. Ltd., Red Rock, Ont. (*St. 1927, Jr. 1930.*)
References: W. B. Crombie, L. S. Dixon, A. T. Hurter, P. C. Kirkpatrick, H. E. Meadd, G. W. Rayner, P. Reynolds, R. G. Saunders.

PIDOUX—JOHN LESLIE, of 6891 Sherbrooke St. W., Montreal, Que., Born at Birmingham, England, June 17th, 1902; Educ., B.Sc., Univ. of Alta., 1934, M.Eng., McGill Univ., 1936; 1928-29 (summers), chainman, rodman and dftsman Calgary Power Co.; 1930 (May-Dec.), rodman on rld. location and constrn., Northern Alberta Rlys.; With Main Highways Br., Dept of Public Works, Alta. as follows: 1931, instr'man., on highway location and constrn., 1932, supervising gravel surfacing, 1934-35, instr'man. on highway location and constrn.; July 1936, to date, struct'l. designer, Dominion Bridge Co. Ltd., Lachine, Que. (*St. 1930, Jr. 1935.*)
References: D. B. Armstrong, J. W. S. Chappelle, R. S. Eadie, H. J. McLean, F. Newell, R. S. L. Wilson.

RACEY—HERBERT JOHN, of 256 Trenton Ave., Town of Mount Royal, Que., Born at Chicoutimi, Que., Mar. 29th, 1904; Educ., B.Sc. (Civil), Queen's Univ., 1928; 1925-26-27, rodman, Ottawa Montreal Power Co., field dftsman and instr'man., Shawinigan Engrg. Co.; 1928-30, field engr. on power development and transmission line surveys, Power Engrg. Co.; 1930-31, res. engr. on constrn. of Mattawin River Storage Dam, Shawinigan Engineering Co., and 1931-32, engrg. inspection work on Rapide Blanc development and res. engr. on constrn. of Poisson Blanc storage dam for same company; 1933-35, in mfg. and export business on own account; 1935-36, industrial engr., Crane Limited; at present, asst. mgr., Canadian Potteries Ltd. (subsidiary of Crane Limited). (*St. 1928, Jr. 1931.*)
References: C. S. Saunders, R. E. Heartz, C. R. Lindsey, B. S. McKenzie, W. P. Wilgar.

## FOR TRANSFER FROM THE CLASS OF STUDENT

ALLAIRE—LUCIEN, of 2182 Sherbrooke St. E., Montreal, Que., Born at Montreal, Feb. 16th, 1909; Educ., B.A.Sc., C.E., Ecole Polytechnique, Montreal, 1935; 8 mos., underground engr. for Tetreault mine; 4 mos., air conditioning for Michel Chouinard Ltd.; at present in charge of field party, surveying lakes, etc., for drainage section, Dept. of Agriculture, Prov. of Quebec. (*St. 1936.*)
References: A. Frigon, S. A. Cyr, G. J. Papineau, O. O. Lefebvre, T. J. Lafreniere, J. A. Lalonde.

BENOIT—JACQUES, of Outremont, Que., Born at Montreal, July 16th, 1909; Educ., B.A.Sc., C.E., Ecole Polytechnique, Montreal, 1933; 1929-30-31 (summers), rodman and instr'man., Dept. Rlys. and Canals; 1931 (summer) and 1933 (6 mos.), instr'man., A. Janin & Co., Montreal; 1934-36, sales engr., Wallace & Tiernan Ltd.; at present, district sales mgr. for same company. (*St. 1933.*)
References: J. A. Lalonde, E. Gohier, C. C. Lindsay, A. Cousineau, A. Frigon, C. E. Hogarth.

BUCHANAN—EDWARD TREVOR, of 17 Station Ave., Shawinigan Falls, Que., Born at Montreal, April 13th, 1906; Educ., McGill Univ., B.Sc. (Elec.), 1928; 1928-33, commercial engr., dealing with toll line and carrier current equipment, Northern Electric Co. Ltd., Montreal; 1934-35, statistical work re transportation in Canada, L. R. Thomson, M.E.I.C., Montreal; 1935 to date, asst. master mechanic, Consolidated Paper Corpn., Shawinigan Falls, Que. (*St. 1926.*)
References: H. E. Bates, L. R. Thomson, E. B. Wardle, E. Brown, C. V. Christie, R. DeL. French.

CAMPBELL—JAMES STOUFFER, of 288 Braeside Road, Toronto, Ont., Born at Toronto, May 3rd, 1909; Educ., B.Sc., 1931, M.Sc., 1933, Queen's Univ.; 1926-27, ap'tice die and toolmaker, D. A. McCowans, Toronto; 1929 (5 mos.), struct'l. dftsman., 1930 (5 mos), plate and tank dftsman., Dominion Bridge Co. Ltd., Lachine; 1931-33, instructor and demonstrator, mech. engrg., Queen's Univ.; 1931 and 1933 (summers), asst. foreman, and 1933-34, foreman, palmolive and dryer depts., Colgate Palmolive Peet Co. Ltd., Toronto; 1934-35, inspr., Industrial Accident Prevention Assn., inspecting mfg. plants throughout Ontario; 1935 to date, supervisor, pricing and routing depts., Massey-Harris Co. Ltd., Toronto. Responsible for labour costs and estimated cost for production of new machines, and for routing through factory of all parts. Setting of piece work prices and development of standard piece work schedules used for predetermination of piece work prices. Time study work, etc. (*St. 1928.*)
References: A. Peden, L. T. Rutledge, D. S. Ellis, A. Macphail.

EVANS—DELANO ERNEST, of 1466 Mansfield St., Montreal, Que., Born at Quebec, Que., Oct. 13th, 1908; Educ., B.Sc., 1930, M.Eng., 1933, McGill Univ.; 1928-29-30 (summers), dftsman. and designer, struct'l. steel and reinforced concrete bldgs., Dominion Reinforcing Steel Co., Montreal; 1930-31, instructor, McGill Univ.; 1931-32, designer, for Beauharnois Power Co., employed by F. B. Brown, M.E.I.C., also asst. field inspr.; 1934 to date, designer, industrial and mining machy., Dominion Engineering Works, Lachine, Que. (*St. 1930.*)
References: J. F. Plow, J. H. Maude, C. D. Evans, S. S. Colle, L. Jehu.

FRIZZLE—HAROLD ROBERT, of 389 King St. W., Brockville, Ont., Born at Lockeport, N.S., Mar. 16th, 1910; Educ., B.Sc. (E.E.), N.S. Tech. Coll., 1933; 1930 (4 mos.), installn. ap'tice, Maritime Telephone and Telegraph Co., and 1930-31 (11 mos.), mtce. man with same company; 1936 to date, with the Phillips Electric Works Ltd., studying mfg. methods, etc., and at present asst. foreman. (*St. 1935.*)
References: S. Ball, C. A. Anderson, G. H. Burchill, P. A. Lovett, A. D. Nickerson.

GORDON—HUGH JOHN, of Montreal, Que., Born at Winnipeg, Man. Feb. 10th, 1910; Educ., B.Eng., McGill Univ., 1933; 1929 (summer), rodman, Geol. Survey of Canada; 1929-30, dftsman., Fraser Companies Ltd.; 1934 to date, dftsman., C.P.R., Montreal, Que. (*St. 1933.*)
References: J. M. R. Fairbairn, J. E. Armstrong, R. B. Jones, R. Mudge, A. R. Ketterson.

HEENEY—CARDEN THOMAS, of Ottawa, Ont., Born at Ottawa, Sept. 16th, 1904; Educ., B.Sc., McGill Univ., 1926; 1926 (summer), instr'man., Quebec Development Co.; 1926-28, instr'man. i/c survey party, Gatineau Power Co.; With the Corporation of Ottawa as follows: 1928-30, asst. engr., engrg. de pt., 1930-32, asst. engr., water dept., asst. to the res. engr., layout and supervision, constrn. of Ottawa water purification plant; 1932-35, operation of plant, and 1935 to date, res. engr., i/c of the water purification plant and the Lemieux pumping station. (*St. 1927.*)
References: W. E. MacDonald, F. C. Askwith, G. F. Taylor, W. F. M. Bryce, R. E. Hayes.

JOLLEY—MALCOLM PORTER, Lieut., R.C.O.C., of Ottawa, Ont., Born at Foster, Que., Dec. 20th, 1909; Educ., B.Eng. (Mech.), McGill Univ., 1933. Ordnance Mech'l. Engr., Military College of Science, Woolwich, England, 1935; 1930-33 (summers), municipal engrg., Granby, Que.; 1935-36, survey of small arms production in England; 1936 to date, asst. to Director of Artillery and Mechanization, Department of National Defence, Ottawa, Ont. (*St. 1932.*)
References: N. O. Carr, N. C. Sherman, G. R. Turner, C. M. McKergow, A. R. Roberts.

LIND—WALTER JOHN, of 333 Reid St., Peterborough, Ont., Born at Hedley, B.C., Sept. 22nd, 1907; Educ., B.A.Sc., 1932, M.A.Sc., 1935, Univ. of B.C.; 1930-31 (summers), B.C. Photographical survey, and Cons. Mining and Smelting Co.; 1934-37, asst., dept. of mech and elec. engrg., Univ. of British Columbia; at present, student, test course, Can. Gen. Elec. Co. Ltd., Peterborough, Ont. (*St. 1930.*)
References: V. S. Foster, G. R. Langley, W. T. Fanjoy, B. Ottewell, H. R. Sills, L. DeW. Magie.

LUNN—FREDERICK RICHARD, of 458 Argyle Ave., Westmount, Que., Born at Montreal, Mar. 21st, 1905; Educ., B.Sc. (Mech.), McGill Univ., 1929; 1924-28 (summers), machinist's ap'tice, and dftsman.; 1929-33, asst. to manager of G. J. Lunn & Co., Montreal, i/c of design of power punch press and drop hammer tools, dies, jigs and fixtures, cost estimating and manufacturing methods; 1933 to date, manager, i/c of general supervision and management of all operations of the above mentioned company (*St. 1927.*)
References: C. M. McKergow, A. R. Roberts, E. C. Kirkpatrick, C. E. Herd, H. M. Lyster, J. H. Summerskill.

MACPHERSON—DONALD CECIL, of 160 Trenton Ave., Town of Mount Royal, Que., Born at Kingston, Ont., Apr. 1st, 1900; Educ., B.Sc., Queen's Univ., 1924; 1922 (5 mos.), instr'man., Erie barge canal; 1923, concrete inspr., Twp. Scarborough; 1924-29, field engr., Dominion Bridge Co. Ltd., Montreal; 1930, res. engr. for owners, Canadian Potteries, St. Johns, Que.; 1931-37, plant engr., Crane Limited and Warden King Limited; March 1937 to date, factory supt., Canadian Marconi Company, Montreal, Que. (*St. 1922.*)
References: D. S. Ellis, M. S. Macgillivray, W. L. Malcolm, D. C. Tennant, W. P. Murray, W. P. Wilgar.

MANNING—WALTER JOHN, of 3203 Maplewood Ave., Montreal, Que., Born at St. Johns, Que., Apr. 2nd, 1905; Educ., B.A.Sc., C.E., Ecole Polytechnique, Montreal, 1927; R.P.E. of Que.; 1927-29, traffic dept., Bell Telephone Co. of Canada; 1929-30, engr., Maison Arthur LeBlanc Inc.; 1930-32, constrn. engr., Hopital Notre Dame; 1932-34, constrn. engr., Catholic School Board; 1934-36, roads and bridges engr., Colonization Dept., Prov. of Quebec; at present, res. engr., Dept. of Public Works, Rimouski, Que. (*St. 1929.*)
References: A. Frigon, J. A. Lalonde, J. A. Duchastel, A. B. Normandin, P. L. Kuhring, A. Paradis, A. Gratton, R. deB. Corriveau, L. G. Trudeau.

MURRAY—WILLIAM MACGREGOR, of Cambridge, Mass., Born at Montreal. Apr. 24th, 1910; Educ., B.Eng., McGill Univ., 1932. S.M., 1933, Sc.D., 1936, Mass. Inst. Tech.; R.P.E. of Que.; Summer employment and ap'ticeship during vacations; 1935 to date, instructor in dept. of mech'l. engrg., Massachusetts Institute of Technology, at present i/c of courses in photo-elasticity. (*St. 1932.*)
References: C. M. McKergow, E. Brown, A. R. Roberts, R. Mudge, W. A. Murray.

McQUEEN—DUNCAN RODERICK, of 229 Woolwich St., Guelph, Ont., Born at Oulton Broad, Suffolk, England, Feb. 27th, 1907; Educ., B.A.Sc., Univ. of Toronto, 1932; 1927-28 and summers 1929-30, asst. to hydraulic engr., H. G. Acres & Co., Niagara Falls, Ont.; 1934 to date, with the Canadian Gypsum Co., Guelph, Ont. 6 mos. in office, 6 mos. as mill foreman, and two years to date as quarry foreman, i/c of power shovels removing overburden from limestone, drilling, blasting, breaking, sorting, transportation and hoisting of limestone in kilns; also drawing up plans for future plant operations and general development. (*St. 1930.*)
References: H. G. Acres, R. L. Hearn, C. R. Young, A. W. F. McQueen, R. E. Smythe.

ORR—WALTER ALYN, of Trenton, Ont., Born at Daysland, Alta., Sept. 5th, 1910; Educ., B.Sc. (E.E.), Univ. of Alta., 1932. Officers Signals Course, Cranwell, England, 1936-37; 1932 to date, with the Royal Canadian Air Force on general duties and as a Signals Officer since April 1934; at present, Adjutant, Wireless School, R.C.A.F. Trenton, Ont. (*St. 1932.*)
References: H. J. MacLeod, W. E. Cornish, R. S. L. Wilson, H. B. Godwin, S. W. Coleman.

PAQUET—JEAN M., of 62 Salaberry, Quebec, Que., Born at Quebec, Nov. 27th, 1909; Educ., B.A.Sc., C.E., Ecole Polytechnique, Montreal, 1934; 1930-33, asst. engr., Canadian Construction Ltd.; 1935-36, dist. engr., Prov. Board of Health; 1936 to date, engr., J. A. Y. Bouchard Ltee., heating, air conditioning, refrigeration. (*St. 1934.*) (*R.P.E. of Que.*).

WILKINS—RONALD EDWARD, Lieut., R.C.E., of Esquimalt, B.C., Born at Vancouver, B.C., Dec. 17th, 1913; Educ., Grad., R.M.C., 1935. B.Sc.(Civil), Queen's Univ., 1936; 1935 (summer), School of Military Engrg., Petewawa; 1935-36, attached to D.E.O., Mil. Dist. No. 3; 1936-37, Officer i/c works, Work Point Barracks, and Sept. 1937 to date, Officer i/c constrn., Albert Head Battery, West Coast Defences, Esquimalt, B.C. (*St. 1935.*)
References: W. P. Wilgar, L. F. Grant, H. H. Lawson, H. L. Sherwood.

WINTER—FRANCIS EDWARD, of Montreal, Que., Born at Montreal, Nov. 15th, 1904; Educ., B.Sc., McGill Univ., 1926; 1920-25, outside plant inspr., Bell Telephone Co. of Canada; 1926-28, test course, course in advanced engrg., design, General Electric Company; 1928-29, test course, meter dept., Shawinigan Water & Power Co. and Quebec Power Co.; 1929-33, sales engr. (asst. to vice-pres.), and in 1933 i/c of production, sales, etc. for one divn., Heinz Mfg. Co., Philadelphia, Pa. (*St. 1924.*)
References: J. F. Plow, H. Massue, G. R. Hale, A. S. Runciman, R. H. Mather, W. McG. Gardner.

## Longest Bridge in Europe

The longest bridge in Europe, the two-mile-long Storstrom bridge, Denmark, was opened by King Christian IV of Denmark on September 26th, 1937.

Steel to the amount of 30,000 tons has gone into the making of this $6,250,000 bridge which joins the Danish islands of Falster and Masnedo. Built by Messrs. Dorman, Long & Co. Ltd., of Middlesbrough, England, the bridge has taken four years to complete and carries a single line track of the Danish State Railways, a motor road, a footpath and a cycle-way.

*Courtesy Industrial Britain*

Storstrom Bridge, Denmark.

The safety and convenience of sea-going traffic under the bridge has been allowed for by the provision of three navigation spans, the largest of which has nearly 400 ft. clear width between piers and is over 85 ft. in height. An official estimate of the number of vessels passing through the Storstrom Channel is 15,000 per annum.

The 49 piers of the bridge are built of concrete, with granite facing and cut-waters to withstand the pack-ice, which in the shallows may reach a height of 22 ft. in the Baltic winter, exerting a tremendous pressure.

About 140,000 cu. yd. of concrete and granite were required for the piers and abutments of the bridge, and its deck contains about 12,000 cu. yd. of reinforced concrete.

---

*United Steel Corporation, Dodge Division*, in a new issue of the B-14 Dodge Catalogue, containing 512 pages, describe their line of conveying and elevating equipment, power transmission equipment and general engineering information. This volume is bound in leather and should be a valuable addition to the libraries of industrial engineers and technical men.

*R. and M. Bearings, Canada, Limited*, in a new catalogue, describe their ball and roller bearings, giving dimensions and price lists. Procedure of bearing selection, the effect of temperature, lubrication, suggested tolerances are described and illustrated. Also included are particulars regarding pillow, angle, vertical, universal and hanger blocks.

Copies of this catalogue may be obtained from the above company at 1006 Mountain Street, Montreal.

## THE ENGINEERING JOURNAL

**The considerable number of requests for additional copies of this issue of the Journal indicate its value as a permanent record.**

**A limited supply is still available at $0.50 to members and $1.00 per copy to non-members.**

## EMPLOYMENT SERVICE BUREAU

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.

*All correspondence should be addressed to*

**The Employment Service Bureau, The Engineering Institute of Canada**
**2050 Mansfield Street, Montreal**

## Situations Vacant

MECHANICAL ENGINEER, with three or four years industrial experience, used to doing design for machine parts, for paper mill in Ontario. Apply to Box No. 1687-V.

SALES ENGINEER, with experience in road construction, drainage and sewerage. State qualifications, experience, age and salary expected. Apply Box 1691-V.

TRANSFORMER DESIGNER. A British engineering firm invites applications for the post of transformer designer capable of taking charge of routine work in design office and control of staff. Location Britain. Apply in confidence, giving full particulars of age, experience and salary required to Box No. 1695-V.

ELECTRICAL ENGINEER, for inspection work, with experience in the operation of electrical machinery. Bilingual preferred. In reply state age, details of education and practical experience. Apply to Box No. 1696-V.

### Civil Service of Canada

List No. 710—Comp. 27136. A forest products engineer, grade 1, for the Dominion Forest Service Division, Lands, Parks and Forests Branch, Dept. of Mines and Resources, Ottawa. Salary $2,220 per annum. To carry out tests pertaining to chemicals suitable for use in the preservation of wood against decay, insects, marine borers and fire; to operate semi-commercial laboratory equipment for testing new preservatives and new methods of treatment, to investigate wood preservation and fire-retardant processes, to determine the toxicity of different chemicals to fungi and insects, and to prepare reports on the results of investigations. Application forms must be filed with the Secretary, Civil Service Commission, Ottawa, not later than December 23rd, 1937.

List No. 711—Comp. 27170. An engineer, mines, grade 3, Metallic Minerals Division Mines and Geology Branch, Dept. of Mines and Resources, Ottawa, to conduct test and research investigations in the dressing and treatment of metallic ores; to investigate the ore treating problems of the mining industry, and to prepare reports on the investigations conducted. Salary $2,820 per annum. Applications properly filled in must be filed with the Secretary, Civil Service Commission, Ottawa, Ont. not later than December 31st.

Application forms are obtainable at all post offices in the larger towns, the offices of the Employment Service of Canada, The Engineering Institute of Canada, Montreal, or from the Secretary of the Civil Service Commission, Ottawa, Ont.

## Situations Wanted

INDUSTRIAL ENGINEERING EXECUTIVE, with wide experience including fourteen years in design, construction, maintenance and operation of pulp and paper mills and power developments. Now employed, desires change of location. Apply to Box No. 320-W.

STEAM POWER PLANT DESIGNER, with wide experience on high pressure steam-electric plant. Available at once. Apply to Box No. 525-W.

CIVIL ENGINEER, B.A.Sc., age 44, structural, harbour, executive. At present designing 32,000-h.p. development in Newfoundland. Available in near future. Apply to Box No. 536-W.

DOMINION LAND SURVEYOR, and graduate engineer with extensive experience on legal, topographic and plane-table surveys and field and office use of aerophotographs, desires employment either in Canada or abroad. Available at once. Apply to Box No. 589-W.

STRUCTURAL DESIGNER AND ESTIMATOR, experienced in detailing, checking and designing structural steel. Graduate in civil engineering University of Toronto. At present in Montreal, but location immaterial. Apply to Box No. 613-W.

ELECTRICAL ENGINEER, B.SC., E.E., age 38. Married. Ten years electrical experience; including, one year operation, one year maintenance, and four years on construction of hydro-electric plants and sub-stations. Four years electric maintenance and construction in pulp and paper mill. Also experience on highway construction and Geological Survey Available at once. Apply to Box No. 636-W.

ELECTRICAL ENGINEER, B.SC. E.E. '28. Two years with large electrical manufacturing company including test course, about two years in supervisory operating office of a large electrical power utility, and considerable experience in electrical and mechanical draughting. Location in Ontario preferable. Apply to Box No. 660-W.

## Situations Wanted

YOUNG CIVIL ENGINEER, B.SC. (Univ. of N.B. '31), with experience as rodman and checker on railroad construction, is open for a position. Apply to Box No. 728-W.

CIVIL ENGINEER, B.SC., M.SC., R.P.E.; Sixteen years municipal, highway and construction, 5 years overseas. Married. Read, write and talk French. Will go anywhere. Apply to Box No. 737-W.

ELECTRICAL ENGINEER, B.SC. '31, JR.E.I.C. Single. One and a half years with contracting firm installing power and lighting equipment. Four years supervision over service and sales staff of electrical and radio company. Draughting and designing experience in power and compressed air layouts. Estimating and designing for electrical and mechanical layouts desired. Available on short notice. Apply to Box No. 740-W.

CIVIL ENGINEER, S.E.I.C., B.SC. in C.E. (Sask. '32). Single. Age 27. Three years experience includes—instrumentman, compiling reports and draughting with a National Park; in charge of construction of water supply and sanitary sewer systems; assistant on city surveys. Excellent draughtsman. Available at once. Location immaterial. References. Apply to Box No. 818-W.

MECHANICAL ENGINEER, JR.E.I.C., technical graduate, bilingual, age 35, married, experience includes five years with firm of consulting engineers, design of steam boiler plants, mechanical equipment of buildings, heating, ventilating, air conditioning, plumbing, writing specifications, etc. Five years with large company on sales and design of power plant, steam specialties and heating equipment. Available on short notice. Apply to Box No. 850-W.

STRUCTURAL ENGINEER, B.A.SC., A.M.E.I.C. Twenty-two years experience in design of bridges and all types of buildings in structural steel and reinforced concrete. Three years experience in railway construction and land surveying. Apply to Box No. 856-W.

ELECTRICAL ENGINEER, B.SC. (McGill '28), age 34. Experience includes transmission line and rural distribution construction and design. Some installation of motors and equipment, also house wiring. Available immediately. Apply to Box No. 940-W.

ENGINEER SUPERINTENDENT, age 44. Engineering and business training, executive ability, tactful, energetic. Had charge of several large projects. Intimate knowledge of costs and prices, reports and estimates. Available immediately. Any location. Apply to Box No. 1021-W.

ELECTRICAL ENGINEER AND GEOPHYSICIST. B.SC. (Man. '23), A.M.E.I.C. Married. Ten years specialized experience in the practical use of magnetic, electrical and mechanical instruments for the prospecting, surveying and mapping of mineral, oil and gas lands. Five years experience with telegraph, telephone and radio equipment. Capable of giving instruction in theory and practice in these lines and in college physics. Available on short notice. Apply to Box No. 1063-W.

CIVIL ENGINEER, A.M.E.I.C., with over twenty years experience in field and office on construction, maintenance, surveying, location, etc., desires position preferably of a permanent nature. At present near Montreal, but willing to locate anywhere. Apply to Box No. 1168-W.

ELECTRICAL ENGINEER, B.SC. '34 (Univ. of N.B.), S.E.I.C. Age 24, single. Desires any kind of electrical work. Will consider any location. Apply to Box No. 1262-W.

ELECTRICAL AND RADIO ENGINEER, S.E.I.C., B.SC. (Elec.) '32, M.SC. '34. Experience includes four years part time operator for radio broadcast station, repairs to radio receivers and test equipment, design and construction of amplifiers and inter-office communication systems. Available on short notice. Apply to Box No. 1283-W.

CIVIL ENGINEER, M.E.I.C., R.P.E., married, age 40. Twenty-two years experience in detail, design, estimating and cost accounting of buildings, bridges, tanks and all types of structures,; organization and management. Apply to Box No. 1367-W.

CIVIL ENGINEER, B.SC. 1910, A.M.E.I.C. Married. Twenty-six years experience on heavy construction work, both field and office; rails, roads, power house, hotels, bridges, etc. Location immaterial. Available at once. Apply to Box No. 1470-W.

## Situations Wanted

CONSTRUCTION SUPERINTENDENT, M.E.I.C. Ag 49. Married. Twenty-two years experience as engineer, superintendent and manager in charge of hydro-electric mechanical production, structural steel erection, als considerable experience in steam plants, combustion transmission lines, millwright work, complete min installations, rock work, rock crushers and conveyors Executive ability. Speaking French fluently. Location immaterial. Apply to Box No. 1482-W.

ELECTRICAL ENGINEER, B.Eng. (McGill '33). One and a half years experience in plant and production routine, and with considerable training in sales work. Bilingual, single, and available at once for any location. Apply to Box No. 1509-W.

ELECTRICAL ENGINEER, B.SC. '31 (Univ. of Alta.), JR.E.I.C. Age 28. Married. One year students' test course with C.G.E.Co. including testing and operation of transformers, meters, industrial control and switchgear apparatus. Two years as instrumentman on highway construction. Desires electrical utility, commercial lighting or air conditioning work, location immaterial and available at once. Apply to Box No. 1522-W.

CIVIL ENGINEER, B.SC. '32, S.E.I.C., P.E.N.B., DY.L.S.N.B., age 32. Experience in mining, both coal and metals, private and legal surveys, railroad construction, geology and building construction. At present in private practice in coal mining district. Desirous of changing location for position either in mining field or construction in Canada. or abroad. Apply to Box No. 1562-W.

RESIDENT ENGINEER, familiar with all types of surveys and construction work including, railway, roads, irrigation, drainage, buildings and air ports. Executive ability. Had charge of several large projects. Intimate knowledge of reports and estimates. Available immediately. Any location. Apply to Box No. 1567-W.

CIVIL ENGINEER, B.SC. '17, O.P.E. Married. Executive and administrative experience. Extensive office and field experience in harbour works, dredging; both steam and electric railways in location, construction and maintenance; telephone works in design, construction and maintenance of pole lines, wire, cable and conduit; highways in location, construction and paving; municipal works in roads, sidewalks, sewers and water mains. Intimate knowledge of estimating, unit costs, cost accounting and analysis. Some knowledge of air conditioning. Willing to locate anywhere. Available at once. Apply to Box No. 1587-W.

ELECTRICAL ENGINEER, B.SC. '27 (McGill), A.M.E.I.C. Age 36. Married. Bilingual. Three years experience in telephone work (installation of manual and automatic exchanges). One year electrical prospecting. Nine years experience with electrical power company. Apply to Box No. 1601-W.

CHEMICAL ENGINEER, graduate McGill '36. Eight months experience in commercial laboratory of large industrial plant. Knowledge of coal chemistry and boiler water treatment. Also some experience in pulp and paper control work. Location immaterial. Apply to Box No. 1617-W.

CIVIL ENGINEER, B.SC. in C.E., A.M.E.I.C. Age 32. Married. Three years of pulp and paper mill experience, draughting, instrumentman and maintenance. One year as instrumentman on highway construction. Five years checking and designing reinforced concrete and steel. Apply to Box No. 1658-W.

METALLURGICAL ENGINEER, graduate 1936. Experienced in gold smeltering and milling, also in steel and pig iron manufacturing. Desires new connection in eastern Canada or Great Britain. Apply to Box No. 1673-W.

ELECTRICAL ENGINEER, B.A.SC., U. of T. '24, A.M.E.I.C., single, age 44. Ten years in supervisory operating office and two years in construction division (office and field) of large city electrical utility commission. One year factory supervision and tool design in manufacture of small electrical equipment. Wide experience with internal combustion engines. Experience handling heavy machinery. Private pilot's license for light aircraft. Full details on request. Available on short notice. Apply to Box No. 1693-V.

MECHANICAL AND ELECTRICAL ENGINEER, age 47, graduate University of Toronto, 1911. Machinist's trade. Two years tool design and quantity production in the U.S.A. Twelve years Canadian shop experience design and producing heavy equipment. Twelve years as chief sales engineer and field man for one of the largest Canadian national concerns. Experience in manufacturing and sales of pumps, engines, paper mill equipment, power plant equipment and specialties, electrical machinery etc. Clean record, excellent connection. Apply to Box No. 1699-V.

ELECTRICAL ENGINEER, B.SC., E.E. (Univ. of Man. '37). Experience in highway construction as inspector. Available at once. Apply to Box No. 1703-W.

ELECTRICAL ENGINEER, B.SC., A.M.E.I.C., age 44, married. Experience includes draughting, construction and maintenance. The last eight years holding the position of electrical superintendent, of a fair sized industrial plant. Apply to Box No. 1718-W.
