# THE ENGINEERING JOURNAL

## INDEX TO VOLUME XXV JANUARY TO DECEMBER, 1942

	Page		Page
Abstracts of Current Literature. . . . .	32, 99, 168, 243, 307, 376, 428, 471, 517, 574, 627, 694	Cabinet Committee on Reconstruction. . . . .	105, 317, 378, 465, 632
Accident Prevention Methods and Results, Wills Maclachlan. . . . .	9	Can Professional Education be Liberalized? Dean C. R. Young . . . . .	554
Discussion . . . . .	459	Canadian Engineers in England . . . . .	639
Air Bombing and Structural Defence, Engineering Aspects of, D. C. Tennant. . . . .	674	Canadian Industry in the War, C. D. Howe . . . . .	147
Air-Locks, The Use of, G. O. Boulton. . . . .	563	Canadian Institute of Steel Construction . . . . .	264
Air Raid Precautions as Related to Building Design, S. D. Lash. . . . .	28	Carrière, Capt. J. P., Construction of a By-pass Highway in England by Royal Canadian Engineers . . . . .	15
Aircraft, Tactics and Unorthodox, Major Oliver Stewart. . . . .	13	Carruthers, A. L., Brothers of the Bridge. . . . .	625
Alaska Highway, J. M. Wardle. . . . .	136	Causes and Effects of Damage to Electrical Machinery and Switching, C. A. Laverty. . . . .	604
Algoma Steel Corporation, Ltd., Moving a Coal Bridge at the, D. C. Tennant. . . . .	615	Charcoal Has War-Time Use . . . . .	235
Allcut, E. A., Producer Gas For Motor Transport. . . . .	223	Civil Defence, Institute Committee on Engineering Features of . . . . .	379, 478, 578, 633, 700
Allcut, E. A., The Significance of Industrial Relations . . . . .	557	Civilian Defence, Some of the Engineering Implications of, Walter D. Binger . . . . .	238
Alternative Babbitts, I. I. Sylvester . . . . .	502	Civilization, We Are In It Together In The Defence of, H. J. Cody . . . . .	686
Alternative Bronzes, G. E. Tait . . . . .	504	Clarke, K. H. J., The Metal Situation . . . . .	498
American Engineering Societies, Publications . . . . .	316	Coal Bridge at Algoma Steel Corporation, Moving a, D. C. Tennant. . . . .	615
American Society of Civil Engineers, Niagara Falls Meeting. . . . .	523, 635	Cody, H. J., We Are In It Together In The Defence of Civilization. . . . .	686
American Institute of Electrical Engineers . . . . .	199	Committee on Engineering Features on Civil Defence. . . . .	379, 478, 578, 633
Annual General and Professional Meeting, Fifty-sixth. . . . .	154	Committee on Industrial Relations . . . . .	379, 479, 578
Programme. . . . .	36	Committee on Post-War Problems . . . . .	378, 478, 632
Papers. . . . .	37	Committee on Reconstruction, Dominion Government. . . . .	105, 378
Report of Meeting . . . . .	154	Committee on the Training and Welfare of the Young Engineer. . . . .	174, 583, 638
Said at the Banquet. . . . .	166	Conservation, Public Health and, A. E. Berry . . . . .	667
Annual General and Professional Meeting, Fifty-seventh. . . . .	523, 623, 699	Conservation of Natural Resources With Some Reference to Post-War Planning . . . . .	663
Annual Reunion, University of Toronto Alumni . . . . .	718	Construction Features on the Extension of the Santurce Steam Plant, Puerto Rico, J. T. Farmer and E. A. Goodwin. . . . .	454
Association of Professional Engineers of Ontario. . . . .	119, 199, 264	Construction Industry, Regulations Affecting the. . . . .	571
Association of Professional Engineers of Saskatchewan. . . . .	719	Construction of a By-Pass Highway in England by Royal Canadian Engineers, Capt. J. P. Carrière. . . . .	15
As the Year Ends, Deau C. R. Young . . . . .	661	Contractor's Claim For Extras, A. . . . .	515
Babbitts, Alternative, I. I. Sylvester . . . . .	502	Discussion . . . . .	639
Banks, S. R., The Lions' Gate Bridge, Part 1. . . . .	210	Control of Man-Power in Canada . . . . .	624
Part 2. . . . .	282	Control of Technical Man-Power. . . . .	241
Part 3. . . . .	347	Controller of Construction, Order No. 12, Regulations Affecting the Construction Industry . . . . .	571
Part 4. . . . .	414	Coote, J. A., The Significance of Industrial Relations. . . . .	557
Barrett Chute Development, A. I. Malcolm. . . . .	402	Correspondence. . . . .	175, 317, 434, 481, 525, 583, 639
Berry, A. E., Public Health and Conservation . . . . .	667	Council For The Year 1941, Report of . . . . .	80
Binger, Walter D., Some of the Engineering Implications of Civilian Defence. . . . .	238	Couper, Dr. W. J., Wages Stabilization . . . . .	406
Birch, L. W., Trolley Coach Overhead Materials and Design. . . . .	231	Coventry, A. F., The Water Situation in Southern Ontario. . . . .	664
Book Reviews. . . . .	199, 316	Damage of Plant Through Enemy Action, Proneness to, Hal Gutteridge. . . . .	559
Boulton, G. O., The Use of Air-Locks. . . . .	563	Davidson, A. E., Mechanical Features of 220-kv. Lines in Ontario, 1940 and 1941. . . . .	496
Branches, Membership and Financial Statements of. . . . .	94	Development of Ground Water Supply, J. W. Simard. . . . .	669
<i>Branches, News of—</i>		Diesel Engines, Supercharging of Two-Stroke, F. Oederlin. . . . .	618
Border Cities . . . . .	48, 257, 325, 440, 646	<i>Discussions—</i>	
Calgary . . . . .	258, 390, 647, 713	The Manufacture of the 25-pounder in Canada, W. F. Drysdale. . . . .	298
Edmonton . . . . .	49, 191, 259, 531, 713	The Justification and Control of the Limit Design Method, F. P. Shearwood . . . . .	303
Halifax . . . . .	49, 114, 191, 259, 391, 532, 647, 713	Rational Column Analysis, J. A. Van den Broek . . . . .	360
Hamilton. . . . .	49, 259, 326, 441, 592, 647, 714	Accident Prevention Methods and Results, Wills Maclachlan . . . . .	459
Kingston. . . . .	441	Doherty, Robert E., Professional Development and Responsibility. . . . .	469
Lakehead. . . . .	50, 191, 327, 486, 714	Drainage Areas of Ontario, Forests and, F. A. MacDougall. . . . .	663
London . . . . .	50, 114, 192, 328, 442, 592	Drysdale, W. F., The Manufacture of the 25-pounder in Canada. . . . .	5
Moncton. . . . .	50, 260, 329, 486, 532	Discussion. . . . .	298
Montreal . . . . .	51, 114, 192, 260, 329, 391, 648, 714	Effect of Wet Coal on Pulverizer and Boiler Performance, Murray D. Stewart. . . . .	609
Niagara Peninsula . . . . .	51, 194, 262, 330, 391, 442	Elections and Transfers. . . . .	43, 109, 179, 253, 320, 386, 437, 528, 586, 642, 707
Ottawa. . . . .	51, 115, 194, 262, 330, 392, 593, 649, 715	Electrical Machinery and Switching, Causes and Effects of Damage to, C. A. Laverty. . . . .	604
Peterborough . . . . .	52, 195, 392, 443	Engineer Looks at Music, An, S. T. Fisher. . . . .	548
Quebec . . . . .	117		
Saguenay . . . . .	55, 115, 195, 393, 443, 486, 534, 716		
Saint John. . . . .	54, 443, 535		
St. Maurice Valley. . . . .	54, 119, 330, 393, 536, 649, 716		
Saskatchewan. . . . .	55, 117, 196, 263, 393, 649, 716		
Sault Ste. Marie. . . . .	55, 263, 330, 394, 717		
Toronto. . . . .	56, 196, 331, 717		
Vancouver. . . . .	196, 394, 443, 593, 649, 717		
Victoria. . . . .	119		
Winnipeg. . . . .	56		
British Aeroplane, The Quality Underlying the, Lt.-Col. W. Lockwood Marsh. . . . .	71		
Bronzes, Alternative, G. E. Tait. . . . .	504		
Brothers of the Bridge, A. L. Carruthers. . . . .	625		
Brown, Dean Ernest, receives honorary degree. . . . .	39		
Building Design, Air Raid Precautions as Related to, S. D. Lash. . . . .	28		
Building Fund, Branch Contributions to. . . . .	39		
By-pass Highway in England, Construction of, by Royal Canadian Engineers, Capt. J. P. Carrière . . . . .	15		

Engineer, The Place of the, Dean C. R. Young . . . . .	684	Malcolm, A. L., Barrett Chute Development . . . . .	624
Engineering as a Career . . . . .	248	Man-Power Control in Canada . . . . .	
Engineering Aspects of Air Bombing in Structural Defence, D. C. Tennant . . . . .	674	Management-Employee Problem for Engineers, The, J. W. Parker . . . . .	236
Engineering Features of Civil Defence, Committee on . . . 379, 478, 578, 633, 700		Manufacture of the 25-pounder in Canada, W. F. Drysdale . . Discussion . . . . .	5 298
Engineering in Canada, The Profession of . . . . .	174	Marsh, Lt.-Col. W. Lockwood, The Quality Underlying The British Aeroplane . . . . .	71
Engineers' Council for Professional Development—		Maude, John H., The New Oil-Hydraulic Press in Munition Manufacture . . . . .	66
Annual Report for 1941 . . . . .	29	Mechanical Features of 220-kv. Lines in Ontario, 1940 and 1941, A. E. Davison . . . . .	496
Guidance Booklet . . . . .	248	Meetings of Council . . . . . 41, 107, 175, 251, 318, 380, 482, 525, 585, 640,	705
Tenth Annual Meeting . . . . .	638, 689	Membership of Branches . . . . .	94
Vocational Guidance Manual . . . . .	583	Message from the President, Dean C. R. Young . . . . .	127
Essential Work Regulations, 1942 . . . . .	241	Message to Canadian Engineers, Lieut.-General A. G. L. McNaughton . . . . .	145
Farmer, J. T., Construction Features on the Extension of the Santurce Steam Plant, Puerto Rico . . . . .	454	Metal Situation, K. H. J. Clarke . . . . .	498
Farmer, J. T., The Modernization of a Puerto Rico Steam Plant . . . . .	342	Modernization of a Puerto Rico Steam Plant, The, J. T. Farmer and E. A. Goodwin . . . . .	342
Fees of Members Overseas . . . . .	433	Moving a Coal Bridge at the Algoma Steel Corporation, Ltd., D. C. Tennant . . . . .	615
<i>Financial Statements—</i>		Munition Industries, Subcontracting in Canada's, F. L. Jeckell . . . . .	279
Of the Institute . . . . .	84	Munitions Manufacture, The New Oil-Hydraulic Press in, John H. Maude . . . . .	66
Of the Branches . . . . .	94	Music, An Engineer Looks at, S. T. Fisher . . . . .	548
Fisher, S. T., An Engineer Looks at Music . . . . .	548	Myers, Charles Samuel, Psychology as Applied to Engineering . . . . .	508
Foreign Correspondents . . . . .	104	National Research Council of Canada, War Activities of, Dean C. J. Mackenzie . . . . .	141
Forests and Drainage Areas of Ontario, F. A. MacDougall . . . . .	663	National Selective Service . . . . .	248, 624
Frampton, A. H., The 220,000-volt System of the Hydro-Electric Power Commission of Ontario . . . . .	21	National Service—A Challenge to the Engineer, E. M. Little . . . . .	151
Fullerton, J. S., Substitute Solders . . . . .	499	Natural Resources With Some Reference to Post-War Planning, The Conservation of . . . . .	663
Gaherty, G. A., Wartime National Efficiency . . . . .	621	New Brunswick Agreement . . . . .	38
Generators in the U.S.A., Water-Wheel Driven, C. M. Laffoon . . . . .	457	New Field and a New Emphasis, A, Dean C. R. Young . . . . .	127
Goodwin, E. A., Construction Features on the Extension of the Santurce Steam Plant, Puerto Rico . . . . .	454	New Oil-Hydraulic Press in Munitions Manufacture, The, John H. Maude . . . . .	66
Goodwin, E. A., The Modernization of a Puerto Rico Steam Plant . . . . .	342	Newly Elected Officers of The Institute, Biographies . . . . .	180
Ground Water Supply, Development of, J. W. Simard . . . . .	669	News of Other Societies . . . . . 47, 119, 199, 264,	718
Gutteridge, Hal, Proneness to Damage of Plant Through Enemy Action . . . . .	559	Niagara Falls Joint Meeting . . . . .	523, 635
Howe, C. D., Canadian Industry in the War . . . . .	147	<i>Obituaries—</i>	
Hydro-Electric Power Commission of Ontario, the 220,000-volt System, A. H. Frampton and E. M. Wood . . . . .	21	Andrewes, Lieut.-Colonel William Edward . . . . .	440
Industrial Relations, Institute Committee on . . . 379, 479, 578, 700		Armstrong, Thomas Stiryaker . . . . .	389
Industrial Relations, The Significance of, E. A. Allcut and J. A. Coote . . . . .	557	Baltzell, Willie Harry . . . . .	591
<i>Institute Prizes—</i>		Blanchard, Joseph Elie . . . . .	47
Prize Awards, 1942 . . . . .	435	Bang, Claus Marius . . . . .	711
For Juniors and Students . . . . .	578	Boyd, William Gamble . . . . .	257
Rules Governing Award of . . . . .	587	Byers, Archibald Fullarton . . . . .	189
Institute Prize Winners, Biographies . . . . .	185	Cregeen, Kenneth Thomas . . . . .	190
Jacobsen, E. R., Letter from Washington . . . 433, 480, 524, 582, 637		Dennis, Earle Munro . . . . .	711
James Committee . . . . .	105, 317, 378, 465, 632	Duckworth, Walter Ritchie . . . . .	113
James Watt International Medal . . . . .	432	Duncan, G. Rupert . . . . .	389
Jane, Dr. R. S., Synthetic Rubber . . . . .	274	Evans, John Maurice . . . . .	530
Jeckell, F. L., Subcontracting in Canada's Munition Industries . . . . .	279	Fuller, Royden John . . . . .	190
Johnson, Howard, Shipyard Production Methods . . . . .	73	Hawley, George Prince . . . . .	47
King vs. Paradis and Farley, Inc., A Contractor's Claim for Extras . . . . .	515	Jackson, Donald Alphonse . . . . .	711
Discussion, E. P. Muntz . . . . .	639	Johnson, Edward Preston . . . . .	257
Letters to Editor . . . . .	703	Johnson, Harold Stanley . . . . .	645
Laffoon, C. M., Water-Wheel Driven Generators in the U.S.A. Landmark Disappears . . . . .	457 249	Johnston, William Morrison . . . . .	113
Lash, S. D., Air Raid Precautions as Related to Building Design . . . . .	28	Kester, Fred Henry . . . . .	530
Laverty, C. A., Causes and Effects of Damage to Electrical Machinery and Switching . . . . .	604	Kirkpatrick, Alexander M. . . . .	531
Legget, R. F., Conservation of Natural Resources with some Reference to Post-War Planning . . . . .	663	MacDiarmid, Archibald Alexander . . . . .	113
Legget's Memorandum . . . . .	379	Macphail, William Matheson . . . . .	711
Library Notes . . . . . 58, 120, 199, 265, 332, 395, 444, 487, 537, 594, 650, 720		Mahon, Harry Wendell . . . . .	485
Lions' Gate Bridge, The, Part 1, S. R. Banks . . . . .	210	McCurdy, Lyall Radcliffe . . . . .	646
Part 2 . . . . .	282	McDowall, Robert . . . . .	325
Part 3 . . . . .	347	Mews, John Courtenay . . . . .	190
Part 4 . . . . .	414	Millidge, Edwin Reginald . . . . .	531
Little, E. M., National Service—A Challenge to the Engineer . . . . .	151	Morrisey, Lieut.-Colonel Henry Fairweather . . . . .	485

## NEW YEAR MESSAGE

CONVENTIONAL messages of cordial greetings and good wishes for the coming year seem out of harmony with the realities of January 1st, 1942. We, as members of The Engineering Institute of Canada, are not ashamed of the part engineers have played to date in the war; it is not, however, with complacency that we face the third year of the war, but with a grim determination to increase not only our efforts but our effectiveness as engineers, as Canadians, as members of an awakened alliance of free peoples joined in deadly and perilous conflict with the most treacherous, unscrupulous and evil forces the world has ever known.

The dark hours through which we are bound to pass in 1942 will call for high courage; not only courage in combat but the courage which is needed to sustain judgement and a sense of proportion as the battle surges back and forth, presenting alternately disheartening defeats and encouraging victories, the courage which enables us to moderate emotional optimism and temper reverses, the courage which enables us to look squarely at our weaknesses and to recognize the strength and resources of our enemies.

It is not courage but folly to dismiss the possibility that before the year is out actual fighting may come to our shores. It is not courage but rather lack of it that makes for unpreparedness. It is nothing but nonsense at this time to think in terms of “national defence” instead of “total war.”

We as engineers have also, I suggest, a particular responsibility in this struggle of machines, power and technical devices. Not only must we as a body design, manufacture and operate innumerable engines of war but we must see to it that the industrial and technical resources of the country, both human and material, are utilized in the most effective way. We must avoid uninformed criticism of delays in “getting into production” for we know how inexorable is the time factor when new designs have to be prepared, new factories built and tooled for new processes, but on the other hand we must demand that there shall be no self satisfaction and that every week and every month efficiency and production must be greater and still greater. We are now entering that phase of the conflict when we must insist that nothing short of the most intelligent and effective utilization of our total human resources can be accepted.

We may take some satisfaction in the fact that for 1942 the lines of battle are clearly drawn. With the entry of the United States the world is now sharply divided into two camps, the time for talk is over, the issues are clear and a fight to the finish is on. To quote the stirring words of Churchill “Conquer we must, conquer we shall” for “without victory there is no survival.”

*President*

# THE MANUFACTURE OF THE 25-POUNDER IN CANADA

W. F. DRYSDALE, M.E.I.C.

Director-General of Industrial Planning, Department of Munitions and Supply, Ottawa, Ont.

Paper to be presented before the General Professional Meeting of The Engineering Institute of Canada, at Montreal, Que., on February 5th, 1942.

Among the projects with which the author has had to do during his services in Ottawa, one of the most interesting from a general and engineering point of view has been the production of the 25-pounder gun.

This weapon is now being manufactured by Sorel Industries at Sorel, Quebec, and the contents of this paper are based on close association with the work at Sorel for the past eighteen months.

Among the major difficulties encountered in building up this industry were the problems of personnel, housing, and the working out of plans to harmonize workers of many different trades from many different localities. The plant is located in a farming area bordering on an inland port, where few men were skilled in the arts which were called for.

The new 25-pdr. has replaced both the old 18-pdr. and the 4.5" howitzer. It was designed for use both as a field gun and a howitzer, and as its name implies, fires a shell weighing 25 lb.

Here it may not be out of place to mention that the 25-pdr. is a gun with separate ammunition; that is to say, the shell is loaded first, followed by the insertion of a brass cartridge case containing the propelling charge. The object of this separate loading is to permit the use of different charges, depending on whether the gun is being used as a field gun or a howitzer; a field gun has a comparatively low elevation and long range, whilst a howitzer generally has a high angle of elevation with a relatively short range, giving the projectile a high angle of descent.

The following brief description will give a general idea of the 25-pdr. gun and its accessories. Beginning at the ground level, the equipment comprises a firing platform, the axle unit and brake gear, the trail and carriage assembly, elevating, traversing and firing gear, the cradle and recuperator, the gun body and breech mechanism (See Fig. 1).

The *firing platform* is a circular fabricated ring, which, when the gun is in position, rests on the ground. The

Fig. 1—Minister of National Defence inspecting 25-pounder field gun at Sorel, Que.

carriage, which is fitted with rubber-tired wheels, has a trail which straddles the platform. On lifting the trail, it is easy to rotate the whole structure and meet the enemy from any direction, or prepare the gun for travelling (See Figs. 2 and 3).

The *carriage* is provided with two rubber-tired wheels, connected by an axle to which in turn is fitted a fabricated box-type *trail*, roughly 8 ft. long. To the end of the trail is fitted a spade which, when embedded in the ground, counteracts the shock of recoil on firing (See Fig. 4).

The *axle* passes through the lower part of a "U" fabri-

cated *top carriage*; on the top of each vertical side of the "U" is a bearing for the trunnion, or axis about which the gun moves in a vertical plane.

The *top carriage* carries a long, rectangular box, also fabricated, to the outside of which is riveted a trunnion band carrying a trunnion on each side.

Inside this long, rectangular box is fitted one of the most intricate parts of the equipment, viz.:—the recuperator.

The *recuperator* is the mechanism which absorbs the energy of the recoil when the gun is fired. Later in this paper this most important component will be further explained.

The top of the recuperator is machined to receive the

Fig. 2—Unlimbering 25-pounder gun ready for firing.

gun body which, when fitted into place, forms an integral part of it.

The *gun body* consists of a jacket, separate barrel, breech ring, breech block and breech mechanism.

From the above brief outline of the main parts of the 25-pdr. equipment, it will be realized that there are innumerable other components not specifically mentioned. Actually over 700 components are assembled to make up a single complete equipment, to which must be added other items, officially known as separately demandable stores, plus ancillary parts, which may include anything from a leather strap to a hand spike or set of drag ropes, or from a bucket to an oil-can.

It may be interesting to note the ways in which the 25-pdr. differs in design from previous field guns.

In the 18-pdr. gun of the last war the gun itself was built up; its inner tube was wound with high tension steel wire to give the necessary resistance to withstand the pressure of the discharge. On this inner, wire-wrapped tube was shrunk a cylindrical steel jacket.

This meant that as soon as the rifling was worn, the gun had to be taken out of service and replaced by a new one whilst the old one was being returned to the factory for repair.

This is where the new 25-pdr. gun has a great advantage, because it is made up of an inner tube or barrel and a separate outside jacket covering roughly half the length of the barrel.

To provide for easy replacement the barrel is fitted into the jacket with a small clearance on the diameter, roughly eight thousandths of an inch, while its breech end fits into a seat having a very slight taper. Thanks to this arrangement it is possible to unscrew the breech ring, withdraw the barrel and insert a new barrel secured by the same breech ring in about fifteen minutes. (See Fig. 5).

Coming now to the recuperator, formerly most field guns had mechanical recuperators whose springs took the recoil and returned the barrel to the firing position. During the last war the French and later the British, introduced the

Fig. 3—25-pounder gun travelling.

hydraulic type of recuperator along the lines of which the 25-pdr. recuperator has been developed.

The recuperator consists of a long steel block, the surfaces of which have been machined to very fine limits. Three or four holes which control the recoil and recuperator mechanism are bored through the entire length of the block, each with mirror-like finish.

Later it may be possible to give a few more details, but for the time being just imagine a block of steel roughly 10 by 5 in. cross section and 5 ft. long, bored and honed through its entire length to approximately  $2\frac{1}{2}$  in. diameter, each hole necessarily accurate in alignment to a thousandth of an inch.

The factory at Sorel which now covers more than 14 acres, is a joint venture between the Canadian Government and Messrs. Simard, who represent and own Marine Industries Limited at Sorel. It is not necessary to recite the details leading up to the formation of this company, nor all the vicissitudes we passed through before reaching the present state, but it may be said that at the present time the plant is producing 25-pdr. equipments at the rate of fifty per month. Incidentally, four-inch naval guns are also being manufactured and will shortly come into full production.

It is noteworthy that Sorel is the only factory on the North American continent manufacturing guns from the scrap metal stage to the finished article.

The buildings, of up-to-date design, consist of a laboratory, power house, steel-making plant, machine shop and fabricating shop.

The steel-making plant, with rolling-mill equipment, a forge shop with presses and hammers ranging from 2,000 tons downward, served by up-to-date heating furnaces, roughing out machinery, heat treating and annealing equipment and complete die-making shop, are housed in one building of three bays covering approximately 250,000 sq. ft.

Alongside this shop is a separate large machining and assembly shop and again adjacent is a steel plate fabricating establishment. It is proposed to span one of the gaps between two of the shops to accommodate increased production.

All necessary services, including oil, electricity, steam and compressed air, are supplied to the various units of the plant by a tunnel system over 2,200 ft. long.

Special attention has been given to that most important organization in any modern engineering production shop, the processing and planning department. Thanks to our good friends, the automobile manufacturers, a planning system has been set up along the lines used in their industry, i.e., the machine tools needed for each individual part to be machined have all been selected and placed together. For instance, in the machining of the recuperator block we have the following operations: planing, milling, slotting, boring, honing, rifling, threading and drilling. All the appropriate machines for the above operations have been gathered together and laid down in the sequence of the different operations.

This procedure has been carried out all through the shop for each component part.

One section of the planning department is responsible for the machining operations and design of jigs, fixtures and gauges, and keeps a constant record of the loading of each machine tool so that the work is continually fed through the shop in a balanced order.

Operation sheets for each individual part have been got out listing the surplus material to be removed, the tolerances to be observed, the appropriate tool or cutter to be used, the speed and feed at which the machine should be run and the jig, fixture or gauge to be used. Thus every process is systematised and all the foreman has to do is to supervise the work and assist his men in getting the best results.

Another section of the planning department is responsible for ordering, either in the shops or from outside sources, the appropriate material and an efficient follow-up organization sees to it that the required material is to hand at the right time.

All this presents a very different picture from the old days when a mechanic having finished his job, walked down the shop to pick up the next of his own choosing.

The steel foundry and rolling-mill shop is a long building, approximately 570 by 440 ft., which contains the three electric furnaces of 4, 8 and 20-tons capacity, respectively.

From these furnaces, fed with scrap and the necessary raw materials, are produced monthly some 3,000 tons of ingots for gun barrels, jackets, breech rings, recuperator blocks and their components. All these parts are of the highest grade steel; for example the gun barrel is manufactured from steel having a yield point in the neighbourhood of 40 to 45 tons per sq. in. A large proportion of this steel is made up of nickel-chrome-molybdenum alloy, but many other grades are being produced. The successful production of these steels requires close adherence to the specifications.

The laboratory being close at hand, tests are taken during the melting process and analysed, and the furnace charge adjusted according to requirements. In the log of each heat, careful records are kept of temperatures when starting and pouring, power consumption, weight of ingot and scrap, and other particulars, so that, should a defect be detected at a later stage, it can easily be traced.

In pouring the ingots from the steel every precaution is taken to prevent segregation. A pouring basin is used to reduce the pressure in the mould to keep inclusions out of the steel and to carefully control the rate of rise in the mould. In pouring, the temperature is controlled by an optical pyrometer and checked by a chill test.

From the ingots a large number of crop ends have to be cut. These ends are reduced to suitable sizes for rolling and thus the rolling mill turns what otherwise might be waste into steel bar of the highest quality.

The benefit of this rolling-mill installation has been such that a second rolling mill is at present being installed.

Fig. 4—Assembling 25-pounder gun, showing arrangement of firing platform, trail, spade, etc.

In the forge shop the ingots are pre-heated in oil-fired furnaces and then forged under the 2,000-ton hydraulic forging press.

In the case of a 25-pdr. the rough gun barrel forging is approximately 12 ft. long and from 8 to 9 inches in diameter.

The barrel is finish-forged on a 6-ton steam hammer, after which it is left to cool gradually in what is known as the soaking pit—really a very large bin of ashes. Throughout these processes great care has to be exercised and pyrometer control installed to govern the temperatures.

In order to produce the various gun components and drop forgings there are, in all, 18 other steam and pneumatic hammers ranging in size from 6 tons to 400 lb. with as many oil-fired heating furnaces.

The next bay of the shop houses the rough machining equipment and the equipment for heating and annealing and die making.

The rough-machining equipment comprises 14 roughing out machines including heavy rough-turning lathes, rough-boring machines, planing machines, milling machines and cut-off saws.

The heating and annealing equipment comprises three oil-fired furnaces, two small electric furnaces and ten vertical electric furnaces, all of the most modern design and fully equipped with the latest automatic control apparatus.

Here the barrel is first rough-turned and bored before being heat treated. The furnaces employed for the final heat treatment of the gun are of the vertical electric type, 4½ ft. in diameter and 27½ ft. deep. These vertical furnaces are equipped for accurate temperature control in five zones, making it possible to realize exact positions in heat treatment of the barrels.

After normalizing, the barrels are straightened if necessary on a horizontal hydraulic press.

Sufficient length of material is left on each end of the forging for the usual tensile, bending, and izod tests. Cylindrical slabs are sawn off from each end of the barrel and submitted for approval to the government inspectors.

Once the barrel tests have been certified and approved the barrel is ready for finish-machining.

Finish-machining includes two sets of operations; those preceding auto-frettage and those following auto-frettage.

Auto-frettage consists of expanding the tube radially by applying hydraulic pressure to the bore. The pressure used is sufficient to exceed the elastic limit of the metal in the bore. This causes the inner layers of metal in the bore to yield plastically and take a permanent set, whereas the metal near the outer surface of the tube has not been stretched beyond its elastic limit, and therefore attempts to return to its original dimensions.

The barrel is thus put into a condition of permanent circumferential stress, such that the inner layers are in

Fig. 6—Muzzle of 25-pounder barrel showing rifling.

compression and the outer metal in tension. This greatly reduces the maximum tensile stress which occurs when the gun is fired.

For the auto-frettage operation the two ends of the barrel are counter-bored, reamed and threaded so that the appropriate connections can be made. One end of the barrel is connected to a high pressure pump whilst the other is connected to a specially designed valve which releases the liquid used (a mixture of water and glycerine) through a pressure pump.

Before the gun is set up for auto-frettage a steel core bar is placed in the bore. This core bar is bored out for a short distance at both ends and at the inner end of each of these bores a radial hole is drilled.

The liquid thus passes through the core, then out through the first radial hole to the outside diameter where it passes along between the barrel and the core bar and re-enters the second radial hole at the opposite end. Thanks to this arrangement the quantity of liquid required is considerably reduced.

After the pipe connections have been made, indicators are placed at four points along the length to obtain readings on diameters 90 deg. apart.

The pressure is applied in four steps with readings taken at 20, 24, 28 and 32 tons per sq. in.

Before the barrel is set up for auto-frettage, it is carefully measured in the bore and on the outside at the four points previously mentioned.

Readings are taken by precision dial gauges while the pressure is being applied and plotted on charts. By this method it is possible to ascertain the amount by which the elastic limit has been exceeded.

After the 32 tons per sq. in. load, the pressure is released and the liquid drained out of the barrel. The barrel is then given a low temperature anneal in one of the vertical electric furnaces.

After annealing, the barrel is again returned to the auto-frettage set for a second test pressure, but this time the pressure is brought up to 32 tons per sq. in. in a single step.

The resulting increase in diameter is twelve to twenty thousandths of an inch in the bore, and six to ten thousandths on the outside. The difference between these two figures indicates the permanent set of the barrel.

Returning to the machining operations, the ends of the barrel, including the threaded portion, are then cut off.

The barrel is then bored out to 3.35 in. after which it is finish-turned on the outside diameter and finally bored out to 3.44 in. It is then honed and the final chambering operations performed.

The outside surface is then ground for receiving the jacket, the barrel being given a slight taper. Then follow two further lathe operations, finishing the breech end, turn-

Fig. 5—Fitting breech mechanisms to gun barrels.

ing the front core and facing the barrel to length. Finally, the barrel is rifled.

Honing and rifling are operations of importance in gun manufacture.

Honing is a surface-finishing operation which has been introduced into gun manufacture comparatively recently. It employs a head on which are mounted a number of carbondum strips. This head, in turn, is mounted on a revolving bar which has also a rapid, relative longitudinal traverse.

The rifling machine is another special tool used in gun manufacture. It consists of a long bar on which is mounted a head carrying a tool in the shape of the groove to be produced; the rifling bar is rotated by the action of rollers on a sine bar, thus controlling the twist of the rifling.

Recent development has greatly improved the method of rifling, because the single tool cutters formerly used have been replaced by cutters with as many teeth as there are grooves to be cut. By using a set of cutters, roughly thirty in number, each a shade larger in diameter than the previous one, and by pulling these 30 cutters through the bore, not only is the machining time reduced to about a fifth of the former time required, but greater accuracy in division of the grooves is obtained.

Time will not permit even a brief description of the different operations in the production of the other main components, namely the jacket, breech ring, breech block and recuperator. These however are practically all machined on general purpose machines.

As previously mentioned, the machine shop, covering roughly 500 by 245 ft. is laid out according to the flow of the various parts. Here we have horizontal boring machines, vertical boring machines, horizontal and vertical milling machines, plano milling machines, grinding machines, gear cutting machines, broaching machines, engine lathes, capstan and turret lathes, planing machines, slotting machines, shaping machines, plus the equipment of a very large, up-to-date tool room, including such special machines as jig borers and thread grinders.

The fitting and assembly lines are installed next to the production machines and here, as in the machine shop,

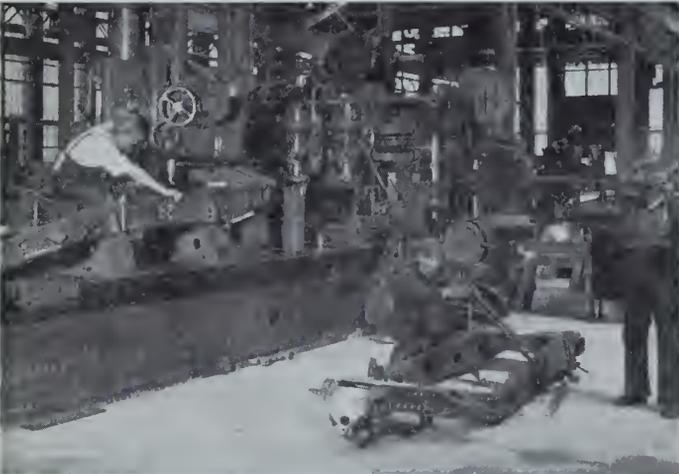

Fig. 7—Machining fabricated under-carriage on a giant multiple milling machine which makes eight cuts in one operation.

fitting and assembly gangs dealing with one component only are grouped together (See Fig. 4).

The last building is the plate fabricating shop, in which the firing platform, trail, top carriage and other components, in which plate work is the principal feature, are produced.

This shop is fully equipped with shears, guillotines, rollers, presses, pneumatic riveters, flame cutting apparatus and welding units.

After the pressings have been produced they are riveted or welded into position and machined where necessary, using jigs wherever possible for location.

In the final stage of production the work coming from the plate fabricating shop meets the machined components from the machine shop on the fitting and assembly floor. Here fitters, each skilled in finishing a certain part, work on a long assembly line of from seventy to a hundred guns.

An interesting feature is the effort that is being made to spread the work among other shops by sub-contracting different components. An outstanding example of this is the production of the carrier dial sight, a component comprising a large number of parts, which is now being produced by a Montreal firm in a satisfactory and creditable manner.

At the present time Sorel has about 80 sub-contractors manufacturing 700 different parts at the rate of 40,000 per

Fig. 8—Inspecting parts of breech mechanism.

month. All these firms have been carefully selected according to the type of work for which they are best suited. It is common practice, when contacting a firm for a specified production, to extend every possible help and part of this scheme is to arrange for a qualified master mechanic to follow up on the spot any manufacturing intricacies.

The results obtained by this sub-contracting branch are most gratifying and have been well worth the pains taken by Sorel Industries who have acted more or less as pioneers in this field.

Another feature worthy of mention is the special engineering department which has been set up by Sorel to take care of suggestions to be submitted to the inspector for passing alternative materials or machining methods; for example, replacing a forged steel entirely machined handle by a die casting requiring no machining at all.

Attention should be drawn to the invaluable help which the Chrysler Corporation have given Canada at Sorel. They came in at a critical time at the suggestion of the Government Control Committee to aid in supplying efficient management. Right nobly they have responded.

Praise is certainly due to the directors of Marine Industries who, by their enterprise, made such a project possible. In mentioning this company the author desires to compliment the Messrs. Simard Brothers personally. He wishes also to pay tribute to the men of Sorel for the wonderful part they have taken. At the present time Sorel Industries employ approximately 1700 to 1800 men of which roughly 85 per cent are French Canadians; it would be safe to say not more than ten per cent of this number had any mechanical training before joining the firm, which adds credit to their achievement.

Such matters as trade schools, the housing of workmen, the provision of hostels, etc., all form part of this vast scheme. Sorel Industries have not forgotten Napoleon's dictum that an army marches on its stomach, and in to-day's warfare when for every man at the front eighteen are needed at home, the word army applies just as much to the men in the shops as the men in the field.

# ACCIDENT PREVENTION METHODS AND RESULTS

WILLS MACLACHLAN, M.E.I.C.

*Secretary-Treasurer and Engineer, Electrical Employers' Association of Ontario, Toronto, Ont.*

Paper to be presented before the General Professional Meeting of The Engineering Institute of Canada, at Montreal, Que., on February 6th, 1942.

**SUMMARY**—An outline of the accident prevention work as carried out during the past twenty-five years for the Electrical Employers Association of Ontario, giving examples of some of the hazards and the results of prevention or remedial work. Statistics are shown in graphic form.

With the country at war it is of importance that men and material shall not be wasted but shall be used in the most effective manner. The wastage from accidents in industry and in war industry has disproportionately increased since the speed-up began.

The industries in Schedule 1 of the Ontario Compensation Act do not include the railways, the Bell Telephone Company, the Hydro-Electric Power Commission, many municipal and all governmental defence operations. Excluding these, the compensation cost of accidents in 1940 was \$8,370,000, a dead loss from our badly needed resources. This sum would have bought 14 corvettes but it represents only one-fifth of the loss because it has been proved repeatedly that "compensation payments constitute only one-fifth of the total employer accident cost." Where can effective ideas, methods and means be found to stop or reduce this loss?

The electrical public utilities of Ontario have been carrying out organized accident prevention work since 1915. Certain methods have been developed; certain objects have been achieved; a review of these may assist in solving the general problem.

The following notes refer chiefly to a group of public utilities in the province of Ontario. A large amount of accident prevention work has been done in other provinces and in industries other than the electrical public utilities, but this paper is based on facts and methods that have come under the author's personal observation.

In 1914 the Legislature of the Province of Ontario passed a Workmen's Compensation Act; this being the result of study by a Royal Commission headed by Sir William Meredith. The fundamental basis of most Workmen's Compensation Acts is the same, and, quoting from the Ontario Act, may be stated as follows:—

"Where in any employment . . . personal injury by accident arising out of and in the course of employment is caused to a workman, his employer shall be liable to provide or to pay compensation in the manner and to the extent hereinafter mentioned." . . .

There are various methods by which the employer can provide this compensation. In Ontario there are two: First, under Schedule 1 of the Act, by paying an assessment on payroll to the Compensation Board, the Board assuming the responsibility for the payment of all costs under the Act. Second, under Schedule 2, by the employers being individually liable for the payment of the said costs on direction of the Board. By far the greater part of employment is placed in Schedule 1. In certain other acts of this character provision is made for injured workmen's compensation by the employer taking out insurance with a regular insurance company; this is a more expensive method than that in effect in Ontario and Quebec.

The Ontario Act provides for the formation of associations of employers for the prevention of accidents, it being better to prevent an accident than to pay compensation. Classes and groups of employers are recognized, and these associations, usually embracing industries of a

like character, are managed by committees of employers in the respective classes. The Workmen's Compensation Board has authority to approve such an association if it believes that it sufficiently represents a class and in its assessment of the class obtains sufficient money so that it can make a grant to the association to carry out its work. Such a one is the Electrical Employers' Association of Ontario. It was brought into being in December, 1914; was approved by the Board and has been carrying out its functions since January 1st, 1915. It deals primarily with accident prevention among employees of the electrical public utilities and telephone systems, placed by the Workmen's Compensation Board under Schedule 1 of the Act, and now for the most part contained in groups 220 and 221. This Association is governed by a Managing Committee. Serving as presidents at different times have been some prominent members of the Engineering Institute of Canada, to mention but four: the late A. A. Dion, R. L. Dobbin, W. H. Munro and the present president, R. Harrison.

## THE PROBLEMS

What are the conditions in the electric public utility industry that increase liability to accidents? The first is scattered employment. In any public utility, the employees are dispersed over a city, town or a large part of the countryside, working for the most part in small groups, often without close supervision. The next condition is the constant hazard, particularly in the electric power industry, of electrical shock or electrical burns. There are many peculiar hazards that develop in the operation and maintenance of power houses and substations, due to the necessity of installing machinery in a confined space and also due to the fact that much of this equipment is energized. The overhead system of a public utility develops another type of hazard. Such a system has to be maintained in all weathers, the butts of poles being subject to rot and in cities the pole tops often being encumbered with cross arms and equipment. Adding to the hazard is the fact that it is important to maintain, as far as possible, continuity of service and hence the necessity at times of working close to or on either moving machinery or energized apparatus or lines. Analogous to this last mentioned hazard is the difficulty of removing apparatus or lines from service and returning them to service. To enlarge slightly on this: a transmission line operating at 44,000 volts needs some insulators removed because of broken petticoats; arrangements have been made to make the line dead so that the men can work on it. The risk is ever present that the line may inadvertently be put back into service prematurely.

Men are supervising, managing and operating public utilities; many machines are involved, but in addition the frailties of human nature are always present.

## HOW HAVE SOME OF THESE PROBLEMS BEEN MET?

### 1. ENGINEERING REVISION AND DESIGN

Consider an example. In 1915 and for some years after, it was common practice to install a number of disconnecting switches side by side on a switchboard or structure in a power house or substation. After the load was taken off a circuit by the oil switch being opened, the operator's problem was to open the disconnecting switches on each side of the oil switch or piece of appar-

atus. With a number of disconnecting switches on the switchboard or structure, there were times when he would open two blades of the circuit that was de-energized and then by mistake a blade in an adjacent live circuit, drawing an arc which at times enveloped the operator, resulting in severe burns or death. This problem was met first, by putting insulated baffle boards between the individual blades of the disconnecting switches of each circuit and, secondly, by clearly naming all disconnecting blades that constituted the disconnecting switch of the circuit. By this means even if the wrong blade was opened, the baffle board often prevented a short circuit arc from developing and the clear naming and designating of the switch was a constant indication to the operator of the blades constituting the circuit. This system of segregation, spacing and marking switches and apparatus and thus clearly designating them, was rapidly extended to the whole of the power house or substation equipment, including power transformers and other major equipment, and materially reduced accidents caused by employees straying into live apparatus.

Still another example of engineering revision: In earlier designs the fly-balls of a governor rotated in the air. Some of these fly-balls were at elbow height and operators' elbows have been fractured by being hit by the fly-balls, so that guards were installed. Later, more effective design was developed by enclosing the fly-balls, making for constant windage, better lubrication and a safe design.

Again, in the development of pole type transformer installations, a very considerable improvement has been made, not only in the service to the consumer but also in safety for the lineman, by creating more elbow room for the workman, perfecting the type of cut-out, re-arranging and improving the whole grounding system, particularly making provision for grounding of transformer cases, and in some later designs making it possible to entirely kill all wires and circuits below the line arm.

In all utility property, the exposed non-current carrying metal parts, such as frames of motors, are effectively grounded. This is to prevent the employee who places his hand on the motor frame from receiving a severe shock if the motor has broken down between coil and frame. This same hazard exists in motors in the manufacturing and other industries but many do not seem to realize the importance of grounding these frames.

## 2. TOOLS AND EQUIPMENT

Tools and equipment enter into many accidents in electric public utilities. One piece of equipment may be mentioned. Formerly there were many cases in which a lineman's belt broke, dropping the lineman, often resulting in serious injury and sometimes in fatal results. A study was carried out in connection with linemen's belts. The hardware had been adapted from horse harness hardware, but the snaps were malleable and at times had blow holes and broke. Drop-forged steel snaps were developed. The D rings in the earlier belt were sewed on the outside of the main body belt; if the stitching or rivets gave way, the man would fall. On redesigning, the body belt was placed through the D ring and the D rings made of drop-forged steel. Advice from leather manufacturers was obtained, a better grade of leather was developed and advice given to linemen for the maintenance of the belts. These details were worked out and the matter placed before a Canadian manufacturer who produced a very satisfactory belt.

In the early days the lineman supplied his own belt, but since, if the belt failed, the employer paid the cost of the accident, the practice developed of the employer providing the belt. This has resulted in a better belt more adequately maintained.

Since the perfected belt went into service some years ago, not one accident has occurred in Ontario to a lineman through failure of this belt. The same method of careful analysis of tools and equipment has been applied to rubber gloves, ladders, line hose, insulator caps, rubber blankets, and other items of equipment.

## 3. METHODS OF WORK

Various methods of doing work were investigated. As was pointed out earlier, one of the distinct hazards in electric public utility work arises in taking a piece of apparatus out of service for work and replacing it in service. This in the old days was guarded against by a clearance rule which with the more complicated systems, has developed into regulations filling many pages of the rule book. The essential features are:

That the foreman shall obtain permission to take the piece of apparatus out of service. This frequently necessitates the approval of a senior official. At the time that the work is to be done, the holder of this permit, usually the foreman, and the operator who receives the permit, see to it that the necessary switches or valves are put in such a position that the piece of apparatus is taken out of service and de-energized. If it is electrical apparatus it is thoroughly grounded and not until that time is it considered dead. Tags giving the name of the man holding the permit are placed on the valves or switches stating that the apparatus is out of service. These tags cannot be removed nor can the apparatus be put back into service without the holders' permission. In transmission line work, it is also necessary to place grounds on each side of the working space. Not until the foregoing is completed is work allowed to commence.

After the work is completed, the foreman makes sure that all working grounds are removed, every man under his supervision is clear and all possibility of contact with the apparatus or line is prevented. Not until this is done does he return his permit and turn it over to the operator.

Although this rule is enforced by all public utilities and is applicable to industry, in ammonia tanks, cranes, industrial substations, air lines, etc., it has not yet received the consideration that it should from those in charge of some manufacturing concerns.

Another simple but very important rule is that some one person should be in definite charge of a power house or substation or control desk at any instant. There should be no divided responsibility. For example at the time of a change of shift, there is danger of the operator and his relief being uncertain as to who is in charge of the power house. This point has been most clearly defined in rules. In one utility the relief does not take over until he has read and signed the log. Every utility man with long experience can remember cases where the lack of such a rule resulted in a near accident or a fatal accident.

## 4. HUMAN FACTOR

Up to the present we have been dealing with the correction of machines and methods of working. Men, however, are doing the operation and maintenance, and the psychological factor must not be overlooked. In certain kinds of work, habit training is of great value and is definitely indicated. This is important in connection with artificial respiration but it is equally applicable in many other phases of the work. For those who have investigated many accidents, the possibility that an experienced man may do something that one would never expect him to do under normal circumstances, is a very considerable worry. One example of this is that of an experienced employee, who while thinking of something entirely foreign

to his work, goes in on clearly marked and designated live apparatus, instead of dead apparatus. Methods have to be developed to assist the man in keeping his mind on the job at critical moments and in hazardous conditions. One simple method has been the instruction to a lineman in climbing a pole to stop 4-ft. below the lowest cross-arm or attachment, put his belt around the pole, have a good look at the pole top, figure out exactly what he is going to do and then go ahead and do his job.

The choice of the suitable man for each type of employment must not be overlooked. A man might be ideal in the operation of a substation but unfitted for the operation of a power plant. A man who would make a splendid lineman might be out of place on a patrol beat. It is not only the physical make-up of the man that is to be taken into consideration, but also his whole personality. If this is important in connection with the rank and file of employees, what of management? Employees must be impressed with the sincerity of management in its endeavour to prevent accidents. It is quite possible to get quick results for a very short period of time by publicity methods, but nothing will replace the mutual confidence between management and employee for the long pull in accident prevention work or for that matter in any phase of employment.

#### 5. METHODS OF CORRECTION AFTER THE ACCIDENT

Given that an accident has happened, the immediate effort becomes one to mitigate or reduce serious consequences, and secondly, an effort to prevent repetition.

Speaking first of mitigation, detailed first aid kits in line with the requirements of the Workmen's Compensation Board adapted for the use of public utilities have been recommended and training in the use of the kits and in simple first aid put forward. Extensive training in first aid has not been recommended, but that pertaining to the public utility field has been specified.

Because of the fact that electrical shock is such a major hazard in the electrical public utility field, a very large amount of time and effort has been expended on this factor. In the early days, methods were crude, so with the co-operation of medical associations and the universities, research into the effect of the passage of electrical current through the body was instituted. While this laboratory research was being done and detailed information of actual cases collected from the field, a careful study was made of all the engineering and medical literature available on this subject. As a result of this work, much information was gained and a practical system of remedial measures after electrical shock was developed.

As it was clear from the studies that these measures must be put into effect without delay after electrical shock, training of all employees in artificial respiration was taught, so that the man closest to the injured would know what to do. In view of the fact that after an accident there is a great tendency for people to lose their heads, constant practice in artificial respiration was required among employees, so that by habit training, these men would be prepared to carry on artificial respiration even though very much excited. Rescue methods were also taught. Co-operation of doctors and nurses was obtained by giving talks and demonstrations in universities and hospitals and before various medical bodies and preparing papers for the medical technical press. As a result of this, many lives have been saved. One case of outstanding character may be cited.

In 1927, about two o'clock one afternoon, a young lineman brought his head into contact with a high tension overhead wire. His feet and hands were in contact with conductors which were grounded. He received a very severe shock and was apparently lifeless, hanging back in

his belt. He was removed from the pole, artificial respiration was started at the foot of the pole, medical assistance called, and telephone communication established with headquarters. About 1½ hours later he was removed to hospital; artificial respiration was continued during transportation and was continuously applied in the hospital. All this was done by public utility men. About ten o'clock that night, they had the man breathing without assistance. This had required eight hours of continuous artificial respiration after electrical shock—the longest case on record.

After an accident, particularly of a serious character, an investigation is usually carried out, but much of the value of these investigations has been lost. If those holding an investigation would not only ascertain the facts but would learn what should be done to prevent repetition and see that such measures are put into effect, much of value would be obtained. Investigations merely to fix the blame are largely a waste of time as it will be found that what one is really discovering is an alibi. Real information has been driven under cover. If, however, the blame is fixed the next step usually is discipline. This develops fear and frequently results in more accidents. Nothing is gained. Time is wasted and valuable information that would have helped to prevent a recurrence is lost.

One phase of mitigation that should be touched upon is that of rehabilitation. At times a lineman is injured in such a way that he cannot continue to be a lineman. How can he be rehabilitated to become a useful citizen? Two approaches are at present in use: first by physio-electro and occupational therapy the man is assisted in overcoming the results of the accident; the injured muscles and nerves are made well and the mental outlook improved. A splendid curative clinic working to this end

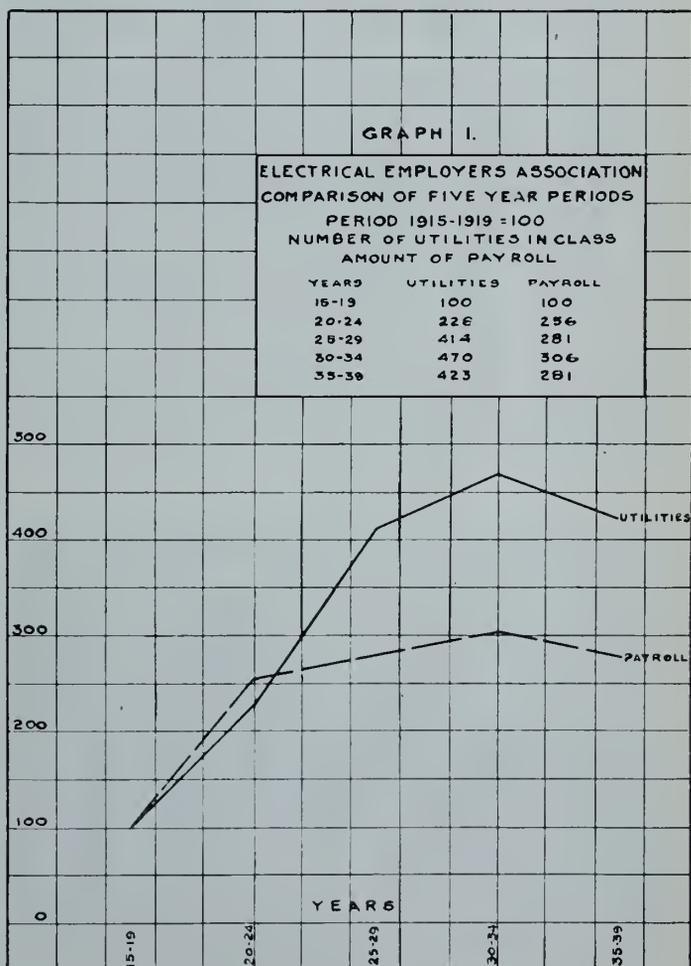

Fig. 1—Number of utilities and amount of payrolls

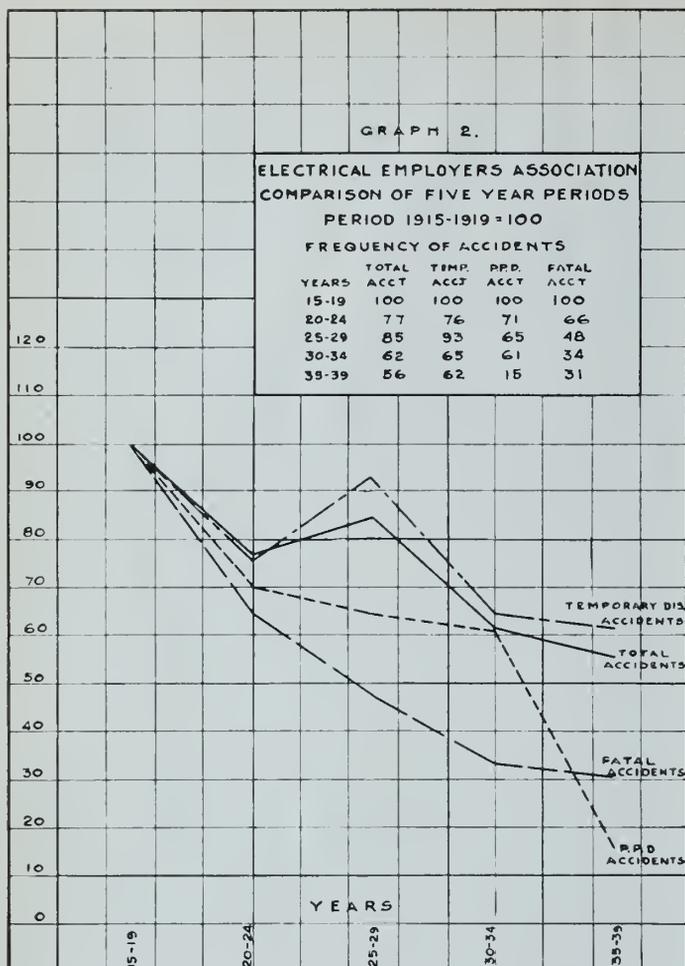

Fig. 2—Frequency of accidents per one million dollars payroll

is maintained by the Workmen's Compensation Board of Ontario. Secondly, by re-education and retraining in schools and industry, the man is prepared to take a new job suitable to his condition. Such rehabilitation is not easy to carry out but anyone assisting to forward the work, will be thoroughly recompensed in seeing some cases carried through to success.

It must not be assumed that this account covers all the various applications employed. Engineering revision and all of the other methods are used in many other ways but these are examples. In addition to this, talks with employees and management, letters and bulletins and the usual forms of approach have been tried, and where successful, proceeded with.

### RESULTS

What have been the results of accident prevention in the Electrical Employers' Association during the twenty-five years 1915 to 1939?

Records have been kept over this period. They have been checked by the statistical department of the Workmen's Compensation Board of Ontario and are in agreement with their records.

As the experience varies from year to year, it has been thought wise to take five-year periods and group the accidents, costs of accidents, and other information within these periods. As a means of comparison, the experience for the years 1915-1919 has been taken as a control and assumed to be 100.

### NUMBER OF UTILITIES AND AMOUNT OF PAYROLL

Figure 1 is a graph showing the increase in the number of utilities in the class and the payrolls for each five-year period taken as a percentage of the five-year period

1915-1919. It will be seen that there was a substantial increase in the number of utilities in the class up to the five-year period 1925-1929; it then shaded off and for the last five-year period there is reduction from the peak. This has been due to a number of different causes: the amalgamation of different utilities into one; some utilities being removed entirely from the utility field and other employers placed in the class for a few years, for example, construction industries were removed from the class, as their work is foreign to that normally done by public utilities. The payroll showed a sharp increase until the period 1920-1924, then a slight increase since that time. This is due to the fact that some of the larger utilities were bought out by those not in the class and to a very great extent in the latter years the utilities entering the class have been of a smaller character.

### FREQUENCY OF ACCIDENTS

In Fig. 2, is shown the frequency for,—  
Total lost time accidents  
Temporary disability accidents  
Permanent partial disability accidents and  
Fatal accidents

The frequency for this graph has been taken as so many accidents per million dollars payroll. It has not been possible to use the more usual comparison of accidents per so many man-hours. This again is for each five-year period, compared with the 1915-1919 period as 100. The sharp increase for the period 1925-1929 in the number of temporary disability accidents is due to the fact that during this period the construction companies were in the class and have since been removed. It will be noted that for the last five-year period under consideration, the fatal accidents per million dollars payroll were less

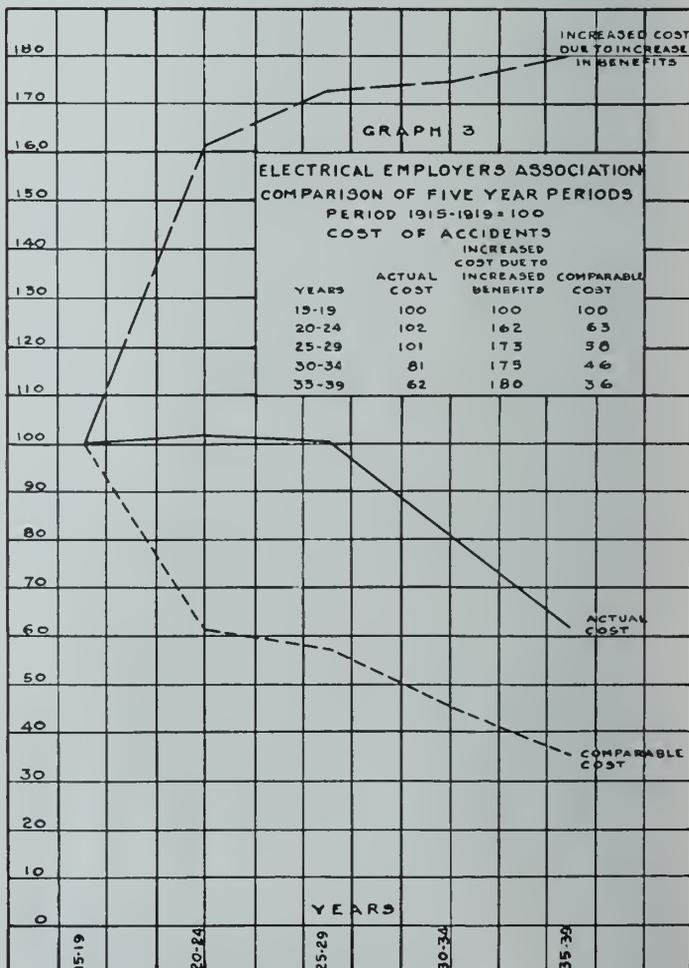

Fig. 3—Cost of accidents per one hundred dollars payroll

than one third of what they were in the period 1915-1919 and the permanent partial disability accidents were but 15 per cent of what they were in the earlier period.

#### COST OF ACCIDENTS

In Fig. 3, the cost of accidents has been compared on the basis of cost per \$100.00 payroll; the solid line shows the actual expenditure by the Board. It will be seen that this actual expenditure for accidents for the period 1920-1924 was slightly over that of 1915-1919 and in 1925-1929 there still was a slight increase; all this seems contrary to what could be inferred from Fig. 2. The last two five-year periods show a sharp reduction. However, when one remembers that amendments to the Act brought in from time to time made the benefits to the injured employee (and hence costs) greater than for the earlier years of the Act, the trend of this actual cost line is explained. With the co-operation of the statistician of the Workmen's Compensation Board of Ontario, a curve of the increased cost of comparable accidents due to increased cost in benefits was worked out and this is shown in the graph. By applying this curve of increased cost due to increased benefits to the actual cost of accidents,

a curve is obtained showing what the costs would have been had there been no increase in benefits. This latter curve is a true comparison of the five-year periods with one another and shows a very marked reduction in cost over each of the five-year periods. This reduction in cost, in part at least, can be attributed to accident prevention efforts.

#### CONCLUSION

In carrying out any accident prevention work, it is most important that a realistic approach be maintained. The prime object before anyone should be to get facts. If this is kept in mind, then naturally the object of any investigation of an accident is to learn the cause and provide measures to prevent a recurrence and not to find out who is to blame. Arising out of this, design of plant or equipment to be efficient must be such that it is safe to install, manufacture, operate and maintain. Rules and instructions should be simple, practical. They should be enforced or else removed. Even with these essentials the sincere leadership of management is vital to the whole matter. Canada needs every man on the job and not in a hospital bed.

## TACTICS AND UNORTHODOX AIRCRAFT

MAJOR OLIVER STEWART

*Editor of "Aeronautics" London, England.*

Unconventional aircraft designs do not often succeed in war. The amazing invention which appears so often in fiction and which—in fiction—wins so many wars seems to have no counterpart in real life. In aviation especially it is usually the orthodox, well-developed aeroplane that proves the best in service. An example is the Armstrong-Whitworth *Whitley*, a bombing aeroplane of perfectly normal conventional design built by conventional methods. At the outbreak of war in September, 1939, the *Whitley* was looked upon by many people as obsolescent if not obsolete. Yet a year later it was one of the mainstays of the British bombing fleet.

The *Whitley* was given a fresh lease of life by being slightly modified and re-engined and in this form it proved completely successful and showed itself capable of operating under difficult conditions.

#### BRITAIN WAS FIRST WITH POWER-OPERATED TURRETS

But although a conventional aeroplane appropriately developed and modified seems usually to play the leading part in war, there are occasions when unorthodox designs or constructional methods or novel equipment come into service with successful results.

If the operations of the Royal Air Force are studied, it will be seen that they owe their successes mainly to steady development of aircraft and aircraft equipment, but also to some extent to strikingly original thinking and to the introduction of unorthodox features.

The power-operated gun turret, which has been, since the beginning, a feature of the big British aircraft, and which is fitted to not only the heavy bombers but also to the medium bombers, is an example of a bold unconventional piece of design work.

No other country in the world thought it possible to introduce a power-operated turret, but British designers went forward with this component, developed it both for electrical operation and for hydraulic operation, and finally brought it to the stage of full efficiency.

At first many different theories were held about the method of operating such turrets, and one of the early Boulton Paul turrets was so arranged that the entire working of the rotatable part was brought about simply by the action of the gunner in aiming his gun. Thus, by swinging the gun to the right, power would be clutched in to the turret and the turret would turn to the right.

Our methods employed the twist grip similar to that found in some motor-bicycles. But all these methods were quickly sorted out under stress of war and the power-operated gun turret is now incorporated in vast numbers of British aircraft and has been responsible more than anything else for enabling Britain's biggest machines to beat off fighter attack.

#### WAR'S MOST SUCCESSFUL BOMBER

Here then is one example of original unconventional thinking brought to a highly successful conclusion in war. It is matched, so far as the structural side is concerned,

Fig. 1—The *Wellington* MKII

Fig. 2—The Hurricane II armed with twelve machine guns.

by the geodetic construction of the Vickers-Armstrong *Wellington*. This form of construction has frequently been described and it is not necessary to repeat the details. In essentials it consists of a basketwork of criss-crossing metal members which themselves give the aircraft not only its strength but also its shape. In other words, the geodetic construction places the strength of the machine where it is needed near the surfaces of the aerodynamic shapes. In this it contrasts with more conventional construction wherein the strength is imparted through girders and struts which are inside the wings or fuselage and which do nothing to impart to them their aerodynamic shape.

The *Wellington* has a right claim to be the most successful heavy bombing aircraft of the whole war. It has worked in many theatres and under difficult conditions. It has been employed on most of the very long range attacks that the Royal Air Force has made and it has invariably given the fullest satisfaction. Here is another case of unorthodoxy proving successful. Constructionally it is probably the most outstanding case of all.

#### WHY R.A.F. FIGHTERS HAVE THE ADVANTAGE

In armament the success achieved by the Royal Air Force fighters must be attributed more to the unorthodox tactical thinking than to any special design novelties. It was decided some time before the war that British fighters would be given the power of hitting harder than any other fighters in the world. The consequence was that guns were packed into them to an extent never before thought possible. One other point is worth noting, that these guns were packed in such a way as to enable them to be used without any synchronising or interruptor gear. In other words, they were so disposed as to be clear of the disc swept by the airscrew blades.

The Vickers-Armstrong *Spitfire* had eight guns mounted in its wings all fixed to fire forward in the line of flight and all outside the disc swept by the airscrew. Similarly, the Hawker *Hurricane* had eight guns mounted in

Fig. 3—A Lysander in flight. The rear gunner is strafing a convoy.

its wings. The later version of the *Hurricane* has no fewer than twelve machine guns, or alternatively, four 20-millimetre cannon.

This tremendously heavy armament for single seat fighters must be looked upon as unorthodox. It was not matched by anything in Germany or in any other country and it gave Royal Air Force fighter pilots a notable and lasting advantage over the enemy. The plan has been pushed even farther in the Bristol *Beaufighter* which carries four 20-millimetre cannon, and six machine-guns.

#### WORK OF THE LYSANDERS

When we turn to other classes of aircraft we find some notable unorthodox types, chief among them the Westland *Lysander* army co-operation machine. This aeroplane has had a long lease of useful life and has earned extremely high opinions from the pilots who have flown it. It has been used for innumerable different tasks, though most of them not of the kind that will see much publicity. It is still regarded as one of the best army co-operation aircraft in service to-day.

Its design is a brilliant piece of specialised work. For army co-operation purposes an aircraft must be able to take off from and land in a comparatively small area. Con-

Fig. 4—The Bell Airacobra in flight.

sequently the wing loading and the general wing arrangement of the *Lysander* is adapted to give a wide speed range. The aeroplane is capable of slow flying under full control yet it has a reasonably high top speed to enable it to meet all conditions under which it may be used. Partly this result is achieved by fitting the wings with Handley Page slots. These devices, by controlling the air flow over the wings, enable lift to be generated at lower speeds than would otherwise be possible.

The *Lysander* is also a masterpiece of internal planning. It packs into its fuselage a vast quantity of equipment. High wing arrangement has the obvious purpose of allowing the pilot to get a clear view downwards. *Lysanders* have been used for an enormous variety of different tasks including message dropping and picking up and the dropping of containers for revictualling troops.

These aircraft are instances of successful departures from orthodox design. They have played a vital part in Royal Air Force operations from the start of the war and they show that although the scope is restricted there still is scope for the novelty and for unconventional feature. More recently the Royal Air Force has taken into service the United States single seat fighter of extremely unorthodox design, the Bell *Airacobra*. This will be watched with especial interest, for many people believe that it may point the way for useful future developments.

# CONSTRUCTION OF A BY-PASS HIGHWAY IN ENGLAND BY ROYAL CANADIAN ENGINEERS

CAPT. J. P. CARRIÈRE, M.E.I.C.

R.C.E. Headquarters, Canadian Corps Troops, Canadian Army, Overseas.\*

## GENERAL

The military engineers' operations, outside of actual fighting, often lead average members of the profession to believe that they consist mostly of carrying out engineering works of a pre-planned and standard type, and that all designs are empirical. The author himself confesses, without shame, that he was of this opinion before being initiated into this branch of the service.

The purpose of this paper is twofold:—

- (a) To offset this false impression.
- (b) To bring to the fore certain interesting technical points and statistics of road construction practice in England.

In the early fall of 1940, the General Officer Commanding Canadian Corps made plans to move his Army wherever and whenever needed. The author disclaims any knowledge of such plans, beyond the fact that certain roads had to be improved and certain by-passes constructed to accommodate the immense mechanical transport of this modern army.

The construction of one of these by-passes will be the subject of this paper.

In the case under consideration, the required by-pass had already been designed and planned in peace-time but its construction had been forcibly put off with the declaration of war. The problem, as regards location, consisted in building a road on the right-of-way of this proposed by-pass, and of such design as would not hinder the construction of the complete by-pass in the future. A scheme was finally agreed to by the Ministry of Transport, the County Council and the Canadian Corps whereby a 22-ft. concrete highway would be built on the exact site of one of the planned carriageways, except at a few sections where such a procedure was impracticable and where a tar-macadam wearing course overlying a "hard core" foundation was designed.

## DESIGN

(a) GENERAL—The by-pass connects two main highways; one is at Elevation 265 and the other at Elevation 135.

The by-pass is 6,500 ft. long and the topography of the ground between the two above mentioned highways con-

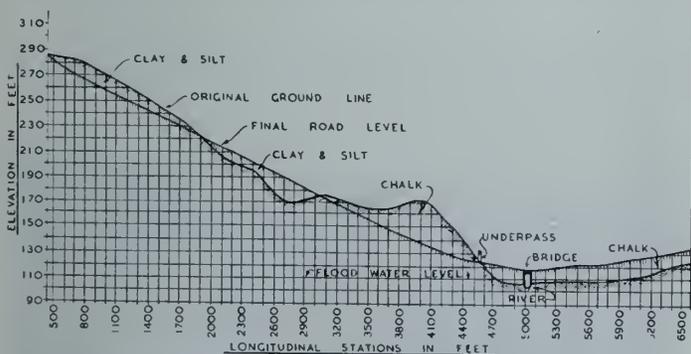

Fig. 1—Longitudinal elevation of road.

\*In civil life Mr. Carrière is Senior Assistant Engineer in the Montreal District office of the Department of Public Works of Canada.

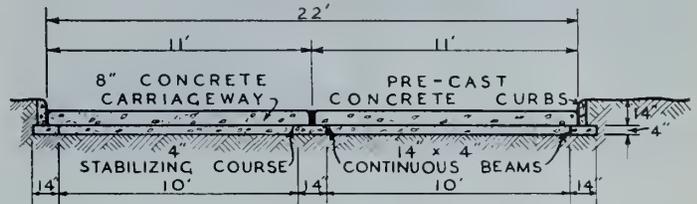

Fig. 2—Cross-section of concrete carriage way.

sists of a valley, with a temperamental river at the bottom and, to complete the modern pastoral scene, a main railroad on a 20-ft. embankment crossing at right angles.

(b) GRADING—The material required for grading consisted of 145,000 cu. yds. of balanced cut and fill. The soil to be excavated in the first 1,800 ft. consisted of a typical English clay and silt of a singularly sticky variety. The remainder consisted of material described as Upper Chalk with Flints (first named by W. Whitaker in 1865). The chalk is apparently fairly pure calcium carbonate composed of very fine granular particles held together by a weak calcarious cement which dissolves easily during rainy weather. This makes the handling of the chalk extremely difficult with consequent discomfort to all those engaged in the operation. The existence of flints in the material adds to the difficulties of handling it. These flints when struck by heavy road building machinery such as was used, break clean, presenting razor-like edges. The modern road building machinery employed on the job was naturally fitted with rubber tires which suffered considerably due to contact with broken flints.

(c) DRAINAGE—The design of the drainage system was a simple operation on paper. Its construction was quite another thing. One portion of the road had to be cut 39 ft. deep; the road bed in that cut has a 4 per cent grade; the bottom of the cut is 124 ft. wide and the 20-ft. railroad embankment lies at the lower portion of the grade. The width of the road is controlled by an underpass 12 ft. wide under the railroad. The drainage system was designed so that all surface water from the road above this point,

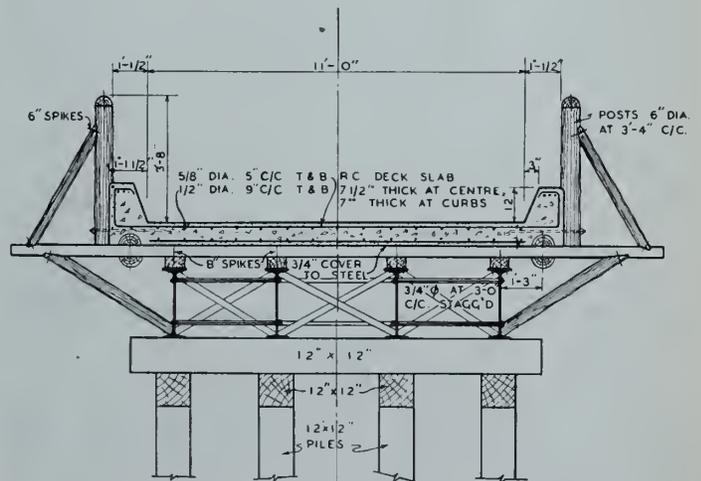

Fig. 3—Cross-section of bridge.

Fig. 4—Winter Flood.

together with surface water from part of the surrounding countryside, which partially drains in this artificial basin, could be collected and carried in sub-surface conduits through the underpass and eventually to the river. The only difficulty was that this work had to be carried out during the rainy season and consequently the site was normally in a very wet condition.

(d) CONSOLIDATION OF FILL:—No special machinery was supplied for consolidating the fills. It was proposed to place the soil in thin layers and depend on the continuous traffic of heavy road-building machinery for consolidation. This proved to be an excellent procedure and gave extremely good results.

(e) DESIGN OF CARRIAGE-WAYS:—The most interesting structural feature of the road is the foundation. This consists of three continuous longitudinal concrete beams 14 in. wide and 4 in. deep laid at 11 ft. centre to centre. Cross-beams of the same dimensions are built at every 80 ft. Where the grade is 4 per cent or more, the cross beams are supported on short concrete piles 2 ft., 6 in. long and 14 in. by 14 in. in cross section. Between this maze of beams is poured what is locally called a stabilizing course—this consists of a low grade concrete continuous slab 4 in. thick. Over this stabilizing course lies the carriage-way proper 8 in. thick; the carriage-way slab is completely isolated from the stabilizing course by a layer of special tar paper to prevent bond between the two courses. Expansion joints in the top slab are built at every 80 ft., except over portions of the fill where serious settlement is expected and where expansion joints are built at every 20 ft.

(f) UNDERPASS UNDER RAILWAY:—An underpass already existed under the railway; it was more in the nature of a cattle-pass. For reasons of economy and to ensure that railway traffic would not be interrupted, it was decided to improve the existing underpass rather than build a new one. In order to get sufficient headroom it was necessary to lower the existing ground line and this necessitated underpinning the foundations of the abutments. These abutments are of brick and have been in position for over 50 years, resting directly on a clay base, and no settlement has ever been recorded. The design of the underpinning consisted of mass concrete blocks, poured in sections. 7 ft. high and 4 ft. wide. Bond between the new concrete foundation and the existing brick piers was achieved through the use of sections of steel rails acting as dowels.

(g) BRIDGE OVER RIVER:—Borings along the banks of the river showed that a layer of chalk existed at a maximum depth of 12 ft. below bottom. This chalk layer was overlain with horizons of clay and gravel (locally called ballast). The location of the bridge to be built for military use was chosen outside the location of the eventual permanent bridge, which is to consist of a single concrete

arch. The gap to be bridged was 79 ft. The controlling loads on the bridge were those to be applied during construction and due mostly to the moving of soil, excavated from one side of the river and transported to the other side for fill. The maximum dynamic load to be applied was estimated at 45 tons, consisting of a train of two vehicles. Another important factor affecting the design was the availability of bridging materials. The material eventually employed consisted of 12-I beams 24 by 7½ in. at 90 lb., 8 of which were 24 ft. long and the remaining four, 31 ft. long; this allowed the construction of a three-span bridge, but the centre span had to be limited to a maximum of 27 ft. to keep the steel within safe working stresses. It is worth noting here that the above mentioned steel beams were by no means new and had been used over and over again. In view of this condition, a working stress of only 16,000 lb. was used for design purposes.

The work on the road having started in November, it was imperative that the bridge be erected without delay in order to keep the work of excavation and transportation of the soil moving. This factor affected the choice of foundations as the river under consideration is 10 ft. deep at the bridge site and it has the unpleasant habit of rising at a rate sometimes reaching 8 ft. in one day, was actually experienced during construction. All those factors led to the choice of mass concrete abutments at each end of the bridge and two intermediate timber pile piers. In order to limit the centre span to 27 ft., double bent pile piers were designed, bents to be 4 ft. centre to centre, and each bent to consist of four piles 12 by 12 in. in cross-section. The superstructure of the pile bents was designed of 12 by 12 in. timbers, cap sills being laid parallel to the length of the bridge and the bridge seats laid at right angles to the cap sills.

The unit working stresses in the bridging material under working loads were estimated as follows:—

- Piles—Max. load on a single pile 7 tons.
- Cap Sills—Max. tensile stress 973 lb. per sq. in.
- Cap Sills—Max. shear 81 lb. per sq. in.
- Bridge seats—Max. crushing stress 163 lb. per sq. in.
- R.S.J.s (I beam)—Max. tensile stress 15,110 per sq. in.

#### CONSTRUCTION:

(a) EARTH WORK:—The equipment employed for cut and fill consisted of eight-60 hp. tractors equipped with carryall scrapers; each tractor could be equipped with angle-dozer blades when required. One trailer type heavy roter was also used to loosen up the chalk before excavating it.

The job was started in early November 1940 and 20,000 cu. yds. of soil were moved by December 31st,—an average rate of 10,000 cu. yds., per month with an average haul of approximately 2,500 ft. From the 1st of January

Fig. 5—Working on wet fill.

Fig. 6—Home-made machine for testing shearing strength of soil.

to the end of March 1941, 21,000 cu. yds. were moved, averaging only 7,000 cu. yds. per month with a haul averaging only 2,000 ft. This lower rate of progress was due mostly to weather conditions. The remainder of the cut and fill, 104,000 cu. yds., was completed between April 1st and July 10th, 1941—an average of 30,000 cu. yds. a month with an average haul of 1,600 ft.

In all the above mentioned instances an average of six tractors and scrapers were being employed. These tractors and scrapers are of American design, and are a fairly common sight in Canada; their efficiency and all around usefulness is still being admired by all who have seen them at work on this job. It is worth mentioning that the sappers who operate these machines in Canadian Corps are the best that Canada can produce.

No trouble was encountered in excavating the clay and silt in dry weather nor in using it as a fill. Unfortunately a few attempts were made to work this type of soil during wet weather to gain time. The results obtained point out very definitely the inadvisability of this procedure. In each case the machines not only ruined the already built-up fill, but also churned up the undisturbed soil of the cut to such an extent that it took days for the soil to dry up sufficiently for operations to be resumed. This is not an original observation, but only an addition to the already established fact that it is economical in the long run not to disturb wet clay.

The chalk cuts and fills were comparatively easy to deal with. The flints played havoc with rubber tires at times and were effective in wearing down scraper blades and tractor treads quickly. However, taking everything into consideration, chalk proved no match for the equipment. During periods of dry weather, a heavy rooter was used to loosen up the undisturbed chalk ahead of the scrapers.

All material used for fill was spread in layers of a maximum thickness of four inches. The normal traffic of trac-

tors, heavy lorries, etc., was depended upon for consolidation. All chalk fill was consolidated to a consistency far beyond what was expected, and no settlement is likely to occur. Clay and silt fills, however, presented another picture, especially in view of the fact that they were disturbed while in a wet condition and that climatic conditions did not offer proper drying. Notwithstanding this condition, the road had to be pushed through over the fills. The critical sections of these fills were the slopes. The ultimate loading and the position of the loads being known it was decided to analyze the stability of the slopes before attempting to lay the carriage-way.

In view of the lack of soil testing equipment, most tests were carried out by "rule of thumb" methods; but the approximate internal shearing strength of the soil at various levels had to be estimated quite closely to give any value to the analysis. For that purpose, a machine was rigged up, consisting of one cross arm fitted with hooks to which were attached two spring balances, each calibrated to 40 lb. A piece of sheet iron 12 in. wide bent to a radius of 3 in. and connected to each spring balance completed the machine. Small trenches were dug at various levels along the worst portions of the fill, deep enough to reach a part of the fill unaffected by exposure. These trenches were so shaped as to allow full use of the testing machine and "bridges" of soil, 12 in. long and of various cross-sectional areas at each end, were carefully shaped in the undisturbed soil. The piece of sheet iron was then placed so as to bear evenly under each "bridge" and connected to the spring balances hanging from the cross arm. Upward forces were then applied at each end of the cross arm, as evenly as possible, until the specimen or "bridge" sheared from the parent mass, and the magnitude of each force, as registered on the balances, was recorded. The sum of the forces was considered as one force evenly distributed and equal to the ultimate shearing strength of the specimen, plus its weight. The unit weight of the soil was checked in place by weighing known volumes of it. The unit shearing strength of the soil was then arrived by weighing the specimens, subtracting this value from the total recorded force, and dividing the remaining value by the sum of the shearing areas, at each end of the specimens. The following values were obtained:—

Average weight: 115 lb. per cu. ft.

Shear strengths: Average for top 12 ft. of fill 384 lb. per sq. ft.

From 12 ft. to 13.5 ft. below top of fill: 156 lb. per sq. ft.

From 13.5 to 14.5 ft. below top of fill; 74 lb. per sq. ft.

At its most critical point, the fill under consideration was 20 ft. high. Between elevations 16 ft., and 14 ft. below the top, a two-ft. layer of chalk was placed during construction as an attempt to overcome part of the dam-

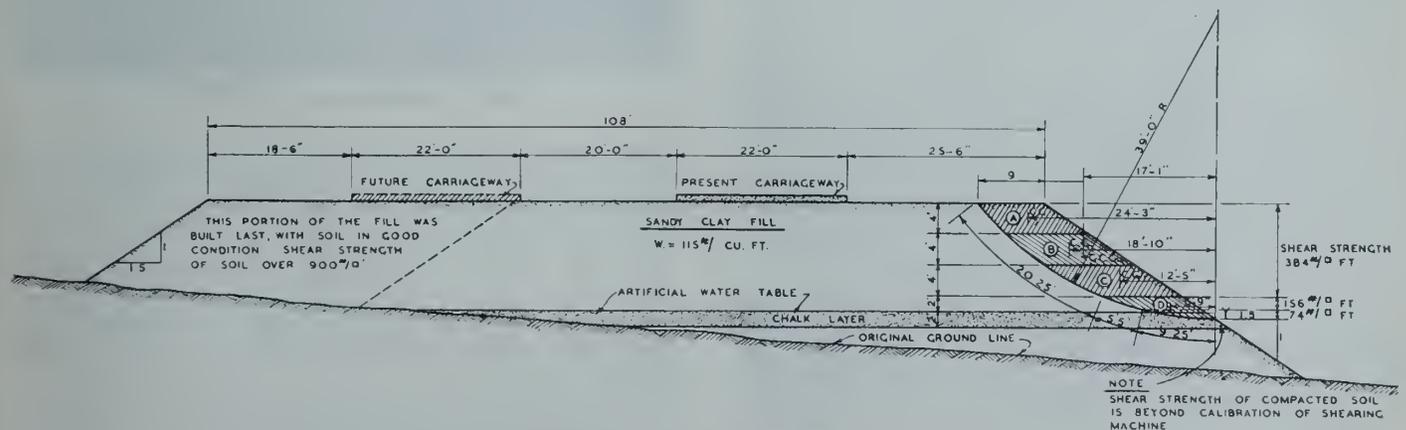

Fig. 7—Diagram of fill showing study of stability.

Fig. 8—Preparing to launch bridge girders.

age done by working the clay in wet weather and to give a foothold to the machinery. This layer consolidated and formed a very stiff horizon of material, apparently not easily soluble in water of infiltration and which acts as an artificial water-table, the top four inches of this layer remaining very wet while the remainder is dry and solid. This artificial water-table apparently limits the downward movement of water of infiltration and causes the overlying mass of clay to retain moisture to degrees varying in intensity from maximum at the chalk layer to minimum at the top of the fill. The variation in shear strength of the clay at the various levels is thus plausibly explainable as the magnitude of this characteristic of cohesive soils is proportional to their water content.

There is no doubt that settlement will occur in this fill; the extent of settlement will vary according to the height of the fill, and the magnitude could only be roughly estimated, due to lack of proper testing equipment. However, for the purpose of record, the County Council engineers set permanent brass plugs in the concrete slab at 20 ft. intervals in the highest fills to record the settlement over a period of years.

The characteristics and dimensions of the fill which presented the worst condition and appeared to have the weakest slopes, were used to make an analysis of stability of slopes. The soil composing the fill being plastic and cohesive, it was assumed (1) that failure of the slopes, should such occur, would take place along a cylindrical plane of rupture; (2) that the centre of this cylindrical plane would be located on the vertical projection of the toe of the estimated failure plane; (3) that the wedge or mass of fill above the plane of rupture would act as a solid body; (4) that this solid body would tend to break away from the parent mass in a circular motion; (5) that this tendency to motion would be resisted by internal cohesion and friction within the soil mass along the plane of rupture; (6) that the sum of the values of cohesion and friction could be translated as internal shear strength; (7) and finally, that the toe of the plane of rupture would not be lower than six inches below the top of the chalk layer described above.

The problem consisted therefore in finding the radius of a cylindrical plane to satisfy the following conditions:—

- (a) Maximum shear stress.
- (b) Minimum shear resistance.

By the method of trial and error, conditions were finally satisfied and the following values were obtained:

Shear stress: 7,245 lb.

Total shear strength along plane of rupture based on values obtained by tests: 9,320 lb.

The factor of safety of this slope against failure is therefore 1.27 and as this represents the worst condition on the job, all fills were assumed safe.

An attempt was made to estimate the rate of settlement, as follows:—

Plugs were driven into the fill at various points on which levels were to be taken at regular intervals. Time being the essence of this job, the road had to be pushed through before sufficient data had been assembled to determine the rate of settlement. The intention was to plot curves of settlement against time, estimate the formula for the average curve thus obtained, and then develop the curve for whatever periods of time were required. It remains to be proved whether such a procedure would have been accurate enough to be of use. However, in order to offset part of the effect of settlement on the concrete carriage-ways, it was decided to build these two inches higher than planned, at the highest fills in clay; as the road at these portions has a grade of 4 per cent, the drainage and other functions were not affected. It was also decided to build expansion joints at every 20 ft. in these portions.

(b) BRIDGE:—*Pile driving equipment*—There were only 16 piles to be driven, each being 24 ft. long and requiring to be driven to a penetration of 10 to 12 ft. To do this job, a timber pile-driving frame (of uncertain age) and a 25 cwt. monkey, were provided. In order to drive the piles in a reasonably short time, it was decided to operate the pile-driving hammer by mechanical means. The power was supplied by the power take-off of one of the tractors, one drum being used to lift the monkey and the other for pitching piles. By providing a makeshift weighted trip-gear at the monkey, a single action, automatic, drop-hammer was obtained.

Each pile was fitted with iron shoes and bands and was held in place during the driving by strong falsework. In most cases, there was a tendency for the piles to shift out of alignment and to twist about their vertical axis; this

Fig. 9—Side elevation of bridge.

latter defect would have been most objectionable in this case and extensive precautions had to be taken to overcome it. This points out the advisability of using round timber piles for this type of work.

All piles were driven to their full penetration. The set per blow on the last five blows averaged  $\frac{1}{4}$  in. with an average drop of 7 ft. This resistance to penetration approximates quite closely the maximum bearing capacity required.

The superstructure was erected by normal methods and presented no points of special interest.

The girders were launched by the derrick and preventer method, using the pile-driving frame as a derrick with a tractor as the power plant on one side of the river, and a second tractor as a preventer on the other. This proved a most efficient and quick method.

As the first function of the bridge was to allow the transportation of 78,000 cu. yds. of fill across the river, and bearing in mind the damaging effect of tractor treads on concrete, strong timber decking was laid to take that traffic. Upon completion of the fill, this timber decking was removed and a reinforced concrete slab was then built for permanent decking.

It is interesting to note that the bridge was submitted to greater loading and vibration before completing the decking than it will have to withstand under normal conditions and it is therefore reasonable to assume that no settlement or disturbance in the structure is likely to occur.

(c) UNDERPASS:—The underpinning of the abutments of the underpass did not present any difficulty and was carried out in a normal manner. The railway traffic was not affected by the work and the regular half hour train schedule was carried out by the railway authorities all through the operation.

(d) DRAINAGE:—The construction of the drainage system did not present any engineering difficulty, although it did involve many physical discomforts during the rainy season. Various makeshift implements were tried in attempts to increase the rate of progress of ditching, two of which are worthy of mention:—

The first consisted simply of a Fresno scraper rigged up fore and aft with steel wire ropes leading through blocks lashed to timber posts set solidly at each end of the proposed trench to the front and rear of a three-ton dump truck. Advancing and retiring the truck along a given line of travel actuated the scraper along the line of the trench causing it to dig, transport and dump soil, thereby reducing manual labour to a minimum.

One trench had to be excavated four to five ft. deep in the chalk along a distance of over 3,000 ft. A  $\frac{1}{2}$  cu. yd. self-propelled bucket excavator was used for this purpose. It was placed so as to straddle the trench, heavy timbers being placed under and at right angles to the tracks, in order to guard against the possibility of failure of the sides of the trench. A heavy rooter was used to loosen up the undisturbed chalk ahead of the excavator. As the excavated soil was being dumped along the sides of the trench, for back-filling, this method was found most satisfactory.

All pipes laid were of concrete and were surrounded with from four to six inches of concrete.

Some inspection chambers and catch basins consisted of precast concrete shapes which, once in place, functioned as the inner forms. They had to be surrounded with concrete so as to withstand the pressures of the soil deposited around them. Inspection chambers were also built of brick and were also surrounded with concrete.

(e) CARRIAGE-WAYS:

1. Concrete:

The three main operations in the pouring of the concrete carriage-ways consisted of:—

1. Pouring longitudinal and cross-beams, including stub piles.
2. Pouring stabilizing course.
3. Pouring carriage-ways proper.

These three operations were carried out by two groups. The leading group poured the beams and laid the forms on the beams for the carriage-way, and the second group poured the stabilizing course and the carriage-way.

The first operation was the longest, requiring the plac-

Fig. 10—Building the drainage system.

ing of forms for the beams, excavating and pouring concrete for stub piles, removing forms after two days setting period and placing and securing forms on the finished longitudinal beams; all this work had to be carried out by hand.

For the second and third operations, a mechanical concrete distributor and two vibrators were utilized, reducing manual labour to a minimum and making possible a fast rate of progress. One vibrator had a vibrating beam 10 ft. long, the other vibrator being equipped with an 11 ft. vibrating beam. This necessitated quite a bit of hand finishing but did not delay operations. This special equipment was supplied by the County Council.

The concrete was mixed at a central mixing plant of a capacity of two cu. yds. per batch. The water-cement ratio, the proportions, grading, volume and moisture content of the aggregates were under constant supervision.

For the carriage-way, and beams, the water-cement ratio was kept at between .44 and .50 and the mix averaged:—

Cement .....	1 part
Sand .....	2½ parts
Stone (5/8" max.) .....	5 parts

(measured by weight of dry aggregates).

For the stabilizing course, water-cement ratio remaining as above, the mix averaged:—

Cement .....	1 part
Sand .....	3½ parts
Stone .....	7 parts

Fig. 11—Inspection—showing also drainage conduit.

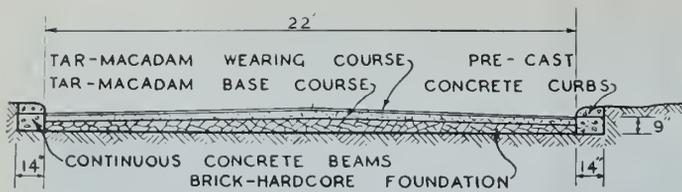

Fig. 12—Cross-section of tar-macadam carriage-way.

Only graded aggregates were employed.

The mixtures resulting from the above had no slump.

The average rates of progress were as follows:—

1. Beams and stub piles, 200 lin. ft. per day.
2. Stabilizing course, 480 lin. ft. per day (10 ft. wide).
3. Carriage-way—320 lin. ft. (11 ft. wide) per day.

Note that 5 days of operation No. 1 (1,000 lin. ft.) equals 2 days of operation No. 2 plus 3 days of operation No. 3.

The average compressive strengths of concrete were as follows:—

Stabilizing course—500 to 700 lb. per sq. in.

Carriage-ways—4,000 lb. per sq. in.

### 2. Tar-Macadam:

As mentioned previously, some portions of the road which are not of a permanent nature were built of tar-macadam overlying a hardcore base. In order to provide good shoulders against which to rest the road metal and to provide a base for curbs, concrete beams 14 in. wide and 9 in. deep were built along each side of the carriage-way.

Hardcore was then placed between these beams to a depth of 6 in. and rolled with a seven-ton road roller to provide a good base.

It is interesting to note that all the hardcore employed consisted of brick, concrete, and cut stone originating from the "ruins of London" and it might be stated here, without idle fancy, that many a relic lies buried under the tar-macadam.

The tar-macadam was laid in two courses; the base course, three in. thick was made with graded aggregates, mostly limestone slag, of a maximum size of two in., while the wearing coat  $\frac{1}{2}$  in. thick is made with graded aggregates up to  $\frac{3}{8}$  in.

The tar-macadam was mixed by the County Council at their plant and a few experts were also supplied by the County Council to finish the tar-macadam according to specifications.

3. *Curbs*:—All curbs were pre-cast in sections 30 in long. Along the concrete carriage-ways they were set upright on the projection of the concrete beams, while along the tar-macadam carriage-ways they were laid flat on top of the beams built for that purpose. In all cases, curbs were grouted in with a sand-cement grout.

4. *Farm Entrances*:—Accesses to a few farms along the

Fig. 13—Junction with existing road.

road had to be provided. The surfacing of these farm entrances consists of what is called locally "hogging" laid over a hardcore base. Hogging is a type of soil stabilization consisting of mixing clay, chalk and gravel in the right proportions and with the right amount of water to reach optimum moisture. This mixture is spread over a prepared base and smooth rolled. When completed, it presents a hard surface not unlike the better type of Canadian consolidated gravel roads.

### OFFICIAL OPENING OF ROAD

The road was officially opened on August 28th, 1941, by the Rt. Hon. William Lyon Mackenzie King, Prime Minister of Canada. He named it "Young Street" to commemorate the name of the Officer Commanding the company of Royal Canadian Engineers who built it, and then, (in a blinding rain), addressed the officers and men of the company. In his address, Mr. Mackenzie King brought out an interesting point, to wit: "War does not consist only of destruction but also of construction, often of a permanent nature and of general benefit to the advancement of civilization."

### ACKNOWLEDGMENTS

To (*censored*).....Chief Engineer Canadian Corps for permitting its publication, to (*censored*).....C.R.E. Canadian Corps Troops Engineers for posting the writer to the company of engineers employed on this construction, to Major E. J. Young, M.C., Officer Commanding the company of engineers to whom the task was allotted and to whom credit is due for the efficiency of the company, for allowing the writer free access to all records of the work and for supplying some of the photographs, and finally to the officers and men of the company for the efficient and exemplary way in which they carried out the work, and for the accurate records which they kept.

# THE 220,000-VOLT SYSTEM OF THE HYDRO-ELECTRIC POWER COMMISSION OF ONTARIO

A. H. FRAMPTON and E. M. WOOD, M.E.I.C.

*Respectively Assistant Electrical Engineer and Planning Engineer, The Hydro-Electric Power Commission of Ontario, Toronto, Ont.*

Paper presented originally at the Summer Convention of the American Institute of Electrical Engineers at Toronto, Ont., June 1941, and delivered again before the Hamilton Branch of The Engineering Institute of Canada, on October 2nd, 1941, and before the Peterborough Branch, on November 6th, 1941.

## INTRODUCTION

At the Summer Convention of the American Institute of Electrical Engineers in 1930, Mr. E. T. J. Brandon presented a paper under this same title<sup>1</sup>, describing the design of the initial components of this system, which had then been in operation approximately one and one-half years. At that time, one and one-half circuits, having a combined length of 350 miles, were in service, transmitting approximately 110,000 k.w. to a receiving terminal station in the Toronto area of 180,000 kva. capacity. At the present time, the Commission is operating a total of 1,000 miles of single-circuit 220,000-volt construction, with one receiving terminal of 420,000 kva. rated capacity and is placing into service immediately 45 miles of double-circuit construction and a second receiving terminal of 150,000 kva. capacity.

This paper presents a brief history of the development of the system and places on record the experience gained in 8,400 circuit-mile-years of operation of the transmission circuits. Data are presented regarding lightning outages and the behaviour of the circuits under sleet and conductor vibration.

These data are then used to indicate the reasons for certain revisions made in the design of new single-circuit construction carried out during 1940-41, and to indicate the factors that influenced the design of a new 45-mile double-circuit extension. The paper concludes with a discussion of the relay protection system and the improvements now being incorporated therein.

## GENERAL SYSTEM ARRANGEMENT

The 220,000-volt system under discussion forms part of the Commission's 25-cycle Niagara System, Figure 1, which supplies a highly developed area of some 12,000 sq. mi. in the peninsula formed by Lakes Huron, Erie and Ontario. This system distributes power over approximately 1,350 mi. of 110,000-volt lines. The total primary load, which equalled 710,000 kw. in December 1929, reached nearly 1,125,000 kw. in December 1940.

This 220-kv. system has been the channel over which

all growth of load in the Niagara System has been supplied since 1928, from generating sources largely in the neighbouring province of Quebec. An initial 60,000 kw. was transmitted over the first circuit in October 1928, increasing to 515,000 kw. transmitted over three such circuits in December 1940.

Until this summer, this supply has been delivered at the Leaside receiving terminal, adjacent to the city of Toronto, which it will be noted lies at the easterly extremity of the main 110,000-volt system. This fact has in itself created problems of distribution, the solution of which will be materially aided by the placing in service of the new terminal shown at Burlington.

## DEVELOPMENT OF 220,000-VOLT SYSTEM

The 220,000-volt system was initially conceived as a two-circuit system, with a mid-point interswitching station, transmitting some 200,000 kw. purchased under contract from the Gatineau Power Company, from that Company's Pagan development some 230 miles east of Toronto. Later contractual undertakings and the construction of the Chats Falls development on the Ottawa River, brought the total capacity, available from eastern sources to approximately 615,000 kw.

The third 220-kv. circuit was constructed in 1931, when the Chats Falls development was first brought into service. The connection shown from Beauharnois to MacLaren to Chats Falls was built during the depression years, to deliver the power which became available from the former sources to Chats Falls for transmission over the three-circuit system. This was an expedient, adopted as the most economical means of effecting this delivery, following an analysis of the transmission capacity of these three circuits in the light of the then existing knowledge of stability problems. This analysis indicated that, even without a mid-point interswitching station, the dependable capacity of these circuits, given proper fault clearance times, could be increased from an earlier rating of 330,000 kw. to approximately 450,000 kw.

The terminal capacity at Leaside has been increased progressively, by the addition of four 45,000-kva. banks,

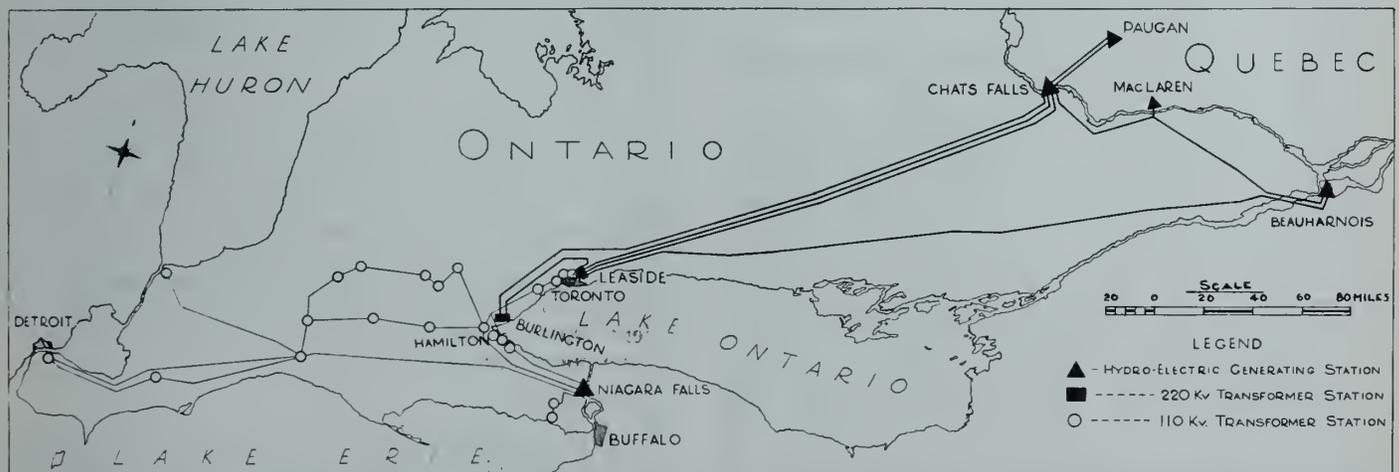

Fig. 1—The Niagara System of the Hydro-Electric Power Commission of Ontario, showing major generating and transformer stations and 220-kv. and 110-kv. lines.

duplicate of the two banks originally installed, and two 75,000-kva. banks, making a total installed rating of 420,000 kva.

Until the outbreak of hostilities in September 1939, it was planned that this system would need to be extended for service in the fall of 1942. The outbreak of hostilities, however, brought the expectation of rapidly accelerated power demands and the construction of a fourth circuit from the Beauharnois development of the Beauharnois Light, Heat and Power Company, in the Quebec section of the St. Lawrence River, was immediately undertaken. The selection of a westerly terminus for that line presented a problem upon which considerable time and study has been expended.

The Leaside terminal, being located in the metropolitan area of the city of Toronto, in which approximately 40 per cent of the total primary demand of the Niagara System occurs, provided a convenient point of distribution for the power delivered during the building-up years. In later years, however, Leaside has been expanded beyond the capacity originally contemplated, so as to make the most efficient use of the transmission system, thereby creating an increasing distribution problem.

Furthermore, as is obviously desirable, the power transmitted over this system was purchased under contracts which require high load-factor deliveries, much higher, in fact, than the load factor of the demands within the immediate vicinity of the receiving terminal.

For these reasons it has been necessary to distribute from Leaside, to gradually increasing distances, power and energy delivered in excess of the Toronto area demands. This distribution distance increases and decreases daily, with the variations of local demand, and is considerably greater in the summer than in the winter. During recent summer months power generated 250 miles east of Toronto has actually been delivered to the immediate vicinity of Niagara Falls.

It had been planned that the second 220-kv. terminal would also be in the Toronto area, but on its westerly outskirts. Further study, in the light of the increased capacity of Leaside, has resulted in the new terminal being located at Burlington, some thirty miles west of Toronto. At that point the new station is adjacent to the rapidly expanding load area of the city of Hamilton and also is situated where a number of existing 110-kv. circuits intersect.

This new terminal is supplied by diverting to it the shortest of the existing 220-kv. circuits, namely, one originating at the Chats Falls development, thus holding the

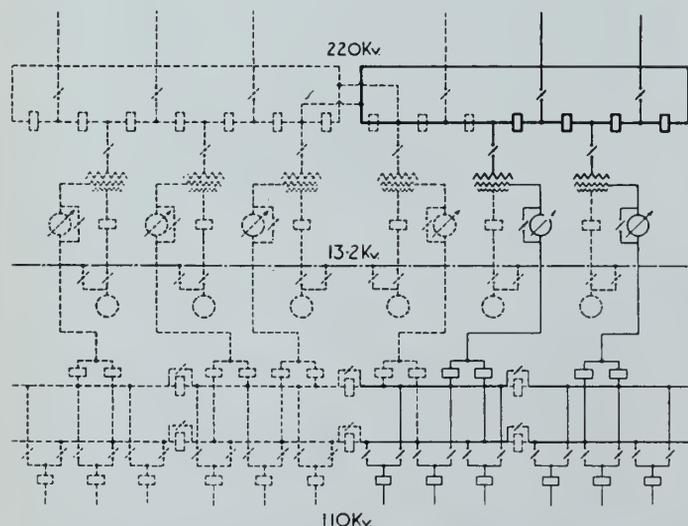

Fig. 2—Burlington 220-kv. receiving terminal. Proposed ultimate diagram for six-220-kv. circuits and six-75,000-kva. transformer banks. Initial (1941) installation in heavy lines.

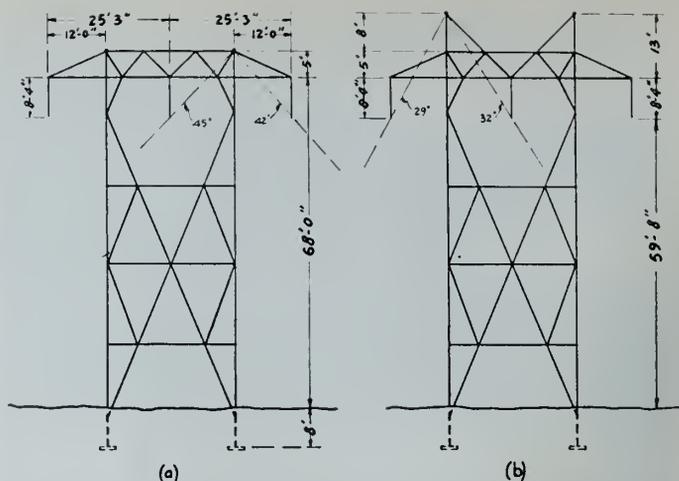

Fig. 3—(a) Outline of original single-circuit 220-kv. tower showing major dimensions and shielding angles. (b) Corresponding outline of revised 1940 tower.

longer Beauharnois circuit to its minimum length by terminating it at Leaside. In addition, a 220-kv. tie-circuit between Burlington and Leaside is provided, interconnecting the 220-kv. lines so that they operate as a four-circuit system. These two circuits are carried around the metropolitan area of Toronto and to Burlington on double-circuit structures, the first of such construction adopted by the Commission.

The Burlington transformer station is being constructed on a sixty-acre site, designed to accommodate ultimately six banks of three-25,000-kva., single-phase, 220/110/13.2-kv., forced-air-cooled transformers. Two banks totalling 150,000 kva. are being installed initially. A schematic diagram of the proposed ultimate station is shown in Fig. 2, on which the initial installation is indicated in heavy full lines. The addition of a third bank at this station will complete the existing phase of development, providing for the delivery of some 675,000 kw. over the four 220-kv. circuits. Beyond that point further delivery at Burlington will depend upon the development of new power resources, as for example, upon the Ottawa or St. Lawrence Rivers.

#### SUMMARY OF OPERATING EXPERIENCE

The first of these 220-kv. circuits was placed in service on October 1st, 1928, since when a total of 560 circuit-miles has been added, making a total of 790 circuit-miles in service as of March 31st, 1941. Of this mileage some 85 circuit-miles are not actually operated by the Commission, being located in the province of Quebec, but are included in the following record. The whole of this construction in general conforms to the designs described in the earlier paper, the standard suspension tower being shown in Fig. 3 (a).

In approximately thirteen years, 8,400 circuit-miles-years of operating experience has been secured and a total of 111 faults due to all causes have been experienced. Of these, four were occasioned by various construction hazards in the early years and eight were due to miscellaneous causes, chiefly external interference. Each of these faults involved only one wire and ground and, except in the period when only one circuit was in service, created no serious disturbance. It is of interest to discuss the salient features arising out of the remainder of this extensive operating record.

#### (a) LIGHTNING

Of the remaining 99 faults experienced in this period, 97 are attributed to lightning, equal to an average of 1.15 lightning outages per 100-circuit-miles per year, in a territory in which the thunderstorm frequency is between

thirty-five and forty storms per year. The classification of these lightning faults as to single-wire-to-ground, two-wire-to-ground and three-wire and as to those involving one, two or three circuits is given in Table I. The frequency of occurrence of such faults has varied tremendously; for example, three outages have been experienced within ten minutes; on another occasion, four within an hour and again five in one day and yet one period of eighteen months passed without a single outage.

TABLE I  
LIGHTNING OUTAGE RECORD

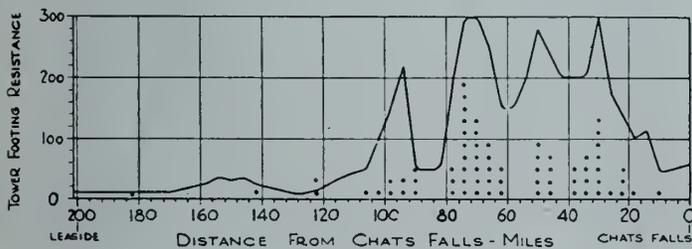

Classified according to the type of fault.

Involving one wire and ground.....	56	—	59%
Involving two wires and ground.....	25	—	26%
Involving three wires.....	14	—	15%
Total .....	95	—	100%
Involving one circuit only.....	95	—	98%
Involving two circuits simultaneously..	1	—	1%
Involving three circuits simultaneously	1	—	1%
Total outages due to lightning....	97	—	100%

These averaged data do not give a complete picture of the performance of these circuits. The three Chats Falls-Leaside circuits are constructed over terrain varying from rich farm land to rocky undeveloped bush country. The latter section, which extends almost continuously for a distance of about 90 miles, is characterized by surface rock formations with pockets of muskeg in the rock depressions. Towers are frequently erected on the rock outcrops. Low footing resistances are, therefore, difficult to obtain. In Fig. 4 an approximate footing-resistance profile for the Chats Falls-Leaside section is given, as compared to the known location of 70 of a total of 89 outages in this section attributed to lightning. It will be seen that some 90 per cent of the located lightning outages occurred in the section of high footing resistance.

In Table II is presented an attempt to co-relate the lightning outage record with footing resistance. The data are presented first for the 70 located faults in the Chats Falls-Leaside section and then for all 97 faults, based on locations for those not traced, as estimated from relay target and oscillograph records. It will be observed that, in the territory where footing resistances are considered to be below 25 ohms, the actual outage record approximates 0.2 outages per 100-circuit-miles per year.

Reference to Fig. 3 (a) shows that the tower design in these lines provides a shielding angle of 42 degrees and a ratio of "height of ground wire above power conductor to total height of ground wire" of 0.182. The experimental results of Wagner, McCann and MacLane<sup>2</sup> and the data presented by Waldorf<sup>3</sup> would indicate that good lightning performance could be expected and the record

• REPRESENTS ONE LIGHTNING FAULT IN THE RESPECTIVE FOUR MILE SECTION (5 TOWERS PER CIRCUIT PER MILE)  
TOWER FOOTING RESISTANCE FIGURES ARE AVERAGE VALUES FOR THE 60 TOWERS IN EACH FOUR MILE SECTION.

Fig. 4—Approximate footing resistance profile of three-220-kv. circuits, Chats Falls to Leaside, showing grouping of 70 located lightning outages.

proves that, given low-footing resistances, such has been the case.

Some crowfoot counterpoise work was done in the rock section along these three circuits during 1934-35. Short sections of highest footing resistance were so treated, with some success in lowering the measured values, but presumably the distances the crowfoot wires were carried to reach good grounds were too great to secure any considerable benefit.

TABLE II  
LIGHTNING OUTAGE RECORD

Classified according to tower footing resistance.  
(a) For 70 located faults on the Leaside-Chats Falls Circuits.

Average Tower Footing Resistance—Ohms	Number of Outages	Circuit-mile—Years of Operation	Outages per 100 Circuit-mile-years
Under 25	3	2,150	0.14
25-50	6	1,950	0.31
50-200	16	2,000	0.8
Above 200	45	1,100	4.1
	70	7,200	0.97

(b) For all outages due to lightning.

Average Tower Footing Resistance—Ohms	Number of Outages	Circuit-mile—Years of Operation	Outages per 100 Circuit-mile-years
Under 25	5	2,600	0.19
25-50	9	2,200	0.41
50-200	27	2,500	1.08
Over 200	56	1,100	5.1
	97	8,400	1.15

(b) MECHANICAL—SLEET AND WIND

In the southern part of the province of Ontario sleet storms of varying intensity may be anticipated both in the early and late winter seasons. December and March are the two worst months, though infrequently sleet may occur in any month from November to April. Storms have been experienced which have disrupted communication circuits and taken down wood pole construction. The phenomenon of "galloping conductors" has been observed, at frequent intervals, on various sizes and spans of conductors up to 605,000 c.m., A.C.S.R. at a span of 880 ft. Consideration must therefore be given to sleet conditions for all lines designed or constructed in this territory.

Two outages in the period under review are attributed directly to sleet, and these, incidentally, occurred within a few minutes of one another. Heavy sleet had formed on both power conductors and ground cables on certain hill tops, but only lightly on an intervening long valley span. As a result, the power conductors in the long span were pulled up by the unbalanced loading on the two sides of the adjacent suspension insulation, so that the ground cables, sagged to their normal loaded positions, appeared below the plane of the power conductors at mid-span. Two flashovers occurred, the second of which burned down a ground cable, resulting, on account of inaccessibility, in 27-circuit-hours of outage. In two other similar cases, a condition of unbalanced sleet loading was set-up, greatly increasing the sag of the ground cables without compensating sag of the power conductors, resulting in inadequate clearances. Fortunately, in these cases, the conductors were not disturbed by wind.

(c) MECHANICAL—VIBRATION

At the time of the construction of the first of these circuits (1927-28), the then relatively recent adoption of much longer spans and higher conductor tensions had brought the problem of conductor vibration strongly to

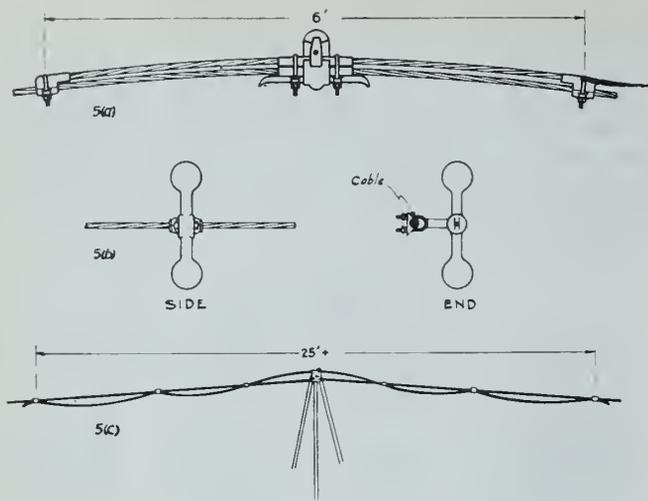

Fig. 5—(a) Conductor reinforcement on first (1927-28) construction.  
 (b) Torsional-type vibration absorber provided on one-half 1940-41 single-circuit construction; Stockbridge damper provided on remainder of such construction.  
 (c) Ground cable festoon used on 1940-41 construction.

the attention of transmission engineers. Remedial or palliative measures were as yet under investigation. In the original design this problem was recognized by providing, at suspension points, a reinforcement consisting of a 6-ft. length of the conductor fastened at its outer extremities and supported above the main conductor in a double-seated suspension clamp, Fig. 5(a). In the second and third circuits this form of reinforcement was replaced by the standard armour rods.

Each of these circuits was designed for a maximum conductor tension, at  $\frac{1}{2}$  in. ice, 8-lb. wind and 32 deg. F., of 10,000 lb., conductors being 795,000 m.c.m., A.C.S.R. having an ultimate strength of 28,500 lb. This represents a maximum tension of 35 per cent of ultimate and also represents a tension at 60 deg. F. of 16 per cent of ultimate. These figures will be recognized as indicating a design in which conductor fatigue due to vibration might be anticipated.

Actually a considerable record of vibration has accumulated in operation, though nothing approaching a serious condition has been observed to date. Quite early a loosening of tower members was experienced, but this was remedied by the use of locknuts or their equivalent at all one and two bolt positions. Careful periodic examination of the conductors has revealed a few broken strands though such damage does not indicate the need for any further palliative measures for some years.

#### REVISION IN DESIGN INCORPORATED IN THE 1940-41 SINGLE-CIRCUIT CONSTRUCTION

The recent extensive additions to this system were naturally not undertaken without re-consideration of the various design factors in the light of the experience enumerated above. It is of interest therefore to mention the revisions that were made and to discuss the reasons associated therewith. The discussion is perhaps best arranged under the previous headings, though it is difficult to separate those adopted for improved lightning design from those which aimed at improvement in the mechanical performance.

##### (a) LIGHTNING

The record indicates that good lightning performance can be expected of the original single-circuit tower, so long as footing resistances are kept sufficiently low. Perhaps, therefore, no change would have been made in the tower design were this the only factor, but as it was decided to raise the ground cables primarily for sleet operation,

this revision may also be taken as improving the expectation of good lightning performance.

As illustrated in Fig. 3(b), the two ground cables were raised eight ft. above their original location, to a point of support 21 ft. above the point of support of the power conductor in the suspension tower. This has had the result of decreasing the shielding angle to 29 deg., while increasing the ratio of "height of ground cable above power conductors to total height of ground cable" to 0.263.

Measurements made by the Meg-Earth tester shortly after tower erection indicated that, in the earth sections, after consolidation of the back-fill, tower footing resistances generally would not exceed 15 ohms. In these sections, no treatment beyond the occasional crowfoot is contemplated. In the rock section, it was decided to lay a continuous counterpoise, consisting of  $\frac{5}{16}$  steel conductors available in salvage stores. These cables are in general buried to an average depth of 18 in. under the out-phase wires. Occasionally, however, they are taken around rock outcrops, when by so doing they could be buried, and, in isolated cases, are actually carried over the top of the rock. The performance of this new circuit will be carefully compared to that of the existing circuits as such performance will largely dictate whether counterpoise should be added to the older construction.

##### (b) MECHANICAL—SLEET AND WIND

Our experience would seem to indicate that, under the operating conditions existing, sleet is more liable to form on the ground cables than on the power conductors, and under such conditions the vertical separation provided between ground cables and power conductors has proved insufficient. Mr. A. E. Davison, Transmission Engineer for the Commission, has actively studied this problem of conductor clearances. These studies are based on Lissajous figures<sup>4</sup> and the locus of motion of the conductor under "galloping" conditions is taken as the criterion. The axes of this motion have been determined empirically

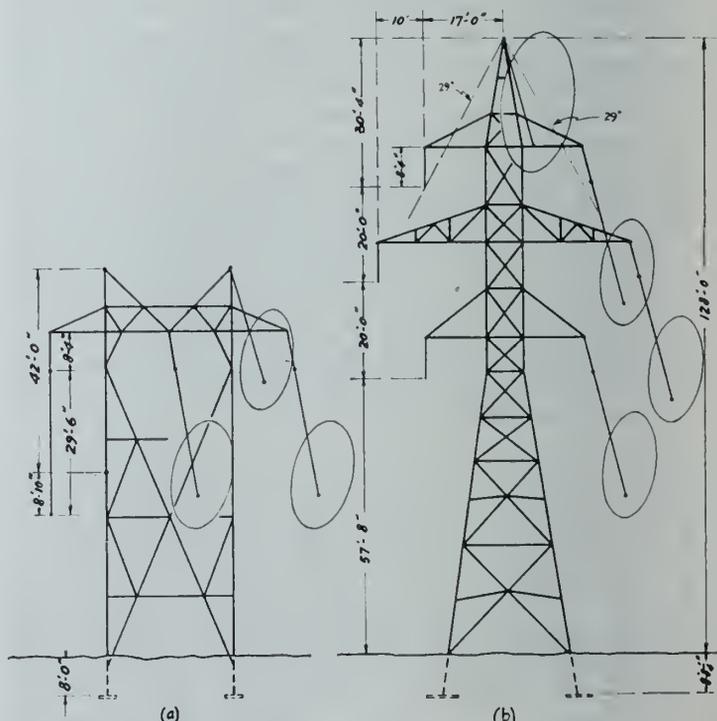

Fig. 6—(a) Clearance diagram (Lissajous figures) for 1940-41 single circuit construction. Loci based on half-loops, i.e., movement of quarter-point in suspension span. Note also mid-span positions of  $\frac{3}{4}$  in. ice-loaded ground cable and unloaded phase conductor.

(b) Corresponding diagram for 1941 double-circuit construction. Note full loop movement of ground wires assumed at 880 ft. span.

from recorded field observations and from analyses of motion picture records of a number of actual occurrences. It is possible to at least approximately delineate the various loci. A tower design in which these approximate loci indicate adequate clearance between all conductors is considered much more satisfactory than one in which overlapping loci occur.

However, the extent to which this method should be applied to heavy conductor, long-span construction is still somewhat of an open question, being largely based on the behaviour of smaller conductors and shorter span construction than is involved in this case. No conclusive data are available indicating that 795,000 c.m., A.C.S.R. at 1,056 ft. spans will "gallop" at all, and, even if it does, whether it will be in one continuous loop between the points of support or in something of a wave motion raising not more than one-half the span above its normal position at one time (that is, in half-loops). Messrs. Oldacre and Wollaston<sup>5</sup>, in describing the Powerton-Crawford line, illustrated the use of Lissajous figures and assumed the movement of the conductor in one loop.

In our case, however, a substantial mileage of towers was available in stock and much quicker deliveries could be obtained if the basic original design was not changed. This design was based on a longitudinal loading equivalent to  $\frac{1}{2}$  in. ice and 8-lb. wind, but with the transverse loading increased to  $\frac{3}{4}$  in. and 11-lb. wind, the latter increase an added factor of safety since considered unnecessary. It was decided that part of this excess strength could be utilized to provide greater vertical separation between ground cables and power conductors, though in designing this improvement it was considered sufficient to assume movement of the conductors in half-loops only. It will be noted in Fig. 6(a) that the re-design has removed the loci of motion of the ground cables from those of the phase conductors, providing adequate clearances under the assumed conditions. The ice-loaded mid-span position of the ground cable at rest, as compared to the corresponding position of the unloaded phase conductor, is also shown, indicating the maintenance of substantial clearances even with a  $\frac{3}{4}$  in. ice differential.

### (c) MECHANICAL—VIBRATION

The balance of the excess strength in the original tower design has been utilized to increase the ruling span from 1,056 ft. to 1,150 ft. In order to maintain the same ground clearance at this longer span, the higher strength 26x7 strand, 795,000 c.m., A.C.S.R. has been used, strung to a maximum designed tension of 12,000 lb. Based on an ultimate strength of 30,900 lb., the designed maximum and "60 degree" tensions therefore approximate 39 per cent and 17.6 per cent of ultimate strength respectively.

The lengthening of the span in the new circuit was based partly upon the vibration record of the existing circuits and partly upon the favourable results obtained from an extensive laboratory and field investigation of damper design and performance<sup>6</sup>. It is felt that the development in this field now safely permits securing the economy inherent in longer spans and higher conductor tensions. The full possibilities in this connection were not realized in this case, due to the decision to retain the basic original tower design, but had a completely new design been permitted, spans as great as those encountered in some other recent construction would have been given serious consideration.

Associated with this increased span length the application of vibration absorbers was decided upon, rather than the previously used armour rods. Approximately one-half the line is equipped with the Stockbridge damper and one-half with the torsional damper, Fig. 5(b), developed in the Commission's laboratory and described in a companion paper by Mr. G. B. Tebo<sup>6</sup>. Both dampers are

used singly, that is, two per span. Vibration of the ground wires is protected against by the use of festoons, Fig. 5 (c).

### DOUBLE CIRCUIT CONSTRUCTION—LEASIDE TO BURLINGTON

In considering the two-circuit extension of these 220-kv. lines, from the existing terminal at Leaside to the new terminal at Burlington, a number of factors were brought into consideration. Single-circuit construction was initially considered, the Commission not having previously operated any double-circuit construction at 220 kv. In fact, there had been evident in the Commission's engineering a tendency to avoid such construction at all voltages, in favour of various single-circuit configurations. However, as some twenty miles of the Burlington extension necessarily encircled the metropolitan area of Toronto, this viewpoint was brought sharply into conflict with the question of right-of-way costs. The final decision was in favour of the double-circuit construction, though it will be noted that a relatively conservative design has been adopted.

The initial decision was to adopt a span of 880 ft., utilizing 795,000 c.m., A.C.S.R. at a maximum designed tension of 10,000 lb. However, a change in this decision was

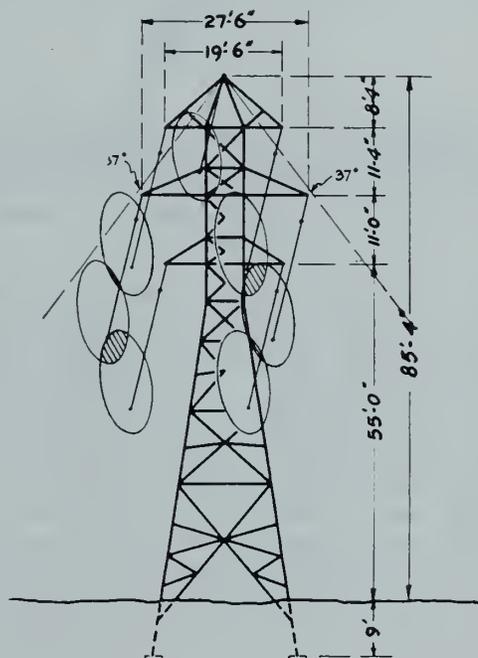

Fig. 7—Clearance diagram for 1920 type 110 kv. double-circuit construction—one-half loops only. Note overlapping loci indicating anticipation of sleet outages.

brought about by the exigencies of the present situation and the line is actually being constructed utilizing the type HH segmental, hollow-core, copper conductors, 500,000 c.m., 1.02 in. outside diameter, seven segments, having an ultimate strength of 21,200 lb. At the 880 ft. ruling span the maximum designed tension, at  $\frac{1}{2}$  in. ice, 8-lb. wind and 32 deg. F., is 9,500 lb., the 60 deg. tension being 4,700 lb., equivalent to 45 per cent and 22 per cent of ultimate respectively.

The tower design adopted is shown in Fig. 6(b). It will be noted that a single ground cable is used, located at the tower peak, 30 ft. above the point of support of the upper phase conductor in the suspension position. A shielding angle of 29 deg. and a ratio of "height of ground wire above power conductors to total height of ground wire" of 0.236 results. Footing resistance data on this construction are not yet available, but the line being all in good agricultural land it is not anticipated any particular treatment of the footings will be found necessary.

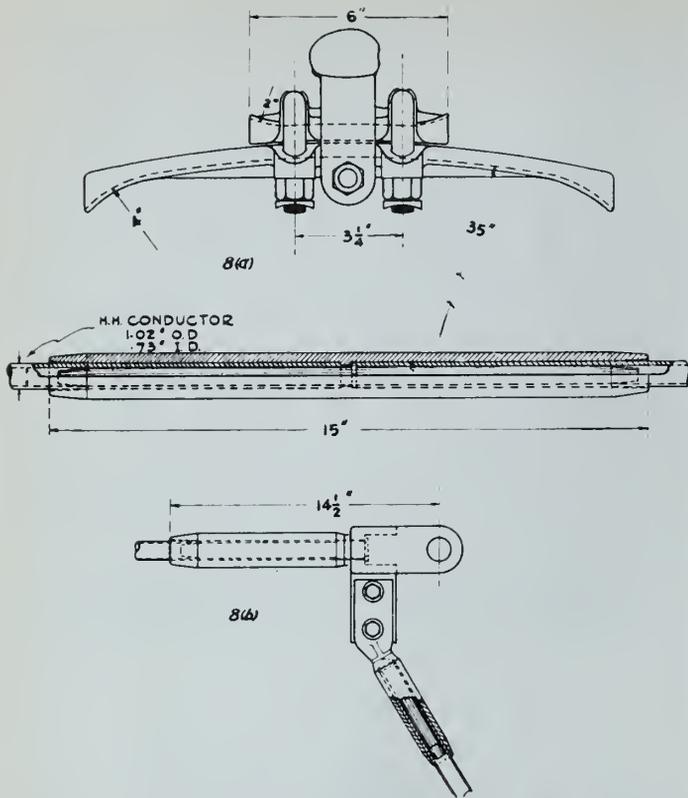

Fig. 8—(a) Suspension clamp adopted for type III segmental copper cable, 500,000 c.m., 1.02 in. outside diameter. Span 880 ft. maximum designed tension 9,500 lb. 45 per cent of ultimate strength.

(b) Jointing and dead-end assemblies for type III copper conductors.

Again in the new double-circuit construction the same principles of design for slect operation were used. It has been found more difficult to provide adequate clearances economically in this type of structure than in the single-circuit design. For example, in an earlier 110-kv. design, utilizing 605,000 c.m., A.C.S.R. conductors at 880 ft. spans and providing a 4-ft. offset of the centre phase wire, Fig. 7, actual outages due to "galloping" have been experienced. That these outages might be anticipated, however, is indicated when the design is analyzed by means of Lisajous figures, though it will be seen that rather extensive revisions will be needed to effect full clearances. The clearance diagram for the 220-kv. design finally adopted is shown in Fig. 6(b), based on half-loop movement of heavy copper power conductors but full loop movement of the relatively light ground cable.

No special precautions are being taken to protect this double-circuit construction against conductor vibration. The extensive studies reported by other authors are interpreted as indicating that, except perhaps in certain cases, no such precautions are necessary. Furthermore, it was decided that no particularly special provisions would be made in the suspension clamp, Fig. 8(a), and that copper compression joints, Fig. 8(b), would be used for both straight joints and dead-end assemblies. Time has not permitted complete investigation of this latter practice, which is at variance with the practice adopted in certain other lines utilizing this form of conductor<sup>7</sup>, but, as the full strength of the conductor is developed in these new joints and as the mass of all parts subject to possible vibratory stresses is reduced to a minimum, no objectionable operating experience is anticipated.

A structural revision incorporated in the double-circuit tower consists of designing the lower panel so that all diagonal connections are made above grade. In earlier designs, including the single-circuit 220-kv. construction, the point of connection of the lower diagonals and the

main legs is located below ground level. In this climate and particularly in clay soils, frost heaving has been found to occur which reacts against this below-grade diagonal, causing bending and in some cases actual failure.

#### RELAY PROTECTION AND SYSTEM STABILITY

It is finally of interest to describe briefly the relay protection provided on this 220-kv. system and to discuss the improvements being made, both in the existing protection and in the protection of the newer construction, associating these improvements with the operating record and with the data obtained from Network Calculator analysis of the system.

For "phase" faults, the earlier relaying consists of directional, two-stage, impedance distance type. The instantaneous range of such relays is set to cover 85 to 90 per cent of the line length, the overlapping second range set to cover the remainder of the line and being given a definite time delay of 0.6 to 0.8 seconds. This protection effects simultaneous clearance of all faults in the mid-section of any line, but results in delayed opening of the distant breaker for end-zone faults.

For "ground" faults, similar protection is used, except that the relays are supplied with line residual current and phase-to-ground voltage and the instantaneous range is set to cover the whole length of the line, with some margin if the remote end is open. This results in simultaneous clearance of mid-sections faults, though it also effects sequential clearance of faults in the end zones, that is, clearance without the delay associated with the timed second range.

Certain of the line sections terminate in breakers of earlier design, which originally gave a clearance time, with instantaneous tripping, as high as 0.5 to 0.6 seconds. The more modern equipment clears within 0.2 to 0.25 seconds. Improvements have been made from time to time,

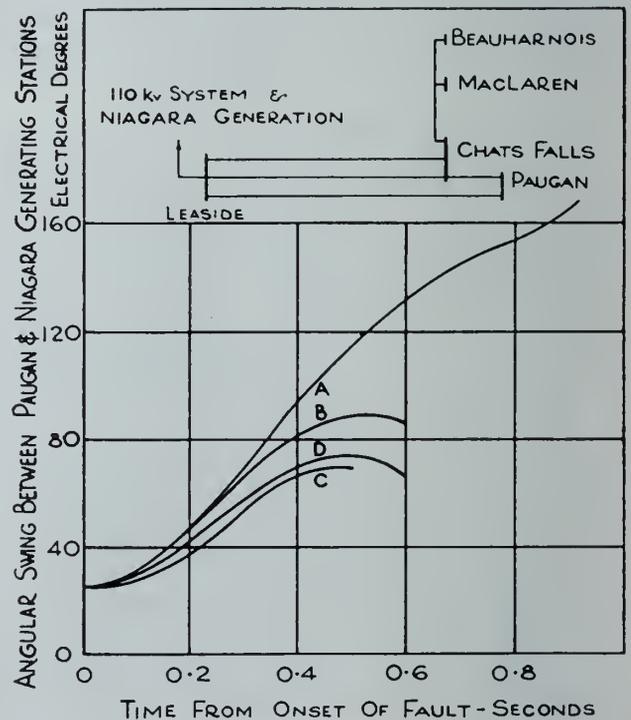

Fig. 9—Stability curves for three-circuit 220-kv. system at loadings of approximately 200,000 h.p. per circuit. (A) Three-phase fault at Chats Falls, cleared sequentially in 0.2-0.5 seconds—unstable. (B) Three-phase fault at Chats Falls, cleared simultaneously in 0.2 seconds—stable. (C) Three-phase fault 30 miles west of Chats Falls, cleared simultaneously in 0.25 seconds—stable. (D) Two-wire-to-ground fault at Chats Falls, cleared sequentially in 0.2-0.5 seconds—stable.

in the original relaying and in the older circuit breakers, so that total clearance times now vary from 4.5 to 10 cycles, with an average of about 6 cycles (based on 25 cycles) for all faults except those cleared by the second ranges.

This protection, though admittedly below present-day standards, has nevertheless given adequate service during the building-up period on this system. Fortunately, all but a very few of the 39 multi-phase faults have occurred in the high-footing-resistance territory in the mid-section of the Chats Falls-Leaside lines, where this protection effects simultaneous clearance.

Improvement necessary in the protective equipment, when operating at the higher recent loadings, has been the subject of several Network Calculator studies. These studies bring out quite clearly the inherent stability of a 25-cycle system. Assuming simultaneous clearance times of 0.2 to 0.25 seconds, as would be obtained with standard modern equipment, it is found that the three-phase fault may be adopted as the stability criterion, rather than the two-wire-to-ground fault usually adopted in 60-cycle systems.

In Fig. 9 is presented a family of curves obtained in such analysis, which indicate the relative severity of different types and locations of faults. At a loading of approximately 150,000 kw. per circuit, Curves A and B indicate that three-phase faults near the generating sources must be cleared simultaneously in approximately 0.2 seconds, if stability is to be maintained. If such faults occur away from the generating sources, Curve C indicates that the increased loading of generators thereby created is sufficient to maintain stability with simultaneous clearance at 0.25 seconds. Curve D shows the relatively lesser severity of the two-wire-to-ground fault, which does not disturb the system stability with sequential clearance as long as 0.2 and 0.5 seconds. These results are taken to indicate that, with protective equipment effecting simultaneous clearance of all faults in 0.2 to 0.25 seconds, loss of system stability at loadings of 150,000 kw. to 170,000 kw. per circuit need not be anticipated.

It is proposed to attain this aim by superimposing carrier pilot control on existing and on all new two-stage impedance relaying. With the exception of the new Leaside-Burlington line, where standard "transfer-block" carrier relaying is proposed, a system of transfer-trip carrier control is being developed. The first of this equipment is being installed on the Beauharnois-MacLaren-Chats Falls connection and on the new Beauharnois-

Leaside circuit. It consists of 400-watt carrier communication transmitters, single-frequency voice-actuated, the speech frequency range being limited to a band of 200 to 2,500 cycles. Tone generators will be used to transmit relay control signals, which operate to remove the time-delay feature of the distant-end second-range relays. Thus simultaneous clearance is obtained over the full line length, the speed of clearance being limited to that of the various terminal breaker equipments. This protection is as yet experimental and its performance in service will form an interesting study.

#### CONCLUSIONS

1. Operating experience with some 8,400 circuit-mile-years of 220-kv. single-circuit overhead line construction is submitted, which to a high degree confirms conclusions which may be drawn from the application to designs of published principles derived from theoretical and experimental analysis.
2. Changes made in the latest designs of towers to provide improved operation under sleet conditions also provide desirable improvements in design against lightning.
3. Counterpoise on towers of high-footing-resistance which has largely been omitted on earlier construction is being installed on 1940-41 lines.
4. Standard two-stage impedance type relay protection has given good satisfaction on these lines. To provide the best operation under heavy line loadings, carrier-current features are being superimposed on both new and old relaying to extend high-speed simultaneous fault clearance to cover the full length of each line.

# AIR RAID PRECAUTIONS AS RELATED TO BUILDING DESIGN

S. D. LASH, M.E.I.C.

Lecturer, Department of Civil Engineering, Queen's University, Kingston, Ont.

**NOTE**—This article was prepared at the request of the Publication Committee of The Institute. It gives a general outline of the information contained in one piece of literature issued by the British authorities.

## INTRODUCTION

Considerable attention has been given in recent months to the problem of air raid precautions in Canada, particularly from the point of view of civilian defence organization. At the same time, many factory buildings have been built for use by war industries and it appears that, in its design of these, little or no thought has been given to the possibility that in the event of air raids such buildings will form important military targets. It is suggested therefore, that architects and engineers responsible for the design of buildings for defence industries, or other vital services, should consider carefully the question of passive protection against air attack.

Although much is yet to be learned, it has been clearly established that certain precautions can be taken which will greatly lessen the probable damage from air attack. Some of these results have been presented in the Wartime Building Bulletins published by the Department of Scientific and Industrial Research in Great Britain. Copies of these bulletins are on file in The Institute library. The following suggestions are largely based upon information contained in the Wartime Building Bulletins, particularly No. 10 "General Principles of Wartime Building."

## PLANNING

Certain buildings can be very easily detected from the air. This may result from the location of such buildings or from their design. For example, buildings should not be placed in close proximity to well-defined topographical features such as lakes or the junctions of railways or main roads. The film "Target for To-Night" provided an illustration of these points. The layout of the buildings and site should be such that a regular arrangement of buildings and roads is avoided, and the natural surface of the ground is disturbed as little as possible. Distinctive features such as traffic circles should also be avoided; road surfaces should be dark in colour; and it is desirable that hedges be planted alongside roads. The best orientation for buildings is with the longest side running east and west.

High buildings are more easily detected from the air than low buildings, and any buildings having inclined roof glazing are particularly difficult to camouflage. Thus the ordinary saw-tooth roof building should be avoided and it is fortunate that this type has never been as popular in Canada as elsewhere owing to problems resulting from the accumulation of snow in the valleys. On the other hand, flat roofs should have a sufficient slope to ensure a rapid run-off of rain water so as to avoid reflections.

## CONSTRUCTION

The precautions mentioned in the preceding paragraph are aimed at preventing the detection of the building from the air. In spite of all precautions a factory may be located by the enemy and bombs dropped in its vicinity. Its vulnerability will then depend greatly upon the construction.

Damage from bombs may result from a direct hit, from blast, or indirectly from fire. The following remarks refer chiefly to the effects of these on single storey factories.

With regard to direct hits, the British authorities state that "it is possible without extravagance to design a sin-

gle storey factory in which extensive collapse of the roof is unlikely, even under a direct hit from a very heavy bomb." This is accomplished by building the structure with a considerable degree of continuity. Thus, for example, steel roof trusses should not rest on masonry bearing walls but should be strongly connected to steel columns so as to produce a fully framed structure. Other things being equal, a building with closely spaced columns may be more vulnerable than one in which the columns are further apart since two or more adjacent columns may be destroyed by a single bomb. Particular care should be taken to prevent the collapse of a whole series of roof trusses through the collapse of one. This can be accomplished by providing suitable continuous beams or trusses at right angles to the planes containing the roof trusses. In general, design to limit damage from direct hits has many things in common with the design of earthquake resisting structures.

It has been shown quite clearly that the effect of blast is greatly increased if the explosion is confined in a small space. Thus when a bomb explodes in a building there is a considerable increase in pressure for a very short period of time and the impulsive forces thus created will shatter windows and possibly push out the walls and lift the roof.

Inclined roof glazing is bad from the point of view of vulnerability, as well as detection, since when the glass is shattered, the arrangement of temporary protection against weather and of blackout measures may be a matter of some difficulty. In fact it will be considerably more difficult to arrange blackout precautions in the first instance. On the other hand it has been pointed out that vertical glazing in walls, if close to the ground, is particularly liable to damage from near, or not so near, misses. Thus it is desirable that walls should have no window openings closer than say five or six feet to the ground and that the walls up to this height should be of sufficient thickness to provide protection against splinters. Such walls should not be anchored to the columns since they can then be blown out without causing collapse of the whole structure. On the other hand, the roof should be securely anchored down. The necessity for adequate roof anchorage against wind loads has been generally recognized since the Florida and New England hurricanes and the use of such anchorage will assist greatly in preventing the displacement of roofs by blast.

The British authorities state that the need for fire protection has been clearly shown. It is stated that for every ton of steel rendered unusable by the direct action of bombs ten tons have been destroyed by fire. Consequently it is strongly recommended that all steel be protected against fire. The amount of protection required in any particular case will depend upon the amount of combustible material in the building. In a great many instances, protection sufficient to provide a fire resistance of one hour, as determined by standard test, will be adequate. In some cases even one half-hour protection may be sufficient to prevent collapse. Many modern building codes include description of such protections. The British authorities refer to the use of sprayed asbestos and sprayed "slag wool" (rock wool and gypsum), in addition to the protections more commonly used; these processes would appear to be worth consideration in Canada.

Limitation of damage by fire is not merely a matter of protection of structural members, though such protection will go far in preventing structural collapse; all fire prevention methods which have proved to be valuable in

the past should be carefully considered. Such methods include the provision of adequate water supplies for fire-fighting, the use of automatic detecting and extinguishing systems, and the use of self-closing fire doors and other barriers to the spread of fire. In these matters the various associations of insurance underwriters can give expert advice. Occasionally wartime requirements differ from ordinary fire protection measures. Thus it has already been pointed out that the subdivision of floor space into comparatively small areas is considered undesirable, since the effect of blast may thereby be increased.

The protection of personnel comes under the general subject of civilian defence but there are one or two matters to which the attention of architects and engineers may be directed. The provision of proper exit facilities is of great importance. Since the primary exit may be blocked it is particularly important that a second exit be available from every floor area. Low walls three or four feet high, subdividing floor areas, are a useful means of protecting personnel and machinery from splinters and from the effects of blast. They will not confine the blast sufficiently to increase general structural damage.

## ANNUAL REPORT FOR 1941 TO THE ENGINEERS' COUNCIL FOR PROFESSIONAL DEVELOPMENT

ROBERT E. DOHERTY  
*Chairman of the Council*

Presented at the Annual Meeting of the Engineers' Council for Professional Development,  
at New York, U.S.A., on October 30th, 1941.

Before reporting specifically regarding the work of the Council I wish to make a few general observations. In the first place, it has seemed clear that before E.C.P.D. could accelerate its progress toward the objectives stated in the Charter it was essential that not only the officers and boards but also the rank and file of the constituent organizations understand much more fully than they have in the past what these objectives are and the importance of their achievement to the welfare of the country. An astonishing number of people, including some comparatively close to the work, have felt that the most important activity and the only significant achievement of E.C.P.D. have been in connection with the accrediting program. Yet the Charter clearly indicates other purposes and activities—relating to selection and guidance, professional training, professional recognition—and these are also actively pursued by standing committees. And from the point of view of further advancement of the profession, and more important still, the welfare of the country, these other purposes and activities are, in the long run, unquestionably of equal importance with accrediting. Good students are not less essential than good schools. Hence, at the beginning of the year I strongly urged an educational campaign among the constituent organizations as one of the most important projects the Council could undertake. And I am confident that as the constructive purposes and results of the Council's work become clear, all constituent bodies will appraise the situation as it exists today, forget misunderstandings of the past, and see their way clear to support the Council's work.

The chairman's views regarding this matter, after discussion in Executive Committee meetings, were presented in a report to the several boards of the constituent groups under the heading "E.C.P.D. Should Look Ahead." This report has been made available to the membership of several of the constituent organizations by publication in their respective journals<sup>1</sup>. It urged that, in the interest of national welfare as well as professional development, the organizations cultivate more effective methods of co-operation than they have had in the past.

The machinery for the cultivation of such co-operation exists in E.C.P.D. The projects represented by its standing committees and by other objectives *having to do with professional development* afford a basis on which the organizations can work together. But the effectiveness of this co-operation will depend, in my opinion, altogether upon the effectiveness of plans devised by the Council to make use of the machinery wisely set up by the sever-

al participating bodies when the Council was organized. These plans must, it seems to me, include a more active participation than in the past by the representatives of the constituent bodies; and to accomplish this, there naturally must be a definite and a constructive program in which they can find an active interest. It is hardly to be expected that each of twenty-four different delegates will, on his own responsibility, think out what his organization should do toward E.C.P.D. objectives or what E.C.P.D. might do to further them. Hence the officers and Committee chairmen of the Council must work with the delegates to formulate plans and procedures. Fostering co-operative effort has thus become one of our definite plans.

And finally, I would say a general word regarding financial responsibility for supporting the work of the Committee on Engineering Schools. From the beginning it has been the policy, and still is, that an engineering school should pay for the expense of the initial inspection to determine whether a curriculum should be accredited. Although all of the colleges have accepted this policy (some, however, under protest), there is nevertheless another side of the inspection plan on which the policy has not been so clear or so widely accepted. This relates to the question who should pay for *re-inspection* of curricula that have already been added to the accredited list. A number of the colleges are unalterably opposed to the principle that they should pay this *re-inspection* fee, and this opposition has made it extremely difficult for the officers of E.C.P.D. who administer the accrediting program. Hence this became a major question of policy. On the one side, such engineering colleges take the position that the E.C.P.D. and other accrediting agencies constitute an intolerable burden and nuisance in view of the combined expense in money and time of staff spent in preparing questionnaires and in looking after visiting delegations of inspection; that they were not responsible for the proposal to start the accrediting program in the first place, but rather it was the state boards and professional societies that wanted it; and that they now make sizeable contributions toward the program through the time their faculty members and their official staff take from academic work in order to carry out E.C.P.D. committee assignments in connection with inspection programs at other institutions and the preparation of reports for E.C.P.D. On the other hand, the argument is proposed by some representatives of the constituent organizations that the accrediting program is valuable to the colleges both on account of the advice and counsel that may come to them as a result of the inspection and *re-inspection* and

<sup>1</sup> *The Engineering Journal*, September 1941, p. 446.

through having their names appear on the accredited list. This matter was a question of extended debate at two meetings of the Executive Committee, since a decision to remove the burden of *re-inspection* fee from the colleges would make an additional appropriation necessary from the constituent organizations. As indicated in detail under finances, the decision of the Committee was in favor of relieving the colleges of this burden, and of asking the constituent organizations for increased appropriations.

#### NEW CHARTER FOR ENGINEERING EDUCATION

Engineering education in this country now has a charter to guide its development. In 1939 a special committee of the Society for the Promotion of Engineering Education undertook the statement of an educational philosophy and the formulation of definite objectives that might serve as the basis for the design of programs in engineering education. After extended work by the committee, representing a wide spread of points of view, the S.P.E.E. issued the report "Aims and Scope of Engineering Curricula."

In view of the fact that the recommendations of this report naturally had definite relationship to the question of accrediting, the report was submitted to the Engineers' Council for Professional Development at the October, 1940 meeting, at which President Donald B. Prentice of the S.P.E.E. made a statement regarding this relationship to the Council's work. The Council of course referred the matter to the Committee on Engineering Schools, and I am happy to note in the report of Chairman Potter of this Committee that the provisions in the S.P.E.E. document have been endorsed by this Committee.

For its educational leadership and the contribution thus made toward professional development by the Society for the Promotion of Engineering Education, the E.C.P.D. should be most grateful, and I here express such gratitude on behalf of the Council.

#### E.C.P.D. ACTIVITIES

The work of the several Committees is fully reported by the chairmen, but there are a few items that I also wish to mention.

In connection with Selection and Guidance, the Council was very appreciative of the proposal made by President Cullimore of Newark College of Engineering and sponsored by Dean Sackett's Committee. It related to a joint study of the E.C.P.D. and S.P.E.E. on "Aptitude Tests and Selective Devices" which have proved to be most effective in the selection of engineering students. The Council enthusiastically approved the project, which it was estimated would cost \$4,500, and expressed its gratitude to President Cullimore for his interest and his willingness to find the funds to finance the project.

Another item is the pamphlet "Engineering as a Career." After protracted study and repeated revisions, Chairman Sackett of the Committee on Selection and Guidance presented it in manuscript to the Council meeting in October, 1940. The Council expressed its gratitude to Dean Sackett for his untiring work in this connection and approved the manuscript for publication provided funds could be obtained for the purpose, and subject to review and approval by the Committee on Information. There was available from the sale of the old pamphlet a balance of approximately \$2,000, which was about one-half of the amount required for publication of a new pamphlet. The Chairman of E.C.P.D. explored without avail every possible source of financial assistance that had been suggested. Hence the only recourse seemed to be a revision of the pamphlet which would reduce its volume and expense to a level that could be financed by the funds that were available. This problem was reviewed by the Committee on Information, and its proposal to undertake the revision was later reviewed and approved by the Ex-

ecutive Committee, the revised manuscript subject to approval by the Executive Committee. The revision will be ready for review and approval at the October, 1941 meeting of the Executive Committee. It is to be hoped that the new pamphlet will promptly make its appearance after the October meeting, because there is great demand—about 10,000 copies per year—and the stock of the old pamphlet is exhausted.

The major effort of the Committee on Engineering Schools has of course been in connection with the accrediting program. The statesmanlike manner in which the numerous difficult problems of the Committee have been handled by Dean Potter and his colleagues has greatly enhanced the prestige of E.C.P.D. Dean Potter's second term on the Committee on Engineering Schools expires this year, and it is with sincere regret that the Council will lose his distinguished leadership. Needless to say, his contributions toward the work of E.C.P.D. were not confined alone to the activities of the Committee on Engineering Schools but spread over the whole program, including an extremely important role in connection with the financial support of the Council's work. And for all of this, I speak the gratitude of his colleagues on the Council.

The Committee on Professional Training also will lose the leadership of its present chairman. Mr. S. D. Kirkpatrick, who was vice-chairman during 1939-40 and chairman during the current year, will be obliged to give up the chairmanship next year on account of his accepting the honor and new responsibility of the presidency of the American Institute of Chemical Engineers. During his first term as a member and later as vice-chairman of the Committee on Professional Training, he had made important contributions to the Council's work, and in his brief term as chairman of the Committee he has carried forward the program with the same characteristic thought and vigor. We are grateful to him and reluctantly give him up to the leadership of his own profession.

Of all the problems with which E.C.P.D. has dealt, professional recognition has proved the most perplexing. The difficulty lies primarily and inherently in the fact that the profession of engineering is itself in a state of evolution and hence there has not yet been evolved a definite concept that would receive general acceptance as to what constitutes the profession. Without this, there is little promise of arriving at a consensus as to criteria of professional recognition. The persistent and unremitting work of Professor C. F. Scott, chairman of the Committee on Professional Recognition, is, I believe, bringing a gradual clarification of the elemental considerations that must be dealt with before a satisfactory solution of the problem can be achieved. With certain *de facto* forms of recognition in different areas and with slowly crystallizing concepts of what the profession is, Professor Scott and his Committee aim first to secure clarification of thought and views, recognizing that the reconciliation or adjustment of fundamentally different concepts calls not for precipitous action but for continuing long-range study and pursuit. Following E.C.P.D. methods it begins with youth, concentrating on the engineering student by aiming to arouse his interest in understanding the engineering profession and "Professional Recognition"—the goal he seeks. The Committee observes that the immediate objective of E.C.P.D.—"the development of the young engineer to professional standing"—concerns the individual; but its culminating aim—"greater effectiveness in dealing with technical, social, and economic problems"—calls for group action, a profession. The young engineer is but partially developed if he lacks the capability and the attitude for group action in a profession.

The work of the Committee on Ethics was inherited from the American Engineering Council when the latter dissolved. At its meeting in January, 1941, the Executive

Committee voted to take over the sponsorship of this work, and the Committee on Ethics under the chairmanship of Professor D. C. Jackson, and with a few additional members appointed by the Council, has continued the study and preparation of a code of ethics. The Committee has made a progress report including a preliminary tentative draft. I strongly recommend that the Council request the Committee to continue its study and look forward to having a final report at the Annual Meeting in 1942.

The educational campaign, to which I have already referred, is another Council activity that I wish to touch more specifically. There have been three lines. One was the Chairman's report to the Boards, "E.C.P.D. Should Look Ahead," which gave not only the Chairman's view as to the opportunities and responsibilities that lie before E.C.P.D. but also a brief report of the active work of the several committees. The second was the plan of the Committee on Information to prepare for the press, especially for the publications reaching members of the engineering profession, informative releases regarding the work of the Council. And finally a plan was made to encourage sessions at meetings of the constituent organizations at which the work of E.C.P.D. would be presented and discussed. There have been two such meetings and two more are scheduled, as reported by Professor Scott, chairman of the Committee on Professional Recognition, who has taken a leading interest in this plan.

In this latter connection, a report from Mr. J. F. Fairman, an American Institute of Electrical Engineers representative on the Council, includes an idea which I think is highly significant. It is that the way to achieve understanding of and active interest in the purposes of E.C.P.D. by the members of the constituent organizations is to have the local chapters take an active hand; and that the way to bring this about is to have the whole matter, including a plan, discussed at the regular Session of Officers, Delegates, and Members at the A.I.E.E. annual convention. These are the people responsible for section activities, and if they understand the plan and are convinced, something will come of it when they go back home. It is the conclusion of Mr. Fairman and his associates that the most likely of the Council's problems about which the local Sections might become active is that of Selection and Guidance. Their work might be patterned along the lines of the procedure already developed in certain metropolitan areas in connection with the work of the Committee on Selection and Guidance. Once this was under way, a second step taken by a section might be in relation to the work of the Committee on Professional Training in helping young graduates to become appropriately oriented and active in their own professional development. And so on. This general point of view and plan seem to me most promising, and the fact that the A.I.E.E., through the leadership of Mr. Fairman and his associates, is proceeding along these lines is most encouraging.

#### TECHNICAL INSTITUTES

The relationship of technical institutes to the whole scheme of technological education in this country has been a matter of continuing concern to the Council. In his annual report last year Chairman Perry outlined the beginning of active consideration of this problem under the sponsorship of E.C.P.D. President Parke Rexford Kolbe of Drexel Institute of Technology and Dean H. P. Hammond of Pennsylvania State College have undertaken the leadership in this important and difficult matter. President Kolbe called a meeting of officers of a number of technical institutes, and as a result a petition was submitted to E.C.P.D. that it consider the problem of accrediting of technical institutes. This was referred by

Chairman Perry to the Committee on Engineering Schools, but after consideration it became clear in this Committee that the question was too involved to allow a prompt decision to be reached; it was then recommended that a sub-committee including President Kolbe be appointed to continue study of the problem, and this was done.

#### CONSTITUENT MEMBERSHIP

Since the organization of E.C.P.D. the question has arisen from time to time as to whether the constituent membership should be increased. As reported by Chairman Perry last year, The Engineering Institute of Canada was welcomed as a new member of the Council, and this was done through the unanimous decision of the existing member organizations to recognize the common purposes and interests of engineers of the two great countries in connection with professional development. The international aspect of this move placed it in an altogether special category as regards institutional membership. There have been other problems in connection with engineering organizations in the United States, but the Council has not yet found it possible to dispose finally of the question of general policy here involved.

#### FINANCES

E.C.P.D. is solvent, but the financial situation is certainly not all that might be desired. As one indication of the limitations on its work I would mention that the funds available to the standing committees, excepting the Committee on Engineering Schools, for the important work they are expected to pursue, are limited in each case within the range of \$300 to \$600. One of the immediate problems before the Council is the provision of something approaching a reasonable appropriation in these cases.

The financing of the work of the Committee on Engineering Schools has had special aspects, as I have indicated earlier in this report. The problem of policy as to whether engineering schools should be assessed for re-inspection of curricula was determined by the Executive Committee at its meeting in March: the schools were not to be assessed. Accordingly, constituent bodies were approached by the Chairman with the request that they increase their appropriations to the work of the Council in order that this policy might be carried out. I am gratified to report that the American Institute of Electrical Engineers, the American Society of Mechanical Engineers, and the American Institute of Chemical Engineers have doubled their appropriations, and that the American Society of Civil Engineers will act upon our request in December. Thus it seems clear that we shall be able to carry out the policy adopted by the Executive Committee, and I express the Council's gratitude to the organizations that are making this possible.

I would report one further action of the Executive Committee. After considerable deliberation as to responsibility for the securing of funds for the Council's work, the Executive Committee decided for the present year to expand the Ways and Means Committee to include one representative from each of the constituent groups. In the absence of any action by the Ways and Means Committee, the Chairman of E.C.P.D., with such assistance as he could find—and he found good assistance—has taken the initiative in raising funds, and he is very grateful to Messrs. Potter, Seabury, Fairman, Davies, Stevenson, Tyler, and Dodge.

I close this report with an expression of my great appreciation of the co-operative attitude and interest of the officers, committees, and members of the Council, and I feel sure that their work during the year has given new impetus to the Council's programs at a time when, for the welfare of the country, this is most important.

# Abstracts of Current Literature

## BRITAIN SCRAPS WHOLE RAILWAY

From Robert Williamson, London, Eng.

Britain is throwing a whole railway into the mobilization of iron and steel for the war. Although it is an old railway, its rails alone will add to the resources of Britain enough steel for no fewer than 384,000 rifles.

Until 1937 the trains of the Welsh Highland Railway chugged over some of the loveliest scenery in the Principality. But in that year it ceased to function and the grass began to grow along its 28 miles of permanent way.

Now the rails, which are modern, are being taken up, 1,200 tons of them. They will be relaid elsewhere on sidings needed for the war effort, so setting free steel-making capacity for armament manufacture.

The two old locomotives are for the dismantler's yard and metal from the rolling stock is for the same destination.

The railway is but an item in a nation-wide hunt for metal to turn into rifles, Tommy guns and tanks, into armour plate for battleships and armoured coastal defences.

A Doomsday Book of park, street and house railings, of ancient steam rollers, engines and boiler-house plant is being prepared and already on walls bills have been posted proclaiming the Government's requisitioning of them. Among the first to respond has been the King himself with many tons of the railings of Buckingham Palace for the collection.

## ALUMINIUM AFTER THE WAR

From *Trade & Engineering* (LONDON), OCTOBER, 1941.

The cessation of hostilities will release, for more peaceful purposes, vast quantities of aluminium and its alloys. Doubt has been expressed in many quarters as to whether the war-time output of the metal can, without artificial stimulus, be absorbed in times of peace, but those familiar with the trends of aluminium consumption before the war entertain no doubt but that the demand for light-weight products will be sufficient to absorb even the present large output.

In one field in particular, that of architecture, both structural and decorative, there will undoubtedly be a considerable increase in aluminium consumption over that experienced up to the outbreak of war. The experience which has been gained in forming or building up large components for the great aircraft and flying-boats now in use will be of direct value to architects and constructional engineers. Another factor which will contribute largely to the use of aluminium in building construction is the reduction in costs of handling and in the fatigue of personnel which is a result of the low weight of the material.

The high coefficient of thermal expansion of the metal has on occasion been advanced as an argument against its employment in large structures, but this can be readily overcome, as it has been in the past, by making the necessary provisions for expansion and contraction. When extruded sections are used it is possible to accomplish this by means of slip joints at junctions of the members, but where solid lengths or cast aluminium spandrels are placed between masonry jambs plastic caulking material will be necessary at the joints.

Many factors are likely to contribute to the extended use of aluminium. First must rank the fact that a substantial reduction in price will be effected immediately

## Abstracts of articles appearing in the current technical periodicals

war-time restrictions regarding price control are removed. This must inevitably follow as a natural consequence of the vast expansion of aluminium production and the rationalization which has occurred with regard to the economic use of the large supplies of high-quality scrap now available.

Improvements in technique resulting from the war-time programme of aircraft construction will also be potent factors in increasing consumption of aluminium for architectural purposes. In particular the advances made in extrusion technique, especially with regard to the production of bulky sections in long lengths, will prove to be of importance. Casting techniques have also been improved, particularly with regard to the production of gravity and pressure die castings. These processes are naturally of value in cases where large quantity production is contemplated. The machining of aluminium alloys has also been intensively investigated, particularly in connection with the use of recently developed hard metal and diamond tools.

## AMERICAN WAR INDUSTRY

From *Civil Engineering and Public Works Review* (LONDON), NOVEMBER, 1941

The rapid expansion of the American war effort in the factories is being reflected in the vast increase of the production of various component parts. The number of factories is being rapidly increased and the existing ones are being extended as rapidly as human ingenuity and labour can devise.

Few branches of the war industry have shown a greater degree of expansion than the manufacture of aeroplanes. This is well seen in the rapid development of the aluminium production industry, particularly of one company, the Aluminium Company of America. This company is fast bringing to completion the expansions of its plants at Los Angeles, California, and at Lafayette, Indiana.

In 1937, in order to serve the aeroplane industry more effectively, the company bought 15 acres of land in Vernon, Los Angeles, and erected on it a sand and permanent-mould foundry and forge plant. The works was completed early in 1938. At the start of the war, the Vernon works had a capacity of 100,000 lb. of aluminium alloy forgings, and 424,000 lb. of sand and permanent-mould castings a month.

In the spring of 1940, an expansion of the facilities in Vernon was announced. This expansion included the addition of an extrusion works and a rivet plant, as well as additions and betterments to the existing aluminium foundry and forge plant. To carry on this expansion, the company acquired an adjacent 30 acres of land.

The buildings necessary to house the additional manufacturing facilities in Los Angeles have now been completed and the equipment is rapidly being installed to handle the increased production, so that very shortly the sand and permanent-mould casting capacity will have been increased to 593,000 lb. a month (an increase of 40 per cent.), and the forging capacity to 450,000 lb. a month (an increase of 350 per cent.); while the new extrusion plant will be turning out extruded shapes at the rate of 1,019,000 lb. a month; and the new rivet plant, rivets at the rate of 70,000 lb. a month. By March, 1942, the forging capacity of the Vernon works will have been increased an additional 50,000 lb. a month.

## STRONG AS CAST IRON

From Robert Williamson, London, Eng.

After two years' continuous research, Great Britain is today able to introduce pottery into many new fields of British industry to take the place of metals, alloys, glass, rubber and wood, on the use of which restrictions have inevitably been placed in war time.

High grade chemical stoneware comparable with grey cast iron in mechanical strength can now be used in place of metal for pipe lines and also for packing purposes either in relatively small units or in bulk.

These novel ceramic wares have certain advantages over the materials in former use. They resist rust and contamination; they can be turned into an almost unlimited number of shapes and sizes, and they are proof against all corrosive chemicals except hydrofluoric acid and hot, strong caustic alkalis.

The new pottery is, moreover, prepared with such scientific thoroughness and fired in the kilns at such a high temperature, 1250 deg. C. or more, that, in compression strength it resembles metals rather than the fragile china or earthenware ornaments of the home.

New applications of ceramic materials have also been introduced in recent months to textiles, rayon, paper-making, printing, soap, perfumery, cosmetics, brewing and food manufacture industries and to many branches of the chemical, metallurgical and electrical industries.

## THE AUTOMATIC DETECTION OF INCENDIARY BOMBS

From *Engineering* (LONDON), SEPTEMBER 5TH, 1941

A brief reference was made in the issue of *Engineering* for June 6 of this year, page 448, to the employment of the light-sensitive selenium cell, known as the Radiovisor, in the detection of incendiary bombs, but some data resulting from a recent investigation are sufficient to justify a more detailed account. The investigation was made to determine to what extent serious fires have occurred in factories from undetected incendiary bombs. In nearly every case the fire-watching organization was efficient in the factory concerned and was able to get every bomb in sight under control without difficulty, it being the undiscovered bombs which had fallen on roofs or in such places as closed yards which were responsible for the subsequent damage. It is stated that in over 70 per cent. of the cases investigated the persons responsible for the safety of the factory stated that their organization would have been quite capable of getting all the fires under control had they known their whereabouts precisely. This does not imply that the patrolling was not efficient; the obvious reaction to an incendiary bomb attack is to put out those bombs, or the fires they may be starting, which are in the immediate vicinity of the patrols. It is possible, moreover, that some of these bombs may fall in positions in which they will do no damage and may thus be left for later attention or perhaps even left to burn themselves out. In the meantime a bomb on, say a roof, may escape notice until a fire difficult to control has been caused.

The primary requirement is, clearly, the indication of the location of every bomb and the grouping of the indications in a central position. This enables the persons in charge at the central position to send fire-fighting squads to the exact spot at which the bomb has fallen and, if the attack is heavy, to distribute these squads to the positions involving a heavy fire-risk; first, for example, to paint stores, pattern shops and woodworking shops, that is, assuming the personnel is not sufficient to deal with all the fires at once. The bombs which fall in localities involving little fire risk, such as yards, brick buildings containing stored metal and the like, should there be a shortage of personnel, may

be dealt with subsequently. The locating of all bomb sites should be accompanied by means for discrimination, should such discrimination be necessary. The system of detection by the selenium cell referred to in our previous note would seem to meet these requirements. It has, indeed, proved effective in factories in which it has already been installed. This system has been developed, as indicated in the previous note, by Messrs. Mortimer, Gall and Company, Limited, 115-117, Cannon-street, London, E.C.4.

In practice, the selenium detectors are installed in the works in positions which appear to be most suitable. Each detector will cover an area ranging from 8,000 sq. ft. to 10,000 sq. ft. of open workshop. Usually some are installed inside and some outside. A common and effective position for the outside detectors is on the ridges of the saw-tooth or north-light roof often adopted for shops of considerable area. A detector is not needed on every ridge, but on alternate ones only, as the valleys of the ridge without a detector are effectively covered by the detectors on the ridges on each side of it. The valleys of such roofs are particularly dangerous spots, since the roof purlins, when of wood, are easily ignited from bombs. The gutters into which a bomb might roll are best protected by a covering of expanded metal. The detectors are easily attached and on some sites on roofs are protected by a small canopy so that they will not respond to, say, a gunflash and so give a false alarm.

There is a set of electrical apparatus for each selenium detector, the wiring between the two usually carrying current at 50 volts. The supply to the apparatus may be at 100 volts, 200 volts, or 250 volts, and may be either alternating current or direct current. The terminals to which the detector is connected are seen at the bottom left-hand corner of the case. Above them is a sensitivity control knob, and to the right a reset switch. The other terminals are for the bell and indicator leads. An earthing terminal is provided. The electrical apparatus includes transformers. The current for the detector has already been mentioned; that for the bell and indicator circuit is supplied from an independent battery and varies from 4 volts to 24 volts, according to the lay-out. The electrical cases can be arranged in groups of three or four in any convenient place in the shops. The indicator panel and alarm bell are situated in the room of the works A.R.P. controller. Each dial of the indicator is labelled in accordance with the position of the detector actuating it, and the panels have generally a much larger number of windows than the demonstration set shown.

In the event of a number of incendiary bombs falling on a works, more than one of the detectors will most probably be actuated, when the warning bell will ring and the discs in the appropriate windows of the indicator will oscillate to show near which detector stations the bombs are lying. The vulnerability of the sections concerned can be immediately assessed and the fire-parties allocated accordingly. The allocation of men is, of course, a matter for the works concerned, but it may be of interest to cite an example in a works in which the selenium-cell detection system is fitted. In this works the controller is provided with a tabulated list of departments showing the minimum number of men that should be dispatched to that department in case an incendiary bomb should fall in it. The actual list is in the following form: pattern shop, 3 men; paint shop, 4 men; office block (west), 6 men; office block (east), 4 men; loading bank, 1 man, and so on. The problem of the undiscovered delayed-action incendiary bomb is also solved by the system above described.

An interesting development concerns the security of special offices and rooms to which access is permissible in cases of emergency only. This consists of a box attached to the door of the room and having a slot into which the door key is dropped when the door has been locked. The key remains inaccessible, but when normal access is required it can be caused to fall out into a tray at the front of the box by the operation of a switch on the control room. In an

emergency, as when incendiary bombs fall, it is delivered automatically, since the actuating mechanism is connected with the detector system.

## GATEWAY TO MIDDLE EAST

From Robert Williamson, London, England

The Turkish Government have given London engineers a contract, worth some £200,000, to reconstruct harbour works at Alexandretta, consisting of a jetty with screwed-cylinder foundation, sheds, railway lines and cranes.

It is understood that a similar contract is pending for the port of Mersin across the gulf, the base of a Turkish army corps. Both Alexandretta and Mersin are connected by rail with Aleppo. The fact that they are so near this vital railway link between Turkey and Iraq, dominating North Persia and the Middle East, gives both ports considerable military importance, apart from their value at the moment for trade between Turkey and Great Britain.

Alexandretta has 8,000 sq. metres of covered warehouses, but there are no quays or dry docks. The harbour is not protected by breakwaters, although it is sheltered and gives the safest anchorage all the year round in that part of the world. Ships anchored half a mile from the shore discharge their cargoes into lighters and other small craft for which there is a basin 80 ft. long.

## THE DESERT AND THE SOWN

From *Civil Engineering and Public Works Review* (LONDON),  
NOVEMBER, 1941

This aspect of the work of the engineer is of the greatest political and economic importance. Over vast regions of the surface of the globe there stretches desert conditions which render the human occupation of hundreds of thousands of square miles quite impossible. A glance at a map of the world shows that these arid places tend to girdle the earth as two zones lying just north and south of the humid equatorial regions. To the north and to the south lie the temperate zones of the earth, which have been the sites of human expansion and progress.

As the growth of population has produced an expanding need to bring fresh land under cultivation for the growth of an ever-increasing demand for foodstuff, there has been a tendency for the peoples of the humid, well-watered areas to spread towards the less well-watered arid regions. The advance into these areas has been spasmodic and has fluctuated according to the needs of the time.

No modern country illustrates to a greater degree this tendency than the United States. Every year sees the completion of one or more vast schemes for bringing the life-giving water to some arid area and so enabling man to encroach more and more into what would otherwise be inhospitable and uninhabitable lands.

This modern struggle to invade and occupy the desert fringes is no new phenomenon. Each year brings forth fresh evidence of the antiquity of this struggle.

Of ancient endeavours in this direction there is none more fascinating than that which took place over 2,500 years ago in the ancient land of Sheba.

To the layman the present-day engineering works for the conservation of water and its distribution to the desert lands seems a modern engineering triumph. Through the ages the engineer has played his part in the struggle for human expansion and betterment. Few sections of any community have made so great a contribution to human progress as the civil engineer.

Recent exploration work in the ancient land of Sheba, the modern Yemen, has disclosed the great part played by the civil engineer, though doubtless he was not known by that name in those days, in the development of the ancient Sabaeen Kingdom of South-West Arabia.

For long it has been a matter of speculation as to how so virile and energetic a people maintained and supported life in so inhospitable a region.

Najran, Marib and Janf were the most important centres of ancient Sabaeen culture. Najran has been described as the most beautiful oasis of Arabia, situated in a great valley of extensive palm groves. Just above the oasis the valley debouches in a great basin, from which escape its flood waters through a narrow straits between sheer walls barely 20 feet wide. Here in ancient times there was a dam, the marks of which still survive. The dam was apparently only 12 feet high, and at this height channels were cut on either side to take the impounded water when it rose to that level at the dam. The dam has been calculated to have had a capacity of 100,000,000 gallons of water.

Anything above this amount would have flowed out by the side canals. In the dry season the sluices of the dam could have been opened to allow the water to flow into the irrigation channels.

The other areas of irrigation in this Sabaeen area show remarkable skill in the conservation and distribution of water and are enduring monuments to the skill of these ancient engineers.

The importance of these ancient works is shown by the interpretation of certain inscriptions dating back to the 7th century B.C. These relate that on the first occasion when the great dam of Marib was destroyed—whether by seismic disturbance or the legendary rat which is supposed to have made a hole through it, they do not say—it was repaired; and for this purpose the Sabaeen ruler of that date mobilised all the people as if they were going to war and by their united effort repaired the damage. The inscription records some interesting details with regard to the number of oxen and the number of loads of dates and honey consumed on that occasion.

Truly man's struggle to improve his lot and increase his heritage goes far back into ancient history, and in that struggle the engineer and his skill have played their part.

## BLUEPRINTS GO WHITE

From our London Correspondent, Robert Williamson

The engineer's prints without which Britain could not produce a single battleship, tank, or aeroplane or even the smallest nut or bolt, are changing their colour. The traditional "blueprint" is gradually being replaced by papers giving diagrams in black, blue or brown on white instead of white diagrams on blue.

The new prints, made by the dyeline process, are positive instead of negative. They can not only be produced much more quickly and in a smaller space but they give a clearer background and a stronger line less subject to fading, so helping the thousands of women and other inexperienced recruits in war production. Moreover, the paper does not shrink, as does the "blueprint" or ferro paper, and the designs are therefore more true to scale, another advantage to the semi-skilled. A valuable feature is that the surface is particularly suitable for receiving ink lines or colour tints.

Dyeline prints are produced by two processes. In one, the dry process, the developer is incorporated in the paper itself, and when this is run over a light with the original tracing and subjected to ammonia gas, the drawings appear on the blank sheet as if by magic. In the other, the semi-dry process, a special solution is spread, by means of a simple machine, over the surface of the print. Here again development is instantaneous and the prints dry in a few seconds.

Dyeline papers have been manufactured in Britain for some years past, and in one London works the chemists have been experimenting continuously with them for the past fifteen years.

## RUSSIA'S AIR FORCE

From Robert Williamson, London, Eng.

When the German propaganda spokesmen loudly asserted at the start of the Russian campaign that the war would be won by 11th August on the Eastern Front, they gave public proof that they were guilty of several major miscalculations. And chief among them was their under-estimation of Russia's Air Force.

For years, the belief had been cleverly fostered abroad that the Soviet warplanes were, at best, semi-obsolete in type and poorly manned. But behind the veil of secrecy flung round the preparations for defence against the program so frankly outlined in "Mein Kampf" Stalin was building up an air force that gave the Luftwaffe the greatest shock it has known since the Battle of Britain.

Russia's fighters include six different types in her first line strength, five being single-seat and one, the "1 19 (X)", a two-seater. It is this last-named machine which played so notable a part in maintaining the stubborn resistance that amazed the world, for not only has the "1 19 (X)" great manoeuvrability allied to high speed, it is so heavily armed that the second member of the crew acts almost solely as a gun-loader.

This machine, like all others in the "1" class, is of Russian design and is the product of the Soviets' "number one" designer, H. N. Polikarpoff. With a ceiling of approximately 40,000 ft. and a reputed top speed in excess of 400 m.p.h., it is one of the finest fighters in the world. Indeed, the Russians themselves think so highly of it that it has been in full production in dozens of State aircraft factories for over a year.

A newcomer to this group is the MIG.3, which corresponds in design and performance with Britain's Hurricanes and Spitfires. In revealing the existence of this model, previously unknown to the German Air Staff, Lord Beaverbrook, broadcasting on his return from Moscow, has characterised it as more than a match for the Messerschmitt.

### BOMBERS CARRY 4-TON LOAD 3,000 MILES

Prominent in the news lately is a new Russian bomber, unknown to the world until mentioned in Lord Beaverbrook's broadcast. This is the Stormovik, a dive-bomber incorporating features of the Spitfire and ME109. It has proved an outstanding success in attacking troop concentrations and breaking up enemy formations.

The astute policy of hiding from the world the development of the Soviet Air Force was incidentally assisted by the fact that Russia's bombers were entirely designed by her own aeronautical engineers. In fact, of the ten standard bomber and two dive-bomber types employed, only two have been at all influenced constructionally by foreign machines. These are the "CKB 26," which is similar to the Martin, and the "TB3B" which is built on the principles of the Junkers.

Most of Russia's bomber types are designed for close co-operational work with her armies, but quite early on in the campaign two types specifically designed for long-range strategic bombing did much valuable work. Two long-range bombers of the "L" type in particular are machines of outstanding capabilities. They have a range of as many as 3,000 miles with a bomb load of almost four tons.

No nation at war will give figures of its first line strength, but even so, it is possible to arrive at an approximate figure based on pre-war reports.

A Russian Air Mission official, who visited England in the early days of the campaign, stated that the figure given by Marshal Voroshilov when he reported to the Central Committee of the U.S.S.R. in 1939 on Russia's first line strength, had been more than doubled since the war began. In his report, the Marshal stated that the total bomb load then carried on one flight was as high as 6,000 tons.

It may, therefore, be assumed that Russia entered the war with a 12,000-ton bomb load, which, allowing an average weight of two tons to every bomber, gives a figure of 6,000 first line bombers. Statistics derived from the same source gave Russia some three thousand first line fighters at the time of the Nazi invasion.

### SOVIET'S 1,100 PILOT SCHOOLS

Russia is fortunate in that all forms of raw materials required for aircraft construction can be found in her own country. And the fact that all her main aircraft factories were established beyond the range of Nazi bombers enable her to drive forward on the vital task of producing warplanes unhindered by day or night bombing.

Her aircraft production strength at the start of the war in the East is believed to have been actually higher than Germany's, and the Russians did all in their power to safeguard against any disruption. Thus, anti-aircraft units and day and night fighters were allotted the task of concentrating on the defence of her great aircraft factories.

Unlike many nations, Russia suffers from no bottleneck in the vitally important matter of output of flying personnel. In addition to her Air Force training schools, Russia established more than 1,100 pilot schools which young workers were encouraged to visit for free instruction.

Here they received a training equal to the passing-out standard of Britain's Royal Air Force Elementary Flying Training Schools. But in addition to these clubs there had existed for some time before the war a civilian training body known as *Ossviachim* numbering more than fifteen million members.

Indeed, so thorough was the national training scheme that every Russian pilot who went on active service when war started had done two hundred and fifty hours' flying.

# FIFTY-SIXTH ANNUAL GENERAL

## MONTREAL —

THURSDAY AND FRIDAY

R. S. EADIE  
Chairman of the Papers  
and Meetings Committee

GORDON D. HULME  
Chairman of the Hotel Arrangements  
and the Publicity Committee

W. MCG. GARDNER  
Chairman of the Reception  
and Registration Committee

K. G. CAMERON  
Chairman of the Plant Visits and  
Transportation Committee

WALTER G. HUNT  
General Chairman

### LADIES' PROGRAMME

A special programme of entertainment for the ladies is being arranged which includes a tea at the Montreal Badminton and Squash Club and a Bridge Party at the Engineers' Club. Visiting ladies will be the guests of the Branch at both luncheons.

### PROGRAMME

#### THURSDAY, FEBRUARY 5th

- 9.00 a.m.—Registration.  
10.00 a.m.—Annual Meeting and Address of Retiring President on the war work of the National Research Council.  
12.30 p.m.—Luncheon—Speaker: Hon. C. D. Howe, Hon. M.E.I.C., Minister of Munitions and Supply.  
2.30 p.m.—Professional Session.  
8.00 p.m.—Montreal Branch Annual Smoker.

#### FRIDAY, FEBRUARY 6th

- 9.30 a.m.—Professional Sessions.  
12.30 p.m.—Luncheon—Speaker: W. L. Batt, President, SKF Industries Inc., Philadelphia, Pa., and Director of Materials, Office of Production Management, Washington, D.C.  
2.30 p.m.—Professional Sessions.  
7.30 p.m.—Annual Banquet—Speaker: Leonard W. Brockington, K.C.  
10.30 p.m.—Dance.

Special return tickets will be supplied by the railways at the rate of one and a third of the regular on

# ND PROFESSIONAL MEETING

## WINDSOR HOTEL

BRUARY 5th AND 6th, 1942

**RALPH C. FLITTON**  
General Vice-Chairman and  
Chairman of the Programme Committee

### VISITS

Visits to war plants of the Mon-  
treal area are being arranged.

**I. S. PATTERSON**  
Chairman of the Special Arrangements  
Committee

### PAPERS

The Work of Research Enterprises Ltd., by Colonel  
W. E. Phillips, President, Research Enterprises  
Ltd., Toronto.

Manufacture of 25-Pounder Guns in Canada, by  
W. F. Drysdale, M.E.I.C., Director General of  
Industrial Planning, Department of Munitions  
and Supply, Ottawa.

The New "Oilraulic" Press in Munitions Manu-  
facture, by J. H. Maude, M.E.I.C., Chief  
Designer, Mining, Metals and Plastics Machin-  
ery Division, Dominion Engineering Co., Ltd.,  
Montreal.

Rational Column Analysis, by J. A. Van den  
Broek, Professor of Engineering Mechanics,  
University of Michigan, Ann Arbor, Mich.

Accident Prevention Methods and Results, by  
Wills Maclachlan, M.E.I.C., Secretary-Treas-  
urer and Engineer, Electrical Employers  
Association of Ontario, Toronto.

National Service—A Challenge to Engineers, by  
E. M. Little, Director, Wartime Bureau of  
Technical Personnel, Ottawa.

Some of the Engineering Implications of Civilian  
Defence, by Walter D. Binger, Commissioner  
of Borough Works, City of New York, and  
Chairman, National Technological Civil Pro-  
tection Committee of the United States.

**MRS. F. W. TAYLOR-BAILEY**  
Convener Ladies' Committee

**A. G. MOORE**  
Treasurer and Chairman of  
Finance Committee

**L. A. DUCHASTEL**  
Secretary

fare. Necessary certificates will be mailed shortly along with a programme of the entire meeting.

# From Month to Month

## PRESIDENT'S MESSAGE

A feature of each January number of *The Journal* is the New Year Message from the President. This year the message is more than usually significant. It should be read carefully by every engineer. It will be found on page three of this number.

## NEW BRUNSWICK AGREEMENT

The December Journal reported a successful ballot on the proposal for further co-operation between the Association of Professional Engineers of New Brunswick and The Engineering Institute of Canada. Since this, arrangements have been made for the ceremony of signing the agreement and the inauguration of its benefits.

The ceremony will take place in Saint John on the evening of January 12th. This corresponds with the annual meeting of the Association, and the combination of important events should draw an unusually large attendance. It is planned that the president and general secretary will sign on behalf of The Institute, and that other officers from Quebec and Ontario will also be present.

This becomes the fourth province in which the provincial body and The Institute have devised a working arrangement whereby the benefits of each will become more readily available to the other. Not only are the privileges increased, but the costs are decreased. The benefits of common membership are apparent to all, and beyond a doubt the profession of engineering has taken a step forward in New Brunswick by this latest decision.

The officers of The Institute look forward with great pleasure to this opportunity of working in close harmony with the officers and members of the Association, and see in this new agreement another and substantial step toward the long hoped-for complete co-operation between engineers throughout Canada.

## GREETINGS FROM ENGLAND

The general secretary, under instructions of Council, sent the following messages of greetings to the secretaries of the five leading British engineering institutions:

"The President and Council of The Engineering Institute of Canada have asked me to present, through you, the season's greetings to the President and other officers of your Institution.

"We appreciate that conditions in your country are far from ideal for the celebration of the holiday season, but are confident that in spite of them you will derive a good measure of Christmas cheer.

"It is our wish that the coming year will bring to the members of your great society strength and encouragement to fight the great fight and that at an early date a just reward may be yours. Our thoughts and our sympathies are with you."

Replies have been received in which all members of The Institute will be interested:

"The President and Council of the Institution of Civil Engineers much appreciate Christmas and New Year greetings received from Engineering Institute of Canada which are heartily reciprocated. Celebrations here will be in a more cheerful atmosphere than last year when air raids were a nightly feature. Furthermore present news instils a spirit of quiet optimism. Warm personal greetings to you from

GRAHAM CLARK, *Secretary*,  
Institution of Civil Engineers."

## News of the Institute and other Societies. Comments and Correspondence, Elections and Transfers

"Many thanks your cable conveying season's greetings to myself, the members of council and the Institution. Generally we much appreciate your kindly thought and heartily reciprocate your good wishes. With you we all hope that New Year will bring with it that reward of just peace for which all members of British Commonwealth and indeed all free peoples are working.

W. A. STADIER, *President*,  
Institution of Mechanical Engineers."

"President and Council much appreciate your kind and encouraging message. They heartily reciprocate your sentiments and pray that your Institute may grow from strength to strength.

W. K. BRASHER, *Secretary*,  
Institution of Electrical Engineers."

"President and Council of Royal Aeronautical Society wish me to thank you for your seasons greetings and to reciprocate them to all the officers and members of The Institute. They are acutely conscious of the great part Canada and Canadian engineers are playing to bring about a world peace. They wish me to add how much they appreciate the close friendship between the two engineering institutions and to hope that the time is not far distant when normal contacts can be resumed.

J. L. PRITCHARD, *Secretary*,  
The Royal Aeronautical Society."

"The President and Council of the Institution of Structural Engineers desire me to express through you their very grateful thanks to your President and all officers of your institution for the kindly thought which prompted the despatch of Christmas greetings and wishes of good cheer. We are immeasurably strengthened by the message of sympathy and support which you send. My President and Council transmit to you all their greetings for 1942 with the hope that the relations of the two institutions may be further cemented and that they may be found working side by side for the benefit of all free peoples during the period of reconstruction.

R. F. MAITLAND, *Secretary*,  
Institution of Structural Engineers."

## TO AVOID CONFUSION

In the December *Journal* attention was called to an organization operating under the name "Canadian Institute of Engineering Technology," pointing out that this was a "spurious" organization.

A letter has been received at Headquarters from the Canadian Institute of Science and Technology Limited, calling our attention to the similarity of names and requesting that we draw our readers' attention to the fact that they are in no way associated with the other organization. This we are glad to do. The Canadian Institute of Science and Technology Limited is a well established business operating as the Canadian Branch of the British Institute of Engineering Technology Limited. We hope that they do not suffer from the publicity which was necessarily given to the spurious outfit.

## REGISTRATION AT UNIVERSITIES

Herewith is shown the registration in engineering at all Canadian universities. This tabulation has been an interesting feature of the *Journal* for several years. The 1941 figures are somewhat different than previous years, but the variations do not seem to establish any particular trend.

At British Columbia, Toronto, Queen's and Ecole Polytechnique, the freshman registration is substantially increased, but at the other universities it is smaller. On the whole the total is 151 more than last year. There has been little change in the order of specialization. Chemical engineering continues to be the best patronized course but mechanical has gained substantially on it, and probably will continue to do so from now on.

## BRANCH CONTRIBUTIONS TO BUILDING FUND

It is with a great deal of satisfaction that the following statement of contributions is distributed to the membership. When President Hogg and President-Elect Mackenzie first requested the assistance of the branches in meeting the costs of repairs to the Headquarters building it was not thought that so substantial a sum would be realized.

All branches have done exceedingly well; but the work of the Montreal Branch committee has been particularly productive. The chairman, R. E. Heartz, and his committee set a high objective and they ran well beyond it. It is gratifying to know that the members were willing to support the cause to the extent of an average of \$5.00 per member, or a total of \$6,000.00.

A special message of appreciation is going from the president to each branch. It is hoped that every member will see this statement and realize the strength that lies in a group of the type of those who make up The Institute membership.

## DEAN BROWN RECEIVES HONORARY DEGREE

Ernest Brown, M.E.I.C., dean of engineering at McGill University, was given an honorary degree of Doctor of Engineering by the University of Toronto at a special convocation held in Convocation Hall, December 15th, 1941. Herewith is the citation read by Dr. Cody, president of the university, and Dean Brown's response:

### PRESIDENT CODY'S CITATION

Engineers have largely helped in the material development of Canada. They are of vital importance in the creation, adaptation and growth of our industries in the mechanized war of to-day. They are among the most constructive and useful of our citizens. The universities do well to recognize their services and to honour them for their amazing achievements. If engineers are to be praised, how much more the men who teach and train them!

In the field of engineering education in Canada, McGill University has for many years played a distinguished role. The University of Toronto with pleasure and high satisfaction wishes to-night to recognize this service of a great sister-institution, and at the same time to honour for his own sake, the Dean of its Faculty of Engineering.

Ernest Brown, who in his time was an 1851 Exhibition Scholar, graduated from University College, Liverpool, with the degrees of Master of Science and Master of Engineering. Following some years of service as a Lecturer in Engineering at Liverpool, he came to Canada in 1905, to become Assistant and then Associate Professor in Applied Mechanics at McGill University. In 1911, he became Professor of Applied Mechanics and Hydraulics, a chair he still retains.

Succeeding the late Dean H. M. MacKay, in 1931, Dean Brown has guided with distinction the fortunes of his Faculty in times that have often been difficult both for the engineer and for higher education. While carrying a heavy load of teaching and administration, he has contributed much to engineering knowledge. His investiga-

Dean Ernest Brown, M.E.I.C.

tions in the field of reinforced concrete are classic. He had an important share in the difficult special studies carried out in connection with the design of the Quebec bridge, and his experiments and researches on the strength of ice have added greatly to the knowledge of the engineer concerning the action of this troublesome substance on his structures and machines. Of notable importance have been his studies, pursued over many years, on model turbine runners. Through these and related engineering investigations, he has made an outstanding contribution to the economical development of the hydraulic resources of the Dominion.

By his old students, Dean Brown has long been acclaimed as a clear and forceful teacher. It is a McGill tradition that those who had the privilege of sitting under him very soon came to regard that period of instruction and personal contact as one of the most fruitful experiences of their lives.

I have the honour to present to you, Mr. Chancellor, for the degree of Doctor of Engineering, *honoris causa*, Ernest Brown, Dean of the Faculty of Engineering of McGill University.

#### DEAN BROWN'S RESPONSE

Your Honour, Mr. Chancellor, President Cody, Members of Convocation, Ladies and Gentlemen:

An old friend of mine, a distinguished graduate of this University, in referring to the lack of the gift of oratory characteristic of my tribe, used to say that the language of the engineer is a blueprint and a grunt. A lecturer on public speaking, seeking to engage the interest of a group of students in engineering, is reported to have begun his first talk as follows: "Some day, speaking as a contractor, you will want to give hell to a city council, and to do it in the nice way." To-night my fear is that my grunt of appreciation of the great honour you have paid me will

fall far short of what it is in my heart to convey. I had never thought to exchange my humble overalls for the brilliant garb of an honorary graduate. I wish to thank you, Dr. Cody, for the gracious, but over-generous terms in which you set forth the reasons for the granting of this degree, and to express my deep sense of the great honour conferred upon me. It is a form of recognition which, to me, outweighs all others. I regard it not only as a tribute to whatever I may have been able to accomplish personally in the field of engineering education and in various professional activities, but also as an expression of goodwill towards an important faculty in a sister-university. All engineering activity is a co-operative undertaking. Without the devotion and support of my colleagues I could have accomplished little, and I feel that much credit is due to them for the great honour you have paid me. It has also been my privilege for over 30 years to number among my good friends many members of this University, and to be associated with them not only in academic and professional affairs, but in fostering and controlling intercollegiate sport and competition. These happy memories add greatly to my pleasure in receiving the degree which has been conferred on me. It has not escaped my notice that you have chosen a time when intercollegiate competition is suspended to make me one of your own, by admitting me into the select company of your honorary graduates. I am thus relieved of the severe strain which feelings of divided loyalty might otherwise have imposed on me. This I regard as showing really great consideration. I am profoundly conscious of the value of all good clean sport, and of the loyalties and abiding friendships which it fosters. Nowhere is the saying that all work and no play makes Jack a dull boy more true than in the universities. Some clever modern cynic defined education as "the inculcation of the incomprehensible into the minds of the ignorant by the incompetent." While this is clever, it is not profound. Aristotle knew better when he said: "The purpose of education is to enable us to enjoy leisure beautifully." To-day life is stern and hard, but it may be good for us even during our greatest trials, to reflect a little on the benefits of properly applied leisure. We *exist*—one cannot call it *living* in the true sense—amid a medley of restraints and controls, under ceilings, and in basements, and many of the worth-while things of life seem far away. They will, I hope, be recaptured when, after many grim trials, our hard discipline has brought us out of the deep shadows of the valleys into the pure sunlight of the uplands. And so, even in these hectic days, I like to reflect on the lasting joy and satisfaction derived from the many hours of freedom afforded by academic life, and to hope that in a re-constructed world the advantages of leisure as a factor in the art of living may be realized for all people.

Stevenson in one of his essays—"An Apology for Idlers"—reminds us that idleness, so-called, does not consist in doing nothing, but in doing a great deal not recognized in the dogmatic formularies of a ruling class, and that it has as good a right to state its position as industry itself. "It is surely beyond a doubt," he says, "that people should be a good deal idle in youth. For though here and there a Lord Macaulay may escape from school honours with all his wits about him, most boys pay so dear for their medals that they never afterwards have a shot in their locker, and begin the world bankrupt. And the same holds true during all the time a lad is educating himself, or suffering others to educate him." And again he says: "Extreme busyness, whether at school or college, kirk or market, is a symptom of deficient vitality; and a faculty for idleness implies a catholic appetite and a strong sense of personal identity. There is a sort of dead-alive, hackneyed people about, who are scarcely conscious of living except in the exercise of some

conventional occupation. Bring these fellows into the country or set them aboard ship, and you will see how they pine for their desk or their study. They have no curiosity; they cannot give themselves over to random provocations; they do not take pleasure in the exercise of their faculties for its own sake; and unless Necessity lays about them with a stick, they will even stand still. It is no good speaking to such folk: they cannot be idle, their nature is not generous enough; and they pass those hours in a sort of coma, which are not dedicated to furious moiling in the gold-mill." This is part of Stevenson's plea for a well ordered leisure, for relief from the rush and turmoil of mere existence.

In looking back over our experiences, few of us older folk regret the full satisfaction of the hours of truantry. Unhappily to-day, people in every walk of life must give up leisure and regiment their lives, devoting all their time and thought to the overthrow of those whose principles would otherwise enslave them. May it not be good for us, even though we can now look forward but dimly,—sometimes hardly daring to hope,—may it not be good for us to dream of happier days when as part of the reward of labour all men may enjoy leisure beautifully. The truant, says Stevenson, need not be always in the streets "for if he prefers he may go out by the gardened suburbs into the country. He may pitch on some tuft of lilies over a burn, and smoke innumerable pipes to the tune of the water on the stones. A bird will sing in the thicket. And there he may fall into a vein of kindly thought, and see things in a new perspective. Why, if this be not education, what is it?"

This brings me to the end of the engineer's "grunt" to which I referred a few minutes ago. There is no blueprint to accompany it. The dream I have spoken of can only come true in the hearts and minds of men. I wish to thank you, Mr. Chancellor, and Dr. Cody, for giving me this opportunity to say a few words at this Convocation. Let me renew my most grateful thanks for the high honour you have conferred on me.

## WARTIME BUREAU OF TECHNICAL PERSONNEL

### MONTHLY BULLETIN

The demand for engineers continues. The need for chemists is increasing. The intensive study of the Bureau records is disclosing a greater number of such persons who are not occupied wholly in war work. The Bureau is now closely engaged in endeavours to transfer such persons to new work where their services may be used to greater advantage.

Such negotiations cannot be concluded quickly. It is necessary to consult the wishes of the individual, and to give proper consideration to the needs of the present employer. There is no form of legal compulsion that can be used, and consequently each case becomes a special affair in which the needs of the country are not always the only consideration. In most cases highly specialized persons are involved, and positions of considerable importance are at issue.

\* \* \* \* \*

The Bureau has just completed a special assignment. The British Ministry of Aircraft Production (M.A.P.) urgently needed twenty-five or more civil engineers and draughtsmen for civilian emergency work in England. A trans-Atlantic telephone call placed the inquiry with the Bureau, and after hurried consultations with government officials in Ottawa to get authorization for the "export" of these men, the work was taken in hand.

Advertisements were run in ten newspapers covering Toronto, Ottawa and Montreal, and other names were selected from the Bureau records. Representatives of the Bureau interviewed all applicants whose written records

indicated some degree of suitability. These interviews were held in Toronto, Ottawa and Montreal.

Eventually about thirty-five men were selected from the one hundred and forty applicants. A representative of M.A.P. came to Canada to make the final selection in company of a representative of the Bureau, and accepted every individual previously selected by the Bureau.

Some of the conditions laid down by M.A.P., involving income tax and the portion of salary that could be returned to Canada, reduced the number of applicants, but eventually the required number were signed up and arrangements made for their transportation.

It is likely that the changes in the international situation will delay the departure of some of these men, but the need for them in the Old Country will become more urgent than ever. It is hoped that the original plans will not be delayed seriously.

\* \* \* \* \*

The Bureau proposes to have a representative at the annual meetings of those organizations whose membership includes technical personnel. It will be the representative's mission to explain the purposes and methods of the Bureau and to answer questions. A supply of questionnaires will also be on hand in case anyone who has been missed previously desires to record his qualifications with the other members of his profession.

Doubtless there will be other matters that can be attended to at the same time, all having a bearing on the Bureau's policy of giving service to the engineer and the employer, to the end that Canada's war effort may be increased.

## MEETING OF COUNCIL

A meeting of the Council of The Institute was held at Headquarters on Saturday, December 13th, 1941, at ten thirty a.m.

Present: Vice-President deGaspé Beaubien in the chair; Past President J. B. Challies; Vice-President K. M. Cameron; Councillors J. H. Fregeau, W. G. Hunt, A. Larivière, H. Massue, C. K. McLeod and G. M. Pitts; Secretary Emeritus R. J. Durley, General Secretary L. Austin Wright and Assistant General Secretary Louis Trudel.

The president-elect, Dean C. R. Young, was also present and Mr. Beaubien extended to him, and to Mr. Hunt, the newly appointed councillor for the Montreal Branch, a very cordial welcome to the meeting.

It was noted that since the last meeting contributions had been received from six more branches, bringing the total up to \$7,324.60. Reporting for the Quebec Branch, Mr. Larivière advised that they had a certain amount collected, but had delayed sending it in as they had hoped to be able to send at least \$100.00 as their contribution. He undertook to ask the branch to send in the amount already collected so that the books could be closed at the end of the year.

Mr. Beaubien stated that the Finance Committee particularly appreciated the co-operation of the branches in this matter, and the secretary was directed to thank them all for the splendid effort which has been made on behalf of the building fund.

At the last meeting of Council it had been decided to take advantage of certain opportunities made available through the National Research Council and the Department of Public Works whereby a member of The Institute could be sent to England to secure information regarding the protection and repair of public buildings and utilities subject to attack by bombing or gun fire.

The general secretary reported that he had recently been in touch with the president who, in view of the changed international situation, felt that it would be unwise to send a man to England at the present time. He

pointed out that in the library at the Research Council here are copies of practically everything that has been written on this subject, all of which could be made available to The Institute, and in view of the added risk, and uncertainty regarding transportation, he doubted whether The Institute would be justified in sending a representative for such an investigation at this time. He recommended that the idea be postponed indefinitely.

While realising the advantage of having some person go over and bring back first-hand information, Mr. Cameron doubted whether the desired results would be obtained under present circumstances. Mr. Doncaster, who had been selected to go over, would be willing to take the risk, but he might be stranded in England and be unable to return with the desired information in time for the Annual Meeting as planned.

Mr. Wright stated that the president has agreed to have the member of his staff who is reading all the literature on this subject, prepare a paper for the Annual Meeting. It was also hoped that it would be possible to get Mr. W. D. Binger, Borough Engineer of New York, to come to the meeting and tell about his recent visit to England. Mr. Binger headed a mission sent over by the United States to obtain similar information.

Mr. Pitts thought that some paid official should be made technically responsible for centralizing the work of various organizations making investigations along this line. Mr. Beaubien suggested that since Mr. Doncaster's services had been made available by the Government, it might be possible to put him on this work.

After further discussion it was agreed that Mr. Doncaster's visit to England should be postponed for the time being, and that the matter be left in the hands of the president and Vice-President Cameron for further action.

Mr. Wright gave a brief description of the various papers to be presented to the annual meeting, the general theme of which will be along the line of Canada's war effort, with particular reference to the work of the engineer and scientist. Plans were also progressing for an exhibit of war materials.

Mr. Hunt, chairman of the Annual Meeting Committee, reported briefly on the general programme. All committees are now organized and are working out the various detailed arrangements. For those members who are interested, it is hoped to arrange visits to certain plants on the Saturday morning.

The report of the scrutineers appointed to open the ballots on the New Brunswick agreement was presented.

The general secretary reported that the results of the ballot of members of the Association of Professional Engineers of New Brunswick showed that eighty members had voted in favour of the agreement and seven against. Seventy-eight members had indicated their willingness to take advantage of joint membership under the terms of the agreement.

These results were noted with considerable satisfaction, and on the motion of Mr. Massue, seconded by Mr. McLeod, it was unanimously resolved that the president, or an alternate appointed by him, and the general secretary be duly authorized to sign the agreement between The Engineering Institute of Canada and the Association of Professional Engineers of the Province of New Brunswick. It was also unanimously resolved that the agreement be put into effect as soon as it is signed.

The general secretary was directed to write to the president of the Association expressing Council's pleasure at the results and their appreciation of the splendid work which had been done by the engineers in New Brunswick in negotiating this agreement. It was left with the general secretary to make the necessary arrangements for the signing ceremony, which would probably be held early in January.

Mr. Beaubien reported that the financial statement to the end of November had been examined and found in a very satisfactory condition. Expenses are a little under and revenue is considerably over the budget.

The recommendation of the Finance Committee that *The Engineering Journal* be sent complimentary for the year 1942 to the engineers from other countries now in Canada on war work was unanimously approved.

Dean Young was particularly pleased with this decision. He stated that there are about twenty Polish engineers in Toronto who are very much interested in Institute affairs, and they will greatly appreciate this gesture on the part of Council.

Mr. Beaubien reported that as a result of correspondence with the Director of the Wartime Bureau of Technical Personnel it had been arranged that the Bureau would reimburse The Institute to the extent of \$150.00 a month to cover part of the additional costs to which The Institute was subjected due to the absence of the general secretary in Ottawa, and activities which were undertaken on behalf of the Bureau. This was a great help to the Finance Committee, and Mr. Beaubien felt that The Institute should express its appreciation to the Bureau.

The secretary presented a revised version of the by-laws of the Calgary Branch, which had been examined and found to be in agreement with The Institute by-laws. On the motion of Mr. Challies, seconded by Mr. Massue, it was unanimously resolved that the by-laws as submitted be approved.

The general secretary read two letters from a member, of Hamilton, Ontario, regarding the interpretation of the by-laws governing the qualifications for membership in The Institute, with particular reference to the requirement for full membership of two years of professional responsibility in charge of work as principal or assistant. There seemed to be some diversity of opinion among members of The Institute with whom he had come in contact as to just how this particular qualification is to be interpreted. He suggested that immediate steps be taken to advise the members, and particularly branch executives, regarding their responsibility in making recommendations for membership, pointing out particularly the difference between executive responsibility not involving engineering work, and engineering or professional responsibility.

A full discussion followed, during which it was suggested that the branches might be advised that representations had been made to Council indicating that in some instances enough consideration had not been given to the question of professional responsibility.

Mr. Cameron suggested that it should be made clear to the author of the letters that each application for membership receives individual consideration by Council, and that very frequently certain cases are referred back to the branch executive for further consideration and inquiry.

Further discussion took place, and it was decided to leave the matter in the hands of the general secretary to take whatever action seemed advisable in order to keep branch executives fully informed.

The general secretary read a letter from the secretary of the Hamilton Branch, pointing out the desirability of giving students, as they join The Institute, full information about the advantages of membership in The Institute and the requirements for their eventual transfer to a higher class of membership.

Mr. Challies thought this was a very important question. In his opinion, every student, upon entering The Institute should be given some sort of a brochure indicating just what The Institute stands for. This was a matter which might very well be referred to Mr. Bennett's Committee on the Young Engineer.

Mr. Cameron suggested that the general secretary, when notifying Students of their admission, should write

a letter to each one encouraging them to continue their membership, sending a copy of the letter to the branch executive. Mr. Pitts thought a brochure such as had been suggested by Mr. Challies would be more helpful.

Mr. Massue thought it should be the responsibility of branch membership committees to keep in touch with the Students and encourage them to transfer as soon as they are eligible, instead of dropping out as a great many do, apparently from lack of knowledge of the advantages of Institute membership.

Dean Young also believed that the branches should be encouraged to follow up on all Student members. A general follow-up under the direction of Mr. Bennett's committee, perhaps through the branches, would be very beneficial.

It was unanimously agreed that special contact should be maintained with Student members to the end that they will transfer to a higher class of membership. It was left with the general secretary to discuss this with Mr. Bennett and see what could be done in addition to the policy already being followed.

A number of applications were considered and the following elections and transfers were effected:

Mr. Challies drew attention to the fact that Miss Caroline Haslett, President of the Women's Engineering Society of Great Britain, had been visiting the United States, and was spending two days in Canada. He felt that her visit should be recognized in some way by The Institute, and it was left with the general secretary to see what could be done.

Mr. Challies reported that a meeting of the executive of the Engineers' Council for Professional Development was being held in New York on December 18th. It would be impossible for him to attend, and as neither Dr. Fairbairn nor Dr. Surveyer could go, he suggested that Council authorize the general secretary to attend and represent The Institute at that meeting. This was unanimously approved.

Council noted with sincere regret the death of Mr. J. B. Hunter, Deputy Minister of the Department of Public Works, Ottawa, and it was unanimously resolved that the following resolution be recorded in the minutes and that a copy be sent to Mrs. Hunter and to the Department.

"The Council of The Engineering Institute has been greatly shocked to hear of the death of Mr. J. B. Hunter, Deputy Minister of the Department of Public Works at Ottawa, and desires to express to Mrs. Hunter some measure of the sympathy which they feel at her loss.

"The Engineering Institute has had very pleasant relations with Mr. Hunter throughout the entire period of his office, and has received frequent and important favours from him. Among the government officials not many have shown a greater sympathy for the work and the needs of the engineer, and his loss will be felt by members of the profession in all parts of Canada."

Mr. Challies commented on the large number of students from the Ecole Polytechnique who were joining The Institute, for which a great deal of credit was no doubt due to Mr. Trudel.

It was left with the president and the general secretary to decide upon the date for the January meeting of Council.

The Council rose at one o'clock p.m.

## ELECTIONS AND TRANSFERS

At the meeting of Council held on December 13th, 1941, the following elections and transfers were effected:

### Members

- Brekke**, Hans Krishan Andreas, Civil Engr., (Prague Univ.), hydraulic engr., City of Winnipeg Hydro Electric System, Winnipeg, Man.
- Duncan**, John Martin, B.A.Sc. (Univ. of Toronto), plant mgr., Canadian Liquid Air Co. Ltd., Hamilton, Ont.
- Howse**, George Wesley, district inspector, Hydro-electric Power Commission of Ontario, Hamilton, Ont.
- McNeil**, John Newson, B.Sc.(C.E.), (Univ. of Man.), engr. i/c field constrn., C. D. Howe Co. Ltd., Port Arthur, Ont.
- Stark**, John Edward, constrn. supt., Hydro-Electric Power Commission of Ontario, Toronto, Ont.
- Westman**, LeRoy Egerton, B.A., M.A. (Univ. of Toronto), president, Westman Publications Limited, Toronto, Ont.
- Wingfield**, Harold Ernest, B.A.Sc. (Univ. of Toronto), director of sales, advertising & purchasing, Imperial Rattan Co. Ltd., Stratford, Ont.
- Wood**, Wells Arthur, B.A.Sc. (Univ. of B.C.), design engr., Harrington Tool & Die Company, Lachine, Que.

### Juniors

- Davis**, Frederick Allan, B.Sc. (Chem.), (Queen's Univ.), asst. refinery engr., British American Oil Co. Ltd., Montreal East, Que.
- Kennedy**, Samuel McNeer, B.A.Sc. (Univ. of Toronto), engr. dept., Defence Industries Ltd., Montreal, Que.
- Mann**, Neville Whitney Davis, B.Sc. (C.E.), (Univ. of N.B.), junior engr., Atlas Construction Co. Ltd., Gander, Nfld.
- Teskey**, Arthur G., B.Sc. (E.E.), (Univ. of Man.), sales engr., Canadian Westinghouse Co. Ltd., Winnipeg, Man.

### Affiliate

- Jones**, Douglas, (McGill Univ.), secretary-engineer, technical section, Canadian Pulp & Paper Association, Montreal, Que.

### *Transferred from the class of Junior to that of Member*

- Nathanson**, Max, B.Sc. (McGill Univ.), owner and engr., Canadian Armature Works, Montreal, Que.
- Pope**, Joseph Morley, B.Sc. (McGill Univ.), Flt.-Lieut., R.C.A.F. (A.M.A.E. Divn.), Ottawa, Ont.
- Tuck**, Joseph Howard, B.Sc. (Queen's Univ.), supt., monel dept., International Nickel Company, Port Colborne, Ont.

### *Transferred from the class of Student to that of Member*

- Baggs**, William Clyde, B.ENG. (McGill Univ.), asst. to the mgr., Bathurst Power & Paper Co. Ltd., Bathurst, N.B.

### *Transferred from the class of Student to that of Junior*

- Laird**, Alan Douglas Kenneth, B.A.Sc. (Univ. of B.C.), material engr., Fraser Brace Engineering Co. Ltd., Winnipeg, Man.
- Thompson**, Arthur McCall, B.Sc. (Univ. of Alta.), apparatus sales engr., Canadian General Electric Co. Ltd., Winnipeg, Man.

### Students Admitted

- Bell**, Frederick Arthur, (Univ. of Toronto), 91 St. George St., Toronto, Ont.
- Bradley**, Whitney Lloyd, (Univ. of Toronto), 31 Welland St., Thorold, Ont.
- Carrothers**, Percival John Godber, (Univ. of B.C.), 1549 Western Crescent, Vancouver, B.C.
- Chinn**, Norman William, (McGill Univ.), 4639 Melrose Ave., Montreal, Que.
- Cohen**, Peter Zelig, (McGill Univ.), 20 Lavolette Ave., Outremont, Que.
- Cross**, Ivor Frederick, (Univ. of Man.), 82 Rosseau Ave. W., Transcona, Man.
- Diamond**, George Bernard, (McGill Univ.), 48 Joyce Ave., Outremont, Que.
- Galli**, Joseph Nicholas, (Univ. of Man.), 749 Ross Ave., Winnipeg, Man.
- Grimble**, Wilf George, (Univ. of B.C.), 3806 West 35th Ave., Vancouver, B.C.
- Hartwig**, Elmer Herman William, 11 Barons Ave. So., Hamilton, Ont.
- Hlibchuk**, Walter (McGill Univ.), 3 Popliger Ave., Montreal, Que.
- Joy**, Richard Joseph, (McGill Univ.), 341 Metcalfe Ave., Westmount, Que.
- Keay**, William Logan, (Univ. of Man.), 464 Bowman Ave., Winnipeg, Man.

**Luscombe**, William Charles Murray, B.Sc. (Queen's Univ.), 126 Fentiman Ave., Ottawa, Ont.  
**Lefebvre**, Marcel, (Ecole Polytechnique), 5025 St. Urbain St., Montreal, Que.  
**Morris**, Wallace Victor, (Univ. of Man.), 688 Jubilee Ave., Winnipeg, Man.  
**Milot**, Raymond, (McGill Univ.), 3539 St. Famille St., Montreal, Que.  
**McDermott**, Arthur G., (Univ. of N.B.), 242 Charlotte St., Saint John, N.B.  
**McLaughlin**, Robert Hugh Benson, (Univ. of N.B.), Beaverbrook Residence, Fredericton, N.B.  
**McNiven**, Hugh Donald, (Univ. of Toronto), Islington, Ont.  
**Orloff**, Irving, (Univ. of Man.), 302 Redwood Ave., Winnipeg, Man.  
**Pichette**, Jacques, (McGill Univ.), 3539 St. Famille St., Montreal, Que.  
**Prideaux**, Norman Llewellyn, (Univ. of Toronto), 33 Monarch Park Ave., Toronto, Ont.  
**Rossetti**, Anthony Bruce, (N.S. Tech. Coll.), 33 Cherry St., Halifax, N.S.

## COMING MEETINGS

**Association of Professional Engineers of Ontario**—Annual Meeting and Dinner, Royal York Hotel, Toronto, Ont., on January 17th, 1942. Walter McKay, Secretary-Treasurer, 350 Bay Street, Toronto, Ont.

**Canadian Electrical Association, Inc.**—Ninth Annual Winter Conference, Mount Royal Hotel, Montreal, Que., January 19th and 20th, 1942. B. C. Fairchild, Secretary, Room 804, Tramways Building, Montreal, Que.

**The Engineering Institute of Canada**—Sixty-sixth Annual General and General Professional Meeting, Windsor Hotel, Montreal, Que., February 5th-6th, 1942. L. Austin Wright, General Secretary, 2050 Mansfield Street, Montreal, Que.

## Personals

**Léo Brossard**, M.E.I.C., has entered private practice in Montreal as a consulting engineer and land surveyor. He graduated from the Ecole Polytechnique in civil engineering in 1936 and after post graduate work obtained a degree of Master of Science in geology from McGill University in 1940.

He has spent some time in the northern mining district of Quebec as a geologist with the Cournot Mining Company and has also done some work for the Department of Mines of the Province of Quebec. Lately he has been connected with dredging work for drainage purposes in the Napierville district in Quebec. Mr. Brossard is a member of the Corporation of Land Surveyors of the Province of Quebec.

**Pilot Officer L. M. Clarke**, M.E.I.C., has recently completed a course at the School of Aeronautical Engineering of the Royal Canadian Air Force at Montreal and has been posted at R.C.A.F. Headquarters, Ottawa.

**Pilot Officer S. V. Antenbring, Jr.**, E.I.C., was also in the class who completed their course at the School of Aeronautical Engineering of the Royal Canadian Air Force in Montreal, and has been posted to R.C.A.F. Headquarters in Ottawa.

**I. D. Mackenzie**, Jr., E.I.C., has been transferred from Shawinigan Falls to the Montreal office of Shawinigan Engineering Company. He graduated from Queen's University in 1940.

**R. C. Robson**, Jr., E.I.C., has recently accepted a position with Bloedel, Stewart and Welch Limited of Vancouver as engineer. He was previously connected with the Consolidated Mining and Smelting Company at Trail, B.C.

**G. O. Sanders**, Jr., E.I.C., is at present stationed at Providence, R.I., U.S.A., as assistant inspector of Naval Ordnance for the British Admiralty. He graduated from Queen's University in 1937 and up until recently was on the staff of Howard Smith Paper Mills Limited at Cornwall, Ont., as maintenance engineer.

**W. C. Weir**, Jr., E.I.C., is now stationed at Brantford, Ont., as engineer officer with the Royal Canadian Air Force. He graduated from the University of Saskatchewan in 1936 and for some time was connected with the Hudson Bay Mining and Smelting Company at Flin Flon, Man.

**Pierre A. Duchastel**, Jr., E.I.C., has recently accepted an appointment with the physics and electrical engineering

## News of the Personal Activities of members of the Institute, and visitors to Headquarters

department of the National Research Council at Ottawa. He graduated in electrical engineering from McGill University in 1938, and since graduation has been connected with the Ferranti Electric Limited, Montreal.

**Squadron Leader Baxter Richer**, S.E.I.C., has recently been appointed to command a squadron at No. 13 Service Flying Training School of the Royal Canadian Air Force at St. Hubert, Que. Squadron-Leader Richer graduated from the Ecole Polytechnique in 1937 and enlisted in the service of the R.C.A.F. in the same year. In December, 1938, he was promoted to the rank of Flying Officer and was made a Flight Lieutenant in May, 1940. Lately he had been stationed at McLeod, Alta., and previously at Regina, Sask.

**Pilot Officer R. J. Doehler**, S.E.I.C., has recently completed a course at the School of Aeronautical Engineering of the Royal Canadian Air Force at Montreal and has been posted at Summerside airport, P.E.I.

**W. H. MacGowan**, S.E.I.C., has accepted a commission in the Royal Canadian Air Force and is at present posted at No. 3 Wireless School, Winnipeg, Man. He graduated from McGill University in 1929.

**Pilot Officer Marcel Papineau**, S.E.I.C., has recently completed his course at the School of Aeronautical Engineering of the Royal Canadian Air Force, Montreal, and has been posted at No. 6 Repair Depot, Trenton, Ont. He graduated from the Ecole Polytechnique in 1940 and was on the staff of the Noranda Mines Limited at Noranda until he joined the air force a few months ago.

**R. M. Morris**, S.E.I.C., has joined the staff of the National Research Council in the Department of Physics and Electrical Engineering at Ottawa. He was previously on the staff of the Shawinigan Engineering Company at Montreal. He graduated from Nova Scotia Technical College in 1940.

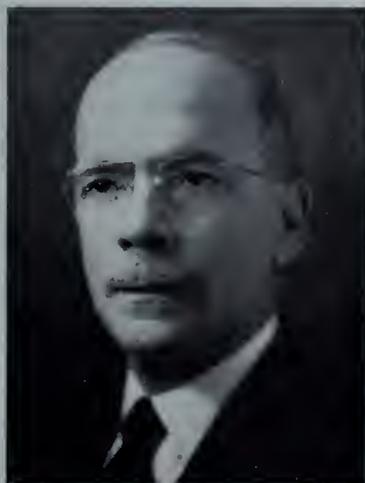

**Pilot Officer Bernard Lavigne**, S.E.I.C., has completed his course at the School of Aeronautical Engineering of the Royal Canadian Air Force, Montreal, and has been posted at No. 11 Technical Detachment, R.C.A.F., at Montreal. He graduated from the Ecole Polytechnique in 1941.

**Richard Noonan**, S.E.I.C., has joined the staff of the English Electric Company, transformer department, at St. Catharines, Ont. He was formerly connected with the electrical department of the Canadian National Railways at Montreal.

**Georges Archambault**, S.E.I.C., has joined the staff of the Aluminum Company of Canada Limited at Arvida, Que. He graduated in mechanical engineering from McGill in 1939 and joined the staff of Minneapolis Honeywell Regulator Company at Montreal. Lately he had been connected with Peacock Bros. Limited, at Montreal.

**J. A. Lalonde**, M.E.I.C., was elected this month chairman of the Montreal Branch of The Institute. He was born at Au Sable, Mich., U.S.A., in 1891 and was educated at the Ecole Polytechnique of Montreal, where he graduated in 1912.

Upon graduation he spent a few months on railway work with the North Railway Company at Hudson Bay. In 1913 he joined the staff of the City of Outremont as assistant

**J. A. Lalonde, M.E.I.C.**

engineer. In 1920 he went with the City of Montreal as assistant superintendent of streets, a position which he left in 1924 to join the staff of Quinlan, Robertson and Janin, Montreal, as manager of the paving department. In addition to these duties he was chief engineer of A. Janin and Company from 1930 to 1939. At that time he became manager and chief engineer of the Quebec Paving Company, Montreal, and associated companies, a position which he holds at present.

Mr. Lalonde has been Professor in Municipal Engineering at Ecole Polytechnique since 1926.

**Colonel H. G. Thompson**, D.F.C., M.E.I.C., is among the three Canadian officers who were recently despatched to the middle East as observers with the British 8th and 9th Armies. Col. Thompson is well known to members of The Institute, having held for over two years the position of editors of indices of The Engineering Catalogue at Headquarters. Since his graduation from the University of Toronto in 1922, he has been engaged in mechanical sales engineering with various firms. In 1934 he joined the staff of Canadian Vickers Limited and in 1935 he was appointed manager of the Toronto office of the Company.

In 1940 he was in England as officer commanding No. 2 Army Field Workshop, R.C.O.C. Upon his return to Canada last year, he was appointed chief ordnance mechanical engineer, Department of National Defence, at Ottawa.

**W. O. Scott**, M.E.I.C., is the newly elected chairman of the Vancouver Branch of The Institute. He graduated from the University of British Columbia with the degree of Master of Applied Science in 1923. Following graduation,

Mr. Scott became connected with J. W. Thompson and Company of Vancouver, and in 1924 he entered the employ of the City of Vancouver as assistant in the water works survey, later becoming smoke inspector. In 1926 he went with Scott Foster and Company as mechanical engineer and later was on the staff of Canadian Utilities Limited at Calgary, Alta. He is at present assistant plant superintendent of the Dominion Bridge Company at Vancouver, a firm with which he became connected in 1933.

**John M. Evans**, M.E.I.C., has been appointed chairman of the newly created Export Control Committee of the Federal Government at Ottawa. Mr. Evans' duties will be to administer control of Canada's export trade in order to protect the Canadian public and manufacturers against serious loss of export markets and to insure that no materials or commodities essential to the Dominion's war effort are manufactured or processed for export trade until the full requirements of the country for war purposes have been filled. The membership will include representatives from the various wartime boards.

**John M. Evans, M.E.I.C.**

Mr. Evans was born in England in 1905. He was educated in public and commercial and technical high schools in Montreal and graduated from McGill University in May, 1929, with a degree of B.Eng., in electrical engineering. He joined the Shawinigan Water & Power Company June 1st, 1929, and after spending two years on system planning, design of pole lines, transformers, and other equipment, he transferred to the department of development and devoted his attention to industrial location studies and the development of new loads. He is at present assistant manager of the department of development of the Company.

**E. M. Proctor**, M.E.I.C., is at present located at Washington, D.C., where he is representing the Canadian Government on the Bureau of Industrial Conservation, which is a branch of the Office of Production Management of the United States. Mr. Proctor is president of James, Proctor and Redfern Limited, Toronto.

**Sub-Lieutenant C. K. Hurst**, M.E.I.C., has been posted to the Naval College at Halifax for training. Previous to his enlistment he was on the hydraulic staff of the canals branch of the Department of Transport, Ottawa.

**Jean P. Carrière**, M.E.I.C., whose paper on "Construction of a By-Pass Highway in England by Royal Canadian Engineers" is printed in this issue of the Journal, is at present serving as a captain with the Royal Canadian Engineers in England. In civil life, Mr. Carrière is senior assistant engineer in the Montreal office of the Department of Public Works of Canada and previous to his enlistment he had been for some time attached to the London, Ont., district office.

**H. A. Gibeau, M.E.I.C.**, has been appointed director of the Department of Public Works of the city of Montreal to succeed the late J. E. Blanchard, M.E.I.C. Mr. Gibeau, who has held the office of assistant director for the past year, was born in Montreal. He took a science course at the Rensselaer Polytechnic Institute in Troy, N.Y., where his brilliant studies won him the chair of applied mechanics at the Villa Nova Institute in Philadelphia.

**H. A. Gibeau, M.E.I.C.**

After teaching for five years in the Philadelphia institute he returned to Canada and was appointed chief examiner of the Montreal Municipal Service Commission, in 1920. Two years later he joined the Public Works Department, and in 1937 he was appointed assistant chief engineer of the city.

**C. Neufeld, M.E.I.C.**, has been transferred to the staff of the Dominion Bridge Company at Calgary as designing engineer. He was previously connected with the Sault Structural Steel Company at Sault Ste. Marie. Mr. Neufeld, who graduated from the University of Saskatchewan in the class of 1935, was the winner of the H. N. Ruttan prize of The Institute in 1938.

**Flying Officer W. Shuttleworth, M.E.I.C.**, has joined the works and buildings branch of the Royal Canadian Air Force and is at present stationed at Newfoundland.

**Americans Honour Canadian Engineer**

At the Annual Meeting of the American Society of Mechanical Engineers in New York, the Hon. C. D. Howe, M.E.I.C., was given an Honorary Membership in the Society. Here he is shown between two other distinguished gentlemen who received a similar honour on the same occasion. On the left is Major General Charles Macon Wesson, Chief of Ordnance of the United States Army, and on the right is Rear Admiral Samuel Murray Robinson, Chief of the Bureau of Ships.

**W. F. Drysdale Participates in Quiz**

At the Annual Meeting of the American Society of Mechanical Engineers held in New York, a special feature was a "clinic" devoted to questions and answers on Conservation and Reclamation of Materials in Industry. On the board of experts was W. F. Drysdale, a Member of The Institute. The above photograph shows other experts who also assisted in answering the many questions.

Back Row: left to right, D. R. Kellogg, Assistant to Manager, Engineering Laboratories and Standards, Westinghouse Electric; W. W. Finlay, Manager, Cincinnati Div'n., Wright Aeronautical Corp'n.

Front Row: W. F. Drysdale, M.E.I.C., Director-General of Industrial Planning and Engineering, Ottawa; John C. Parker, President A.S.M.E., Vice-President Consolidated Edison Co.; C. E. Smith, Vice-President N.Y., N.H. & H. Railroad.

#### VISITORS TO HEADQUARTERS

**Lieut.-Colonel G. E. Cole, M.E.I.C.**, Wartime Bureau of Technical Personnel, Ottawa, Ont., on November 27th.

**R. I. McCabe, M.E.I.C.**, office manager, Sherbrooke Machineries Limited, Sherbrooke, Que., on November 27th.

**G. St. Jacques, M.E.I.C.**, engineer, Public Service Board, Quebec, Que., on November 28th.

**A. C. R. Yuille, M.E.I.C.**, consulting engineer, Vancouver, B.C., on November 28th.

**T. S. McMillan, Jr., E.I.C.**, maintenance engineer, Plastic Division, Canadian Industries Limited, Brownsburg, Que., on December 3rd.

**E. M. Nason, Jr., E.I.C.**, No. 3 Training Command, R.C.A.F., Moncton, N.B., on December 4th.

**B. Gray, M.E.I.C.**, mechanical and resident engineer, Canadian International Paper Company, Temiskaming, Que., on December 6th.

**R. H. Findlater, M.E.I.C.**, Inspection Board of the United Kingdom and Canada, Ottawa, Ont., on December 6th.

**M. G. Saunders, M.E.I.C.**, Councillor of The Institute, mechanical superintendent, Aluminum Company of Canada Limited, Arvida, Que., on December 9th.

**Roger Lord, S.E.I.C.**, Beauharnois Light, Heat & Power Company, Beauharnois, Que., on December 11th.

**Major C. B. Bate, R.C.E., M.E.I.C.**, St. Johns, Newfoundland, on December 18th.

**Sergeant Eric Grant, M.E.I.C.**, Department of Works and Buildings, R.C.A.F. Headquarters, Eastern Command, Halifax, N.S., on December 22nd.

**Professor R. F. Legget, M.E.I.C.**, Department of Civil Engineering, University of Toronto, Toronto, Ont., on December 24th.

**T. M. Moran, M.E.I.C.**, Vice-President, Stevenson and Kellogg Limited, Toronto, Ont., on December 29th.

**J. H. Bradley, M.E.I.C.**, engineer with Holcroft and Company, Detroit, Mich., on December 31st.

**Geoffrey Stead, M.E.I.C.**, Saint John, N.B., on January 2nd.

# Obituaries

*The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.*

**Joseph Elie Blanchard**, M.E.I.C., died in the hospital at Montreal on December 12, 1941. He was born at Montreal on August 3rd, 1881. He received his early education at the Plateau Academy and his engineering training at the

J. Elie Blanchard, M.E.I.C.

Ecole Polytechnique of Montreal, where he graduated in 1902. He worked for some time with F. C. Laberge, consulting engineer of Montreal, and in 1904 he was engineer in charge of the construction of the waterworks at St.

Boniface, Man. In 1905 he became chief engineer of the City of St. Henry and when this latter was annexed to Montreal, he remained on the public works personnel. In 1915 he was appointed in charge of the roads and sewers division of the City of Montreal. In 1918 he was made engineering superintendent of the roads department of the city, a position which he occupied until 1930 when he became director of the Department of Public Works of Montreal. The department underwent marked improvements under the direction of Mr. Blanchard and the recent reorganization had been carried out under his supervision and that of the Quebec Municipal Commission.

Mr. Blanchard joined The Institute as a member in 1920.

**George Prince Hawley**, M.E.I.C., died at Santa Monica, Cal., on November 26th, 1941. He was born at Niagara Falls, N.Y., on August 22nd, 1872, and was educated at the University of Wisconsin. After spending a few years in municipal and railroad work, he joined the staff of Wallace C. Johnson at Niagara Falls in 1900 and was engaged on the design and construction of hydro-electric power plants, particularly at Shawinigan Falls, Que. From 1905 to 1911 he was city engineer at Depere, Wis. He returned to Canada in 1911 with the Shawinigan Water and Power Company and in 1912 he joined the staff of the Montreal Light, Heat and Power Consolidated as resident engineer in charge of the construction of the Cedar Rapids plant on the St. Lawrence river near Montreal. Later he was engaged on the construction of the Rivière-des-Prairies plant of the Montreal Island Power Company, a subsidiary of the Montreal Light, Heat and Power Consolidated. He remained at this plant as resident engineer until four years ago when he retired. He had since visited Florida and many other states, finally establishing his home at Santa Monica, Cal.

Mr. Hawley joined The Institute as a member in 1920.

## News of Other Societies

### BRANTFORD GROUP

Vice-President K. M. Cameron of The Institute visited the Brantford group of engineers on Saturday, November 22nd. He was the guest speaker at the monthly dinner and told an interesting story of the work done in and around Brantford by the Department of Public Works. His knowledge of the history and geography of the locality doubtless was a surprise to many, and indicated that civil engineering is a broad calling by which one learns much about the country in which he works. As chief engineer of his Department, Mr. Cameron is never in a strange land in any part of Canada.

Many questions were asked which, along with the

K. M. Cameron speaks to the Brantford Group of Engineers. On the left is Chairman W. A. T. Gilmour of the Hamilton Branch of The Institute and on the right is President Frank Westaway of the Group.

### Items of interest regarding activities of other engineering societies or associations

informal friendly style of the talk, made the whole evening a delightful affair. The president of the group, Frank Westaway, was in the chair, and had as other head table guests, W. A. T. Gilmour, chairman of the Hamilton Branch of The Institute, General Secretary L. Austin Wright, and a past-president of the group, E. T. Sterne, now of Montreal. Mr. Wright spoke briefly on the work of the Wartime Bureau of Technical Personnel.

James A. Vance was present to represent the London Branch of The Institute, and besides the chairman, the Hamilton Branch was represented by the chairman-elect, Stanley Shupe, of Kitchener, and the secretary-treasurer, A. R. Hannaford.

### PROFESSIONAL ENGINEERS OF ONTARIO

The Association of Professional Engineers of Ontario have announced that Flt.-Lieut. Henry Cotton, Padre of the Technical Training Centre, R.C.A.F., St. Thomas, will be the guest speaker at the dinner of the Association which is being held in the Royal York Hotel, Toronto on January 17th. He will speak on the subject, "The Battle of Brains."

Flt.-Lieut. Cotton who was attending McGill University when the last war broke out, enlisted as a Private and finished as Captain in the old Royal Flying Corps. He was in dog-fights with Richthofen and Voss, the celebrated German war aces. Shot down on his fortieth flight to Germany, he was for two years a prisoner of war. He was cited in the London Gazette "for gallant and distinguished service," his copy being signed on the King's behalf by Winston Churchill, then Secretary of State for Air.

## BORDER CITIES BRANCH

W. P. AUGUSTINE, M.E.I.C. - *Secretary-Treasurer*  
J. B. DOWLER, M.E.I.C. - *Branch News Editor*

The November meeting of the Border Cities Branch was held on Friday, November 14th, at the Prince Edward Hotel, Windsor. In the absence of the branch chairman, G. M. Medlar, the Branch was honoured by having Councillor E. M. Krebser in the chair. After dinner, the speaker, Mr. Donald Ramseyer, was introduced by Mr. J. Blowey.

Mr. Ramseyer is superintendent of the soy bean plant of the Ford Motor Company at Dearborn, Mich. He has been associated with soy bean work at the Ford Motor Company since its inception in 1930. The subject of his talk was **Soy Beans in Industry**.

In order to introduce his subject, Mr. Ramseyer first showed a slide film entitled **Farms of the Future**. It has long been one of Mr. Henry Ford's principles that there must be the utmost co-operation between the American farmer and industry before we can obtain true prosperity on this continent. Industry must absorb the products of the farmer in order that the farmer may absorb the products of industry.

With this in mind, Mr. Ford started research to find products of the farm most useful to industry. Many products were experimented with—corn stalks, wheat straw, vegetables, sunflower seeds, weeds and many others. Finally the soy bean was chosen as having the greatest possibilities. This is because of the high protein content.

The soy bean was introduced into America about 1800, but very little was done with it until about 1914. Its chief uses were as a silage crop and the oil was used as a substitute for cotton seed oil.

One of the difficulties with early methods for utilization of soy beans was that all the oil could not be removed from the meal and this was the first problem attacked by Mr. Ford's research laboratory. They developed a method by which 100 per cent of the oil can be absorbed from the crushed beans leaving a meal not unlike some prepared breakfast foods. The soy bean oil can then be recovered from the solvent and the solvent used over and over again. The meal can be dried and converted into many different products.

The oil is now used in the enamels for the Ford car. The enamels now contain up to 50 per cent of soy bean oil.

A new process has been the hydrogenation of the oil to produce glycerine and stearic acid, both very necessary for war-time production.

The original product developed by Ford research laboratory was the combination of the meal and bakelite to mould the gear shifter knob. Practically all the buttons, handles and ignition parts are now being moulded from this material.

Soy bean water paint has been developed from the meal. This is a very cheap paint for factory work, excellent for stonework and cement, retaining its whiteness longer than other paints. It can be washed but is rather porous and therefore is not suitable for painting steel. It can be mixed with pigment to give different colours.

The Ford research laboratory is also experimenting with gaskets made of fabric impregnated with the soy bean protein. This is a very severe application and large scale tests are now under way. The tests look very promising but it has not yet been applied commercially.

The soy bean meal is also used in the Ford steel mill as a substitute for corn flower as a core binder. Replaceable hot pops for steel ingot casting is another use.

One of the most amazing of the Ford developments is protein wool made from the soy meal. This wool has a texture and quality very similar to sheep's wool. It is equal in strength when dry to 80 per cent of strength when wet,

## Activities of the Twenty-five Branches of the Institute and abstracts of papers presented

and has 20 per cent more stretch. As a comparison it requires two acres of land per sheep to produce 12 lb. of wool, whereas two acres of land will produce 200 lb. of soy bean wool. This material has been used to make automobile upholstery of 30 per cent soy bean fibre and 70 per cent sheep's wool. It has been used very satisfactorily. Even suits have been made and felt for hats, successfully. Mr. Ford is now building a plant to produce this wool.

Mr. Ramseyer was asked whether plastics would greatly affect the production of aeroplanes and other articles during the war-time rush. He stated that at the present time there were not nearly enough soy beans grown to meet the demand. This year production was about 110,000,000 bushels of beans and next year it is expected to reach 125,000,000 bushels. Even this would not meet the demand. However, after the war, he predicted, there would be huge developments along this line.

The Border Cities group at the dinner held in honour of the president.

One other great advantage of soy beans is that the plant adds great quantities of nitrogen to the soil and is therefore of great benefit to the soil.

A special meeting of the Border Cities Branch was held on Wednesday, November 26, at the Prince Edward Hotel, Windsor. The occasion was the visit to the branch of the present, Dean C. J. Mackenzie, accompanied by Vice-President K. M. Cameron from Ottawa. The president was also accompanied by Mr. J. A. Vance and Mr. H. F. Bennett of the London Branch.

A dinner meeting was held with Mr. George E. Medlar in the chair. After the dinner, the chairman welcomed the president and his party on behalf of the branch, and turned the meeting over to Vice-President J. Clark Keith. Mr. Keith gave a brief review of President Mackenzie's career leading up to his present work as acting president of the National Research Council and chairman of the Federal Board of Inventions.

President Mackenzie spoke of his visits to the various branches throughout Canada, and his appreciation of the opportunity to be president. He spoke of the prominent part being played by engineers in Canada to-day, especially in the Department of Munitions and Supply, and the increasing importance of engineering as a profession.

President Mackenzie then reviewed the work of the Research Council. The work to-day is probably more development engineering than long term research but the work requires the same type of mind and in either case extensive training for the job.

As an outstanding example of the value of research, it may be said that scientific research saved Britain in 1940 as it gave them the Spitfire and Hurricane aeroplanes and their equipment. The air force was quite small but superbly trained and with superior equipment they saved Britain.

President's visit to Windsor. From left to right: J. A. Vance, J. Clark Keith, President Mackenzie, K. M. Cameron and H. F. Bennett.

Without this equipment in the air and on the sea nothing else could have stopped the Germans.

The war will not be won by any spectacular or new weapons but will be won by careful, consistent and continual attention to detail and constant attention to research and development of men and equipment.

After President Mackenzie's address, Chairman George Medlar asked Councillor E. M. Krebsler to introduce Vice-President K. M. Cameron.

Mr. Cameron paid tribute to the speaker of the evening and said that it was exceedingly fortunate that Canada was able to call on a man of President Mackenzie's calibre to take over the duties at the National Research Council.

Mr. Cameron then discussed several Institute affairs of great interest to the members, particularly the papers presented for the John Galbraith prize. One of our members, Mr. A. H. Pask, has presented a paper for this prize.

Councillor J. A. Vance then spoke briefly and praised the work of President Mackenzie and past presidents in visiting the different branches and bringing them more closely together.

Mr. H. F. Bennett of London spoke briefly on the work of the Committee on the Welfare of the Young Engineer and spoke of the booklet which is being prepared for early distribution to Canadian high schools giving information regarding the engineering profession.

At the close of the meeting, Mr. T. H. Jenkins, on behalf of all the members, moved a hearty vote of thanks to our president for his visit and extremely interesting address. Mr. J. F. Bridge seconded this motion.

#### EDMONTON BRANCH

F. R. BURFIELD, M.E.I.C. - *Secretary-Treasurer*  
L. A. THORSSON, Jr.E.I.C. - *Branch News Editor*

The second general meeting for the year of the Edmonton Branch was held in the Electrical Engineering Laboratories of the University of Alberta, on November 18th. A paper was given in connection with a visit to the new Broadcasting Station, CKUA, of the University of Alberta by Mr. J. W. Porteous, of the department of electrical engineering, who was chief engineer and designer of the new installation.

Prior to the visit Mr. Porteous outlined the problems confronting the designer of a broadcasting station and very clearly showed the various steps from the source of sounds to the antenna into the air and finally to the radio receiver. These various steps were illustrated by a laboratory set-up in which he explained the transfer of sound into electric currents by the microphone, how these currents were stepped-up by radio tubes, then showing the combination of these currents and voltages, known as audio frequencies, with the radio frequency wave, in order to produce a wave that can travel out from the antenna for great distances. With the laboratory set-up, Mr. Porteous actually broad-

cast various sounds showing the combination of the audio and radio frequencies by the use of an oscillograph. These sounds were picked up by an ordinary radio receiving set in the far end of the laboratory.

After the paper, Mr. Porteous conducted the members around the transmitter and antenna tower of the new station, pointing out the various steps described in his paper.

With an excellent turn-out of members and guests, it was a very interesting and enjoyable evening.

#### HALIFAX BRANCH

S. W. GRAY, M.E.I.C. - *Secretary-Treasurer*  
G. V. ROSS, M.E.I.C. - *Branch News Editor*

Mr. M. Walsh, chief engineer of the Gunitite and Waterproofing Co. Ltd., was speaker at the November 27th dinner meeting of the Branch. Seventy-seven members and guests were present.

Mr. Walsh described the **Pre-stressed Concrete** process used by his company in the construction of water and oil tanks, a topic of special interest here as several tanks of this type are soon to be built in the vicinity of Halifax. Mr. Walsh spoke of the causes of failure due to cracking and separation of concrete from steel in tanks of conventional design. He then dealt with the pre-loaded concrete design, which overcomes these causes of failure, and explained the method of placing and pre-stressing the reinforcing steel, and illustrated his talk with a motion picture of tanks under construction.

Mr. R. L. Dunsmore, of the Imperial Oil Company, extended an invitation to the Branch members to visit the site when construction gets under way.

The tanks to be erected are 130 ft. in diameter, 42 ft. wall height with domes bringing the total height to 58 ft. and with a capacity of 100,000 barrels.

S. L. Fultz was chairman of the meeting.

#### HAMILTON BRANCH

A. R. HANNAFORD, M.E.I.C. - *Secretary-Treasurer*  
W. E. BROWN, Jr.E.I.C. - *Branch News Editor*

The December meeting of the Branch was held at McMaster University on the 16th, with an attendance of 40. Since the meeting was to be one on tool steels, a Tool Steel Quiz was held prior to the meeting. This proved very interesting and the prize was won by a visitor, Mr. Trane.

T. S. Glover introduced the speaker, Mr. H. B. Chambers, metallurgist of Atlas Steels Limited, of Welland, Ont.

Mr. Chambers, in speaking on **Tool Steels for Engineers** explained that generally the engineer had a very poor conception of tool steels and their proper application.

Basically tool steel is a mixture of iron, carbon varying from 0.7 to 1½ per cent, silicon ¼ per cent for soundness of steel, and manganese ¼ per cent for workability. These are water-hardening steels and can be divided into four groupings, according to a 20 point carbon range, as follows:

1.30 to 1.50 carbon  
1.10 to 1.30 carbon  
0.90 to 1.10 carbon  
0.70 to 0.90 carbon

The higher carbon steels have a maximum of wear resistance and the lower carbon steels a maximum of toughness or resistance to shock load. It must always be remembered that as the resistance to wear is increased, the toughness of the steel must be sacrificed and vice-versa. The intermediate groups give a combination of these two properties.

But it is necessary to have tool steels which can be hardened without any appreciable change in section. Therefore, by the addition of chromium, molybdenum and in some cases manganese, the oil-hardening steels are obtained but still with same carbon range and groupings, so that the oil-hardening steels add four more groups.

But in applications such as forging or high speed lathe work the die or tool must resist heat. Therefore, there

arises the need for high speed tool steels or in other words, heat-resisting tool steels and these are obtained by the addition of tungsten and in some cases additional molybdenum. The same carbon range is maintained and thus four more main groups of tool steels are added to the available tool steels.

To recapitulate, we have:

Water-hardening steels—4 groups.

Oil-hardening steels—4 groups.

Heat-resisting steels—4 groups.

It should be remembered that each of these three classifications maintains the range from maximum wear resistance to maximum toughness. Thus the whole tool steel picture can be given in 12 groups.

Mr. Chambers also pointed out the dangers of poor die design, showing how the use of fillets and an attempt to keep dies of irregular cross-section to a balanced cross-section will avoid the strains and resultant cracks sometimes experienced in the heat-treating of dies.

Mr. Chambers went on to deal with some specific applications of tool steels and also answered many questions.

E. M. Coles moved the vote of thanks, expressing the appreciation of the meeting for the very clear picture of tool steels presented by the speaker.

The meeting adjourned for the usual refreshments.

### LAKEHEAD BRANCH

W. C. BYERS, M.E.I.C. - *Secretary-Treasurer*  
A. L. PIERCE, M.E.I.C. - *Branch News Editor*

The regular monthly meeting of the Lakehead Branch was held on Wednesday, November 19th, at 8 p.m. The members gathered at the new Shell Plant at Fort William for an inspection trip.

Later in the evening the members re-assembled at the New York Lunch in Fort William, where a short general meeting was held and lunch was served. The scheduled speaker of the evening, Mr. J. M. Paton, general manager of the Shell plant was unable to be present. In his absence, Mr. J. Heald, production manager of the plant, spoke a few words of welcome.

Mr. Krzywoblocki, a Polish engineer now resident at the Lakehead, attended the meeting and was warmly welcomed and invited to attend all future meetings of the Branch.

A short discussion took place during which some of the members expressed their pleasure upon having been given the opportunity of visiting the Shell plant. A vote of thanks from the membership was extended to Mr. J. M. Paton, who had made the visit possible.

The Lakehead Branch held its monthly meeting on December 3rd at the New York Lunch in Fort William. Following dinner, the members were shown two moving pictures. The first of these was the **Tacoma Narrows Bridge**. Mr. P. E. Doncaster, who had previously seen the film, then gave a few statistics regarding the structure and a lively discussion followed. A film called **Photo-elastic Stress Analysis**, filmed at the University of Manitoba, was next shown and was followed with a great deal of interest by the members. Mr. J. M. Fleming led the discussion which followed.

Both pictures were thoroughly enjoyed by the members and guests. Mr. G. R. Duncan was tendered an expression of thanks by the chairman for the use of his projector.

B. A. Culpeper, the chairman, presided. Thirty-nine members and guests were present.

### LONDON BRANCH

H. A. STEAD, M.E.I.C. - *Secretary-Treasurer*  
A. L. FURANNA, M.E.I.C. - *Branch News Editor*

On Wednesday, November 26th, the London Branch held its monthly meeting jointly with the Canadian Club to welcome The Engineering Institute's president, Dean C. J. Mackenzie. The meeting took the form of a dinner in the Crystal Ball Room of the Hotel London.

Introduced by Mr. H. F. Bennett, the president spoke on **Research and War**. Dean Mackenzie in his capacity as acting president of the National Research Council outlined the purpose, functions and organization of research in Canada at war.

As for the importance of research in war, he said, it need only be stated that it is highly endorsed by Major General A. G. L. McNaughton. Before the war, scientific work in Canada was well organized and the change-over from peace to war was made with high efficiency. He said that the purpose of research in war is to develop the equipment to be placed in the hands of the fighting forces. To give some idea of the vastness of this undertaking, it is only necessary to realize that one division carries power equipment totalling a capacity equal to that required by the city of Toronto.

Dean Mackenzie stated that in this war of mass production there are four distinct phases: development, design, tooling-up and training. But time is the predominating factor throughout, and this limits what can be done in research. While it is impossible to design new battleships or even big guns, much is being done in the middle-class projects such as small guns and improvements on aeroplane parts. However, most of the work is being done in the small appliance class including radio, medical apparatus and optical instruments. Thus there are three prime considerations in any problem. Is it scientifically sound? Is it tactically sound? Can you make it?

Organized research in Canada is carried out by the National Research Council. The most important function of this body is to coordinate and supervise research across the country. Originally there were no laboratories; however, there are now several laboratories in Ottawa.

Research is carried on under four classifications: mechanical engineering, electrical engineering, chemistry and biology with associate interests in medicine, field conservation and forestry. The Council has mobilized across Canada so that now there are 70 projects under study in 15 universities throughout the Dominion.

Constant liaison is maintained with England and the United States, the object being not to repeat any work already done elsewhere nor to do anything which cannot be carried through.

Finally, the president warned that we must do away with wishful thinking. This war will not be won by any miracle of science. We must be prepared to make real sacrifices and do away with petty criticisms. He said the reason we feel so futile about this war is that although we have been trying, we are not doing our best. Something is lacking—sacrifice.

After the meeting two tours were conducted. The first trip was to the Ordnance Mechanics Training School at Queens Park and was arranged by Lt.-Col. W. M. Veitch.

The second trip was to the Fleet Aircraft plant at Crumlin, under the direction of the architect, Mr. Loreen Oxley.

### MONCTON BRANCH

V. C. BLACKETT, M.E.I.C. - *Secretary-Treasurer*

**Centralized Traffic Control** was the subject of an address delivered before a branch meeting on November 28th, by R. M. Phinney, S.B., engineer of train operation, General Railway Signal Co., Rochester, N.Y. The meeting was open to the public and in addition to branch members, a large number of railway men were present. F. O. Condon, chairman of the branch, presided.

Mr. Phinney's paper dealt with the despatching of trains. He compared the present method of written train orders, time-table authority and hand-operated switches, with the newer mechanized system whereby trains move under the instruction of way-side signals, which together with the operation of important track switches are under the control of a single operator located in a central office. Mr. Phinney's remarks were illustrated with motion pictures.

A vote of thanks to the speaker was moved by T. H. Dickson and seconded by E. R. Evans.

#### SACKVILLE MEETING

On November 29th, the Moncton Branch combined with the Engineering Society of Mount Allison to hold a meeting in the Science building of the University at Sackville. There was a large attendance of engineering students together with members of the branch, and also of the technical staffs of the Robb Engineering Company and the Canadian Car and Foundry Company at Amherst. Laine Jamieson, president of the Engineering Society, was in the chair. The speaker was R. M. Phinney, who gave an illustrated address on **Centralized Traffic Control**. A vote of thanks was extended Mr. Phinney by Dean H. W. McKiel.

#### MONTREAL BRANCH

L. A. DUCHASTEL, M.E.I.C. - *Secretary Treasurer*  
G. G. WANLESS, JR.E.I.C. - *Branch News Editor*

Dr. R. R. Williams addressed the Montreal Branch on December 11th, on the subject of **The Chemical Descent of Man**.

Dr. Williams, who is Chemical Director of the Bell Telephone Laboratories, has specialized in the field of vitamin chemistry. He was born in 1886 at Rampatnam, India, where he had ample opportunity to become acquainted with the scourge of beriberi. After receiving his m.sc. degree from the University of Chicago in 1908, he returned to the far east and began work in the Bureau of Science at Manila on this same problem of beriberi. Not until 1933 did he succeed in isolating pure vitamin B<sub>1</sub> (thiamin) from rice polishings, and in proving that this was the specific substance whose absence from polished rice causes beriberi in oriental peoples. By 1936 he had accomplished the synthesis of thiamin. This great work was carried on, for the most part, in addition to his regular duties at the Bell Laboratories.

Although we seldom hear of beriberi in this hemisphere, moderate deficiency of B<sub>1</sub> in our diet can be responsible for an impairment of physical and mental efficiency. This is of especial interest to the armed forces. Dr. Williams has been awarded the Willard Gibbs medal for his brilliant work.

By comparing the behaviour of certain vitamins in the physiology of man, animals and plants, Dr. Williams was able to show how closely related are their basic living functions. Such examples are accepted as evidence in support of the theory of man's evolution. It is much more precise evidence than physical and character resemblances which formed the basis of Darwin's famous book of 1870. Some chemical illustrations of the interdependence and similarities of man, animals and plants are:—

(1) Plants synthesize carbon dioxide and water into starches, sugars and celluloses, which become the basic plant structures. Man and animals consume these products, producing energy and causing a reversion of the process.

(2) Exactly the same vitamins, amino-acids and other functional chemicals are found in man and other higher animals.

(3) It is of interest to note that the physiological behaviour of food and drug on man can be predicted from laboratory tests performed on animals.

(4) The hormones, stimulating agents of human endocrine glands, have the same effects on behaviour in other animals.

(5) The functioning of the nervous systems in men and animals are known to be actuated by electrical impulses, which resemble chemical chain reactions. Their temperature coefficients are the same as those of wired electrical circuits.

(6) All the vertebrates have similar visual systems which function by the reversible oxidation and reduction

of certain carotinoid pigments in conjunction with one of the vitamins. The light filters of chickens' eyes contain the same chlorophyll and xanthophyll found in the plant world, and vitamin A. Lack of this same vitamin contributes to night blindness in humans.

(7) The principal substances in the blood stream of man (haemoglobin) and that of the plant circulatory systems (chlorophyll) were shown to have comparable chemical space structures.

(8) Some evidence is reported which indicates that both man and animals exhibit some instinctive craving for vitamins in which their bodies may be deficient. It is now suspected that all of the vitamins may prove to be essential chemicals in plants and animals, as are the hormones in man.

Dr. Williams presented his complicated subject in clear and understandable terms. The broad interest of his engineer audience was indicated by the extensive discussion which followed. In moving the vote of thanks, Dr. Struthers paid tribute to the brilliant investigations of this world-renowned scientist.

Dr. Williams delivered a classical lecture, and it was a rare opportunity to hear it.

#### NIAGARA PENINSULA BRANCH

J. H. INGS, M.E.I.C. - *Secretary-Treasurer*  
C. G. CLINE, M.E.I.C. - *Branch News Editor*

A joint meeting of the Niagara Peninsula Branches of The Engineering Institute of Canada and the American Institute of Electrical Engineers was held on November 20th at the Welland House, St. Catharines, with an attendance of 60. Mr. A. L. McPhail, chairman of the local branch of The Engineering Institute, presided. Mr. Norman Franks introduced the speaker, Mr. J. W. Bateman, manager of the lighting service department of the Canadian General Electric Company Limited, whose subject was **Some Interesting Applications of Light, Ultra-Violet and Infra-Red Radiations**. Mr. Bateman had with him a large amount of electrical equipment with which he illustrated his subject in a most interesting manner. He also used lantern slides to show various types of lighting installations. The vote of thanks was proposed by Mr. George Morrison, chairman of the local branch of the American Institute of Electrical Engineers.

#### OTTAWA BRANCH

R. K. ODELL, M.E.I.C. - *Secretary-Treasurer*

At the noon luncheon on November 20, Commander H. N. Lay, R.C.N., Director, Operations Division, Naval Service Headquarters, Ottawa, addressed the Branch on **The Royal Canadian Navy**. He traced briefly the history of the Royal Canadian Navy from its inauspicious beginning in 1910 to its present importance as a vital part of Canada's war effort.

G. J. Desbarats, C.M.G., who was deputy minister of the Naval Service at the time of the Navy's inception, was at the head table. For this reason the Commander hesitated to go into details too deeply. "Mr. Desbarats would be able to correct me if I made a mistake" he said.

The commencement of the Canadian Navy dates from 1910 when the Canadian Government officially took over the Royal dockyards at Halifax and Esquimalt and purchased two fairly old cruisers, the *Niobe* and the *Rainbow*. The former was stationed in eastern waters and the latter in western waters. The next year the Royal Naval College was started at Halifax.

During the first great war the Navy did its part and in 1917 Halifax became the first convoy assembly point on this side of the Atlantic. In 1918, after the close of the war, the personnel was reduced from 6,000 officers and men to 1,000 and subsequent cries for economy reduced the number in 1923 to less than 400 officers and men with estimates at one time as low as two million dollars.

In 1928 the Navy began to be built up again so that at

the commencement of the present war there were six destroyers and four mine sweepers. Naval personnel totalled 1,700 which was soon stepped up to 20,000. This great increase was enlisted during the first few months of the war and taxed to the utmost the facilities of Halifax and Esquimalt.

Discipline in the Royal Canadian Navy and the Royal Australian Navy, stated the speaker, is patterned after that of the Royal Navy. Officers go to England for instruction and there obtain "wonderful experience."

Canadian shipyards started building and in 1940 undertook an extensive building programme. As convoys were started immediately war was declared some sort of ships had to be commissioned at once for anti-submarine work as a stop gap, such as converted yachts of 400 to 500 tons. Three *Prince* class liners were converted to auxiliary cruisers and have been very successful, serving and making captures all over the world. Canadian destroyers also assisted at the evacuation of Dunkerque.

The corvettes, he characterized as "marvellous little ships, by far the cheapest and quickest to build for use against submarines." Tremendous credit must be given to Canadian shipyards for the facility with which they can now turn them out. In the short period of eleven months, he said, they can be laid down, completed, do their trials, cross the Atlantic and be placed in commission against the enemy. Within the next month it is expected that from 30 to 40 ships of various categories will be accepted by the Royal Canadian Navy.

The Royal Canadian Navy has gone through 31 years of pretty doubtful existence, stated the Commander, and it is to be hoped that the service is firmly established. Canada can no longer entirely depend upon the British Government for protection. On account of her extensive sea-borne trade, as long as there are any foreign navies in existence that might attack this traffic, there must be a Canadian Navy, he declared.

A talk on **Air Co-operation** was given at the noon luncheon of the Ottawa Branch at the Chateau Laurier on December 4. Squadron Leader W. W. Ross of the R.C.A.F., commanding the School of Army Co-operation and stationed at Rockcliffe, was the speaker. Chairman of the Branch, T. A. McElhanney presided.

Operations in modern warfare often call for the closest kind of co-operation between units of the army, the navy, and the air force, with the last-mentioned occupying a most important place in that co-operation. The speaker outlined the manner in which such co-operation may be maintained. He stated that the present-day pilot, whether engaged in fighter, bomber, reconnaissance or army co-operation manoeuvres must have plenty of initiative and self confidence. Frequently they are definitely on their own when the success of the job in hand is entirely up to the individual.

Squadron Leader Ross went over to England in February, 1940, with the 110 Army Co-operation Squadron, went through the September attack of that year and returned to Canada in March, 1941. "I really had a grandstand seat at the blitzkrieg on London," he commented, referring to a visit he made to that city while on leave during which time enemy attacks were at their worst.

He paid tribute to the remarkable bravery exhibited during these attacks by the English population. "Just about the bravest thing that I ever saw" he stated, "was the manner in which two young girls drove an ambulance through the burning city of London one night when the enemy really tried to set it on fire. They rumbled over the rubble of the streets, picking up the casualties here and there whenever they heard anyone yelling for help. Before the night was over the cover of their ambulance was burned away but they thought nothing of that and simply took it all in their stride. I undertook to assist them and accompanied them for several hours although I did not even learn their names. I am willing to admit that all the time I was with them I was just about scared to death."

## PETERBOROUGH BRANCH

D. J. EMERY, M.E.I.C. - *Secretary-Treasurer*  
E. WHITELEY, Jr. E.I.C. - *Branch News Editor*

The twenty-third Annual Dinner of the Peterborough Branch was held at the Kawartha Club on November 19th, and was attended by about ninety engineers. The meeting was addressed by four notables of the engineering world in the persons of Dean C. J. Mackenzie, president of The Institute and acting president of the National Research Council of Canada; K. M. Cameron, Vice-President of The Institute and Chief Engineer of the Department of Public Works, Ottawa; deGaspé Beaubien, Vice-President of The Institute, Joint National Chairman for War Savings, and Consulting Engineer, Montreal, and L. Austin Wright, General Secretary of The Institute, Montreal, and Assistant Director of the Wartime Bureau of Technical Personnel, Ottawa.

The theme carried throughout the addresses urged engineers to make plans now to avoid post-war dislocations. It is becoming apparent that engineers must face a two-fold challenge—to win the war, and to organize a plan to avoid its aftermath of destructive dislocation.

The first appeal to make this a total war came from L. Austin Wright. He claimed it was the duty of the engineers of Canada to give leadership on the subject of air-raid precaution work, and, he added, with this in view,

The Headquarters party. President Mackenzie, Vice-Presidents Cameron and Beaubien, and General-Secretary Wright.

arrangements had been completed to send a competent engineer to Britain to study and investigate the work being done, that is from a structural and engineering standpoint, and to report back at the annual meeting to be held next February. The study will include defence from bombs, repairs from damage, restoration of public utilities, and the many other phases of this work.

Mr. Wright said The Institute was in a healthy condition, both in membership and financially, but, he added, the war had brought manifold problems.

He spoke, too, of the problems of the Wartime Bureau of Technical Personnel, and explained that an attempt was being made to catalogue and organize the engineers of Canada so that they would be able to tackle every problem in all fields of engineering during the war.

The second appeal to organize and avoid post-war dislocation and depression came from G. R. Langley, chief engineer at the local plant of the Canadian General Electric Company, Limited.

"This is an appeal for action on a matter that vitally concerns everyone in Canada. No one here to-night would dispute that our job is to win the war. Too many of us, however, think of this job solely as a matter of production of tanks, ships and guns, the training of men and the complete defeat of Hitler and his armies. We can win that

phase of the war and still meet defeat if we fail to adequately plan to avoid post war dislocations that may destroy the things we are really fighting for, our standards of culture, and living and our democratic institutions.

"At the close of hostilities, Canada will probably have her wealth-producing facilities (factory building and machinery, transportation, power supply, mines, farms, forests, and trained personnel) in better shape than ever before in her history, most of them not merely unimpaired by the war effort, but actually improved. There is no theoretical or practical reason why these facilities cannot be used to give a higher standard of living for everyone, than has ever been reached in the past. This happy result can only be achieved by adequate planning. Lacking such planning there is good reason to fear a business recession of terrific proportions."

A stirring appeal for more support in the form of War Savings Certificates, coupled with the assurance that the citizens of Quebec are striving with all Canada for a national unity and an early peace through victory, was brought to members of the Branch by deGaspé Beaubien.

"You need not worry about the great race I represent, when you think of national unity. If we can get Quebec to know the other provinces better, and the other provinces to know Quebec as she is, then everything will be better."

"The great task ahead of us will require more production, and greater production requires money. More War Savings Certificates must be sold, and I would urge that you renew your effort if at all possible, and this appeal comes from your country."

The guest speaker of the evening, Dean C. J. Mackenzie, was introduced by Hubert R. Sills of the Peterborough Branch.

Dean Mackenzie spoke on the part scientific workers are playing in this war and he prefaced his talk with a few remarks to show the great difference in the World War I of 1914-18 and the present struggle. For example, he stated that one division alone has 500,000 horse power, as much as is used in the city of Toronto.

"Our science and technology was adequate when this war began, but we lacked quantity of war weapons. What we had was of good quality, but we had little. In 1916 the National Research Council had been formed and it has gone on ever since in a modest way.

"To-day, this Research Council is in high gear with four branches, and 30 associate committees, of these latter the one perhaps making the greatest progress is the committee engaged in medical research.

"Our job is to co-operate, co-ordinate and stimulate the country's effort towards winning the war."

Jack Cameron, president of the branch, was chairman during the dinner meeting, which was attended by 90 people including engineers from Hamilton, Toronto, Ottawa and Montreal, and also including ten girls, graduates of different universities who are being trained as inspectors at the C.G.E. plant. The thanks of the gathering to the speakers was voiced by Stanley O. Shields, of the branch. Entertainment was provided by Rex Slocombe of Toronto, a magician and a musician.

### SAINT JOHN BRANCH

V. S. CHESTNUT, M.E.I.C. - *Secretary-Treasurer*

Thirty-three members and guests attended a supper meeting of the Saint John Branch held in the Admiral Beatty Hotel on Thursday, December 11th. The Branch chairman, F. A. Patriquen, presided. Mr. C. C. Kirby reported that the professional engineers of the province voted strongly in favour of co-operation with The Engineering Institute. Mr. Kirby also outlined the progress being made in the formation of a Demolition Committee for the city of Saint John and in which the Saint John Branch is taking such a leading part.

Mr. G. W. Berry, Saint John manager of Ford Company of Canada, Ltd., the guest speaker of the evening, was

introduced by the chairman, Mr. Patriquen. Mr. Berry outlined to his audience the vast strides made in Canada's industrial contribution to the war effort. In the last war, an infantry battalion unopposed by the enemy could travel fifteen miles per day, while to-day the same battalion could travel 150-200 miles in the same period. There is more horse power in an armoured division of to-day than in the whole of the maritime provinces. The motor car industry of Canada had naturally specialized in army trucks and carriers of all kinds, and had supplied thousands of these machines to numerous battlefronts of the world. If necessary, Canada could supply 25,000 of these machines per month.

In the field of tanks, Canada was building the light infantry and the medium cruiser tank. An additional fighting unit, the light destroyer tank, is still in the hands of the designers.

At the conclusion of his address, Mr. Berry showed films outlining the manufacture and testing of the equipment manufactured at the Ford plant. From these tests it was apparent that any defects would be discovered before export to the various fields of battle and that Canada should be proud of the equipment she is supplying in "providing the tools to finish the job."

### ST. MAURICE VALLEY BRANCH

C. G. DE TONNANCOUR, S.E.I.C. - *Secretary-Treasurer*

The fall activities of the branch were resumed on September 4th when the branch and the Shawinigan Chemical Association were invited to participate in a joint dinner meeting sponsored by the Canadian Club, at the Cascade Inn.

The guest speaker was Sir W. Lawrence Brogg, noted for his work on X-ray analysis of crystal structure, and one of the world's leading scientists, specializing in the structure of metals.

Sir Lawrence, acting in Canada as liaison officer with the National Research Council, spoke on **Canadians are British Scientists in the War.**

The meeting was very well attended, and the Canadian Club must be thanked for the initiative in sharing their distinguished guest with the engineers and the chemists.

Sir Lawrence stressed the evident preparedness of Germany long before the invasion of Poland and explained by means of examples the part played by chemists and

Mr. George Long speaks to the St. Maurice Valley Branch. Next to him are Chairman A. H. Heatley and H. G. Timmis.

physicists in gearing British industries to war production; he mentioned that their contribution was more on solving the problems of development and expansion of known processes than on last minute inventions.

The next event was a dinner meeting at the Château de Blois, in Trois-Rivières, presided over by Dr. H. Heatley, branch chairman. Mr. George Long, historian of the Bell Telephone Company of Canada, spoke on **Wartime Communications**. Amidst an impressive array of electrical equipment illustrating the development of the telephone from A. Graham Bell to our times, Mr. Long gave his audience a vivid picture of the part played by the Bell Laboratories, the Bell network and equipment manufacturers in World Wars I and II. Mr. Long was presented by Mr. J. M. Mitchell, and thanked by Mr. H. G. Timmis.

On November 3rd, at the Laurentide Inn, in Grand'Mère, Mr. Jean Flahault, S.E.I.C., made a successful escape from work at Arvida to address the branch on **Some Engineering Aspects of the German Army**, gathered from his personal experience with the Germans in France, his capture and subsequent escape to Canada. Mr. Flahault submitted willingly to a bombardment of questions and ended by giving the World War I veterans among his audience an eagerness to be "over there" once more, not to talk of the younger members' reaction. Mr. Flahault was introduced by Mr. Alphonse Trudel, and thanked by Mr. R. Dorion.

### SAGUENAY BRANCH

D. S. ESTABROOKS, M.E.I.C. - *Secretary-Treasurer*  
J. P. ESTABROOK, JR., E.I.C. - *Branch News Editor*

A meeting of the Saguenay Branch of The Institute was held on Tuesday, November 25th, in the Arvida school.

Previous to hearing the guest speaker on this occasion, the members were shown a film depicting the placing of the "obelisk," used to turn the water into the diversion canal of the present Chute-à-Caron power development. The "obelisk" was a concrete structure in the shape of a block 40 ft. square in cross-section and 92 ft. long made to fit the contour of the river bed and first supported in an almost upright position by a thin concrete column, placed to prevent it from tipping. When all was ready this thin column was blasted away and the massive obelisk fell into place in the river, leaving an eight foot gap at each end that was later sealed with stop logs. By means of instruments used to study the fall, it was learned that 99.6 per cent. of the energy had been absorbed by the water.

The speaker, Mr. C. D. McCoy of the refining division of the Foster Wheeler Corp., New York City, was introduced by our chairman, Mr. N. F. McCaghey.

Choosing as his topic, **The General Principles of Petroleum Refining**, Mr. McCoy first dwelt on the various products available from crude petroleum: toluene, acetone, alcohols, rubber, ammonia, and hydrogen, later stressing the part played in the war by lubricants and high octane gasoline. In a review of Canadian production facilities, the Athabaska oil shales were mentioned and also the fact that Canadian refineries have five times the capacity that would be required if they were handling only Canadian crude.

The refining of petroleum is essentially a distillation process with a fractionating action enabling the operators to obtain the different grades of distillate at definite levels in the fractionating tower.

The exact treatment depends on the type of crude being treated and each refinery has its own characteristic operations. However, the general design of the equipment used is similar. The crude oil is preheated, enters the tubes of a furnace and thence goes to the bubble tower where fractionation takes place. Gasoline vapours are taken off overhead and naphtha, kerosene and fuel oils, etc., at a lower level. Wax distillate is drawn off at the bottom. Other special equipment such as stripping columns and coke units enter the process.

As gasoline is now the most useful constituent, the present policy is to increase this cut as much as possible. This is done by cracking and polymerization of the heavy fraction and the lighter gaseous fractions respectively.

Catalytic hydrogenation, using an aluminum chloride catalyst is playing its part in this aim to produce more gasoline.

In conclusion, Mr. McCoy explained the use of the octane rating system and the importance of high octane gasoline in our present day world. The keen interest aroused by the speaker was shown by the large number of questions that followed in the discussion period.

### SASKATCHEWAN BRANCH

STEWART YOUNG, M.E.I.C. - *Secretary-Treasurer*

A meeting of the Saskatchewan Branch was held in the Kitchener Hotel, Regina, on November 21st, jointly with the Association of Professional Engineers and the Saskatchewan Section of the American Institute of Electrical Engineering. The attendance was 45.

For a short period after dinner the meeting was conducted as a meeting of the Association of Professional Engineers to consider certain proposed amendments to the by-laws. These were put to a vote and adopted.

Mr. H. I. Nicholl called attention to the departure for Bolivia in the near future of one of our members, Mr. L. M. Howe, active during the past several months on the papers and meetings committee. Mr. Howe replied in a few appropriate words.

The showing of a two-reel silent film, the **Tacoma Narrows Bridge**, occupied the balance of the evening and proved of more than usual interest.

### SAULT STE. MARIE BRANCH

O. A. EVANS, M.E.I.C. - *Secretary-Treasurer*

The sixth general meeting for the year 1941 was held in the Grill Room of the Windsor Hotel on Friday, November 28th, 1941. Nineteen members and guests sat down to dinner at 6.45 p.m.

The chairman called upon David L. Mekeel, Steel Mill Consultant, to address the meeting. Mr. Mekeel had for his topic **The Steel Industry**.

The speaker dealt with the steel industry from its birth as small isolated furnaces to the present gigantic groupings in strategic centres. He also sketched briefly the rise of the American steel industry. The first cargo of ore that was shipped from the Lake Superior Mines was in the 1850's. Not much hope was held at that time for the iron mines of the lake district. The speaker held the interest of the audience with stories on the human side of the steel industry, relating the personal touch that men such as Bessemer, Jones, Carnegie, Schwab have given to the industry. The speaker then gave a brief review of the steel industry in Canada, paying particular emphasis to the Algoma Steel Corporation and its possibilities.

At the conclusion of his speech the meeting was thrown open for discussion. The speaker was deluged with a flood of questions on all phases of the industry. The discussion kept up for quite some time.

A. E. Pickering moved a vote of thanks to the speaker, H. W. Adams seconded it.

The annual meeting for the year 1941 was held in the Grill Room of the Windsor Hotel at 6.45 p.m. on Friday, December 12, 1941. Twenty-one members and guests sat down to dinner.

The business portion of the meeting began at 8.00 p.m. with L. R. Brown, vice-chairman, presiding.

The secretary presented his report. The highlights were a successful year as regards papers and meetings but a loss of membership and a financial loss of \$36.27. J. L. Lang, M.E.I.C., and G. W. MacLeod, M.E.I.C., moved that the secretary's report be adopted.

The chairmen of the various committees then brought in their reports. They were as follows:

N. C. Cowie, Junior Engineers' Committee;  
R. A. Campbell, Legislation and Remuneration;  
A. E. Pickering, Papers and Publicity;  
J. L. Lang, Entertainment;  
A. M. Wilson, Membership.

A. E. Pickering paid tribute to J. S. Macleod, the chairman of the Papers Committee, who was absent from the meeting but had done splendid work throughout the year. A. M. Wilson told the branch that there was a great field for the incoming membership committee, as many engineers were moving into town.

A. H. Meldrum and N. C. Cowie were then appointed auditors for the year 1941 on motion of R. S. McCormick and C. Stenbol.

Before accepting the chair for the year, L. R. Brown called for further nominations. After some time G. W. MacLeod and A. M. Wilson moved that nominations be closed. The chairman then called for co-operation for the year 1942.

The chairman then called upon F. W. Fraser to give a short summary on the causes of the failure of the Tacoma Bridge, which was done in a very capable manner, G. W. MacLeod acted as the projectionist for the film. The rest of the evening was spent in a social way.

### TORONTO BRANCH

J. J. SPENCE, M.E.I.C. - *Secretary-Treasurer*  
D. FORGAN, M.E.I.C. - *Branch News Editor*

On November 29th the Toronto Branch of The Engineering Institute participated in a joint meeting with the Royal Canadian Institute in Convocation Hall to hear Dr. H. Ries, A.M.Ph.D., professor of geology, Cornell University, present his views on **What Use the Engineer Makes of Geology**.

The branch chairman, Mr. H. E. Brandon, following the chairman of the R.C.I., welcomed the speaker on behalf of The Engineering Institute, a considerable number of our members attending.

Professor Ries' lecture was profusely illustrated with lantern slides and motion pictures of his own taking. His references to the part which the geologist should play in the siting and design of engineering structures and the use which engineers have made of such available knowledge and experience, were provocative of considerable comment and given proper appreciation by those engineers fortunate enough to hear them.

The regular meeting of the branch was held in the theatre of the Royal Ontario Museum at 8.00 p.m. on December 4th. It had been felt that the subject for the evening was of sufficiently wide and popular interest to warrant the branch engaging this accommodation, and inviting the public and other interested organizations. These expectations were fully realized, some 350 people attending the meeting. All expressed opinion testified to the very great general interest which the meeting held, and it was felt that the evening's programme more than maintained the high level which has characterized the branch meetings this season. It is impossible to escape the conclusion that even a few meetings of this type, presented where the general public could share in them, would do much to further the standing and usefulness of the engineering societies.

The subject of the meeting was **Conservation of Natural Resources, with Special Reference to Post-War Planning**. In his opening remarks the branch chairman, Mr. H. E. Brandon, pointed to the steadily mounting public interest in the subject, which though frequently thought of as being associated with tree planting, wild life, and soil erosion, actually is a matter which intimately affects many more phases of life and community activities. Many activities of the engineer are affected and so the interest of the engineer in conservation is important. The chairman welcomed those members of other bodies present, among

whom were: the Ontario Federation of Naturalists; the Southern Ontario Section of the Canadian Society of Forest Engineers; the Toronto Field Naturalists Club; the Society of Biologists, Toronto Branch; the Toronto Hunters' and Anglers' Association; the Toronto Branch of the Canadian Society of Scientific Agriculturists.

The programme was conducted by Mr. R. F. Legget, assistant professor of civil engineering, University of Toronto, to whose efforts much of the success of the meeting was due. Three speakers participated, each one an authority on his particular phase of the subject. As each took up his theme he was introduced by Professor Legget who briefly outlined the field to be covered. The first speaker was Mr. F. A. MacDougall, Deputy Minister of Lands and Forests for Ontario, who presented a comprehensive illustrated talk on the **Forests and Drainage Areas of Ontario**. The second speaker, Professor A. F. Coventry, department of biology, University of Toronto, spoke on the **Water Situation in Southern Ontario**. His lecture, also illustrated, was most startling and effective in the information he presented, and vividly drew attention to the effect of indiscriminate clearing and drainage, and the consequent serious results on farming operations in southern Ontario.

Dr. A. E. Berry, chief sanitary engineer, Ontario Department of Health, followed. He spoke on **Public Health in Ontario** and its relation to conservation and, illustrating his lecture with numerous slides, forcefully brought before the audience the effects of floods and droughts on the nation's health problem.

The fourth item on the programme was a documentary film entitled **The River**. Kindly loaned by the United States Soil Conservation Service, the film deals with the Mississippi River, what it has done and what man has done to it. It depicts vividly the vital part that this river has played in the development of the United States and shows how man, by abusing natural conditions, has in many cases turned the river from a natural blessing into an uncontrollable menace. It goes one step further and points out how through agricultural practices and engineering projects, which in themselves are beneficial to the country as a whole, control of the river can be regained. It is a conscious attempt to present a fundamental problem so factually and so dramatically that those who see the picture will be moved to action. The film was a fitting climax to the three addresses, and left everyone in the meeting faced with the impression that something must be done before it is too late, if it is not already so, to preserve the natural resources of our Dominion, especially the part each one lives in.

On Monday, December 8th, as arranged by the Institute of Radio Engineers, Toronto Section, a joint meeting was held in the Physics Building of the University of Toronto of the following societies: Institute of Radio Engineers (Toronto Section); Engineering Institute of Canada (Toronto Branch); Illuminating Engineering Society (Toronto Chapter); American Institute of Electrical Engineers (Toronto Section).

The speaker, Mr. Harris Reinhardt of the Hygrade Sylvania Corporation of Salem, Mass., gave to the meeting a wealth of information on **Fluorescent Lighting and Equipment** well demonstrated by slides and apparatus. There was keen interest shown by all engineers in this well-delivered address on a comparatively new development in lighting practice.

About 350 engineers were present.

### WINNIPEG BRANCH

C. P. HALTALIN, M.E.I.C. - *Secretary-Treasurer*  
T. A. LINDSAY, M.E.I.C. - *Branch News Editor*

On November 6th, one hundred and three members of the Winnipeg Branch visited the offices and repair base of Trans-Canada Air Lines at Stevenson Field. Mr. J. T. Dymont, Chief Engineer of T.C.A., addressed the gathering and outlined the functions of the various specialized shops

which comprise the repair base. He also described the various aircraft used by the system and gave an interesting comparison of their performance characteristics.

Trans-Canada Air Lines maintains a fleet of twenty Lockheed twin-engined aircraft, six of which are Lockheed 18's. These ships have seating accommodation for 14 passengers, and can carry a total load of 5,500 lb. The Lockheed 14, of which T.C.A. has twelve in operation, carries ten passengers, and the same total load as the 18, but its maximum speed is only 244 m.p.h. as compared with 263 m.p.h. for the larger ship.

Mr. Dymont gave some very interesting figures on air system transportation. During the month of September, T.C.A. carried an average of 305 passengers daily, an average distance of 499.5 miles each. In the same period 99.3 per cent. of all scheduled flights were made. This fact alone speaks for the efficiency of the organization when one considers that the T.C.A. fleet flies 20,500 miles per day.

At the conclusion of Mr. Dymont's remarks, the membership inspected the shops and hangars of the base, under the guidance of T.C.A. personnel.

The Repair Base has fourteen shops, fully equipped to handle all the multitudinous details connected with the maintenance and operation of one of the world's finest airlines. Of particular interest to the members was the instrument repair shop, and the engine testing shop.

The inspection over, members of the branch adjourned to the recreation room where refreshments were served through the courtesy of T.C.A.

On November 20th the Winnipeg Branch met in the business offices of the City of Winnipeg Hydro-Electric System.

Gathering figures, printing bills and keeping accounts by punching holes in cards was the theme of an address given by Mr. F. J. Malby, Business Manager. Analysis of

electric sales to produce the revenue in each class of business, the number of minimum bills, empty houses, water heaters of different sizes and whether in use or not, the electric consumption in homes of different sizes, average rates, etc., are just a few samples of the mass of detailed information obtainable from the electric tabulation of punched cards. These cards are also used to automatically print the customers bills and finally are used as a ledger card system. Although there are 80 columns of figures on the card, only approximately 15 holes have to be manually punched thus reducing the possibility of error to a minimum. All the other holes are either automatically pre-punched from the previous month's card, where standard information is transferred or from master cards which represent every possible bill that is sent out. The latter is based on the fact that all persons using the same amount of electricity under the same base rate will have identical bills.

The master card is sorted into the groups with the same consumption and automatically reproduces the figures for the complete bill on all cards following. The key to the whole electric tabulating system is the sorting machine which separates the cards into their respective groups by electric contact through the hole punched for code purposes. During Mr. Malby's talk, the card punching and sorting machines were demonstrated, and finally the members present spent a considerable time watching and marvelling at the intricacies of the various machines. Moving picture films showing the same machines handling 30 million cards for the United States Social Security Act were exhibited. During his address the speaker paid tribute to the engineering profession for their contribution to the emancipation of office workers, by removing the drudgery from accounting, through the scientific application of machine methods. A very educational and entertaining meeting was closed with the serving of a buffet supper.

## News of Other Societies *(Continued from page 47)*

After the war, he graduated from Victoria University in Theology and the University of Toronto in Social Science. He had done considerable lecturing in Canada, United States and Germany. He is a very pleasing speaker and has a real message for the members of the Association.

The General Meeting of the Association will be held at the Royal York Hotel, Toronto, on Saturday afternoon, January 17th, 1942, at 2.30 p.m. (D.S.T.) The dinner will be held at 7 p.m. (D.S.T.) in the Roof Garden, Royal York Hotel. Reception for members at 6.30 p.m.

### ANNUAL DINNER OF U. OF T. ENGINEERING ALUMNI

The Annual Meeting of the Engineering Alumni of the University of Toronto took place on November 26th. As usual, the graduating class was featured, and H. E. Wingfield, president of the Alumni, presented the traditional gavel to J. P. D. Rogers, president of the class. Another interesting feature was the presentation of a life membership to Dr. J. L. Morris, the first graduate of the "School,"

who is now celebrating the sixtieth anniversary of his graduation.

Similar "Toike Oike" nights were held in many cities from coast to coast, and telegraphic greetings from all of them were read to the meeting by M. B. Hastings, vice-president of the Engineering Alumni and president of the University of Toronto Alumni Federation.

One side of a table of distinguished graduates. From left to right: Professor Treadgold, Professor Haultain and past-president Dr. T. H. Hogg.

The speaker of the evening was C. R. Young, Dean of Engineering, and president-elect of The Engineering Institute.

The special guest and speaker of the evening was C. R. Young, recently appointed Dean of Engineering at Toronto. Dean Young reported that this year's registration in engineering had made a new record—1,148 students, and over four hundred in the freshman year.

Referring to the recent survey made at Toronto, the speaker pointed out changes in the curriculum which had been made, based on the recommendation of the report. Now 83 per cent of first year time is spent in studies common to all departments. Class room hours have been reduced to 33 a week, and instruction in English and economics has been doubled.

Dean Young spoke of the decision to continue the work at the professional level, although because of the war, proposals had been made to offer courses of a technical type. He thought this work could be done better by the secondary schools.

He also referred to the possibility of shortening courses to hasten graduation, in order to meet the demands of the active service forces and industry. The Wartime Bureau of Technical Personnel, after an investigation, had advised that teaching should be carried on as normally as possible, at least for the present, and the university was following this course.

He asked for the assistance of graduates in establishing prizes and scholarships particularly for post-graduate work, and in obtaining additional accommodation for the greatly expanded enrolment.

H. E. Wingfield, M.E.I.C., president, was chairman. The speaker was introduced by Dr. Cody, president of the University, and was thanked by Austin Wright, M.E.I.C., Ross Robertson, M.E.I.C., immediate past-president, pre-

sented the fourth year men to the chairman. An interesting feature was the regular news commentary of Wilson Woodside, which was broadcast from the head table. Mr. Woodside is a graduate of the "School." About 450 were in attendance.

President H. E. Wingfield, M.E.I.C., presents a Life Membership to Dr. J. L. Morris, M.E.I.C., the first graduate.

## Library Notes

### ADDITIONS TO THE LIBRARY

#### TECHNICAL BOOKS

##### Hydraulics:

4th ed., by Horace W. King, Chester O. Wisler and James G. Woodburn. N.Y., John Wiley and Sons, Inc., 1941. 6 x 9 1/4 in. \$2.75.

##### Hydraulics of Steady Flow in Open Channels

By Sherman M. Woodward and Chesley J. Posey, N.Y., John Wiley and Sons, Inc., 1941. 6 x 9 1/4 in. \$2.75.

#### PROCEEDINGS

##### Society for the Promotion of Engineering Education:

Proceedings of the 48th Annual Meeting held in June, 1940, and papers, reports, discussions, etc., printed in the Journal of Engineering Education, Vol. 31, 1940-41. Office of the Secretary, Pittsburgh, Pa., 1941.

#### REPORTS

##### Smithsonian Institution:

Annual report of the Board of Regents for the year ending June 30, 1940. Wash., U.S. Govt. Printing Office, 1941. \$1.50 (cloth cover).

Geology and Ground Water resources of the Balnearia Area Western Texas, 849-C; Underground leakage from Artesian Wells in the Las Vegas area, Nevada, 849-D; Geology of Dam Sites on the Upper tributaries of the Columbia River in Idaho and Montana, 866-A; Investigations of methods and equipment used in stream gaging, 2 parts, 868A and B. Surface water supply of the United States 1939; pt. 1 North Atlantic slope basins, 871.

##### Province of Quebec—Bureau of Mines—Geological Report:

Hallivell mine map-area by G. S. MacKenzie, report No. 7; Eustis-Mine area Ascot township by G. Vibert Douglas report Na. 8.

**Canada, Department of Mines and Resources—Geological Survey:**

*Palaeozoic geology of the Brantford area, Ontario*, by J. F. Caley, *Memoir No. 226*; *Jacquet River and Tetagouche River map-areas, New Brunswick* by F. J. Alcock, *Memoir No. 227*; *Mineral industry of the Northwest Territories* by C. S. Lord, *Memoir No. 230*; *Bousquet-Joannes area, Quebec*, by H. C. Gunning, *Memoir No. 231*; *Mining industry of Yukon, 1939 and 1940* by H. S. Bostock, *Memoir No. 234*.

**BOOK NOTES**

The following notes on new books appear here through the courtesy of the Engineering Societies Library of New York. As yet the books are not in The Institute Library, but inquiries will be welcomed at headquarters, or may be sent direct to the publishers.

**AMERICAN MINERS' ASSOCIATION**

By E. A. Wieck. *Russell Sage Foundation, New York, 1940. 330 pp., illus., 9½ x 6½ in., cloth, \$2.00.*

A record of the origin of coal miners' unions in the United States is presented in this volume. The two main sections deal respectively with the origin and backgrounds and with the development of organization. A large section containing contemporary records is appended, and there is a bibliography.

**ANYBODY'S GOLD, The Story of California's Mining Towns**

By J. H. Jackson. *D. Appleton-Century Co., New York and London, 1941. 467 pp., illus., 9 x 6½ in., cloth, \$5.00.*

In narrative form, the author tells first of the California gold rush, with special emphasis on the life of the usual miner, but highlighted with tales of the more colorful personalities. The second section of the book deals with the mining towns as they are to-day, many of which are now merely ghost towns. In this manner the absorbing history of the earlier days is continued into the present. The drawings of these towns as they are to-day, by E. H. Suydam, are most attractive.

**BUILDING INSULATION**

By P. D. Close. *American Technical Society, Chicago, Ill., 1941. 238 pp., illus., diags., charts, tables, 8½ x 5½ in., cloth, \$3.00.*

The principles and applications of insulation are described as used to retard heat losses and heat gains, and to guard against fire, sound, vibration and condensation in buildings. Considerable reference data and many practical examples of calculation procedures are included. A set of review questions is appended.

**DIFFUSION IN AND THROUGH SOLIDS**

By R. M. Barrer. *Macmillan Co., New York; University Press, Cambridge, England, 1941. 464 pp., illus., diags., charts, tables, 9 x 5½ in., cloth, \$6.50.*

This book presents a study of the permeability of materials to solutes, and of the diffusion constants of solutes within them. The author's aims are: to keep a balance between experimental methods and their mathematical and physical interpretations; to provide lists of permeability and diffusion constants for ready reference; and to outline current theories of processes of permeation, solution and diffusion.

**ELECTRICITY AND MAGNETISM, Theory and Applications**

By N. E. Gilbert, rev. ed. *Macmillan Co., New York, 1941, 585 pp., diags., charts, tables, 8½ x 5½ in., cloth, \$4.50.*

Fundamental principles are covered in this textbook for non-technical students, with illustrative applications to engineering and to appliances in common use. Not intended as an

introduction to electrical engineering or an exposition of the mathematical theory of electricity, the book simply presents a thorough survey of the topics considered, with physics in the foreground.

**FIRE ENGINEERING HYDRAULICS**

By G. O. Stephenson. *Emmott & Co., Ltd., Manchester and London, England, 1941. 20 pp., illus., charts, 7½ x 5 in., paper, 1s.*

This little pamphlet contains graphic charts from which can be quickly obtained the discharge from nozzles, the loss of pressure because of friction in hose, and the height and reach of jets. These charts are based on John R. Freeman's experiments.

**FLIGHT, Aircraft Engines, a General Survey of Fundamentals of Aviation**

By R. F. Kuns. *American Technical Society, Chicago, 1942, pagged in sections, illus., diags., charts, tables, 9½ x 6 in., cloth, \$3.25.*

A discussion of elementary engines precedes chapters on light plane engines and radial aircraft engines. Other chapters provide practical information on engine fuels and fuel systems, electrical equipment, lubrication, and valve and ignition timing. There are many photographs and cross sectional diagrams, and a section of review-questions with answers is included.

**FLIGHT, Meteorology and Aircraft Instruments, a General Survey of Fundamentals of Aviation**

By B. Wright, W. E. Dyer and R. Martin. *American Technical Society, Chicago, 1942, pagged in sections, illus., diags., charts, maps, tables, 9½ x 6 in., cloth, \$3.25.*

Beginning with a general chapter on the atmosphere, this practical book discusses atmospheric circulation and weather forecasting. It covers weather maps, airway weather service and airway marking, and describes aviation radio and other instruments made necessary by atmospheric conditions. There is a question and answer section for review purposes.

**FLUID MECHANICS AND STATISTICAL METHODS IN ENGINEERING (University of Pennsylvania Bicentennial Conference)**

By H. L. Dryden, T. von Kármán and others. *University of Pennsylvania Press, Phila., 1941. 146 pp., illus., diags., charts, tables, 9½ x 6 in., cloth, \$1.75.*

The eight papers by recognized authorities contained in this work are divided into two groups. Four of them deal with turbulence and related topics in the field of fluid mechanics. The other four, grouped under the heading of statistical methods in engineering, range from the contribution of statistics to purchasing specifications to the application of the statistical method in legislation.

**HANDBOOK OF SLEEVE BEARINGS**

By A. B. Willi. *Federal-Mogul Corporation, Detroit, Mich., 1941, illus., diags., charts, tables, 9½ x 6 in., cloth, (available only to those directly concerned with sleeve bearing installations).*

This practical guide for the engineer, designer and draftsman deals with the selection, design and application of sleeve bearings. It discusses, for example, the effect of design, materials and manufacturing methods upon sleeve-bearing efficiency and other special topics of major importance in setting up bearing specifications. There is a large reference section listing many sizes and types of bearings for which major manufacturing tools are now available.

**HIGH POLYMERIC REACTIONS, Their Theory and Practice. (High Polymers, Vol. 3)**

By H. Mark and R. Raff, translated from the manuscript by L. H. Weissberger and

I. P. Irany. *Interscience Publishers, New York, 1941. 476 pp., diags., charts, tables, 9½ x 6 in., cloth, \$6.50.*

The object of this volume is to describe the present state of our knowledge concerning the mechanism of chemical processes during which high polymers are formed. It is divided into two parts: the general part, which presents important general relationships in a quantitative manner; and the special part, which collects the literature on the subject, arranging the material according to the classification which is usual in organic chemistry.

**HIGHER MATHEMATICS FOR ENGINEERS AND PHYSICISTS**

By I. S. Sokolnikoff and E. S. Sokolnikoff, 2 ed. *McGraw-Hill Book Co., New York and London, 1941. 537 pp., diags., charts, tables, 9½ x 6 in., cloth, \$4.50.*

The purpose of this book is to give students of engineering and other applied sciences a bird's-eye view of those mathematical topics beyond the elementary calculus which are indispensable in the study of physical sciences. Underlying principles are emphasized, rather than direct application to specific problems, so as to provide an introduction to advanced mathematical treatises. The new edition has been considerably revised and enlarged.

**INDUSTRIAL ACCIDENT PREVENTION, a Scientific Approach**

By H. W. Heinrich. 2 ed. *McGraw-Hill Book Co., New York and London, 1941. 448 pp., illus., diags., charts, tables, 8½ x 5½ in., cloth, \$3.00.*

The essential principles and basic philosophy of accident prevention are presented in the first two chapters. The next three are devoted to an explanation of the practical application of these principles in industry. Further development of various phases of the subject and specific illustrative examples are found in succeeding chapters. Historical and statistical data are appended.

**INDUSTRIAL INSTRUMENTS FOR MEASUREMENT AND CONTROL. (Chemical Engineering Series)**

By T. J. Rhodes. *McGraw-Hill Book Co., New York and London, 1941. 573 pp., diags., charts, tables, 9 x 6 in., cloth, \$6.00.*

This new text is designed to provide a theoretical and practical treatment of the measurement and control of the four fundamental physical factors encountered in industrial processing and manufacturing: temperature, pressure, fluid flow and liquid level. Automatically controlled continuous processes are thoroughly analyzed, and practical rules are established for the design and maintenance of controlling instruments.

**INTRODUCTION TO PHYSICAL STATISTICS**

By R. B. Lindsay. *John Wiley & Sons, New York; Chapman & Hall, London, 1941. 306 pp., diags., charts, tables, 9½ x 6 in., cloth, \$3.75.*

This work is intended for the graduate student who wishes a thorough but not too lengthy introduction to the method of statistical physics. It calls for a background of theoretical physics. It presents a survey of the various ways in which statistical reasoning has been used in physics, from the classical applications to fluctuation phenomena, kinetic theory and statistical mechanics to the contemporary quantum mechanical statistics. Emphasis has been laid on methodology and numerous illustrative problems are included.

**LINCOLN'S INDUSTRIAL-COMMERICAL ELECTRICAL REFERENCE,**

*Edited by E. S. Lincoln. First edition. Electrical Modernization Bureau, 60 East 42nd St., New York, 1941, pagged in sections, illus., diags., charts, tables, 11 x 8½ in., cloth, \$15.00.*

The entire field of industrial electric operations, from service entrance through utilization equipment, is covered in this reference book. The material is divided into sections containing tables, diagrams, illustrations and descriptions of typical equipment in the respective fields, and other practical information. Special sections cover electrical and other related associations, safety precautions and the National Electrical Code provisions.

#### MacRAE'S BLUE BOOK, 49th Annual Edition, 1941-42

MacRae's Blue Book Co., Chicago and New York, 1941. 3,728 pp., illus., 11 x 8 in., cloth, \$15.00.

The new edition of this well-known and useful directory follows the plan of preceding ones. It includes an alphabetical list of manufacturers, producers and wholesalers, with the addresses of branch offices; a minutely classified list of products, with an extensive index; a list of towns of one thousand or more population; with their trade facilities and railroad connections; and a list of trade names.

#### (The) MECHANISM OF THE ELECTRIC SPARK

By L. B. Loeb and J. M. Meek. Stanford University Press, Stanford University, California; Humphrey Milford, Oxford University Press, London, 1941. 188 pp., illus., diags., charts, tables, 9½ x 6 in., cloth, \$3.50.

This work analyzes the status of the theory of the mechanism of the electric spark in air at this time and, on the basis of this analysis, the streamer theory of spark discharge is developed. The three chapters deal respectively with the Townsend theory of the spark, with the development of the streamer theory, and with the calculation of breakdown in various types of gaps. Bibliographies are included.

#### MUNICIPAL AFFAIRS

By E. W. Steel. International Textbook Co., Scranton, Pa., 1941. 389 pp., diags., charts, tables, 8½ x 5 in., cloth, \$3.50.

Intended both as a textbook for college students and a source of information for those interested in municipal affairs, this book covers two fields. The first section is devoted to the development and forms of municipal government and its relation to state and federal authority. Administrative principles are treated in the latter part of the book including discussions of departmental work city financing methods, etc.

#### OUTLINES OF GEOLOGY

Outlines of Physical Geology, by C. R. Longwell, A. Knopf and R. F. Flint, 381 pp.

Outlines of Historical Geology, by C. Schuchert and C. O. Dunbar, 291 pp. 2. ed., John Wiley & Sons, New York; Chapman & Hall, London, 1941. illus., diags., charts, tables, maps, 9 x 6 in., cloth, \$4.00.

Combining two well-known elementary texts on physical and historical geology, the present volume was developed to furnish a brief treatise covering the salient features of the entire subject. In the first part, the principles of physical geography are explained as a key to the reading of geologic history, and the relation of these principles to practical human affairs is emphasized. The historical geology section presents a concise, general survey of the past history of the earth.

#### PHOTOMICROGRAPHY

By R. M. Allan. D. Van Nostrand Co., New York, 1941. 365 pp., illus., diags., charts, tables, 9½ x 6 in., cloth, \$5.50.

The process of photographing minute objects through a microscope is comprehensively covered. Essential information concerning microscopic technique is provided for

those unfamiliar with such work, although the emphasis is upon photographic equipment and methods, which are described in detail. Excellent examples of various kinds of photomicrography are included, with explanatory paragraphs.

#### PIPING FLEXIBILITY AND STRESSES

By S. D. Vineratos and D. R. Zeno. Cornell Maritime Press, New York, 1941. 85 pp., diags., charts, tables, 10 x 7½ in., paper, \$3.00.

The grapho-analytical method of determining flexibility and stress from an examination of bending-moment diagrams is presented in this book for the design of piping systems, particularly steam piping in marine service. The fundamentals of the method are first briefly described, and its application is then explained, working from simple cases to problems with pipes intersecting in space.

#### PRINCIPLES OF ELECTRON TUBES

By H. J. Reich. McGraw-Hill Book Co., New York and London, 1941. 398 pp., illus., diags., charts, tables, 9½ x 6 in., cloth, \$3.50.

Essentially an abridgment of the author's "Theory and application of electron tubes," the present volume is designed to meet the need for a text suitable for students not specializing in communication. In this edition some of the material has been deleted and the rest modified to give unity and coherence. New material includes a brief treatment of electron dynamics and an introductory treatment of frequency modulation.

#### RAILROADIANS OF AMERICA, New York, Book No. 3

Apply to W. A. Lucas, Editor and Chairman, Publication Committee, Railroadians of America, 56 Tuxedo Ave., Hawthorne, New Jersey, 1941. 128 pp., illus., diags., charts, tables, maps, 11 x 7½ in., paper, \$2.50.

Number 3 of this series presents an illustrated record of the motive power and growth of the Delaware and Hudson railroad. Originally printed in two sections by the Delaware and Hudson Railroad Corporation, additional material has been included to bring the information up to date.

#### (The) REFERENCE LIBRARY OF THE WELDING RESEARCH COUNCIL, Section I, Classified Library Catalogue, June, 1941

Published by Institut of Welding, 2 Buckingham Palace Gardens, London, S.W.1, England. 136 pp., 8½ x 5½ in., paper, 2s.

The major part of this publication is devoted to a catalogue of the reference library of the Welding Research Council, containing both author and subject entries in one alphabetical list. Additional information concerning the organization, staff, services and publications of the Institute of Welding is also included.

#### SHOP MANAGEMENT FOR THE SHOP SUPERVISOR

By R. C. Davis. Harper & Brothers, New York and London, 1941. 333 pp., diags., charts, tables, 8½ x 5½ in., cloth, \$2.00.

This book is concerned with the problems which confront the shop supervisor in all phases of production control. Topics covered include organization, plant and equipment, production and quality control in various types of shops, motion and time study, materials control, stores, and labor management.

#### THEORY OF GASEOUS CONDUCTION AND ELECTRONICS

By F. A. Maxfield and R. R. Benedict. McGraw-Hill Book Co., New York and

London, 1941. 483 pp., illus., diags., charts, tables, 9½ x 6 in., cloth, \$4.50.

The fundamental theory of high-vacuum electronic equipment is presented with a systematic interpretation of the underlying phenomena upon which the properties of all types of gaseous-conduction devices depend. The discussion covers not only high vacuum conduction as found in electron tubes, but also the theory and application of corona, sparking, glows and arcs. Stress is placed upon scientific principles rather than upon specific apparatus and applications.

#### TRAFFIC ACCIDENTS AND CONGESTION

By M. Halsey. John Wiley & Sons, New York; Chapman & Hall, London, 1941. 408 pp., illus., diags., charts, tables, 10 x 7 in., cloth, \$4.00.

This volume sets forth the principles which underlie the scientific methods currently being developed to reduce traffic accidents and congestion. It is an engineering approach to these problems as they affect the movement of persons and merchandise. Application of the principles here outlined presents a basis for evaluating all elements of the traffic problem. There is a large bibliography.

#### TRUE STEEL, the Story of George Matthew Verity and His Associates.

By C. Borth. Bobbs-Merrill Co., Indianapolis and New York, 1941. 319 pp., illus., 9 x 6 in., cloth, \$3.00.

Mainly a biography of George Matthew Verity, the directing genius of the American Rolling Mill Company, this book is also a history of the Company and an exposition of the development of the steel industry. Both the technological and sociological aspects of the man and his work are presented.

#### UNIVERSITY PHYSICS, Part 3, LIGHT

By F. C. Champion. Interscience Publishers, New York; Blackie & Son, London and Glasgow, 1941. 172 pp., diags., charts, tables, 9 x 6 in., cloth, \$1.50.

One of a group of books on the several major divisions of physics, this particular volume covers the subject of light for intermediate students who have previously studied the elements of physics. The text is supplemented by numerous clear and helpful diagrams, and exercises and problems are supplied for review purposes.

#### WAVES, a Mathematical Account of the Common Types of Wave Motion

By C. A. Coulson. Oliver & Boyd, London, England, and Edinburgh, Scotland, 1941. 156 pp., diags., charts, tables, 7½ x 5 in., cloth, 5s.

The subject of waves is usually treated in separate branches of applied mathematics. In this book, as many different kinds of wave motion as possible are discussed as one whole, in an elementary way. Starting from the standard equation of wave motion, the author investigates waves on strings, in membranes, bars and springs, and in liquids, sound waves and electric waves; concluding with a chapter on some general properties of waves.

#### WELDING AND ITS APPLICATION

By B. E. Rossi. McGraw-Hill Book Co., New York and London, 1941. 343 pp., illus., diags., charts, tables, 9½ x 6 in., cloth, \$2.50.

Welding and cutting processes, with the emphasis on electric-arc welding, are comprehensively covered, with their related phenomena, their techniques and their general application in industry. The intention is to present fundamental facts for the beginner, give the experienced operator a wider understanding of the welding process, and provide a source of reference for draftsmen, designers, engineers and any others interested in the subject.

# PRELIMINARY NOTICE

of Applications for Admission and for Transfer

FOR ADMISSION

December 31st, 1941.

The By-laws provide that the Council of the Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

**Communications relating to applicants are considered by the Council as strictly confidential.**

The Council will consider the applications herein described at the February meeting.

L. AUSTIN WRIGHT, General Secretary.

\*The professional requirements are as follows:—

A Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science or engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainment or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

GEDDES—ALVIN BROOKS, of Calgary, Alta. Born at Calgary, March 7th, 1904; Educ.: B.Sc., Iowa State College, 1927; 1927-28, motor test dept., 1928-29, correspondence dept., 1929-30, sales dept., and 1930 to date, sales engr., Canadian Westinghouse Company, Calgary, Alta.

## SITUATIONS VACANT

**MECHANICAL DESIGNING DRAUGHTSMAN**, Graduate preferred, urgently needed for work in Arvida for specification drawings for plate work, elevators, conveyors, etc., equipment layouts, pipe layouts and details. Apply to Box No. 2375-V.

**MECHANICAL GRADUATE ENGINEER** with machine shop experience required for work in Mackenzie, British Guiana, on essential war work. Apply to Box No. 2441-V.

**ENGINEERING DRAUGHTSMAN** with experience in machine and structural design, proficient in steel design calculation, and having ability for estimating. We require a man with at least five years' industrial experience, preferably in the paper mill field. Position is permanent. State experience and give physical description. Include small photograph and a sample of draughtsmanship. Apply to Box No. 2458-V.

**MECHANICAL DRAUGHTSMAN**, experienced in making layouts for various installations, piping, etc., around a paper mill. Applicant must be a college graduate. State previous experience, wages expected, etc. Apply to Box No. 2461-V.

**MECHANICAL DRAUGHTSMAN** preferably with pulp and paper experience. Good salary and permanent position. Apply giving details of experience to Box No. 2480-V.

**GRADUATE MECHANICAL ENGINEER** required for Mackenzie, B.G., immediately on work of plant and mining equipment maintenance. We are prepared to do necessary training which will give exceptional opportunity for experience. Apply to Box No. 2481-V.

**MECHANICAL ENGINEER** preferred with experience on diesels and tractors, for work in Mackenzie, B.G. Apply to Box No. 2482-V.

**MECHANICAL DRAUGHTSMEN** and engineers for pulp and paper mill work. Experienced men preferred. Good salary to qualified candidates. Apply to Box No. 2483-V.

**ELECTRICAL ENGINEER**, young French Canadian graduate engineer to be trained on work involving hydro-electric plant operation, transmission lines and

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party. Notices appearing in the Situations Wanted column will be discontinued after three insertions, and will be re-inserted upon request after a lapse of one month. All correspondence should be addressed to THE EMPLOYMENT SERVICE BUREAU, THE ENGINEERING INSTITUTE OF CANADA, 2050 Mansfield Street, Montreal.

construction, meter testing and inspection. Good opportunity to acquire first-hand electrical power experience. Apply to Box No. 2487-V.

## ENGINEER OFFICERS WANTED

Applications are invited for Commissions in the Royal Canadian Ordnance Corps for service both overseas and in Canada as Ordnance Mechanical Engineers. Since it is probable that several new units will be organized in the near future, a number of senior appointments may be open, and applications from engineers with a good background of military experience would be welcomed in this connection. Applications should be submitted on the regular Royal Canadian Ordnance Corps application forms, which can be obtained from the District Ordnance Officers of the respective Military Districts.

## SITUATIONS WANTED

**ELECTRICAL ENGINEER**, B.E. in electrical engineering, McGill University, Age 24, married, available on two weeks notice. Undergraduate experience, cable testing and cathode ray oscillography. Since graduation, five months on construction of large and small electrical equipment in plant and sub-station. One year operating electrical engineer in medium size central steam station paralleled with large Hydro system. At present employed, but is interested in research or teaching. Associate member of the American Institute of Electrical Engineers. Apply to Box No. 2419-W.

**CIVIL AND STRUCTURAL ENGINEER**, M.E.I.C., R.P.E. (Ont.), Age 49. Married. Home in To-

ronto. Experience in Britain, Africa, Canada, Turkey. Chief engineer reinforced concrete design offices, steelworks construction. Resident engineer design and construction munitions plants, and general civil engineering work. Extensive surveys, draughting, harbour and municipal work. Location immaterial. Available now. Apply Box No. 2425-W.

**ELECTRICAL, MECHANICAL ENGINEER**, age 35. Dip. and Assoc. R.T.C., Glasgow, A.M.I.E.E., (Students Premium) G.I. mech.E., M.E.I.C., Assoc. Am.I.E.E. Married. Available after December 22nd. Seventeen years experience covering machine shop apprenticeship, A.C. and D.C. motors, transformers, steel and glass bulb arc rectifiers, design, testing and erection sectional electric news and fineprints paper machine drives, experience tap changers H.V., L.V. and marine switchgear. Apply to Box No. 2426-W.

**MECHANICAL ENGINEER** age 55 years. Married. Available at once. Thirty years experience in draughting and general machine shop and foundry work. Fifteen years as works manager. Considerable experience in pump work, including estimating and inspection. Apply to Box 2427-W.

**ELECTRICAL ENGINEERING** student in third year, age 27, desires summer position starting in April, with view to permanency on graduation. Two summers on design of shop equipment and electrical apparatus. Three years experience on test and experimental work for relays and control equipment. Student E.I.C., and Associate member American Institute of Electrical Engineers. Location immaterial. Apply to Box No. 2428-W.

## PUBLICATIONS OF ENEMY ORIGIN

At the request of Mr. S. J. Cook, officer in charge, Research Plans and Publications Section, National Research Council, we are pleased to reproduce the following letter addressed by the acting president of the Council to presidents of universities and other research organizations in Canada.

In view of the restrictions on the importation of scientific

books and periodicals of enemy origin into Canada since the outbreak of war, there has been an increasing demand for photostats or other reproductions of specific articles appearing in such publications which are known to be available in United States libraries.

The National Research Council has been informed by the Department of the Secretary of State that educational institutions and industrial or research organizations in Canada are now permitted to order direct from United States libraries photostat copies of articles appearing in scientific journals which are known to be in such libraries but which are not in circulation in Canada.

The Commissioner of Customs and the Postal Censors have been asked to place no restrictions on the importation and safe delivery of photostats or other reproductions of this kind direct to university and other responsible scientific bodies in Canada when such importations are made from recognized and responsible United States libraries.

It is to be noted that the foregoing procedure applies only to photostats or other copies of articles from journals in the United States. Universities and other institutions that wish to secure scientific books or periodicals of enemy origin must still conform with the procedure authorized by the Secretary of State, which is briefly that—

(i) A certificate must be furnished to the National Research Council stating that the publications wanted are essential to the conduct of scientific work in Canada during the war;

(ii) A copy of the order must be filed with the National Research Council;

(iii) Orders must be placed with an organization in a neutral or allied country;

(iv) The shipper must be instructed to send the book or periodical in care of the National Research Council at Ottawa for Customs and Censorship clearance;

(v) Payment for such publications must be arranged between the concern placing the order and the firm with which the order is placed, and the regulations of the Foreign Exchange Control Board must be observed in such transactions.

# THE NEW OIL-HYDRAULIC PRESS IN MUNITIONS MANUFACTURE

JOHN H. MAUDE, M.E.I.C.

Chief Designer, Mining, Metals and Plastics Machinery Department, Dominion Engineering Company Limited, Lachine, Que.

Paper presented before the General Professional Meeting of The Engineering Institute of Canada, at Montreal, Que., on February 6th, 1942.

During the last world war, the hydraulic press was a slow, powerful, ponderous machine, and considered from both a theoretical and practical aspect it was a crude instrument for applying controlled severe stress to metal. It was affected by a multitude of maintenance troubles, caused by a water system with triplex pumps, weight loaded accumulators, long downshop pipe lines and shock alleviators, and in consequence it did not give entire satisfaction when employed in modern mass production.

Since then, however, the automobile and other allied industries have demanded and obtained radical improvements in machinery available for the fabrication of their various components, and one of the most progressive developments has been the design of an entirely new type of press, which has given much better results.

This press employs oil as the pressure medium, and is entirely self-contained with a circulatory system. A high pressure radial piston pump is used as the power unit, direct coupled to its motor, and the whole with suitable starting equipment and oil tanks is carried on the press proper. Extreme rigidity is provided by side housings. The machine of this type manufactured by the Dominion Engineering Company is known as the Speed-Hy-Matic press; its main features are indicated in Fig. 1. The fundamentals of its working are indicated diagrammatically in

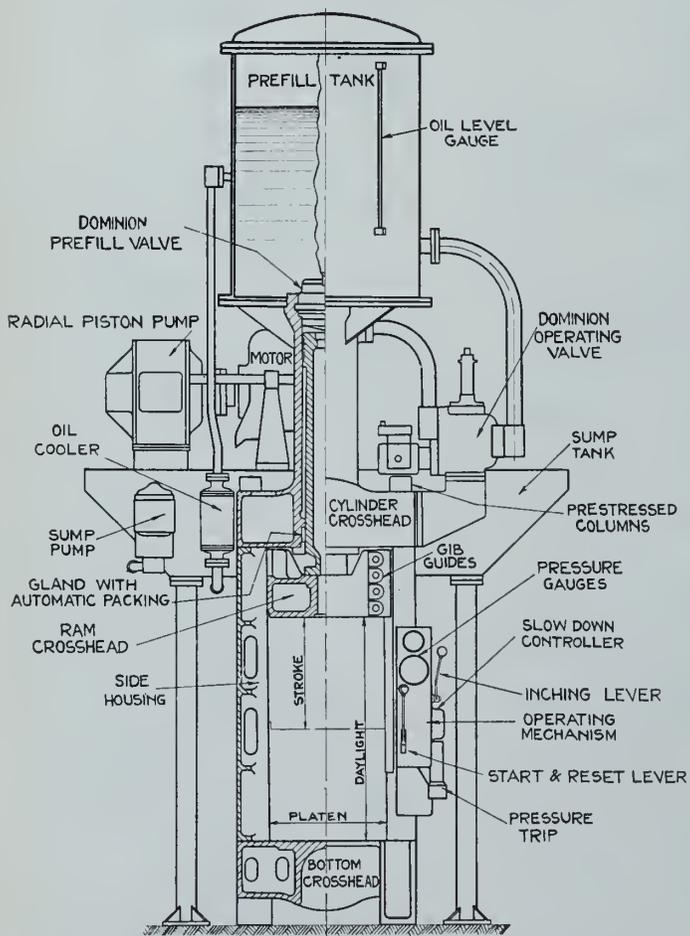

Fig. 1—Principal features of Speed-Hy-Matic press.

the circuit shown in Fig. 2 which particularly applies to a drawing press. The oil supply is carried overhead in the prefill tank with a filling check of special design in the centre of the top head. During the approach or prefill part of the stroke, when the ram and slide advance by gravity, the prefill valve opens and pump discharge at no pressure augments the flow into the cylinder. This prefill valve is a development of the filling check valve, streamlined for flow in both directions. As soon as the work piece is contacted, the prefill valve closes automatically, and the pumps take hold to develop pressure. It is essential that the filling of the main cylinder should occur without turbulence or cavitation, or there will be time lag before the pressure develops. With this streamlined prefill valve, approach

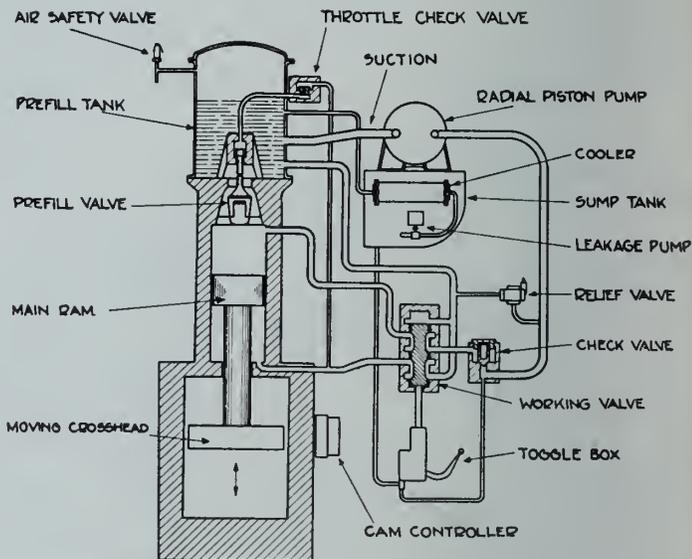

Fig. 2—Working circuit of drawing press.

speeds of 20 inches per second are obtained without cavitation. It is seen that the pumps develop pressure immediately against the work resistance to complete the work stroke and this occurs at absolutely uniform speed. Devices are provided, such that at the end of the work stroke the machine is tripped automatically, either on the attainment of a certain predetermined adjustable pressure, or by distance in any portion of the stroke, and the press then automatically returns to its upper position. This top position is also adjustable at the will of the operator, so that the daylight\* is variable as well as the length of the pressure stroke. When the slide or moving crosshead reaches the desired upper position limit, the pumps, which run continuously, are stroke neutralized so as to pump only as much fluid as will make up for the leakage content of the system, and also so as to develop no more pressure than is essential to hold up the moving mass. It is readily seen that a most economical work cycle is thus obtained.

The heart of the press is the high pressure radial piston pump, of positive displacement type, which is direct coupled to the motor and supplies the oil under pressure to the press cylinders. This pump is shown in Fig. 3 and

\* "Daylight" means the maximum distance between the upper face of the bottom crosshead and the under face of the ram crosshead when at the top of its stroke.

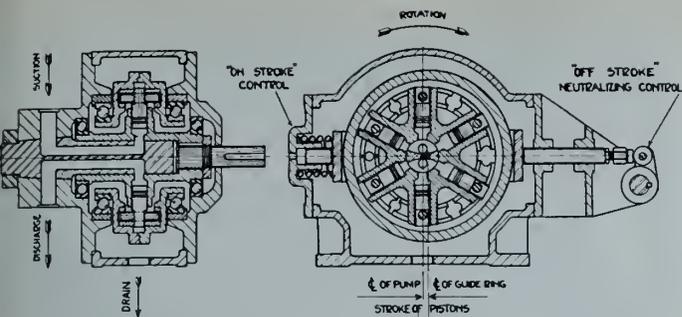

Fig. 3—Working parts of radial piston pump.

consists essentially of a cylinder assembly mounted in ball bearings, fitted with a number of radial plungers and driven by a spindle. The cylinder assembly rotates so as to carry the plungers with it. These plungers are ground and lapped in the cylinder, and have their outer ends pivoted in slippers, the thrust of each being taken in the floating ring assembly. The floating ring is moved by one of several devices in a lateral direction with respect to the shaft. The ported valve pintle in the centre is fixed to the "fluid end" cover. It is seen that rotation of the pump shaft and cylinder block will rotate the pistons also. If the axis of the floating ring coincides with that of the shaft, there is no pumping action because the pistons have not any stroke, but when the floating ring is moved off centre, piston displacement occurs, the discharge of the pump will be proportional to the shift of this ring, and the plunger stroke will be twice the ring movement. The multiplicity of plungers develops an overlapping discharge which is without noticeable pulsation, e.g., a seven cylinder pump rotating at 840 r.p.m. will develop 5880 small pressure crests per minute or 98 per second.

The pump or pumps are equipped with a special dual automatic stroke control as shown in the figure. One side has a "stroke holding cylinder," while the other side has a "cam lever stroke neutralizing control."

As previously stated, the system fluid is lubricating oil, approximately SAE. 45, having a viscosity approximately 920 SUV\* at 100 deg. F., and highly temperature-stable so as to retain a viscosity better than 340 SUV at 132 deg. F.

The fluid medium being lubricating oil, permits the use of a simple balanced piston valve, with the beat lapped into the body. Since it is entirely submerged in oil, wear and maintenance are practically eliminated.

Mention has already been made of semi-automatic operation from a single hand lever for the start only, and a patented simple mechanism has been developed whereby all the essential automatic motions may then be obtained.

Manual operation may also be employed, in which case press movement will follow the hand of the operator. Manual inching at creepage speeds for die setting is provided for by the insertion of a reduction gear. For semi-automatic operation, a full lever stroke will lock the toggles so that the valve is in the work stroke position, and either after pressure development or alternatively after a certain length of stroke, the toggles are automatically broken so as to reverse the valve, when the press immediately returns to the open position.

#### AN ANALYSIS OF VARIOUS PRESSES EMPLOYED

In the selection of a press required to perform a prescribed duty in cartridge case manufacture, one should choose a machine which is designed to suit the nature of the work, and if possible it should be capable of handling another allied operation just as efficiently when another machine in line is temporarily shut down for adjustment or repair. At first sight this requirement of double duty in

emergency, with maximum efficiency for both cycles, appears to be almost impossible. An examination of the leading characteristics of available machines indicates that this is not the case, and that they may be fitted into either of two most important classifications:

1. The fixed stroke type with fixed daylight.
2. The variable stroke machine with variable daylight.

The two groups are so fundamentally different, that a comparison of the leading characteristics shows that the former lacks certain desirable features. A fixed stroke press may be described as a machine whose mechanism, such as slider crank and crank toggle, will employ a low force or effort over a long distance to produce a higher effort through a shorter distance, and thus develop mechanical advantage. In this kind of machine, the opening, gap, or daylight is a fixed dimension except for a minor essential adjustment, and the stroke of the machine is definitely fixed by the throw of crank. Once a mechanical press of this kind is set up for a certain operation, and the crank speed decided upon, the maximum drawing speed becomes fixed, and this is not a desirable feature.

Experiments in a certain arsenal, where special tools and carboly dies were employed, indicate a limit draw speed for cartridge case brass as follows in connection with 75 MM. cases:—

1st and 2nd draw	—35 feet per minute
3rd draw	30 feet per minute
4th draw	25 feet per minute

and this under favourable conditions, with a laboratory atmosphere, accurate annealing control, with trained workmen and first class technical supervision.

In Canadian factories, with the new oil-hydraulic press, raw labour, and standard commercial high carbon steel tools, we regularly draw at speeds of 27 feet per minute and this on the 4th draw operation of the 25 pdr. case.

A 60-ton Speed-Hy-Matic press with an adept operator has regularly produced 1,450 first-draw pieces per hour for the 25 pdr. cartridge case.

Figure 4 shows the velocity-stroke diagrams of a crank press compared with the modern oil-hydraulic press, with the tooling employed in the 4th draw of a 25 pdr. cartridge case. Cyclic times for the operations are also given.

It is axiomatic that the velocity diagram is a sine curve, and it is seen that the tool must strike the work with a very considerable impact, for at the instant of contact the speed is 70 feet per minute, which diminishes to 27 feet per minute throughout the stroke according to the law of simple harmonic motion. This means that as the draw punch proceeds, the metal is constrained to move at a speed which varies greatly; this is not the best practice for drawn work. Present evidence borne out in practice indicates that this

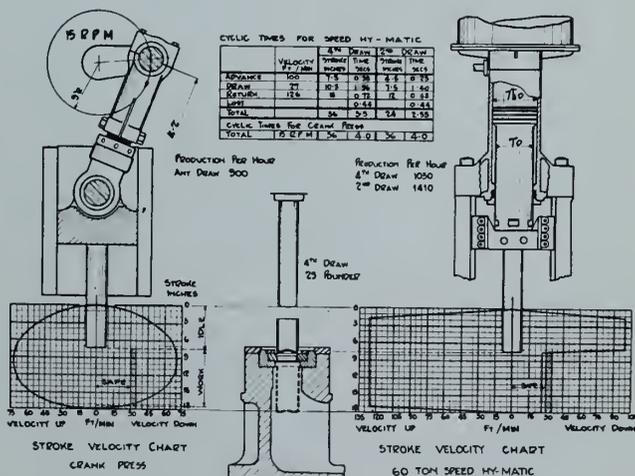

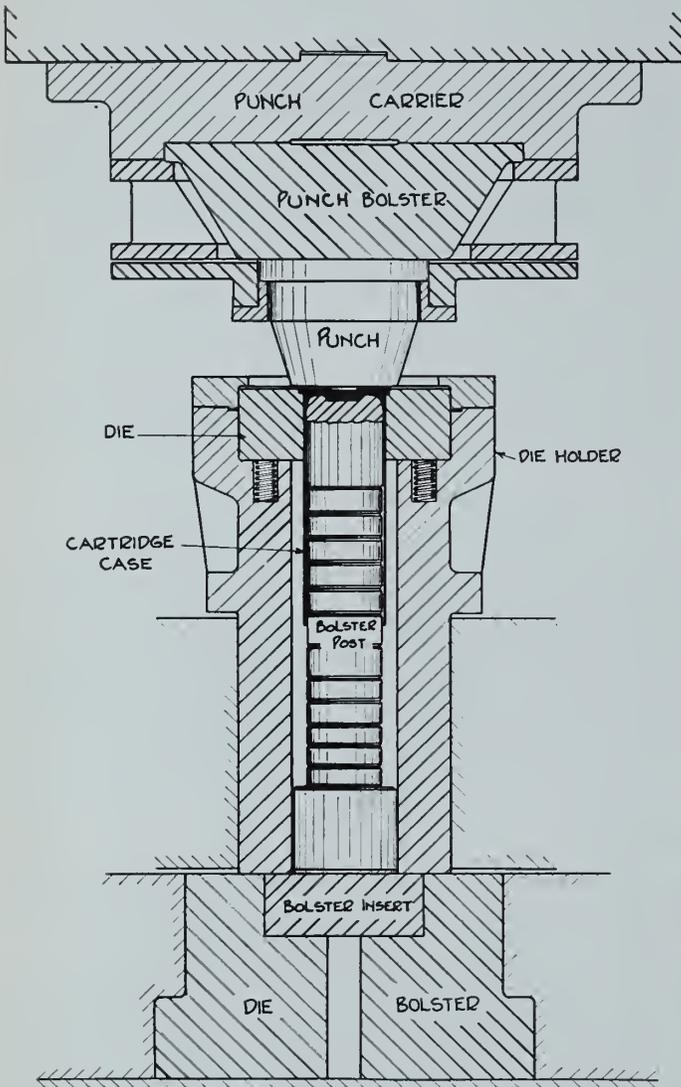

Fig. 4—Velocity-stroke diagrams of crank press and Speed-Hy-Matic press.

\* Saybolt Universal Viscosity.

rapidly changing velocity prevents full advantage being taken of the metal's capacity to suffer plastic deformation, and rupture may occur.

### INDENTING AND HEADING CARTRIDGE CASES

Indenting is the operation of making the pressed depression in the head of the case which is subsequently machined to take the primer.

TOOLING FOR HEADING OPERATION  
25 PDR. CARTRIDGE CASE

Fig. 5—Tooling for heading operation on cartridge cases.

Heading is the term used to describe the pressing operation to increase the hardness of the head and form the retaining flange. Automatic variable-tonnage\* heading and indenting is now accepted as standard practice. In both of these operations the press must necessarily operate against solid resistance in the form of a tool post. With mechanical presses it is essential that the tool post be set accurately as regards height, but a gradual reduction of tool post height occurs by repeated operation due to the ironing and work hardening of this member which must necessarily occur, and the effect is expressed in reduced tonnage on the work so that adjustments become necessary. Whenever a tool post is replaced due to breakage or undue wear the tonnage adjustment on a mechanical press must be repeated, for without this there is risk of mechanical failure due to excess tonnage developed at the end of stroke.

\* "Tonnage" means the total load in tons applied by the press to the work piece.

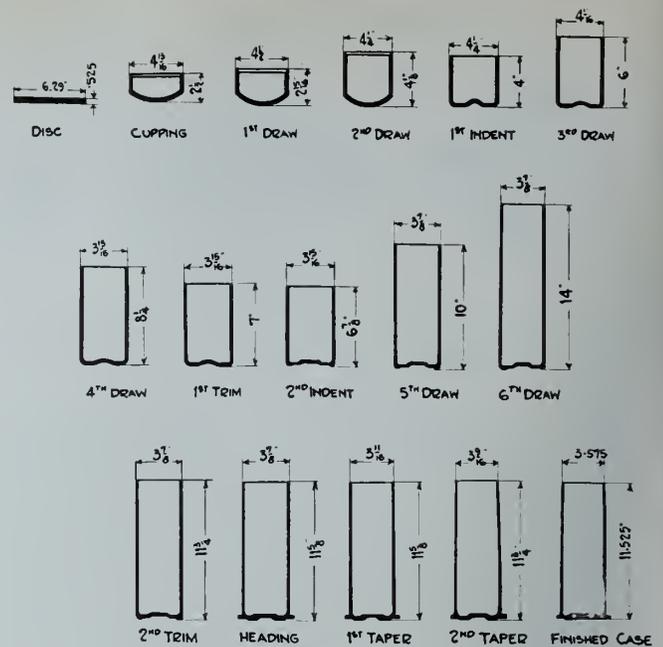

Fig. 6—Stages in manufacture of cartridge case.

In the new oil-hydraulic press it is stressed that the stroke and daylight may be varied so that variation in tool post height does not affect either the safety or the life of the press or of the dies themselves.

Figure 5 shows the typical tooling employed in either of these operations. In an oil-hydraulic press, overloading is impossible, first due to a pressure trip which is adjustable up to the maximum tonnage of the press, and also because of relief valve protection.

Heading and indenting generally have to be done in two stages, and it is possible to employ two separate selected tonnages each as best suited for either stage of the work.

Fig. 7—Cupping 4-inch cartridge case on 300-ton press.

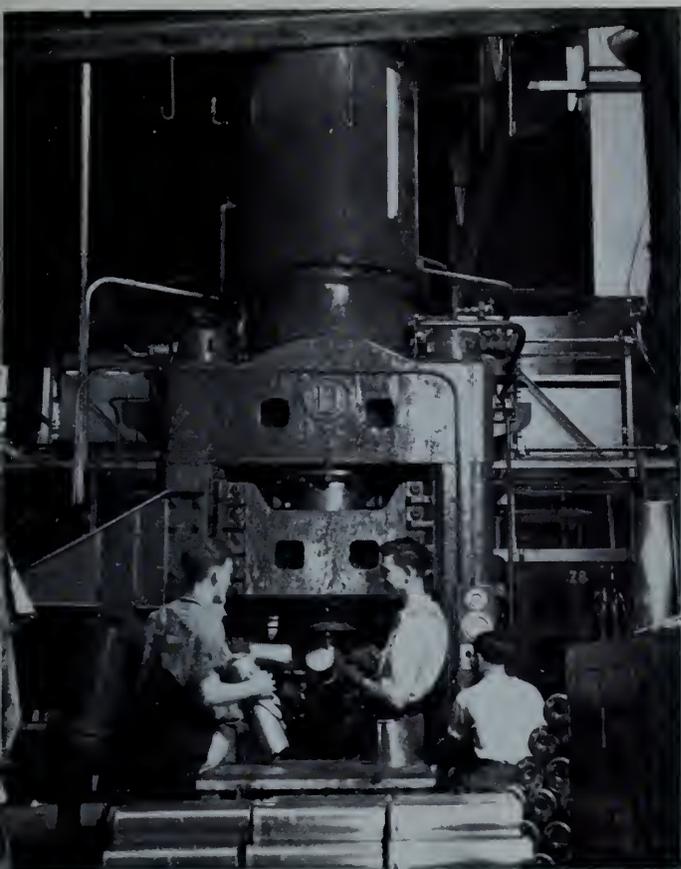

Fig. 8—Indenting 4-inch cartridge case on 800-ton press.

In a toggle operated press there is no slowdown at work contact, whereas in an oil-hydraulic press this feature is normal design so as to eliminate the impact on the work piece, and in addition on work contact the pressure is gradually built up hydraulically against resistance until the desired maximum is exerted. This gradual pressure build-up means that in heading some cases, such as in 75 MM. cases, double stage heading has been found unnecessary.

#### THE MANUFACTURE OF CARTRIDGE CASES

In order to withstand the increased charge of propellant, improvements in the manufacture of cartridge cases for fixed ammunition were found necessary. A number of plants are now in full production in the manufacture of cases of different sizes including 2 pdr., 40 MM., 75 MM.,

Fig. 9—Heading 4-inch cartridge case on 2000-ton press.

25 pdr., 4.5 in., 3.7 in. and 4 in. with arrangements to manufacture up to the 6 in. case when deemed necessary. Millions have already been shipped overseas and additional plants will soon be in operation. The brass is obtained from the brass manufacturer in the form of discs, as this holds the necessary scrap at its source of supply.

It may be of interest to give particulars of the manufacturing methods employed on two widely different examples, namely the 25 pdr. 3.45 in. cartridge case which is for the field gun replacing the old 18 pdr., and also the one necessitating the longest draw in practice to-day, namely the 4 in. naval case. The first operation is one known as cupping, after which follow certain draws, indents, heading and tapering operations substantially in the order as stated, with annealing necessarily placed between certain operations. The various stages for the 25 pdr. case are shown in Fig. 6.

#### OPERATIONS ON THE 25 PDR. 3.45 IN. CARTRIDGE CASE

In all, this requires 34 operations, as listed below:—

- |               |                |                    |
|---------------|----------------|--------------------|
| 1. Cup        | 13. Clean      | 25. Heading        |
| 2. Anneal     | 14. 4th draw   | 26. Wall Anneal    |
| 3. Clean      | 15. 1st trim   | 27. 1st taper      |
| 4. 1st draw   | 16. 2nd indent | 28. 2nd taper      |
| 5. Anneal     | 17. Anneal     | 29. Bullard Lathes |
| 6. Clean      | 18. Clean      | 30. Oakite Clean   |
| 7. 2nd draw   | 19. 5th draw   | 31. Stress Relieve |
| 8. 1st indent | 20. Anneal     | 32. Buffers        |
| 9. Anneal     | 21. Clean      | 33. Inspection     |
| 10. Clean     | 22. 6th draw   | 34. Stamping       |
| 11. 3rd draw  | 23. 2nd trim   |                    |
| 12. Anneal    | 24. Steam Heat |                    |

In the selection of a suitable press to perform a set operation it is advisable to have excess tonnage available so that any imperfections in annealing will not cause the work piece to stall in the machine.

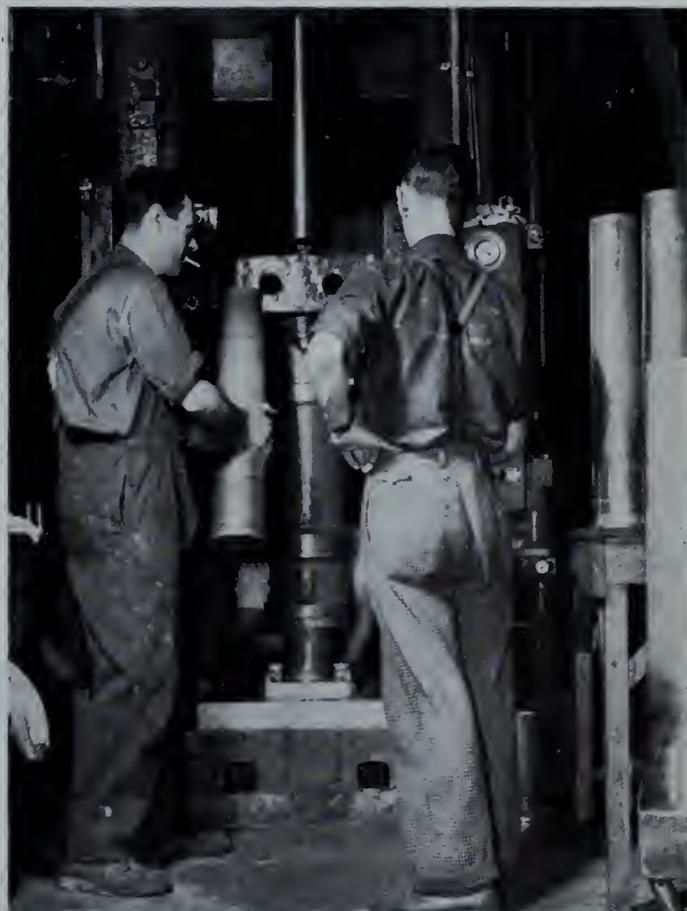

Fig. 10—Necking 4-inch cartridge case on 60-ton press.

This case probably represents one of Canada's biggest achievements in this field of endeavour, because it requires the longest draws, extremely difficult hardness graduation over a large area, and the highest tonnage for heading.

There are 39 separate operations required in the manufacture of a 4 in. cartridge case from the brass disc.

OPERATIONS ON 4-IN. NAVAL CASES

- |                |                 |                      |
|----------------|-----------------|----------------------|
| 1. Cup         | 16. Anneal      | 29. Wall Anneal      |
| 2. Anneal      | 17. Pickle      | 30. Pickle           |
| 3. Pickle      | 18. 5th draw    | 31. 2nd taper        |
| 4. First draw  | 19. 2nd trim    | 1st operation        |
| 5. Anneal      | 20. 2nd indent  | 32. 2nd taper        |
| 6. Pickle      | 1st operation   | 2nd operation        |
| 7. 2nd draw    | 2nd operation   | or necking           |
| 8. Anneal      | 21. Anneal      | 33. Mouth anneal     |
| 9. Pickle      | 22. Pickle      | 34. Base turn        |
| 10. 3rd draw   | 23. 6th draw    | 35. Drill clip holes |
| 11. Anneal     | 24. 3rd trim    | 36. Marking          |
| 12. Pickle     | 25. Heading     | 37. Stress relieve   |
| 13. 4th draw   | 26. Wall anneal | 38. Buffing          |
| 14. 1st trim   | 27. Pickle      | 39. Inspection       |
| 15. 1st indent | 28. 1st taper   |                      |

A number of these operations are illustrated in Figs. 7 to 11, as follows:

300-ton press engaged in cupping (Fig. 7).

Indenting on 800-ton press. A two-position shuffle feed is employed. (Fig. 8).

2,000-ton press engaged in heading, (Fig. 9), work going in and product coming out.

Necking on a 60-ton press. Tapered cases are on the right; a case is in the press, and the product is held by the operator on the left (Fig. 10).

Mouth annealing after necking (Fig. 11). This is done in a continuous furnace.

SHELL FORGING PRESSES

Whereas in the last war and with previous manufacturing methods the shell cavity was finish-machined, a finish-forged cavity to fine finish and tolerance is now prescribed.

The punch and draw method was usual, and to-day we

Fig. 11—Mouth annealing 4-inch cartridge case after necking.

find plants still using this same technique except that the draw rings are replaced by draw rollers. This process necessitates two machines, one punch and one draw. There is also a single machine on the market which is of the multiple progressive punch type, and as many as five or six separate operations must occur successively on the billet. In general the forging technique of the last war caused the metal to flow in the direction opposed to punch travel. This involved extrusion of the metal, resulting in rapid wear of both punch and die liner. It is thus seen that any forging process for the manufacture of shells which employs this

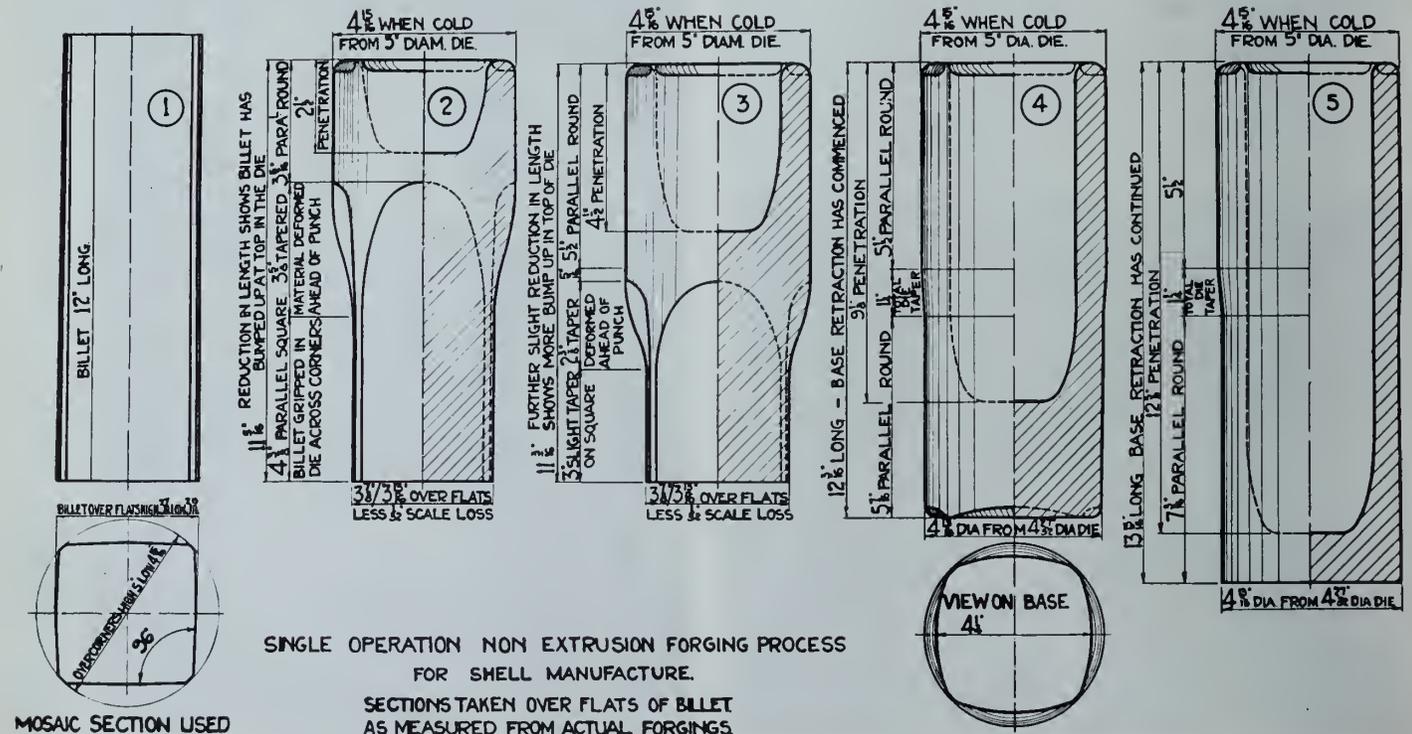

Fig. 12—Diagram of various stages in the single operation non-extension forging process for 4 and 5-inch shell.

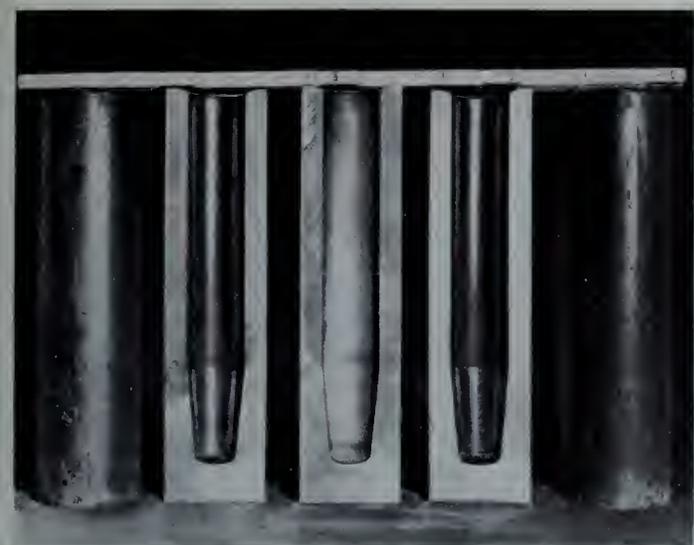

Fig. 13—Finish-forged cavity forgings for 25-pounder shell.

extrusion method must show a relatively high tool cost if accurate forgings with a finish-forged cavity are to be produced. After an extensive study of the various shell forging methods an entirely new protected one-operation process for forging shells with finish-forged cavity was evolved. The press, which has a three-station turret on the moving crosshead, employs but a single stroke of the punch into the billet with a special self-opening hydraulically cushioned die, and uses a non-extrusion process of forging.

Figure 12 shows the way in which the billet for a 4.5-in. shell becomes a finish-forged cavity forging. See also Fig. 13 and note.

As was anticipated, the forging pressure required has proved to be about half of that required for the straight punch method, thus permitting the use of a refined cast iron punch tip instead of tips of heat-treated tool steel. The overall tool cost has thus been considerably reduced, for cast iron die liners are also employed, and the average tool cost including all components works out at about  $9\frac{1}{2}$  c. per shell. It is seen that the metal is constrained to move downwards in the same direction of motion as the punch, but in advance of it as illustrated in Fig. 12. This better metal flow gives a more desirable form of grain structure without any evidence of the button

which was so prevalent in previous processes. The principal advantages of this new process include substantial savings in material cost, base thickness is reduced to a minimum and eccentricity is remarkably small; more rapid production of forgings is permitted to closer tolerances; an extremely low tool cost which has hitherto been unattainable; savings in forging labour; substantial reduction in rejected forgings and better material as regards grain structure in the forging itself.

Eccentricity in a piercing operation is one of the first troubles which must be overcome. It will be observed that in order to avoid this, a press has been designed having very rigid construction with side housings and prestressed columns and adequate guides to the moving crosshead. Again it was found that in the last war it was practically impossible to punch a hole whose length exceeded four

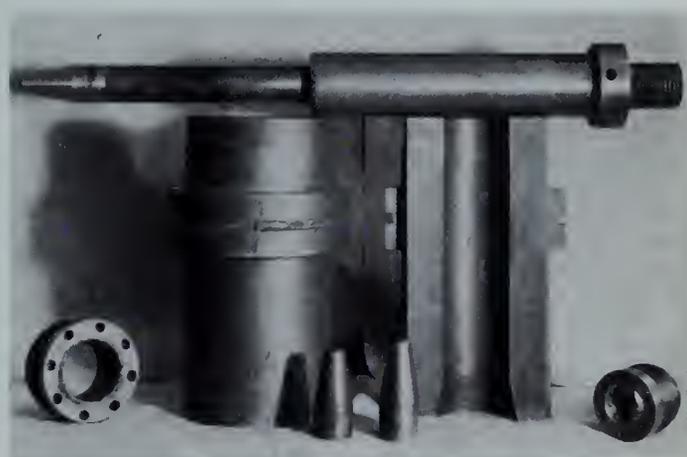

Fig. 14—Tools for 4-inch naval shell forging.

punch diameters. With this new process we are able to punch a finished cavity to perfection with a six-to-one ratio of punch length to diameter. Another important improvement embodied in the machine is the very good guide provided for the punch itself, which not only makes the punch start in the centre of the billet, but tends to hold it along this line of action. Again it will be noted that a billet of square or mosaic form is employed, and by the use of a split die it is positively gripped in position, because the distance across the corners of this billet is greater than the diameter of the die itself. The punch, tips, dies, and guide bushings for 4-in. naval shell forgings are shown in Fig. 14.

## THE QUALITY UNDERLYING THE BRITISH AEROPLANE

LT. COL. W. LOCKWOOD MARSH  
EDITOR OF "Aircraft Engineering"

The 'Battle of Britain' proved beyond all cavil the superiority in performance and fighting qualities of British aeroplanes of the fighter class, but numerous cases of the safe return to their bases of bombers (flying in some instances, hundreds of miles in a badly shot-about condition) have, though in a less spectacular way, equally demonstrated the excellence of the materials incorporated and the high standard of workmanship used in their production.

This is, in the first place, the result of years of research work and technical development in the gradual evolution of new materials. It has been estimated that it has, on occasion, taken fifteen years to develop, to the stage of being a commercial product suitable for introduction into some part of an aeroplane or aero-engine, a light alloy from the time when the first stages in the process were begun in the laboratory—at the Government National

Physical Laboratory or, it may be, in the works of some private firm.

It, is perhaps, interesting to examine this process and follow the stages by which the new material is developed in this way. Owing to the growing claims arising from rapid progress in aeroplane design, the need sooner or later arises, let us say, for a material which will stand up to more strenuous conditions of operation than those which have hitherto proved satisfactory. The chemist and the metallurgist consider the physical properties that will be necessary in the material to meet these fresh demands and investigate the precise effects that various changes in the composition—by the introduction of new elements, or variation in the quantities of existing ones—will have on these properties. The 'perfect' composition may then be found to produce a material which is ideal for the purpose so far as one strength characteristic is concerned but

fails to give satisfaction in other respects; owing, possibly, to its being too brittle, or possessing some other defect. This difficulty may be overcome by close study and patient experiment in the heat treatment, or some other process to which the material is subjected during the various stages of working it up into the finished part. This may necessitate a long series of experiments lasting over a considerable period of time; until eventually, a satisfactory 'laboratory' product is produced which fulfils the requirements that have originally been put before the research workers. Even then, however, there is still much to be done, because it is a commonplace in the materials world that something which can be produced time after time by the leisurely and closely-controlled methods of the laboratory to give the same results under tests, is not by any means always suitable at first for rapid turning out in quantity by the more rough and ready means which only are possible in a factory. Bars of the material are, therefore, tried out and produced by ordinary commercial processes. This again is a matter of trial and error involving alteration of existing methods, tried and proved, and, frequently, the installation of new and improved machinery and equipment.

All this procedure naturally takes time and requires much patient thought and experiment. Suppose the material has passed all the tests, and is shown to be satisfactory for the purpose for which it is designed, it then has to receive approval before it can be used in an aeroplane to be built for the Royal Air Force so that there is no fear of it lowering the standard of strength insisted on in every part of a machine.

All the principal British aeroplane firms, including of course aero-engine firms, are scheduled by the Ministry of Aircraft Production as 'approved for design and construction', which means that such a firm is authorized to use a new material once it is manufactured and provided that it conforms to the specification drawn up by the firm. This covers its use so far as the types of aeroplane designed by this individual firm are concerned. But it may be that the utility of the material is such that it is desired to use it more widely. In this case the specification is taken up by the Directorate of Technical Development

and is issued as a draft specification. This is a preliminary step to a still wider adoption, which will be explained in a moment. During this stage, the specification is circulated in the Aircraft Industry, and to the technical staffs of any other engineering firms concerned with the production of the material, for criticism and comment. These are examined by the Directorate of Technical Development, amendments incorporated, and it is then issued as a 'D.T.D. Specification' with a number. Even this is still only a preliminary stage in the journey of the new material on its long road to becoming a fully approved 'British Standard'. It frequently happens that it does not achieve popularity, or for some reason is found only to have a limited application—in which case it remains a D.T.D. Specification throughout its career. If, however, it proves to be a material of widespread utility for which there is a considerable demand, it goes a stage further and becomes a 'B.S. (British Standard) Specification'. To achieve this final distinction, it is handed over to the British Standards Institution, a semi-official body supported by all the various branches of the engineering industry of this Country, and is exhaustively examined and considered anew by one of the Institution's technical committees, which are composed of individuals, either in Government establishments or firms, with special experience and knowledge of the particular subject concerned; who give up part of their busy lives entirely free and voluntarily to this most important work. If the material passes this final scrutiny, it is issued by the Institution as a new 'British Standard'; than which there can be no higher hall-mark.

Even after this, however, the material itself is still subject to constant and repeated examination and test by inspectors on the staffs of the 'approved' firms, or by A.I.D. (Aircraft Inspection Directorate) inspectors, all through its career, from its first start as a bar or billet or what-not until it at last takes its place as a vital part, or fitting, in the complete aeroplane—when it carries for all to see the indentation made by the final inspection stamp showing that it has passed the vigilant eyes which have carefully scrutinized it at each stage in its evolution to the finished product.

COMPARISON OF FIRE POWER OF LEADING GERMAN, BRITISH AND U.S. FIGHTERS (1)

Country	Type	Armament	Rounds per Minute	Lb. per Minute	Duration of Fire

(1) The figures are based on the following rates of fire: .303 in. machine guns, 1,200 rounds per minute, weighing 40 rounds per lb.; 20 mm. cannon, 600 rounds per minute, weighing 4 rounds per lb.; 20 mm. Mauser cannon, 900 rounds per minute, weighing 4 rounds per lbs.; 37 mm. cannon, 120 rounds per minute; .50 in. machine gun, 750 rounds per minute. The weights of the projectiles of the two latter (U.S.) guns are not known.

(2) Interrupted. Firing through airscrew disk.

(3) *Airacobras* supplied to the R.A.F. are fitted with a 20 mm., in place of the 37 mm., cannon.

# SHIPYARD PRODUCTION METHODS

HOWARD JOHNSON, M.I.N.A. (London), M.E.I.C.  
*General Manager, Midland Shipyards Limited, Midland, Ont.*

Paper presented before the Montreal Branch of The Engineering Institute of Canada, on January 8th, 1942

**SUMMARY**—An outline of building operations for steel vessels, giving the proper sequence of erection phases in order to obtain a maximum output. Charts are used to illustrate the progress of the work and to determine and correct the causes of delay.

Prime Minister Churchill has stated that the key to winning the war is ships and still more ships.

The lay mind has little knowledge of the tremendous effort necessary to accomplish the building of the great number of vessels required. Obviously no more ships can be brought into service than those which can be supplied with the essential equipment to run them. Looking at a modern standard specification, such as that of a 10,000-ton deadweight cargo vessel, we may well reconsider our attitude towards the battles of the Atlantic and Pacific and redouble our efforts in the face of such complexity.

## PLANT LAYOUT

The importance of shipyard layout and lifting and handling equipment cannot be overstressed. When it is considered that the general cargo vessel of, say, 10,000 tons deadweight requires about 3,000 tons of steel to build the hull, the necessity of careful layout is apparent. As the costs of labour rise, more careful planning must be applied to the mechanical handling of this steel from the freight car, through the various operations, until it becomes part of the structure. Transport must be reduced to a minimum from punch and welding sheds to erection at ship.

To attain rapidity of erection on the berth, in recent years, great improvements have been made in crange facilities. Formerly the old "sling pole" was the prime means of lifting; today, tower cranes, jib revolvers, gantries and lattice racking and slewing derricks are in use according to the layout of plant, type and size of ship to be built; economical, mechanical power supplanting manpower and so speeding up erection. The wood staging, generally shutting out the layman's view of a ship until she is almost ready for launching, is now largely superseded by steel uprights on special bases, quickly adjustable to breadths of various ships. Assuming that supplies are available to pre-fabricate large portions of the vessel, ample storage space near the berths is very important so that the number and travel of lifts is a minimum.

If pre-assembly work is well organized, two efficient cranes are capable of easily erecting the entire hull of the present standard cargo vessel in under 14 ordinary working weeks whilst, at the same time, liberally serving adjacent berths. It is essential, too, that ample road area be arranged to feed the erection cranes. Experience has actually shown that in some yards an improved output can be attained by reducing the number of berths but arranging better access roads and lifting facilities.

In laying out a new shipyard the method of estimating the amount of heavy equipment required is not difficult. Having surveyed the available site and decided on the largest type of ship to be built, the launching frontage or waterfront is measured and the number of berths settled. Given reasonably skilled labour and technique, it is mere arithmetic to arrive at the annual potential output for all complete hulls and the plant and equipment necessary to feed these berths. Balance between production, equipment and berth facilities is essential; this implies an intimate knowledge of the output capacity of every machine.

In earlier shipbuilding most of the heavy, external

transport was provided by steam locomotive cranes whilst the lighter materials were hauled by manual power on small bogies or trucks, the ground being graded but untreated. To-day there is a growing tendency towards the use of concrete over the site and on the berths, while rubber-tired motor cranes and low trucks are in use for all general transport. No matter what means of transport is employed, the modern shipyard has adopted the factory principle of routing. That is to say, from receipt of steel from the mills until its erection in the ship, the layout should be such that materials pass along a straight-line route through the various machines to the berths. The best exponents of such methods have been the Dutch, although yards in other countries are developing along similar lines: the increasing use of electric welding has helped in this connection.

The advance of shipbuilding has developed in three general stages.

- (a) Elimination of manual labour in haulage and erection,
- (b) Elimination of skilled labour by the extension of the use of moulds, and,
- (c) Elimination of unskilled labour through the use of improved tools and appliances.

There is also the tendency to build specific types of vessels in particular yards, rather than for each firm to develop its plant to cope with every class of ship. The economical advantages of such a development are obvious, as a different layout, from balance-sheet considerations—the acid test of efficiency—is required for the building of passenger vessels from that needed for merchant vessels.

## PLANNING

Attention can now be focussed on the processes of production. Under to-day's conditions, when builders need not haunt ship-owners' offices and when repeat orders are flowing fairly freely, even though in a somewhat jerky manner, from Government departments, every one will

agree that shipbuilding can, and indeed must, be systematically planned and intensively organized to obtain those results essential to the winning of our oceanic battles.

The facts of the war at sea should be prominently displayed on every vacant space in all shipyards, supply-fields, and allied spheres; for only those who have, in some manner or other, been in direct contact with that war, either on the high seas or in the repair yards, have any real conception of its intensity.

The author will try to sketch the procedure in planning and building typical 10,000-ton cargo vessels, assuming that all drawings are available and orders forthcoming as berths become vacated. A ship of this type is shown in Fig. 1.

A shipyard to be capable of building such ocean-going vessels efficiently must have the necessary equipment to process materials within reasonable time. For this size of ship, 20 weeks on the berth, from laying of keel to the launch, is a fair period for building; five weeks after the launch she should be on trial trip, and then ready to take her place at the loading berth to await convoy.

We shall assume this is a four-berth shipyard. The first sheet prepared is the Master Chart, shown in Fig. 2. commonly known as the Programme. On this is marked a period roughly equal to five months or 20 working weeks. As yet no dates are inserted; for the purchasing department is hard at work contacting the various supply controllers, steel mills, and priority experts in an endeavour to secure a smooth and ample supply of steel.

It is essential that the technical staff should be familiar with the sequence of works operations and the time occupied on key operations, such as frame bending, pre-fabricating bulkheads and other large parts of the hull structure. If this planned series is not understood, considerable time-lag and much disorder can arise in the works because these operations form the basis on which steel must be ordered for mass-production methods to be in any way effective. A chart is drawn up indicating the groupings of steel for various operations ensuring that each section shall be complete with all its attachments.

Standard instructions must be issued to the mould loft, as well as to each department, indicating the entire system of erection, so that moulds and templates will be prepared in correct sequence in parallel with speed of production in the shops.

As the drawings are, in the main, already available a large amount of the mould loft work will be completed ahead of steel deliveries. Should there be any prospect of this loft work not being in advance, overtime or other means should be worked to avoid the expense of slowing down production.

When the date for steel deliveries is decided, the time required to manufacture the frames and floors over half-length amidships is added: this fixes the date of laying the keel; processing of keel, centre girder and bottom shell takes about the same time as the framing for the half length amidships.

As regards questions of production, not finance, it is a waste of process time to lay the keel before sufficient material is prepared to ensure continuity in erection. Once erection starts this should be a continuous process, each step tying-up the preceding one in correct sequence.

The same process by which the date of laying the keel was decided is repeated for each berth until the programme is filled and all berths occupied; dates are then inserted on the programme. Simply by adding 20 weeks to the keel dates the approximate launch dates are established for the first four vessels. The period of 20 weeks is hypothetical and will vary in relation to the layout. These dates might not be final, and might have to be modified when the erection chart is drawn up.

Even greater co-operation will be given by the mills regarding deliveries of steel, when the multiplicity of shapes used in the vessels are grouped into as few sizes as possible and ordered *en bloc*. The same applies to steel plates. The erection programme, however, must not be forgotten in the interests of bulk tonnage delivered; sequence is essential: a point regularly overlooked by the inexperienced.

The purchasing department will be working at high pressure ordering the thousand-and-one items called for by the specification. Remember, we are working to a production schedule; every part of a ship has immediate relationship to some other, therefore the outfitting bears closely on the hull. The purchasing agent must have before him a complete list of items to be fitted, on which the required dates for delivery are clearly shown.

As the buying market to-day is exceedingly limited, price is for the time being of secondary importance to that of delivery. It has often been a practice of purchasing agents to plan their delivery requirements on the basis of so many weeks after laying of keel. Modern methods of construction, however, leave that method open to question. For instance, many fittings for various piping systems throughout the vessel are now fitted direct to bulkheads during welding or riveting on the fabricating skids of these parts of the structure, even before the keel is laid. Rather than relating deliveries to one particular part of the hull such as the keel, it is preferable to relate them to the method of production. To think in terms that this, that, or the other will not be needed until after the launch is definitely wrong. There is only one time for fitting anything—that time is the moment the hull, or any portion of the hull is sufficiently far advanced to receive it. For instance, the steering engine cannot be bedded until the quadrant is fitted, but telemotor piping can be fitted, except for small ends, as soon as the upper deck is riveted or welded. The object is to have every department working as early as possible on the ship and so avoid, on the day of delivery, that all too common sight of profane humanity unable to extricate itself.

#### PROCESSING

The output of every machine in the punch shed must be accurately determined. Before any particular job is commenced, all material for that job should be located and placed so that it can proceed without interruption until ready for assembly at the riveting or welding skids. Finished material should not be allowed to lie in the shed but immediately removed to the skids. Only in this way can the humps and hollows of labour curves be smoothed out. In cases where all the material for a particular job is not available, the job should still proceed unobstructed on its path to the ship. Temporary parts can be fitted to

facilitate erection. The non-delivery of apparently insignificant items can do more than any other factor to break-down erection output.

Some parts of the structure require longer periods to manufacture or assemble than others, and care must be taken so that these are advanced and available at their appropriate erection time.

It is often found that congestion arises at certain machines, such as plate edge-planing machines, counter-sinkers and scarpers. There are many ways of overcoming this, either by working shifts or adopting alternatives; but the best way is to make an independent programme for that particular machine and observe the results. It is surprising how often unnecessary work is applied, and how often an operator puts through material without any relation whatever to sequence. As a result, urgently required materials are buried under piles of steel not at present needed. Weak links in the production chain must be carefully nursed, but deviations from programme should not be countenanced without previous adequate discussion.

Of great importance is the disposition of the machines in the shops. A brief survey of the route of materials, from stockyard through the shops to the skids, frequently reveals a most erratic course; from the skids to the ship may be similar to going from Montreal to Vancouver via Cape Horn. A study of the problem and redistribution of, perhaps, one or two machines in the first case, or the removal of some small obstacles from the path on leaving the skids in the second instance, will be found to pay handsome dividends by way of easier flow.

Considering the movement, lifting and transporting of these 3,000 tons of steel, for every ship through all its processes, it will be agreed that correct routing saves tremendous time and expense. The ideal is to reduce routing to a straight line path from stockyard to ship, with a minimum of transit paths.

### ERECTION

We have seen how the programme was drawn up with provisional keel-laying and launching dates inserted. The Erection Chart is now needed. (See Fig. 3).

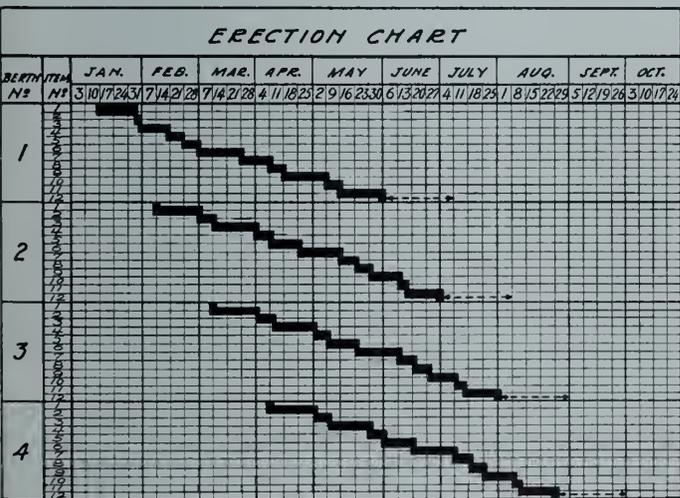

Fig. 3—Erection chart.

This is an elaboration of the programme chart, based on the assumption that the required periods for various operations are known, from either previous data or experience. A midship section and perspective of the hull of a cargo ship is given in Fig. 4, and indicates various parts of the structure.

In planning anything, there is a tendency to over-elaboration. It is easy to become bogged in detail. The erection chart has 12 key periods and in practice these

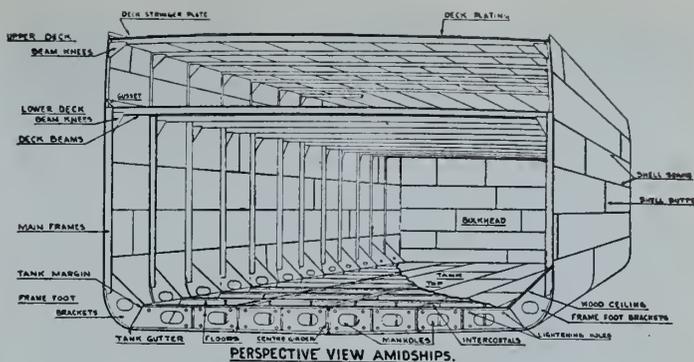

Fig. 4—Midship section and perspective of hull.

have been found to cover all the needs of erection planning in the building of ten-thousand-tonners as well as almost all other types of ocean-going vessels.

**No. 1 Erect Keel to Margin Bars Riveted.** This period covers the erection of keel, centre girders, floors, side girders, bottom developed shell, tank margins, outside and inside margin lugs and margin bars, also the amidships part of tank top.

It is recommended that all riveting or welding work on margins be kept well in advance before erection of frames is commenced.

**No. 2 Erect Tank Top.** This covers all tank top other than between the engine and boiler room bulkheads.

**No. 3 Erect Frames, Bulkheads and Forgings.** By forgings is meant stem bar and stern frame whether cast, forged, or fabricated. Bulkheads include shaft tunnel, centre line, and transverse and bunker bulkheads, also pillars up to lower deck. Frames cover all frames throughout between forgings.

**No. 4 Lower Deck, Hatches and Casings.** Lower deck covers entire deck plating, beams, hatch-end beams, deck girders and doubling plates. Hatches represent coamings, lugs, and bridles. Casings include casing trunk, coal shoots and saddle backs, from the lower deck to the casing top.

Tween deck centre-line bulkheads and pillars are also within this group.

**No. 5 Shell Stern and Bulwarks** embraces every shell plate, developed or lifted, (except bottom shell laid with the keel,) including stern plating and bulwarks.

**No. 6 Upper Deck, Hatches and Deck Houses** covers beams, deck plating and doublings. Hatches includes all coaming around deck openings complete with stays and stiffeners. Deck houses covers officers', engineers' and other deck houses, also navigating bridges.

**No. 7 Tank Testing** includes all hydraulically tested tanks; double bottom, deep tanks, peak tanks and hosing of the shell.

**No. 8 Wood Decks and Accommodation Soles.** To-day, wood decks and soles are disappearing in favour of patent compositions or linos. This implies all deck coverings.

**No. 9 Joiners on Ship.** Under this section comes the period from joiners commencing until accommodation is ready for soft furnishings.

**No. 10 Lining Up to Propeller Fitted.** This covers time from first sighting the boss until the cone and nut are fitted. Sea valves and openings must be finished during the same period.

**No. 11 Launch Way to Launch** is the period required to set up the launch-ways and launch the vessel.

**No. 12 Launch to Trial Trip.** By this is implied handing over the vessel.

In shipyards where several types and sizes of vessels follow one another on the same berths, similar charts are used: but, naturally, the periods for each operation will

Fig. 5—Tank top showing centre strake, margin and floors.

differ according to the amount of work involved. Under these conditions it then becomes necessary to draw up a cross-sectional chart of any one operation for all vessels. This is simply to a base of weeks, as in the erection chart, on which is laid down the period of, say, the shell erection for each vessel. At a glance it is seen, well in advance, whether a particular operation is going to be applied to too many ships at the same time. The yard may not possess the capacity for swelling plant and labour to meet the increased load. At once this would indicate the need for a spreading out of the programme or preparations put in hand to install equipment in time to forestall trouble. To cross-check is a wise precaution, even when the type is standardized, so that operations are nicely balanced. Peaks in the labour curve are thus avoided at times when labour is frequently difficult to obtain.

The cross-sectional method should be tested on any of the jobs where it is felt that weakness may exist and the programme and erection chart immediately amended if real benefits of planning are to be forthcoming.

We can now expand a few points on these twelve stages of the erection chart.

*Item 1.* For approximately four weeks prior to laying the keel the punch shed and riveting skids should be had at work on all double bottom steel. Centre girder, floors, bottom and reverse frames should be assembled and riveted; developed keel and bottom shell will be coming through together with tank margins. During this time the centre-line of keel will be sighted on the berth and keel and bilge blocks in course of preparation for the date of laying keel. As these items are completed, they are transported and placed as near to the berth as practicable, ready for erection. Where it is necessary to stack finished and partially fabricated materials, they must be placed in correct sequence. Stacks should never be built to the height when top-weight can distort buried portions or when the stack is then liable to slip.

On the planned date, work is commenced on erecting the keel and centre girder. It is not advisable, in multi-berth yards, to commence erection before fixed dates for keel, as this quickly puts craneage out of balance and foremen have the tendency to throw men on a job before it is absolutely necessary. This will be clearly shown on the labour chart, mentioned later.

The bottom shell is next laid, and then follows the erection of floors, tank-end floors and girders. These floors are then faired up and all longitudinal girders immediately put in place and thoroughly screwed up. The tank top centre strake is then fitted, tying up the floors and correcting them to their true distances on each side of the centre girder. The tank margins over the vessel's flat amidships are now erected and loosely bolted. All the amidships tank top, between the engine and boiler room bulkheads is then laid and tested. This is usually all developed plating and the purpose of erecting only the

amidships portion is to be certain of the plating meeting and fitting squarely across the ship from margin plate to margin plate. Actually this process is the first principle of fairing the structure. Any previous fairing is but tentative. Should discrepancies be found, such as the floors lying on a slightly diagonal line across the centre line of the vessels, and this is by no means as unusual as one would imagine, the work has not proceeded too far to render corrections costly. When it is clear that the amidship tank top plates are fitting, from bilge to bilge, squarely to the centre girder, they are thoroughly bolted up, the margins secured and run out to meet the fore and after peak bulkheads. The tank top (see Item 2) can now be laid throughout the vessel. While this is being done all foundation bars for centre line bulkheads, bulkheads and bulkhead stiffener brackets, shaft tunnel, shaft stools, auxiliary and boiler seats, etc., are at once laid down in preparation for the next stage in erection. The margin plates and bars are riveted or welded, commencing always amidships and working from this point towards the ends as soon as possible after the amidship tank top is squared. The tank margin bar, if riveted, is caulked immediately on the heels of the riveters and carried straight through to conclusion.

*Item 2.* This item covers all the tank top except the amidship fairing belt. It should be spread and riveted or welded up as early as possible to prevent dirt, moisture and other foreign matter from accumulating on the bottom shell on which riveting has not yet commenced. Once the amidship belt has been faired, there is no valid objection to riveting the bottom shell in the vicinity, even before or at the same time as the tank top. But in no case should the shell bottom be riveted before the tank top above it is squared, because skeleton floors, unless carefully watched, are at times out of alignment, causing bad rivet holes in either the tank top or the shell. (See Fig. 5.)

*Item 3.* When the stacks of pre-assembled material for the double bottom dwindle, or sooner if ground is available, the bulkheads and centre-line bulkheads should be making their appearance, pre-assembled, to be stacked in two piles; one pile with the after peak bulkhead at the bottom, covered by the after-main and engine room bulkhead; the other having the fore peak bulkhead at the bottom followed by the fore main and boiler room bulkheads. It may, however, be possible to lay each bulkhead opposite its appropriate place in the ship. In between these stacks the side bunker bulkheads are placed. During this time riveters should be at work on the skids, riveting beam knees and frame brackets to the side frames assembled there. As soon as a reasonable number are riveted they are collected and laid in correct sequence alongside the berth, port and starboard.

Now the gunwale staging should be up and the gunwale ribband resting on it, awaiting the frames. Erection of the shaft tunnel can commence as soon as the foundation bars are riveted and caulked. (See Fig. 6.)

The first frame to be erected is that forming the boundary bar of the boiler room bulkhead and is erected together with that bulkhead. Immediately following this is the centre line bulkhead connecting with it. This done, the two portions will stand rigid without additional support. The process is repeated with the engine room bulkhead and its related portion of centre-line bulkhead above the thrust recess already erected with the tunnel.

Side bunker bulkheads are now dropped into place and bolted up. These will also act as further supports to, and assist in, the truing up of the boiler room bulkheads. When this is completed the erection of the side frames commences. At this stage, tie wires are run fore and aft from the boiler room bulkhead frame and side shores are applied, so that the bulkhead is trued up, plumb and square.

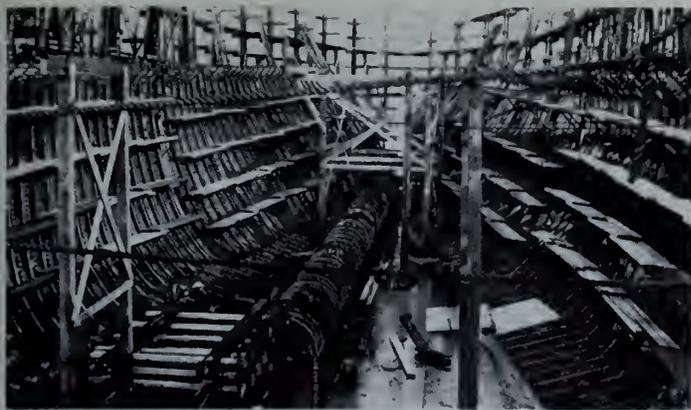

Fig. 6—After end of vessel showing tank top, frames and shaft tunnel being erected.

The gunwale ribband is at once attached to the bulkhead frame. From this point develops all subsequent fairing.

The side frames erection proceeds, but a halt is called at the forward hatch, the end of the after main hatch and at the after beam of the cross bunker hatch. The reason for this will soon be evident. When these frames are reached, all beams and half beams over this area are erected together with the appropriate deck girders and Item No. 4 on the erection chart commences.

Attention might be called, at this stage, to the fact that no operation actually stops; subsequent operations merely overlap their predecessors. Emphasis, however, must be laid on the reasons underlying each stage in the operations. It will be understood, too, that the execution of each operation so far described will be proceeding for both ends of the ship at the same time. A very important point is to be certain the next operation follows at the critical moment, so as to ensure fairness in the whole; and, furthermore, to be confident that pre-fabricated structures, developed in the mould loft, will fit accurately in their appointed places. Ships have an unfortunate habit of creeping and spreading, particularly in a downhill direction.

*Item 4.* It has been noted that the developed tank top is used to square the tank margins athwartships and to keep true relationship with the centre girder. The lower deck plating is now used for the same purpose in relation to the centre line bulkheads and the two main amidship transverse bulkheads. Between the two hatch-end beams above mentioned, the whole of the deck area is covered in and all casing sides and deck girders thoroughly faired up and squared, casing trunks being tested by diagonals in case of distortion. A good precaution at this stage is to shore up both casing and hatch corners one inch high. These corners are notorious for sagging before they are riveted. By so shoring, a lot of heartbreaking later work is avoided. Before the deck and its attachments are finally bolted up for welding or riveting, Item No. 5 commences.

*Item 5.* The developed shell plating, from lower deck gunwale to bottom shell, is next completely erected between, and overlapping, the engine and boiler room bulkheads. Checked and squared, this acts, in the vertical plane, in precisely the same manner as do the horizontal planes at tank top and deck.

There is now a complete, boxlike form, like the middle cut of a salmon, which is true and fair in every way. It is now safe to proceed with the previous items to conclusion as the fairing and checking act almost automatically onwards from this stage. The great advantage of this amidships fairing is that both ends of the ship proceed simultaneously. At all stages of erection great attention must be paid to a thorough shoring of the vessel. The increasing weight of the top structure, during erection, tends

to sag the frames, beams and bulkheads, until they are sufficiently strengthened to resist by riveting the connections. It is unpleasant to see that some lugs and brackets, which should have fitted, must be burned off and discarded because of inadequate shoring. The usual practice merely to put two holes in the beam knees and drill the remainder is not necessary if this attention to shoring is given. Should the material, moulded from the loft, fail to fit in place, some flaw is evident in the yard method. These faults can be eliminated.

*Item 6.* A point not yet mentioned is the advantage of attaching the 'tween deck frames to the main frames before erection. This saves double craning and further allows the work of erecting the upper deck to proceed as soon as Item 4 is sufficiently advanced to permit of it. Work on the upper deck follows the same pattern as laid down in Item 4 for the lower deck. When the centre line bulkheads, if fitted, are in place, the beams are dropped into position followed by the deck girders and deck plating over the amidships area.

Where no 'tween deck centre line bulkheads are fitted, the centre line deck runners, with their pillars, are erected. In this case, the beams are erected first and supported by longitudinal planking shored just off the centre line to allow for easy runner and pillar erection. After the amidship squaring is completed, the deck forward and aft is run out and hatch coamings, deck houses, and so on are forthwith placed. It should be noted that on both decks, as in the case of the tank top, foundation bars for all further erection should be laid immediately, from loft moulds, and riveted or welded together with the decks. It is, perhaps, difficult to establish this as standard practice; but the effort is worth making, if only for the purpose of reducing the number of odd rivets to be cleaned up and, more important, to prevent men having to come back on unfinished jobs. The greatest advantage, however, is that deck house erection can immediately commence as soon as the amidship belt is squared.

*Item 7.* Tank testing, on ships of the type under discussion, generally commences about the time the running of the upper deck plating is almost completed. Under this system the first tank generally is that under the engine room. This is natural, because in this vicinity the tank top is part of the amidship fairing process and so will be first completed. Often there is some difficulty in getting the small work around the auxiliary seats and side bunkers cleaned up; but if a tank testing chart is prepared, indicating the sequence of testing, this tardiness can be overcome. Most firms already adopt this as standard. It is an advantage also, if machinists have the supplies, to have all fittings connected to the tank top in place before the test. Ballast suction passing through tank ends should also, by this time, be in place. Indeed double bottom suction should be inserted while the floors are being erected. It might seem that tank testing could begin much earlier than the time indicated. It is suggested that, if the situation is carefully surveyed, no useful purpose is served by an earlier start. This method of construction allows of one tank being caulked as the next is being filled, in simple progression until the ship has been fully tested. Furthermore a smaller number of caulkers are in continuous working attendance from start to finish.

It is imperative that the fitters give early and adequate attention to the after peak tank. Frequently, accommodation and steering gear are directly above this tank and delay in testing, arising from small omissions, can have serious results on the launch and even on final delivery. Another point concerning the after peak is discussed under Item 10.

*Item 8.* As little of the joiner, electrical, piping, and other work around accommodation can commence before wood or patent decks are laid, this is the touchstone to

releasing a great deal of work. The advantage of laying foundation bars for deck houses with the deck plating will now be observed in relation to the laying of wood decks. Where 6 x 3 in. foundation bars are used, it is frequently possible, during dry spells, to commence laying accommodation soles before the deck houses are erected, for deck house plating, being of light material, is often delayed in delivery.

*Item 9.* This item needs no further elaboration than to say that charting it indicates a given time in which steelwork, in way of accommodation, is to be well advanced and painted before joiners commence. Sidelights must also be fitted as soon as the steel is erected.

*Item 10.* Experience over many ships has demonstrated the advantage of boring out the stern frame for fitting the stern tube before the boss plates are fitted. Probably there are many who will disagree; but the advantage lies in having light and access directly on both sides of the boss. Boring-out can commence as soon as the stern frame is adequately attached to the structure to prevent subsequent movement. The tube should, if possible, be fitted before the after peak test but this is not important if to do so delays the test. Nor is it a serious or expensive matter to pump up the after peak and test the tube when the ship is afloat. A little judgment has to be exercised

Fig. 7—Ready for launching.

at this stage in relation to the available time before launching. As the shipping of the rudder stock can take place only after the peak test,—unless the after peak is designed to suit—the question as to which operation, boring out or testing, should take precedence is often debatable. Only the particular circumstances can decide this. In any case, whatever result deliberation may bring, the time necessary to strip the after end staging should not be forgotten.

*Item 11.* This period of launch-ways to launch will vary in most yards, but three weeks is more than ample to avoid overtime, except for one tide before the launch. Figure 7 shows the ship ready for launching.

*Item 12.* From the launch to the trial trip is probably the worst period in the building of a ship. This is when

## LABOUR CHART

Fig. 8—Labour chart.

all concerned would swear that a conspiracy existed to prevent the ship from sailing. In the middle of cleaning up the thousand-and-one items the dock trial takes place, bringing to light various minor omissions. Just as this atmosphere is lifting, the crew arrives whose officers immediately demand every thing to be re-arranged. After each is supplied with some unspecified personal comfort, they accept the ship, though always retaining a feeling that she is not quite as good as the one just left! It is good policy to have a list prepared of the various jobs connected with dock trials, trial trips and such items as derrick and lifeboat tests. Attention to details can then be given well in advance.

### GENERAL

Should a break down occur during erection, or delay arise resulting in an undue extension of any allowed period, the erection chart must be scrutinized and cross-checked to see the effect of the stoppage on the programme. Steps must then be taken to restore the position and make any necessary amendments.

If the delay cannot be retrieved, departments concerned, and also suppliers, should be informed at once of the new dates. Suppliers will be grateful that a little of the pressure on them is relieved. By early advice, confidence and goodwill is established. Departments may not be quite so grateful but at least they know where they stand and are in a position, in ample time, to make amendments to their plans.

### LABOUR CHART

This chart (shown in Fig. 8) is a fairly sound indication of the disposition of the men employed on the various ships when used in conjunction with the erection chart. It is not uncommon in shipyards to find one vessel receiving more than its allotted share of attention. By the time this is discovered, overtime will be probably required on some other vessel to restore balance. The simplest method of establishing the contour of the curve is by closely following its application to a particular vessel which is known to have held smoothly to programme. Each yard will, of course, have its own specific contour. Yard facilities have great influence over it. The sketch shown is for only one ship; an estimated curve of labour required can be laid down for any ship at any time by lifting the dates of various operations from the erection chart and superimposing the outline of the labour curve over the new base line.

All charts, of course, should have this weekly base registering the same day of the week.

The curve for each ship is started as soon as labour is employed on the contract, the time office entering the weekly totals. Squared paper should be long enough to

cover a two-year programme allowing comparisons to be made at a glance.

It is astonishing how, immediately following launches, or some other psychological date, wholesale migrations of labour develop; they should be carefully guarded against and checked in good time.

The curve shown is an actual curve of a standard vessel similar to those under discussion, built in a four-berth yard with all berths full.

#### RIVETING CHART: PROGRESS

As a means of measuring progress from keel to launch the author would strongly recommend a Riveting Chart, like that shown in Fig. 9. Many shipyards use it. It is simple and remarkably accurate for vessels the structure of which is largely riveted. An estimate is made of the total number of rivets in the ship. The cumulative total of rivets driven each week is then calculated as a percentage of the total number to be driven and entered opposite its date.

The curve has a fairly regular contour and, once established for a particular ship, can be used by marking its dotted contour on the chart for the new vessel over the appropriate period of time she will be on the berth. As the work proceeds a full line is drawn in. Generally the full line should coincide with the dotted one. If un-

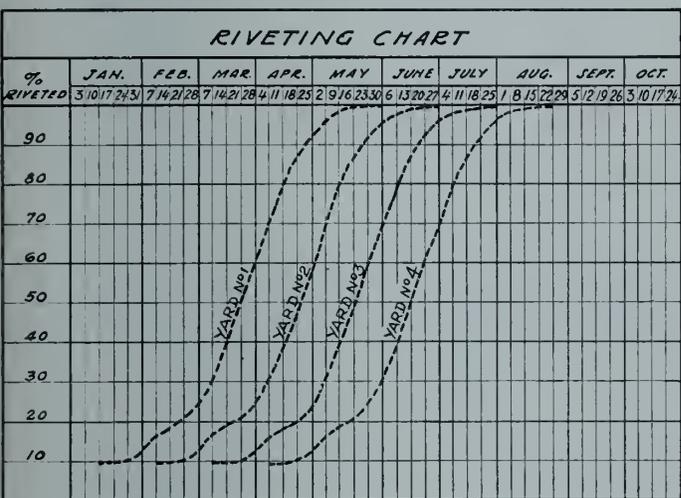

Fig. 9—Riveting chart.

usual circumstances arise, causing a marked deviation from its path, this would call for an investigation at once. Either totals have been miscalculated or a serious breakdown has occurred in the plant. Steps should be taken by introducing overtime, double banking or otherwise to bring the curve back to normal. If such a deviation occurs it is useful to scrutinize the labour chart for the same period. On most occasions it has been found that some of the birds had flown south; one of those labour migrations had taken place. This is easily rectified.

#### SUPPLY

In these days when the supply field stands aloof from the pathetic appeals of shipyards and where government departments control much of the manufacturing programmes, perhaps it will be pertinent to suggest that too many people are guessing at what they can deliver. This applies equally to shipbuilders.

Output should never be based on either guesses or hopes. In times like these, output estimates should be based, in the first instance, on the established capacity of the plant, after taking into consideration factors such as

Fig. 10—The ship leaves the ways.

available labour, and then acting on those estimates. Programmes of consumption based on facts project the true picture on which the supply field can be properly organized; similarly if suppliers also would simply state the facts, consumers in their turn would know the basis on which to plan.

Once it is established that a firm can and does act up to its promises, every assistance should be given to that firm, whether they are suppliers or consumers, so that their organization already functioning well under difficulties, can have some of those difficulties eased by way of encouragement. With such assistance firms can intensify their production at less cost to the country. Properly planned effort is essential to winning the war.

Consumers who give comprehensive, detailed and accurate forecasts of their requirements immediately on receipt of contracts are helping the supply field to organize. But the vicious practice of demanding deliveries well in advance of requirements, in the hope that they may mature somewhere near the mark, merely causes chaos. Nothing is more demoralizing to planned effort than to be kept dangling at the end of false promises.

When talking of mass production of ships, we must think in terms of every component part; not merely of hulls and propelling machinery. Successful accomplishment of large scale production depends on an adequate survey of the supply field and an intimate knowledge of consumption, capacity and requirements. Programmes, to be real, must be based, in the first instance, on the worst feature of the field. Attention must then be focused on that feature until the bottleneck is broadened and removed. Although acceleration is the aim, balance must always be borne in mind. Wherever improvement appears in any particular field, at once steps should be taken to swell all others to that same high level.

#### CONCLUSION

It has been necessary to omit many details of both organization and method; the author would plead the vastness of the subject and the few leisure hours left to a shipbuilder to-day. The points put forward will arouse interest; test them out in practice. The adoption of these methods has served well in recent years—to-day the need is paramount.

The shipbuilding resources of the Axis Powers are tremendous; their organization superb. Few with knowledge doubt their efficiency or unity of purpose. By this we must measure the magnitude of our task. Shipping in the Pacific can now no longer await a decision in the Atlantic Ocean; this is a two-ocean war; the conflict is world wide. To imagine we are doing our best is idle and dangerous; efforts must be doubled, intensified.

Effort itself is not enough. Effort applied and directed; that alone can bring victory.

# REPORT OF COUNCIL FOR THE YEAR 1941

## TOGETHER WITH COMMITTEE AND BRANCH REPORTS

Another year of war has come and gone, and through it all The Institute has continued to function in all its departments. Emphasis has been placed on certain activities and others have been allowed to subside, but on the whole it has been a year of greater activity. Increases in membership, and a substantial financial statement indicate that even under the disturbed conditions of to-day the engineers still look on The Institute as a vital part of the life of Canada, and an integral part of the war effort.

Members in all parts of the world are taking a leading part in the prosecution of the war. Information coming to Headquarters shows such persons in the active service units in Hong Kong, Singapore, South Africa, Australia, Libya, and almost every part of the Empire that is mentioned in the despatches, and in the countries of our allies as well. When the time comes that it can all be told, our members will be shown to have written brilliant pages in the book of history, adding lustre to themselves and to their profession.

The participation of members in civilian war activity is also great. The lists of personnel in almost all those departments of government which are most concerned with the war are full of the names of members. This is particularly true of the Department of Munitions and Supply, which operates under the competent guidance of the Hon. C. D. Howe, HON. M.E.I.C. In private industry, as well, members are found in positions of executive control, down to the more modest but yet important places filled by Students and Juniors. It is certainly an engineers' war and surely a vital activity of The Institute.

### BRANCH ACTIVITIES

From the branch reports which accompany this Report of Council and from the information which is reported regularly to Headquarters it is apparent that the branches have carried out a programme which compares favourably with their activities of previous years. Some branches have had an influx of new members or of old members transferred from other branches due to war activities. This interchange of members has brought new interests and even though these members all return to their normal locations after the war the branches will have benefited from the development. The experience of the Ottawa Branch is particularly noticeable. With the tremendous increase in the government staff and in the active service units the branch has experienced increased attendance at all meetings. There have been also many visitors from other countries who are members of sister societies.

### VISITS TO BRANCHES

The president visited the branches in all the zones, although unfortunately he could not attend meetings at all branches. In view of the importance of the president's position on the National Research Council The Institute is fortunate in having had him visit seventeen different branches, including Halifax and Vancouver. Necessarily, the trips have been hurried as it was not possible for him to be absent from his office for any great period of time.

On all trips he was accompanied by other officers of The Institute. On the trip to the Maritimes he was accompanied by Vice-President K. M. Cameron, Past-President J. B. Challies, Councillor J. A. Vance, R. L. Dobbin, G. A. Gaherty, and the general secretary. On his western trip he was accompanied part of the way by Vice-President Cameron and the general secretary.

The general secretary made 16 branch visits.

### COUNCIL MEETINGS

During the year Council held eleven meetings, six of them being regional meetings held at branches. This makes a new record for meetings held away from Headquarters. The attendance, including guests, was as follows: Hamilton (40) and (24), Toronto (34), Saint John (23), Kingston (26), Quebec (26). It is apparent that regional meetings contribute a great deal to the activities of the branches, and at the same time increase the interest in Council.

### FINANCES

It is a pleasure to record another successful year from the point of view of the Finance Committee. A substantial increase in revenue has made it possible to meet a large part of the costs of repairing the Headquarters premises and still show a satisfactory balance.

The steady increase in membership and the continued success of *The Journal* explain the increase in revenue. The Finance Committee had expected some loss of income by virtue of the remission of fees of members on active service overseas and other members resident in combatant areas. It is gratifying to know that even with this loss of income the net result is an increase.

Once again, the amount collected for arrears of fees is surprisingly great. This has been an important factor in the year's financing. The figures are shown on the accompanying statement.

### REPAIRS TO HEADQUARTERS PREMISES

The necessity of underpinning the main portion of the Headquarters premises resulted in an extraordinary expenditure of \$10,000.00. To meet this expense Past-President Hogg and President Mackenzie sent out a joint appeal to all branches for contributions. This has resulted in the collection of over \$8,000.00. The branches are all to be congratulated on the splendid manner in which they took up the appeal. It is encouraging to know that such excellent support can be obtained from the membership from coast to coast. The work of the Montreal Branch should be noted particularly. Under the stimulus of the chairman, R. E. Heartz, the committee collected \$6,000.00.

### ANNUAL MEETING

All those who attended the 1941 annual meeting at Hamilton carry very pleasant recollections of that function. It is doubtful if a more enjoyable meeting has ever been experienced. The Hamilton Branch arranged everything in great detail and extended a very heartfelt welcome to all who came from out-of-town. There were some unusual social features which added much to the success, and the attendance at the professional sessions was extremely encouraging.

The method of financing the meeting was particularly gratifying to Council. It is a long time since an annual meeting has been carried out with so little expense to Council.

### BY-LAW CHANGES

A new edition of the booklet describing the charter and by-laws was issued in June of this year. There have been some changes in the wording and in the arrangement of the by-laws but no changes in the by-laws themselves. A new index has also been established and several matters cleared up which were somewhat confusing in the previous edition. The preparation of the booklet and the re-

arrangement of the contents involved a great deal of work. This was very ably carried out by Secretary Emeritus R. J. Durley.

#### CO-OPERATION

Negotiations between the two branches of The Institute and the Association of Professional Engineers in New Brunswick resulted in an almost unanimous approval of the proposed co-operative agreement. As a consequence the agreement will come into effect at the first of January, 1942. The preliminary canvas indicates that joint membership will be applied for by the great majority of engineers.

This makes four provinces in which The Institute has a co-operative agreement with the Association. In the three provinces where co-operation has already been in force, very satisfactory results have been obtained. Officers of the associations and of the branches have reported themselves as well satisfied. It is expected that the same results will be obtained in New Brunswick, and it is hoped that a continuation of negotiations may result in similar agreements being adopted in other provinces.

The adoption of the agreement in New Brunswick requires members of the Association to pay a much higher fee for the joint membership. Previously they have enjoyed extremely modest dues. It is gratifying to see the agreement accepted by such a splendid majority in spite of this increased financial obligation. The officers of the Association are to be congratulated on the splendid manner in which they have guarded the interests of their members and at the same time promoted the advancement of co-operation within the profession.

The principal point of contact between The Institute and sister societies in Canada continues to be the Wartime Bureau of Technical Personnel. Such joint efforts do much towards pointing out the common interests and provide opportunities for better understanding of each other's problems and ambitions. The Institute is very pleased to work closely with these bodies and hopes for an ever increasing activity in such things.

#### INTERNATIONAL RELATIONS

The splendid co-operative relationships which have always existed between The Institute and sister societies in other parts of the world have continued. There has been a substantial exchange of correspondence with the British organizations and arrangements have been completed whereby their members who are in Canada on war work are given the privileges of The Engineering Institute, and whereby members of The Institute who are in the Old Country may make use of the British institutions without fee.

The officers and members of the American societies continue to be most helpful and cordial. It is a real pleasure and an inspiration to know that these societies are interested in our progress and are willing to contribute to it in whatever manner we may require. The presence of officers of these organizations at our annual meeting is a source of great pleasure. Frequently, officers of The Institute attend the American societies' meetings, and it is through such contacts that the excellent relationships continued to expand.

Beyond a doubt the advent of war in the United States will bring about a further development in the co-operative relationships with these American societies. Ever since the outbreak of war in 1939 the engineers of the United States have expressed sympathy and support for the ideals of their fellow engineers in Canada. It will be a source of much satisfaction and gratification to Canadian engineers to work side by side with their friends south of the border.

#### ENGINEERS' COUNCIL FOR PROFESSIONAL DEVELOPMENT

1941 marked the first full year of The Institute's participation in the activities of this Council. It has demonstrated the value of such affiliation and has indicated further channels through which The Institute may assist the profession.

At the annual meeting held in New York in October The Institute's representatives on E.C.P.D. were in attendance in full strength. In addition, President Mackenzie and Past-President Cleveland, of Vancouver, were in the group.

The plans of E.C.P.D. are comprehensive and will have an important bearing on the welfare of engineers both in Canada and in the United States. The membership of E.C.P.D. consists of—American Society of Civil Engineers, American Institute of Mining and Metallurgical Engineers, The American Society of Mechanical Engineers, American Institute of Electrical Engineers, The Society for the Promotion of Engineering Education, American Institute of Chemical Engineers, National Council of State Boards of Engineering Examiners, The Engineering Institute of Canada.

#### WARTIME BUREAU OF TECHNICAL PERSONNEL

The Bureau is being operated by The Engineering Institute of Canada, The Canadian Institute of Mining and Metallurgy, The Canadian Institute of Chemistry, and the eight provincial associations of professional engineers. The head office is at Ottawa. The object is to locate all technical personnel in Canada so that the war activities of the government and of industry may be assisted.

Forty-eight thousand questionnaires have been circulated, and from the completed forms a very elaborate filing system has been established so that engineers of any particular classification or experience can be found without delay. The records indicate not only a person's qualifications but his availability for war work. From this information it has been possible to obtain for war work several hundreds of persons who were not previously so engaged. The demands upon the Bureau are increasing but with the records practically complete and the staff now thoroughly experienced it is possible to locate the required persons in a minimum of time.

Hundreds of industries, departments of government, and the active service forces have used the Bureau's facilities. The wisdom of such a system is being proven every day, and it is expected that the facilities of the Bureau will be more and more in demand for the duration.

The Institute's interests in this development are that the general secretary has been loaned to the Bureau to act in the capacity of assistant director, and that many members throughout the country have used the Bureau either to secure engineers or to find more suitable work for themselves. Beyond a doubt the Bureau renders a real service to the entire profession and The Institute is well justified in supporting it.

#### BAND INSTRUMENTS FOR THE ROYAL CANADIAN ENGINEERS

During the course of the annual meeting at Hamilton, a collection was made to raise a sum of money as a contribution towards the purchase of band instruments for the Royal Canadian Engineers at Petawawa. An amount of \$160.00 was raised and transmitted to Lieut.-Colonel J. P. Richards, Officer Commanding. A grateful acknowledgment has been received, accompanied by an invitation for members of The Institute to visit the camp any time that they might be in the locality.

#### CHRISTMAS CARDS

On account of the additional activities brought about by the war, Council decided to discontinue for the year the practice of issuing Institute Christmas cards. In pre-

vious years these have been distributed up to a quantity of over two thousand. Special greetings were sent by mail and cable to the officers of sister societies in different parts of the world.

#### ROLL OF THE INSTITUTE

The membership of all classes now totals 5,373, which appears to be the highest figure ever attained in The Institute's history. This number does not include new members who will come into The Institute at the first of January, 1942, by reason of the New Brunswick co-operative agreement. New names added to the roll for the year 1941 amounted to 451, but deaths, resignations and removals reduce the net figure to a gain of 253. This new figure will be very gratifying to all members of The Institute, particularly when it is understood that the number of members in arrears of fees is smaller now than it has been for many years. Special efforts were made to collect arrears, and the Finance Committee has taken a firm stand with those members who have failed to keep reasonably up to date. Consequently, the figure representing to-day's membership is indicative of a healthy condition.

During the year 1941, four hundred and thirty-nine candidates were elected to various grades in The Institute. These were classified as follows: One hundred and twenty-three Members; thirty-three Juniors; two hundred and seventy-one Students, and twelve Affiliates. The elections during the year 1940 totalled four hundred and thirty-six.

Transfers from one grade to another were as follows: Junior to Member, twenty-eight; Student to Member, twenty-eight; Student to Junior, seventy-one; Affiliate to Junior, one, a total of one hundred and twenty-eight.

The names of those elected or transferred are published in *The Journal* each month immediately following the election.

#### REMOVALS FROM THE ROLL

There have been removed from the roll during the year 1941, for non-payment of dues and by resignation, seventy-one Members; eighteen Juniors; sixty-six Students, and two Affiliates, a total of one hundred and fifty-seven. Twelve reinstatements were effected and sixteen Life Memberships were granted.

#### DECEASED MEMBERS

During the year 1941 the deaths of forty-one members of The Institute have been reported as follows:

##### MEMBERS

Adams, Francis Porter	Lumbers, William Cooper
Bishop, William Israel	Mitchell, Charles Hamilton
Blanchard, Joseph Elie	Moloney, James Grant
Bloomfield, James Munro	Morrison, John William
Brandon, Edgar Thomas John	Perrin, Vincent
Coke-Hill, Lionel	Philip, Patrick
Cook, Archibald Sinclair	Phillips, George
Cross, Frederick George	O'Reilly, Francis Joseph
Dawson, Alexander Scott	Ramsay, Robert
DuCane, Charles George	Sandwell, Percy
Fripp, Frederick Bowles	Silliman, Justus Mitchell
Gray, John Hamilton	Sinclair, Malcolm
Harry, Wilmot Earl	Stewart, William Lewis Reford
Hawley, George Prince	Sullivan, William Henry
Hill, Edgar Murray MacCheyne	Uniacke, Robert Fitzgerald
Holt, Sir Herbert Samuel	Vermette, Joseph A.
Johnstone, William Morrison	Weir, James
Kipp, Theodore	Wright, Athol Choate
Lamoureux, Joseph Arthur	

##### JUNIOR

Benny, Walter Robert

##### STUDENTS

Lalonde, A. Gaston  
McClung, Joseph Eldon  
Murray, Robert Leslie

#### TOTAL MEMBERSHIP

The membership of The Institute as at December 31st, 1941, totals five thousand, three hundred and seventy-three. The corresponding number for the year 1940 was five thousand, one hundred and twenty.

1940	
Honorary Members .....	15
Members .....	3,465
Juniors .....	588
Students .....	985
Affiliates .....	67
	5,120
1941

Members .....	3,560
Juniors .....	638
Students .....	1,084
Affiliates .....	75
	5,373

Respectfully submitted on behalf of the Council,

C. J. MACKENZIE, M.E.I.C., *President*,

L. AUSTIN WRIGHT, M.E.I.C., *General Secretary*.

#### TREASURER'S REPORT

The President and Council:

It gives me great satisfaction to report that in spite of the heavy expenditures for repairs to the Institute building, the Financial Statement again shows an improvement over the preceding year.

The contributions made towards the repairs undertaken have permitted to show an increase of \$1,771.99 in the surplus account.

Investments are shown at cost, which is \$1,006.49 less than the present market value.

In spite of this condition, it is urged that all possible means should be exercised to conserve the resources of the Institute.

Respectfully submitted,

JOHN STADLER, M.E.I.C., *Treasurer*.

#### FINANCE COMMITTEE

The President and Council:

The auditors' report of the finances of The Engineering Institute shows that they are in sound condition.

There is a surplus of \$1,771.99, after allocating \$3,120.05 to building repairs. The repairs to the building cost \$10,441.63 towards which special subscriptions were raised by the branches, amounting to \$7,321.60 (on December 31st last, with more coming), leaving a balance to be made up from general funds of \$3,120.05.

The Finance Committee takes the opportunity of congratulating the Montreal Branch which has subscribed more than \$6,000. to this fund.

The report has been drawn up in the usual manner, with the exception that the land and buildings of the Institute were carried in the auditors' statement, at cost, which is \$91,495.22. As this amount is in excess of the true value, the land and buildings are henceforth carried at their assessed value by the City of Montreal, which is \$36,000, and the balance of the cost, or \$55,495.22, is written off as depreciation. This will have the effect of very substantially decreasing the surplus account which stood before this change at \$110,459.44. The surplus ac-

count now stands at \$54,964.22, an amount very much closer to its true value.

Respectfully submitted,

DEGASPE BEAUBIEN, M.E.I.C., *Chairman.*

### PUBLICATION COMMITTEE

The President and Council:

The principal duty of your Committee is, of course, the supervision of the publication of the *Journal*, and while no major changes have been made in policy or in arrangement of it, a number of problems have been presented to us.

Several members have sent in suggestions for changes, and to them we wish to express our appreciation, as the criticisms have all been of a constructive nature. If we have not complied with their requests, it is because a canvass of other members has indicated that no change, or an alternative change, was desirable.

There has, at times, been a scarcity of good papers for publication, but we feel that the standard has been well maintained. Occasionally, papers are presented of such length that, if printed in the *Journal*, they would increase the cost too greatly. For this reason we have at times had to ask authors to abbreviate their articles, and in other instances have had to decline the paper.

One large paper of outstanding merit is that by S. R. Banks, on the Lion's Gate Bridge, and it has been decided to publish it in full. Fortunately, this work divides itself quite readily into three sections, and it will shortly be published in three successive issues of the *Journal*. For this paper Mr. Banks has been awarded the Gzowski medal.

One of the duties of this Committee is, in conjunction with the general secretary, to approve all publications issued in the Institute's name. Consequently, Mr. Bennett's Committee submitted the manuscript for the new booklet "The Profession of Engineering in Canada", and the committee spent considerable time in a careful study of it. The Committee has felt that as this is one of the most important publications ever issued by the Institute particular care should be taken in the preparation of the material. Mr. Bennett and his Committee have completed a tremendous task and their work should be of considerable benefit to prospective students of engineering throughout Canada. The Committee hopes that its comments and suggestions have been of some assistance to Mr. Bennett.

We again wish to thank those who have offered suggestions for improvement of the *Journal*, and we hope members will continue to take an active interest in this publication.

Respectfully submitted,

C. K. McLEOD, M.E.I.C., *Chairman.*

### PAPERS COMMITTEE

The President and Council:

During the year the activities of the Papers Committee have not been as extensive as desired. Owing to the pressure of war it has been difficult for engineers to find time to arrange an itinerary to visit and speak at branch meetings. However, the branch programmes have been greatly assisted by the visit of the president who was often accompanied by past-presidents, vice-presidents, the general secretary and other officers of The Institute.

The increased number of regional meetings of Council and the more frequent visits of officers and members at other branches is a good development in The Institute. It stimulates the branch activities and promotes greater co-operation among all engineers.

Co-operation between branches is steadily improving. This has proved to be a benefit in arranging programmes. Notices of meetings indicate that where a branch has a particularly good meeting, the speaker is soon found addressing another branch.

There is increasing evidence of the desirability of Headquarters becoming a clearing house for papers and films to a greater extent. When a good film is secured and the branches advised, there is a demand for its showing at branch meetings.

In this connection, the film showing the Tacoma Bridge Disaster has helped considerably in completing programmes for branch meetings. The film has been routed from Halifax to Victoria; in several branches special meetings had been arranged and the showing accompanied by commentaries from a member specialized in bridge engineering. The film was also shown in most of the engineering colleges under the auspices of the local branches.

The unanimous satisfaction expressed by those who have had the opportunity of seeing the Tacoma Bridge film indicates that it was well worth the small disbursement made for its purchase.

Through the courtesy of the University of Manitoba it has been possible to borrow another film entitled, "Photoelastic Stress Analysis." It has already been shown to some of the branches and it is expected that the others will be given the same opportunity.

There is a broad field for this committee in assisting the branches with papers and films. Some assistance can be given by officers and members by taking every opportunity to attend meetings of their own and other branches.

Respectfully submitted,

JAMES A. VANCE, M.E.I.C., *Chairman.*

### COMMITTEE ON THE TRAINING AND WELFARE OF THE YOUNG ENGINEER

The President and Council:

Subsequent to the submission of the last annual report as published on pages 69 and 70 of the February, 1941, *Journal*, five members of the committee, Messrs. Hartz, Ellis, Macdonald, Legget and the chairman, together with Mr. Murray, representing Mr. R. M. Smith, met at Hamilton to review the work of the committee and to determine the future activities.

The committee discussed pre-college training and entrance requirements, student selection and guidance, engineering curricula, scholarships, summer employment for engineering students, extra-mural studies and branch activities for younger members.

It was decided to ask authority of Council to proceed with the publication of a brochure on student guidance as the first extensive activity of the committee and to supplement this with a pamphlet on counselling for distribution to The Institute branches. This was approved by Council.

A draft of the proposed brochure was distributed to the committee members and to the members of Council in the early summer of 1941, and after much correspondence and discussion it was finally approved by Council and is now in the hands of the printers. It is hoped that distribution to all secondary schools in Canada will be made during February and March, 1942.

When this brochure is distributed, each branch will be asked to co-operate by naming a Student Counselling Committee so that all secondary schools in Canada may have the benefit of the advice of practicing engineers in the matter of student guidance.

During the year we have maintained close contact with the several committees of the E.C.P.D., and we value very highly the opportunities offered to meet with their members and to discuss our common problems.

We have noted the increased interest in the younger members by our several branches, and we hope to be able to stimulate this interest by the distribution of information covering the several fields of activity of this committee.

Respectfully submitted,

HARRY F. BENNETT, M.E.I.C., *Chairman.*

### LIBRARY AND HOUSE COMMITTEE

The President and Council:

Your committee carried on with the same membership as last year because of the major repairs to headquarters building which had been recommended and authorized. It was agreed by Council that a separate Library Committee would be appointed this year to study the requirements and possibilities of establishing the library on a satisfactory and adequate basis, in keeping with the status of The Institute. The unique opportunity of a fresh start had been presented by the elimination of a tremendous

accumulation of obsolete files and records due to the building renovation.

Unfortunately pressure of other activities has prevented Council from taking the necessary steps to provide the proper support for such a committee, and no appointment was made. It is the strong recommendation of your chairman, voicing the opinion, previously expressed, of the committee, that action be taken as soon as possible.

Tabulated below is a summary of the accessions to the library in the past year together with the number of requests for information received by the librarian:

Accessions (for the most part Reports, etc.).....	440
Books Borrowed.....	234
Bibliographies prepared (a total of 66 pages)...	24
Photostats furnished (a total of 70 pages).....	6
Requests for information.....	1,021
by telephone.....	413
by letter.....	364
in person.....	244
Books presented for review by publishers.....	44

### COMPARATIVE STATEMENT OF REVENUE AND EXPENDITURE FOR THE YEAR ENDED 31ST DECEMBER, 1941

	<u>\$ 4,289.56</u>	<u>\$ 5,559.73</u>	
REBATES TO BRANCHES.....	\$ 6,111.03	\$ 6,304.00	
<b>TOTAL EXPENDITURE FOR YEAR.....</b>	<u>55,189.15</u>	<u>51,245.92</u>	
<b>SURPLUS FOR YEAR.....</b>	<u>1,771.99</u>	<u>3,221.61</u>	
<b>TOTAL REVENUE FOR YEAR.....</b>	<u>\$56,961.14</u>	<u>\$54,467.53</u>	

The foregoing figures show that the library continues to be of great use to the members and proves one of the most valuable services provided by The Institute.

The removal of the periodicals files in the basement, occasioned by the repairs made early in the year, has provided an opportunity for establishing a more convenient classification. This is under way and should be completed soon.

The only activities of your committee during the year were connected with the repairs to headquarters. This work was fully reported in *The Journal*, but for purposes of this record the following details are repeated.

The whole of the auditorium section was underpinned with concrete piers to hardpan. The work was done by A. F. Byers & Company, Limited, at a contract sum after calling for competitive bids. The total cost of the repair, including minor patching of plaster and redecoration, was \$10,441.63. The front section of the building was not underpinned. It shows signs of post settlement but this was not connected with the evidence of current trouble

in the newer auditorium section built in 1913. It was agreed that the front building, an old remodelled residence, was not of sufficient value and not of the proper layout to warrant the expense of underpinning.

In studying and carrying out this work Messrs. J. A. McCrory and J. A. Lalonde were added to the committee because of their experience in construction matters.

During the year the caretakers' quarters were completely redecorated and some repairs made to roof, skylights, etc. Hardwood floors were laid in most rooms.

Respectfully submitted,

BRIAN R. PERRY, M.E.I.C., *Chairman.*

### LEGISLATION COMMITTEE

The President and Council:

During the year 1941, your committee was not presented with any business or problems concerning Institute legislation.

The committee has been ready at all times to be of

### COMPARATIVE STATEMENT OF ASSETS AND LIABILITIES

### AUDIT CERTIFICATE

We have audited the books and vouchers of The Engineering Institute of Canada for the year ended 31st December, 1941, and have received all the information we required. In our opinion the above Statement of Assets and Liabilities and attached Statement of Revenue and Expenditure for 1941 are properly drawn up so as to exhibit a true and correct view of the Institute's affairs as at 31st December, 1941, and of its operations for the year ended that date, according to the best of our information and the explanations given to us and as shown by the books.

(Sgd.) RITCHIE, BROWN & Co.,  
*Chartered Accountants.*

MONTREAL, 13th January, 1942.

assistance if called upon, and is very pleased to report that no legislative difficulties interrupted the activities of The Institute during this time of national emergency.

Respectfully submitted,

E. M. KREBSER, M.E.I.C., *Chairman.*

### BOARD OF EXAMINERS AND EDUCATION

The President and Council:

Your Board of Examiners and Education for the year 1941 has had prepared and read the following examination papers with the results as indicated:

	Number of Candidates	Number Passing
I. Elementary Physics and Mechanics ..	2	1
II. (a) Strength and Elasticity of Materials .....	2	1
V. (a) General Metallurgy .....	1	1
V. (b) (1) Metallurgy of Iron and Steel	1	1

Respectfully submitted,

R. A. SPENCER, M.E.I.C., *Chairman.*

### COMMITTEE ON WESTERN WATER PROBLEMS

The President and Council:

A very comprehensive report was prepared by the Committee on Western Water Problems and approved by Council February 5, 1941, as set out in minutes 1527 to 1539, and published in the Journal for May 1941. This report was formally and officially submitted to the Rt. Hon. W. L. Mackenzie King, Prime Minister, under date of April 26, 1941.

As a result of representations made to the Dominion Government by various individuals and organizations, including members of our Committee, the Dominion Government, by Order-in-Council dated February 17, 1941, appointed a committee to be known as The St. Mary and Milk River Waters Development Committee, consisting of Mr. Victor Meek, M.E.I.C., Controller, Dominion Water and Power Bureau; Mr. George Spence, Director, Prairie Farm Rehabilitation; and Mr. W. E. Hunter, of the Department of Finance.

This committee is charged with the duty of making a thorough study and reporting within a year upon all aspects of the proposals that further storage and irrigation works be built in Canada on the St. Mary and Milk rivers. Without limiting the generality of the foregoing, the committee shall consider the following matters:

(a) The water supply in Canada's share of international streams in Southern Alberta, the water requirements of the presently constructed projects and water available for further irrigation development.

(b) The most feasible plan to put these waters to beneficial use, including selection of lands to be irrigated, estimates of cost of storage reservoirs and other works required for complete development.

(c) Construction programme with annual estimated expenditure over the period of years required to complete full development.

(d) The arrangements necessary with the owners of the present irrigation projects and the owners of the further lands to be irrigated.

(e) The benefits which this water development would confer on Canada, the province of Alberta and the residents of the districts affected.

(f) The allocation of costs and methods of financing.

(g) The administrative control to be exercised over the projects after completion, including maintenance and operation of the works constructed and colonization of the irrigable lands.

The committee shall not hold public hearings. With that limitation, it may invite and receive representations,

in person or in writing or both, from interested bodies and individuals.

The committee may invite the co-operation of Departments of the Canadian Government not represented thereon. In particular, the committee shall invite the co-operation of the Department of External Affairs in dealing with international aspects of the proposals.

The Dominion Government also invited the Government of the Province of Alberta to designate one or more persons to work with their committee. The Province complied with this request by appointing a committee, to be known as the Alberta Water Development Committee, consisting of Hon. N. E. Tanner, Minister of Lands and Mines; Hon. D. B. McMillan, Minister of Agriculture, and Mr. P. M. Sauder, M.E.I.C., Director of Water Resources.

The two Government committees have held three hearings in western Canada, lasting from three to five days each, at which the western members of the E.I.C. Committee and Sub-committee, and other members of the Institute were present and gave whatever assistance they could to the Government committees. On the occasion of the inspection of the dam site on the St. Mary river by the full membership of the two Government committees, on September 21, 1941, the following members of the Institute Committee and Sub-committee were present: Messrs. G. A. Gaherty, Chairman; T. H. Hogg, Past-President, E.I.C.; S. G. Porter, Past-President, E.I.C.; A. Griffin; P. M. Sauder; D. W. Hays; H. J. McLean.

Other members of the Engineering Institute of Canada present were: Messrs. B. Russell, Senior Consulting Engineer, P.F.R.A., (Prairie Farm Rehabilitation Act); W. L. Foss, District Engineer, P.F.R.A., in charge of St. Mary Surveys; O. H. Hoover, Officer in Charge, Dominion Water and Power Bureau, Calgary.

The members of the Government committee and other officials and individuals interested in this problem have expressed their appreciation of the very material assistance that has been rendered by the Institute Committee, both through its report and through the advice and help given by the individual members of the Institute Committee. The Dominion Government Committee now has all the data it requires in hand, and is engaged in preparing its final report and recommendations to the Government.

It is recommended that the Committee of the Institute be continued for another year in order that it may stand by and give whatever other assistance it is able to render to the Government Committee.

Respectfully submitted on behalf of the Committee on Western Water Problems.

G. A. GAHERTY, M.E.I.C., *Chairman.*

### COMMITTEE ON INTERNATIONAL RELATIONS

The President and Council:

During the past year an effort has been made by the Committee on International Relations to further wherever possible the contact of members of The Institute and of Canadian engineers generally with the engineers of other countries.

The most formal and extensive of these contacts has been through the participation of The Engineering Institute of Canada in the deliberations of the Engineers' Council for Professional Development. Several members of The Institute who have served on committees of E.C.P.D. have attended meetings of their committees in the United States, and at the annual meeting of E.C.P.D. held in New York City, on October 30, nine Institute members, including the president and four past-presidents took part in the deliberations. The reception that has been accorded the representatives from Canada on these occasions has been most gratifying and it is evident that much benefit in an international sense has flowed from their participation.

Useful international work has been done in showing courtesies to refugee engineers and other non-Canadian engineers temporarily in Canada. This has been most outstanding in connection with members of the Association of Polish Engineers in Canada and of the Institution of Electrical Engineers. At the first meeting of the Toronto Branch of The Institute for the season, sixteen Polish engineers were the guests of the Branch and one of them presented an excellent paper. Thanks to the generosity of Council, *The Engineering Journal* will be sent free of charge for the year 1942 to engineers from other countries now in Canada on war work.

Isolated cases of useful international contacts were found in the participation of members of The Institute in two important annual conventions of American engineering organizations held in Toronto during the past summer. For the summer convention of the American Institute of Electrical Engineers, Mr. M. J. McHenry, a member of The Institute's Committee on International Relations, was the chairman of the Convention Committee and The Institute was formally represented by Past-President Hogg and by the general secretary. At the annual meeting of the American Water Works Association, held also in Toronto during the past summer, many members of The Institute took part and the chairman of The Institute's Committee on International Relations was asked to represent President Mackenzie at the banquet.

Past-President Camsell, another member of the Committee has, as a member of the Board of Directors of the American Institute of Mining and Metallurgical Engineers, been able generally to further international goodwill and understanding and has taken pains to explain to his fellow directors Canada's war activities and our vital relationship to Great Britain and to the United States in the present crisis.

On the occasion of the granting of honorary membership in the American Society of Mechanical Engineers to the Honourable C. D. Howe, HON.M.E.I.C., The Institute was appropriately represented by Past-President Challies, Professor R. W. Angus, HON.M.E.I.C. and by the general secretary.

Respectfully submitted,

C. R. YOUNG, M.E.I.C., *Chairman.*

### MEMBERSHIP COMMITTEE

The President and Council:

In these strenuous times all citizens have assumed more work and added duties or are ready to do so. Engineers are particularly in the forefront. Their services are so much in demand that their efforts must be organized, regulated and co-ordinated in order that they may be applied in the most effective manner. The very splendid part that our Institute has been able to play in this work brings a glow of satisfaction and pride to every member.

With particular reference to membership, however, we can note that the record of service and help rendered by The Institute impresses other engineers who have not been Institute members. They should want and no doubt many of them do want to become members of the organization in which they can identify themselves with such nationally helpful activities.

In wartime there is, of necessity, considerable shifting around from place to place. Membership in The Institute makes available the facilities of the widespread branches throughout Canada. If an engineer finds himself moved to United States or England or elsewhere, the benefits from Institute membership are more important. A certificate of membership in The Institute affords opportunity to meet men of the same profession who are members of similar organizations in their own land. It is a valuable professional introduction.

These points are mentioned here to remind the membership committees of the various branches of the expectancy of new memberships at this time. We are being afforded opportunities of meeting and being of service to many who are not Institute members. Let us point out to them the effective work The Institute has been able to perform for the war effort and emphasize what services The Institute has to offer them.

Respectfully submitted,

H. NOLAN MACPHERSON, M.E.I.C., *Chairman.*

### COMMITTEE ON DETERIORATION OF CONCRETE STRUCTURES

The President and Council:

The Committee on the Deterioration of Concrete has been relatively inactive for the past year, due largely to the fact that its members are very busy men and under present conditions have not been able to devote the usual time to its work. Therefore, the Committee can only report that certain papers recording the success of important repairs made to concrete structures, which it had hoped to have ready for publication this year, are still in preparation and may not become available for some time.

The Committee is continuing to gather data as circumstances permit and it hopes at a more favourable time to place these data before the Institute.

Respectfully submitted,

R. B. YOUNG, M.E.I.C., *Chairman.*

### COMMITTEE ON PROFESSIONAL INTERESTS

The President and Council:

The policy of the Council in promoting closer co-operation with the provincial professional associations is still achieving definite results. As a result of protracted negotiations, an agreement between The Institute and the Association of Professional Engineers of New Brunswick has been approved by both bodies. The extraordinarily strong support given in the formal balloting within both The Institute and the Association augurs well for a mutually satisfactory consummation of the desire of the great majority of the members of both organizations resident in New Brunswick for a simplification in engineering organization that will lead to greater solidarity in the profession. This agreement is to be formally completed at the Annual Meeting of the Association in Saint John on Monday, January 12th, 1942.

The committee is glad to report that close co-operation is being achieved on a mutually satisfactory basis between The Institute and the associations in the provinces of Saskatchewan, Alberta and Nova Scotia.

There is nothing definite to report from the province of Manitoba apart from a renewed intimation by the president and the general secretary when they were in Winnipeg in September last that The Institute would be glad to discuss a co-operative agreement with the Association of Professional Engineers of Manitoba whenever the officers of the Association desire it.

The committee feels that it should again record its appreciation of the sympathetic understanding that has always existed between The Institute and the Corporation of Professional Engineers of Quebec. As for the provinces of Ontario and British Columbia, the readiness of The Institute's committee to discuss co-operation with the very efficiently operated registration bodies is well known.

Respectfully submitted,

J. B. CHALLIES, M.E.I.C., *Chairman.*

### EMPLOYMENT SERVICE

The President and Council:

The work done during the year is summarized in the following table and the corresponding figures for 1940 are given for purposes of comparison:

	1940	1941
Registered members.....	129	77
Registered non-members.....	89	75
Number of members advertising for positions	41	14
Replies received from employers.....	21	9
Vacant positions registered.....	260	229
Vacancies advertised in <i>The Journal</i> .....	43	35
Replies received to advertised positions.....	143	110
Men's records forwarded to prospective employers.....	179	302
Men notified of vacancies.....	178	306
Placements definitely known.....	147	71
Registered vacancies cancelled.....	2	10
Registered vacancies still open.....	33	31

Early in the year, the Government established the Wartime Bureau of Technical Personnel at Ottawa. It will be recalled that this Bureau is operated by The Institute and other engineering societies. The services of the general secretary have been made available by Council to the Bureau, in the office of assistant director.

The activities of The Institute Employment Service have been affected greatly by the Bureau in that all information relative to openings or men available has been sent to the Bureau and frequently subsequent placements have resulted from a combination of the efforts of both organizations.

Originally it was hoped the Bureau might establish an office in Montreal in which case it was expected that all employment activities of The Institute would be transferred to it in order to give a better national service to all engineers. This still remains a possibility in which The Institute will be glad to co-operate.

The facilities of The Institute and its twenty-five branches across the country have been made available to the Bureau for the verification of qualifications in the case of candidates for important war positions.

It may be interesting to record an example of close co-operation with the Wartime Bureau. Through one of its members in England, The Institute received during the year an urgent request from the British Ministry of Aircraft Production for twenty-five engineers and draughtsmen. The Institute Employment Service communicated immediately with the Wartime Bureau and, with the facilities of the two organizations, many candidates were assembled. When the British representative came from England, the candidates from the district of Montreal were interviewed at Headquarters and our Employment Service files were again of great assistance.

The figures tabulated above indicate the vacancies registered and the placements effected by The Institute Employment Service alone; they do not record the work done in co-operation with the Wartime Bureau.

It can be said that no member of The Institute has been unemployed for any long period of time during the year. As might be expected the demand has been larger than the supply. This applies particularly to engineers with plant experience in mechanical, electrical and chemical engineering. The result is that several civil engineers whose previous experience had been mostly in the field have entered the plant and are being trained to do mechanical or other industrial work.

The unusual demand from industry and from Government departments has resulted in several retired engineers resuming their activity. The Employment Service has been able to assist in several such instances.

It is significant that very few from the graduating classes this year have found it necessary to make use of the Employment Service. The great majority had already secured positions before graduation. On the other hand a large number of engineering students have obtained summer employment through our facilities.

The active forces have again this year resorted to our files and it has been possible for us to help frequently in recruiting technically qualified men for the various units.

In spite of the numerous vacancies conspicuously advertised in the press, we have again this year interviewed many applicants for work. These were mostly members of The Institute who wanted to make sure that their qualifications were used to the best advantage in the war effort. We have thus been able to help in the transfer of several engineers from non-essential industries to important war work. Canadians who had been employed outside of the country for the past few years have enquired whether their services could be used in the war effort and several have returned upon our advice and have been placed advantageously.

L. AUSTIN WRIGHT, *General Secretary.*

#### PAST PRESIDENTS' PRIZE COMMITTEE

The President and Council:

Your Committee on the Past-Presidents' Prize has nothing to report. No papers were received this year, and no meetings of the committee have been held.

The committee awaits with interest the reaction of Council to the suggestions regarding a change in procedure which were presented by the committee two years ago.

Respectfully submitted,

R. DEL. FRENCH, M.E.I.C., *Chairman.*

#### GZOWSKI MEDAL COMMITTEE

The President and Council:

It is the unanimous recommendation of your committee that the award be made to Mr. S. R. Banks, M.E.I.C., for his paper, "The Lion's Gate Bridge, Vancouver, B.C."

So many excellent papers have been found eligible for consideration this year that your committee members have found it very difficult to make a choice.

Among many other papers of outstanding interest may be mentioned Mr. J. A. McCrory's paper, "Construction of the Hydro-Electric Development at La Tuque";—Mr. F. P. Shearwood's paper, "The Justification and Control of the Limit Design Method";—and the paper by Messrs. W. Storrie and A. E. Berry, "Modern Sanitation and Water Supply Practice."

Respectfully submitted,

H. O. KEAY, M.E.I.C., *Chairman.*

#### DUGGAN PRIZE COMMITTEE

The President and Council:

Your committee, entrusted with the task of selecting and recommending papers worthy of this award, has carefully reviewed the papers presented to The Institute during the period July 1940 to June 1941, and now begs to report.

After a careful review, your committee selected five papers which, in its opinion, appeared to meet the conditions attached to this award.

Of the papers considered, each could be said to be a contribution of distinct value, and certainly worthy of consideration for the award. The diversity of subjects covered made it rather difficult to set up a standard of comparison; and in any case, it was felt by the committee that the margin between the different papers was very narrow. It was therefore rather gratifying to discover that the three members of the committee had, after due consideration and without previous consultation, arrived at the same decision.

We recommend that the Duggan Medal and Prize be awarded to Mr. O. W. Ellis for his paper "The Forgeability of Metals."

Respectfully submitted,

JOHN T. FARMER, M.E.I.C., *Chairman.*

### PLUMMER MEDAL COMMITTEE

The President and Council:

Your committee considers that the papers presented do not quite measure up to the standard of previous medal papers, and that it would be in order to omit the award of the Plummer Medal this year.

Respectfully submitted,

J. F. HARKOM, M.E.I.C., *Chairman.*

### LEONARD MEDAL COMMITTEE

The President and Council:

Your committee, consisting of Messrs. L. L. Bolton, A. E. Cameron, G. E. Cole and V. Dolmage, with myself as chairman, recommend that the Leonard Medal for this year be awarded to Mr. G. Reuben Yourt for his paper called "Ventilation and Dust Control at the Wright-Hargreaves Mine," published in the November 1940 issue of the *Canadian Mining & Metallurgical Bulletin*.

The committee is pleased to give honourable mention to Mr. M. F. Goudge for his paper on "Magnesia from Canadian Brucite" published in the September 1940 issue of the *Canadian Mining & Metallurgical Bulletin*.

Respectfully submitted,

A. D. CAMPBELL, M.E.I.C., *Chairman.*

### STUDENTS' AND JUNIORS' PRIZES

The reports of the examiners appointed in the various zones to judge the papers submitted for the prizes for Students and Juniors of The Institute were submitted to Council at its meeting on January 17th, 1942, and the following awards were made:

H. N. Ruttan Prize (Western Provinces). No papers received.

John Galbraith Prize (Province of Ontario), to A. L. Malby, J.R.E.I.C., for his paper "Carrier Current Control of Peak Loads."

Phelps Johnson Prize (Province of Quebec—English), to G. N. Martin, J.R.E.I.C., for his paper "Characteristics and Peculiarities of Some Recent Large Power Boilers in England."

Ernest Marceau Prize (Province of Quebec—French), to A. T. Monti, S.E.I.C., for his paper "Vedette de 40 Pieds de Longueur."

Martin Murphy Prize (Maritime Provinces). No papers received.

### NOMINATING COMMITTEE

*Chairman:* E. P. MUNTZ.

# Abstracts of Reports from Branches

## BORDER CITIES BRANCH

The Executive Committee met eight times during the year for the transaction of branch business.

Eight branch meetings were held including a special meeting honouring the visit of our president and the annual meeting.

Information about the various meetings follows, attendance being given in brackets:

- Jan. 10—Mr. R. K. Scales of the Ethyl Corporation, Detroit, addressed the branch on **Fuels and Engines of the Future**. (35).
- Feb. 14—Mr. H. Lloyd Johnson, Resident Engineer, Canadian Industries Limited, addressed the branch on the **Warden System of Civilian Defence**. (27).
- Mar. 14—Mr. J. A. McCrory, Vice-President and Chief Engineer of the Shawinigan Engineering Company, addressed the branch on the **Power Development of the St. Maurice River**. (59).
- April 25—Mr. Cyril Cooper, Manager of the Windsor Elementary Flying Training School, addressed the Branch on the **British Commonwealth Air Training Plan**. (31).
- May 17—Dr. N. W. McLeod, of the Imperial Oil Ltd., addressed the branch at the Sarnia Riding Club on **Soil Technology as Applied to Modern Highway and Air port Construction**. (29).
- Nov. 14—Mr. D. Ramseyer, Superintendent of the Ford Soy-Bean Plant, Dearborn, Michigan, addressed the branch on **Soy-Beans in Industry**. (53).
- Nov. 26—Special meeting honouring Dean C. J. Mackenzie, our President, accompanied by Vice-President K. M. Cameron, Councillor J. A. Vance and H. F. Bennett, from the London Branch. Dr. Mackenzie spoke on the **Work of the National Research Council**. (31).
- Dec. 12—Annual meeting and election of officers, complimentary dinner to F. H. Kester. An address on **Recruiting and Training Activities of the Air Force** was given by Flight-Lieutenant Hugh C. Flemming, Commanding Officer of the Windsor recruiting station of the Royal Canadian Air Force.

## CALGARY BRANCH

The following report covers the activities of the branch for the year 1941. Attendances are shown in brackets:

### MEETINGS

- Jan. 16—**Soil Mechanics**, by Prof. R. M. Hardy. (50).
- Jan. 30—Seven reels of motion pictures loaned by the U.S. Bureau of Mines were shown. These pictures depicted the **Manufacture of Steel**. (51).
- Feb. 13—Students and Juniors night. Speakers: Mr. Langston, **Gun Perforation in Oil Wells**; Mr. Stanley, **Cascade Power Project**; Mr. Sharp, **Motion Picture Projectors**. (47).
- Feb. 27—**Explosives**, by R. W. Watson. (46).
- Mar. 8—Annual Meeting following luncheon (35).
- April 15—**Organization of the R.C.A.F. Civilian Staff**, by T. M. Moran (38).
- Oct. 9—**Exploring for Oil by Geophysics**, by W. H. Gibson (63).
- Oct. 23—**Power Plants in Australia**, by H. K. Dutcher (58).
- Nov. 6—**Aircraft Design**, by Flight-Lieutenant W. Thornber (57).
- Nov. 20—A motion picture was shown by Mr. Davidson and Mr. Pettinger of the Alberta Wheat Pool entitled **The History of Power in Canada** (53).
- Dec. 4—Business meeting to discuss the proposed new By-laws of the Calgary Branch (15).
- Dec. 17—Showing of coloured scenic pictures by Dr. Pilchard and Mr. S. G. Coultis. This was our annual ladies night (81).

In addition to the above regular meetings, a banquet was held on September 26, in honour of Dr. C. J. Mackenzie, president of The Institute.

During the year, the Branch Executive Committee met eight times.

## EDMONTON BRANCH

1941 saw a large increase in the membership of the Edmonton Branch, due to the agreement with the Association of Professional Engineers.

During the year nine meetings in all were held. All but two of these were preceded by a dinner. The following

## Note—For Membership and Financial Statements see pages 94 and 95.

summary gives particulars. Attendances are shown in brackets:

- Jan. 14—**The Development of the Combustion Chamber of the Diesel Engine**, by E. A. Hardy, Professor of Agricultural Engineering, University of Saskatchewan (40).
- Jan. 27—Motion picture in seven reels showing the manufacturing of steel. Meeting arranged by the Engineering Students Society of the University of Alberta.
- Feb. 25—**Arc-welding in Industry**, by C. W. Carry, Standard Iron Works, Edmonton (40).
- April 1—Annual ladies night. Entertainment by the Belasco Players and showing of a motion picture entitled "Silvercraft" (52).
- April 22—**Compressed air—Its application in construction and effect on workers**, by D. Hutchison, Mackenzie River Transport. This was the final meeting of the 1940-41 session and election of branch officers took place (25).
- Oct. 2—The visit of the president, Dr. C. J. Mackenzie, coincided with the banquet of the Regional Convention of the Canadian Institute of Mining and Metallurgy. The president of the Engineering Institute was guest-speaker at a banquet arranged by the C.I.M. & M. Eleven members of the Institute and their wives attended, while others were present as members of C.I.M. & M.
- Oct. 29—The motion picture **Tacoma Bridge Failure** was shown. I. F. Morrison, Professor of Civil Engineering, University Of Alberta, lead an interesting discussion. Chrysler Corporation films were also shown (53).
- Nov. 18—**CKUA New Broadcasting Station**, by J. W. Porteous, University of Alberta (47).
- Dec. 16—**St. Mary and Milk River Irrigation Development**, by W. L. Foss, of the Prairie Farm Rehabilitation Office (30).

## HALIFAX BRANCH

The following is a resume of the activities of the branch for the past year.

In spite of the increased burden placed on practically all members by the war, we are able to report that all meetings have been well attended, and would like to thank the members for their continued interest.

During the year five dinner meetings were held, as follows:

- Feb. 20—Mr. C. D. Harvey, Provincial Archivist, spoke on **The First Settlers of this Province and their Effect on its Future**. Also Mr. R. L. Dunsmore gave a brief outline of the recent Annual Meeting of the Institute at Hamilton. At this meeting Mr. S. W. Gray took over the duties of secretary-treasurer of the branch.
- Mar. 20—Mr. R. L. Dunsmore presented a technicolour talking picture, **Friction Fighters**. At this meeting, Mr. I. P. MacNab presented the certificate for the Institute Student Prize to Wallace A. MacCallum, of Amherst, N.S.
- May 12—This was the most important meeting of the year, as our guests included our President Dean Mackenzie, Vice-President K. M. Cameron, General Secretary L. Austin Wright, Councillor J. A. Vance, and R. L. Dobbin and G. A. Gaherty. The guest speaker of the evening was Father Burns, Professor of Philosophy at St. Mary's College, whose subject was **Social Reconstruction after the War**. President Mackenzie spoke briefly on the contribution being made by engineers to the war work, and the fact that their value is recognized, particularly in Great Britain. Mr. Wright gave a short talk on, **The Progress and Problems of the Wartime Bureau of Technical Personnel**. The Institute film showing the collapse of the Tacoma Bridge was the final feature of the evening.
- Oct. 23—Mr. Guina, Assistant General Manager of the Canadian Colloid Company, spoke on the subject of **Boiler Feed Water and its Control**.
- Nov. 27—Mr. M. Walsh, Chief Engineer of the Gunite and Waterproofing Company, described the **Method of Prestressing Concrete**, and presented a film showing the construction of large storage tanks by gunite.
- May 22—Mr. P. A. Lovett presented the Institute Student Prize to Harold T. Rose at the Graduation Exercises of the Nova Scotia Technical College.

During the year the Executive held eleven meetings, at which the ordinary routine business was transacted.

Pactically all matters in connection with the co-operation of the Institute and the Association of Professional Engineers have been cleared up.

The membership of our branch since the agreement was completed, has increased by 107 members,—only four corporate members are not members of the Association.

The purchase of an \$80.00 War Savings Certificate was made during the year from monies saved by not having any musical entertainment at our Dinner Meetings.

### HAMILTON BRANCH

The branch has continued in the co-operation with allied societies by having joint meetings when possible. The following is a brief account of meetings and activities during the year, attendances being shown in brackets:

Jan. 6—Annual Business Meeting and Dinner held at the Rock Garden Lodge. **Current Events** was the subject chosen by Colonel Beauchemin, who gave an excellent address until being relieved of his disguise when it became evident that the imposter was Mr. T. S. Glover, M.E.I.C. Chairman. Alex. Love closed his term of office and turned the affairs of the Branch to the incoming Chairman, W. A. T. Gilmour (64).

Feb. 6 and

Feb. 7—The Fifty-fifth Annual General Meeting of the Institute re-convened at the Royal Connaught Hotel, Hamilton. The Hamilton Branch wishes to thank all of the branches for their attendance and support which helped to make the meeting an outstanding success. An unusual and enjoyable feature was the joint dinner (615) with the Niagara District Electric Club and the demonstration and lecture given by Mr. J. O. Perrine, Assistant Vice-President of the American Telegraph and Telephone Company.

Mar. 10—**Aerial Surveying**, by Professor K. B. Jackson, held at McMaster University (52.)

Apr. 18—**Electricity in National Defence**, by Mr. C. A. Powell, of the Westinghouse Company, Pittsburgh, held in the Westinghouse Auditorium. This was a joint meeting with the Toronto Section of the American Institute of Electrical Engineers (226).

May 9—**Alcohol from Wheat**, by Dr. H. B. Speakman, Director of Ontario Research Foundation, Toronto. Held at McMaster University (36).

Oct. 2—**The 220 Kv. System of the Hydro Electric Power Commission**, by Mr. A. H. Frampton, of the H.E.P.C. of Ontario. Held in the Westinghouse Auditorium. This was a joint meeting with the Toronto Section of the American Institute of Electrical Engineers (168).

Nov. 7—**War Production** was exemplified during an evening visit to the plant of The Dominion Foundries and Steel Limited. The tour of inspection was conducted by guides under the able direction of Mr. W. D. Lamont, Chief Metallurgist. The light supper served in the cafeteria after the long tour was thoroughly appreciated by our party (65).

Dec. 16—**Tool Steels for Engineers**, by Mr. H. B. Chambers, Metallurgist, Atlas Steels Limited, Welland. Held at McMaster University (46). During this meeting a quiz of ten questions about tool steel was handed out to members and guests. Each one checked his neighbour's paper while Mr. Chambers gave the correct replies. The prize, a current novel, was won by a guest.

After our meetings at McMaster, it is our general practice to serve coffee and sandwiches and enjoy half an hour of good fellowship.

### OBITUARY

The Branch will miss the kind and genial presence of Mr. F. P. Adams, City Engineer of Brantford, who passed away during the year after so many years of work in the Institute.

### PUBLICITY

The Executive wishes to express some appreciation to the press, especially *The Hamilton Spectator* and *The Daily Commercial News* for their generous support.

### GENERAL

The usefulness of the Branch has been greatly enlarged by the many courtesies and help given to us by the management of McMaster University and we record, here, our very deep appreciation for all these things.

The Executive Committee held eight business meetings with an average attendance of seven.

### KINGSTON BRANCH

The branch held the following meetings during the year:

Jan. 30—Dinner meeting at Queen's Students' Union. Lt.-Col. LeRoy F. Grant presented the award of the Institute to Mr. James M. Courtright, Science '41, a student at Queen's. Mr. M. N. Hay, of the Aluminum Co. of Canada Ltd., Kingston, spoke on **The Aluminium Industry of the World**.

Feb. 25—Meeting held in conjunction with a dinner at Queen's Student's Union. The chairman, Mr. T. A. McGinnis, presided. The guest speaker was Dr. A. E. Berry, Director of the Sanitary Engineering Division of the Ontario Department of Health. His subject was **The Engineer in Public Health**.

Mar. 13—Joint meeting was held with the Queen's University Engineering Society to enable a large number of science students the opportunity of hearing Mr. Otto Holden, Chief Hydraulic Engineer of the Hydro-electric Power Commission of Ontario speak on **The Ogoki River and Long Lake Diversions**.

June 14—Special dinner meeting was held at the Catarqui Golf Club in honour of the election of Principal Wallace of Queen's University to honorary membership in the Institute. Many out of town guests were present as the Council had been invited to hold a meeting in Kingston to celebrate the occasion. During the afternoon Chairman and Mrs. McGinnis entertained at tea.

### LAKEHEAD BRANCH

The branch held the following meetings during the year:

Jan. 15—Dinner meeting at the Royal Edward Hotel, in Fort William. The chairman, Mr. H. G. O'Leary, presided. The speaker was Mr. J. I. Carmichael of the Canadian Car and Foundry who spoke on **Some Problems in Aircraft Production**.

Feb. 14—Annual ladies night was held. This year it took the form of a St. Valentine's supper dance in the Norman Room of the Royal Edward Hotel.

Mar. 20—Meeting was held in the City Council Chambers in the Whalen Building, Port Arthur. The vice-chairman, Mr. B. A. Culpeper, presided in the absence of the chairman. The speaker was Mr. R. B. Chandler, Manager of the Port Arthur Public Utilities Commission, who spoke on **The Ogoki and Long Lac Diversions**.

April 23—Dinner meeting was held at the Royal Edward Hotel, in Fort William. The chairman presided. The speaker was Mr. R. R. Holmes of the Thunder Bay Paper Co., who spoke on **The Treatment of Boiler Feedwater**.

May 21—Annual dinner meeting was held at the Port Arthur Golf and Country Club. The chairman presided and presented his report. He welcomed the incoming officers and handed over the chairmanship to Mr. B. A. Culpeper.

Aug. 16—Special meeting was called to make an inspection tour of Temporary Grain Storage Buildings and conveyor galleries being constructed for the bulk storage of grain. The storage buildings inspected were those being constructed for the United Grain Growers Limited at Port Arthur.

Sept. 22—Dinner meeting was held at the Royal Edward Hotel, in Fort William. The president, vice-president and general secretary were special guests. Dr. Mackenzie spoke on **The National Research Council in Relationship to the War**.

Oct. 15—Dinner meeting was held at the Italian Hall, in Port Arthur. Five short addresses were given as follows: G. H. Burbidge, on **Lakehead Winds**; J. Koreen, **Building of a Ship**; S. T. McCavour, **The Trials and Tribulations of the Pulp and Paper Industry in Wartime**; R. J. Prett, **Prefabricated Hangars**, and H. P. Sisson, **Building of a Road**.

### LETHBRIDGE BRANCH

The regular meetings of the branch were held in the Marquis Hotel, on Wednesdays, with refreshments served after the meetings, in accordance with the policy decided on in the previous year. One meeting, at which the Tacoma Bridge film was shown, was held in the Auditorium of the Collegiate Institute.

The following is the list of the meetings held, with the speakers and subjects, with attendance shown in brackets:

Jan. 15—Mr. J. H. Ross, Director of Y.T. for Alberta, **Co-ordination of the Youth Training Movement with the National Defense Movement** (29).

- Feb. 5—Preceded by corporate members meeting. Mr. John Dykes, **The Life of Robert Burns**. (14).
- Mar. 22—Joint meeting with the Assoc. of Prof. Eng. of Alberta. Mayor D. H. Elton, **History Repeats Itself**.
- Feb. 26—Mr. L. B. George, Div. Master Mech. C.P.R., **A Visit to an Aeroplane Plant** (25).
- Nov. 5—Subject: Films: 1. **Tacoma Bridge Disaster**; 2. **Crude Oil Refining**; 3. **Crude Oil Production**.

The annual meeting of the branch was held on April 2nd.

On May 10, 1941, R. B. McKenzie, Jr.E.I.C. was appointed secretary-treasurer, E. A. Lawrence having volunteered for active service.

### LONDON BRANCH

During the year 1941, the executive held six business meetings. Nine regular and special meetings were held as follows. Attendance is given in brackets:

- Jan. 15—Annual meeting and election of officers held at the Grange Tea Rooms, London. **The Machinery of Law**, by R. E. Laidlaw of the Canadian National Railways legal staff (56).
- Feb. 19—Regular meeting held in the Board of Education board rooms, City Hall, London. **The Analysis of Stresses by Polarized Light**, by H. C. Boardman of the Chicago Bridge & Iron Works (56).
- Mar. 13—Regular meeting held in the Board of Education board rooms, City Hall, London. **Power Development on the St. Maurice River**. J. A. McCrory, Chief Engineer of The Shawinigan Engineering Co. (37).
- Apr. 17—Regular meeting held in the Board of Education board rooms, City Hall, London. **Junior Engineers Meeting**, A. L. Furanna, Chief Draftsman Public Utilities Commission, London, spoke on **The 1940 Analysis of London's Low Voltage Network**, A. F. Hertel, Engineer, Dept. of Public Works, spoke on **Some Ways of Winning the War**. H. G. Stead, Chief Engineer, E. Leonard & Sons, spoke on **The Development of Power** (28).
- May 21—Regular meeting held in Gettas Tea Rooms, Talbot St., St. Thomas. Supper meeting followed by showing of the film **The Failure of the Tacoma Bridge** (40).
- Oct. 1—Regular meeting held in the Officers' Mess of the Talbot St. Armouries, London. **Recent Electrical Engineering Developments**, J. M. Galillee, Assistant Advertising Manager of The Candian Westinghouse Co. (70).
- Oct. 29—Regular meeting held in the Drill Hall of the Talbot St. Armouries, London. **Films depicting various scenes of the Present War**. (150)
- Nov. 26—Special luncheon meeting held in the Crystal Ball Room, Hotel London, London. **Research and War**. Dean C. J. Mackenzie, President of the Institute. Meeting was held in conjunction with the Canadian Club (30).
- Dec. 10—Regular meeting held at the Hume Cronyn Memorial Observatory, University of Western Ontario, London. **The Planets and Stars**, by Prof. Kingston, University of Western Ontario.

Average attendance of all meetings: 50.

### MONCTON BRANCH

The Executive Committee held four meetings. Six meetings of the branch were held as follows:

- Mar. 18—A meeting was held in the City Hall. A motion picture sound film entitled **The Mining, Smelting and Refining of Copper-Nickel Ores** was shown.
- Apr. 22—A combined meeting of Moncton Branch, and the Engineering Society of Mount Allison, was held in the Science Building of Mount Allison University, Sackville. C. S. G. Rogers, Bridge Engineer, Atlantic Region, Canadian National Railways, gave a review of the causes of the Tacoma Bridge collapse. Mr. Rogers' remarks were illustrated with moving picture film.
- May 14—A dinner meeting was held at the Riverdale Golf Club, for the purpose of meeting the president of the Institute, Dean C. J. Mackenzie, Vice-President K. M. Cameron, Chairman of the Papers Committee, J. A. Vance, and R. L. Dobbin, member of the Legislation Committee.
- May 30—The annual meeting was held on this date.
- Nov. 28—A meeting was held in the City Hall. R. M. Phinney, S.B., Engineer of Train Operation, General Railway Signal Co., Rochester, N.Y., gave an illustrated address on **Centralized Traffic Control**.
- Dec. 1—A combined meeting of Moncton Branch, and the Engineering Society of Mount Allison, was held in the Science Building of Mount Allison University, Sackville. R. M.

Phinney repeated his address on **Centralized Traffic Control**.

It is with regret that we record the passing of Robert Leslie Murray, S.E.I.C., whose death occurred on November 17th.

### MONTREAL BRANCH

Notwithstanding the difficult conditions imposed by the war, the affairs of the branch have been conducted as usual. Though engineers and technical men have been unusually busy, the attendance has been good, and the interest and enthusiasm most encouraging. As in the past, members of all committees have given active and efficient support to all branch activities.

The outstanding achievement of the year was the campaign for funds to effect repairs to the Headquarters building of the Institute. The responsibility of contacting the membership of the branch was undertaken by the Executive Committee who were ably assisted by Past Presidents, Councillors and several members of the branch in carrying out this important assignment. The splendid result achieved speaks for itself, an amount of \$6,000 has been collected for the fund.

A special committee was organized to co-operate with the Royal Canadian Engineers in finding suitable candidates for officers and other ranks. Several meetings were held—the initiative now being in the hands of Lt.-Col. P. M. Knowles, O.C., R.C.E., Montreal.

On February 11, through the courtesy of the Rotary Club of Montreal, the members were invited to a luncheon which was addressed by the Honourable C. D. Howe, Hon.M.E.I.C., Minister of Munitions and Supply, who had recently returned from England.

On April 28, l'Association des Anciens Elèves de l'Ecole Polytechnique invited all members of the Branch to attend a lecture in the new auditorium of l'Ecole Polytechnique on **The Place of Soil Technology in Modern Highway and Airport Construction**, by Mr. N. W. McLeod, D.Sc., C.E.

### PAPERS AND MEETINGS COMMITTEE (Chairman: J. M. CRAWFORD)

The regular Thursday night meetings have been carried on as usual despite the increased tempo of activity in industrial and engineering circles. In some cases, however, it has not been possible to secure what would have been most interesting papers due to the necessary restrictions placed upon the publicizing of certain phases of work directly connected with the war effort.

Mention is here made of the visit on June 12, to the plant of Canadian Vickers Limited. A record crowd of 300 taxed the well-organized preparations of Vickers, showing the keen interest of Institute members in such plant visits.

Following is a list of the papers delivered during the calendar year of 1941, with the attendance shown in brackets:

- Jan. 9—Annual Meeting of the Branch (80).
- Jan. 16—**Our Cities: Their Role in the National Economy**, by George S. Mooney (50).
- Jan. 23—**Diesel Electric Locomotives**, by Prof. Louis E. Endsley (100).
- Jan. 30—Annual Branch Smoker (482).
- Feb. 3—**Energy, Frequencies and Noise Relations in Line and Amplifiers of Coaxial Cables and Other Multi-Channel Telephone Systems**, by Dr. J. O. Perrine (100)
- Feb. 13—**Recent Installations of Large Boilers in England**, by Gerald N. Martin (65).
- Feb. 20—**Development of Transport Mechanization**, by R. L. Martin (80)
- Feb. 27—**Transmission Line Fault Location**, by E. W. Knapp, M.E.I.C. (90).
- Mar. 6—**Automotive Industry's War Effort**, by R. D. Kerby (77).
- Mar. 13—**Destructive Forces, Damage and Repair**, by John Dibblee, M.E.I.C. (68).
- Mar. 20—**Departures in Bridge Foundation Construction**, by A. Sedgwick (125).
- Mar. 27—**Utilization of the Power Resources of the Upper St. Maurice River**, by E. V. Leopoldt, M.E.I.C. (85).

- April 3—**War Time Communications**, by G. L. Long and J. L. Clarke (60).
- April 17—**Improving Operations in Industrial Plants**, by W. T. Johnson (95).
- April 24—**Soil-Cement Paving**, by Roy A. Crysler (75).
- June 12—**Plant Visit—Canadian Vickers Ltd.** (300).
- Oct. 2—**Opening meeting—Movie and Refreshments** (160).
- Oct. 9—**Modern Power and Distribution Systems in Industrial Plants**, by J. L. McKeever (85).
- Oct. 16—**Control of Operating Costs by Budget**, by H. M. Hetherington (55).
- Oct. 23—**The Aluminum Industry Related to our War Effort**, by A. W. Whitaker, Jr. (190).
- Oct. 30—**Municipal Management and the Engineer**, by J. Asselin (50).
- Nov. 6—**Centralized Traffic Control for Railway Operation**, by Robert M. Phinney (65).
- Nov. 13—**Glass in National Defense**, by C. J. Phillips (120).
- Nov. 20—**Annual Student Night** (170)
- Nov. 27—**Portland-Montreal Pipeline**, by W. R. Finney (225).
- Dec. 4—**The Trolley Bus**, by L. W. Birch (65).
- Dec. 11—**The Chemical Descent of Man**, by Robert R. Williams, M.S.Sc.D. (125).

#### JUNIOR SECTION

(Chairman: A. P. BENOIT)

The Junior Section has had another successful year, in spite of the fact that the war activities both in the military and industrial fields, have somewhat impeded its progress. The student engineer and the young engineer are for a good part doing military training in the evenings and have little time to attend meetings as often as they would like.

As in previous years, the Students' Night, which took place on November 20, was the highlight of the Junior Section's activities. Mr. H. A. N. Holland, of McGill University, carried off first prize with a very original paper on construction and Mr. R. Quintal, of l'Ecole Polytechnique was awarded second prize for a most interesting talk in Geophysical Prospecting. One of the main objects of the Junior Section is to interest students in Institute affairs. It has been suggested that students should join the Institute, when registering with their respective universities each fall, and this plan will be tried out next year. This year, Mr. R. E. Hertz addressed the McGill Students while Mr. L. Trudel spoke at l'Ecole Polytechnique.

The executive of the Junior Section is at present drafting a circular letter which will be sent to all students, to invite them to present papers and to take a more active part in the Institute's activities and the discussions at the meetings.

The Junior Section was instrumental in securing a Branch News Editor, Mr. Graham Wanless having kindly consented to assume the duties.

The following is a list of the Junior Section meetings with the attendance given in brackets:

- Jan. 27—**Annual Meeting**—Prof. R. E. Jamieson, M.E.I.C., spoke on the **Corporation of Professional Engineers of Quebec** (40).
- Feb. 10—**Experimental Research on Soil Stabilization**, by Jacques Hurtibise, Jr. E.I.C. (16).
- Feb. 24—**Aspect Légal de l'Arpentage**, par Gabriel Dorais, Jr. E.I.C. (20).
- Mar. 17—**Some Aspects and Problems encountered in Television Broadcasting** by W. B. Morrison, B.A.Sc. (39)
- Mar. 31—**A Simple Explanation of Ship Model Testing**, by A. Monti, S.E.I.C. (20).
- Oct. 6—**Opening night. Talk by Mr. R. E. Hertz on Policy and the Young Engineer** (90).
- Oct. 20—**Transformer Troubles**, by Pierre Duchastel (21).
- Nov. 20—**Student night. Synthetic Gasoline**, by R. M. Rousseau (Ecole Polytechnique), **First Summer in Construction**, by H. A. N. Holland (McGill); **Geophysical Prospecting**, by R. Quintal (Ecole Polytechnique); **Surveying and Mapping in Newfoundland**, by M. C. Baker (McGill). A motion picture was shown through the courtesy of The Canadian General Electric Co. (170).
- Dec. 5—**Synthetic Rubbers in War-Time**, by J. W. Crosby (80). (Joint meeting with Quebec Rubber and Plastics Group held at the Faculty Club.)
- Dec. 15—**Engineering Services of the Montreal C.N.R. Terminal**, by Richard Noonan, Jr. E.I.C. (25).

#### MEMBERSHIP COMMITTEE

(Chairman: P. E. SAVAGE)

The Membership Committee this year concentrated its efforts on students at McGill University and the Ecole Polytechnique. This work was done mainly through the Junior Section, which carried it out very thoroughly, and with gratifying results.

The second main effort of the Committee was directed at non-members who made use of the Institute Employment Service. Most of these men who had obtained positions in the past two years were canvassed by means of personal letters, but with very disappointing results. It was noted that most of the men in this group would qualify for Affiliate Membership.

#### OBITUARIES

It is with regret that we record the names of those who have died during the year, and we wish to extend to their families the most sincere sympathy of the Branch.

#### MEMBERS

William Israel Bishop	Patrick Philip
Joseph Elie Blanchard	Robert Ramsay
George Prince Hawley	William Lewis Reford Stewart
Sir Herbert Samuel Holt	James Weir
Joseph Arthur Lamoureux	

#### STUDENT

Gaston Lalonde

#### PUBLICITY COMMITTEE

(Chairman: GORDON D. HULME)

In order to establish and maintain friendly relations with the press, representatives of the Montreal newspapers were invited to discuss with the Publicity Committee steps which should be taken to publicize the Branch's activities during the coming season. Three representatives from the *Gazette*, two from the *Montreal Daily Star* and one from *La Presse* attended a Committee meeting.

Announcements concerning each Branch function were included in the city items of the various papers, at the request of the committee.

On the organization of the Annual General Meeting Committee, the Branch publicity committee was invited as a group to handle the publicity for that function. The invitation was accepted and the committee is now operating in that capacity as well as continuing the publicizing of items of local interest.

#### RECEPTION AND ENTERTAINMENT COMMITTEE

(Chairman: W. W. TIMMINS)

A smoker was held at the Ritz-Carlton Hotel on Thursday evening, January 31, for which a record number of 545 tickets were sold. The smoker was organized by Mr. W. P. Malone and was intended to create the atmosphere of the gay nineties.

Refreshments were served at the Annual Meetings and the opening fall meetings of the Branch and of the Junior Section and also at the Student Night. Several courtesy dinners were given to out-of-town speakers, but due to small attendances the Executive Committee has decided to drop this function for the present. Out-of-town guests are to be entertained by the sponsors of the papers and any members wishing to join are entirely welcome to do so.

Throughout the world, the Branch is represented in various units of the armed forces. We look to our fellow members with pride and keep them constantly in our thoughts. Our hope is that they may have a safe and speedy return.

#### NIAGARA PENINSULA BRANCH

The Executive held four business meetings and one electoral meeting to conduct the affairs of the branch.

The programme committee arranged and conducted the following professional meetings:

- Jan. 24—Dinner meeting at the Leonard Hotel, St. Catharines. The speaker, Professor R. W. Angus, gave an illustrated talk on **The History of the Development of Water Turbines and Pumps**.
- Mar. 21—Dinner meeting at the Reeta Hotel, Welland. The speaker, Mr. H. B. Chambers, of the Atlas Steel Company, gave an illustrated talk on **Some Fundamental Steel Characteristics of Special Interest to Engineers**.
- May 16—Joint dinner meeting with the Ontario Chapter of the American Society for Metals, held at the Leonard Hotel, St. Catharines. The speaker, Mr. O. W. Ellis of the Ontario Research Foundation, talked on **Forgeability** as applied to both ferrous and non-ferrous metals.
- June 16—Annual dinner meeting held at the General Brock Hotel, Niagara Falls. After the dinner, the newly elected branch officers and executive were introduced to the membership. The speaker, Mr. E. L. Durkee of the Bethlehem Steel Company, gave a talk on **The Erection of the Steel Superstructure of the Rainbow Bridge**. This most interesting talk was illustrated with three reels of motion pictures.
- Oct. 29—Dinner meeting held at the General Brock Hotel, Niagara Falls. The principal speaker was Dr. Shortridge Hardesty of Waddell and Hardesty, New York, who spoke on **The Rainbow Bridge** from the viewpoint of design. Mr. E. L. Durkee, resident engineer of the Bethlehem Steel Company, provided a running commentary to the Bethlehem Steel Company's movie on the construction of the bridge. The co-operation of the Niagara Falls Bridge Commission is appreciated for making this meeting possible, and for opening the work to inspection in the afternoon.
- Nov. 20—Joint dinner meeting with the Niagara Group of the American Institute of Electrical Engineers, held at the Welland House, St. Catharines. The speaker, Mr. J. W. Bateman of the Canadian General Electric Company, gave a talk and demonstration on **Some Interesting Applications of Light, Ultra-Violet and Infra-Red Radiations**.

### OTTAWA BRANCH

During the year the Managing Committee held ten meetings for the transaction of general business.

It is with deep regret that we report the deaths of four of our members: W. M. Johnstone, M.E.I.C., J. A. Vermette, M.E.I.C., A. C. Wright, M.E.I.C., and J. A. Lamoureux, M.E.I.C., of Fort Coulonge, P.Q.

As in previous years the Branch donated two sets of draughting instruments to the Ottawa Technical School for presentation as prizes for proficiency in draughting. A copy of "Technical Methods of Analysis" by Griffin was presented to the Hull Technical School to be awarded to one of its students.

The following is a list of meetings held during 1940, with attendance figures in brackets. Unless otherwise stated, these were luncheon meetings at the Chateau Laurier:

- Jan. 9—Evening meeting, Auditorium, National Research Council Building. Annual meeting, Ottawa Branch, E.I.C. Address by Dr. C. A. Robb, **Gauges for Mass Production** (80).
- Jan. 30—**Air Raid Precautions**, by Mr. Alan Hay, Consulting Engineer, Federal District Commission (96).
- Feb. 13—**Military Explosives**, by Mr. E. T. Sterne, Allied War Supplies (122).
- Feb. 27—**Planning and Construction of Aerodromes**, by Mr. G. L. McGee, Department of Transport (114).
- Mar. 13—**Fighter Squadron**, by Flying Officer H. T. Mitchell (145).
- Mar. 27—**Research and Security**, by Mr. L. A. Hawkins, General Electric Company, Schenectady, N.Y. (76).
- April 10—Evening Meeting, Auditorium, National Research Council Building. Mr. A. E. Davison, Hydro Electric Power Commission of Ontario, spoke on **Dancing Cables and Bridges** (198).
- Aug. 17—Visit of members of the Ottawa Branch and their friends to the Royal Canadian Engineering Training Centre at Petawawa on invitation of the Commanding Officer, Lieut.-Col. J. P. Richards (80).
- Oct. 23—**The Role of Research in War**, by Dr. C. J. Mackenzie, Acting President, National Research Council (105).
- Nov. 20—**The Royal Canadian Navy 1911-1941**, by Commander H. N. Lay, Naval Service Headquarters, Ottawa (105).
- Dec. 4—**Air Co-operation**, by Squadron Leader W. W. Ross, R.C.A.F. Station, Rockcliffe (77).
- Dec. 18—**Construction Features of the Barrett Chute Development**, by Mr. A. L. Malcolm, Hydro Electric power Commission of Ontario (81).

### PETERBOROUGH BRANCH

The following meetings were held during the year 1941, with attendance shown in brackets:

- Jan. 16—**Power Transmission**, A. E. Davidson, Electrical Engineering Dept., Hydro Electric Power Commission, Toronto, Ontario (66).
- Feb. 13—**Modern Trends in Industrial Applications**, L. E. Marion, Apparatus Sales Dept., Canadian General Electric Co. Ltd., Toronto, Ontario (33).
- Feb. 27—**Processing of Copper**, C. L. Sherman, Metallurgist, Phillips Electrical Works Ltd., Brockville, Ontario (51).
- Mar. 20—**Juniors and Students Night. Some Aspects of Railway Signalling**, J. M. Mercier, Test Dept., Canadian General Electric Co. Ltd., Peterborough (64).
- April 24—**Carrier Current for Peak Load Control**, A. L. Malby, Industrial Control Eng. Dept., Canadian General Electric Company Ltd., Peterborough (39).
- May 15—Annual Meeting and Election of Branch Executive (36).
- Sept. 27—Joint Meeting E.I.C., Peterborough Branch and A.I.E.E., Toronto Section. **Short Time Rating of Electrical Equipment**. (108).
- Oct. 23—**Plastics**, A. E. Byrne, Appliance and Merchandise Dept., Canadian General Electric Co. Ltd., Toronto (30).
- Nov. 6—**The 220,000 Volt System of the H.E.P.C.**, A. H. Framp-ton, Assistant Electrical Engineer, Hydro Electric Power Commission, Toronto, Ontario (46).
- Nov. 18—Annual Dinner. Attended by President C. J. Mackenzie, Vice-Presidents de Gaspé Beaubien and K. M. Cameron and other guests (72).
- Dec. 11—**The causes of Accidents to Electrical Equipment**, C. A. Laverty, Engineer and Electrical Inspector, Boiler Inspection and Insurance Co., Montreal (24).

The number of Branch Executive meetings held during year 1941-7.

### SPECIAL COMMITTEES

- Meetings and Papers Committee—A. J. Girdwood, Jr. E.I.C.  
Social and Entertainment Committee—R. L. Dobbin, M.E.I.C.  
Membership and Attendance Committee—A. L. Malby, Jr. E.I.C.; J. M. Mercier, S.E.I.C.  
Branch News Editor—E. W. Whiteley, Jr. E.I.C.  
Auditor—E. R. Shirley, M.E.I.C.  
Peterboro Representative on Nominating Committee—W. M. Cruthers, M.E.I.C.

### QUEBEC BRANCH

Ten general branch meetings were held through the year: as listed below with the attendance given in brackets.

- Jan. 27—**Municipal Management by an Engineer**, by Robert Dorion, M.E.I.C., Manager of Shawinigan Falls, Quebec (45).
- Feb. 8—**Annual Branch Dance** at Quebec Winter Club (116).
- Feb. 17—**Nickel Industry**, sound films presented at Palais Montcalm Theatre (200).
- Feb. 28—**Mining and its Importance in the War**, by Hon. T. A. Crerar, at a luncheon-meeting, Chateau Frontenac. (Joint meeting with Canadian, Rotary and Kiwanis Clubs).
- Mar. 10—**The Engineer and Hydroelectric Development**, by MM. Huet Massue, M.E.I.C., and Guy Rinfret, M.E.I.C., sponsored by Shawinigan Water & Power Co. (500).
- April 28—Visit to the Building and Laboratories of the New Science Faculty, Laval University, and film presentation **Tacoma Bridge Disaster** (50).
- Sept. 15—**First Annual Golf Tournament** at Royal Quebec Golf Club (44).
- Nov. 15—President C. J. Mackenzie visit and Institute's Regional Council Meeting at Chateau Frontenac (37).
- Dec. 1—General Annual Meeting and election of Officers of the Quebec Branch. Film **Colourful Gaspesian Tour**, by Alex. Larivière (55).
- Dec. 15—**Technical Principles of Radio-Communication**, by G. E. Sarault, chief engineer C.B.F. Radio-Canada and "Rambling Radio-Canada Stations" films in Technicolor, which Mr. Aurèle Séguin of C.B.C. explained (200).

During the year six meetings of the Executive Committee were held, at which the attendance averaged seven, or sixty-five per cent.

## SAGUENAY BRANCH

- The branch held the following meetings during the year:
- Jan. 14—**Experiences of an Engineer in China**, by A. T. Cairncross of the Aluminum Co. of Canada Limited.
- Feb. 21—**Combustion Boiler Installations**, by W. H. D. Clark, Chief Engineer of the Combustion Engineering Corporation.
- Mar. 28—**Engineering in the Battle of France**, by Jean Flahault, Aluminum Co. of Canada Limited.
- May 2—Film showing **Tacoma Bridge Disaster**. Also **Electric Welding and Brazing of Copper and Aluminum**, by H. Brayne of the Aluminum Co. of Canada Limited.
- May 28—Film on **Fighting Oil Fires by the Water Fog Method**, shown by the Rockwood Sprinkler Co.
- July 4—Annual Meeting and election of Executive Committee.
- Aug. 22—**Sub-surface Engineering**, by Professor R. F. Legget of the University of Toronto.
- Oct. 14—**Construction Problems**, by V. G. Younghusband, Vice-President of the Foundation Co. of Canada.
- Nov. 25—**The General Principles of Petroleum Oil Refining**, by C. D. McCoy, Oil Refining Division of Foster Wheeler Corporation.
- Dec. 16—**Road Building**, by J. A. E. Gohier, Chief Engineer of the Quebec Roads Department.

## SAINT JOHN BRANCH

Six meetings of the Executive Committee were held during the year, and five general branch meetings were held, as follows. Attendance is given in brackets:

- Jan. 15—Annual joint dinner meeting with the Association of Professional Engineers of the Province of New Brunswick. A paper on **The LaTuque Development** was presented by J. A. McCrory, of Shawinigan Engineering Co. (42).
- Mar. 21—Supper meeting. An International Nickel Co. four-reel picture **The Nickel Industry** was shown (16).
- April 18—Evening meeting. A two-reel film **The Tacoma Bridge Disaster** was shown, followed by several coloured reels of New Brunswick, shown by H. P. Lingley (20).
- May 16—Annual dinner and election of officers of the branch. Special guests were Dean C. J. Mackenzie, President of the Institute, K. M. Cameron, Vice-President for Ontario, J. A. Vance and H. Massue, Councillors, L. Austin Wright, General Secretary, R. L. Dobbin and G. A. Gaherty. The president spoke on the relation of the engineer and the engineering profession to the War (43).
- Dec. 11—Supper meeting. Address on **Mechanization in War**, by G. W. Berry, Manager of the Ford Motor of Canada at Saint John, illustrated by a film "Tools for the Job." (33).

## ST. MAURICE VALLEY BRANCH

The following meetings were held by the Branch this year:

- Mar. 22—Annual dinner meeting at the Cascade Inn, Shawinigan Falls. Retiring Chairman C. H. Champion introduced the newly elected chairman, Dr. A. H. Heatley, of Shawinigan Falls. L. Austin Wright, general secretary, spoke on **The Wartime Bureau of Technical Personnel**.
- April 29—Meeting was held at the Laurentide Club, Grand' Mère. The guest speaker was Dr. P. L. Pratley, who gave a brief outlook on the design of suspended bridges. The Institute film **Tacoma Bridge Failure**, was shown.

## SASKATCHEWAN BRANCH

Twenty-four members of the Branch are on active service with His Majesty's Forces, nine being overseas and all holding commissions in the Navy, Army or Air Force.

As in the past several years all meetings, except the annual and one special meeting, were held jointly with the Association of Professional Engineers and the local branch of the American Institute of Electrical Engineers. The programme for the year was as follows:

- Jan. 24—**The Making and Shaping of Steel**, a nine-reel film loaned by the United States Bureau of Standards.
- Feb. 21—Annual Meeting.
- Mar. 21—**Air Gunnery and Bombing**, by F/L. Geo. Thornber, illustrated by lantern slides.
- Sept. 25—Special meeting to meet President C. J. Mackenzie.
- Nov. 21—**The Tacoma Bridge**, a two-reel film depicting structural problems and failure after four months of life.
- Dec. 16—Talk by Major T. G. Tyrer giving personal reminiscences of his recent military trip overseas.

The average attendance at the meetings was 46, a decrease of 11 from last year, explainable in part by the fact that a number of the members are absent on active service.

## SAULT STE. MARIE BRANCH

The Executive Committee met on January 8th, 1941, and appointed standing committees. The committees and the chairman are as follows:

- Papers and Publicity . . . . . J. S. MACLEOD, M.E.I.C.  
Entertainment . . . . . J. L. LANG, M.E.I.C.  
Membership . . . . . A. H. RUSSELL, M.E.I.C.  
Legislation and Remuneration . . . F. SMALLWOOD, M.E.I.C.  
Junior Engineers . . . . . N. C. COWIE, JR. E.I.C.

It will be noted that an additional committee, the Junior Engineers' Committee, was formed this year. A meeting was held this year under the auspices of the Junior Engineers' Committee. This committee also furnished the Papers Committee with an additional speaker during the year.

The executive met three times during the year to conduct and promote the activities of the Branch and Institute.

Seven dinner meetings were held during the year. The average attendance was 20 members and guests. While the meetings were usually held on the last Friday of the month, this was not a rigid rule as some were arranged to suit the convenience of the speaker.

Programmes of the meetings held were as follows:

- Jan. 31—**Installation and Operation of Modern Strip Mills**, by L. F. McCaffrey.
- Feb. 28—**Kilowatts, Horse-power and Water**, by N. C. Cowie, Jr. E.I.C.
- Mar. 21—**The Queen Elizabeth Highway**, by A. L. MacDougall.
- April 22—**The St. Lawrence Deepening and Its Possibilities**, by J. H. MacDonald.
- Sept. 26—**Blast Furnace Plant of the Algoma Steel Corporation**, T. F. Rahilly, Jr. E.I.C.
- Nov. 28—**The Steel Industry**, by David L. Mekeel.
- Dec. 12—Annual Meeting and **Tacoma Bridge Film**.

## TORONTO BRANCH

The annual meeting of the Branch was held at the Granite Club on Thursday, April 3rd, 1941. The meeting was preceded by a dinner at 7 p.m., at which several representatives from the outside branches and sister societies were present. Among these J. A. Vance, Councillor, London Branch; Prof. W. G. McIntosh, representing the A.S.M.E.; Norman J. Howard, President American Waterworks Association; Stanley R. Frost, President, Association of Professional Engineers of Ontario; A. R. Hannaford, Secretary-Treasurer, Hamilton Branch; J. M. Thomson, representing the A.I.E.E.; Wills Maclachlan, representing the Royal Canadian Institute and Bruce Wright representing the Ontario Association of Architects.

During the past year the executive committee has held nine meetings with an average attendance of eight members.

The regular meetings held during the year are listed below with attendance given in brackets:

- Jan. 16—Student's Competition, **Relay Protection of Transformers**, by P. B. Smith; **The Co-Axial Cable in Telephone Transmission**, by G. M. Nixon. **Wind Tunnel Testing**, by D. P. MacVannell. **Estimation of Aircraft Performance**, by B. Etkin. **A Modern Method of Placing Concrete**, by W. D. Ramore. **Future Trend in Aircraft Design**, by J. W. Ames (55).
- Feb. 20—**The Helen Mine and Beneficiating Plant**, by George W. MacLeod, M.E.I.C. (70).
- Mar. 8—**The Achievements of Engineering**, by Professor C. R. Young, M.E.I.C., This was a joint meeting with the Royal Canadian Institute.
- Mar. 20—**Ground Line Preservation of Poles**, by T. H. Chisholm. **Measurement and Control of Conductor Vibration**, by G. B. Tebo. **Fatigue of Metals**, by D. G. Watt. **Recent Developments in Concrete Technology**, by R. B. Young. This was a session on research development and given by members of the Research Laboratory of the Hydro-Electric Power Commission of Ontario (70).

- Oct. 16—**Plastic Moulded Wood in Aircraft Construction**, by Mr. J. W. Jakimiuk (100).
- Nov. 6—**Air Bombing and Structural Defence**, by D. C. Tennant, M.E.I.C. (180).
- Nov. 29—**What Use the Engineer Makes of Geology**, by Professor H. Ries. This was a joint meeting with the Royal Canadian Institute.
- Dec. 4—**Water Situation in Southern Ontario**, by Prof. A. F. Coventry. **Forestry Situation in Ontario**, by Mr. F. A. MacDougall. **Public Health in Ontario and Conservation**, by Dr. A. E. Berry, M.E.I.C. Introduction of the speakers and the film **The River**, by Professor R. F. Legget, M.E.I.C. (400).
- Dec. 8—**Fluorescent Lamps and Lighting Materials**, by Mr. Harris Reinhardt. This was a joint meeting with the I.R.E.; I.E.S. and A.I.E.E.

Previous to each regular meeting, dinner has been held in Hart House. These have been well attended and enjoyed by all who have availed themselves of the opportunity to attend.

A Social Evening was held on Saturday evening, January 11th, for the members and their wives at the Engineers' Club. The President, Dr. T. H. Hogg and Mrs. Hogg, the chairman of the Branch, Nicol MacNicol and Mrs. MacNicol, received the guests. Dinner was served and was followed by entertainment. There were 143 present on this occasion.

It is with deep regret that we record the death of the following members of the branch during the year:—A. S. Cook, H. B. Kippen, Brig.-Gen. C. H. Mitchell, Grant Moloney and R. F. Uniacke.

#### VANCOUVER BRANCH

The following meetings were held by the Branch this year:

- Jan. 20—Programme meeting was held at U.B.C. Dean J. N. Finlayson, chairman, presided. F. O. Forward, associate professor of metallurgy, and W. O. Richmond, assistant professor of mechanical engineering, were the guest speakers. Their subjects were **The Heat Treatment of Steel** and **The Application of Material Tests to Design**.
- Feb. 26—Meeting was held at the Hotel Georgia. The chairman presided and the guest speaker was Mr. Ralph Hull, professor of mathematics at U.B.C., who spoke on **The Origin, Theory and Dynamics of Tides**.
- Mar. 7—Meeting was held at U.B.C., when the speaker was Mr. E. C. Gosnell, chemical engineer, Lukens Steel Co. of America. His subject was **Clad Metals, their Manufacture, Application in Industry and Anti-Corrosive Properties**.
- Mar. 27—Meeting was held to hear an address by A. H. Eggleton, manager of the Industrial X-Ray Co., Vancouver, on **Industrial Applications of the X-ray**.
- May 21—Meeting was held in the Georgia Hotel. The vice-chairman, Mr. W. O. Scott, presided in the absence of the chairman. The speaker for the evening was Mr. W. N. Kelly, whose subject was **Woodenwalls and Iron Clads**.
- Sept. 29—Dinner meeting was held at the Hotel Georgia in honour of the president, Dean Mackenzie. He gave a most interesting address on **The National Research Council and War Work**.

- Oct. 16—Programme meeting was held in the Medical Dental building. The speaker was Mr. Jack Cribb, superintendent of West Coast Shipbuilders Ltd. His subject was **Some Marine Salvage Experiences of the Pacific Coast**.
- Nov. 6—The guest speaker at this meeting was W. O. Scott, vice-chairman of the branch, and assistant superintendent of the Dominion Bridge Co. in Vancouver. The subject of his address was **Tool Steels—their Use from the View-point of the Shop**.

#### VICTORIA BRANCH

Five meetings of the executive committee and four general branch meetings were held during 1941 as follows:

- Jan. 17—Dinner meeting. Annual meeting and election of officers. Motion pictures of interest to engineers by Mr. D. S. Scott.
- Oct. 27—Dinner meeting. Address, **Spans in Time and Space**, by Sir Heaton Forbes Robinson, C.G.M., M.I.C.E.
- Nov. 10—Dinner meeting. **Tacoma Bridge Films**, together with additional pictures and explanations by Mr. A. L. Carruthers, M.E.I.C.
- Dec. 16—Nomination luncheon meeting. Owing to the prevailing blackout in the Pacific Coast region, a general meeting of the branch called for early in December, at which a paper was to have been read, had to be postponed to a later date.

The branch regrets to report the loss by death of three of its Life Members during the year in the persons of F. J. O'Reilly, J. H. Gray, and George Phillips.

Despite the loss by death and removals to other jurisdictions, the membership of the branch has been increased by 8 to 66, mainly through transfer of members of His Majesty's Services to this branch district. Several applications for membership are at present under consideration.

#### WINNIPEG BRANCH

The following meetings were held by the Branch during the year:

- Feb. 6—Annual meeting. The retiring chairman, H. L. Briggs gave his address and was thanked by Professor G. H. Herriott. Following the election of the new officers a sound film entitled **There is a difference** was shown.
- April 3—Meeting in the Theatre of the University of Manitoba. Two coloured movies were shown through the courtesy of the Department of Mines and Natural Resources of the Province of Manitoba. **Base Line Survey** was prefaced with remarks by Mr. H. E. Beresford, director of Surveys and **The Summerberry Fur Rehabilitation Project** had a running commentary by the Honourable J. S. McDiarmid, Minister of Mines and Natural Resources.
- Sept. 24—Luncheon meeting in the Georgian Dining Room of the Hudson's Bay Company. D. M. Stephens, vice-chairman, presided in the absence of the chairman. We were privileged to have as guests the president, vice-president and general secretary of the Institute. President Mackenzie was the principal speaker at the meeting.
- Oct. 16—Meeting in the Broadway Building of the University of Manitoba. The speaker was J. C. Trueman, designing engineer, Dominion Bridge Co., Winnipeg. He presented a motion picture on **The Tacoma Bridge Failure**, introducing the picture with a short historical paper.

## CALCUTTA UNDERGROUND RESERVOIRS

From *Indian Engineering* (CALCUTTA), JULY, 1941

Following the sanction by the Government of Bengal for the construction of 130 underground reservoirs in Calcutta, work is in progress on some of them by the Corporation of Calcutta in consultation with the Chief Officer of the Calcutta Fire Brigade. These are being constructed with a view to providing an alternate source of unfiltered water for fighting fires that might be caused in the city by air raids. The reservoirs, which will each have a capacity of about 8,000 gallons, will cost about 11½ lakhs of rupees. For the balance of the reservoirs, the Government have requested the Corporation to prepare a list of sites.

## GASOMETERS

From *Indian Engineering* (CALCUTTA), JULY, 1941

Many people appear to think that if a bomb explodes on a gasholder, it is bound to blow up. In general it has been proved in Europe that the gasholders commonly used are comparatively free from danger. What would happen if a bomb effects a direct hit on a gasholder is a troublesome question, but it does not follow that the gasometer would blow up. It is a question difficult to answer because it depends on many factors, viz., the type of holder, its age and amount of gas in store, and the type of bomb with which it has been struck. There are two main types of holders, which, between them, store approximately 90 per cent of domestic and industrial gas storage. These are the guide-framed water-sealed holder, and the spiral-guided water-sealed holder. In one large undertaking in Britain a gasholder received a direct hit. The incendiary bomb, on contact with the holder, which was two-thirds filled, burst the side sheets and ignited the gas; two high explosive bombs following penetrated the same lift, burst through the tank plates, and exploded in the raft, causing a large hole in the tank. The effect of this was to release the water. Immediate attention averted worse damage.

## BURMA ROAD

From *Indian Engineering* (CALCUTTA), JULY, 1941

It is reported that a determined effort is being made to speed up the transport of vital supplies to China via the Burma road. As a step towards this end, all the Highway Administration's engineering bureaux throughout China which have hitherto been under various Government Departments are to be placed under the centralised control of the Transport Control Board of the National Military Council. Reports are to hand that floods and landslides in the northern Shan States of Burma have interrupted traffic on the China Highway. It is hoped to replace a vital wrecked bridge within a few days. Transport in Burma has also been affected. This is unfortunate, but only to be expected at this time of the year with the Monsoon in full strength. Moreover, the road may be bombed again by the Japs, particularly following a recent message from New York to the effect that President Roosevelt recently issued a proclamation suspending "foreign discriminating duties on tonnage and imposts within the United States" in respect of vessels to Burma and their cargoes. This is apparently designed to help to expedite the flow of war materials to China over the Burma road.

## Abstracts of articles appearing in the current technical periodicals

### AUSTRALIAN MUNITION INDUSTRY

From *Trade and Engineering* (LONDON), NOVEMBER, 1941

"No business in the history of Australia has been expanded to such a magnitude, with such violence and under such pressure, as the vast munitions industry," said Mr. Menzies recently. The amazing growth of new industries since the war, he added, had made Australia a first-class manufacturing country, with a great export potentiality, and had laid a strong foundation for a new peace-time order. There are now 150,000 Australians working in war industries, of whom over 50,000 are directly engaged in munition-making, and Mr. Menzies indicated that before the end of 1942 this latter number would be increased threefold.

In the last war munition-making in Australia employed only 2,700 persons. To-day, in South Australia alone, which before the war was a minor industrial State, there are already more persons working on munitions than there were in Australia by the end of the last War. One of South Australia's largest industrial enterprises, General Motors-Holdens, is over 90 per cent engaged in war production. It is already employing 20 per cent more hands than before the war and will soon employ more. Over 5,000 workers are producing in its plant anti-tank guns, large presses for explosives, bomb bodies, pontoons, folding boats and aeroplane parts. The hundredth two-pounder anti-tank gun produced at this factory was recently delivered. The production of the requisite toughened steel presented a problem in overcoming which Australian engineers devised new forging and machining processes.

Over 300 3-7 in. anti-aircraft guns have now been delivered, the Government ordnance factory having achieved an output in excess of that for which it was designed. Searchlight units, anti-aircraft predictors, and telephone and radio equipment for anti-aircraft posts are being produced. The Bren gun is in mass production, and the universal carrier, a development of the Bren-gun carrier, is being produced at the rate of more than double what was expected of the factory. Hundreds of firms in all parts of the Commonwealth are making components, and four shops will soon be engaged in assembling the vehicles.

Australia is making her own lenses for optical munitions such as range-finders, telescopic gun sights and tank periscopes, with all the tools essential to their manufacture. Plans for the establishment in Government factories, in Victoria and Queensland, of annexes for building marine engines for the standard merchant ships which the Ship-building Commission has ordered are being pushed ahead. These annexes will carry the heavy engineering capacity of Australia a further stage forward. The Commission intends to foster also the making of ships' equipment such as compasses and chain cable.

### AIRCRAFT MANUFACTURE

Working round the clock with a staff of 800, ultimately to be increased to 1,200, the Commonwealth Aircraft Corporation's new factory, which has cost £A1,500,000, has begun to build the Pratt and Whitney twin-row Wasp engine, the production of which will lift Australia into the ranks of the principal air powers. Factories elsewhere have long been producing Gipsy Major and single-row Pratt and Whitney Wasp engines. With the twin-row engines and with duralumin, to be fabricated at the Aus-

tralian Aluminium Company's new workshops, Australia can build some of the speediest aeroplanes yet designed. These engines will be used in the Australian-built Bristol *Beaufort* bomber and in the new twin-engined fighter-bomber, designed by Wing Commander L. J. Wackett, general manager of C.A.C., and also in a new British twin-engined fighter which the Government hopes to produce later.

The completion of the works in under 20 months from the drafting of plans to the beginning of manufacture sets a remarkable standard in speedy organization. Before the war experts declared that Australia could not build even motor-car engines, yet she has turned out 150 h.p. and 600 h.p. aero engines in considerable volume, and now she is about to produce 1,200 h.p. aero engines. Scores of engineering firms in New South Wales, Victoria, and South Australia are making engine parts as sub-contractors. The factory is already being extended to facilitate an increasing output of engines for new types of aircraft, and when completed it will be comparable to the largest aero-engine factories overseas. The magneto, carburettor, and ball-bearings of the twin-row Wasp are imported but the magneto will soon be manufactured in Australia, and later the other parts mentioned.

The Aircraft Commission estimates that of a total aeroplane production to the value of £A20,000,000 in 1942 exports will be valued at over £A12,000,000. The Commission expects to produce over 1,000 aeroplanes next year. From June, 1939, when C.A.C. completed its first *Wirraway*, to the end of December next, the value of the industry's output will be £A10,000,000, the value of this year's production being £A7,000,000.

These figures give some indication of the rapid expansion of the industry. Already Australia is producing far more training machines than she needs for herself, and elementary trainers are being exported at the rate of 50 a month. The first Bristol *Beaufort* assembled in Australia from imported parts, with certain adaptations to local needs, has proved a faster machine than its oversea prototype. It attained an average ground speed of 270 m.p.h. in an 850-miles flight from Melbourne to Brisbane—a new Australian record. Later, in a non-stop flight of 1,500 miles from Cairns (Queensland) to Melbourne in 7¾ hours it averaged nearly 200 m.p.h. against a head wind, easily the best combination of speed and distance an aeroplane has achieved in Australia. It is designed as a dive-bomber, as well as a high-level attack machine, and is expected to be exceptionally fast. Everything is in readiness for quantity production as soon as it has satisfactorily completed its tests. Many of its components are inter-changeable with those of the *Wirraway*.

### THE DEMAND FOR TECHNICIANS

From *Indian Engineering* (CALCUTTA), JULY, 1941

Some of the results of the Eastern Group Supply Conference, held at Delhi last year, are now becoming visible. The factories and workshops of this country are pouring out an ever-increasing stream of products in demand for the immediate needs of war. We are producing more and more, some of the things are a mere multiplication and extension of established industry, others are new to us from the point of view of local manufacture. In this way, the aim to increase this country's contribution to the paramount task of victory is being achieved. All India should be proud of the contribution we have made already towards the great defeats of the Italian Dictator's ambitions in Africa, but it is far too early to rest on our laurels. A lot, a great lot more, remains to be done. We are comparatively still only at the beginning of our maximum effort, for our capacity to produce is immense. It is true India is looked upon mainly as an agricultural

country, which she is, but there is also more than ample room for vast industrial enterprise to redress the balance of a one-sided national economy. In time of peace, industrialisation was with us a very slow process. Many natural and artificial obstacles had to be overcome, and only some vital emergency provided the necessary impetus for more rapid strides forward. The last Great War set us going, and the present still greater emergency is driving us forward at a terrific speed for the habits and hesitations of this country. Even so, when compared with the more industrialised countries, our rate of progress is still far too slow, in spite of the actual stream of production now flowing to supply and replenish the stores and equipment in such immense demand. There are two very adequate reasons to account for it:— There is first the lack of trained technicians, and, secondly, the difficulty of securing the plant and tools needed. Gradually both these obstacles will be overcome, but we ought not to allow this opportunity to pass without learning our lessons. None of these tremendous obstacles need have arisen had we taken long ago a wider view of the potentialities of industry in this vast country, with its immense reserve of raw materials. Had we given sufficient encouragement and taken steps to create and assemble sufficient cadres of trained technicians in the years gone by, industry might well at this time have been sufficiently ahead to largely resolve the difficulties of personnel and equipment now encountered. In this connection it is no less useful to consider the lack of enterprise on the part of capital and individuals in this country, as well as the wrong bias in the educational sphere. In both these spheres we have largely failed to appreciate the needs and requirements of the present age. Let us, therefore, keep carefully in mind the fact that the present vast expansion of industrial enterprise for a specific purpose is bound to have wide repercussions later, and to consider the remedies needed to repair past mistakes. We must draw the moral now for future guidance.

### DEVELOPMENT OF "BRISTOL" AIRCRAFT GUN TURRETS

From *The Engineer* (LONDON), NOVEMBER 21, 1941

One of the first aeroplanes to be fitted with an enclosed gun turret, necessary for the protection of the gunner from the air flow at high speeds, was a *Bristol* machine, known as type 120, which was developed in 1930 and 1931. In this case the turret was mechanically operated. The first *Bristol* hydraulically operated power-driven gun turret was developed in 1935 and fitted in the nose of the *Bombay* bomber transport; and the first *Bristol* power-operated gun turret to be located amidships was fitted to the *Blenheim*. These turrets proved of great value from the very first, enabling the air gunner to aim and fire steadily and accurately on the beam when flying at high operational speeds.

But the successful development of the power-driven gun turret depended in the first place on the equally important development of the successful hydraulic system, which should be simple, reliable, and, above all, light in weight. The advantages claimed for the *Bristol* hydraulic system are greater flexibility of control, a quick yet smooth reversal of motion without shock, a useful "slip" for overloads or obstruction, an easily convenient location of transmission members, and the use of relief or control valves to safeguard against overloading. This hydraulic system was developed in 1935, in a research department specially devoted to the purpose. Unit testing was undertaken of such items as pumps, control valves, undercarriage jacks or "rams", and flap controls, etc. The most important development, however, resulted from prolonged and active research into the design of suitable hydraulic pumps, as the existing types suffered from the

drawbacks of insufficient capacity and pressure to be suitable for the requirements of high-performance aircraft. The plunger type of pump suffered from violent fluctuation of pressure, which caused breakages; so that either the vane type had to be employed with its considerable limitations for high pressures, or else the gear pump, in which the faults were that it was difficult to get clearances sufficiently fine to reduce the "slip", and when they were obtained there was a resulting tendency to seize up. The first "Bristol" pump was tested early in 1936. It was a multi-stage gear pump, which stepped up the pressure very considerably.

Realising that existing types of gear pump would only work satisfactorily up to a pressure of about 300 lb. per square inch, several such pumps were placed in series. To ensure a full supply of oil to each it was arranged that the output from each unit should be theoretically in excess of the requirements for the succeeding stage. To control the output from each section a small adjustable relief valve was introduced between the stages. This design has since been developed to the extent of producing a practical three-stage hydraulic pump which will give pressures of 1,500 lb. per square inch or more, with a flow of 6 gallons per minute at normal engine revolutions.

The modern pump has three stages, the main production version covering a range of pressures up to 1,200 lb. per square inch, with a delivery up to 180 gallons per hour. Actually this unit is known in the industry as the B.H. integral type, though it is built under Bristol patents. The first of these pumps to be type tested completed a hundred hours' test satisfactorily in February, 1936. It is claimed to have been the first successful hydraulic pump to meet aircraft requirements, and it is now being produced in very large numbers by sub-contractors. These hydraulic pumps form part of the back cover auxiliary equipment for all types of aero-engines, water-cooled and air-cooled radial types, British and American.

The Bristol hydraulic system is operated as an open system, thus obviating the use of a "recuperator" or supplementary air pressure, which is necessary with a "closed system", involving, as it does, the use of auxiliary pumps operated either by hand or by motor.

The hydraulically operated gun turret on the *Blenheim* was small—having only a 30" ring—and it was housed in a low-drag retractable cupola which was operated mechanically. The low drag of the Bristol cupola was attained largely by the use of a moving seat for the gunner, synchronised with the gun movement. Another feature of this Bristol turret was the "secondary motion" of the column on which the guns were mounted. It could be operated independently to enlarge the field of fire and to cover such areas as could not be reached by normal rotation. The first *Blenheim* turret was fitted with one Lewis gun and later with the Vickers G.O. or "gas-operated" gun. This turret was then developed for twin Browning guns, with which it is fitted to-day. The design was such that it could be manufactured with ordinary engineering plant without requiring unduly skilled labour. It was probably the only turret in the early days that could be sub-contracted and built straight from the drawings, while the hydraulic system could be serviced by the ordinary R.A.F. personnel in the Service without "sending for the makers."

The fitting of a power-operated gun turret amidships in the fuselage involved the problem of a simple and efficient "fire cut-out", as well as "gun restrictor gears" to avoid shooting off the tailplane, fin, wireless masts or airscrew discs, etc., or fouling the fuselage itself. The Bristol turret, it is claimed, was the first to be provided with a compensator for rotational speeds on the "fire cut-out" mechanism. It ensures that a minimum of "cut-out cover" is provided for slow operational speeds of rotation,

the cut-out cover being automatically increased in proportion to the increased speed of rotation.

A special gun mounting incorporating a "harmonisation gear" and a shock absorber system incorporated with a quick-release mechanism has been developed. The "harmonisation gear" is very simple and enables four guns to be lined up quickly and independently on the target. The quick release device enables the guns to be removed at the touch of a lever and to be as easily replaced without handling anything but the gun, which becomes automatically locked in position when it is pushed home.

## HIGH-SPEED ARC WELDING

By S. G. P. de Lange and E. S. Waddington

From *Electrical Review*, DECEMBER 5, 1941

In devising the series of experiments here described as to the possibility of obtaining a substantial increase in welding speed, it was decided that the line of research should be bounded by the following limitations:— Existing personnel to be used; cost of production not to be more; existing machines and equipment in the average works to be used with a minimum of additions for which reasonable delivery could be obtained or which could be fabricated in the works themselves; the process to be applicable to all types of firms and to shop as well as yard work and site fabrication.

These limitations ruled out such methods of increasing production as the use of automatic welding and of very heavy electrodes, leaving two alternatives for investigation. The first was the use of normal electrodes with increased currents and higher operating speeds. Preliminary tests, however, showed that currents in excess of makers' normal recommendations on normal types of electrodes resulted in a very small increase in welding speed and in considerable difficulties in many cases.

The second possibility was the use of electrodes with a high depositing speed due to the type of coating employed. Preliminary investigation of theoretical depositing speeds with such electrodes showed that probable results would be so striking as to justify complete investigation and the obtaining of practical proof. Jigs and mechanical manipulators are not dealt with because they should be employed with either type of electrode, but the speed obtained by their use will be greatly increased with high-speed electrodes.

TABLE 1 — SPEED OF DEPOSITION

Gauge	Unit of Deposit	Time per unit deposit in one foot of weld
10 single run	30 grams.	Not more than 70 sec.
8 single run	54 grams.	Not more than 90 sec.
6 single run	60 grams.	Not more than 90 sec.

The next step was to decide the specification of high-speed electrodes. So as to eliminate the human element, since the actual amount of deposited metal varies to a certain extent with individual welders, the speed of a rod was based on a definite weight of deposit in a given time, and the figures in Table 1 were taken to represent the minimum depositing times for a high-speed electrode. Other deposit weights of multi-runs were based on calculations from these figures.

A programme of experiments was then drawn up with the object of covering a large number of welds that would prove the advantages in production of the method advocated, involving the minimum of variables and eliminating as far as possible human error. As it was essential to obtain tests that could be easily compared with results in practice without unnecessary elaboration, the theoretical depositing efficiency, power consumption, efficiency of the welding plant, extra time, cost of electricity, welding arc and energy in watts were not incorporated in the

tests. An efficiency test was, however, carried out on all the electrodes used, so that if necessary a more elaborate form of findings could be presented for those interested more in the theoretical side than the practical increase in production.

The efficiency test consisted in taking three of each type and gauge of the electrodes employed on the speed tests, removing their coating and weighing the core wire. The total weight of the three selected electrodes was divided by three so as to give the average weight of steel per electrode. The electrodes were then deposited at the makers' recommended currents on suitable bases of steel. The increased weight of plate after welding was taken after allowance had been made for the weight and length of rod remaining in the holder. The weight of the welding deposit was taken to an accuracy of half a gramme and the figure of the percentage yield by weight was used for the efficiency of the electrode in question.

In the tests, pieces of mid-steel plate  $\frac{1}{4}$ ,  $\frac{3}{8}$  and  $\frac{1}{2}$ " thick were taken, the length of each piece being slightly in excess of 12". The plates were weighed to an accuracy of one gramme. A large number of pieces were prepared so that fillet and butt welds could be carried out. The fillet welds were made to two standards; one with a reasonable throat thickness such as is common practice in many works and suitable for a large number of ordinary production jobs, and the other with a full-throat thickness to comply with British Standard Specification No. 538. The butt-weld test pieces were vee'd to 70°.

First the fillet weld tests were carried out, the procedure being to deposit the selected electrode with the maximum speed and the highest possible current that could be used with satisfactory mechanical and physical properties. After welding, the test pieces were thoroughly cleaned and accurately weighed in order to ascertain the amount of deposited metal. Exact times were taken with a stop-watch of first-grade accuracy and the operating currents were measured by an external ammeter.

For the butt welds a similar procedure was carried out and the whole of the results were brought together in a large number of tables from which Table 2 is quoted.

De-slagging times were not taken into account, as these varied very considerably with the different makes of electrodes. The high-speed electrodes employed were of the instantaneous de-slagging types, so that a comparison that included these times would be even more favourable; also if the efficiency figures had been used in the calculations, the result again would have been more favourable, as the efficiency of the high-speed electrodes varied from 89.5 to 96 per cent. compared with 62.6 to 90.5 per cent for the normal electrodes.

TABLE 2. — SAVINGS IN MAN-HOURS AND WAGES ON 1 MILLION FEET

No. of Test	Average man-hours saved (based on average of slowest and fastest normal electrodes)	Average saving (based on slowest and fastest times) (per cent.)	Average saving in wages—at 2s per hour
1	9.305	32.9	930
2	10.278	21.2	1027
3	11.805	24.1	1180
4	15.972	38.7	1597
5	24.306	26.1	2430
6	17.222	21.1	1722
7	11.945	33.1	1194
8	43.333	27.0	4333
9	51.250	46.0	5125

The average number of man-hours saved in the nine tests was 21.712.

Dealing with the summary of savings the following striking figures are found. The average saving based on

the slowest and fastest times is 30 per cent. and the highest average is 45 per cent. for the heavier plate.

Then again in one million feet of weld the average of nine tests shows a saving of 21.712 man-hours with a maximum saving of 51.250 man-hours, again based on one million feet of weld, but without taking into account de-slagging times or electrode efficiency.

Photographs taken of welds obtained in the tests prove that the high-speed welds were equal, if not superior, to the normal welds.

As all the pieces were satisfactory, the findings from the tests can be taken as conclusive proof that these results can be obtained by any works which desires to increase welding production without having to alter existing equipment or train operators in an entirely new technique and methods.

For instance, let us suppose that a general fabrication shop has a large contract to carry out involving 1 million ft. of  $\frac{1}{4}$ " plate and 2 million ft. of  $\frac{3}{8}$ " plate, fillet weld, both of normal throat thickness, and  $\frac{1}{2}$ " million ft. of  $\frac{1}{2}$ " plate, butt weld, the corresponding savings would be 32.9, 38.7 and 46 per cent.

Assuming that the average wages for a first-class welder are 2s. per hour and that the overheads on labour are 150 per cent., then the saving on the above work alone would represent £16.716, apart from the saving in man-hours and production in a far shorter time. Even this figure would be increased in many cases, due to taking into account electrode efficiency.

## WOMEN WAR WELDERS

FROM ROBERT WILLIAMSON\*

Managers of Britain's war factories are discovering that the women now coming into their works from shops, offices, the professions and private life, have very definite likes and dislikes about the kind of work they wish to do. Some take to turning wheels, others prefer to use hand-tools; some enjoy work calling for concentration, others would sooner have simple repetition work.

Welding is a job that many women are turning to now, but even here there are two distinct camps, those who like the fireworks of electric arc welding and those who prefer fusion welding. It is often very difficult to get women to transfer from one method to the other.

But in one important British factory fusion welding has been made much simpler and more effective by a new process which eliminates the usual defects. Its main feature is the application of a controlled temperature applied before and during either a manual or a machine weld. Other features prevent the formation of gas crevices or pockets. Formerly, in spite of X-ray examination, weaknesses were liable to occur, and could be finally detected only in mechanical tests.

## PAPER AND MUNITIONS

From *Engineering* (LONDON), November 28, 1941

The war of 1914-18 was the first conflict, we believe, which really qualified for the description of a "paper war"; not merely on the score of the innumerable Notes and other diplomatic communications which passed and re-passed in bewildering profusion, but by reason of the quantity of "paper work" which complicated the existence of everyone concerned in it. There are various "establishments" laid down for the quantity of ammunition, food, and other consumable stores with which a warship, or a military unit of whatever size, from a battalion upwards, is required to take with it when on active service, but we do not recall having seen anywhere in such lists an item, "paper, tonnage of"; yet the account books which even

\* London Correspondent of *The Engineering Journal*.

a company quartermaster-sergeant had to take with him to the front needed some carrying. But, in that war, paper had not really come into its own as a munition; war was still very much an affair of steel, and brass, and the more expensive kinds of timber. Ammunition boxes were made of walnut; why walnut, we have never heard explained. Towards the end of the war, someone in authority began to see reason, and cheaper timbers were used; but the war was hardly over before stocks of practically new walnut ammunition boxes were being sold for firewood. A North-East Coast workhouse-master bought 50 tons of them for his clientele to chop up.

This is a more expensive war than the last but in a few ways it is being conducted more economically. Ammunition boxes, and many other really useful military stores, are now made from waste paper, as the Press of the country has been telling the public with unwonted unanimity for the past month or more. It is for this purpose, and not to relieve the shortage of paper for printing (for which, in any case, the salvaged waste is not suitable) that Lord Beaverbrook made his appeal for an immediate 100,000 tons—a total which, large as it appears, represents only about 3 per cent of the pre-war annual consumption of paper in Great Britain. The progress of the various local collections suggests that a great part of this amount should be forthcoming from domestic sources, but this is a reserve which, once consumed, cannot be replenished while the war lasts. For the regular flow that will be still required, therefore, it is probable that increased reliance must be placed on industrial accumulations. How extensive these are is probably not fully realised even yet by many firms and public-utility undertakings. We should not have thought it possible, had the question been put to us at the outbreak of war, before the paper problem became acute, that the offices of *Engineering* could contribute over 11 tons of paper to the national collection; yet this has proved to be the case. Admittedly, this total has been achieved only by the sacrifice of some files of periodicals which, in happier times, we should have preferred to keep for a year or two longer, for possible reference purposes; but the issues concerned can all be consulted in such public reference files as those of the Patent Office (where photographic copies of particular articles can still be obtained), the Science Library at South Kensington, and the libraries of the technical institutions, the value of which has not been so fully appreciated in the past by industry as it has been by research workers.

This is one direction in which firms might look for the quota of waste paper that the national need requires of them. Like all purges, however, it should be conducted with discrimination; and we would suggest once again that, before jettisoning files of periodicals that are not likely to be widely preserved in this country, but which are of technical value, firms or individuals should inquire

of the more important public and semi-public libraries whether any particular issues are needed to complete their own sets. This precaution is especially desirable, of course, in the case of Continental publications, though there are some British works of reference, complete files of which are not to be found even in the great national libraries.

There are many other directions, however, in which engineering firms may be able to assist, one of the most promising being the masses of blue prints which are frequently retained as shop records of finished work, even though they may show no departure whatever from the original tracings. The preservation of such prints is very liable to become a habit; and, even if some copies must be kept as records of modifications, they usually represent only a fraction of the prints that are pigeon-holed away because it is no one's particular responsibility to decide their fate. Timekeepers' records, stores issue books, and similar papers of purely ephemeral utility are not infrequently preserved for years after they have ceased to have any real value. Among the more technical publications which are apt to outlive their usefulness may be mentioned proof copies of papers read before institutions, and obsolete issues of *British Standard* and other specifications, long superseded by revised editions.

While, realising the need for waste paper, we have been glad to do our share in striving to bring it home to those who may not yet appreciate its real urgency, we still feel that Government departments themselves might do much more to set a national example in avoiding the wasteful use of paper. The case, reported in *The Times* on November 25, of the shipmaster who collected 5 tons of waste paper from his holds and 'tween decks after the cargo had been discharged, but was forced to take it to sea and dump it overboard because, if landed, it would have been classed as an "import", for which no authority existed, is a typical piece of official absurdity; but it is not so much worse than some of the waste of new paper that occurs when an all-powerful department decides to set up a publishing organisation. We have recently received a copy of No. 1 of *The Midnight Watch*, the wall-sheet with which apparently, the whole country is to be placarded in the supposed interests of the fire guards and other civil defence forces. As an example of the wasteful use of paper, it is outstanding. Other departments continually shower upon us, and presumably on other editorial offices also, quantities of notices, memoranda and circulars of no conceivable interest to any engineering journal; in one case, at least, after we had written to request that no further matter should be sent and had received the thanks of the department for doing so. When such official waste persists, it is not easy to persuade the public of the necessity for such drastic economy as is enforced by the Control of Paper (No. 36) Order, the full scope of which they have not yet begun to realise.

## HALIFAX BRANCH MOVES UP

The fourth branch in Canada to pass the two hundred mark in membership is Halifax. At the January meeting of Council, acknowledgement of the new status was made by approving the selection of a second councillor for the branch. Halifax now joins with Montreal, Toronto and Ottawa to make the "big four."

The workings of the co-operative agreement have aided considerably in bringing about this change, but principal credit must go to the engineers themselves who have worked unceasingly towards building up the membership and consolidating the profession in the province. It was this group which worked out the agreement and saw to it that co-operation became more than a word.

The membership of two hundred in a city the size of Halifax is something of which to be proud. It must not be thought that this figure has been reached by transfers from other branches or by other newcomers to the city. It was made up of the citizens in Halifax, who are showing their approval of the co-operative efforts of both the Association and The Institute by joining both organizations.

It is interesting to note that after two years of co-ordinated activity ninety-six per cent of all members of The Institute in the province are now members of the Association as well. In Nova Scotia under a voluntary agreement, joint membership—the first step towards real co-operation—has become a reality.

Congratulations to Halifax and to Nova Scotia.

## FOREIGN CORRESPONDENTS

*Journal* readers will have noticed, for some time, occasional short articles written by Robert Williamson, and more recently, articles by Lt. Colonel W. Lockwood Marsh and Major Oliver Stewart. These gentlemen write from London, England, and *The Journal* is very pleased to have their contributions.

Mr. Williamson is a free-lance writer in the field of general engineering. He has sent us interesting accounts of developments in such fields as civil engineering, metal trades, aircraft, railways and so on.

Lt. Colonel Marsh is editor of *Aircraft Engineering*, published in London, and frequently prepares articles on aircraft for the Ministry of Information. He is recognized as an expert in this field. His paper "Equipment and Armament of the Royal Air Force" in the October *Journal* was one of the most informative papers of its kind published on this side of the Atlantic. The present issue also carries an interesting article by the same author on the quality of the British aeroplane.

Major Stewart is editor of *Aeronautics*, and is a regular contributor to the *London Evening Standard*, in addition to doing a regular weekly air review for the *Sunday Observer*. His contributions are largely restricted to the subject of aeronautics, a field in which he is well qualified to speak. His article "Tactics and Unorthodox Aircraft" in the January *Journal* has received much favourable comment. As would be expected, this paper had to be submitted to the Canadian censors, and it was only after a clearance had been obtained from the English censors that permission was given for publication in *The Journal*.

It is expected that further contributions will be received from these "London Correspondents." *The Journal* counts

## News of the Institute and other Societies, Comments and Correspondence, Elections and Transfers

itself fortunate to be able to secure up-to-date engineering articles from the centre of Empire by such competent authors.

## POLISH ENGINEERS IN CANADA

A short time ago, on instruction of Council, a letter was sent to all those newcomers to Canada who are members of the Association of Polish Engineers in Canada, informing them of the Institute's desire to welcome them to this country, and inviting them to participate in Institute activities. For their convenience the communication was translated into Polish.

Herewith is an acknowledgment from the president of the Association. For obvious reasons his name is not published. All of these visitors have relatives still in Poland, and everything possible must be done to protect them from the diabolical activities of the Hun invader. The letter expresses appreciation of the Institute's assistance, but most significant is the note of courage and hope. It says "our Fatherland . . . still remains proud and unbroken."

The story of the Hun invasion, its unspeakable cruelties, the courage of the Polish people and their continued defiance of their despicable enemy will some day be known to the world. In the meantime, in Canada we have the opportunity of knowing some of these people who have come here to continue their fight against the despoilers of their homes and country. It is a privilege to be associated with them.

Herewith is the president's letter.

### ASSOCIATION OF POLISH ENGINEERS IN CANADA

Montreal, Que.,  
January 9th, 1942.

L. AUSTIN WRIGHT, ESQ.,  
GENERAL SECRETARY OF THE  
ENGINEERING INSTITUTE OF CANADA, MONTREAL.

Dear Mr. Wright:

I have been asked, as President of the Association of Polish Engineers in Canada, to express to you and to your Institute, the deep gratitude of our members for your more than kind letter of January 7th.

We appreciate very much the sympathetic feelings of your association, so nicely expressed in your letter, written in our mother tongue; as well as the cordial hospitality we are enjoying in your noble country.

This hospitality enables us to continue in a most effective manner—producing war tools in the Canadian war factories—the task, the only task we have now, to fight the enemy—the common enemy—the invader of our unhappy Fatherland which, though oppressed, still remains proud and unbroken.

I have been assured by my colleagues that they already love your beautiful country, as I do myself.

After this war is over, the friendship and love between the Canadian and Polish peoples, in spite of the distance separating our countries, will be deep and sincere.

Thanking you for the promise to send us *The Engineering Journal*,

I am,

Sincerely yours,

ASSOCIATION OF POLISH ENGINEERS IN CANADA.  
President.

## POST WAR RECONSTRUCTION

Today one hears so much about post war problems that it would seem as if the war problems had all been solved. Many persons and organizations are rushing into print and discussions as if each thought the problem the most important matter on the world agenda. Doubtless it is important, but with victory still not fully arranged for, its sudden appearance in the forefront of our deliberations may, to some, appear to be inappropriate.

Several months ago and at frequent intervals since, proposals have been made that some attention should be paid to such matters by the Council of the Institute. Council did investigate the situation and was informed that a committee which appeared to be competent had been appointed by the Federal government to go into the problem in a national way. Council agreed that sectional thinking or planning would offer no satisfactory solution, and undertook to wait until the committee had had a chance to examine the situation and prepare a solution that would include all parts of Canada and all occupational groups within it. It was Council's thought that in such a plan there must be a section which would be of particular interest to engineers and the Institute, to which it might apply its influence and energies.

Insufficient publicity has been given to the creation and the work of the Federal "Committee on Reconstruction." Doubtless this has contributed to the anxiety of many people and led to the belief that no planning was being done. This in turn has caused many organizations to start something of their own without any idea that others were already active and that each was duplicating or complicating the work of the other. To the end that a better understanding of the situation and the problem may be had, the *Journal* publishes herewith a "release" which has been furnished it in consequence of an interview with Dr. Cyril James during which permission was asked to publicize the establishment and the work of the committee.

Branches of the Institute may give real assistance to the committee by attacking specific problems that may be placed before them. By virtue of the national character of the Institute, it may be that comprehensive information can be assembled that will show the variation in the needs and desires of different parts of the country. In such things the Institute may find a real activity and render a real service.

Council has these matters before it and is in close touch with the committee. As soon as specific direction is given to it, instructions and advice will be sent to the branches. It is desired to emphasize that planning to be constructive and effective should be done on a national co-operative basis. If every separate interest or group strikes out by itself, there will be much overlapping, many omissions and constant confusion.

### COMMITTEE ON RECONSTRUCTION Dominion Government, Ottawa

The Dominion Government gave its first attention to the problems of reconstruction after the war as early as December, 1939, when a special Committee of the Cabinet was constituted (by P.C. 4068½) "to procure information respecting and give full consideration to and report regarding the problems which will arise from the demobilization and the discharge from time to time of members of the Forces during and after the conclusion of the present war, and the rehabilitation of such members into civil life." The Committee, in February, 1941, advised that "the scope of its duties should be enlarged to include an examination and discussion of the general question of post-war reconstruction, and to make recommendation as to what Government facilities should be established to deal with this question." By P.C. 1218 of February 17th, 1941, the functions of the Cabinet Committee were enlarged accordingly; and an advisory Committee on Reconstruction was set up shortly afterwards.

Speaking before the Parliamentary Committee on the Pension Act and the War Veterans' Allowance Act (April 4th, 1941), the Hon. Ian A. Mackenzie, Minister of Pensions and National Health referred to this as follows:

"It has been found that all the bodies, official and unofficial, which have been giving consideration to the question of rehabilitation of our ex-service men have become concerned about the question of post-war reconstruction. It must be clear that this matter of reconstruction is much wider than that of the rehabilitation of our serving soldiers, sailors and airmen. So great indeed are the implications, so wide the variety of problems, and so significant for the future of our whole Dominion, that the study of the question should be begun now—and obviously it cannot be confined to any one group of men or Department, but must be the concern of every branch of the public service, and of every provincial and municipal authority in Canada. Such being the case, the difficulty arises as to where a start can be made. The General Advisory Committee has at many points touched this problem, and as it is representative of many Departments of the Government, its co-operation in any study of the matter is essential. It seemed wise that a small Committee should undertake a survey of the whole field and look on the problem in a broad way. In consequence P.C. 1218 amending P.C. 4068½ empowers the special Committee of Cabinet to examine and discuss the general question of post-war reconstruction, and to make recommendation as to what Government facilities should be established to deal with this question."

The powers and functions of the Committee on Reconstruction, as the advisory body set up to report to the Cabinet Committee on these matters, have recently been codified by Order-in-Council (P.C. 6874). This order authorizes the Committee to secure all necessary information "with regard to reconstruction policies and activities in Canada and abroad" and charges all departments or agencies of the government to co-operate with the Committee in the performance of its duties.

The chairman of the Committee is Dr. F. Cyril James, Principal and Vice-Chancellor of McGill University. Other members are Mr. Tom Moore, president of the Trades and Labour Congress of Canada and former vice-chairman of the National Employment Commission; Mr. D. G. McKenzie, vice-president of United Grain Growers, Ltd., and former Minister of Agriculture in the Province of Manitoba; Mr. J. Stanley McLean, of the Canadian Chamber of Commerce; Dr. R. C. Wallace, Principal of Queen's University and past president of the Royal Society of Canada, and Dr. Edouard Montpetit, K.C., Secretary-General of the Université de Montréal. All these members serve without remuneration. Ex-officio members are Dr. W. A. Mackintosh, chairman of the Joint (Canadian-American) Economic Committee; Mr. Walter S. Woods, Associate Deputy Minister of Pensions and National Health; and Brig.-Gen. H. F. McDonald, chairman of the Advisory Committee on Demobilization and Rehabilitation. Dr. Leonard C. Marsh, formerly Director of Social Research at McGill University, is Research Adviser; and Mr. Robert England, formerly Director of the Canadian Legion Educational Services, is Executive Secretary.

By P.C. 6874 it is provided that the chairman of "any other committee which may be appointed to consider any question of post-war economic reconstruction" shall attend meetings of the Committee on Reconstruction, and in other ways offer the fullest co-operation to the Committee.

On the nature of the Committee and the formidable tasks before it, the Minister (in the same speech previously cited) has said the following:

"It will be observed that the Cabinet Committee is not, under (the) additional term of reference (of P.C. 4068½) instructed to submit a programme for post-war reconstruction; it is asked to consider the whole problem,

and to make recommendation as to what facilities the Government should establish to deal with the question. It was therefore thought wise that a small group of able and distinguished citizens who were not already under pressure of Departmental war work in the public service, should be charged with the study of this work and asked to report to the Cabinet Committee. This Committee will assemble information from various bodies now engaged in a study of the aspects of economic, social, and international trends during war-time, and the probable direction of trade and development subsequent to the war. Through the Department of External Affairs, our High Commissioners and Legations abroad are sending us details of plans being made in Great Britain and the sister Dominions, and an effort will be made to secure as complete documentation as possible upon the whole problem. The forecast of a possible international system, the principles of social security which may be basic in a reconstruction programme, technological change, regional specialization in relation to probable new methods and types of international trade, will have to be taken into account when consideration is given to planning of our post-war economy. This suggests at once a whole series of very difficult questions. What war-time controls now imposed upon industry and agriculture should be relinquished or maintained, either partially or wholly? How can transfer of war-time industry for peace-time purposes be achieved? How can such transfer and new equipment be financed? What will be the relation of our regional economies resting on raw material export to world trade? Can unemployed labour be absorbed by the subsidizing of public works or by the use of public credit or funds? What measures of physical reconstruction are necessary for the improvement of housing and health? Questions of social policy as well as economic policy will be involved . . ."

The Advisory Committee has formulated a comprehensive programme of inquiry to cover the wide range of post-war economic and social problems which constitute the territory of "reconstruction." A number of exploratory studies are now under way, all for the moment specifically Canadian in their area of reference, but geared to close co-operation with the work of similar Committees in Great Britain, other Dominions, and the United States. The special problems of demobilization of the armed forces are not included, as these are receiving the detailed attention of the Committee on Demobilization and Rehabilitation and its several sub-committees. The Committee on Reconstruction, like the Committee on Demobilization, reports directly to the Cabinet Committee, so that its documents are necessarily not public unless so authorized by the government. The Committee, is, however, open to receive suggestions from interested agencies and individuals, and welcomes the co-operation and interest of the citizen body of the Dominion.

In addition to the above information the following extracts from correspondence are submitted to explain or illustrate the field and the work of the committee.

Two special committees have been set up by the Dominion Government. Each of these is an advisory body charged with recommending on facilities and relevant policy, to a special Cabinet Committee set up in December, 1940, empowered to act on all matters relating to rehabilitation and reconstruction.

#### 1. Demobilization and Rehabilitation

One of these is specifically concerned with the demobilization of the armed forces and their re-establishment into civil life. This is composed of ranking civil servants, and is also an inter-departmental committee, so that it brings together all kinds of governmental personnel concerned. The parent committee has set up a series of sub-committees, all of which are busily engaged. Its activities range all the way from immediate demobilization techniques to admin-

istrative procedures and provisions necessary for getting in the ex-service man on and across the threshold of civil employment.

Undoubtedly the major product of the work of this committee so far is that embodied in a recent Order-in-Council, P.C. 7633, which provides particularly for two things: the extension of unemployment insurance provisions to members of the forces; and secondly, comprehensive facilities for all men who wish to continue training or education after their period of military service. I know that the Demobilization Committee attaches great importance to this measure, and I think with good reason.

#### 2. Reconstruction

The second committee is the Committee on Reconstruction, which is charged with all phases of economic and social reconstruction over and above the problems of specific demobilization.

This committee is of a different character, in accordance with the scope, and undoubtedly with the controversial nature of its task. It is directly linked with the Demobilization Committee through its joint executive secretary (Mr. England), and has other liaisons with governmental committees both in Canada and elsewhere. But its primary members receive no remuneration and are in a position to give completely independent expression of their views.

The secretariat of the committee has, among other things, built up as comprehensive as possible a body of information on the economic and social problems which must be the subject of reconstruction. The committee sketched out the general territory of reconstruction; and has undertaken a series of special studies relating to particular divisions of this territory. Since the reports and memoranda of the committee are the property of the Cabinet, they cannot, of course, be made public unless the government so desires. And in any case, the scope of the field is so vast that it would be futile to expect cut and dried plans to be drawn up at this stage. It is quite easy for this silence to be interpreted as meaning that the committee is not doing any work; but I can assure you that such an impression would be wholly erroneous.

But there is, of course, no secret about the territory of reconstruction, and the type of problems which have to receive consideration. They include:

- (i) The problems of re-employment and the structure of the post-war labour market; probably extending to the relations of the social services and educational facilities.
- (ii) The re-adaptation or re-orientation of the industrial and other economic expansion now proceeding at rapid pace for the prosecution of the war. It is of course possible to break this down into divisions of manufacturing industry, construction, agriculture and primary resources, etc.
- (iii) The redirection and restoration of international trade; and allied reconstruction in the sphere of monetary systems and international investment.
- (iv) The redirection, abandonment, or other modification of the structure of legislative economic controls.
- (v) Works programmes, whether for emergency employment provision or as part of the major tasks of physical and economic restoration. This of course may be conceived broadly as including such important matters as housing, and also natural resources conservation.

All these topics will, of course, be the subject of much public discussion; there is already growing evidence of this interest, though it can hardly take precedence over interest in our first winning the war.

I am sure there is no suggestion in the minds of any one connected with the Committee that this discussion of post-war problems and policy is the monopoly of the govern-

ment's advisory committee. Public opinion itself is part of the reconstruction picture. From another angle, provincial and local governments are obviously concerned in present planning and future administration. Yet again, there is the vital fact that Canada's economic future is tied up inextricably with that of Britain, the Dominions and the United States. The Committee is well aware of these ramifications.

### MEETING OF COUNCIL

A meeting of the Council of The Institute was held at Headquarters on Saturday, January 17th, 1942, at ten thirty a.m.

Present: Vice-President K. M. Cameron, in the chair; Past-President J. B. Challies; Vice-President de Gaspé Beaubien; Councillors J. H. Fregeau, J. G. Hall, W. G. Hunt, A. Larivière, C. K. McLeod, and G. M. Pitts; General Secretary L. Austin Wright, and Assistant General Secretary Louis Trudel.

Vice-President Cameron reported on the joint meeting of the Association of Professional Engineers and The Institute branches in New Brunswick held in Saint John on January 12th, at which the co-operative agreement between The Institute and the Association had been signed. The president had been unable to make the trip, and had asked Mr. Cameron to sign on behalf of The Institute, an honor which he had greatly appreciated.

A very successful meeting had been held. The Premier of the Province was present and gave a notable address on public affairs, which had been widely quoted in the press. Mr. Cameron remarked that this made four provinces out of eight in which there was a co-operative agreement between The Institute and the Provincial Professional Association. There is no Professional Association in Prince Edward Island. From general reports he believed that the movement would gradually extend to the other provinces. Mr. Wright spoke of the forthcoming annual meeting of The Institute, and from conversations with the Premier and other officials it seemed to Mr. Cameron that there would be a good representation of engineers from the province of New Brunswick at the meeting.

The general secretary reported briefly on the meeting of the executive committee of the Engineers' Council for Professional Development which he had attended, at Council's request, in place of Dr. J. B. Challies, The Institute's representative on the Council. Although a great deal of work had been done at this meeting, there was little new to report, the business consisting mostly of confirming the policies adopted at the recent annual meeting and the setting up of machinery necessary to carrying them out. Mr. Henninger, of the Committee on Information had submitted a dummy of the new booklet "Engineering as a Career." It would be distributed at a cost of ten cents a copy, or seven and a half cents a copy in lots of one hundred or more. Mr. Wright explained that Mr. H. F. Bennett had thought this would be a good booklet to distribute to heads of engineering schools and high schools, although it covered much of the same ground as our own booklet, which is also in the course of preparation.

Mr. Beaubien, chairman of the Finance Committee, presented the auditors' statement for the year 1941. He pointed out that the report was made up in the usual way as far as the various items were concerned, but at the meeting of the Finance Committee some changes had been suggested. The land and buildings are carried on the books at actual cost, \$91,495.22, which is out of proportion with their present value. In past years very little depreciation had been shown, and the Finance Committee recommended that an amount of \$55,495.22 be allowed for depreciation, which would show the land and buildings at their assessed value, namely \$36,000.00.

Mr. Beaubien explained the various items on the state-

ment, and pointed out that the financial condition of The Institute is better than it has been for a number of years.

Mr. Wright reported that arrangements for the Annual Meeting were progressing favourably, although there was still some uncertainty as to whether or not two of the principal speakers will be able to be present. However, some very distinguished American engineers were expected at the meeting, and it was hoped that it would be possible to arrange for substitutes should there be any last minute cancellations.

Mr. Hunt, chairman of the Annual Meeting Committee, gave a detailed report on the financing of the meeting. The desirability of asking for subscriptions from outside organizations was discussed, and it was agreed that the decision on this should be left to the annual meeting committee. In any case, Council would assume the responsibility for any deficit.

The general secretary presented a report from the Provisional Committee of the Julian C. Smith Memorial Medal in which it was recommended that for the year 1941 three additional awards be made which, in conjunction with the eight made last year, would be known as inaugural awards. It recommended that the following persons receive the medal:

WILBERT GEORGE MCBRIDE MONTREAL  
*Professor and Head of Department of Mining Engineering, McGill University.*

For outstanding academic service to a great university and for his contribution to the Canadian mining industry.

WILLIAM GEORGE MURRIN VANCOUVER  
*President, British Columbia Power Corporation, Limited.*

For his contribution to the development of the Province of British Columbia as a leading utility, banking and business executive.

ERNEST WALTER STEDMAN, O.B.E. OTTAWA  
*Air Vice-Marshal*

For professional service of vital importance to the Empire as Air Member of the Air Council for Aeronautical Engineering in the Royal Canadian Air Force.

Council accepted the report unanimously, and directed that copies of it be submitted to all members of Council and to all past-presidents. It also requested that the three additional recipients be appropriately advised by the president.

The Provisional Committee's report also made certain recommendations with regard to rules and regulations for future awards. These are to be considered at the February meeting of Council.

The general secretary reported that the corporate membership of the Halifax Branch has now passed the two-hundred mark, and that, in accordance with the by-laws, the branch is now entitled to a second councillor. On the recommendation of the executive, it was unanimously **RESOLVED** that John R. Kaye, M.E.I.C., be appointed as the second councillor representing the Halifax Branch.

A letter was presented from the secretary of the Toronto Branch requesting Council to hold a regional meeting of Council in Toronto on a Saturday early in April. The Council of the Association of Professional Engineers of Ontario holds its regular quarterly meeting about that time, and it was proposed that the two bodies should meet on the same day and devote the evening to a joint dinner to honour C. R. Young as the new dean of the Faculty of Applied Science and Engineering at the University of Toronto and also as president of The Institute.

A letter from the secretary of the Association indicated that Saturday, April 18th, would be the most suitable date

for the Association meeting. Accordingly, subject to the approval of the incoming Council, it was unanimously agreed that the April meeting of Council should be held in Toronto, on Saturday, the 18th, and that a joint dinner be held in the evening, at which the guest of honour would be Dean C. R. Young.

The general secretary reported on the work of the War-time Bureau of Technical Personnel. He mentioned the possibility of a change in regulations whereby the Bureau might be given additional work to do along with additional responsibilities. He also stated that he was endeavouring to arrange things in such a way that he would have to spend less time at Ottawa and therefore would have more time for Institute affairs.

It was noted that the Association of Professional Engineers of Ontario was holding its annual meeting on the evening of the Council meeting, when W. C. Miller, M.E.I.C., of St. Thomas, would be installed as the new president. The general secretary was directed to send the congratulations and good wishes of Council to the Association and to Mr. Miller.

In view of the fact that The Institute's representative on the National Construction Council of Canada is now residing in Montreal, and as his term of office will expire within the next month or two, it was suggested that some member of The Institute in Ontario, who would be in a better position to take an active part in the deliberations of the Council, should be asked to accept this appointment. Accordingly, it was unanimously **RESOLVED** that Mr. D. C. Tennant, M.E.I.C., of Toronto, be appointed as The Institute's representative on the Council for the coming year.

On the motion of Dr. Challies, seconded by Mr. Hall, it was unanimously **RESOLVED** that Dr. P. L. Pratley, M.E.I.C., be renominated for a further three-year period as The Institute's representative on the Main Committee of the Canadian Engineering Standards Association.

Letters were presented from Mr. Fraser S. Keith and Mr. Mudge suggesting that the gun which stands on The Institute's property on Mansfield Street should be turned over to the government for war purposes. There was an interesting story in connection with the gun, which Mr. Keith could supply, and which might be published if the gun were presented to the government.

Mr. McLeod understood that all such guns were the property of the government. The City of Westmount had been informed that the government was calling for tenders to collect all these guns and salvage them. After discussion, it was left with the general secretary to make inquiries and find out just what the situation is, and dispose of the gun to the best advantage of the government-sponsored salvage campaign.

A resolution from the Lakehead Branch of The Institute was presented to Council. This resolution dealt with post-war problems and concluded with a recommendation that the resolution be submitted for discussion at the next annual meeting, in the belief that out of such a discussion could be developed a policy for The Institute to follow. The resolution made certain specific recommendations for an Institute organization, and concluded with the recommendation "that planning for the post-war period be undertaken and continued as one of the major activities of The Institute until such time as normal peacetime conditions have been restored."

A long discussion followed. It was pointed out that this matter had been before Council several times, and that at previous meetings it was decided to take no action at the moment in view of the fact that the Dominion government had set up a non-partisan committee to examine the whole problem. Council's attitude had always been that it was undesirable to step into this very complicated

field without first determining what had already been done by the main committee. In this way The Institute's efforts could be made to work in conjunction with the general plan, eliminating any possibility of hindering the work of the main committee.

The general secretary reported that under instructions from the president he had interviewed Dr. F. Cyril James, principal of McGill, and chairman of the Federal Committee on Reconstruction, in order to offer the co-operation of The Institute and to determine the lines upon which any Institute activities should be developed. It was Dr. James' opinion that such an offer would be very helpful, and he announced that a sub-committee was being established to investigate that portion of the problem which had to do with construction. He also announced that he had asked Mr. K. M. Cameron, chief engineer of the Department of Public Works, to accept the chairmanship.

Mr. Cameron then outlined the situation as explained to him by Dr. James and by Dr. Marsh, who is the research adviser to the committee. He stated that very clear "terms of reference" had been given to him prescribing the work which his committee was to do. He also stated that the organization work was not yet complete and that very careful consideration was being given to it so that the persons most competent to contribute would be appointed.

Mr. Cameron pointed out that no publicity had been given to the work of Dr. James' committee, and that consequently there was little likelihood at the present time of publicity being given to the appointment of the committee of which he was chairman. However, he hoped that when details of the organization were finally drawn up, proper announcement could be made. In the meantime he recommended that further consideration by Council be left in abeyance until he could report some more definite plans towards which Institute attention could be directed.

Several councillors took part in the discussion which followed, and it was agreed that as the situation is still in a state of flux further activities on the part of The Institute should await advice from Mr. Cameron. It was hoped that something conclusive could be reported to the annual meeting of Council in February, which, in turn, might be announced to the annual general meeting.

The general secretary was instructed to inform the Lakehead Branch that Council appreciated its interest and would be glad to follow up on their resolution after further intimation had been received from Dr. James or Mr. Cameron. It was also suggested that some publicity might be given to the fact that a national committee is already considering the post-war problems so that members would know that something was already under way, and that The Institute was standing-by at the request of Dr. James to assist as soon as clear definite lines had been established.

A number of applications were considered, and the following elections and transfers were effected:

**ADMISSIONS**

Members .....	12
Juniors .....	1
Students .....	20
Affiliate .....	1

**TRANSFERS**

Junior to Member.....	1
Student to Member.....	2
Student to Junior.....	3

It was noted that the next meeting of Council would be held at Headquarters in Montreal on Wednesday, February 4th, 1942, at ten thirty a.m.

## ELECTIONS AND TRANSFERS

At the meeting of Council held on January 17th, 1942, the following elections and transfers were effected:

### Members

**Barratt**, Ernest F., B.A.Sc. (Univ. of Toronto), county engr. and road supt., Hamilton Suburban Roads Commission, Hamilton, Ont.  
**Brown**, Raymond Warrington, B.Sc. (Mech.), (Univ. of Sask.), asst. mech. supt., Winnipeg Free Press Co. Ltd., Winnipeg, Man.  
**Gagnon**, Paul Edouard, Chem. Engr. (Laval Univ.), D.Sc. (Univ. of Paris), D.I.C. (Univ. of London), Ph.D. (Laval Univ.), director, dept. of chem. engrg., president, Graduate School, Laval Univ., Quebec, Que.  
**Gunn**, George John Tait, B.Sc. (Engrg.), (Heriot-Watt College), chief asst. engr., Trinidad Electricity Board, Port of Spain, Trinidad, B.W.I.  
**Helwig**, Carl Everett, B.A.Sc., M.A.Sc. (Univ. of Toronto), lecturer, dept. of civil engrg., Univ. of Toronto, Ont.  
**Irwin**, Harold Stephen, B.A.Sc. (Univ. of Toronto), squad boss, Dominion Bridge Co. Ltd., dtg. room, Toronto, Ont.  
**McRitchie**, Charles Bell, (Glasgow & West of Scotland Tech. Coll.), partner, R. A. Rankin & Co., Montreal, Que.  
**Price**, Gordon James, chief dftsmn., Ont. Divn., Dominion Bridge Co. Ltd., Toronto, Ont.  
**Short**, Harold William, sales engr., Dominion Bridge Co. Ltd., Toronto, Ont.  
**Smith**, Duncan Norman, B.S. (C.E.), (Tri-State College of Engrg.), struct'l designer & estimator, Dominion Bridge Co. Ltd., Toronto, Ont.  
**Whiteley**, Frederick Bryan, res. engr., Dept. of Transport, Belleville, Ont.

### Junior

**Holgate**, David Crossley, B.Eng. (Civil), (McGill Univ.), dftsmn., Dominion Bridge Co. Ltd., Toronto, Ont.

### Affiliate

**Beaudoin**, Hector Oswald, chief electrician, Price Bros. & Co. Ltd., Riverbend, Que.

### Transferred from the class of Junior to that of Member

**Paterson**, Walter Howard, B.Sc. (Queen's Univ.), field engr., Geological Dept., Tropical Oil Co., Barranca Bermeja, Colombia, S.A.

### Transferred from the class of Student to that of Member

**Nowlan**, Brete Cassius, Jr., B.Eng. (Elec.), (McGill Univ.), Lieut., E. Section Comdr., 4th Cdn. Divn. Sigs. (A.F.), Debart Camp, N.S.

**Thorne**, James Lawrence, B.Sc. (Elec.), (Queen's Univ.), asst. shift charge engr., London Power Co., London, England.

### Transferred from the class of Student to that of Junior

**Bridges**, Robert James, B.Sc. (Elec.), (Univ. of Man.), wire & cable sales engr., Northern Electric Co. Ltd., Winnipeg, Man.

**Smiley**, Donald Charles, B.Sc. (Queen's Univ.), instructor, R.C.A.F., Radio Detachment, Queen's Univ., Kingston, Ont.

**Turanna**, Anthony Louis, B.Sc. (Queen's Univ.), asst. to chief engr., Public Utilities Commission, London, Ont.

### Students Admitted

**Anderson**, John MacDonald, (McGill Univ.), 102 Fentiman Ave., Ottawa, Ont.

**Archambault**, Jean-Jacques, (Ecole Polytechnique), 6650 De Normandie St., Montreal, Que.

**Brett**, John Edward, (McGill Univ.), 4180 Melrose Ave., Montreal, Que.

**Cann**, John Leonard, (Univ. of Man.), 497 Craig St., Winnipeg, Man.

**Dalkin**, Robert S., (McGill Univ.), 9 Willow Avenue, Westmount, Que.

**Dancose**, Leon, (Ecole Polytechnique), 3591 Jeanne-Mance St., Montreal, Que.

**Le Grandmont**, Marcel, (McGill Univ.), 3647 Durocher St., Montreal, Que.

**Griesbach**, Robert Johnston, (McGill Univ.), 185 Dufferin Rd., Hampstead, Que.

**Hand**, Dennis Herbert, (Univ. of Man.), 273 Eugenie St., Winnipeg, Man.

**Laquerre**, Maurice, (Ecole Polytechnique), 5025 Delorimier Ave., Montreal, Que.

**MacEachern**, Clinton Whitman, (McGill Univ.), 419 Prince Arthur St., Montreal, Que.

**Moffatt**, Allan Gray, (Univ. of Toronto), 150 Lascelles Blvd., Toronto, Ont.

**McCulloch**, Urban Francis, (McGill Univ.), 127 Percival Ave., Montreal West, Que.

**McFarlane**, Howard William, (Univ. of N.B.), 210 Lancaster Ave., West Saint John, N.B.

**Mills**, John Wesley, (Queen's Univ.), 72 Craig St., Ottawa, Ont.

**Nathanson**, Herzl King, (McGill Univ.), 376 Clarke Ave., Westmount, Que.

**Park**, John Kenneth, (McGill Univ.), 177-17th Ave., Lachine, Que.

**Pearson**, Edward Bernard, (McGill Univ.), 477 Prince Arthur St. West, Montreal, Que.

**Petitpas**, Marcel, (Ecole Polytechnique), 5509 Laurendeau St., Cote St. Paul, Montreal, Que.

**St-Jacques**, Maurice, (Ecole Polytechnique), 386 St. Catherine Road, Outremont, Que.

## R.A.F.'S AIRACOBAS

From *Trade and Engineering* (LONDON), NOVEMBER, 1941

For many months conflicting reports have been reaching this country from the United States regarding the performance and capabilities of the Bell *Airacobra*. Not for many years has such a controversy existed about an aeroplane. The strange thing about the statements on the *Airacobra* is that they ranged from the sublime to the ridiculous. Some spoke of speeds of about 500 m.p.h., others 400 m.p.h.; still others raised doubts whether the Allison engine would stand up to the work required of a modern fighter. The reason for all this discussion and for the discrepancy in the reports was no doubt that few people had seen the *Airacobra* flying and not many more had even seen it on the ground.

The most striking feature of the machine is that although it has a tractor airscrew the liquid-cooled engine is installed behind the pilot's cockpit, the airscrew being driven by a long shaft which passes through the pilot's cockpit under the seat. It is also fitted with the tricycle under carriage which is becoming almost a regular feature of all new American aircraft. It was not until the first *Airacobras* had been in this country for a week or two that some rational opinions could be obtained about the aircraft and its performance. Now the first squadron equipped with *Airacobras* has been formed as part of Fighter Command, and it has just become fully operational. The writer was permitted to visit the squadron recently to watch the machines in the air and on the ground and to ask the pilots what they thought about their new aircraft. The machines were deployed on the airfield and, with their tails held in the air by the tricycle undercarriage near the nose of the fuselage, they presented a strange picture.

The pilots of this squadron have now had their *Airacobras* sufficiently long to know all there is to be known about them. The squadron commander, a pilot of great experience who has flown *Spitfires*, *Blenheims*, *Hurricanes*, *Beaufighters*, and several other types, expressed the view that, up to certain heights (which may not be specified), the *Airacobra* is the finest fighter in the world—and he did not exclude the British *Spitfires* and *Hurricanes*. Up to these heights, he said the American fighter was faster. Its manoeuvrability was about the same as that of the *Spitfire* and slightly less than that of the *Hurricane*. The *Airacobra*, he added, has limitations in altitude, but, as he pointed out, one cannot have everything in a single machine, and for the work to which it would be put he did not ask for a better all-round machine.

In appearance the *Airacobra* is not unlike the *Hurricane*, though on the ground its tricycle undercarriage gives it a distinctive appearance. The front wheels of the undercarriage retract inwards, the outside shields of the wheels folding back flush with the floor of the fuselage. This single-seat, low-winged monoplane is powered by a liquid-cooled Allison 12-cylinder engine of 1,150 h.p. No performance figures are available in respect of the type used by the R.A.F. There are several versions of armament. One consists of a 20mm. cannon, firing through the airscrew hub, two machine-guns located in the nose and firing through the airscrew, and four machine-guns in the wings. Another version has the 20mm. Oerlikon cannon in the nose, and four machine-guns in the wings—two 0.5 and two 0.303.

**Louis O'Sullivan**, M.E.I.C., has been appointed general executive assistant with Montreal Light, Heat and Power Consolidated. He has been on the staff of the company since 1923 and has held the positions of field engineer, designing engineer and transmission and right-of-way engineer, his duties being connected with the design and construction of electrical substations, transmission and dis-

L. O'Sullivan, M.E.I.C.

tribution lines, as well as supervision of land surveys, property purchases and title records.

Mr. O'Sullivan is a graduate of McGill University where he obtained the degree of Bachelor of Science in 1921. From 1921 to 1923 he worked for the City of Montreal on construction of its new aqueduct canal.

**Major-General H. F. G. Letson**, M.C., M.E.I.C., has recently been appointed Adjutant General in the Department of National Defence Headquarters at Ottawa. Previously he was Canadian Military Attaché in Washington.

Born at Vancouver, B.C., in 1896, he served in France with the 54th Battalion, C.E.F., in the Great War. He was severely wounded, and was awarded the Military Cross. Major-General Letson maintained his military interest after demobilization and had been associated with the Non-Permanent Active Militia.

He received his education at the University of British Columbia, where he graduated with the degree of B.Sc. in mechanical engineering in 1919. In 1923 he was granted the degree of Ph.D., in engineering by the University of London, England, and was appointed assistant professor of mechanical engineering at the University of British Columbia. In 1931 he became associate professor of mechanical engineering, a position which he retained until 1934. At that time he became chief engineer and managing director of Letson and Burpee, Vancouver. In 1936 he was president of the Association of Professional Engineers of British Columbia.

**Major-General J. P. Mackenzie**, D.S.O., M.E.I.C., of Vancouver, has been appointed Quartermaster-General in the Department of National Defence Headquarters at Ottawa. Until this appointment he was in command of an infantry brigade with the Canadian Army overseas.

Major-General Mackenzie was born at Boissevain, Man., in 1884 and was educated at the University of Glasgow. He served overseas in the first great war with the Canadian Expeditionary Forces and upon his return to Canada in 1919 he became engaged in construction work. From 1920 to 1927 he was chief engineer of Henry and McFee at Seattle, Washington. In 1927-1928 he was field engineer

## News of the Personal Activities of members of the Institute, and visitors to Headquarters

for the St. John Dry Dock and Shipbuilding Company at St. John, N.B. He joined the staff of the Western Bridge Company at Vancouver as general sales manager in 1929 and in 1932 he was made general manager, a position which he occupied until the outbreak of war.

**Stanley Shupe**, M.E.I.C., is the newly elected chairman of the Hamilton Branch of the Institute. He was educated at the University of Toronto where he received the degree of Bachelor of Applied Science in 1914. Mr. Shupe is city engineer of Kitchener, Ont., and has had extensive experience in municipal engineering having been county engineer of Haldimand, Ont., and later town engineer of Oshawa. He is a past president of the Canadian Institute on Sewage and Sanitation.

Stanley Shupe, M.E.I.C.

**J. B. Stirling**, M.E.I.C., is the newly elected president of the Canadian Construction Association for the current year. He is vice-president of E. G. M. Cape and Company, contractors, Montreal.

Born at Dundas, Ont., Mr. Stirling graduated from Queen's University as a Bachelor of Arts in 1909 and as a Bachelor of Science in 1911. In the early days of his career he worked on municipal construction projects. During the last war he served with the Canadian Expeditionary Force overseas, in the Royal Canadian Engineers. He has been associated with E. G. M. Cape and Company for the past twenty-six years, first as a field engineer and later as a supervising engineer. In 1928 he became a partner in the firm and a few years ago he was made vice-president in charge of operations.

Mr. Stirling has been connected with construction projects such as the Banting Institute in Toronto, docks and grain elevators at Saint John, N.B., and at Georgian Bay, and the Canadian Vickers plant in Montreal.

He is a member of the executive of the Montreal Branch of the Institute.

**C. C. Lindsay**, M.E.I.C., has recently been appointed by the government of the province of Quebec a member of the Montreal Tramways Commission. Mr. Lindsay is in private practice at Montreal as a consulting engineer and land surveyor. He has been a member of the Institute for several years having been particularly active in the Montreal Branch.

**W. B. Scoular**, M.E.I.C., division engineer of the Wayagamack Division of the Consolidated Paper Corporation, has

obtained a leave of absence to accept a position as works manager of the gun plant of the Dominion Bridge Company at Vancouver, B.C. Mr. Scouler graduated from Glasgow University in 1923, with the degree of Bachelor of Science. He came to Canada in 1929 and accepted a position on the staff of Dominion Bridge Company with whom he remained until 1936 when he went with Consolidated Paper Corporation, Laurentide Division.

**Flying Officer Walter L. Rice**, M.E.I.C., has accepted a commission with the Royal Canadian Air Force and has been posted to No. 3 Training Command Headquarters, Works and Buildings, Montreal, where he has been employed as senior assistant engineer since July, 1941.

**D. D. Whitson**, M.E.I.C., plan examiner, Department of Buildings, City of Toronto, is now with the Works and Buildings Branch, Naval Service, Department of National Defence, Ottawa.

**William A. Hillman**, M.E.I.C., is with the Foundation Company of Canada at Kenogami, Que., as superintendent of crushing and mining plants on the Shipshaw power project.

**G. W. Holder**, M.E.I.C., who, at the beginning of last year had relinquished his position as manager of the Sturgeon Falls division of the Abitibi Power and Paper Company Limited, has now been transferred to the engineering department of the Sault Ste. Marie mills of the Company. In the meantime, he had spent last winter as chief draughtsman at Iroquois Falls, and last summer his services had been loaned to the Government for the organization of the Wartime Machine Shop Board of the Canadian Pulp and Paper Association.

**H. Lloyd Johnston, M.E.I.C.**

**H. Lloyd Johnston**, M.E.I.C., has been elected chairman of the Border Cities Branch of the Institute. Born at Vancouver, B.C., he was educated at the University of British Columbia and at McGill University where he graduated in 1927. In the same year he became connected with the Canada Power and Paper Corporation as engineer in charge of building construction. In 1928 he was designing engineer and until 1936 was plant engineer for the same company at Windsor Mills, Que. He joined the staff of Canadian Industries Limited at Montreal in 1936 and in 1938 he was transferred to the Windsor, Ont., plant of the company.

**Drummond Giles**, M.E.I.C., vice-president of the Canadian SKF Company Ltd., has been appointed associate director-general of the subcontract branch of the Department of Munitions and Supply, Ottawa.

**Professor E. A. Allcut**, M.E.I.C., professor of mechanical engineering at the University of Toronto, has been appointed technical advisory editor of *Manufacturing and Industrial Engineering*, a monthly publication from Toronto.

**Jacques E. Hurtubise, Jr.**, E.I.C., is the newly elected chairman of the Junior Section of the Montreal Branch of the Institute. He was educated at Ecole Polytechnique where he received his degree in civil engineering in 1934. Upon graduation he joined the teaching staff of the Ecole Polytechnique as an instructor in the laboratory for testing

**J. E. Hurtubise, Jr., E.I.C.**

materials. In 1937 and 1938 he was reinforced concrete designer for Baulne and Leonard, Montreal. He is at present in charge of the laboratory for testing materials at the Ecole.

**André P. Benoit**, Jr., E.I.C., has recently obtained a leave of absence from Dominion Rubber Company Limited, Montreal, to join the inspection staff of the Department of Munitions and Supply. A few days after he had been posted at the Montreal Locomotive Works Limited he suffered an accident when he slipped and fractured his right leg while testing a newly constructed tank. He is at present recovering in the hospital. Mr. Benoit was chairman of the Junior Section of the Montreal Branch of the Institute last year. His friends wish him a rapid and complete recovery.

**T. M. Moran, M.E.I.C.**

**T. M. Moran**, M.E.I.C., vice-president of Stevenson and Kellogg Limited, was recently elected president of United Tool Engineering and Design Ltd., Toronto.

**H. A. Crombie**, M.E.I.C., has been recently appointed administrator of plant machinery, equipment and supplies for the Wartime Prices and Trade Board with offices in Montreal. Mr. Crombie is assistant manager of the Dominion Engineering Company Limited, Montreal, having joined this firm in 1920.

**Flight-Lieut. E. H. Jones**, M.E.I.C., who was commissioned in the Royal Canadian Air Force in June, 1941, is now officer commanding, Works and Buildings Division, No. 1 Service Flying Training School, at Camp Borden, Ont.

**A. E. K. Bunnell**, M.E.I.C., partner, Wilson and Bunnell, consulting engineers, Toronto, is serving in the office of Mr. James Stewart, National Administrator of Services, the Wartime Prices and Trade Board, Toronto. Mr. Bunnell is director of Public Utility services.

**Robert W. Tassie**, M.E.I.C., has joined the staff of Empresa Electrica de Guatemala at Guatemala, C.A. Mr. Tassie, who is vice-president of Empresas Electricas Brasileiras, has been located in South America since 1911. At one time he was manager of the operating department of the Latin American projects of the Montreal Engineering Company.

**Stanley R. Frost**, M.E.I.C., has been granted leave of absence by the North American Cyanamid Company Limited to take a position on the staff of the Wartime Bureau of Technical Personnel at Ottawa. Mr. Frost is the immediate past president of the Association of Professional Engineers of Ontario.

Stanley R. Frost, M.E.I.C.

**Jean V. Arpin**, Jr.E.I.C., has recently been put in charge of the inert component shop at Canadian Car Munitions Ltd. at St. Paul L'Ermite, Que., and at the same time he acts as technical advisor for the shell-filling groups. After graduating from the Ecole Polytechnique in 1938, he took a post graduate course in chemical engineering at the Ecole and in 1939 he was with the Department of Roads of the Province of Quebec. In 1940 he joined the staff of Canadian Car Munitions Ltd., and was sent to England, from where he returned to help organize the production in the company's plant.

**N. W. D. Mann**, Jr.E.I.C., is stationed at Ottawa as junior engineer on construction of the new headquarters building of the Royal Canadian Air Force. He graduated with the degree of Bachelor of Science in civil engineering at the University of New Brunswick in the class of 1937. From 1937 to 1940 he was with the Department of Highways of New Brunswick as instrumentman and junior engineer. In 1940 he joined the works and buildings division of the Department of National Defence at Gander, Newfoundland.

**John T. Mazur**, S.E.I.C., has accepted a position with Massey-Harris Aircraft at Weston, Ont., as a tool and jig designer. He graduated from the University of Manitoba in 1940 with the degree of Bachelor of Science in civil engineering.

**S. D. Levine**, S.E.I.C., has recently been transferred from the inspection staff of the Republic Steel Corporation in Buffalo, New York, to the Crucible Steel Company, at Harrison, N.J., with the Inspection Board of the United Kingdom and Canada. He graduated from the University of Toronto in 1939.

**D. C. R. Miller**, S.E.I.C., has accepted a position with Research Enterprises Limited at Leaside, Ont. Previously he was connected with the Duplate Safety Glass Company at Oshawa.

**E. R. Jacobsen**, M.E.I.C., was recently appointed personal assistant to L. R. Macgregor, director-general of the recently formed Australian War Supplies Procurement in Washington, D.C. Mr. Jacobsen is on temporary leave of absence from the Dominion Bridge Company, Limited, Montreal.

**T. S. Glover**, M.E.I.C., manager, industrial department, Russell T. Kelley, Limited, Hamilton, has obtained a leave of absence to join the staff of the Wartime Bureau of Technical Personnel at Ottawa. He is vice-chairman of the Hamilton Branch of the Institute.

T. S. Glover, M.E.I.C.

**B. H. Geary**, S.E.I.C., has recently been transferred from the Peterborough Works to the Davenport Works of the Canadian General Electric Company in Toronto. He graduated in electrical engineering from the University of New Brunswick in the class of 1940.

#### VISITORS TO HEADQUARTERS

**H. F. Lambart**, M.E.I.C., Life Member, Ottawa, Ont., on January 9th.

**W. E. Ross**, M.E.I.C., manager, apparatus sales department, Canadian General Electric Company, Toronto, Ont., on January 15th.

**Wills Maclachlan**, M.E.I.C., secretary-treasurer and engineer, Electrical Employers' Association of Ontario, Toronto, Ont., on January 20th.

**G. H. Thurber**, M.E.I.C., Department of Public Works, Ottawa, Ont., on January 22nd.

**J. W. MacDonald**, M.E.I.C., Avon River Power Company, Windsor, N.S., on January 26th.

**R. W. Boyle**, M.E.I.C., Director, Division of Physics and Electrical Engineering, National Research Council, Ottawa, Ont., on January 26th.

**E. B. Horton**, M.E.I.C., Boston, Mass., on January 30th.

# Obituaries

*The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.*

**Walter Ritchie Duckworth**, M.E.I.C., died in Vancouver, B.C., on January 13th, 1942. He was born at Montreal on December 31, 1870, and was educated at the Montreal High School, McGill University and later at St. Paul, Minn. From 1890 to 1892 he worked in the office of Chas. F. Loweth, consulting engineer in the department of bridge engineering and construction of the Northern Pacific Railway Company and the Chicago, Milwaukee and St. Paul Railway Company. In 1892 he joined the staff of Dominion Bridge Company at Montreal as a designing draughtsman on swing bridge machinery. In 1896 he was appointed chief inspector and in 1912 he went to Vancouver. He was for some time connected with the Granby Consolidated Mining & Smelting & Power Company at Anyox, B.C., and later with the Greater Vancouver Water District Board. Lately he had been connected with the Dominion Bridge Company at Vancouver as plant engineer and assistant superintendent.

Mr. Duckworth joined the Institute as an Associate Member in 1912 and became a Member in 1940.

**Robert Leslie Murray**, S.E.I.C., died at Vernon, P.E.I., on November 17th, 1941. He was born at Vernon on November 11th, 1913, and received his education at Mount Allison University and Nova Scotia Technical College. From 1937 until 1940 he was engaged on highway construction for the Department of Highways of Prince Edward Island. In 1940

R. L. Murray, S.E.I.C.

he joined the Department of National Defence of Canada and worked on airport construction at Summerside, P.E.I. He was appointed assistant engineer in charge of construction in April, 1941.

Mr. Murray joined the Institute as a Student in 1931.

**William James Smither**, M.E.I.C., died at his home in Toronto on January 18th, 1942, after a short illness. He was born at St. Thomas, Ont., on November 29th, 1880, and received his education at the University of Toronto, where he graduated as a Bachelor of Applied Science in 1905. Following his graduation he spent some years engaged in engineering work in Vancouver, B.C., San Francisco and Los Angeles, Cal. His work in the latter two cities was in connection with the installation of hydraulic plants. In 1911 he joined the engineering staff of the University of Toronto as a demonstrator in structural design. In 1915 he became lecturer, and in 1921, assistant professor of structural engineering. Later he became associate professor.

Professor Smither joined the Institute as an Associate Member in 1914 and he was transferred to Member in 1925.

**William Morrison Johnstone**, M.E.I.C., died at his home in Ottawa on December 22nd, 1941. He was born at Stamford, Ont., on October 11th, 1889, and was educated at Queen's University where he received his Bachelor of Science degree in 1913. Upon graduation he joined the engineering staff of the City of Toronto and after a few months he became resident engineer on sewer construction. In 1916 he joined the staff of the International Nickel Company at Copper Cliff, Ont., and worked for this firm as construction cost engineer until 1918 when he went overseas. In 1919, upon his return to Canada, he joined the staff of the City of Hamilton, where he was employed on sidewalk construction. Later he became in charge of sewers and underground construction. In 1930 he became managing director of Stanley Contracting Limited, Hamilton, and in 1932 he joined the engineering staff of the City of Ottawa as deputy engineer. In 1934 he became assistant commissioner of works for the city, a position which he occupied at the time of his death.

Mr. Johnstone joined the Institute as an Associate Member in 1921. He became a Member in 1940.

**Archibald Alexander MacDiarmid**, M.E.I.C., died at his home in Quebec city on January 7th, 1942. He was born at Covey Hill, Que., on May 13th, 1885, and was educated at McGill University, where he received the degree of Bachelor of Science in 1910. Upon graduation he joined the engineering department of the Montreal Light, Heat and Power Consolidated and after two years he became in charge of this department.

In 1914 he was employed by the Bathurst Lumber Company at Bathurst, N.B., as chief engineer of the Lumber, Pulp and Paper Division, on the design, construction and operation of mills. For seven months in 1916 Mr. MacDiarmid was the chief engineer of the Mattagami Pulp and Paper Company at Smooth Rock Falls, Ont. From there he transferred to the Anglo-Newfoundland Development Company at Grand Falls, Newfoundland, as manager. In 1918 he was the special representative of the Federal Trade Committee in the Newsprint Price Fixing Case at Washington, D.C. From 1919 to 1921 he was employed as chief engineer of the Ironsides Paper Board Company, Norwich, Conn.

In 1922 he joined the staff of Price Bros. & Co. Ltd., as chief engineer, a position which he occupied until his death.

Mr. MacDiarmid joined the Institute as a Student in 1909. In 1914 he was transferred to Associate Member and he became a Member in 1926.

## COMING MEETINGS

**Ontario Good Roads Association**—Annual Convention, Royal York Hotel, Toronto, February 25-26th. Secretary, T. J. Mahony, Box 485, Hamilton, Ont.

**Canadian Institute of Mining and Metallurgy**—Forty-sixth Annual General Meeting, Royal York Hotel, Toronto, March 9-11th. Secretary, E. J. Carlysle, 906 Drummond Bldg., Montreal.

**American Water Works Association, Canadian Section**—Annual Convention at the General Brock Hotel, Niagara Falls, Ont., April 15-17th. Secretary, Dr. A. E. Berry, Ontario Department of Health, Parliament Buildings, Toronto.

**American Water Works Association**—Sixty-second Annual Convention at Stevens Hotel, Chicago, Ill., June 21-25th. Executive Secretary, Harry E. Jordan, 22 East 40th Street, New York, N.Y.

## HALIFAX BRANCH

S. W. GRAY, M.E.I.C. - - - - Secretary-Treasurer  
G. V. ROSS, M.E.I.C. - - - - Branch News Editor

The annual meeting of the Halifax Branch was held as an informal dinner at the Halifax Hotel on December 18th. Fifty-five members and guests were present.

S. W. Gray, secretary-treasurer, presented his financial statement and report for the past year. The report of the scrutineers showed the following new executive members had been elected: Percy A. Lovett (Chairman), J. D. Fraser, G. T. Clarke and G. J. Currie of Halifax, G. T. Medforth, Amherst, and J. W. MacDonald, Windsor.

S. L. Fultz, retiring chairman, reviewed the activities of the branch during 1941. Since the co-operative agreement between the Institute and the Association of Professional Engineers of Nova Scotia, the membership of the branch has increased by 170 to a total of 256, of whom 216 are full members. Five dinner meetings were held during the year, also the joint E.I.C. and A.P.E.N.S. banquet. Branch members have contributed ninety-five dollars to the Headquarters Building Fund and eighty dollars has been invested in War Savings Certificates. The latter amount is the result of a decision to eliminate musical entertainment from the monthly dinner meetings and use the money for this purpose.

Mr. Lovett took over as chairman and asked the members to support the executive as they have in the past. He stated that the recent increase in membership would entitle the branch to representation by an additional member on the Council.

It was decided to hold the joint banquet with the Association of Professional Engineers in January.

An entertainment feature of the evening was provided by a General Electric Company film—"Exploring With X-Rays."

## LONDON BRANCH

H. G. STEAD, M.E.I.C. - - - - Secretary-Treasurer  
A. L. FURANNA, S.E.I.C. - - - - Branch News Editor

The December meeting of the branch was held on December 10th in the new Cronyn Memorial Observatory at the University of Western Ontario. Dr. H. R. Kingston, head of the Department of Mathematics and Astronomy, and Rev. W. G. Colgrove, a member of the university staff, presented a most interesting programme.

The first part of the evening was spent in the dome of the observatory where Rev. Colgrove explained the principles of their fine telescope. This telescope has a 10-inch lens and is the largest of its kind to be cast and ground on this side of the ocean. Unfortunately, the sky was overcast and there was no opportunity to view the planets through the telescope.

For the second part of the evening, Dr. Kingston gave a lecture on astronomy, in which the meeting was given some idea of the complicated workings of our universe and of its enormous size. The lecture was illustrated by many models made by Rev. Colgrove.

Rev. Colgrove then demonstrated his working model of our sun, earth and moon. This model showed simultaneously all the motions of the earth and moon around the sun. The model also illustrated the seasons, the midnight sun, midday night and the phases of the moon.

At the close of the lecture demonstration, R. W. Garrett, the branch chairman, called upon W. C. Miller who thanked both Dr. Kingston and Rev. Colgrove for their very interesting programme.

Following the meeting a number of members remained to see the observatory's prized possession, a meteor.

Many members took advantage of the invitation extended to their wives and lady friends.

## Activities of the Twenty-five Branches of the Institute and abstracts of papers presented

## MONTREAL BRANCH

L. A. DUCHASTEL, M.E.I.C. - - - Secretary-Treasurer  
G. G. WANLESS, JR., E.I.C. - - - Branch News Editor

On January 8th Mr. Howard Johnson, a naval architect and ship surveyor, general manager of Midland Shipyards Ltd., addressed the branch on **Shipyard Production Methods**. He has had wide experience in a number of shipbuilding firms in England and Scotland, and has had the opportunity of visiting many yards in different countries.

The paper deals with the application of straight-line production methods to construction of standardized 10,000 ton cargo vessels, as a means of speeding up shipbuilding during the emergency. It is published in this issue of the *Journal*.

Mr. Johnson said that it is presently possible to complete a 10,000 ton standardized cargo vessel by such means in 25 weeks, of which 20 weeks are in the berth. During the discussion, Mr. R. E. Hertz described progress in Canadian yards, along these lines. It is expected that the 6 $\frac{1}{4}$ -month building period will be reduced to 4 $\frac{1}{2}$  months in time. This will be a major contribution to our defence.

The branch was privileged to have present at its Annual Meeting on January 15th, Dr. C. J. Mackenzie, President of The Institute.

The chairman, R. E. Hertz, discussed the 24th Annual Report which had been mailed to all members and commented on the good and active work of all committees. All activities had been maintained at full level despite the pressure of emergency duties. The membership committee showed a 90 per cent increase. A broader presentation of the Institute to the public was ably begun by Mr. Hulme's Publicity Committee. The Junior Section was complimented on their being able to maintain attendance; one of their meetings drew 170 members. The chairman expressed regret that Mr. André Benoit, Junior Section Chairman, should have had an unfortunate accident at this time.

The following officers were elected for the coming year: J. A. Lalonde, Chairman; R. S. Eadie, Vice-Chairman; L. A. Duchastel, Secretary-Treasurer; R. E. Hertz, Past-Chairman; J. Comeau, J. M. Crawford, J. B. Stirling, H. F. Finnemore, R. C. Flitton, G. D. Hulme, Councillors.

Mr. Hertz presented to Dr. Mackenzie, as the Montreal Branch contribution to the Headquarters Building Fund, a cheque for \$6,000.

Dr. Mackenzie said that success in the building fund campaign had had a salutary effect in solidifying the national organization. The Institute is the best developed of such national organizations, and being such should be capable of playing an outstanding part in general affairs, which of necessity must be more collectivistic in the future. He spoke of the Institute, through its early beginnings in Montreal, as "an organization born a bit before its time, in an era when specialization and individualism were dominant." This had made it possible for some groups to survive more easily than others. Now collectivism was necessary for survival, as many European countries have learned before now.

The speaker mentioned the large number of key positions now held by engineers in Army, Navy, Air Force, as well as Government Departments directly connected with the war effort. Industrial production was seen as just now entering its fourth stage in which quantity production would be shortly achieved and a shortage of manpower would become evident.

In addition to creating the fighting services and equipping them, Dr. Mackenzie foresaw a third major engineering problem—that of maintaining a price ceiling without reduction of quality standards.

Mr. L. O'Sullivan moved the vote of thanks to the speaker which was most heartily endorsed by all those present.

Mr. Heartz expressed his sincere thanks to the secretary-treasurer and all committee chairmen for having made his term of office so successful.

The new Chairman, J. A. Lalonde, was escorted to the chair by Past-Presidents O. O. Lefebvre and F. P. Shearwood. Mr. Lalonde, addressing himself to Dr. Mackenzie, Mr. Heartz and the members of the branch, promised to keep us busy and pledged his energy to maintaining the high standard of the Montreal Branch. He spoke in English and in French.

By courtesy of the St. Maurice Power Co., a most instructive film was presented, which showed stages in the building of the La Tuque dam.

Mr. W. G. Hunt discussed highlights of the Annual Meeting to be held February 5th and 6th.

The meeting adjourned for refreshments.

### OTTAWA BRANCH

A. A. SWINNERTON, M.E.I.C. - - *Secretary-Treasurer*

At the noon luncheon on December 18th, 1941, A. L. Malcolm, B.A.Sc., senior field engineer in charge of hydro-electric development construction for the Ontario Hydro-Electric Power Commission, spoke upon some of the **Construction Features of the Barrett Chute Development** on the Madawaska river in Ontario, about 25 miles southeast of Pembroke. His talk was illustrated by coloured motion pictures.

This development was begun in September, 1940, and is expected to be complete early in midsummer of 1942. It is designed to supply an additional 54,000 horsepower which will mean much to Ontario where a large part of Canada's war industries are concentrated.

Mr. Malcolm's paper dealt in large part with the construction of the dam itself and was listened to with a great deal of interest by the members. It is the intention to publish this paper in *The Journal*.

The Annual Meeting of the Ottawa Branch was held on the evening of January 8th at the auditorium of the National Research Laboratories, followed by an illustrated address and demonstration by J. W. Bateman of Toronto on the **"Magic of the Spectrum."**

At the Annual Meeting the usual reports were presented and the results of the elections to the branch were announced. Chairman for the forthcoming year is N. B. MacRostie, secretary-treasurer is A. A. Swinnerton, and new members of the Managing Committee are W. H. G. Flay, G. A. Lindsay and R. Yuill. The retiring secretary-treasurer, R. K. Odell, was presented with a handsome travelling bag and a gold Engineering Institute pin.

Mr. MacRostie presented an interim report on the work of the Committee on Air Raid Shelters and stated that a survey was being made of downtown and commercial buildings and of residences and apartments in other sections of the city in connection with air raid shelter facilities. He said the libraries had secured books and pamphlets on the question of air raid shelters and these were available to the public.

The secretary-treasurer's report showed an increase in branch membership of 26 during the year, the total now being 402 resident and 103 non-resident members. Two sets of drafting instruments were donated to the Ottawa Technical School for presentation as prizes for proficiency in drafting and a copy of "Technical Methods of Analysis" by Griffin was presented to the Hull Technical School to be awarded to one of the students. The meeting voted unanimously to set aside \$30 for the same purposes again this year.

President C. J. Mackenzie and General Secretary L. Austin Wright of the Institute spoke briefly on the reconstruction plans of the Institute.

The address and demonstration by J. W. Bateman required the use of considerable apparatus and was listened to with rapt attention on the part of the audience. Mr. Bateman traced the history of artificial indoor lighting from the days of the general use of the candle to the ultra-modern methods of present-day illumination. He was thanked by Lieut. Commander C. P. Edwards and A. K. Hay.

At the conclusion of the meeting refreshments were served.

### SAGUENAY BRANCH

D. S. ESTABROOKS, M.E.I.C. - - *Secretary-Treasurer*  
J. P. ESTABROOK, J.E.I.C. - - *Branch News Editor*

A meeting of the Saguenay Branch was held on December 16th in the Arvida Protestant School.

Before being addressed by the speaker, the members were shown a film on **"Photoelastic Stress Analysis"** as it had been developed and investigated at the University of Manitoba. Transparent plastic models were used in this work and various engineering problems were given attention.

Following this, the speaker, Mr. Jas. A. E. Gohier, was introduced by our chairman, Mr. N. F. McCaghey. As chief engineer of the Quebec Roads Department, Mr. Gohier was able to give a clear and interesting presentation of his subject—**"Road Building in Quebec."**

Three factors must be considered in this work, namely, speed, density of traffic, and the size and nature of the vehicles to be accommodated. The severe changes experienced in these characteristics has demanded an alert and progressive planning of road projects during the past twenty-five years. An outline of the maximum and average traffic densities experienced on the main routes showed this to be the governing factor in the selection of a road type. In this regard, there are four important classes—two-lane, three-lane, four-lane divided and four-lane undivided highways.

A two-lane highway can handle 3,500 cars per day with a percentage of trucks of from fifteen to twenty. However, with variations of crown and other features, the capacity may be reduced to 3,000. The three-lane can accommodate from six to ten thousand cars per day and is usually of concrete or asphalt construction. Although it is in a lower accident class, other characteristics do not usually warrant its use in this province.

The four-lane undivided highway takes care of a traffic flow of from ten to twenty thousand cars and has the advantage of adaptability during peak hours when traffic is predominantly in one direction. At such times three lanes may serve in one direction and one in the other.

In the future we may expect to see our highways constructed with a maximum curvature of four degrees and a greatly increased range of visibility.

The speaker pointed out that accident increase was completely out of proportion to the increase in registration of automobiles and mentioned the aids being provided the driver to induce him to be more careful. Pavement marking machines are in use and 874 miles of pavement have already been marked. The standard highway markings as used in the New York and Ontario road systems are to be closely followed.

Films shown and explained by Mr. Gohier depicted road building as it has recently been carried out in the province. In making the pavements, an eight-inch layer of crushed stone is first put down as a cushion, covered with tar paper, and a concrete layer placed on top of this. This base is still abrasive and a finishing layer of pavement one and a half inches thick completes the road surface. Following this, the new concrete is covered with burlap and then with a special type of curing paper for five-days. Earth is no longer used at this stage of the work.

Special mention was made of the construction of a traffic circle at Dorval and in closing Mr. Gohier stressed the importance of roads in times of an emergency.

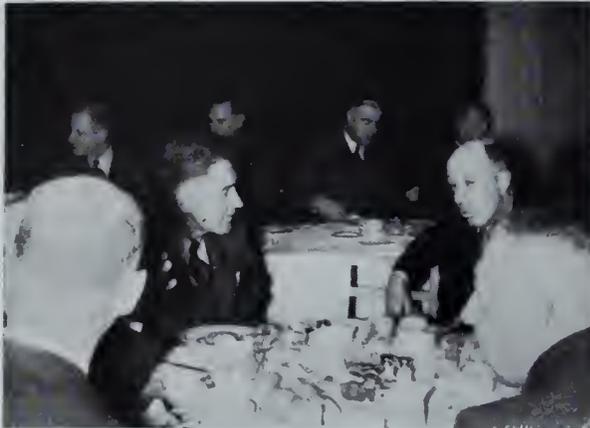

Councillor W. J. W. Reid, Col. D. A. White, Commandant, Army Trades School, Hamilton, and Councillor W. L. McFaul.

Professor E. A. Allcut of Toronto, guest speaker, and W. A. T. Gilmour, Branch Chairman for 1941.

Professor Allcut, W. A. T. Gilmour, General Secretary L. Austin Wright and new Branch Chairman Stanley Shupe.

F. R. Leadlay, H. A. Cooch and J. F. Crowley.

W. E. Sprague, F. H. Midgley, Mark Yong, E. G. Mackay and J. R. Dunbar.

*Left:*  
J. T. Thwaites,  
Geo. Howse and  
J. Elliott.

*Right:*  
N. S. Braden,  
H. A. Lumsden and  
J. Hannaford.

A. J. Turney and T. J. Boyle.

Geo. Foot and C. H. Hutton.

## QUEBEC BRANCH

PAUL VINCENT, M.E.I.C. - *Secretary-Treasurer*

Lundi soir, le premier décembre, les membres de la section de Québec, tenaient leur trente-troisième Assemblée Générale Annuelle, dans la salle de réception de Québec Power à Québec. Cinquante-cinq membres y assistaient.

Après la nomination des scrutateurs chargés de dépouiller le scrutin pour l'année 1941-42, le secrétaire donnait lecture du procès-verbal de l'Assemblée Annuelle du 25 novembre 1940, du rapport du Conseil sur les activités de l'année 1941 et il présentait le rapport financier pour l'année écoulée.

L'assemblée procéda ensuite à la formation des divers comités de la Section, qui s'établissent comme suit:

- Législation:* MM. O. Desjardins, président,  
J. O. Martineau et J. G. O'Donnell.
- Recrutement:* MM. Hector Cimon, président,  
E. D. Gray-Donald et Paul Vincent.
- Excursions:* MM. Théo. Miville Dechêne, président,  
W. R. Caron et Yvon R. Tassé.
- Bibliothèque:* MM. A. V. Dumas, président, René  
Dupuis, Théo. Miville Dechêne, J. O.  
Martineau et Burroughs Pelletier.
- Nominations:* MM. Gustave St-Jacques, Jean St-  
Jacques et Théo. Miville Dechêne.

Les scrutateurs, Yvon de Guise et Lucien Buteau, présentèrent alors leur rapport sur le résultat des élections de la section de Québec pour 1941-42 et le président de l'assemblée, Monsieur L. C. Dupuis, en donna lecture aux Membres comme suit:

- Président:* L. C. Dupuis—réélu par acclamation  
*Vice-Président:* René Dupuis— élu " "  
*Secr.-Trésorier:* Paul Vincent—réélu " "  
*Conseillers élus pour deux ans:* Stanislas Picard  
Ludger Gagnon  
G. W. Waddington.

Trois autres conseillers ont encore un an d'office ce sont: MM. O. Desjardins, R. Sauvage et Gustave St-Jacques.

Le conseil est complété par les membres ex-officio: MM. Hector Cimon, E. D. Gray-Donald, Alex. Larivière, R. B. McDunnough et Philippe Méthé, et enfin Monsieur A. R. Décar, président honoraire à vie de la section de Québec.

Il avait été décidé que la coupe du premier tournoi de golf joué au Royal Quebec Golf Club, le 15 septembre 1941, serait présentée au champion avec les inscriptions de circonstance gravées sur la coupe. Le président, L. C. Dupuis, offrit donc officiellement cette magnifique coupe, donnée par la Maison Geo. T. Davie & Sons, à Monsieur Ph. A. Dupuis, le champion pour 1941. Cette cérémonie raviva des souvenirs nombreux et variés et amena la discussion sur cet événement que tous souhaitent voir se répéter les années prochaines.

L. C. Dupuis, le président réélu, termina l'assemblée en adressant quelques mots aux membres. Il les remercia d'abord de leur vote de confiance en le réalisant pour une seconde année, il exhorta les membres à venir en grand nombre à toutes nos réunions et il les félicita de s'être rendus aussi nombreux à l'Assemblée Annuelle. Il termina ces quelques mots par des tributs marques de reconnaissance à l'adresse des officiers de Québec Power pour avoir mis leur salle à la disposition des membres de la section.

M. Alex. Larivière nous fit ensuite apprécier durant une heure ses talents de cinématographe, en nous promenant autour de notre péninsule Gaspésienne. Ce fut un voyage magnifique. M. Larivière tint toute l'assistance en suspens par des films excitants sur la destruction de la flotte française à Dakar, la chute du Pont Tacoma, et les belles ondines du New York World's Fair.

La réunion se clôtura par des rafraîchissements servis aux membres pendant qu'ils échangeaient leurs vues sur les sujets d'actualité.

Le 15 décembre 1941, la section de Québec avait une des réunions les plus instructives de l'année, dans la Salle des Comités du Château-Frontenac, à 8.15 hrs.

Sous la présidence de Monsieur L. C. Dupuis, président de la section, MM. Gilles E. Sarault, ingénieur régional à Radio-Canada, Poste CBF, et Aurèle Séguin, commentateur de la même Société, nous entretenaient de la radio-diffusion.

Les ingénieurs, accompagnés de leurs épouses ou amies, se rendirent au nombre de 200 pour écouter ces conférences compétentes.

M. G. E. Sarault nous parla de "**La Technique de la Radiodiffusion.**" Il commença par donner à son auditoire un rapide aperçu des principes fondamentaux de la radio; puis il passa à l'application pratique de ces principes, en faisant une revue de l'organisation nécessaire à une radiodiffusion complète. Cette conférence, brillamment illustrée par des projections de diagrammes et de schémas très bien imaginés et de nombreux appareils installés dans la salle, eut un vif succès dont tout le monde parle encore.

M. Aurèle Séguin commenta ensuite un film en couleur préparé par la Société Radio-Canada et présenté pour la première fois à Québec. La Section de Québec de l'Institut profita de cette primeur et sût goûter la merveilleuse présentation de ces films. Chacun eut l'occasion de voir à l'écran ses artistes préférés de la radio dans les sketches populaires "*Pension Velder*," "*Un Homme et son Pêché*," "*S.V.P.*," etc. Ces films commentés par l'excellent conférencier qu'est Monsieur Séguin n'ont pas manqué d'intérêt pour toute l'assistance et ce dernier nous faisait des remarques et des réflexions intéressantes et très instructives, même des vers que nous citons ici:

Si tu veux, faisons un rêve.  
Montons sur deux électrons;  
Tu m'emmènes, je t'enlève,  
Vois! déjà nous démarrons.

Nous filons à toute allure  
Sans quitter notre fauteuil;  
Pas besoin d'autre monture  
Pour faire un voyage à l'oeil.

Autrefois les pauvres types  
Qui voulaient franchir l'octroi,  
Risquant de casser leur pipe,  
Enfourchaient un palefroi.

Pour aller chercher fortune  
Chez le Turc ou le Castillan,  
Il suffit, chose opportune,  
D'un' p'tite antenne d'appartement.

Les conférenciers ont été ensuite remerciés: Monsieur Gilles Sarault par un de ses confrères de McGill, Monsieur Henri F. Béique, et Monsieur Aurèle Séguin par Monsieur Philippe Méthé.

Monsieur Adrien Morin, l'auteur de ces films était à l'appareil de cinématographie et de reproduction. Ces films des mieux réussis furent vivement appréciés par tout l'auditoire.

La soirée eu le résultat d'enthousiasmer tout le monde, tel qu'on pouvait s'y attendre.

## SASKATCHEWAN BRANCH

STEWART YOUNG, M.E.I.C. - - - *Secretary-Treasurer*

The Saskatchewan Branch met in joint session with the Association of Professional Engineers and the American Institute of Electrical Engineers at the Kitchener Hotel, Regina, on Tuesday evening, December 16th, 1941, to hear an address by Major T. G. Tyrer, recently returned from overseas. The meeting was preceded by the usual dinner, at which 30 members and guests were in attendance.

Major Tyrer gave an outline of his personal experiences while on active service, following which there was a general discussion on conditions in the old land and a hearty vote of thanks to the speaker.

**JOINT MEETING OF INSTITUTE BRANCHES IN NEW BRUNSWICK AND ASSOCIATION OF PROFESSIONAL ENGINEERS—for Signing of Co-operative Agreement.**

G. L. Dickson, immediate Past-President of the Association and Councillor of the Institute representing the Moncton Branch.

A. A. Turnbull, C. C. Kirby, signing the agreement, G. L. Dickson and Hon. J. B. McNair, Premier of New Brunswick.

Above: Left to right around the table, T. C. Macnabb, W. A. S. McLanson, D. C. Oxley, F. G. Thompson, A. R. Bennett.

Left: Premier J. B. McNair, F. O. Condon and Vice-President K. M. Cameron.

Right: H. R. Logie, A. R. Crookshank, Past-President H. W. McKiel addressing the meeting, and A. O. Wolff.

Sydney Hogg, R. Judge, C. C. Kirby, F. A. Patriquen, W. Ganderton.

Left to right around the table, Councillor G. G. Murdoch, G. A. Vandervoort, H. W. McKiel, A. O. Wolff, A. Gray, J. P. Mooney.

## ST. MAURICE VALLEY BRANCH

C. G. DE TONNANCOUR, S.E.I.C. - *Secretary-Treasurer*

On December 3rd, at 8 p.m., in the Cascade Inn, Shawinigan Falls, the members of the Shawinigan Chemical Institute and the Canadian Club were guests of the St. Maurice Valley Branch, forming an audience of over a hundred.

The subject under discussion was a difficult and controversial one, indeed, the St. Lawrence Deep Sea Waterway, but it was very well treated by our members, Messrs. J. R. Eastwood, of Grand'Mère; R. H. Ferguson, of Trois-Rivières; and J. W. Stafford, of Shawinigan Falls; and illustrated by up-to-date maps and charts prepared for the occasion by the speakers.

The meeting was jointly presided over by Dr. A. H. Heatley, Branch Chairman, and Mr. Hembly, Chairman of the Chemical Institute. Due to the last minute absence of Mr. Stafford, Dr. Heatley delivered his paper, while Mr. Timmis replaced Dr. Heatley in the chair.

The evening was a success, and the credit goes to our speakers who must have spent considerable time and effort in its preparation. Their aim was to give the audience a clearer knowledge of the work already done, of the size and cost of the enterprise, and of the immediate results of its realization.

The speakers were purely objective in their views. A general discussion followed, Messrs. E. R. Williams, Hembly, E. B. Wardle and A. H. Heatley being the leading contributors, among many others.

## VICTORIA BRANCH

J. H. BLAKE, M.E.I.C. - - - - *Secretary-Treasurer*

The University of Manitoba film, "Photoelastic Stress Analysis," kindly loaned to the Victoria Branch through Professor A. E. Macdonald of the Department of Civil

Engineering, was the subject of a very interesting hour following the annual meeting of the branch on January 16th.

This film was taken around a series of particularly interesting experiments based on the study of internal stresses in plastic models of structures by means of the application of the principle of polarized light. Prior to the showing of this film, the executive of the branch arranged for a brief explanation of the principle of polarized light by a recent graduate of the University of British Columbia, Mr. Wm. H. Mathews, of the Provincial Department of Mines. Mr. Mathews' explanations greatly assisted in a more complete understanding of the experiments shown on this film.

The film deals with the preparation of suitable plastics for the construction of models by which stresses due to various fixed and movable loads are studied by means of the passage of light being controlled by means of polarization. By rotation of these planes the internal stresses can be visibly plotted and studied as by no other means, and pictorial records of them made. A number of various models are studied under actual proportionate load conditions and the resulting stresses, many of which are shown by coloured bands, can be seen under duplicated operating conditions. This process opens up an entirely new field for the determination of internal stresses otherwise only obtainable by theoretical mathematical calculations.

It is a long time since any engineering subject has provoked such a lengthy discussion period following presentation as that resulting from the showing of this film, and the University of Manitoba and Professor Macdonald in particular are to be complimented on the production of this film and for making it available to the branches of the Institute.

This branch is looking forward to an active and interesting year under the direction of the new officers elected at this annual meeting.

# News of Other Societies

## ASSOCIATION OF PROFESSIONAL ENGINEERS OF ONTARIO

Warren C. Miller, M.E.I.C., City Engineer, St. Thomas, has been elected president of the Association of Professional Engineers of the Province of Ontario and assumed office at the General Meeting of the Association which was held in the Royal York Hotel, Toronto, on January 17th.

Warren C. Miller, M.E.I.C.

Born in Point Edward, Ontario, he received his preliminary education at St. Thomas. After graduating from Queen's University in 1917, he served overseas with the Royal Canadian Engineers. In 1919, he went to St. Thomas

## Items of interest regarding activities of other engineering societies or associations

as an inspector in the city engineer's department. Six months later he was appointed city engineer, a position which he has held continuously since that time.

Major Miller has been a member of the Council of the Association for the past four years, and during that time has been chairman of the Legislation Committee. He is a past-president of the Canadian Institute on Sewage and Sanitation, a past chairman of the Canadian Section of the American Waterworks Association, and has served on the Council of The Engineering Institute of Canada. He was a member of the committee appointed jointly by the American Waterworks Association and the Municipal Finance Officers' Association that prepared the new waterworks accounting manual. He is also a member of the American Public Works Association.

Most of his spare time is devoted to his job as Churchwarden which he has held for eight years. He is also Lay Chairman of the Archdeaconry of Elgin and a member of the Executive Committee of the Synod of Huron.

The following have been elected as members of the Council of the Association of Professional Engineers of the Province of Ontario for the year 1942:

VICE-PRESIDENT: R. A. Elliott, General Manager, Deloro Smelting & Refining Co. Ltd., Deloro; PAST-PRESIDENT: S. R. Frost, M.E.I.C., Sales Director, North American Cyanamid Ltd., Toronto.

COUNCILLORS: *Civil Branch*—J. Clark Keith, M.E.I.C., General Manager, Windsor Utilities Comm., Windsor; J. L. Lang, M.E.I.C., Lang & Ross, 620 Queen St., Sault Ste. Marie; N. D. Wilson, M.E.I.C., Wilson & Bunnell, 388 Yonge

St., Toronto; *Chemical Branch*—R. M. Coleman, Smelter Supt., International Nickel Co. of Canada Ltd., Copper Cliff; E. T. Sterne, Manager, G. F. Sterne & Sons Ltd., Brantford; H. P. Stockwell, Chem. Engr., Ottawa Water Purification Plant, Ottawa; *Electrical Branch*—M. J. Aykroyd, Outside Plant Engineer, Bell Telephone Co. of Canada Ltd., Toronto; C. P. Edwards, M.E.I.C., Deputy Minister, Dept. of Transport, Ottawa; H. J. MacTavish, Secretary, Toronto Electric Commissioners, Toronto;

*Mechanical Branch*—C. C. Cariss, M.E.I.C., Chief Engr., Waterous Limited, Brantford; G. Ross Lord, M.E.I.C., Asst. Professor of Mechanical Engrg., University of Toronto; K. R. Rybka, M.E.I.C., Associate, Walter J. Armstrong, Cons. Engr., 989 Bay St., Toronto; *Mining Branch*—J. M. Carter, Mill Supt., McIntyre-Porcupine Mines Ltd., Schumacher; C. H. Hitchcock, Vice-President, Smith & Travers Co. Ltd., Sudbury; D. G. Sinclair, Asst. Deputy Minister, Ontario Dept. of Mines, Toronto.

### Book notes, Additions to the Library of the Engineering Institute, Reviews of New Books and Publications

#### BOOK NOTES

The following notes on new books appear here through the courtesy of the Engineering Societies Library of New York. As yet the books are not in the Institute Library, but inquiries will be welcomed at headquarters, or may be sent direct to the publishers.

#### ACOUSTICS OF BUILDINGS, including Acoustics of Auditoriums and Sound-proofing of Rooms

By F. R. Watson. 3 ed. John Wiley & Sons, New York; Chapman & Hall, London, 1941. 171 pp., illus., diags., charts, tables, 9½ x 6 in., cloth, \$3.00.

This well-known text has been rewritten to take account of developments during the last ten years, and again offers a convenient account of current opinion and practice. The conditions for perfect acoustics, the behavior of sound waves in rooms, the design of auditoriums and methods of sound insulation are discussed in detail.

#### AIR BASE

By B. T. Guyton. McGraw-Hill Book Co. (Whittlesey House), New York and London, 1941. 295 pp., illus., 8½ x 5½ in., cloth, \$2.50.

In narrative style the author describes the environment and activities of a modern air base from his personal experience. The training of pilots, the how and why of cruises, and the human side of life in the squadrons are some of the topics considered in this picture of air base life for the layman.

#### AN APPROXIMATE MEASURE OF EARTHQUAKE EFFECT ON FRAMED STRUCTURES

By R. S. Chew. Revised June 25, 1941. Richard Sanders Chew, 844-a Mills Building, San Francisco, Calif. 96 pp., diags., charts, tables, 11 x 8½ in., paper, manifold, \$5.00.

The intention of this work is to provide architects and engineers with a practical viewpoint and solution of the earthquake problem within certain defined limits. The major part of the book consists of a practical rather than mathematical attempt to indicate approximately the effect on a structure of oscillation of its foundation in a horizontal direction. A theoretical treatment of the problem is appended.

#### BELT CONVEYORS AND BELT ELEVATORS

By F. V. Hetzel and R. K. Albright. 3 ed. rev. & enl., John Wiley & Sons, New York; Chapman & Hall, London, 1941. 439 pp., illus., diags., charts, tables, 9½ x 6 in., cloth, \$6.00.

This standard work on belt conveyors and belt elevators explains the principles of these mechanisms in a comprehensive, practical manner. Belt manufacture is covered, driving

*Area, Quebec, by H. C. Gunning, Memoir 231; Mining Industry of Yukon, 1939 and 1940, by H. S. Bostock, Memoir 234.*

##### Portland Cement Association:

*Continuous hollow girder concrete bridges. 39 pages.*

and supporting equipment is discussed, particular uses for certain types of conveyors are indicated, and reasons are given for the various technical details described.

### **BOULDER CANYON PROJECT FINAL REPORTS. Part IV—Design and Construction**

*Bulletin 1—General Features. 301 pp.*  
*Bulletin 2—Boulder Dam. 253 pp.*  
*U.S. Dept. of the Interior, Bureau of Reclamation, Denver, Colorado, 1941.*  
*Illus., diagrs., charts, tables, maps, 9½ x 6 in., cloth, \$2.00 each; paper, \$1.50 each.*

Continuing the series on the Boulder Canyon project, the present bulletins deal with design and construction work. Bulletin 1 presents general descriptive information about the preliminary construction, the power plant and other appurtenances to the dam, Lake Mead and the All-American Canal system. Bulletin 2 presents detailed data and information regarding the design and construction of the dam itself.

### **BRIDGES AND THEIR BUILDERS**

*By D. B. Steinman and S. R. Watson.*  
*G. P. Putnam's Sons, New York, 1941.*  
*379 pp., illus., diagrs., woodcuts, 9 x 6 in., cloth, \$3.75.*

The development of the bridge through the ages is told in narrative style. The bridges are considered not only as pieces of engineering construction but also as expressions of the periods in which they were erected, and the characters and achievements of the builders are set forth against the background of the conditions under which they worked. With respect to the more important bridges a considerable amount of technical and factual data has been included.

### **CAREER IN ENGINEERING, Requirements, Opportunities**

*By L. O. Stewart. Iowa State College Press, Ames, Iowa, 1941. 87 pp., illus., tables, 9 x 6 in., paper (\$0.75, single copies; \$0.50 for five or more).*

The first objective of this booklet is to furnish information about engineering to young men who are considering a career in that field. To do this the author presents answers for the three standard questions: what does an engineer do; what are the necessary qualifications; and what are the prospects for the future in the field.

### **CIVIL DEFENCE**

*By C. W. Glover. 3 ed. revised and enlarged. Chemical Publishing Co., Brooklyn, New York, 1941. 794 pp., illus., diagrs., charts, tables, 9 x 5½ in., cloth, \$16.50.*

This practical manual presents, with working drawings, the methods required for adequate protection against aerial attack. The comprehensive nature of the work is indicated by the inclusion of material on bombs and their effects, war gases, camouflage, civilian instruction, training of A.R.P. personnel, and cost estimates (British figures), in addition to the large amount of space devoted to the construction of all types of protective buildings and shelters. There is a bibliography.

### **COLLECTIVE WAGE DETERMINATION**

*By Z. C. Dickinson. Ronald Press Co., New York, 1941. 640 pp., diagrs., charts, tables, 8½ x 6 in., cloth, \$5.00.*

Problems and principles in bargaining, arbitration and legislation are discussed in this general treatment of the question of remuneration of workers. The material is divided into five parts, as follows: survey of the field; factors commonly invoked in collective wage adjustments; wages and industrial fluctuations; wage policies and practices in private collective bargaining; and influences of public policy on wages.

### **ELECTRIC POWER STATIONS, Vol. I**

*By T. H. Carr, with a foreword by Sir L. Pearce. D. Van Nostrand Co., New York, 1941. 376 pp., illus., diagrs., charts, tables, 9 x 5½ in., cloth, \$7.50.*

Volume I of this work on electric power stations deals mainly with the mechanical engineering aspects. Topics treated include the circulating water system, cooling towers, coal and ash handling, the boiler plant, pipe-work and turbines. There is an introductory chapter on design fundamentals, and the construction and layout of buildings are covered. Many sketches and diagrams illustrate the text.

### **ELECTRICAL WIRING SPECIFICATIONS**

*Edited by E. Whitehorne. McGraw-Hill Book Co., New York and London, 1941.*  
*181 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, \$2.50.*

This book is a simple working guide for those concerned with the design of wiring installations, laying out systems and preparing specifications for any given job in an industrial, commercial or residential building.

### **ENGINEERING ELECTRICITY**

*By R. G. Hudson. 3 ed. John Wiley & Sons, New York, 1941. 284 pp., illus., diagrs., charts, tables, 8 x 5 in., lea., \$3.00.*

Written primarily for technical students not specializing in electrical engineering, this textbook is designed to provide a course with a broad objective. To this end an outline is presented of the fundamental principles and of the applications of electricity and magnetism most frequently encountered in engineering practice. There is a large section of practice problems with answers.

### **ENGINEERING TOOLS AND PROCESSES, a Study of Production Technique**

*By H. C. Hesse. D. Van Nostrand Co., New York, 1941. 627 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, \$4.50.*

Engineering shop processes and practices are covered by this comprehensive text. The first three chapters offer a survey of basic materials, elements and devices. The text then takes up the usual shop processes and machines for foundry work, wood shop and machine shop. Succeeding chapters discuss production machinery and processes not ordinarily presented in college laboratories, and illustrates their application to the manufacture of specific parts. A large bibliography and a section of questions and problems are appended.

### **GASEOUS CONDUCTORS, Theory and Engineering Applications. (Electrical Engineering Texts)**

*By J. D. Cobine. McGraw-Hill Book Co., New York and London, 1941. 606 pp., illus., diagrs., charts, tables, 9½ x 6 in., cloth, \$5.50.*

Discussion of the fundamental principles of physics involved in the conduction of electricity in gases is combined with a complete presentation of the field of application in engineering. The treatment is thorough and logical, and covers the principles essential to an understanding of conduction phenomena, such as the kinetic theory of gases, ionic motion, atomic structure, ionization and de-ionization processes, emission phenomena and space charge effects.

### **HANDBOOK FOR CIVILIAN DEFENCE**

*By H. Mayer-Dexland. Civilian Advisory Service, 41 Park Row, New York, 1941.*  
*88 pp., illus., diagrs., 9 x 6 in., paper, \$1.00.*

This elementary handbook for civilian defence workers has two objectives. First, it deals in a simple, concise manner with all phases of civilian defence training and organization for war conditions; and second, it shows the value of such training for various peace-time emergencies and natural disasters.

### **HOUSING FOR HEALTH, Papers Presented under the Auspices of the Committee on the Hygiene of Housing of the American Public Health Association**

*Science Press Printing Co., Lancaster, Pa., 1941. 221 pp., diagrs., charts, tables, 9 x 6 in., paper, \$1.00.*

A variety of subjects is considered in this collection of papers presented under the auspices of the American Public Health Association. Housing codes and surveys, slum-clearance, health and recreational facilities in housing projects, noise control, house construction, and social implications are among the topics dealt with by various authorities in the field.

### **AN INTRODUCTION TO THE OPERATIONAL CALCULUS**

*By W. J. Seeley. International Textbook Co., Scranton, Pa., 1941. 167 pp., diagrs., tables, 8½ x 5 in., cloth, \$2.00.*

The first part of this book is devoted to a rapid review of long established methods of solving linear differential equations with constant coefficients. The use of the notation and nomenclature of the operational calculus prepares the student for the development of the operational method which, with its applications, mainly to circuit analysis, occupies the rest of the book.

### **MACHINE SHOP, Theory and Practice**

*By A. M. Wagener and H. O. Arthur. D. Van Nostrand Co., New York, 1941.*  
*306 pp., illus., diagrs., charts, tables, 11 x 8½ in., cloth, \$2.28; paper, \$1.60.*

The introductory and closing chapters of this textbook for beginners and apprentices in the machine trades describe respectively the commonly used precision and semi-precision tools found in the shop, and the uses of the so-called bench tools and small hand tools. The construction and operation of the various machines, from shapers to grinders, are dealt with in between in a practical order and manner. Safety suggestions, review questions and many illustrations are included.

### **OUTLINES OF PAINT TECHNOLOGY, based on Hurst's "Painters' Colours, Oils and Varnishes"**

*By N. Heaton. 2 ed. rev. J. B. Lippincott Co., Phila. and New York, 1940. 413 pp., illus., diagrs., tables, 9 x 6 in., cloth, \$12.00.*

Concise, practical information concerning the raw materials and manufacture of all types of paints and of many allied compounds is presented in this general guide for students of paint technology. The various pigments, driers, solvents, etc., are described and this new edition has an added chapter on synthetic resins. A bibliography and glossary of the names of pigments are appended.

### **PLASTICS MOLD DESIGNING**

*By G. B. Thayer. American Industrial Publishers, Cleveland, Ohio, 1941. 64 pp., illus., diagrs., tables, 9½ x 6 in., cloth, \$2.50.*

The fundamentals of plastics mold design are discussed and applied to representative types of compression and injection molds. Some space is devoted to fixtures, mold sinking methods are described, and product design is discussed in relation to mold building methods. There is a glossary.

### **PRACTICAL MATHEMATICS FOR SHIPFITTERS and Other Shipyard Workers**

*By L. Q. Moss. Pitman Publishing Corp., New York and Chicago, 1941. 108 pp., diagrs., charts, tables, 8½ x 5 in., cloth, \$1.50.*

This simple presentation of mathematics is intended for use by organizations participating in the current programme for training shipyard workers. Every problem illustrates an application of a mathematical process to a real trade situation, and the text has been thoroughly tested in the classroom.

(Continued on page 123)

# PRELIMINARY NOTICE

of Applications for Admission and for Transfer

January 30th, 1942.

The By-laws provide that the Council of the Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.—

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

**Communications relating to applicants are considered by the Council as strictly confidential.**

The Council will consider the applications herein described at the March meeting.

L. AUSTIN WRIGHT, General Secretary.

\*The professional requirements are as follows:—

A **Member** shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupillage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science or engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A **Junior** shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A **Student** shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An **Affiliate** shall be one who is not an engineer by profession but whose pursuits, scientific attainment or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

## FOR ADMISSION

ALLAN—GEORGE WILLIAM, of 3814-14th Ave. West, Vancouver, B.C. Born at Stirling, Scotland, Sept. 28th, 1889; Educ.: 1909-11, Technical College, Glasgow; R.P.E. of B.C.; 1905-11, ap'ticeship, 5 years all depts., 1 year, engrg. office, Mirrless-Watson Co., Glasgow; 1911-12, engrg. office, B.C. Sugar Refining Co., Vancouver; 1912-18, Allan and McKelvie, Engineers, Vancouver; 1918-26, vice-president, 1926 to date, president, Canadian Sumner Iron Works Ltd., Vancouver. (Designing and manufacturing of steam engines, saw mill, pulp mill and shingle mill machy., coal stokers, steam marine steering engines, and ships equipment).

# Employment Service Bureau

## SITUATIONS VACANT

**MECHANICAL DESIGNING DRAUGHTSMAN.** Graduate preferred, urgently needed for work in Arvida for specification drawings for plate work, elevators, conveyors, etc., equipment layouts, pipe layouts and details. Apply to Box No. 2375-V.

**MECHANICAL GRADUATE ENGINEER** with machine shop experience required for work in Mackenzie, British Guiana, on essential war work. Apply to Box No. 2441-V.

**ENGINEERING DRAUGHTSMAN** with experience in machine and structural design, proficient in steel design calculation, and having ability for estimating. We require a man with at least five years' industrial experience, preferably in the paper mill field. Position is permanent. State experience and give physical description. Include small photograph and a sample of draughtsmanship. Apply to Box No. 2458-V.

**MECHANICAL DRAUGHTSMAN**, experienced in making layouts for various installations, piping, etc., around a paper mill. Applicant must be a college graduate. State previous experience, wages expected, etc. Apply to Box No. 2461-V.

**GRADUATE MECHANICAL ENGINEER** required for Mackenzie, B.G., immediately on work of plant and mining equipment maintenance. We are prepared to do necessary training which will give exceptional opportunity for experience. Apply to Box No. 2481-V.

**MECHANICAL ENGINEER** preferred with experience on diesels and tractors, for work in Mackenzie, B.G. Apply to Box No. 2482-V.

**MECHANICAL DRAUGHTSMEN** and engineers for pulp and paper mill work. Experienced men preferred. Good salary to qualified candidates. Apply to Box No. 2483-V.

**ELECTRICAL ENGINEER**, young French Canadian graduate engineer to be trained on work involving hydro-electric plant operation, transmission lines and construction, meter testing and inspection. Good opportunity to acquire first-hand electrical power experience. Apply to Box No. 2487-V.

**GRADUATE DRAUGHTSMAN**, for industrial plant design and detailing. Apply to Box 2497-V.

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party. Notices appearing in the Situations Wanted column will be discontinued after three insertions, and will be re-inserted upon request after a lapse of one month. All correspondence should be addressed to THE EMPLOYMENT SERVICE BUREAU, THE ENGINEERING INSTITUTE OF CANADA, 2050 Mansfield Street, Montreal.

**MECHANICAL DRAUGHTSMAN**, for piping and general equipment layout work. Apply to Box 2498-V.

**CIVIL ENGINEER**, 25-32 years of age, for heavy construction work in British Guiana. Apply to Box 2499-V.

**MECHANICAL ENGINEER**, for general maintenance work at Arvida, Que. Apply to Box 2500-V.

## ENGINEER OFFICERS WANTED

Applications are invited for Commissions in the Royal Canadian Ordnance Corps for service both overseas and in Canada as Ordnance Mechanical Engineers. Since it is probable that several new units will be organized in the near future, a number of senior appointments may be open, and applications from engineers with a good background of military experience would be welcomed in this connection. Applications should be submitted on the regular Royal Canadian Ordnance Corps application forms, which can be obtained from the District Ordnance Officers of the respective Military Districts.

## SITUATIONS WANTED

**ELECTRICAL ENGINEER**, B.E., in electrical engineering, McGill University, Age 24, married, available on two weeks notice. Undergraduate experience, cable testing and cathode ray oscillography. Since graduation, five months on construction of large and small electrical equipment in plant and sub-station. One year operating electrical engineer in medium size central steam station paralleled with large Hydro system. At present employed, but is interested in research or teaching. Associate member of the American Institute of Electrical Engineers. Apply to Box No. 2419-W.

**CIVIL AND STRUCTURAL ENGINEER**, M.E.I.C., R.P.E. (Ont.), Age 49. Married. Home in To-

ronto. Experience in Britain, Africa, Canada, Turkey. Chief engineer reinforced concrete design offices, steelworks construction. Resident engineer design and construction munitions plants, and general civil engineering work. Extensive surveys, draughting, harbour and municipal work. Location immaterial. Available now. Apply Box No. 2425-W.

**ELECTRICAL, MECHANICAL ENGINEER**, age 35. Dip. and Assoc. R.T.C., Glasgow, A.M.I.E.E., (Students Premium) G.I. Mech.E., M.E.I.C., Assoc. Am.I.E.E. Married. Available after December 22nd. Seventeen years experience covering machine shop apprenticeship, A.C. and D.C. motors, transformers, steel and glass bulb arc rectifiers, design, testing and erection sectional electric news and fingerprints paper machine drives, experience tap changers H.V., L.V and marine switchgear. Apply to Box No. 2426-W.

**MECHANICAL ENGINEER** age 55 years. Married. Available at once. Thirty years experience in draughting and general machine shop and foundry work. Fifteen years as works manager. Considerable experience in pump work, including estimating and inspection. Apply to Box 2427-W.

**ELECTRICAL ENGINEERING** student in third year, age 27, desires summer position starting in April, with view to permanency on graduation. Two summers on design of shop equipment and electrical apparatus. Three years experience on test and experimental work for relays and control equipment. Student E.I.C., and Associate member American Institute of Electrical Engineers. Location immaterial. Apply to Box No. 2428-W.

**ENGINEER ADMINISTRATOR**, experienced in public utilities, shipyard construction, airplane construction, crane construction, general mechanical engineering and inspection work, also sales promotion. Open for appointment. Apply to Box 2429-W.

## LIBRARY NOTES (Continued)

**PRINCIPLES OF SEWAGE TREATMENT.** (National Lime Association Bulletin 212)

By W. Rudolfs. National Lime Association, Washington, D.C., 1941. 128 pp., illus., diags., charts, tables, 9 x 6 in., paper, \$0.50

This booklet has been prepared for those who desire information on the subject but lack the time or training for an extended study. The sources and composition of sewage are briefly noted, the microbiology of sewage treatment and sewage stabilization are discussed, methods of treatment, disposal and analysis are described, and plant operation is covered.

**RHOMBIC ANTENNA DESIGN**

By A. E. Harper. D. Van Nostrand Co., New York, 1941. 111 pp., diags., charts, tables, 11½ x 8½ in., cloth, \$4.00.

This is an eminently practical discussion of the design and construction of rhombic antennas, based upon the work of the engineers of the Bell Telephone System. Much of this has been unpublished heretofore. An introduction discusses directional radio transmission. This is followed by a description of methods for designing horizontal rhombic antennas and for their construction. The data needed in computation are included, and plans of typical transmitting and receiving antennas are appended.

**TECHNICAL REPORT WRITING.** (Chemical Engineering Series)

By F. H. Rhodes. McGraw-Hill Book Co., New York and London, 1941. 125 pp., charts, tables, 9½ x 6 in., cloth, \$1.50.

This guide to report writing is based on long experience in teaching the art to engineering students and can be recommended as

an excellent one. By confining himself to reports, and omitting the material on other technical writing usually found in texts on the subject, the author has been able to cover the subject thoroughly and practically in a small book.

## TRAINS IN TRANSITION

By L. Beebe. D. Appleton-Century Co., New York and London, 1941. 210 pp., illus., tables, 11½ x 8 in., cloth, \$5.00.

The third of Mr. Beebe's books on American railroading offers the same attractive combination of readable text and excellent photographs that its predecessors displayed. In this volume, the author is concerned with the changes in practice and equipment which have taken place in recent years, especially the effects of the diesel-electric locomotive, light weight cars and air-flow design.

Look at it from any angle...

It's in your own interest to

"INVEST" in CANADA'S VICTORY BONDS

## STEAM JET EJECTORS

Elliott Company, Jeannette, Pa., has recently issued a 32-page booklet G-7 which, accompanied by many illustrations, describes the company's single-stage, two-stage, three-stage, four-stage and five-stage ejectors and also contains sections dealing with the many advantages of the steam ejector, ejector characteristics and factors affecting ejector selection. The final section features, under several main classifications, the fields in which ejectors are used most extensively. A pressure-temperature conversion table and other data are also included.

## TOOLING TURRET LATHES

A 4-page Bulletin, No. 141, published by Kennametal of Canada Ltd., Hamilton, Ont., features the use of Kennametal steel cutting carbide tools for tooling turret lathes for small lot production. Includes turret lathe setups using Kennametal tools.

## WATER TREATMENT

"Supplementary Treatment of Boiler Feedwater" is the title of a 12-page Bulletin, No. 2420, made available by the Permutit Co. of Canada Ltd., Montreal, Que. Presents a complete discussion on the supplementary treatment of boiler feedwater by the addition of chemicals to the water at various points in the feedwater line and the methods of feeding these chemicals. Such treatment generally consists in feeding phosphate, sodium sulphate, and sodium sulphite in varying amounts.

## PUBLICATIONS AVAILABLE

An 8-page List "B" entitled "List B For Facts About Monel, Rolled Nickel and Inconel," recently issued by The International Nickel Co. of Canada Ltd., Toronto, Ont., contains a list of current publications of the company with the various bulletins and booklets grouped under various classifications or under the names of industries to which they are most pertinent. A number of new publications issued since the last edition of the list are included.

## DRILLING MACHINES

Canadian Blower & Forge Co. Ltd., Kitchener, Ont., has available a 16-page Bulletin, No. 2730-D, which describes the company's "Buffalo No. 16" drilling machines (No. 2 Morse Taper). These machines are available in 1 to 6 spindles, with 8-in., 12-in., and 15-in. overhang, and in sensitive type or power feed according to the descriptions, illustrations, and tables and specifications contained in this bulletin. Round column floor, bench, and pedestal types are shown.

## INDICATING INSTRUMENTS

The company's line of "U-Type" and "Well-Type" manometers, draft gauges, flow meters, mercury pressure gauges, tank gauges and accessories for accurately measuring pressures, vacuums and flows of liquids and gases are described in the 8-page Catalogue, No. C-10, published by the Meriam Company, Cleveland, Ohio. Illustrations and descriptions of the equipment, suggestions for use, size ranges, dimensions, weights, list prices, etc., are also included.

## DISTRIBUTOR APPOINTED

It is announced that the X-Pando Corp., New York, have appointed LaSalle Products Limited, Montreal, as Canadian distributors for their complete line of materials. X-Pando is a compound which expands after setting, preventing all leaks and making a perfect tight bond. The distribution of this product in Canada will be under the supervision of E. F. Vincent, who is well-known to the industrial trade.

## Industrial development — new products — changes in personnel — special events — trade literature

### MECHANICAL RUBBER GOODS

Dunlop Tire and Rubber Goods Co. Ltd., Toronto, Ont., has issued a 36-page Catalogue, No. 104, which contains descriptive and technical data with accompanying illustrations covering the company's wide range of mechanical rubber goods including various types of belts, conveyors, launder lining, agricultural supplies, hose, rubber covered rolls, mats, packing, tape and miscellaneous items.

### PUMPS FOR DIVERSIFIED INDUSTRIAL APPLICATION

Practical information concerning pump adaptation for a wide range of duties under varying conditions is the theme of a new 24-page Bulletin, No. 29-A107, published by the Pomona Pump Co., Pomona, Calif. It describes and illustrates a variety of actual applications, accompanying each with an installation drawing. The design of the Pomona pump is also illustrated and explained.

### INDUSTRIAL ADVERTISING USED TO AID WAR EFFORT

During the past year many advertisers of industrial equipment have developed the theme of their copy along lines directed towards the publicizing of some branch of Canada's war effort.

Some of these advertisements feature specific developments in war industries; others carry messages of the importance of subscribing to Canada's Victory Loan; while others have adopted more diversified themes intended to emphasize the great cause for which everyone is playing his part. Outstanding in this category is the series of inserts published by the Canadian SKF Company Limited. This issue of *The Journal* contains a number of these special advertisements, among which may be mentioned those of Northern Electric Co. Limited, Canadian Ingersoll-Rand Co. Limited, and Canadian Controllers Limited.

Commencing with the March issue of *The Journal*, the English Electric Co. of Canada Limited will run the first of a special series of advertisements designed for reproduction as posters. One of these advertisements, reproduced in miniature, is shown below. Copies of this series, in wall poster size, will be supplied by the company to any interested parties upon request.

### HEATING SYSTEMS AND PRODUCTS

C. A. Dunham Co. Ltd., Toronto, Ont., has released a series of looseleaf data sheets for inclusion in their engineering catalogue on "Dunham" heating systems and products. There are seventeen of these sheets covering control equipment, convectors and unit heaters.

### ONTARIO REPRESENTATIVE APPOINTED

The Permutit Co., New York, N.Y., has recently appointed S. A. McWilliams Ltd. as its representative in the Province of Ontario. The company continues to be represented in Montreal by C. K. McLeod and in Winnipeg and Calgary by Stanley Brock Ltd.

### NEW LINE ANNOUNCED

Burlec Limited are building in Canada an extensive range of gasoline engine electric power supplies for use as emergency supplies of lighting or power. These are available in sizes up to 60 kilowatts and for all voltages and frequencies. The gasoline engines have automatic speed governors and the generators are controlled by voltage regulators so as to give a smooth, closely regulated power output. The controls provided include complete gasoline engine instruments such as temperature gauge, ammeter, fuel gauge, oil pressure gauge and tachometer. The generator output is controlled by an appropriately sized switch which is trip free and has thermal overload. Necessary meters are also supplied.

### FUSE CUTOUTS

"A 3-Minute Story of the 'PVD' Fuse Cutout," the title of a 20-page booklet published by Canadian Line Materials Ltd., Toronto, Ont., presents the story in a novel manner by the use of an ingenious design of the booklet. In order to show the action of the fuse, a large cutaway illustration is used with short and long pages superimposing the part of the illustration showing each change so that the complete sequence of action from the initial fused state to the final "blown" state is depicted graphically. Each action is described, while the simplicity of "re-fusing" and other important features are explained in detail and illustrated.

### NEW C-G-E COLOUR MOVIE

Canadian General Electric's latest movie entitled "Curves of Colour," highlights scenes of the experiments performed by Sir Isaac Newton discovering the visible spectrum and an explanation of why that spectrum is only one small part of the vast electro-magnetic spectrum which has since been discovered by modern men of science. The film explains a new scientific device called a recording photoelectric spectrophotometer which is capable of distinguishing accurately more than two million colours. This ten-minute movie is one of a number that the company lends, free of charge, to educational institutions, churches, social and civic groups, etc.

### NEPTUNE BUILDS NEW PLANT

As announced by Mr. W. T. Randall, vice-president and general manager of Neptune Meters Ltd., Toronto, the company moved into its new plant on December 29th. The new Neptune Meter plant is located in Long Branch, with 400 feet frontage on Lakeshore Road. It occupies 10 acres and offers 30,000 square feet of floor space. Designed by T. Pringle & Son, industrial engineers, the new Neptune Meter plant is of structural steel and brick construction.

## LIST OF INSTITUTE MEDALS AND PRIZES

Sir John Kennedy Medal	For outstanding merit or noteworthy contribution to science of engineering, or to benefit of the Institute.	Leonard Medal	Gold medal	For a paper on a mining subject, open to members of the Canadian Institute of Mining and Metallurgy as well as The Engineering Institute.
Duggan Medal and Prize	Medal and cash to value of \$100	Students and Juniors	Books to the value of \$25 (5 prizes)	For papers on any subject presented by Student or Junior members.
Gzowski Medal	Gold medal	University Students	\$25 in cash (11 prizes)	For the third year student in each college, making the best showing in college work and activities in student or local branch of engineering society.
Plummer Medal	Gold medal			

## A NEW FIELD AND A NEW EMPHASIS

IN THE affairs of both men and institutions there are times when, after long uncertainty and painful orientation, the way of progress becomes clear and notable advances are made with comparative ease. During the pause which follows, gains are consolidated, new plans are developed and in due season the forward movement is resumed.

Such has been the lot of the engineering profession in Canada. Its early years were devoted to laborious technological tasks, well and faithfully performed—tasks that brought to the engineer heightened prestige and the confidence of the public in his ability and integrity. Thus was laid the sure and firm foundation of trust upon which wider recognition of engineering as a learned profession was to be reposed.

With the outbreak of total mechanized war, governments and corporations have instinctively turned to the engineer as one possessing not merely the indispensable technical background but that decisiveness, dependability and sense of proportion everywhere sought in times of national distress.

And so the engineering profession finds itself in the highest favour that it has ever enjoyed. From the Commander-in-Chief of the Canadian Corps overseas down, engineers are giving distinguished service in the armed forces. In less stirring wartime tasks very many are occupying vital executive and directional posts. This is but natural. Creating, marshalling and distributing the equipment and commodities of war is an undertaking not different in kind from those about which gathers the normal practice of the engineer. In large measure wartime duties represent no more than another of the periodic transfers of activity to which practitioners in many branches of the profession have long been accustomed.

In parallel with this resurgence in the profession, the usefulness, power and influence of The Engineering Institute of Canada has grown. Its membership is at a new high; its financial position is sound and constantly improving; it is rapidly growing in the public esteem.

While conscientiously fulfilling its role as a forum for the dissemination of engineering knowledge, The Institute has in co-operation with the 'provincial associations of professional engineers and in its vigorous participation in the work of the Engineers' Council for Professional Development, embarked upon activities that promise to be of far-reaching consequence. A new emphasis is being placed upon those things that represent the significant difference between a professional engineer and a technologist.

It is impossible to overestimate the long-range importance of those attributes of a well-rounded professional man that lie beyond and above a mere knowledge of the techniques and procedures necessary to the attainment of the physical objectives of his work. If he is to be accorded whole-hearted public recognition as a member of a learned profession he must earnestly seek to acquire and manifest these characteristics.

To those activities that bring a development of individual professional stature in all of its implications The Engineering Institute of Canada may well and profitably devote increased attention. There could scarcely be a more attractive field of endeavour and none offering greater prospect of service to the profession.

President.

# THE ORGANIZATION AND WORK OF RESEARCH ENTERPRISES LIMITED

A government-owned company established for the production of precision instruments

COLONEL W. E. PHILLIPS

*President, Research Enterprises Limited, Toronto, Ont.*

Paper presented before the General Professional Meeting of The Engineering Institute of Canada, at Montreal, Que., on February 5th, 1942

The story of Research Enterprises is an interesting example of the problems associated with the establishment of a specialized industry in war time.

In the early summer of 1940, new industries seemed to spring from the head of the new Department of Munitions and Supply. In some cases such as explosives or ammunition, the facilities and experience of existing industry lent themselves readily to large-scale expansion. But, in other instances, as in the case of the precision instruments required for fire control and other purposes, neither facilities nor experience in Canada were available for the task.

In October, 1939, General McNaughton suggested to the War Supply Board that consideration might well be given to the production of optical parts in Canada, and indeed proposed at that time that this work should be commenced on a small scale at the National Research Council. It would appear that in the press of business no decision was made; the matter was only re-opened on the organization of the Department of Munitions and Supply, and was brought to their attention in connection with an urgent demand for binoculars. In the meantime the technical problems involved had received some study at the National Research Council Laboratories.

It was soon found that the requirements ranged from binoculars to dial sights, including such highly specialized instruments as range-finders.

To meet this demand, Research Enterprises Limited was organized in August, 1940, as a wholly-owned government company operating under the Minister of Munitions. This decision recognized the clear line of demarcation between research and production.

The need for optical glass was the immediate justification for the creation of the company. This was to be followed, as a matter of course, by the production of a variety of optical instruments. At the same time it was realized that such a company might well undertake the quantity production of other types of instruments which might be developed by the National Research Council.

In the United Kingdom a long-established separate industry supplied optical glass blanks in pressings to a number of experienced instrument firms, each of which was principally concerned with the production of a few specific types of optical instruments.

The position in Canada was quite different. Provision had to be made for completely integrated operation starting with the raw materials for glass-making and ending with the delivery of some twenty-five types of finished instruments in small quantities.

On September 3rd, 1940, a start was made in Toronto with two employees. Despite the race against time and almost complete lack of experience progress has been made, and by the end of January, 1942, some 3,000 optical instruments valued at \$475,000 have been completed and shipped.

In ordinary times the design of such an enterprise would require a detailed manufacturing knowledge of the products to be produced, and information as to quantities and rates of delivery. Under existing circumstances only the most fragmentary information was available, and it was necessary to embark on a series of limited gambles,

creating facilities in what looked like minimum economic units, expanding, altering and adjusting these as the real requirements became apparent.

As things have turned out, the rapid expansion of our manufacturing programme has more than occupied the capacity provided.

The conception of a company, totally owned by the government, but operating with the full freedom of a private enterprise, was due mainly to the late Gordon Scott, Mr. Henry Borden, and Mr. R. A. C. Henry, members of the Executive Committee of the Department. Such a scheme provided the conditions essential to the rapid development of a large-scale enterprise for which obviously there was no adequate departmental precedent.

In November, 1940, a demand was made for the production of a series of secret detection devices, of which, by now, some general information has reached the public by way of the press. Soon finding that we knew less and less about more and more, the task was to sort out and study the separate components which had to be worked into a going industrial concern. These are indicated in Table I.

TABLE I.  
THE SCOPE OF THE ENTERPRISE

1	2	3	4

{ Design Engineering & Planning }	{ Field Station }	{ Cathode Ray Tubes }	{ Mobile Assembly }	{ Admini- stration }

Figure 1 shows the general form of the organization evolved, establishing the skeleton upon which the enterprise has been built.

Great importance was attached to the question of organization, for in such a case good organization is even more important than good personnel. In matters of organization it seems a natural instinct of the Anglo-Saxon to choose a static form of design, fixed, as it were, from the top downwards. In our case, it seemed important to plan for a more dynamic framework, sensitive and responsive to changes perceptible at first only from the lower levels of the organization. In other words, it was more a question of "learn how" than "know how." In any event, compromise was the order of the day, as experienced personnel simply were not available.

In the early stages, committees and groups were the rule rather than the exception, but as time goes on, familiarity with the task makes it possible to assign clearly defined responsibility to individuals who have proved their merit, and at the same time to give them complete authority within their own sphere.

## PERSONNEL

As may be easily imagined, our requirements for technical personnel covered a wide field. The technical staff

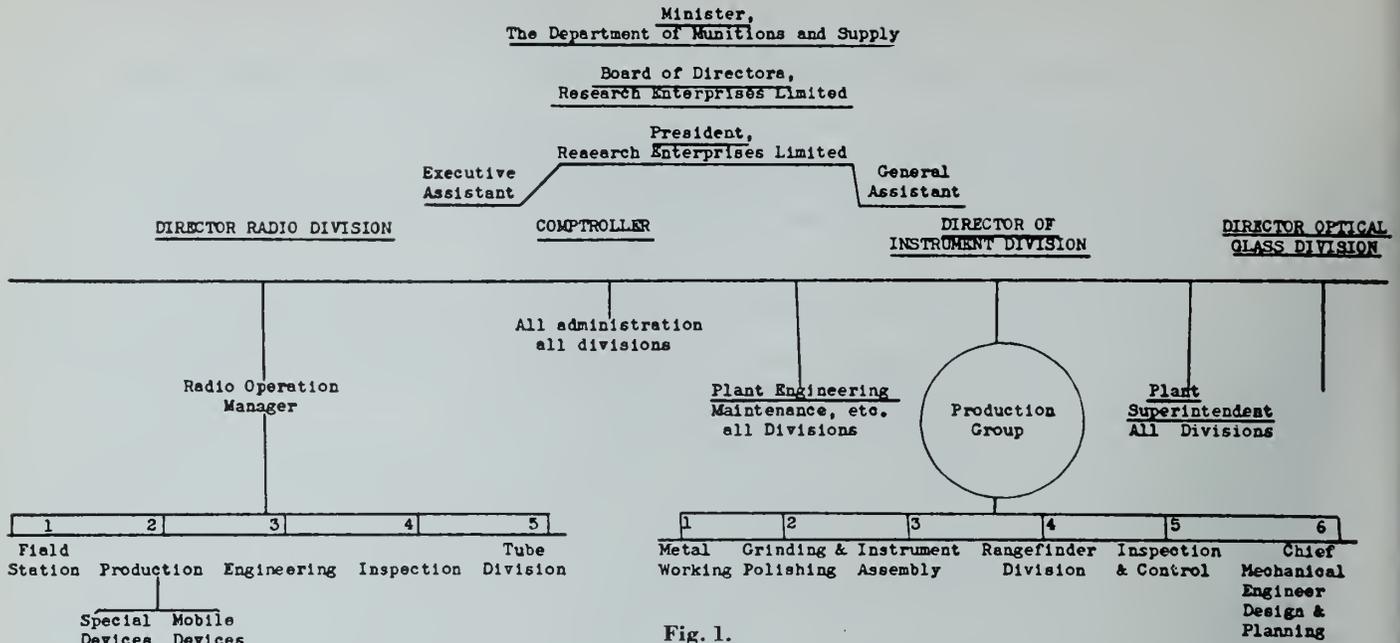

Fig. 1.

today numbers over a hundred, including 56 graduate engineers, 20 physicists, 3 graduates in engineering physics, and 5 chemists, with some 13 general technical assistants in miscellaneous fields. Of this total, some 84 are graduates of Canadian universities, which should be a matter of general satisfaction. The total number of employees is 3,000, of whom 700 are women.

TRAINING CLASSES

From the beginning it was evident that training must be provided for many of the workers. Courses have been established for machine operators, drafting, radio, glass blowing, and in addition, a fairly extensive series of night classes are held for our own employees. This policy has been highly successful, and over 400 present employees are graduates from such classes.

OPTICAL GLASS

Optical glass is now a fundamental requirement in the production of fire control instruments for warfare because modern artillery practice is concerned almost altogether with indirect targets, invisible to the gunner, but whose positions have been accurately located on the map. Thus methods of instrumental aim, known as indirect fire control, are essential. This involves the use of surveying instruments in order to determine the line of sight and the range of the targets with reference to certain fixed points visible to the battery.

The instruments used are for the most part of the telescopic type. Obviously, glass must be an integral part of the optical systems involved, and as the accuracy of the instrument is largely dependent upon the quality of the image, it follows that the glass must be of the very best.

The use of glass in lenses and prisms is based on its property of refraction. Speaking generally, its function in instruments is to so bend the rays of light from any distant point that they will converge to a single, corresponding point in the image.

To better understand the problems associated with the manufacture of optical glass, a general knowledge of the principles of refraction is needed. Figure 2 shows a ray of light, incident on a glass surface, and traces its path through the glass until it emerges.

Actually, the velocity of light in glass is less than that in air. Thus in passing from air into glass the ray is deflected so that the angle between its path and the normal to the surface is reduced. The ratio of the sines of the two angles (AOB and COD in the figure) is called the "index of refraction," and is a number  $N$  which expresses the ratio between the velocity in air  $V_0$  and the velocity  $V$  in the given medium. In fact  $N = \frac{V_0}{V}$ .

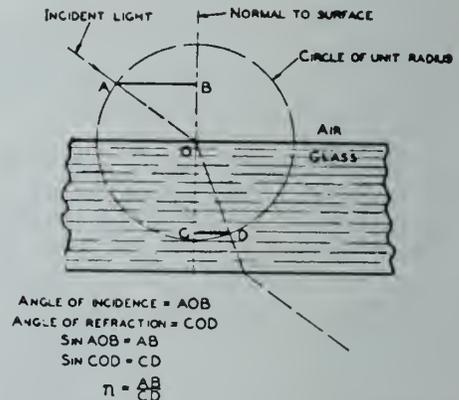

Fig. 2—Measurement of index of refraction.

It will be seen that a ray of light slows up and swerves when it meets a medium of greater optical density, just as a motor car slows up and swerves when one wheel leaves the concrete and gets on the softer shoulder of the road.

In practice, the refractive index measured for the D line of sodium ( $A^\circ .5893$ ) is the value used for commercial purposes. Its symbol is  $N_d$ .

DISPERSION

Another property of glass which is of great importance in determining its optical characteristics is its "dispersion." Radiations of the seven colours of the visible spectrum travel with the same velocity in a vacuum. The result to the eyes is white light. This is true to all intents and purposes in air.

In an optically denser medium, however, such as glass,

the longest-legged colour, red, travels fastest. The shortest-legged colour, violet, travels the slowest. Thus, in the denser medium, the colours of white light are dispersed, producing the familiar colours of the rainbow. The effect of a prism is shown in Fig. 3.

The angle of refraction evidently varies with the wavelength of the incident light. The difference in the refrac-

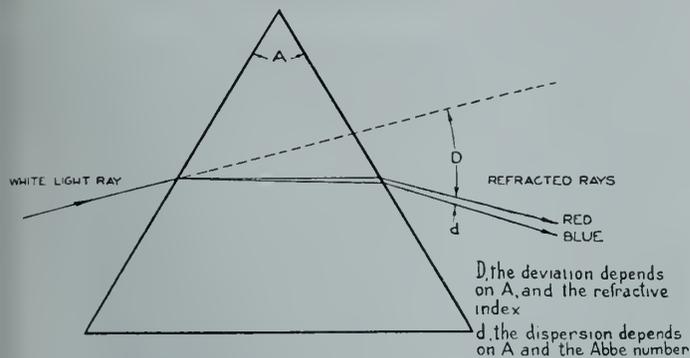

Fig. 3—Refraction of white light by a prism.

tive indices of a particular glass for light of different wavelengths is known as its "partial dispersion" between those particular wavelengths.

This phenomenon is obviously of great importance in the design of optical systems.

In commercial practice, four different wavelengths of light, the red, blue and violet of hydrogen and the yellow of sodium are used as standards.

The refractive indices for these various wavelengths are designated as  $N_c$ ,  $N_f$ ,  $N_g$ , and  $N_d$  respectively.

#### REFRACTION AND DISPERSION

In specifying the optical constants for the glasses in this list, nine spectral lines are used. Table II gives the wavelengths, etc., of these nine lines.

The "mean" index of refraction in air is given for the d line, and the "mean" dispersion between the C and F lines.

From these data is obtained the reciprocal dispersive power (constringence)  $\frac{n_d-1}{n_f-n_c}$  usually denoted by  $v$  or  $V$ .

The partial dispersions b to C, C to d, d to e, e to F, F to g, and g to h are given, and the ratios these partial dispersions bear to the mean dispersion (relative partial dispersions). In addition, for reference, the indices of refraction for the sodium D line and the hydrogen G<sup>1</sup> line are quoted.

The routine measurements of refractive indices of meltings are made with a Pulfrich refractometer (which has been standardised by reference prisms carefully measured on an accurate spectrometer). It will, therefore, be generally recognised that the values of the dispersions sent to customers with each melting of glass cannot be relied on to within less than .00003.

Special care has been taken to ensure that the relative dispersions given in the list are accurate. In each case an optically worked prism has been measured on an accurate spectrometer.

The value derived from these differences in refractive

index, as between different wavelengths, is known as the "Abbe number," and is given by the formula

$$V = \frac{N_d - 1}{N_f - N_c}$$

The reciprocal of this value is a measure of the dispersive power of the glass.

The term, which is in general use, serves to measure dispersion, and, together with  $N_d$  the refractive index for the D line of sodium, is sufficient to characterize any optical glass.

The fundamental task in lens design is to bring together, to the same focus, rays of one or more colours. This procedure can be successful only to the degree that the relative dispersions in the two glasses are similar. If this be not the case, there is residual colour in the image which cannot be eliminated. (See Fig. 4.)

By the proper combination of different types of glass of suitable index and dispersion, we can eliminate the effects of dispersion and produce an image free of colour.

By combining lens elements of glasses of different refractive indices and dispersions, it is possible for the designer to obtain much more perfect images and optical performance than with single lenses.

#### TYPES OF GLASS

Although the fundamentals of glass-melting were known from the very earliest times, it was not until the end of

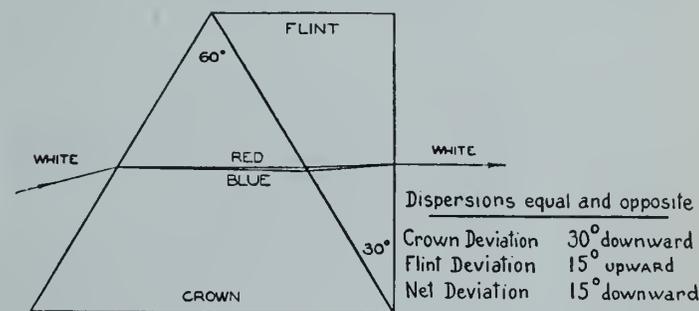

Fig. 4—Achromatic prism combination.

the 18th century that satisfactory optical glass became available. This followed the discovery by Guinand in 1790 that, by stirring the molten glass, it was possible largely to free it from physical imperfections, such as stones, bubbles, seeds, etc.

For many years, there were but two general types of glass available: the "flints" and the "crowns." The "flints" contained appreciable quantities of lead oxide and were characterized by higher refractive index and greater dispersive qualities than the "crowns." The relationship between refractive index and dispersion was fixed, inasmuch as the dispersion always increased as the refractive index increased.

The materials used in the manufacture of these glasses were largely the oxides of silica, sodium, potassium, lead, aluminium, and possibly thellium.

It was apparent that improved performance in optical

systems depended upon the development of additional types of glass with a different relationship between index and dispersion.

In 1890, Schott and Abbé at Jena, using many new materials, developed glasses which were characterized by a relationship between refractive index and dispersion quite different from that of the older types.

The new types included borosilicate crowns, barium crowns, barium flints, borate flints, and opened up a completely new field to the optical industry.

For many years Jena led the world in the production of these glasses, but long before the last war Chance Brothers, in England, had achieved an enviable reputation for the quality of their optical glass.

Following the last war, and working closely with the Admiralty, Chance Brothers have concentrated on the development of optical glass, and for many years they have occupied a technical position at least equal to Schott und Genossen at Jena.

Chance Brothers' present catalogue lists well over a hundred different types of optical glass. Our instrument programme here requires some fifteen different types, all of which we have now made successfully.

In 1917, the United States was faced with the necessity of establishing its own optical glass industry from the ground up. The situation was in many respects similar to the one we faced in 1940. Fortunately, a very complete record of their experience is available. It discloses the great difficulties they encountered.

Prior to this war, there was an established optical glass industry in the United States. One manufacturer, Bausch & Lomb, in particular, had continued production and developed a variety of types of glass designed for use in the manufacture of their own instruments.

There was also a small commercial operation in the Bureau of Standards in Washington, the output of which went largely to the United States Government workshops.

The types of glass developed by American industry have been generally standardized as to optical characteristics. These differ considerably from those in use in the United Kingdom, and the American types do not lend themselves readily for use in the optical systems of the British instruments which had to be copied.

Thus after thorough study of the record of the difficulties met by the Americans in 1917 and '18, it seemed best to follow the successful methods of the outstanding British manufacturer—Chance Brothers, of Birmingham.

Chance Brothers have been making fine glass for over one hundred years and were well entitled to place a very

high value on their manufacturing knowledge. Nevertheless a very satisfactory arrangement was concluded with them, and they have made available to us every detail in connection with their operations. Now that our Glass Division is established on a modest commercial basis, it must be admitted that the mere copying has taxed our abilities, but had this arrangement not been made with Chance Brothers, we might still be experimenting instead of producing.

In the early stages, there was no information upon which to estimate the quantity of optical glass required, so it was decided to set up the smallest economic unit, which was estimated to have a capacity of 5,000 pounds of usable glass per month.

The first melt was made on June 5th, 1941. The colour was perfect. Of course there were plenty of seeds and bubbles, etc., but a few thousand pounds of good quality glass were produced in July and August. In September, this increased to 4,000 pounds; in October, to 10,000; in November, to 12,500; and it is expected to maintain this rate until March, when two new furnaces will be in operation and the monthly yield should reach 20,000 pounds of usable glass.

Our methods differ only in minor details from those of Chance Brothers. The quality of the glass produced has been excellent—surprising even ourselves—and, as experience is gained, the yields of good glass, which even now are very satisfactory except in the more difficult barium glasses, will steadily improve.

A few general observations on the process may serve to explain some of the operations in glass manufacture.

#### POTS

The problem of refractory pots for glass-melting is one of the most difficult. For many years, an old type of hand-built clay pot, laboriously constructed by skilled workmen, was the only satisfactory type available. So far as we were concerned, the production of old-style pots was quite out of the question, as no skilled workmen were available. We, consequently, followed the method of making pots by slip-casting, and received very considerable assistance from the work which had been done at the Bureau of Standards in Washington.

The characteristics of the pot are all important. It must be mechanically strong at temperatures up to 1500 degrees C., not only to hold approximately 2,000 pounds of melted glass, but to permit its being handled by mechanical means, and it must, above all else, be chemically resistant to the action of the molten glass at these high temperatures.

Very serious problems arise with certain of the glasses, particularly those containing barium. Although we are able to maintain very high standards of purity in our batch chemicals, it is not so easy to obtain clays equally free from impurities, and it therefore becomes doubly important to restrict solution of pot impurities by the action of the molten glass.

There is no definite scientific procedure for the control of pot-making. The methods are largely empirical. We use a mixture consisting of three types of china clay and two types of ball clay, together with sodium silicate and sodium hydroxide as deflocculants.

Apart from close mechanical control, success depends largely upon the skill of the potter, the modern representative of the oldest of the crafts.

After many disappointments we have had extremely good luck, and appear to have solved the pot problem for even the most difficult of the glasses made. The pots, normally, take about three months to dry; it may prove necessary to adopt some mechanical means to hasten the drying period without impairing the qualities of the pot.

The pot is used only once, but the remains of the burned

begins. This lasts for, roughly, five hours, with speed and stroke varying according to the type of glass. When this stirring is complete, the pot is removed.

### ANNEALING

Good optical glass must be isotropic, that is to say its properties—such as refractive index and dispersion—must be the same in all directions.

When glass is cooled, two general effects appear. First, a molecular effect which depends on the rate of cooling and which is uniform throughout the whole body of the glass. Under these conditions, for example, glass of similar composition, cooled rapidly, will have a different refractive index, etc., from the same glass cooled slowly. This effect must be considered in cooling the pot after its first removal from the furnace.

The second effect may be described as a mass or volume effect, and results from differential cooling within the same pot of glass. For example, if one part of the glass cools more rapidly than another, stress will be set up between the two parts and strain will result. This is the phenomenon which causes the greatest difficulty.

Glass which is non-uniformly strained will have one refractive index for light travelling parallel to the direction of strain and a quite different refractive index, etc., for light travelling at right angles to it. In other words, it becomes doubly refractive. This is, of course, a familiar phenomenon, and inasmuch as the birefringence is proportional to the magnitude of the strain, the precise value and location of the strain may be measured by polarized light.

It is clear, therefore, that the annealing of optical glass in its various stages of manufacture is of the greatest importance. In the early stages, the process is known as "rough annealing", although it is controlled as closely as possible, but when the glass reaches its final shape, either as a slab or a pressing, it undergoes a last "fine annealing" operation in which the rate of cooling is very closely controlled.

It is of interest to note that the actual fine annealing requirements involve the treatment of large amounts of glass at the one time. The holding temperature, ranging from 430 to 570 degrees C. (which represents the first stage in the operation), requires the maintenance of tem-

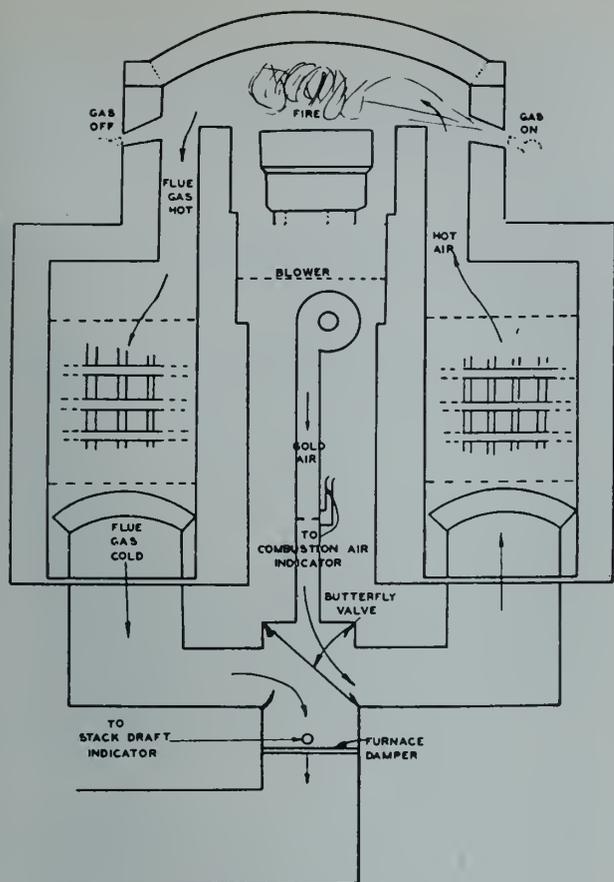

Fig. 5—Regenerative Furnace.

pot are carefully separated from particles of glass, then pulverized and screened, and used again to provide about half of the raw material for the making of new pots.

### FURNACES

The furnaces are of the single pot type and may be either regenerative or recuperative. (See Figs. 5 and 6.)

The pots are mostly heated by radiation from the furnace crown, and it is essential that the temperatures be uniform and subject to close control.

The regenerative type of furnace (Fig. 5) is the more popular type in America, but more expensive to construct. The recuperative furnace (Fig. 6) has been found quite satisfactory in English practice and is simpler to build. Both types will be in operation in Canada.

City gas of 490 B.T.U.'s is used. This is an ideal fuel from the point of view of cleanliness, but as the consumption, even now, is some ten million cubic feet per month, the question of cost becomes a serious one. Under existing conditions, our fuel costs are from four to five times as high as the corresponding costs at Chance Brothers, who use producer gas. Having gained sufficient confidence in the technique of the melting operation, oil-burning equipment is being installed for the two additional furnaces.

### MELTING

Previous to the melting operation the pots are preheated in the pot-arches to 1100 degrees C., and are moved quickly to the melting furnace. The temperature is then raised to above 1450 degrees, the pot is glazed by throwing in cullet of the same type of glass as that to be melted, and the batch is then "filled on."

Chemical reaction follows quickly, resulting in the fusion of the constituents and the formation of various silicates. In the process there is an evolution of gases which rise to the surface, and when all these have escaped, the glass is said to be "fined," and the stirring process

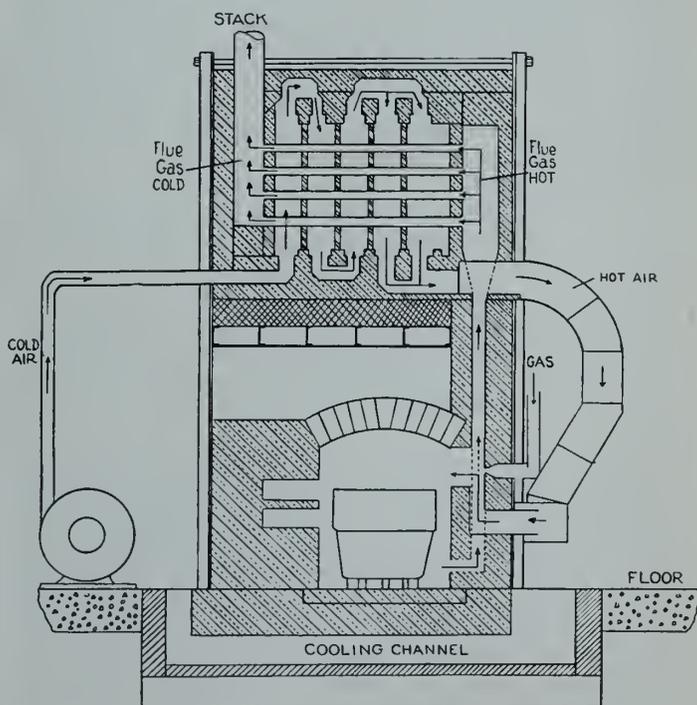

Fig. 6—Recuperative Furnace.

perature within one degree, plus or minus, for periods of 24 hours at least.

Further the cooling temperature requirements involve the maintenance of rates of temperature drop as low as 5 degrees per 24 hours. With modern equipment, we are able to control this operation entirely automatically.

Minimum standards for ordinary optical components require that the strain shall not produce birefringence equivalent to more than ten millimicrons per centimetre of light path. In many cases, our own product shows no detectable strain whatever.

#### FORMS OF PRODUCT

Optical glass is available in three standard forms:

1. *Chunks*: as they come from the broken pot;
2. *Slabs*: which are made from chunks of glass by softening and pressing in a mould, then grinding and polishing the edges;
3. *Mouldings or pressings*: These latter represent the form in which the largest proportion of the output is delivered.

The pot of glass is broken down by hand until the lumps are approximately of the required weight and it is then softened and pressed in an iron mould, which is made, roughly, to the shape of the finished optical component, sufficient allowance being made to provide for the grinding and polishing operations.

This method has many advantages and meets the requirements for all instruments other than those of the highest precision. In the latter case, the optical glass must be cut by means of a saw from selected slabs or plates.

#### OPTICS

The production of finished optical glass parts appeared at first to be one of our most serious problems. There was no similar operation anywhere in Canada, nor was trained personnel available anywhere on this continent.

Fortunately, Dr. Jones was secured from the National Research Council, and he threw himself wholeheartedly into the problem. Arrangements were made with Bausch & Lomb to take nine of our carefully selected learners and put them in their own plant for some four to six months.

Tooling for this work is just as much a problem as tooling for machine work, and there is the further complication that the computation of optical systems is a highly specialized mathematical problem. Dr. Crooker, of the University of British Columbia, was engaged as optical designer. Despite the impression in the industry that years of practical experience were essential, Dr. Crooker has solved our design problem.

By the end of June, a few polished components were actually being produced every week, but the rejections were in the neighbourhood of ninety per cent. By one means or another, this has been removed from our list of problems. In the second week of January, for example, over 8,000 individual, finished, polished optical components were turned out, and the rejections were 13.7 per cent. This is an encouraging record, and proves that much can be accomplished if the urgency is sufficiently great.

The fabrication of optical parts differs from that of metal parts in a number of respects, perhaps the most conspicuous of which is the considerable amount of hand-work which is still found necessary even in the largest plants. This state of the art will almost certainly continue in the case of the more precise parts used in small quantities on large, expensive instruments, while on the smaller parts, required in greater quantity, the traditional methods are considerably modified in order to produce more rapid results. There are two principal operations in the production of optical parts:

#### (a) GRINDING

This is usually done with loose abrasive on a cast-iron tool. Whenever possible, multiple fixtures are used to facilitate production. A number of operations are also done with milling machines, using diamond charged cutters.

#### (b) POLISHING

All precision polishing is done with a lap, coated with pitch and using an oxide, usually iron oxide, as the polishing material.

Polishing differs from grinding operations in that it is necessarily a lapping operation in which the floating tool principle is used and the accuracy is not contingent on the accuracy of machine ways. The method of holding the work differs from machine practice in that the glass part is either held to an iron tool by pitch or by bedding in plaster of paris, or in the most accurate work, by optical contact with a finished optical surface on a holding fixture.

The testing of the accuracy of the polished surface is based on optical interference. The familiar Newton rings are observed between the work and a master test plate. In the case of low power telescope lenses, the work is held to a tolerance of five rings. In the case of higher power instruments, the tolerance may be as little as one ring, or in the case of master test flats, the surfaces are worked so that no rings show. In this latter case, the accuracy is 1/6th wave length or better.

Translating these into terms of ordinary measurement, an interference ring is equal to 1/2 wave length and is equal to approximately 1/100,000th of an inch. In flat work, the tolerances are commonly more stringent than in lens work, and in certain cases good performance demands a surface which is flat within 1/1,000,000 of an inch.

Linear dimensions of optical parts are held to tolerances somewhat similar to those in the metal-working industries. Diameters are held to the same tolerances as lens cells, commonly plus or minus .0005. In some prisms extremely high accuracy is required in the angles; for example, we are turning out deflecting wedges in which the tolerance is five seconds of angle, plus or minus.

Optical methods of measurement and optical contact blocking permit the obtaining of this accuracy with very few rejections. The final correcting of the angles, although done in a multiple fixture, is usually a hand operation. In fact, it is true that the high performance of all the more precise instruments, such as the rangefinder, heightfinder, etc., depends on optical components which are finally finished by hand.

#### MANUFACTURE OF METAL INSTRUMENT PARTS

In the early stages of our planning, we quite underestimated the difficulties associated with the production of metal instrument parts. We took it for granted that our real difficulties would lie in the field of glass-making and optics.

Instrument-making is more than a mere extension of fine machine shop practice. It demands a slightly different point of view, which is a good reason for the special term "instrument-maker".

The design of the British instruments we are reproducing has not been greatly influenced by considerations of quantity production. The standards are very high. Indeed, in many cases, it would seem that some lowering of peacetime design standards might be well justified by the exigencies of war-time demand for quantities.

There appears to be a difference in instrument-making practice between Bausch and Lomb, for example, in the United States, and at least the many smaller instrument firms in the United Kingdom.

In the United Kingdom, the ample supply of instrument-makers seems to justify the use of these highly skilled workmen on machine tools of types we would consider old-fashioned. Nevertheless, in skilled hands, the quality of the work is up to the necessary standard.

In American practice, on the other hand, the tendency is to make much greater use of turret lathes and automatic machines, leaving the final fitting to the relatively smaller number of instrument-makers.

In our case, however, the instrument-maker simply did not exist, and it has been necessary to take the best type of tool-maker available; he has had to learn the requirements of the job by hard experience.

Practically all the drawings which have been supplied to us contained insufficient information on tolerances to permit their use in the manufacture of interchangeable parts. As a rule, these drawings are prepared for third angle projection which, in many cases, is confusing to men who were used to first angle projection. The wide use of Whitworth, B.A. and B.S.A. screw thread standards created problems which could only be solved by time.

In practice, it was necessary to adopt the expedient of making a model instrument in every case by hand, altering it until it came up to the established performance specifications, and then preparing our own manufacturing drawings. Under existing conditions, this has proved to be a tremendous task.

The actual operations involved follow familiar lines, with special emphasis on the close fits required, the high finish necessary, and the great number of threaded components. Most metal part manufacturing is done on standard and universal type machines with suitable fixtures, etc. Very few single performance machines are used.

It may be of interest to note that the large majority of our threaded parts are more satisfactorily threaded by chasing rather than by cutting with a tap or die.

Our gear-making problem is unique in that many of the gear trains demand extremely high accuracy, in which no backlash can be tolerated. Some of these gear trains demand special cam gears in which the teeth are cut on the contour of a specially calculated cam.

Most of our gear work consists of very small units and extensive use is made of the standard machines as produced by Barber-Coleman, Gleason and Fellowes, together with a variety of checking equipment.

Assembly of the metal parts involves a very large degree of hand-fitting. In general, it is more economical to manufacture the parts to a high commercial accuracy, and do this small amount of hand-fitting to achieve the necessary sensitivity, rather than to attempt to manufacture parts individually to the highest degree of gauge precision.

There are, however, many instruments, such as the tank periscope, in which virtually no fitting whatever is required, and the assembly is done by girls trained in a few weeks.

The assembly of the optics in the metal parts is an operation which never has been done on any large scale in Canada prior to the building of Research Enterprises. These operations require the use of carefully constructed and calibrated collimators and the best of careful workmanship. As an indication of the care with which optical parts must be mounted, here are the tests to which one small instrument is subjected.

It is heated to 150 degrees F., cooled to minus 40 degrees F., placed in a vacuum for one-half hour, then immersed in a steam bath and finally vibrated with an amplitude of 1/32 inch and frequency of 2,200 vibrations per minute. After these tests, the instrument must be as optically perfect as before the tests were made. Such tests obviously require that the optical parts be very securely mounted, very carefully sealed, and further that there be no strain transferred to the glass by the mounting.

Of our activities in connection with secret devices, it is not permitted to speak. It might, however, be said that the work is in a field hitherto practically unknown on this continent. It is based on research and development work undertaken in the United Kingdom and on the extension of this work in the laboratories of the National Research Council.

Some idea of the magnitude of the whole operation may be gathered from the fact that we have approximately \$100,000,000 worth of orders in this field, as against some \$10,000,000 in the instrument field. These are astronomical figures, and we interpret them to mean that all that we can make can be used as rapidly as we can produce it.

It is obvious that any undertaking of such scope as that of Research Enterprises must present many deficiencies, but it appears that the technical aspect of our problem has practically been solved, so far as personnel and facilities are concerned. The immediate task is to complete and perfect, so far as may be possible, the organization for production.

It is difficult to find an index to indicate progress to date but it may be interesting to learn that our billings, up until the end of January, amount to over \$1,300,000, with some \$5,000,000 worth of work in process nearing completion.

The author wishes to take this opportunity of emphasizing the debt owed to the countless people and institutions who have helped in so many ways. It is impossible to list them by name, but, above all else, the practical effective co-operation from the Department of Munitions and Supply should be recognized.

# THE ALASKA HIGHWAY

J. M. WARDLE, M.E.I.C.

*Member of International Fact Finding Committee 1931-33.*

*Member of British Columbia-Yukon-Alaska Highway Commission, (Canada).*

**EDITOR'S NOTE**—Since this article was written, a decision has been reached to build a highway for military purposes. A location following generally the air route from Edmonton to Alaska will be developed immediately.

From time to time projects arise whose magnitude and character stir the imagination and challenge the ability of the engineer. Such a project is the proposed highway to Alaska. It involves the location and construction of 1,200 miles of highway through unsettled and mountainous territory, far off the beaten track; the extension of the highway systems of Canada and the United States to the 65th parallel of latitude, and the making accessible to the motor car of areas which, a few short years ago, could only be reached by pioneer methods of transportation.

An overland connection between the United States and Alaska was first suggested forty years ago, when Mr. E. H. Harriman, of railroad fame, planned a railway through the Pacific Northwest, that would pass not only through British Columbia and the Yukon to Alaska, but would cross Bering Strait to Asia. In later years, Pan-American enthusiasts spoke of a highway from the southern tip of South America northerly through Panama, Mexico and the United States and Western Canada, to Alaska. Some investigation has already been made of a route through Panama and Central America, and its possibilities have been the subject of several articles.

Insofar as a highway to Alaska through British Columbia and the Yukon is concerned, it seemed to take definite shape in 1929, when various public bodies on the Pacific coast began to support and encourage the project.

These groups felt interested because, as Alaska lies to the north, and is west of Canada, they regarded the highway as a project associated with the states, provinces, and territories bordering the Pacific. The inhabitants of Alaska itself were naturally strongly in favour of a road connection with the United States, and the whole Pacific area supported the project, with some reservations as to the distribution of construction costs between Canada and the United States.

The claim of the people of Alaska for an overland connection with the continental United States is outlined by the United States Alaskan Highway Commission in its report of April 1940. A few quotations from this report follow:—

“People generally believe this territory (Alaska) to be the land of ice and snow. They look upon it as a point, and not as an area. They do not know that Alaska alone covers 590,000 square miles; that it is over 1,200 miles from the southern point to the northern tip and 3,000 miles to the western extremity of the Aleutian Islands, with all the variations of climate from that of the temperate zone to arctic conditions. In many portions the climate equals that of the eastern seaboard of the United States. Juneau, Alaska, has milder winters than Washington, D.C.”

\* \* \* \* \*

“The gold fields of Atlin and Dease Lake, the silver, lead, and zinc deposits of the Ingenika region, the rich gold-gravel deposits of the Omineca, and vast gold fields of Groundhog, in British Columbia, alone justify a road. Heap on the known resources of Alaska and the total potential dividends should so far exceed the capital investment of an international highway as to make it almost folly not to proceed on the basis of the mineral wealth alone.”

“Furthermore, Alaska and the Canadian Northwest provide a natural vacation ground which, because there is no through highway, is inaccessible to thousands of motorists desiring the opportunity to drive farther north rather than south for their summer vacation. During the four months from June through October the mild northern climate is, for the most part, ideal. Hay fever is practically unknown.”

\* \* \* \* \*

“The small population of Alaska should not be used as an argument against the international highway, for economically this small population is one of the richest in the world. With less than 80,000 people in the Territory, about equally divided between whites and natives, the annual wealth production in the Territory is close to \$100,000,000. This is a world-high average of \$1,250 per capita per year and, inasmuch as at least 75 percent of the native population is not in industrial competition, the figure is amazing. On the basis that 1 in 5 persons is gainfully employed, which is maximum for Alaska, each Alaskan producer is yielding \$5,000 in actual wealth. In addition to its own produce, Alaska imports more than \$40,000,000 worth of supplies per annum, or an average of \$500 per capita. The exports amount to \$80,000,000. These statistics show that Alaska is probably the greatest producer and consumer of produce per capita in the world.”

\* \* \* \* \*

Even while the report quoted was being written, Alaska had leaped into prominence as the site of great northern United States air bases, and these are being developed with characteristic speed and vigour.

The first official recognition of the possibility of an Alaska highway was given late in 1930, when the Congress of the United States authorized three representatives to meet with three representatives selected by the Canadian Government, and constitute an International Fact Finding Committee, for the purpose of investigating the proposed highway. The committee members at once began collecting information, the Government of British Columbia promptly placing at their disposal reports on reconnaissance surveys by ground and air that had been underway on road routes northerly from Hazelton, B.C. The initial responsibility of the committee was to decide whether or not there was a feasible route to Alaska through British Columbia and the Yukon Territory, and at a meeting held late in 1931, sufficient information was found to be available for this purpose. The view of the Fact Finding Committee on the highway at that time was expressed as follows:—

“The final conclusion was that the committee considered the project of constructing a road as an extension of the Pacific Highway north from Hazelton through Northern British Columbia, Yukon and Alaska to Fairbanks as being feasible from an engineering standpoint; that there was not sufficient information available to determine whether the undertaking was economically sound, that further information is to be obtained, and that the committee will meet again at the call of the chairman.”

Enough information was collected on a route that seemed feasible, to arrive at a very rough estimate of cost. This was based on a passable road from 14 to 16 feet wide, with no provision for any improvements to existing roads leading from Blaine on the International Boundary, to Prince George or Hazelton, B.C. This very preliminary estimate is summarized herewith:—

Blaine to Hazelton, B.C. ....	815 miles	
(Passable road)		
Hazelton to Yukon Territory, ..	610 miles	
(New work) .....		\$ 7,320,000.00
Yukon Boundary to Alaska		
Boundary, .....	530 miles	
(Improvements and new work)		4,575,000.00
Alaska Boundary to Fairbanks	270 miles	
(of which 180 miles new ....		
work) .....		3,000,000.00
Totals .....	2,225 miles	\$14,895,000.00

Investigations in regard to probable revenue from tourist traffic, development of natural resources, and economic benefits to Canada and the United States were carried out by the Committee until 1933, and a good deal of interesting information collected. However, interest in the project waned during the depression, and there was no further activity until 1938.

In that year, the question of the highway was again raised by the United States, and an inter-departmental committee was formed in Ottawa to review the situation from the Canadian standpoint. This committee, on which were represented the Departments of External Affairs, Justice, Mines and Resources, and National Defence, completed their report in July of that year. Briefly, it expressed the view that the Alaska Highway was feasible from the engineering standpoint, but that information available did not indicate that it was justified from the economic standpoint at that time.

Further exchanges between the governments of Canada and the United States resulted in a communication from the United States Government, in regard to the desirability of providing for the construction of the highway, which stated that the President of the United States was empowered to appoint a commission of five persons "to co-operate and communicate directly with any similar agency which may be appointed in the Dominion of Canada in a study for the survey, location, and construction of a highway to connect the Pacific Northwest part of continental United States with British Columbia and the Yukon Territory in the Dominion of Canada and the Territory of Alaska."

On the President appointing the United States Commission of five persons, Canada did likewise by order-in-council.

The wording of the United States communication confined immediate investigations to a highway through British Columbia and the Yukon Territory to Alaska, and both commissions proceeded on this basis.

Since approximately 1,800 miles of the proposed road would be in Canada, and only some 225 miles in territory of the United States, the Canadian commission was obliged to assume much greater responsibilities than the United States commission, insofar as investigations were concerned.

The Canadian commission undertook to collect information and do necessary reconnaissance survey work on the highway through British Columbia and the Yukon, while the United States Commission was to submit estimates on a route or routes from the Alaskan-Yukon boundary to Fairbanks.

The Canadian commission was fortunate in having immediately available most useful information, obtained by the Province of British Columbia through exploration and reconnaissance surveys in northern sections of the province,—as well as a great deal of material collected by the Fact Finding Committee of 1931-33.

This was supplemented during the course of the commission's work by aerial and ground reconnaissance surveys, by evidence taken at public hearings at such geo-

graphic centres as Prince George, Hazelton, Atlin and Whitehorse; and by the examination of the large amount of pertinent data available in Dominion and Provincial Government records.

In collecting information, engineers covered 4,000 miles by aerial reconnaissance, and over 3,000 miles by ground reconnaissance surveys. Exploration by air was not so much to discover new routes as to "eliminate those that were definitely unfavourable, thus saving the cost of ground investigations, and to confirm the possibility of routes on which favourable reports had already been received." It was only the great advantages of air reconnaissance that permitted the commission to examine, in the short space of three seasons, the main features of the large mileage involved in main and alternate routes. Thousands of dollars were thus saved through avoiding expensive ground reconnaissance over routes that on aerial observation proved impractical.

The Alaska Highway presents a very interesting problem from the standpoint of general location, and one that is but rarely afforded. In the first place it is not a local, provincial, nor national project, but an international one. This characteristic had to be kept in mind continually when possible diversions with substantial local advantages were under consideration. Probably no highway problem has required closer attention to climatic conditions, since these will affect construction, maintenance and operation. The advantages which the route selected might afford to air transportation were also dependent on weather conditions. Maximum elevations, always important in mountainous areas, have still greater weight at northerly latitudes.

The location of the highway in relation to the development of Canada's natural resources in the north-west was a factor of vital interest. Any route chosen should make forested and mineral areas reasonably accessible, and should not overlook the tourist traffic possibilities of new recreational areas.

The desire of towns and smaller settlements in northern British Columbia, the Yukon Territory, and the Alaskan panhandle to be on the highway or within striking distance of it, was still another factor.

The members of the United States commission, who were deeply interested in the route of the highway through Canadian territory, naturally hoped a feasible route could be found near enough to the Pacific Coast to benefit the Alaskan panhandle.

The extent to which existing roads should influence the general location was considered, and in this respect the Canadian commission in its report states "that while existing roads below the standard of construction required had great value as aids to construction, they could not be regarded as conclusive factors in determining routes."

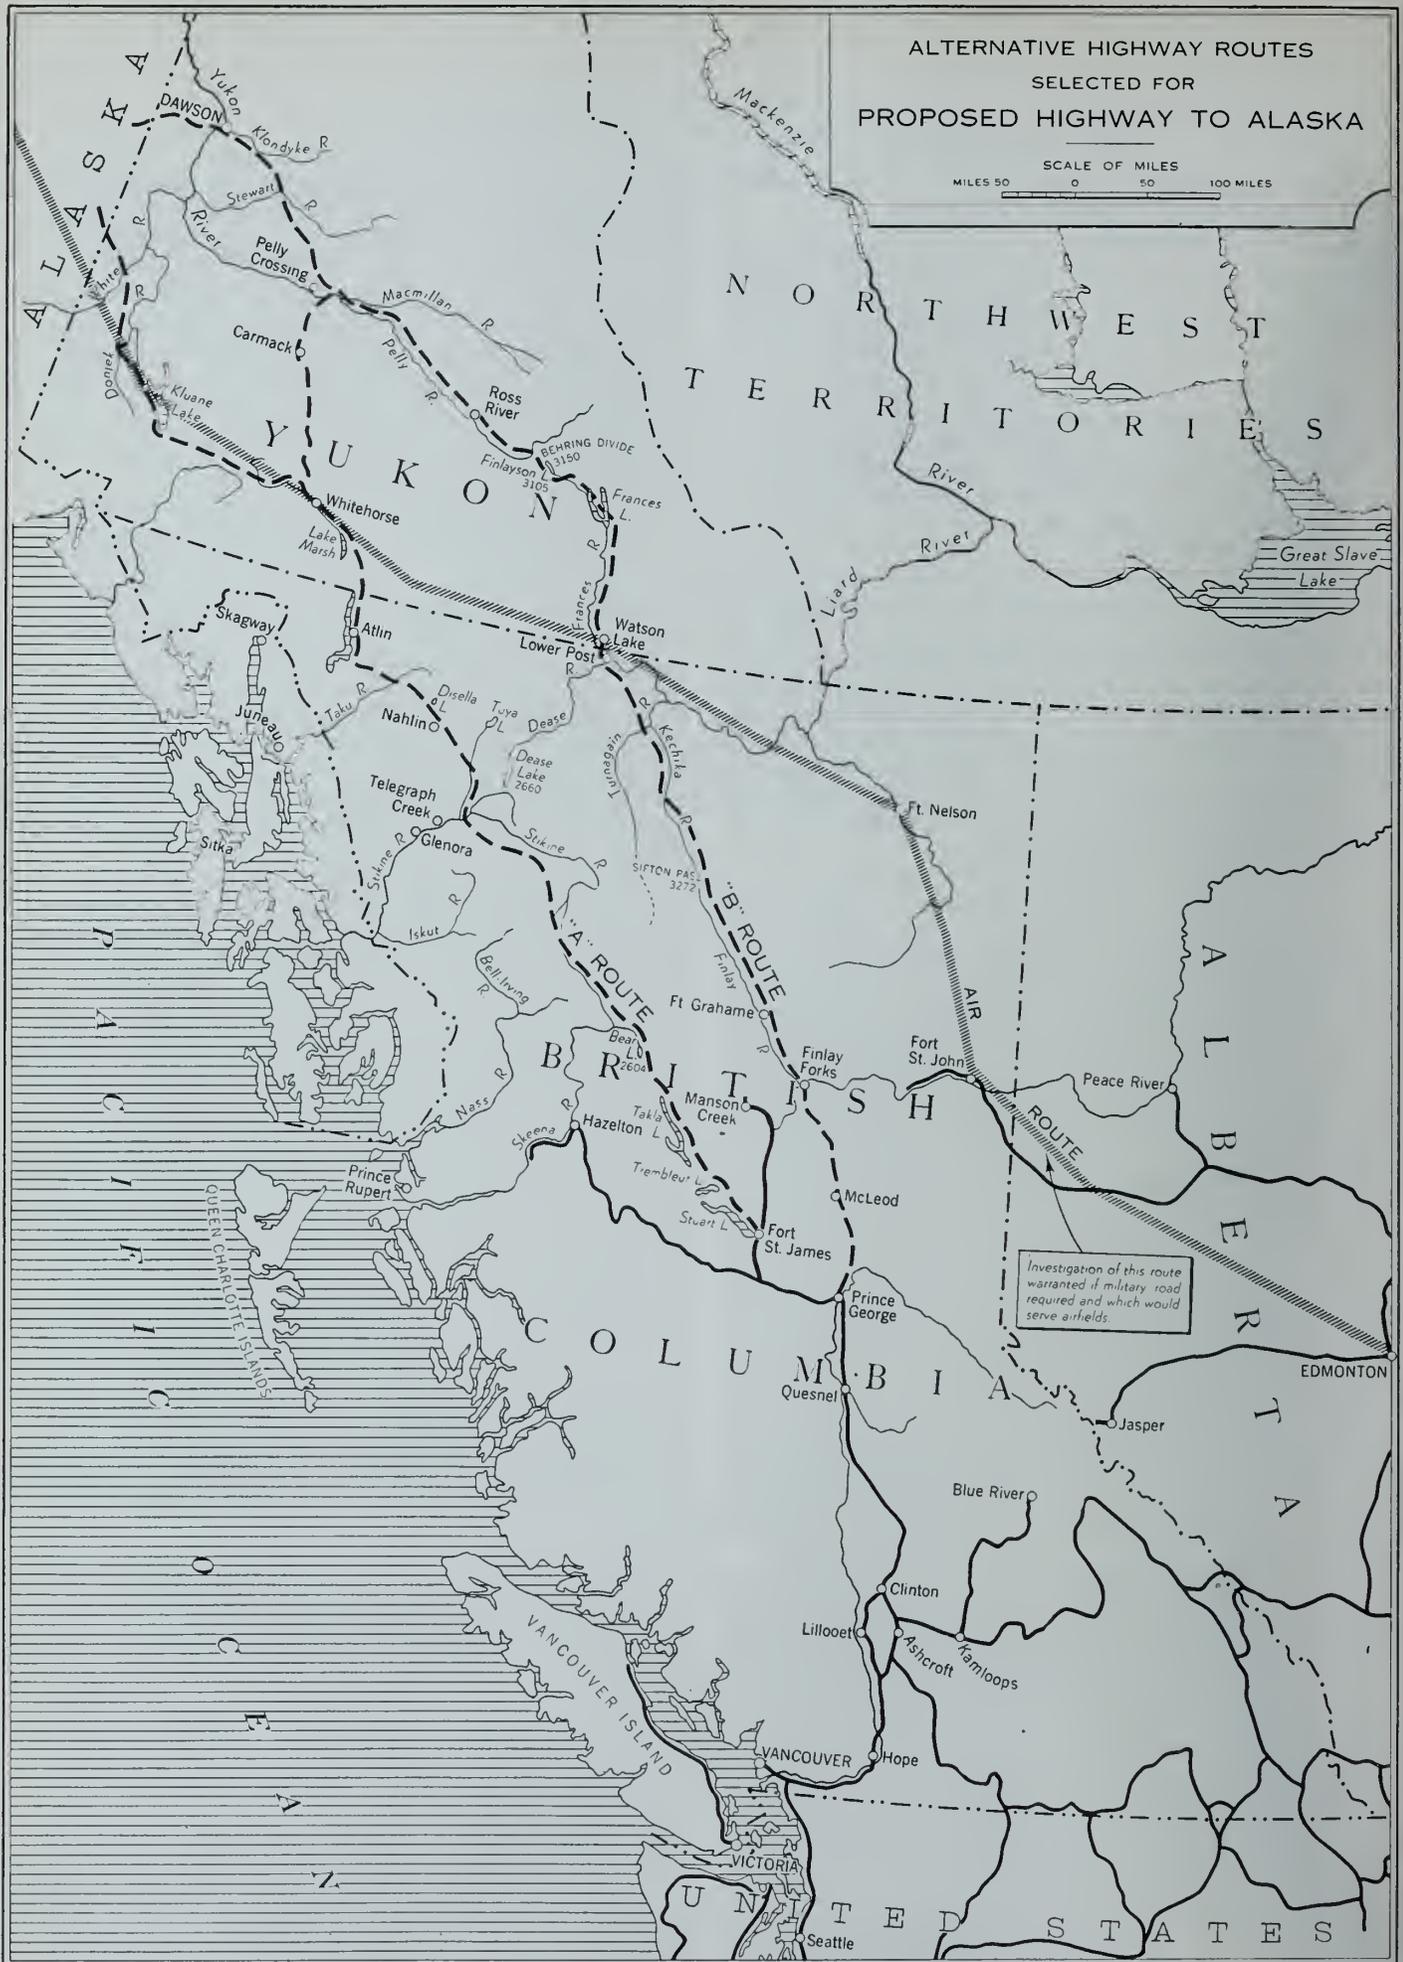

Various meetings were held by the commission from time to time as its investigations progressed, and several joint meetings with the United States commission took place.

The instructions of the Canadian commission made no reference to investigation of the highway from a military standpoint. This question at once arose when war broke out in 1939, and became increasingly important with the formation of the Joint Defence Board of Canada and the United States. On asking for advice, it was suggested to the commission that it continue and complete its investigations, supplying to the Canadian section of the Joint Defence Board such information as the latter might require from time to time.

In April 1940 the Canadian commission presented to the Dominion Government authorities a preliminary report covering its findings to that date. At about the same time, the United States commission issued a report, which used the preliminary Canadian report as a basis for its information on routes through Canadian territory.

ALTERNATIVE HIGHWAY ROUTES  
SELECTED FOR  
PROPOSED HIGHWAY TO ALASKA

SCALE OF MILES  
MILES 50 0 50 100 MILES

The Canadian commission presented its main report in November 1941, and it was tabled in the House of Commons on November 13th, 1941, and in the Senate on January 21st, 1942.

In its report the Canadian commission found that north from the existing east and west highway connecting Prince George and Hazelton, two main routes through British Columbia and the Yukon Territory were acceptable from the engineering standpoint. Both these routes take advantage of the north and south trend of drainage in British Columbia, this feature being an important factor in keeping estimated costs to a reasonable figure.

One of these routes, designated as "A", leaves the existing road system at Fort St. James and follows approximately the centre of the province. It traverses the valleys of Stuart and Takla Lakes, the Driftwood River, and the Skeena River. Leaving the latter near its source it follows the Klappan River valley to the Tanzilla River east of Telegraph Creek. From this point the Tuya River valley and the country in the vicinity of Gun and Disella Lakes is followed to the Atlin Lake drainage basin. The east shore of this lake and Lake Marsh is then followed to Whitehorse. From the Klappan River north, the "A" route conforms to the route regarded as practical by the 1931 Fact Finding Committee.

From Whitehorse there are two possible routes, one striking westerly to Kluane Lake and then north-westerly to the Alaska boundary, and the other following approximately the established overland route through the Yukon to Dawson and thence west to the Alaska boundary by the upper valley of Sixtymile Creek.

The first alternative is favoured by the United States commission since it reports an easier location through Alaskan territory; the second by the Canadian commission in view of its greater benefit to the Yukon Territory. Mileage of new road in Alaska is approximately the same by either route.

The "A" route as described has the advantages of medium precipitation, scenic value, and accessibility to areas with natural resources in minerals and timber. It affords attractive new fishing and hunting districts and the promise of some ranching areas. Satisfactory grades and alignment are possible without excessive cost.

The other route selected by the commission is well to the east of "A" and is known as the "B" route. It utilizes, north of Prince George, B.C., the Rocky Mountain Trench or its extension, which the Canadian commission states in its report is "a feature with great advantages from the highway or railway location standpoint."

Leaving the existing road at Prince George, "B" route goes northerly via Fort McLeod, Finlay River, Sifton Pass, the Kechika River and the Liard to the Frances River. Following up this stream it skirts Frances Lake and reaches the Bering Divide by way of Finlayson Lake. North of the Divide it strikes the headwaters of the Pelly River and follows this stream to where, near Pelly Crossing, it joins the "A" route, following it to Dawson and the Alaska boundary.

The "B" route is shorter and more direct than the "A" route, and would have the advantage of lower construction and maintenance costs.

While not as centrally located from the geographic standpoint as the "A" route, it would afford reasonable accessibility to mineral areas in central British Columbia, is subject to very moderate precipitation, and presents no difficulty in regard to grade and alignment. The topographical features of the country lend themselves to easy building of pioneer or tote roads, which would facilitate the undertaking of main construction operations.

Climatic conditions along "B" route are favourable from the standpoint of air transportation. The air route between Edmonton, Whitehorse, and Fairbanks, Alaska,

crosses it at Watson Lake, and there is contact at Prince George with the air line from Vancouver.

From the military standpoint, "B" route is well to the east of those coastal areas that might be subject to attack, and lends itself to rapid construction to any standard in case of emergency. The location of this route in the eastern part of the province also makes possible convenient connections with the Peace River Block and the province of Alberta.

Inspector Moodie, of the Royal North West Mounted Police, on his historic overland trip in 1897-98, from Edmonton to Fort Selkirk, Yukon Territory, blazed a trail that from Finlay Forks north is practically the "B" route. Moodie's party made a westerly diversion into Dease Lake, following down the Dease River to Lower Post on the Liard River, otherwise the general route is the same. In his 411-day journey the inspector travelled 1,800 miles, recording carefully the features of the country traversed. His topographical sketch map is remarkably accurate, and with his diary, would furnish ample guidance for anyone ambitious enough to follow in his footsteps.

It is likely that a route fairly near the Pacific coast was in the minds of the first supporters of the Alaska Highway, as such a route, if feasible, would afford the possibility of short lateral connections to Pacific coast settlements. Early in the investigations, however, it became evident that such a route was impracticable because of heavy precipitation and unfavourable topographical features. Climatic conditions were also unfavourable from the stand point of air transportation. The coast range is a very formidable obstacle to any east and west highway that might be considered north of the 55th parallel, and the report states that "even if expensive surveys revealed locations on which a road might be built, the cost of construction and maintenance, combined with a short season, would in no way be justified by the advantages that might be gained."

In developing the two general routes finally selected, the commission made preliminary investigations of a large number of alternative locations, of lengths varying from 5 or 6 miles to as much as 60 miles. One important alternative on "A" route was only considered practical after winter reconnaissance had established that snow conditions were not as bad as indicated by first reports. In many cases, final decision as to the best general location must await the outcome of location surveys. In this respect, the report states that "all estimates of costs given . . . are based on reconnaissance surveys, and are therefore necessarily only approximate. Before construction could begin, location surveys would be necessary to decide on the final location of the road where certain alternative routes are available and to confirm and enlarge information already obtained."

It was appreciated by the commission that neither the time nor the funds available permitted estimates of cost to be based on actual location surveys. The preparation of these estimates is thus interesting, in that the commission believes fairly reliable figures have been secured through careful ground reconnaissance supported by air observation. In the main reconnaissance flights, planes flew at a constant elevation in relation to the ground, and the type of country was carefully noted. Information so obtained was supplemented by aerial photographs taken at numerous points. Ground reconnaissance parties travelled over various sections of the same routes, and their findings in regard to topography, forest growth, drainage, and nature of soil were compared with the conclusions reached through aerial observation. Before investigations were completed, practically all of the "A" and "B" routes were covered by ground reconnaissance surveys, some sections being covered more than once and by different engineers.

Some eight engineers in all undertook ground and aerial reconnaissance, all of whom had had location or construction experience in terrain similar to that through which the highway would pass. The cost estimates of these engineers were then compared and adjusted so that the resulting figures would reflect with reasonable accuracy the character of the country traversed. Such estimates were adjusted on the basis of actual cost figures that were available in Dominion and provincial records for construction in similar types of country and with comparative climatic conditions. All estimates were based on a finished graded road 24 ft. in width, with gravelled surfacing 20 ft. wide.

The commission was careful to emphasize in its report that the estimates were based on wage rates, and material and equipment costs, that prevailed in British Columbia and the Yukon in April 1940, and records of such figures were kept for further reference. Under this arrangement, estimates can be quickly revised to cover construction at any period by comparing current wages and material costs with those prevailing in April 1940. The latter date was chosen for basic costs as a good many estimates had been prepared by that time, and as it antedated increased costs and taxes arising from the war.

A summary of estimated costs of "A" and "B" routes is given herewith:—

#### ESTIMATED COSTS

24-foot grade with gravelling 20 feet wide. Based on wages, material, and equipment costs as prevailing in April, 1940.

<b>"B" Route</b>		Miles	Cost
Section 1	Vancouver to Prince George, B.C., via existing highways (Improvement and revision) . . . . .	525.5	\$4,710,000
Section 2	Prince George to Yukon boundary, via Summit Lake (New construction) . . . . .	526	7,900,000
Sections 3 4 and 5	Yukon boundary to Dawson . . . . .	586	8,310,000
Section 6	Dawson to Alaska boundary, via routes "A" and "A-1" . . . . .	68	1,880,000
TOTAL . . . . .			\$22,800,000
Engineering and contingencies (10% approx.) . . . . .			2,200,000
TOTAL—Vancouver to Alaska . . . . .		1,705.5	\$25,000,000

#### **"Central A" Route via Dawson**

Section 1	Vancouver to Fort St. James, via existing highways (Improvement and revision) . . . . .	639.5	\$ 5,760,000
Section 2	Fort St. James to Yukon boundary (New construction) . . . . .	736	12,170,000
Sections 3 4 and 5	Yukon boundary to Dawson . . . . .	458	6,790,000
Section 6	Dawson to Alaska boundary, via routes "A" and "A-1" . . . . .	68	1,880,000
TOTAL . . . . .			\$26,600,000
Engineering and contingencies (10% approx.) . . . . .			2,600,000
TOTAL—Vancouver to Alaska . . . . .		1,901.5	\$29,200,000

#### **"Central A" Route via Whitehorse and Kluane Lake to Mirror Creek**

Section 1	Vancouver to Fort St. James, via existing highways (Improvement and revision) . . . . .	639.5	\$ 5,760,000
Section 2	Fort St. James to Yukon boundary (New construction) . . . . .	736	12,170,000
Section 3	Yukon boundary to Whitehorse . . . . .	76	1,170,000
Section 4	Whitehorse to Alaska boundary at Mirror Creek, via Kluane Lake . . . . .	307	4,000,000
TOTAL . . . . .			\$23,100,000
Engineering and contingencies (10% approx.) . . . . .			2,300,000
TOTAL—Vancouver to Alaska . . . . .		1,758.5	\$25,400,000

The estimates provide for the construction of from 1,100 to 1,260 miles of new highway, depending on the route taken, and the improvement to the standard required of the existing highway from Vancouver to Prince George or Fort St. James, as the case may be. Some fairly substantial revisions in existing roads are provided for.

The commission's report deals only with possible routes through British Columbia and the Yukon. Since it was submitted, war with Japan has made the Alaska Highway a live question for defence authorities, and introduced a new factor, namely that of building a highway primarily for military purposes. This involves consideration of possible routes through other areas in the Pacific northwest in the light of advantages they might afford in this particular respect.

Since the commission's instructions did not include examination of routes east of the Rockies, the absence of information in its report on possible routes through northern Alberta does not necessarily mean these do not exist. The report, however, reviews at some length existing and possible road connections between the northern highway systems of Alberta and British Columbia.

That there will be benefits to Canada from the construction of the Alaska Highway cannot be doubted. Natural resources in much of the country traversed are wholly undeveloped, and these will attract a great deal of attention after the war. With the opening up of vast new areas for motoring, hunting, fishing, and other recreational purposes, the tourist traffic field offers great possibilities. Whether or not Canada will be paying too much for these opportunities, will depend on what arrangements can be made to meet construction costs.

When the highway will be built is not known at this time. It is a matter of international policy that will be governed by events. It is conceivable that the defensive and offensive strategy of the Allied Nations may make it a vital issue over night, and will also determine the route on which the road must be built. On the other hand, it may be destined to take its place as a post-war project, contributing to the development of a Northern Empire.

# THE WAR ACTIVITIES OF THE NATIONAL RESEARCH COUNCIL OF CANADA

C. J. MACKENZIE, M.E.I.C.

*President, The Engineering Institute of Canada, 1941; Acting President, National Research Council, Ottawa*

**Retiring address delivered at the Annual General Meeting of The Engineering Institute of Canada, at Montreal, on February 5th, 1942**

Tradition and custom prescribe a presidential address at the end of a year of office but neither precedent nor practice restricts the form it may take. The presidency of The Engineering Institute of Canada is essentially an honour and distinction; the administrative accounting and history of the year's activities have been presented in the report of the general secretary who is the chief executive officer of the Council.

In the more leisurely days of peace, presidents often chose for discourse some question of general interest to the profession, treating it in a philosophical manner reflecting long interest and matured thought. Other past-presidents have presented at length valuable technical contributions to the literature of our profession, arising out of their personal work and experiences. Neither of these alternatives seems appropriate in February 1942 when practically the entire world is locked in deadly conflict in a fight to the finish between two diametrically opposed ways of life. The issues are so grave, our perils so great, that it seems to me, if we are to survive, our thoughts must not wander far from the immediate tasks before our hands. Military experts know well that to make good soldiers they must be taught to think continually in terms of war and, by the same token, if in this totalitarian struggle we are to win, most of us civilians must put aside for the moment strictly peacetime interests and speculations, and concentrate intensely on war activities and objectives.

This morning, therefore, I intend to speak of the war activities of the National Research Council of Canada, but, before entering formally into my subject, I would like to acknowledge the great honour I have felt in being your president for the past year. The presidential office of the Institute carries with it honourable traditions and every new incumbent finds his path made bright by the reflected glory of a line of great past-presidents, and his duties made light by the invaluable and freely given advice and guidance of his immediate predecessors. It is also a pleasure to pay tribute to the active vice-presidents whose responsibilities are real, not nominal, and all of whom have made my year easier by their loyalty and devotion to duty. It was my good fortune to visit most of the branches from Halifax to Vancouver and everywhere I was impressed with the fine work branch chairmen, secretaries and executives are doing, and also with the high quality of the membership at large, their interest and their enthusiasm. In the four provinces where co-operative agreements have been reached with the local provincial professional associations there is a complete and amicable merging of professional life and to me personally one of the most outstanding Institute events of the year was the signing in New Brunswick, the province of my birth, of an agreement between The Engineering Institute of Canada and the professional association.

The committees of the Institute all deserve commendation but I would like to pay special tribute to the chairman of the Montreal Branch and his committee on their contribution to the Building Fund; the performance of the branch was magnificent and its success a personal tribute to R. E. Heartz, the branch chairman.

An Institute such as ours depends for success more on its general secretary than on its presidents: The Engineer-

ing Institute has been fortunate in its general secretaries, and Mr. L. Austin Wright is maintaining the high tradition of that office. To him goes the credit of administering the affairs of the Institute in a most efficient, effective and agreeable manner; his innate courtesy, his kindness coupled with enthusiasm, loyalty and energy have gained for him and the Institute the confidence and friendship of branch officers and the entire membership across Canada. This year without extra compensation he has voluntarily carried a double burden and his war service as assistant director of the Wartime Bureau of Technical Personnel has been a great credit to him personally and to this Institute.

## THE NATIONAL RESEARCH COUNCIL

The National Research Council to-day probably touches as many aspects of Canada's war effort as does any other agency and the ramifications of its direct and associated activities extend to nearly every field of scientific research and development work in connection with our war effort both civil and military. The reason for this is that, while the Council operates directly extensive research laboratories, it was not designed for that particular purpose but was set up to serve as the Government's agency for the stimulation and co-ordination of co-operative scientific and industrial research in Canada. It carries no mandatory power to enforce the acceptance of any of its research findings; its function is to assist, advise and organize research projects. It does not compete but co-operates with universities or other private or governmental scientific laboratories, and the actual investigational work is done wherever the best facilities are available. That this method of co-ordinating research in a country of Canada's size is sound has been proved by the way the Research Council has been able to mobilize the nation's scientific resources to meet the war emergency.

## GENERAL HISTORY

I propose to sketch briefly the origin and early history of the Council to indicate how, in September 1939, it was transformed for war service, and, within the limits of security restrictions which prevent the disclosure of the most interesting details, to present a general picture of the war projects underway.

The National Research Council was established in 1916 on the suggestion of the Imperial Government that the Dominions should create a scientific organization to co-operate with similar organizations in Britain in order to correlate allied war research. Brought into being in one war which it was too young to serve, it developed and matured in the intervening years of peace and was ready and competent when called upon for service in a second war in 1939.

Until 1932 the functions of the Council were restricted to granting financial aid to research students and workers in the various universities and organizing and supporting co-operative research programmes of a national character which were carried out in laboratories across Canada. In 1929, under the wise and experienced guidance of President H. M. Tory, plans were drawn and in 1932 the Council's own laboratories were opened in Ottawa and these added facilities permitted a rapid expansion of investiga-

tional work and scientific standardization in Canada. From 1935 to 1939, under the able and brilliant presidency of Lt.-Gen. A. G. L. McNaughton, the National Research Council Laboratories were extended and in anticipation of inevitable war more attention was paid to co-operation with the Department of National Defence on military problems. When hostilities broke out in 1939 Canada had in the Research Council a virile, enterprising, rapidly growing institution with a young but highly qualified and experienced staff particularly suited for adaptation to the urgent scientific needs of war.

#### ORGANIZATION

The Council's activities can be divided broadly into three main categories. Granting financial aid to individual workers in pure science and scholarships to research students at Canadian universities; supporting and directing co-operative researches across Canada through the medium of Associate Committees, and thirdly the administration of its own extensive laboratories in Ottawa.

By its policy of grants in aid of research and of scholarships over a period of 20 years, pure research centres have been fostered and nearly 1,000 of the country's most brilliant students have been assisted in their graduate work. A really remarkable result, which is often overlooked, is that in the present emergency, when scientific personnel is so much in demand, Canada has been able to supply all of its own needs, and in addition give aid to Britain.

The organizing of co-operative researches through the medium of Associate Committees is one of the Council's most useful functions. By this governmental device many major research programmes of significance have been successfully carried out. To cite only one or two examples, aeronautical research in Canada has long been directed by an Associate Committee headed by Air Vice-Marshal E. W. Stedman, M.E.I.C., and composed of expert officers of the R.C.A.F., the Department of Transport, civil air-transport companies, aircraft manufacturers, the Meteorological Service, the Department of Mines and Resources, universities and the National Research Council. The operation of the Associate Committees on medical research is another excellent example of projects administered in this way, where the entire research studies are carried out in the various medical research laboratories of the Dominion, and where the committees bring together experts from the medical schools, the profession, the armed forces and the many scientific branches of departments of the Government.

Altogether there are over 30 Associate Committees in active operation in such widely diversified fields as field crop diseases, storage and transport of food, laundry research, coal classification, metallic magnesium, industrial radiology, radio, fish culture, and oceanography.

Since war broke out many special committees have been set up such as those on gauge testing, wooden aircraft construction, gasoline substitutes, and high explosive testing, which deal with special and secret projects of interest to the services and the Department of Munitions and supply.

In all such extensive programmes of national interest there is the most intimate and cordial co-operation of the well-equipped and competently staffed Mineralogical, Metallurgical and Forest Products Laboratories of the Department of Mines and Resources, the extensive laboratories of the Department of Agriculture, the National Research Council Laboratories and other government, university and private laboratories of the Dominion.

#### NATIONAL RESEARCH COUNCIL LABORATORIES

In the National Research Council Laboratories there are four research divisions—Mechanical Engineering, Physics and Electrical Engineering, Chemistry, and Applied Biology, each headed by a director who carries the

professional responsibility of directing all research in his division. There are also sections on Research Plans and Publications, and Codes and Specifications.

#### DIVISION OF MECHANICAL ENGINEERING

The Division of Mechanical Engineering under Mr. J. H. Parkin, M.E.I.C., is essentially an aeronautical engineering laboratory. In peacetime, this division was busy with aerodynamic problems relating to civil aviation, wind tunnel and model basin testing, studies on skis, floats and a variety of special assignments. In the engine testing, gasoline, lubrication and fire hazard testing laboratories well qualified and trained staffs were engaged on civil work. When hostilities broke out, strictly peacetime problems were curtailed and with little dislocation the emphasis placed on problems directly related to war. The division has expanded, new laboratories have been built and the staff is busy with a growing programme of work covering a wide field; in addition to the study of aerodynamical and wind tunnel problems, a comprehensive investigation of plastic plywood construction for aeroplanes is underway, calibration and repair of aeroplane instruments continues, and studies of gasolines and lubricants both for planes and tanks have assumed large proportions. With the growth of the aeroplane industry in Canada, an increasing number of problems are arising and the new, well-equipped engine testing laboratory, where facilities are available for testing engines equipped with propellers, will soon be enlarged to permit the full scale testing of the largest engines now in use.

In addition to laboratory investigations, experimental studies with full-scale aircraft are made in co-operation with the Test and Development Establishment of the R.C.A.F. where a wide range of special devices and developments are tested in actual flight and many important and extensive programmes such as those on de-icing are carried out.

The Model and Instruments Shops, as originally planned, were designed to serve the needs of all the divisions for experimental equipment and instruments, but the war has brought a heavy demand for the design and manufacture of special gun sights, a large range of secret ordnance and other special service equipment. Moreover, work on gauges for the Department of Munitions and Supply has been undertaken and when the extension now being built is finished the shop will be equipped to handle a shift of 100 mechanics, and if, as seems probable, it is put on a 24-hour basis it will become in essence an industrial shop employing several hundred highly specialized mechanics.

#### DIVISION OF PHYSICS AND ELECTRICAL ENGINEERING

The Division of Physics and Electrical Engineering under the director, Dr. R. W. Boyle, M.E.I.C., is one of the largest and most interesting divisions, and has grown rapidly during the war. In the years prior to 1939 its principal function was that of a Bureau of Standards. The sections of metrology, electrical measurements, optics, acoustics, heat, radiology, radio and general physics were responsible for setting up Government standards and maintaining the official units such as those of mass, length, and of many others in electricity, light, heat and sound. In addition to this high grade type of standards and approval work, the division had started a number of investigational projects in the fields of radio, vibration, ballistics, aerial photography, etc., and when the war broke out was in the fortunate position of being well equipped and staffed with competent and experienced staff particularly well suited to meet the great demands that war has placed on physicists.

It is possible to mention only a few of the major activities. The metrology section which is responsible for maintaining the standards of length undertook the task of

Setting up a gauge testing laboratory so necessary in munitions production. Early in October 1939, in anticipation of the demands which it was known would materialize, an Associate Committee on Gauges was set up with representatives from the Department of National Defence, the J.K. Inspection Board, the Supply Board (now the Department of Munitions and Supply), the Ontario Research Foundation and the National Research Council. Decisions were taken as to the equipment which would probably be needed, orders were placed at once to equip laboratories at the Ontario Research Foundation and the National Research Council, and arrangements made to select and train staffs in anticipation of future demands. This procedure proved wise, and to date the gauge examination laboratories operated by the Ontario Research Foundation and by the National Research Council have been able to meet all demands. The National Research Council laboratory has increased steadily and is still expanding. At present there is a staff of over 70, mostly women, and to date over 2,000 different types of gauges have been measured.

The Optics Section at the outbreak of war, in co-operation with representatives of the Master General of the Ordnance and latterly with officials of the Department of Munitions and Supply, undertook a survey of the possibilities of the manufacture in Canada of optical glass and fire control instruments. Visits were made to establishments in the United States, and laboratory equipment for cutting, grinding and polishing glass was installed and experience gained in the art. In the summer of 1940 the Department of Munitions and Supply decided that it would be wise to undertake manufacture in Canada on a sizeable scale, and it became apparent at about the same time that in the radio field much equipment of a secret nature developed by the Research Council would also have to be manufactured in mass quantities and the Department of Munitions and Supply decided to set up a Government-owned company for these purposes. As a consequence, Research Enterprises Limited was established, and under the energetic, competent and enterprising direction of the president, Colonel W. E. Phillips, is now, in record time, in production on a very large programme of optical glass, fire control instruments and special equipment.\*

The Optical Section of the National Research Council is now working on many important secret developments in connection with aerial photography and the design and construction of optical devices for synthetic training equipment and many other purposes.

The Radio Section has been one of the most spectacular developments of the Council. Starting with only a few men in 1939 it now employs nearly 300 and has already produced for the forces of Canada and the United Kingdom many important secret devices in the field of radio location, and has developed prototypes of many equipments for reproduction by Research Enterprises Limited.

The sections on general physics, acoustics and electrical engineering are engaged on important work for the Navy and Army in connection with anti-submarine, anti-mine, ballistics, sound ranging, electrical plotting and many other technical and scientific aspects of warfare. In addition to the laboratories for naval work at Ottawa, stations have been established at two centres on the eastern coast and one on the western coast of Canada.

Investigational and standardization work in the technique of x-ray examination of metals carried on in co-operation with industrial firms has been of the greatest value in connection with light alloy casting production for the aircraft industry, and steps are now being taken to work out similar procedures in the heavy metal field.

In the Heat Laboratories investigations in connection with the de-icing and defrosting problem of aviation are

being actively pursued and studies have been made of the possible use of infra-red radiation.

#### CHEMISTRY DIVISION

The war work of the Chemistry Division, under Dr. E. W. R. Steacie, can be divided generally into three broad groups: chemical warfare, emergency production of materials urgently required, and a general advisory consulting service in connection with preparation of specifications, testing and reporting on a wide range of materials.

The work on chemical warfare is carried on in the closest co-operation with the Department of National Defence, and all phases of this work are covered in a most comprehensive manner by the integrated effort of the two bodies. Active work on selected problems is being carried out at 13 Canadian universities and the Ontario Research Foundation, and large programmes are underway not only at the National Research Laboratories but at several other stations and laboratories in Canada.

Some idea of the work done by this division in connection with materials may be had from the fact that this year over 3,000 reports have been made to the Departments of National Defence and Munitions and Supply on different questions referred and samples submitted.

The textile laboratory has been particularly busy in testing, writing specifications for and advising on army uniforms and clothing, parachute fabrics, impregnating and gas proofing of materials. The rubber laboratory has investigated a variety of products used for the armed forces and has studied a total of seventy different substitutes for rubber.

In the colloid section a great deal of work has been done on plastics for use in plastic plywood construction and several special developments have been made involving the substitution of plastics for metals in connection with military needs.

The work of the paint laboratory has increased many fold and tests have been carried out on hundreds of different special paints used by the services.

In co-operation with a group of industrialists a process for the production of metallic magnesium, developed by a member of the Council's staff, has been carried through the pilot plant stage. Limited quantities of very pure magnesium have been sold to the Department of Munitions and Supply regularly for some months. The process is receiving keen attention from interested bodies and large scale production plants, both in Canada and the United States, are being designed for early construction.

Numerous other problems are being studied, such as the corrosion of aluminum and steel alloys, the manufacture of various components of gas masks, asbestos products, and the development of special gas indicators. Several small plants have been built for the production in small quantities of fine chemicals and such urgently needed materials as special fuse charcoal.

In addition to actual laboratory work the officers of the Chemistry Division have spent much time, at the request of the Departments of National Defence and Munitions and Supply, in preparing Canadian equivalents of British material specifications to bring them into line with Canadian production methods.

#### DIVISION OF BIOLOGY

The Division of Applied Biology, under Dr. W. H. Cook, has been used extensively on war work, chiefly in connection with the handling and transportation of perishable foods under the restricted shipping facilities resulting from the war. A contribution of major importance has been made in the development of a method of low cost temporary refrigeration of ordinary ships holds which has already permitted large quantities of bacon to be shipped satisfactorily to England.

\*A paper on this project by Col. W. E. Phillips appears on pages 129-135 of this issue.

The general problems of preparing, processing, packing and preserving foods for transport are being intensively studied and the shortage of refrigerating space on ocean vessels has made doubly urgent the studies on preservatives for bacon and shell eggs. Methods for the drying of eggs and meats are also being actively studied, and canning processing methods have been improved and standards worked out.

#### GOVERNMENT SPECIFICATIONS

The Special Committee on Government Purchasing Standards, an organization set up in peacetime to prepare standard specifications for commodities purchased by two or more Government departments, has been found very useful in war. While the committee has no mandatory power to enforce adoption of its specifications, there has been general acceptance by the departments concerned, and in 1940 over 10,000 copies of different specifications were distributed on request, and in 1941 this figure increased to 17,000 of which 12,000 were distributed to war departments of Government and outside parties interested in war contracts. This committee apart from its normal functions has placed its staff and organization at the service of the Department of National Defence and has given advice and assistance in the preparation of many special specifications.

#### MEDICAL RESEARCH

Medical research has developed rapidly in Canada during the war and the initiative and impetus originally given by the late Sir Frederick Banting has been maintained by Dr. J. B. Collip, Colonel Duncan Graham, and Dr. C. H. Best as chairmen of the Main Associate Committee on Medical Research and the special ones on Aviation and Naval Medical Research. The main committee has tended more and more to direct its research to problems of war importance and valuable results have already been obtained on shock, blood substitutes, wound infection, and other aspects of medicine and surgery accentuated by war.

The Committees on Aviation and Naval Medical Research are not concerned with disease but with health; their interest is not with medicine as a healing art but with means of lessening the physiological strains under which aircrews and sailors must operate in order to increase their efficiency and security. Work of the greatest importance has already been done to overcome the natural handicaps of low partial oxygen pressure and low temperatures encountered at high altitudes, and the effects of exposure to unnatural forces, noise and fatigue on both ships and planes. Numerous other problems in connection with selection, diet, and general health are being attended to in intimate co-operation with the medical services of the three armed forces.

#### LIAISON

As has been indicated, all of the war work under the Research Council in Canada is done in the closest co-operation with officers of the defence departments. Problems and suggestions for study originate in many ways; most arise directly out of needs felt by the services but many of the important developments have originated in scientific laboratories or have been suggested by in-

dividuals. But no matter where the studies originate, all proposed developments are thoroughly canvassed at an early date, not only as to their scientific soundness but as to their tactical usefulness, the requirements of service operations and what is becoming of greater importance daily, the possibilities of obtaining production in quantity in a reasonable time. This procedure ensures that Canada's limited resources will not be dissipated in investigations of questionable use in this war.

The scientific departments and professors of the universities of Canada have been of the greatest service. While staffs have been depleted by the drafting of individuals to many important positions, those left, in addition to increased teaching burdens, have undertaken still further work and at the present time nearly every university in Canada is co-operating with the National Research Council, and over 70 different research problems, many of the greatest importance, are being solved in the different Canadian institutions. When the detailed history can be written it will be found that in the field of war research the universities of Canada have made a contribution of first magnitude.

Effective liaison is also closely maintained with war research establishments in the United Kingdom and the United States. The British Government has maintained a liaison office at the National Research Council since early in 1940 and the chief scientific officer has always been a distinguished and senior scientist well informed on all phases of war work. The National Research Council maintains a permanent liaison office at Canada House in England and through these two offices all reports of work done are immediately available to workers in the respective countries. In addition, experts are continually crossing the Atlantic and, since 1940, 35 expert scientists and engineers from the Council have spent periods varying from a few weeks to months in England in order to bring back the most up to date information from their laboratories and research stations.

A similar and even more intimate liaison has existed between scientific stations in Canada and the United States ever since the summer of 1940 and experts from our respective countries visit freely and frequently laboratories and stations across the border. On many important projects, co-operative action is obtained by an actual exchange of personnel on committees.

#### CONCLUSION

As a concluding summary it can be said that war has greatly increased the activities of the National Research Council. At present over 210 different projects are being vigorously attacked; the staff has grown from less than 300 to over 1,000, the yearly expenditures have increased four fold and the direct expenditures this year will be over \$4,000,000. The interests and activities cover a wide field and touch nearly every phase of the war effort. The close liaison and co-operation at home with the services, government departments and agencies, and abroad with research stations in the United Kingdom and the United States, guarantees that the research facilities of Canada are being well and realistically focussed on important and urgent problems and it can be said that results of great value and significance are being obtained.

# A MESSAGE TO CANADIAN ENGINEERS

LIEUT.-GENERAL A. G. L. McNAUGHTON, C.B., C.M.G., D.S.O., M.E.I.C.

*Officer Commanding, Canadian Army Corps, England, and President, National Research Council of Canada.*

An address delivered at the Fifty-Sixth Annual Banquet of The Engineering Institute of Canada, at Montreal, on February 6th, 1942.

You must forgive me to-night if the warm welcome you have just given me has made it almost impossible to address to you any coherent message, except that which comes straight from the heart.

I feel on many counts that this, for me, is a most memorable occasion. I recall the words that have been said to me by the mothers and the sisters of the men in the Canadian Corps who stand on guard in the great island of Britain. They remind me of my responsibility for looking after those men and seeing that their lives, which have been given as hostages to fortune, shall be used in the way that they should be, in order to bring to an end the terrible calamity which now afflicts the world.

The words of the presidents of the American engineering societies have greatly impressed me. Every one of them has the vision which looks beyond the trials and tribulations of the present to the great task which faces us when the dictator powers, with the forces of evil they have let loose on us, shall have been brought into subjection and we are free once more to resume the onward march of civilization.

In the dire straits in which we stand to-day it is a great inspiration to receive that message of hope and that challenge to use engineering for the purpose for which engineering should be used, the happiness of humanity. That purpose should be uppermost in the minds of all engineers.

I feel too, in coming here tonight, that I have an opportunity to acknowledge publicly the great debt of gratitude which I owe to the distinguished engineer who now occupies the chair as president of this Institute.

Some years before the outbreak of war, it had been my lot to leave active military work and become president of the national Research Council of Canada. The work was of a most enthralling nature, and of a character which interested me deeply as an electrical engineer. I was supported by a splendid staff that had been gathered there, which I inherited. In fact the position was one which should completely satisfy the aspirations of any engineer. The opportunities for useful service were abundant, and were opening day by day in front of us; we had the sympathy of the members of the Government—both the Government that was then in office, and the Government that succeeded them. There was every possibility of doing something that was worth while.

Then the shadow of war appeared on the horizon, and it fell to my lot, through past experience and past service, to be given the honour of taking our First Division overseas. When I was sent for by the Prime Minister and heard of the obligation which was to be placed on my shoulders, my greatest anxiety was as to what would happen in the Research Council. As I listened to that invitation to undertake the new task, the names of many possible successors passed through my mind in quick review. It was soon clear who that man should be.

Actually I made Dean Mackenzie's appointment one of two conditions that were attached to my accepting office as a soldier again. And all the time, through the long

Lieut.-General A. G. L. McNaughton, C.B., C.M.G., D.S.O., M.E.I.C.

months that we have been away, he has been good enough to send me each month a running account of what was going on. In each of his letters one could see the seed of the purpose which we had held in our mind before in the Research Council growing, coming to flower and bearing fruit, not only in implementing the war effort of the Dominion of Canada, and contributing to the war effort of Great Britain and of the sister Dominions, but also in the constant thought that the organization which was growing would be of service in the years that are to come, beyond the war.

Standing here tonight, with a very considerable knowledge of the situation, I can say that one of the happiest thoughts in my mind is the feeling that the National Research Council, and all it stands for under Mackenzie's

leadership, is performing that duty of scientific leadership and helpfulness in the way in which it is being carried out to-day. And it is indeed fortunate for the Dominion of Canada, for the Empire, and for all those associated in the war effort that it should be so. For, as one of the speakers has already said, this is an engineers' war. We have to do more than follow the patterns of existing weapons and implements of death. These were developed slowly in the years of peace—far too slowly in the democratic countries, because we neglected our defence and we put our trust in the pledged word. We could hardly conceive of the villainy of people who would deliberately plunge the world into the agony in which we find ourselves at the present time. It was unbelievable, and in consequence we neglected our defence. So we started not only with weapons short in quantity, but with weapons and tools of war that were antiquated in design. Now we must equip our forces with new and more effective weapons.

This is a war in which the development in the whole of the Axis countries of the powers of science, of engineering and art and everything else, has been focussed by our enemies on one purpose only, and that is our death. To meet that we have to focus our own attention likewise, to insure that we will emerge triumphant, as we will.

Now we have taken the patterns of equipment and so on that were available to us at the outbreak of war in our country and the other countries of the Empire—and we are happy to say, in the United States also—and our industry has been converted from peace-time uses to produce and improve those weapons and articles of war.

But it seems to me, as I move about, that I can detect some little complacency as to what has been done. It has been a great achievement. Nobody knows that better than we who have had to stand on the front, awaiting the perils of invasion from the theatre of war on many occasions without weapons in our hands at all, knowing that the weapons were coming forward, and now seeing the supply arriving in abundance. But this is not enough.

One of the primary reasons of my return to Canada at this time was to carry a message to Canadian industry and to the Canadian engineers that we want to win this war, not by the blood of our sons—and our daughters, because our daughters stand in the line as well—but by

our intelligence. We must take our wits and put them to work, and the engineers must not only think out newer weapons, and better types of weapons, but must forge them and design them so they can be mass-produced; industry must give these newer and better weapons in the vast quantities which we shall need in order to bring this chaos to a satisfactory conclusion without the expenditure of more than is necessary of the precious lives that have been entrusted to our care.

We have to win this war by our wits, and it is through our wits, and through intelligence in the production of newer and better weapons that we should win it. I appeal to The Engineering Institute of Canada, and to all those associated with us, to see that we never rest content, and that there is no complacency in this eternal struggle for better, more powerful, more far-reaching weapons.

This is a mechanical war. We appeal to you for tools with which to multiply the power and the speed of man to add to the range and effectiveness of the weapons which are created and put in our hands, and to give us that equipment in quantities.

It is true that many engineers are with the Forces overseas. But we have need of many more engineers to handle the complex machinery we are about to use.

At the moment the Canadian Forces are standing on guard in Britain. They are doing so because the best authorities in the land, including the Prime Minister of Great Britain, have said that that was the task we should perform. The war will not be won by standing on guard. We have been given a period of grace while we are doing one task, and we have got to use that period in order to forge these more powerful weapons, and the organizations to handle them, and that is what the Canadian Corps is doing to-day.

I have described its purpose more than once. It is to be a dagger pointed at the heart of Berlin, and that is the description which I think best fits the case, because the time will come when we can use that instrument to put an end to this tyranny and this menace which afflicts the world.

To my many old friends here—including my old friend, Jack Mackenzie, Mr. Fairbairn and Mr. Challies, and those with whom I have been privileged to be associated on committees of The Engineering Institute, the Canadian Engineering Standards Association, and other bodies—may I say, I thank you from the absolute bottom of my heart for the welcome that you have given to-night to my wife and myself.

The Fifty-Sixth Annual Banquet of the Institute.

# CANADIAN INDUSTRY IN THE WAR

C. D. HOWE, HON. M. E. I. C.

*Minister of Munitions and Supply of Canada, Ottawa, Ont.*

A luncheon address delivered at the General Professional Meeting of The Engineering Institute of Canada, at Montreal, on February 5th, 1942.

When I received an invitation to address you on this occasion, I was placed in an embarrassing position. I could not show any possible discourtesy to my fellow engineers at a time like this, and especially at a time when I was receiving so much assistance, freely and generously given, from them.

But on the other hand, with the work of my Department and the additional time required for the session of Parliament, I felt that it would be impossible for me to prepare a paper. Therefore I agreed to speak on the understanding that I would not have a written document, and that I could speak to you quite informally about the work and policies of the Department of Munitions and Supply.

The idea of civilian buying for the armed services dates back to some three or four months before the war. For many years it has been the prerogative of the army, the air force and the navy to purchase their own supplies. However, while trying to cool up for this war before its outbreak, we found that the army was not properly organized to do the kind of buying that is required in modern warfare, and it was decided to set up a civilian body to do that work, with the title of the Defence Purchasing Board.

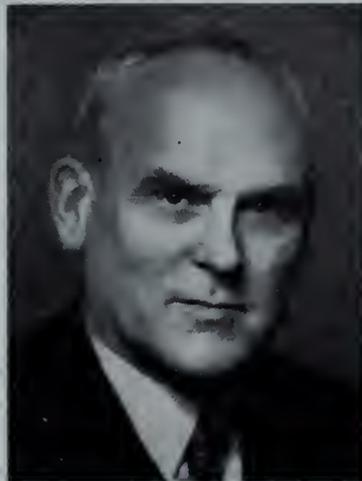

It was thought wise at the time to hedge this body about with restrictions. As yet there was no war, no one was in very much of a hurry, and it was felt that the public should be safeguarded in war buying by limitations of profits in several ways. But it was well understood that in the event of actual war the restrictions would be too onerous to permit the speed of operation necessary to meet the situation.

Therefore, after the outbreak of war, the Board was renamed the War Supply Board. At the same time, legislation was passed setting up the Ministry of Munitions and Supply, and charging the Minister with two duties; first, to purchase all the requirements of the Army, the Navy and the Air Force; and second, to mobilize industry for the maximum output of war munitions and war supplies.

I think that while our legislation in that respect was unique, we were fortunate in having hit upon a sound form of organization. It is interesting to note that quite recently Britain has come to our form of organization. The organization for buying in Britain as originally set up was based on three Ministries. The Ministry of Supply purchased the requirements of the Army, the Ministry of Aircraft Production purchased those of the Air Force; and the Navy did its own purchasing.

An over-riding Ministry has now been set up in Britain with jurisdiction over these three buying agencies, thus avoiding the difficulties that arose because the three services were competing for supplies with each other in the same factories.

There has also been a movement in the United States to change from buying by the services themselves to buying by a civilian agency. There seems to be a trend there towards the type of organization that we now have in Canada.

C. D. Howe, HON. M. E. I. C.

The early problems in the Department of Munitions and Supply were not the problems that we have to-day. You remember that the Department started from absolute zero. We first had to find an office, a typewriter and desk, and a stenographer, and then build up a competent organization.

Frankly, we were quite ruthless. We looked over the whole field of industry and business in Canada, and we picked out the men that we thought were most able to do a job in the new Department. Having practised engineering in Canada for a number of years, I had a very wide acquaintanceship among my own profession and throughout Canadian industry, and I used that acquaintanceship to help me in selecting the men who would work with me in the job at hand.

I am very proud of the organization that we have built up in Ottawa to handle munitions and supply problems. Its personnel now comprises over three thousand men and women. From the outbreak of war these men and women have not stinted the time or effort they have given to the work of the Department. You can drive by the Munitions buildings in Ottawa at any hour of the night and find lights burning and people working in a great many of the offices. We have been, I think, fortunate in attracting able people to our Department.

Our first task was to buy personal equipment, uniforms, and things that had to be furnished immediately.

Then we undertook to provide the munitions of all the types required by the Army and the Navy and the Air Force, and there we had a real problem. Canada is not a military country. In peace time it kept a very small nucleus of an army, practically no air force at all, and a navy which, I think, consisted of some thirteen or fourteen craft.

At first we had very little designing organization, and we had none of the plans and specifications and information required to produce types of munitions which were needed in the war, but which were new to this country.

In the last war we had developed the technique of making shells and components of finished rounds of ammunition, and we were able to tackle that problem fairly rapidly, so that our first progress was made in the field of ammunition.

We had at the Quebec arsenal a plant for making small arms ammunition, and we started immediately to expand that greatly. I think at the outbreak of war Quebec arsenals were making three million rounds of small arms ammunition a year. To-day they are making more than three million rounds every two weeks; this will give some idea of the expansion that has taken place in that particular field.

We also had a very efficient Canadian motor industry with a strong designing staff. Thus we were able to start very quickly in the making of the mechanized equipment for our army, which is required in such vast quantities for the type of warfare that we now have to provide for.

We have continued to expand that industry and I think to-day we have delivered over 216,000 motor vehicles of

army type, either to our own forces or overseas to the many theatres of warfare.

However, we had no experience in manufacturing guns in this country, except the old Ross rifle, which did not turn out so well. Therefore we had to call on the Old Country for technicians and for designers to enable us to set up a technique for producing guns of all types.

Just before the outbreak of war we had undertaken to make the Bren machine gun in this country. This project was under way when war began, but was the only step which had been taken to develop a gun industry.

To-day, we are building almost every type of gun used in the war, except the very large coast defence guns. We are building naval guns of every calibre; naval gun-mountings; 25-pounder field artillery; 6-pounder tank guns, anti-tank guns, and several types of heavy guns. In the field of automatic guns the Bren gun production is now more than three thousand a month, and we expect ultimately to reach 4,500 a month. We have stepped up the production of Colt Browning guns up to about 2,000 a month. The Bofors anti-aircraft gun is coming into large production; we are making the Sten sub-machine guns, and are producing great quantities of Lee-Enfield rifles.

The year before the war I think we turned out 200 aircraft. We had only a small industry working mostly on small planes for transport work, and one or two types of army planes. Today we are turning out planes at the rate of about 70 a week or 300 a month. We are independent now of outside help in furnishing planes for our great Air Training Plan, and we are also building several of the most modern types of planes that are used by the fighting forces. From a small nucleus we have built up a very strong aircraft industry.

In the field of shipbuilding, we formerly built ships to some extent in Canada, but during the depression years that industry reached a low ebb, and its activities had been confined largely to repair work. Trained mechanics were scarce and it was necessary to start gradually in stepping up production. However, we commenced immediately to build several types of naval ships. The corvette, which is a small edition of the destroyer, was put in hand, with several types of minesweepers, and also a great number of the small craft which are necessary as auxiliaries of the navy.

From some fourteen or fifteen vessels at the outbreak of war, our naval strength has now risen to about 330 ships of all types, and we expect that the year 1942 will see another large increase.

Then with the sinkings on the Atlantic, the Battle of the Atlantic was taking such a course that it was necessary to divert some of our shipbuilding capacity from naval work to the building of merchant ships. A programme has been established which for this year should produce almost as many new merchant ships as will be launched by the merchant shipbuilding industry of Great Britain; this I think is rather an accomplishment.

During the last war we built up an explosives industry, but, unfortunately, it was all scrapped when peace came and we had to start again from zero. Before making the explosives themselves, we had to provide for the manufacture of the many components of explosives, and we have to-day in that field built some twenty-five new plants, with an expenditure of about \$125,000,000. To-day we have an explosives programme large enough to enable us to cover our own needs, supply the deficiencies of Great Britain, and also help our friends in the United States with quite a quantity of chemicals and explosives of which they are short at the moment. I should say something about the help that we have received from science, from the scientists of Canada, and particularly from the National Research Council and its staff under the direction of Dean Mackenzie.

At the outset we knew very little about the many secret devices that have played such a great part in winning the Battle of Britain and fending off the attack of aircraft on that island. Dean Mackenzie undertook the work of developing that equipment and to-day I believe that Canada is not only abreast of Britain in the quality of its secret equipment, but at the moment possibly a step or two ahead.

We established a government-owned plant, Research Enterprises Ltd., to manufacture this apparatus, and have spent a good deal of money on it, but the results to-day are exciting the interest of every country that is taking part in this war on the side of the Allies.

I suppose Colonel W. E. Phillips has more technical visitors to that plant than come to any other plant we have. It is a revelation to see what he is doing there, for he has orders in hand for over \$100,000,000 worth of equipment of that type.

In addition, he has developed the manufacture of optical glass, so that Canada is making all the optical glass needed for her war instruments, such as lenses and periscopes. Here again, we are able to help out our Allies, by exporting certain quantities of optical glass.

Another triumph of the staff of Dean Mackenzie is the development of a new process for manufacturing magnesium. Magnesium is a metal very highly valued in the war, both as a light weight metal of great strength, and as a powder in connection with pyrotechnics and incendiary bombs.

Dean Mackenzie's organization has developed a plant that will produce magnesium with about one-half the capital expenditure of the old method, and that can be built in about one-half the time required for the chemical plants that have been producing magnesium up to this time. The new process will produce magnesium at about the same price as the older more elaborate method.

The United States are now faced with a shortage of that metal, and you will be interested to know that their programme involves the construction of a number of magnesium plants of the kind and type that have been invented by our own research laboratories. And we, ourselves, are building plants following that process, to produce Canada's magnesium requirements.

It has not been possible, of course, to build up this output of munitions without greatly increasing our production of raw materials. I think our aluminum production has been expanded five fold since the war began. We are now producing about 43 per cent of all the aluminum that is made in North America and we are supplying Great Britain with about 85 per cent of her aluminum requirements.

We are producing larger amounts of zinc and copper and lead, and all the lesser minerals that are essential to the war effort. Our production of steel in this country has more than doubled and we are still expanding that industry. We have multiplied the output of the alloy steels used for gun production by five since the war began, and it is still increasing. We have also stepped up greatly the output of brass which, as you know, is used for cartridge cases and a great number of war requirements.

We have kept abreast of the raw materials situation as well as we could, and have it fairly in hand, although we have still to depend on the United States for considerable supplies of steel.

Many problems have had to be met as we have gone along. One of the first of these was the method to be used by the government in expanding plants. Of course, in the early days it was not necessary to expand many plants. The task was rather to fill up the capacity that already existed, but very soon machine capacity had to be added to existing plants, and new plants had to be established.

Our policy has been to ask private industry to expand where we thought that the industry was strong enough to

be able to do the expansion at its own expense, and in those cases we have provided special depreciation to allow the war expenditure to be written off.

We have set up a Board which assesses the post-war value of a privately built improvement, and sets a figure and a rate of depreciation for the war expenditure. That is a method used where the industry itself is able to take care of its financial requirements for expansion.

In the matter of installing new machinery we have decided that the government would purchase the machinery and own it, place it in the plant, and reclaim it from the plant after the war period. I think we have purchased some \$60,000,000 worth of machinery which has been installed in plants and of which the government has retained ownership.

Where a new building has been required, or a new project required, it has been our policy that the government would build and own this requirement, that it be operated at cost, and that the management would be obtained by a management fee arrangement with an organization capable of providing that management. I think the government's investment in that type of plant to-day is in excess of \$600,000,000.

We own the land these buildings are put on. We insist that the land be deeded outright to the government for a dollar. We own the buildings, we own the equipment and when the war is over we can turn the key of the lock, if we like, and take that building out of competition with private industry. Thus it has been our policy to take our depreciation at the start, rather than to write it off against the cost of the goods produced. We pay for the plant; we pay for the machinery, and we obtain our goods at cost.

The year 1941 was not a great production year in war munitions, for the reason that so much of the year was used in building and tooling and getting under way. However, in that year Canada did produce munitions on a very considerable scale.

You know that Canada's munitions programme in the last war was a worth while effort. You know the story of Sir Joseph Flavelle and Lloyd Harris, and the success that they had in turning out munitions in that war. So, when I tell you that in the year 1941 we made more munitions in Canada than we did throughout the whole history of the Great War, you will realize that it was not a lost year by any means.

A statistical study of the possibilities for 1942 indicates that we will turn out about two and one-thirds times as many munitions as we did in the year 1941, so that in this year our munitions industry will really be going. We are still starting new projects, and as the requirements of warfare change, with the flowing tide of battle, we shall continue to start new plants and take on new obligations.

Now, where are these munitions going? You read in the papers that they are short of rifles on the west coast, or short of this and that in other areas. That may be perfectly true. We are not attempting to hold these munitions of ours in Canada. We are building them to help win the war and we are sending them where they will do the most good for that purpose. Huge quantities of our munitions have gone to England to equip our own troops there, and to bring British formations up to strength in the matter of equipment.

We have shipped still greater quantities to the Middle East. I believe the battle there has been fought very largely with Canadian mechanical transport and Canadian Bren gun carriers, to say nothing of artillery and machine guns that we have been shipping there for many months. We had Canadian munitions and lots of them in the battle of Greece. We have Canadian munitions in the Far East, in the Netherlands East Indies, in Singapore and Java and the other battle areas.

We have sent great quantities of raw materials and munitions to our sister Dominions, Australia, New Zealand, South Africa, India and Burma. We have supplied large amounts of munitions to China. You have heard a good deal about North American aid to China. I can tell you that the first shipment of North American aid to China, taken in over the Burma road, consisted of a thousand Bren guns and ten million rounds of Canadian ammunition.

Incidentally, one of my Christmas presents, which I value highly, was a photograph of Generalissimo Chiang Kai-Shek, sent from China and autographed in Chinese characters, with a message of thanks to myself.

Our entire production of Valentine tanks has been for several months going to Russia and we are sending across three tanks every day to assist the Russians in their great fight against Germany. I may say that we have valued letters of appreciation from the Russians on the type of work that those tanks are doing.

When the sudden crisis came to the United States we were proud to be able to offer munitions for shipment to Hawaii and to the Philippines; Canadian munitions are in the fight in both those areas.

We are making a munitions programme to help win the war. If it were merely a question of equipping Canadian troops, only a small fraction of our present output would be required, but we have taken the view that until the Allies have a parity of munitions with the enemy in every battlefield, it is our job to turn out as many munitions as we can and to send those munitions where they are most needed.

Occasionally I get a little disturbed by criticism. Recently, a complaint was made in the House of Commons that our troops on the west coast were using old rifles. Well, it is true they are using old rifles. They are perfectly good rifles, but still it is a very natural question: why, if Canada is such a great munitions making country, cannot the troops on the west coast have new rifles?

I said to my friend, Colonel Ralston, "Let us stop this criticism. Let us take a month's production from our small arms plant and give our troops new rifles."

He said, "Not at all. Those rifles are promised to Singapore, they are going to Singapore, and we will take the criticism."

I would like to make it clear that any success we have had in developing an arms industry in Canada and in expanding our industrial capacity has been due to the splendid support that I have had from industry, from the engineering profession and particularly from the ranks of labour. I think that we can compare our effort in this country with that of any country in the world in any of those respects.

I do not believe that, even in England, industry has been more full-out to help the government and to do everything asked of it in turning over its facilities for the manufacture of munitions. And I am sure that when the record of organized and of unorganized labour in this country has been written, it will be seen that we have had as much co-operation from labour as has been attained by any of our Allies in this war.

Lord Beaverbrook has said on two or three occasions, and said publicly, that on a per capita basis Canada is turning out more munitions of war than any one country in the world, including the enemy countries. This may well be true, as far as any statistics I can find would indicate, but, even if true, it is not a matter for complacency. It is our job to turn out everything that Canada can turn out.

If anyone had told me a year ago that we could bring about the expansion of industry that has taken place in the last year, I would have said that I hardly believed it.

We have been constantly raising our sights. What is true of our position I think is true of industry itself. If you had gone into one of our large manufacturing plants a year and a half or two years ago and said that we wanted them to expand their plant up to what they are actually doing to-day, I think the management would have told us that that would be quite impossible.

The limitations of our programme are, we find, the limitations of skilled management. We have yet to run into a serious shortage of manpower and womanpower—and womanpower is playing a part in our plans to an increasing extent every day—but we do find difficulty in developing skilled management. We are still looking for firms that can take on more work, but we find that firms with what we believe to be the required experience have about all they can handle at the present time.

Throughout the year we have greatly increased production by encouraging sub-contracting and expanding

a programme that we call our bits and pieces programme. We have carried the work of making small bits of ordnance or small bits of some other type of production into the very small factories. In fact, I think the smallest plant we have is a two-car garage with three lathes which is making a part of a 25-pounder gun.

That is necessarily a slow and difficult development. It is not easy to get large manufacturers to break down their contracts into small bits and it is difficult to get the small bits all out to the small firms. However, a process of education has been going on and is achieving splendid results. The bits and pieces system, I think, will continue to be an effective means of further expanding our industrial output.

I see my time is up. May I say how glad I am that I did not let the lack of a paper prevent me coming here. I have enjoyed speaking extemporaneously, and thank you very much for having invited me.

# NATIONAL SERVICE—A CHALLENGE TO THE ENGINEER

E. M. LITTLE

*Director, Wartime Bureau of Technical Personnel, Ottawa, Ont.  
General Manager, Anglo-Canadian Pulp and Paper Mills, Quebec, Que.*

Address delivered at the General Professional Meeting of The Engineering Institute of Canada,  
at Montreal, Que., on February 6th, 1942

I welcome the opportunity to speak of two matters which I hope you, as engineers, will find of some interest: first, a brief review of the activity of the Wartime Bureau of Technical Personnel; and, second, the necessity of planning for the period of post-war rehabilitation and construction. Planning for the post-war period is, for the engineer, both an opportunity and a duty.

Most of you are familiar with the part already played by the engineers and chemists of Canada, through your Institute, the Canadian Institute of Chemistry, The Canadian Institute of Mining and Metallurgy and the provincial professional engineering associations, in plans to mobilize the technical personnel of Canada for the war effort. The leadership shown by the three Institutes has been helpful in promoting the establishment, about a year ago, of the Wartime Bureau of Technical Personnel, under the Department of Labour at Ottawa.

It is not intended to dwell at any length on the activities of the Bureau, as these have been, and will continue to be, reported, from time to time, through your journals and other media. However, a brief summary of what has been accomplished and a statement of a few of our difficulties may be timely.

Our first job was to find out how many engineers and chemists there were in Canada, where they were, what they were doing, what they could do, and since we were operating under the voluntary system, what they *would* do. All of that information was not available anywhere in Canada.

For an all-out effort, which we believed necessary—and which we felt the technical men knew to be necessary—we needed that information. The result was the questionnaire and classification list, now familiar to most of you.

The Bureau now has, we believe, the most comprehensive data on technical personnel ever available in Canada. While the register is not yet complete, it is rapidly approaching completion. Some have not filled in the questionnaire, because they have not received one due to change of address or errors in the mailing list; while others have not seen fit to reply, because they do not appreciate the need for providing the information or they are not too anxious to risk being inconvenienced. Those engineers and chemists who have not yet received a questionnaire may be assured that the Bureau is making every possible effort to correct this condition. As regards those who have not seen fit to respond, we believe suitable measures are being taken to the end that the information shall be forthcoming. On the whole, however, the response has been splendid, both in the promptness with which the information was supplied, and the willingness of nearly all of those answering, to be transferred to more essential work, including service in the armed forces.

Our questionnaire has the weakness of all questionnaires—it is only up to date in some respects, as from the date it was filled out. Changes in address and employment and experience acquired since signing the questionnaire cannot yet be secured except by a cumbersome time-and-labour consuming follow-up system. We believe this difficulty will be overcome in the very near future by a simple, efficient, continuing inventory of our technical personnel.

The cost of operating the Bureau to the end of 1941 has been less than half of our appropriation for the Gov-

ernment fiscal year, ending March 31st, 1942. However, the demands on the Bureau are expanding and our staff and cost of operation will increase accordingly. We have secured over five hundred engineers and chemists for essential industries and for civilian occupations in the armed forces. The requests for help through the Bureau are increasing so fast that we are having difficulty in locating and/or arranging for the transfer of the numbers required. With demand greater than supply, each request for help must be investigated carefully by the Bureau. We appeal to employers to search carefully within their own organizations, before they ask for outside assistance. Employers must expect and provide for the necessity of turning out more and more production with less and less men, and in addition must be prepared to train and release engineers and artisans for the armed forces.

We have placed appreciable numbers of Polish engineers and skilled artisans, whose qualifications and sympathies have been carefully scrutinized by the proper authorities before being turned over to the Bureau for placement. And as a result of an urgent call from London, we have secured engineers for special work in England.

The placement work of the Bureau cannot be likened to, or compared with, the function of a peacetime employment office dealing with professional engineers. The problem now is not to find work for the engineers; but to find the engineers for the work—in most cases very special work, and in many instances several jobs for the one engineer. These conditions introduce problems not experienced by peacetime employment agencies and necessitate more effort in the handling of each individual case.

Almost from the date of its establishment, the Bureau has maintained close contact with the universities. There is some confusion in the minds of both the university authorities and the students as to what they should do to make their full contribution. Should the student finish his course or enlist now—should the university graduate him early with or without a degree? The different branches of the armed forces suggest one thing and our Bureau suggests something else. We are doing everything we can with the authorities at Ottawa to secure greater co-operation between ourselves and the armed forces, to the end that this confusion may be minimized, and so that the universities may better meet the combined needs of the armed forces and war industries.

We are being requested by certain government departments to assist in the adjudication of an increasing number of cases affecting technical personnel.

The shortage of technical personnel is becoming more acute. The work of the Bureau is increasing and will continue to do so. We will centralize our activities in Ottawa only to the extent necessary for planning. We now propose to decentralize as may be necessary for the execution of the work. Within the next few weeks we shall start placing field men in the larger industrial centres so that local or more direct contact may be made with the employer and the technician. We shall need the most intelligent understanding and sympathetic attitude on the part of both the employer and the technician in our efforts to ration properly the technical skill of the country.

In our work at Ottawa, we have become impressed with the lack of adequate information on the manpower of

Canada. No proper machinery has ever existed to obtain it and to keep it up to date. The National Registration of 1940 gave some essential basic information on the numbers, sex and age groups of our people as of August, 1940, but it falls far short of giving all the information necessary as of February, 1942. We need a running or continuing inventory of our manpower. We must know quickly of the improvement in the skills of our people. We must know where they are to-day and what they are capable of doing to-day, and if three months or one year from now conditions require new information, we must have the machinery to get it and get it quickly, on such portion of our manpower as may be affected. How we can plan an all-out war effort on either a voluntary or compulsory system without such a running inventory, remains a mystery. It is not only essential to have this information for our war planning, but as will appear later in this talk, it will be equally desirable in post-war planning. It is satisfactory to note that considerable attention has been given to this matter during the past few months by officials in the Department of Labour and others at Ottawa, and I am hopeful that some suitable plan will be evolved on which action will be taken in the near future.

The privilege given some of us to serve the war effort in a modest way through the Bureau has enabled us to appreciate some of the work and difficulties of government departments. We are particularly impressed with the need for each of us, as Canadians and as engineers, to do more toward the solution of immediate and future matters of national interest and import, than we have heretofore. We have all been critical of the government, but based on our experience in the Bureau, we are satisfied that the collective stupidity of Ottawa is at least equalled if not surpassed by that of the public. Nor are all the prima donnas, quacks and crackpots, great or small, in the government service.

Too many of us turn to some heavily laden government department, expecting it to find a solution to our problem. Many of us, when a reasonable solution is found, prevent its adoption either through ignorance or because it appears to clash with our own selfish interests. On the other hand, some of us are prepared to give all the answers to all the problems of the country, past, present and future, without any real knowledge of such problems. As citizens we are grossly ignorant of, or apathetic towards, national questions and too many of us are chronic protesters. Our national affairs will never be properly conducted by this or any future government unless we wake up and cease to be a nation of leaners. To be effective, a government needs the support of an informed public. We are not an informed public, and the only way to become informed is to work and think. And, with the critical job now facing us and with the problems that will confront us in the post-war period, the time to start working to make our full contribution to the solution of national problems is *now*.

No words from me are needed to give you a better appreciation of the seriousness of our present job,—winning the war. I am sure you realize the totality of effort *in time* which we must put forth to win, and the terrible consequences to all of us, if we should lose the struggle, or even if it should result in a draw. Planning for the post-war days means nothing but waste effort unless we win;—but plan we must, as failure to do so may have results almost as serious as those due to our lack of planning for defence prior to the outbreak of war.

Each job, the winning of the war and the planning for the post-war period, must be given its proper weight and timing.

Canada, as one of the allied nations, must go all-out in its effort. Every pound of essential material and every man-hour of labour which can be diverted to that one purpose will be necessary. And the more closely we ap-

proach that all-out effort the more difficult the re-adjustment will be, unless planned.

What are the problems that we shall face immediately the war is won? How shall we plan and prepare to meet them, where and how do we get the information on which to plan, and who shall do the planning?

In my opinion, the one fundamental and all-important problem of the immediate post-war period, upon the solution of which the measure of prosperity we are to experience will largely depend, will be the finding of *useful* employment for the men and women of Canada of working age,—*useful* employment for the men and women who, by the end of the war, will be in the active forces, in the factories producing war materials, and in other directly or indirectly associated industries in which the employment level may then be abnormally high due to the war production boom.

That, I believe, is *the* post-war problem. As one begins its study it becomes apparent that because of the inter-relationship between employment and our whole national economy, its solution will provide the answers for many other questions. To solve any problem it is first necessary to have a clear appreciation of its nature. To avoid fumbling we must know where and on what to start, for a job well started is half done. I suggest that we start on that one problem, believing that in solving it we solve many others.

Before we try to visualize the size of the job of providing *useful* employment to those who may be thrown out of work when the war ends, let us note briefly how the study of that problem takes us into many phases of national activity

Employment prior to the war was provided principally by agriculture, industry, governments and professional services of various kinds. Our agriculture, particularly wheat, has been largely dependent on export markets. Thus the level of employment which can be provided for the wheat farmer depends on our success in securing a sufficiently large and remunerative export market, or increase in our domestic market, or both. The wheat farmer, and all Canadians affected by the degree of prosperity secured for him, have an interest in point four of the Atlantic Charter in which Mr. Churchill and Mr. Roosevelt declare: "they will endeavour, with due respect to their existing obligations, to further the enjoyment by all states, great or small, victor or vanquished, of access, on equal terms, to the trade and to the raw materials of the world which are needed for their economic prosperity."

What does access on equal terms mean?

And how are we to build up the domestic market for wheat and other agricultural products? Can we consume more with the same population, or do we need more people? Would immigration help? Would it lessen or add to employment? If we decide on immigration, who shall come in, what kind of people can best be assimilated into our social life, at what rate shall they be allowed to enter, and how do we attract them to Canada? Should any immigration plan be short or long term,—and if long term, how do we ensure its continuity?

Our industries can be divided into two principal classes, those depending largely on export markets, such as forest products (pulp and paper), and mining, and those depending on domestic markets which include importing industries. The exporting industries must concern themselves with the improvement of their export position, or reduce their dependence on the export markets by increasing their domestic markets, or both. They also, therefore, are concerned with point four of the Atlantic Charter. Must they prepare to compete with subsidized exports and depreciated currencies, or does "access on equal terms" mean "currency equalization" or "quotas," or both? All our industries, exporting, domestic and importing,—must

be concerned with the development of our domestic market, if the levels of employment are to be sufficient for the needs.

The measure of prosperity which we can secure for our agriculture and our industries will have a large bearing on our ability to provide useful employment after the war.

For how many people must we find *useful* employment in the post-war re-adjustment period? It is conceivable that if the war should continue, Canada may have a million men and women in the active forces. It is also conceivable, if the war is prolonged, that one to two million men and women may be thrown out of employment when we stop producing war materials and as employment in other activities diminishes as the war production boom abates. We should, therefore, prepare to face the job of finding *useful* employment for two to three million men and women.

If, with the luck of the devil and a fast outfield, we happen to experience a prosperous immediate post-war period our worries may be minimized,—but if we don't, what then? The problem of finding and/or making *useful* employment for two to three million people, *in time*, will not be easy;—indeed it will be extremely difficult. But it must be done, and if planned well and soon enough, if boldly conceived, intelligently organized and vigorously pursued, it can be done.

What kind of work do we plan for those two to three million men and women? Is it not necessary to know not only how many there are, but what kind of people they are, their education, their training, their experience? Are we only to plan for numbers and waste those assets?

How do we get this information? Up to now there has not existed any machinery by which this information could be obtained in sufficient detail, and *in time*. But the same machinery which is necessary to get information on our manpower in wartime can be used to secure the information for the post-war planning. And that machinery must be kept working and well oiled until Canada is rid of unemployment. Our last period of unemployment, necessitating direct relief, with all its attendant evils and abuses, was in the opinion of many, not well handled for two principal reasons,—first, because we, as individuals, assumed little or no responsibility for it; and, second, because it was poorly planned, due to lack of information. We cannot build anything unless we know what we want to build and what we have to work with. Full and accurate information on our people is a prerequisite to planning.

Assuming we shall have available, *in time*, all the necessary information on those to be rehabilitated at the end of the war, what kind of work do we plan? As far as is humanly possible, we must plan *useful* work. It will not do merely to have people occupied digging post holes and filling them in again. The doctor, the engineer, the nurse, the lawyer and the mechanic should, if possible, be provided with the work they are best qualified to do. The kind of work we plan must, where possible, take cognizance of the training of our people, and be consistent with the long-term economic development of Canada.

If the number already stated, for whom we must find suitable employment, is a reasonably close estimate, we are facing quite some job. It is of such national importance that it needs the consideration first of the Federal Government. It should be their responsibility to see that plans are drawn up in their broader outlines; to secure, *in time*, the necessary information on the men and women for whom employment is to be found; to initiate, *in time*, plans for Federal Government projects; and to enlist, *in time*, the support and active assistance of all the provincial governments and of industry, large and small.

It will not suffice to confine our work planning to gov-

ernment undertakings. All the useful projects which governments can undertake must be supplemented by all the work all our industries and enterprises can provide. The delaying of every job, large or small, which can be delayed till war is over, the planning by industry of plant improvement and expansion, the study to determine how to convert our war plants to new peacetime use, the development of new industries, the conservation and development of our natural resources, reafforestation, necessary housing projects, slum clearance and a comprehensive health programme, are only a few of the many possibilities to which proper attention must be given *soon*, considering the time required for planning.

Now what has all this to do with the engineer? At some stage in this planning, all these broad outlines, all the projects and undertakings, any new industries, or plant rehabilitation, any conservation or reforestation, must be worked out and translated into pounds or other quantities of materials; into man-hours of work for the production, preparation and transportation of that material; and into the man-hours of work for fabricating the material into the finished products. And then those man-hours must be broken down into work for the miner, the carpenter, the mechanic, the mason, the forester, the engineer, the architect and so on up and down the whole list. The engineer is so important to this part of the planning that I can safely say it cannot be done without him.

But there is another function the engineer can perform which is important at an earlier stage in the planning. Many of you know from experience that some well conceived plans fail in their execution because some detail has been overlooked, that undertakings supposedly well organized missed something in the organization, that people who are eminently capable of planning in broad outline may neither have time for, nor appreciation of, the details necessary to carry those plans to complete fulfilment. The engineer must do his part to see that in this planning no detail is omitted, that in the organization of this vast job no step is missed. Those who are, or may be, charged with the planning of the broad outlines, should enlist the engineers' assistance as early as is desirable, or permissible.

The prophecy of President Wickenden, of the Case School of Applied Science, in his able address delivered at your Hamilton meeting a year ago, is, let us hope, about to be realized. He said "They (the engineers) will be called upon to share the control of disease with physicians, the control of finance with bankers, the bearing of risks with underwriters, the organizing of distribution with merchants and purchasing agents, the supplying of food with packers and purveyors, the raising of food with farmers and the operation of the home with the housewives."

But he also said "In few of these new fields, if any, will engineers be self-sufficient;—to be useful they must be team workers; and they must be prepared to deal with 'men and their ways' no less than 'things and their forces'."

Planning for the post-war period will take us into an ocean of problems. We cannot have too many skippers, else they may want to chart different courses, and the ship will be left stranded. If the Federal Government (or its nominees), must chart the course,—and in view of the national scope of the problem, it seems logical that this should be done—then let us be part of the crew, and do our full part.

Though the job may be large, and the difficulties great, team work will do it. The opportunity for the engineer to render national service has never before presented itself on such a scale. Will the engineer meet the challenge without for one moment forgetting the job in hand—that of having a post-war period in which *our* plans shall prevail?

# THE FIFTY-SIXTH ANNUAL GENERAL MEETING

Convened at Headquarters, Montreal, on January 22nd, 1942, and adjourned to the Windsor Hotel, Montreal, on February 5th, 1942.

The Fifty-Sixth Annual General Meeting of The Engineering Institute of Canada was convened at Headquarters on Thursday, January twenty-second, nineteen hundred and forty-two, at eight forty-five p.m., with Councillor Huet Massue, M.E.I.C., in the chair.

The assistant general secretary having read the notice convening the meeting, the minutes of the fifty-fifth annual general meeting were submitted, and, on the motion of J. A. Lalonde, M.E.I.C., seconded by J. M. Crawford, M.E.I.C., were taken as read and confirmed.

## APPOINTMENT OF SCRUTINEERS

On the motion of W. B. Korcheski, M.E.I.C., seconded by C. F. Davison, M.E.I.C., Messrs. E. V. Gage, M.E.I.C., P. E. Poitras, M.E.I.C., and J. K. Sexton, M.E.I.C., were appointed scrutineers to canvass the officers' ballot and report the result.

There being no other formal business, it was resolved, on the motion of A. S. Runciman, M.E.I.C., seconded by W. H. Moore, M.E.I.C., that the meeting do adjourn to reconvene at the Windsor Hotel, Montreal, at ten o'clock a.m. on the fifth day of February, nineteen hundred and forty-two.

## ADJOURNED GENERAL MEETING AT THE WINDSOR HOTEL, MONTREAL, QUE.

The adjourned meeting convened at ten o'clock a.m. on Thursday, February 5th, 1942, with President C. J. Mackenzie in the chair.

The general secretary announced the membership of the Nominating Committee of the Institute for the year 1942 as follows:

### NOMINATING COMMITTEE—1942

Chairman: E. P. MUNTZ

Branch	Representative
Border Cities.....	C. G. R. Armstrong
Calgary.....	F. K. Beach
Cape Breton.....	J. A. McLeod
Edmonton.....	W. R. Mount
Halifax.....	R. L. Dunsmore
Hamilton.....	A. Love
Kingston.....	A. Jackson
Lakehead.....	P. E. Doncaster
Lethbridge.....	J. M. Davidson
London.....	V. A. McKillop
Moncton.....	B. E. Bayne
Montreal.....	R. DeL. French
Niagara Peninsula.....	C. G. Moon
Ottawa.....	J. H. Parkin
Peterborough.....	W. M. Cruthers
Quebec.....	A. O. Dufresne
Saguenay.....	N. D. Paine
Saint John.....	J. R. Freeman
St. Maurice Valley.....	E. B. Wardle
Saskatchewan.....	R. A. Spencer
Sault Ste. Marie.....	K. G. Ross
Toronto.....	W. E. Bonn
Vancouver.....	J. N. Finlayson
Victoria.....	S. H. Frame
Winnipeg.....	H. W. McLeod

## AWARDS OF MEDALS AND PRIZES

The general secretary announced the awards of the various medals and prizes of the Institute as follows, stating that the formal presentation of these distinctions would be made at the annual dinner of the Institute on Friday evening:

\* For an additional name, H. E. T. Haultain,

154 see Council minute 42/1866.

*Gzowski Medal*—To S. R. Banks, M.E.I.C., Montreal, for his paper, "The Lions' Gate Bridge, Vancouver."

*Duggan Medal and Prize*—To O. W. Ellis, M.E.I.C., Toronto, for his paper, "Forgeability of Metals."

*Leonard Medal*—To G. Reuben Yourt, STUD. C.I.M.M., Kirkland Lake, for his paper "Ventilation and Dust Control at the Wright-Hargreaves Mine."

\* *Julian C. Smith Medals* (Additional Inaugural Awards), "For Achievement in the Development of Canada," to W. G. McBride, M.E.I.C., Montreal, W. G. Murrin, M.E.I.C., Vancouver, and E. W. Stedman, M.E.I.C., Ottawa.

## STUDENTS' AND JUNIORS' PRIZES

*John Galbraith Prize* (Province of Ontario)—To A. L. Malby, Jr. E.I.C., Peterborough, for his paper, "Carrier Current Control of Peak Loads."

*Phelps Johnson Prize* (Province of Quebec—English)—To G. N. Martin, Jr. E.I.C., Montreal, for his paper, "Characteristics and Peculiarities of some Recent Large Boilers in England."

*Ernest Marceau Prize* (Province of Quebec—French)—To A. T. Monti, S.E.I.C., Montreal, for his paper, "Vedette de 40 Pieds de Longueur."

## REPORT OF COUNCIL

On the motion of R. L. Dunsmore, seconded by J. G. Hall, it was RESOLVED that the report of Council for the year 1941, as published in the February *Journal*, be accepted and approved.

## REPORT OF FINANCE COMMITTEE, FINANCIAL STATEMENT AND THE TREASURER'S REPORT

On the motion of G. A. Walkem, seconded by P. B. Motley, it was RESOLVED that the report of the Finance Committee, the financial statement and the Treasurer's report, as published in the February *Journal*, be accepted and approved.

## REPORTS OF COMMITTEES

On the motion of C. R. Young, seconded by K. M. Cameron, it was RESOLVED that the reports of the following committees be taken as read and accepted: Publication; Papers; Training and Welfare of the Young Engineer; Library and House; Legislation; Board of Examiners and Education; Western Water Problems; International Relations; Membership; Deterioration of Concrete Structures; Professional Interests, Employment Service.

## BRANCH REPORTS

On the motion of T. R. Durley, seconded by M. G. Saunders, it was RESOLVED that the reports of the various branches be taken as read and approved.

## LIFE MEMBERSHIPS

Mr. P. B. Motley presented a memorandum outlining Council's present method of granting Life Membership, and moved that Council consider and report at the next annual general meeting on the desirability of amending the by-laws so that Life Membership would be removed from the section dealing with exemptions from the payment of annual fees, and placed in a section similar to that dealing with Honorary Membership, and that such Life Membership be granted automatically and as an honour, without application from the member.

Mr. Motley's motion was seconded by Mr. S. Blumental, and after some discussion, was carried.

## POST-WAR RECONSTRUCTION

The president announced that the Lakehead Branch had submitted a resolution asking Council to take definite

tion with regard to post-war reconstruction. The resolution had been considered by Council at two meetings, and had finally been referred to the incoming Council for consideration and action. However, as Mr. P. E. Doncaster, from the Lakehead Branch, was present, he would ask him to present the resolution to the meeting.

Mr. Doncaster explained that he was not presenting this resolution for action by the annual meeting as it was already before Council. However, he did wish to let the meeting know of the resolution and, if possible, obtain some discussion which might be helpful in pursuing the matter further. He then read the resolution as follows:

The Lakehead Branch of The Engineering Institute of Canada submits to the annual meeting of the Institute for discussion and action the following resolution:

WHEREAS, it is generally agreed that, immediately after the cessation of the war in which this country is presently engaged, some millions of our citizens in the fighting forces or in employment in the production of war equipment and materials must be afforded opportunity for employment in peace-time occupation; and

WHEREAS, it is incumbent on all citizens of this country who are competent and whose time, training, and abilities are not fully employed in the war effort should be engaged in planning for the post-war period; and

WHEREAS, a lead in the direction and carrying out of the plans for the post-war period must be given and be sustained by competent individual organized groups and authorities acting alone in their respective fields, and also in co-operation with others in co-ordinating efforts; and, inasmuch as post-war employment will, in large measure, be based on technological surveys, investigations, planning, direction and supervision; and

WHEREAS, The Engineering Institute of Canada is peculiarly organized and fitted to take an active and a leading part in the planning herein referred; to Therefore,

BE IT RESOLVED that this resolution be submitted for discussion at the 1942 annual meeting of The Institute, and, if endorsed: that Council be instructed to set up at once a strong "SPECIAL PLANNING FOR POST-WAR" committee, composed of a central group of four members, which will initiate and promote enquiries, and from which group any member may be assigned by Council to represent The Institute on one or more other groups or committees set up by other organizations or authorities on similar planning work;

THAT, Council appoint one or more members from each of the Institute Zones who will act with the central committee as an advisory group, and who shall in turn arrange for the appointment of a chairman and two to four members of each branch of The Institute to act as a local or branch planning committee charged with the responsibility of carrying out instructions of the central committee in promoting planning within the boundaries of its branch area.

In giving effect to the foregoing organization it is suggested the services of vice-presidents and councillors of The Institute be utilized to the greatest possible extent, consistent with their availability for the project, and

FURTHER, that planning for the post-war period be undertaken and continued as one of the major activities of The Institute until such time as normal peace-time conditions have been restored.

Mr. Doncaster then referred to the federal committee which had been appointed under the chairmanship of Dr. F. Cyril James of McGill University, to investigate post-war conditions from coast to coast. He informed the meeting that Mr. K. M. Cameron, a vice-president of The Institute, has been selected by Dr. James and his committee as chairman of the sub-committee to investigate the construction phases of the general problem. He expressed the hope that Mr. Cameron's committee would consult with all organizations qualified to contribute to the thinking

on the problem, and would not confine itself to a small circle. He hoped that every member of The Institute, no matter where he resided, would be given a chance to participate in the deliberations.

The president pointed out that the subject of the motion was not a new one. It had been before Council for many months, and nobody disagreed with the general principle that thought should be given to it. He pointed out that Council, at yesterday's meeting, had instructed the incoming officers to give this matter their consideration.

Mr. K. M. Cameron then told something of the sub-committee of the federal committee under Dr. James. He assured Mr. Doncaster and the meeting that everyone would be given an opportunity to express his ideas. He emphasized that it was only natural that on such a subject The Institute would be vitally concerned. At the present time he thought that there was little that could be done as the organization of committees and sub-committees required a lot of thought in order to make certain that the proper persons were appointed. He recommended that every person attend the professional session the following day, at which Mr. E. M. Little was presenting a paper on post-war problems, in the discussion of which Dr. Leonard C. Marsh, research adviser to the federal committee, would participate. He pointed out that in the last war post-war planning was left almost until the end of the war. He hoped things would be much better this time. Mr. Cameron intimated that discussion on this matter might more properly be made at the professional session the following day than at this meeting.

#### ELECTION OF OFFICERS

The general secretary read the report of the scrutineers appointed to canvass the officers' ballot for the year 1942 as follows:

President.....C. R. Young

Vice-Presidents:

Zone B (Province of Ontario).....J. L. Lang

Zone C (Province of Quebec).....H. Cimon

Zone D (Maritime Provinces).....G. G. Murdoch

Councillors:

Victoria Branch.....E. W. Izard

Lethbridge Branch.....J. Haines

Calgary Branch.....S. G. Coultis

Winnipeg Branch.....J. W. Sanger

Sault Ste. Marie Branch.....A. E. Pickering

Hamilton Branch.....W. J. W. Reid

Niagara Peninsula Branch.....A. W. F. McQueen

Ottawa Branch.....T. A. McElhanney

Toronto Branch.....Nicol MacNicol

Peterborough Branch.....H. R. Sills

Montreal Branch.....J. E. Armstrong

R. E. Heartz

W. G. Hunt

Quebec Branch.....E. D. Gray-Donald

Moncton Branch.....G. L. Dickson

Cape Breton Branch.....F. W. Gray

On the motion of P. G. Gauthier, seconded by S. N. Tremblay, it was RESOLVED that the report of the scrutineers be adopted, that a vote of thanks be tendered to them for their services in preparing the report, and that the ballot papers be destroyed.

The general secretary announced that the newly elected officers would be inducted at the annual dinner on the following night.

The president then delivered his retiring address on "The War Activities of the National Research Council of Canada," which will be found on page 141 of this issue of the *Journal*.

On the motion of G. F. St. Jacques, seconded by Paul Vincent, it was unanimously RESOLVED that a hearty vote of thanks be extended to the Montreal Branch in recognition of their hospitality and activity in connection with the Fifty-Sixth Annual General Meeting.

# THE PRESIDENT'S DINNER

*Left to right: Past-presidents G. H. Duggan, A. Surveyer and F. P. Shearwood.*

*Past-president G.H. Duggan.*

*Past-presidents T. H. Hogg, O. O. Lefebvre and G. A. Walkem.*

*Below: The chairman and host talks to Beaudry Leman.*

*Below, left to right: N. F. McCaghey, Walter G. Hunt, J. H. Fregeau, L. A. Duchastel.*

*Below, left to right: J. G. Hall, J. E. Armstrong, K. M. Cameron, J. A. Vance, M. G. Saunders and P. M. Sauder, C. K. McLeod in the foreground.*

# THE LUNCHEONS

The chairman, J. A. Lalonde.

The speaker at the Thursday luncheon, the Hon. C. D. Howe.

Above: deGaspé Beaubien speaks for the Victory Loan.

Above: The speaker at the Friday luncheon, James W. Parker. On his right, J. H. Maude, W. G. Hunt, Mrs. F. W. Taylor-Bailey, L. A. Duchastel.

Mayor Adémar Raynault welcomes the delegates to Montreal.

On the motion of T. A. McElhanney, seconded by H. A. Lumsden, it was unanimously **RESOLVED** that a hearty vote of thanks be accorded to the retiring president and members of Council in appreciation of the work they have done for The Institute during the past year.

There being no further business the meeting adjourned at eleven forty-five a.m.

## THE GENERAL PROFESSIONAL MEETING

### PROFESSIONAL SESSIONS

The attendance at professional meetings exceeded anything recorded previously. The Prince of Wales Salon will seat two hundred and fifty comfortably. It was full and overflowing practically for every session. At least another hundred were crowded in on several occasions, and all audiences were well rewarded for their attendance and attention.

On the afternoon of Thursday, the programme was opened by Colonel W. E. Phillips, president of Research Enterprises Limited, who described the work of that Crown company in interesting detail. His talk was illustrated by moving pictures and "delineographs"—the latter being

coloured photographs projected on the screen without benefit of film or slide. He also offered an exhibition of optical glass produced in record time at the plant. McNeely DuBose was in the chair. The paper is presented in full in this issue of the *Journal*.

W. F. Drysdale, M.E.I.C., vice-president, Montreal Locomotive Works, Limited, also Canadian Steel Tire and Wheel Company, Limited, Montreal; Director-General of Industrial Planning, Department of Munitions and Supply, Ottawa, presented his paper "The Manufacture of 25-Pounder Guns in Canada." This gun plant appears to be the only one in America where the continuous operations begin with the scrap metal. Mr. Drysdale also used movies and delineographs to illustrate his talk. John T. Farmer was chairman. This paper appeared in the January *Journal*.

Friday morning three papers were presented. "Accident Prevention Methods and Results" by Wills MacLachlan, M.E.I.C., Chairman R. E. Hartz, and "Rational Column Analysis" by Professor J. A. Van den Broek, Chairman C. M. Goodrich, were run simultaneously in the Prince of Wales Salon and the Oak Room. Both papers have appeared in the *Journal*, the former in the January number and the latter in the December number. Discussions of Professor Van den Broek's paper were so extensive that an afternoon session was arranged at the request of the audience.

The third paper, "The New 'Oil-hydraulic' Press in Munitions Manufacture" was presented by J. H. Maude, M.E.I.C., with Dean Armand Circé in the chair. The author

The American guests visited Headquarters during the meeting. *Front row—left to right:* Dr. A. H. White, President, Society for the Promotion of Engineering Education; Ernest B. Black, President, American Society of Civil Engineers; Dr. Eugene McAuliffe, President, American Institute of Mining and Metallurgical Engineers; George T. Seabury, Secretary, American Society of Civil Engineers; Dr. C. J. Mackenzie, Acting President, National Research Council of Canada. *Standing—left to right:* Dean C. R. Young, President, The Engineering Institute of Canada; A. B. Parsons, Secretary, American Institute of Mining and Metallurgical Engineers; C. E. Davies, Secretary, American Society of Mechanical Engineers; H. H. Henline, Secretary, American Institute of Electrical Engineers; S. L. Tyler, Secretary, American Institute of Chemical Engineers; James W. Parker, President, American Society of Mechanical Engineers; D. C. Prince, President, American Institute of Electrical Engineers; S. D. Kirkpatrick, President, American Institute of Chemical Engineers; Professor C. F. Scott, Chairman, Committee on Professional Recognition, Engineers' Council for Professional Development; C. C. Knipmeyer, President, National Council of State Boards of Engineering Examiners; J. A. Van den Broek, Professor of Engineering Mechanics, University of Michigan, Ann Arbor.

*Right:* The ladies register. In the group are Mrs. L. C. Jacobs, Mrs. J. A. Lalonde, Mrs. R. S. Eadie and Mrs. F. W. Taylor Bailey.

The committee goes to work. *Left to right:* Gordon D. Hulme, J. A. Lalonde, A. G. Moore, Walter G. Hunt and I. S. Patterson.

The Joint Conference Committee of the Founders Societies meet with Presidents and the Secretary of the Institute. *Seated, from left to right:* C. R. Young, E. B. Black, J. W. Parker, H. H. Henline, Eugene McAuliffe, C. J. Mackenzie. *Standing:* Col. C. E. Davies, D. C. Prince, G. T. Seabury, A. B. Parsons, L. Austin Wright.

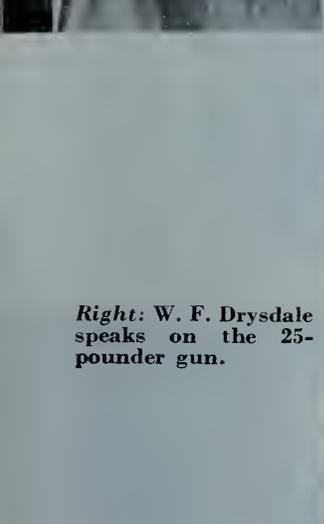

## PROFESSIONAL SESSIONS

**Left: Col. W. E. Phillips, president of Research Enterprises Limited, Toronto.**

**Right: Walter D. Binger of New York and Chairman H. A. Gibeau.**

**Right: W. F. Drysdale speaks on the 25-pounder gun.**

should be helpful to Government planning which is now underway. It appears in this number of the *Journal*.

The last professional session was an address "Some of the Engineering Implications of Civilian Defence," by Walter D. Binger, commissioner of Borough Works, City of New York, and chairman, National Technological Civil Protection Committee of the United States. H. A. Gibeau was in the chair. Mr. Binger had visited England to obtain first-hand information upon which he based his talk. He appears to be the only civil engineer in America who has studied this problem on the ground from the engineering point of view. His comments and recommendations are founded on experience, not just on the written word. Although Mr. Binger spoke from notes only, a verbatim

had an interesting exhibit which showed the work turned out by the press, and the method of operating. This paper has been published in full in the February *Journal*.

In the afternoon the first professional session was given over to "National Service—a Challenge to Engineers," a paper by E. M. Little, director of the Wartime Bureau of Technical Personnel, general manager of the Anglo-Canadian Pulp and Paper Mills, Limited, and president of the Gaspesia Sulphite Company, Limited, Professor R. DeL. French was chairman. This paper dealt with post-war planning in relation to labour, and emphasized the need of keeping in mind, in all such planning, that work provided should be useful or economically sound, and not just any kind of work. Mr. Little's paper

**Left: E. M. Little, discusses the Wartime Bureau of Technical Personnel and conditions after the war.**

**Left: A portion of the audience. From left to right: W. H. M. Laughlin, D. Forgan, W. P. Dobson, and A. B. Cooper, all from Toronto.**

**Right: Chairman Armand Circé introduces J. H. Maude.**

## SPEAKERS AT THE BANQUET

*Above:* President Mackenzie is a perfect chairman. On his right are J. W. Parker and Mrs. J. M. R. Fairbairn.

*Right:* General McNaughton praises Dean Mackenzie while Ernest B. Black and Mrs. McNaughton give close attention.

*Above:* Right to left, Ernest B. Black, President Mackenzie, Gen. McNaughton, Mrs. Mackenzie, J. W. Parker, Mrs. J. M. R. Fairbairn and Eugene McAuliffe.

*Above:* Ernest B. Black, president of the American Society of Civil Engineers.

*Left:* D. C. Prince, pres. American Institute of Electrical Engineers.

*Below:* Eugene McAuliffe, pres. American Institute of Mining and Metallurgical Engineers. Mrs. Fairbairn, Mr. Parker, right.

*Above:* Dean Mackenzie greets Pres. C. R. Young. *Below:* A. H. White, pres. Society for the Promotion of Eng. Education. Mrs. George Walkem, right.

*Above:* S. D. Kirkpatrick, president, American Institute of Chemical Engineers, Mrs. R. P. Vaughan, left.

*Left:* C. C. Knipmeyer, president, National Council of State Boards of Engineering Examiners. *Left,* Mrs. Surveyer. Past-President Walkem in the background.

## AT THE BANQUET

*Above:* General McNaughton presents the Julian C. Smith Medal to Air Vice-Marshal Stedman.

*Above:* General McNaughton presents the Phelps Johnson Prize to G. N. Martin. W. J. W. Reid in the left background.

*Right:* General McNaughton presents the Gzowski Medal to S. R. Banks.

*Above:* E. J. Carlyle, secretary-treasurer of the Canadian Institute of Mining and Metallurgy and Mrs. Carlyle.

*Above:* General McNaughton presents the Ernest Marceau Prize to T. A. Monti.

*Left:* Wing-Commander T. R. Loudon and Mrs. Loudon talk with Mrs. Walter D. Binger of New York.

The receiving line. From right to left: Dean Mackenzie, Mrs. Mackenzie, Mrs. Young, President C. R. Young, Mrs. McNaughton, General McNaughton, Mrs. Lalonde, Mr. J. A. Lalonde.

Professor French enjoys the company of Dr. A. H. White of Ann Arbor, Mich. In the background, S. N. Tremblay and Martin Wolff.

Mr. Howe aids Jules Comeau in the draw for War Savings Certificates.

Left to right: Max V. Sauer, R. B. Young and W. A. M. Cook of Toronto.

was obtained and will appear in an early number of the *Journal*.

## THE PRESIDENT'S DINNER

It would be difficult to imagine a more pleasant affair than the dinner given by Dean Mackenzie on Wednesday evening at the University Club. The delightful custom of the retiring president entertaining his predecessors and officers of The Institute at dinner has become one of the most enjoyable features of an annual meeting. It is always an informal occasion, but this year, with such an inimitable chairman and host, it had added to it, a brilliancy that made it a most unusual occasion.

In the company, which totalled sixty-four, there were nine past presidents and each one of them spoke for a few minutes. C. C. Knipmeyer, President of the National Council of State Board of Engineering Examiner was also present and contributed a delightful impromptu speech in which he explained that he came from the west and therefore was very much at home in such a friendly atmosphere.

A feature of the programme was the presentation by the president of a Julian C. Smith medal to Mr. Beaudry Leman, M.E.I.C., president of the Banque Canadienne Nationale. This award was made last year but the presentation had not taken place as Mr. Leman could not attend the annual meeting in Hamilton. In a short speech he expressed his thanks and reminded the audience of his long association with Mr. Smith, both in engineering and in

business. This long enduring friendship made him more than ever grateful for the honour which had been done him.

As would be expected, the chairman kept the pitch of the meeting at a high level. He emphasized the values that came from social gatherings such as this, and thought it might be a good idea to continue developing this day so that eventually it would become sufficiently attractive that officers and past officers without fail, would come from all over Canada to share in it. It would afford an opportunity for the development of social contacts before the business of the annual meeting took up the time and attention of the members. It might be called "President's Day."

## SOCIAL EVENTS

J. A. Lalonde, chairman of the Montreal Branch, presided at the luncheon on Thursday. His Worship the Mayor, Adhémar Raynault, welcomed the visitors to Montreal—in both French and English, and Vice-President deGaspé Beaubien spoke on behalf of the Victory Loan. The speaker of the day was the Hon. C. D. Howe, HON.M.E.I.C., Minister of Munitions and Supply, who gave the best talk yet heard on Canada's war production. Although Mr. Howe spoke without manuscript or notes, his address was recorded and appears in full in this *Journal*.

R. E. Heartz, retiring chairman of the Branch, thanked the speaker in a manner that met the enthusiastic approval of the audience.

The attendance was a tribute to the speaker. It amounted

to six hundred and twenty-five—almost two hundred higher than any previous luncheon attendance.

#### PAST-PRESIDENTS' DINNER

On Thursday evening at the St. James's Club the past-presidents and their ladies were dinner hosts to the outgoing and incoming presidents, C. J. Mackenzie and Mrs. Mackenzie, and C. R. Young and Mrs. Young, the party breaking up in time to join with the others—the ladies at the Engineers' Club for bridge, and the men at the Windsor Hotel for the smoker.

#### THE SMOKER

The annual smoker of the Montreal Branch has been a successful affair for years, but when combined with the annual meeting of The Institute, it reached new heights. An attendance of eight hundred, and an excellent programme of entertainment provided an evening "packed" with fun and amusement (packed is the right word for it).

#### LUNCHEON FRIDAY

This luncheon was presided over by deGaspé Beaubien, vice-president of The Institute. The speaker was James W. Parker, president of the American Society of Mechanical Engineers and vice-president and chief engineer of the Detroit Edison Company. His subject was "The Management-Employee Problem for Engineers." This was a very timely topic and the address can be studied with great advantage to labour and the profession. It is printed in this number of the *Journal*.

#### THE BANQUET

On Friday evening, under the chairmanship of retiring President C. J. Mackenzie, the annual banquet was held in Windsor Hall. No other Institute function has ever equalled this in numbers, enthusiasm or emotional attainment. Under the inspired direction of the chairman, a difficult programme was carried out in a manner that brought great pleasure to the entire assembly.

Lieut.-General McNaughton and Mrs. McNaughton were the guests of honour. Other special guests included the presidents of the seven leading engineering societies in the United States, and the secretaries of six of them. The seven presidents spoke first—for about three minutes each. These were Ernest B. Black, American Society of Civil Engineers, Dr. Eugene McAuliffe, American Institute of Mining and Metallurgical Engineers, James W. Parker, The American Society of Mechanical Engineers, D. C. Prince, American Institute of Electrical Engineers, Dr. A. H. White, Society for the Promotion of Engineering Education, S. D. Kirkpatrick, American Institute of Chemical Engineers, C. C. Knipmeyer, National Council of State Boards of Engineering Examiners. Their remarks are printed elsewhere in this number of the *Journal*.

When General McNaughton rose to speak a most unusual demonstration developed. Applause and cheering broke out from every person in the hall. It was sustained through a long period and clearly demonstrated the place which this great man holds in the minds and hearts of the engineers and the Canadian people.

He spoke of the need of more and better equipment so that precious lives could be spared in the battle for freedom. He spoke with the emphasis that comes from knowl-

edge and conviction. He had no notes, but his interest and his earnestness carried him on without pause or hesitation. His address in full appears in this number.

Past-President H. W. McKiel, of Sackville, N.B., expressed to the American officers the appreciation of The Institute for their attendance at the meeting and the kindly greetings which they had presented.

The retiring president introduced Dean C. R. Young and turned over to him the chair and gavel. Dean Young thanked the members for his election and spoke enthusiastically of the future of The Institute. He introduced the new officers and members of Council, and closed the session with the singing of "O Canada."

#### THE RECEPTION

After the banquet a reception was held in the Rose Room. General McNaughton and Mrs. McNaughton graciously joined in the receiving line with Branch Chairman and Mrs. J. A. Lalonde, President and Mrs. C. R. Young and Past-President and Mrs. C. J. Mackenzie.

#### THE DANCE

Until some early hour in the morning dancing held forth in the Rose Room. As usual this was a popular feature of the whole meeting, both with senior members and juniors.

#### PLANT VISITS

War industry afforded an unusual opportunity for inspection tours. The Canadian Car and Foundry plant at Longue Pointe was visited to see the making of shell forgings by the new methods, followed by an inspection of the tank arsenal at the Montreal Locomotive Works adjacent to the forging plant. This was a greatly appreciated privilege, and the number requesting tickets exceeded the quantity that could be handled. Many persons were disappointed, but only the first three hundred to register could be accommodated, and admission was limited to members.

Transportation by bus was excellently arranged right from the hotel to the plants—a convenience much appreciated by out-of-town members and local members as well.

#### SOCIAL CENTRE

The feature inaugurated last year at Hamilton and known there as "Muriel's Room" was repeated this year at Montreal. Such a centre conveniently located and satisfactorily "equipped" makes it possible for members and guests to meet socially under the most favourable circumstances. It helps to keep the crowd together and to promote that spirit of friendliness and cordiality that means so much to the success of a meeting.

As a tribute to the Hamilton Branch, the Montreal committee used the same title as was developed at last year's meeting. Incidentally, the Hamilton room was formally known as the Mural Room. A slip of the tongue suddenly transformed it into "Muriel's Room." Perhaps it will now become a tradition—certainly it has much to recommend it.

All in all, the meeting was outstanding from every point of view. About eleven hundred were registered. It may not be possible to maintain or repeat such records in the future, but it is a source of great pleasure and gratification to know that they have been reached and experienced in this year of grace 1942.

# SAID AT THE BANQUET

## SHORT SPEECHES OF PARTICULAR INTEREST

### Greetings from American Guests

ERNEST D. BLACK  
*President*

AMERICAN SOCIETY OF CIVIL ENGINEERS

It is my privilege and honour on this occasion to bear greetings from the American Society of Civil Engineers to The Engineering Institute of Canada, and to assure you that at this time our close neighbourly and professional ties, prevailing in times of peace, are strengthened and made more binding at this time because of our united stand in the war against a common enemy.

Ten days ago, the chief of the United States Corps of Engineers in addressing the District of Columbia section of the American Society of Civil Engineers declared that this is an engineers' war, that for a long time to come there will be no engineering as usual in this country, and that the demands of the war effort have taken and must continue to take precedence over everything else.

In spite of the necessary readjustments in the personal work and plans of the engineer in order to meet the changed conditions while they are on the "no engineering as usual" basis, there can be no doubt that the engineers of Canada and the United States will meet the war situation at least as effectively as it has been met by the engineers of the other united nations.

The engineer has and accepts a responsibility outside of his usual activity, and that is to do his part in helping to determine the route the nations of the world must follow in order to return all peoples to the lasting peace we must eventually secure. In accomplishing this as we look forward into a somewhat obscure future, we should not forget the laborious conditions of the past. We should give them new considerations, and keep alive the experiences on which our country has been so firmly built.

We have every reason to believe in the ultimate success of our course if we can combine and continue the endeavours of the united engineers of the nations, for the purpose of winning this war against civilization, and it will help us to accomplish this end if we remember that this is an engineers' war.

DR. EUGENE McAULIFFE  
*President*

AMERICAN INSTITUTE OF MINING AND METALLURGICAL  
ENGINEERS

I want to bring you the greetings of the American Institute of Mining and Metallurgy, including our students, some 15,500 strong. It is a far-flung body covering a wide range of territory, for we have members on every continent and in practically all of the islands of the Seven Seas. Many are in Canada.

For me it is a special pleasure to be here, for I was born under the Union Jack, and as a child lived in Canada. Unfortunately my visits have not been frequent, perhaps about four times in seventy years, but whenever I do come back here it is refreshing to meet people of my blood and my faith. It is a great privilege to be here tonight.

JAMES W. PARKER  
*President*

THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS

When I had the honour of speaking at the luncheon today; I felt a little on my dignity in representing The American Society of Mechanical Engineers. I brought that society's

greetings and ask you to consider that they have been repeated. The friendship of The American Society of Mechanical Engineers for this sister institution in Canada is of long standing, and is a very firm and cordial relation.

But this evening I speak for myself. It seems impossible that in the short space of time in which I have been in Montreal I could be made to feel so perfectly at home. I often think that we need not be at all sentimental over the friendship between the people of the United States and the people of Canada. We are peoples of many common heritages. We look back to the same literature, the same historical past, the very beginnings of freedom—those things that you Canadians look back to with reverence, we look back to with reverence, too, because they are our heritage as well as yours.

As for being friends with you, these facts make it very natural. I remember the comment of a newspaper editor on a news item on his desk which reported that a boy had stolen a dog. The editor said, "What an impossible statement. A boy doesn't steal a dog. The boy looks at the dog and the dog looks at the boy and they go off together."

Well, Ladies and Gentlemen, our friendship with Canada is just about as easy as that.

D. C. PRINCE  
*President*

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS

I feel today like one of the children saying his part of "The House that Jack Built." For instance, Mr. Black had all his notes and went along as smoothly as could be. Then others come along, each having thought of the nicest things to say. Now, my turn comes and it is my pleasure as well as my privilege to echo the friendly sentiments that have been expressed.

But I want to put in a few words for myself and my group. We are by these gatherings learning how to fight the war together; they give us valuable opportunities to learn how to work together, so we may combine effectively in fighting for peace afterwards.

DR. A. H. WHITE  
*President*

SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION

You will notice that the Society for the Promotion of Engineering Education does not have the title of "American" in front of it. I am really at home here, and not a foreigner, because the Canadian universities are members of that society as institutional members. Indeed most of the teachers in your engineering schools are also members of the Society for the Promotion of Engineering Education, so I can speak here as a host and welcome you.

We have all been made to feel at home. We have had a wonderful time. For me there are special memories attaching to Montreal, because fifty-two years ago I was a freshman in McGill University. It is true that I only stayed there one year and I won't say anything about that. But it is a very great pleasure to learn about the wonderful work the Canadian universities are doing, and the achievements of their engineers. We are in fact all working together to make engineers better trained, not only for war but for the future.

S. D. KIRKPATRICK

*President*

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS

I would like to take a minute or two to bring you greetings, not from one of the great founder societies, but from a mere foundling, that at the beginning of the century was just a baby left on the doorstep of the Engineering Societies Building in New York.

When that was discovered, some rather searching questions about its parentage were asked. Some there were who insisted the father was mechanical engineering. Others thought that perhaps electrical, or even civil engineering, was the father. Whether or not this strange Institute of Chemical Engineering had been sired by mechanical engineering, we all knew it had been damned by chemistry.

You see the infant was allowed to claim the proud name of chemical engineering, but was not welcomed into the inner circles of engineering. Rather, it was sent back to the crowded tenements of modern chemistry. They put chemical engineering in the attic or down in the basement, and it came to be known as industrial chemistry.

It was not a bad boy, but was always getting into trouble blowing up things with its crazy experiments, so that a sigh of relief went up when he enlisted in the first World War, and listed for the duration.

In four years the youngster helped his country to build a great chemical industry that supplied munitions for America and the Allies, and when peace came made a valuable contribution to the health, happiness and security of the nation. The basis was laid, too, for what some of us think is an important branch of the engineering profession.

In our country, in most of the educational institutions (and I think it is the same here in Canada), chemical engineering is second only to mechanical in enrolment. It leads all others in the graduate schools. In chemical engineering one graduate in six goes on for a Master's or a Doctor's degree, compared with one in ten in all branches of engineering.

One of our distinguished members, the late Dr. Arthur B. Little, a great and good friend of the Dominion, worked for the Canadian government on a survey of the resources of the Dominion, and he used to like to say that chemical engineering was in its energetic and elastic youth, with the last chapter of the Book of Genesis yet to be written.

Mr. Tyler and I have thoroughly enjoyed your meeting, and the duty of representing the American Institute of Chemical Engineers has been a pleasure.

So, on behalf of the little foundling, I want to express deep appreciation for the honour and the courtesies we have received at your hands.

C. C. KNIPMEYER

*President*

NATIONAL COUNCIL OF STATE BOARDS OF ENGINEERING EXAMINERS

Before coming to this meeting of The Engineering Institute I knew that I would meet with many fine engineers and good neighbours. I expected to make some ends, but did not dream that such warmth of friendship would be showered on me. My feelings have been very deeply stirred by your welcome and I shall be proud and

happy to report this to each member of each board of the forty-six Boards of Engineering Registration in the United States regarding my reaction to things here. They, in turn, will pass the word to all of the seventy thousand registered engineers of the United States.

## Dean Mackenzie Introduces Dean Young

I have come to my last duty as the outgoing president of The Engineering Institute of Canada. It is a great privilege to have the very pleasant task of inducting the new president, Dean C. R. Young.

Dean Young needs no introduction to Canadian or American engineers. Crowning his long years of service as a leading Canadian educationalist he has recently been appointed dean of the largest engineering school in the British Empire.

As a consulting engineer he has had long and extensive practical experience; the many structures he has designed and built are in themselves a lasting monument to his ability. As an author he has to his credit several books and innumerable papers and withal he has been one of the most industrious, competent and distinguished workers in Institute and public affairs that Canada has produced. The Institute is most fortunate in its new president.

I hand over the reins of office to you, Dean Young, with every confidence that in the critical year of 1942 this Institute could not be in better hands.

## President Young Takes the Chair

Anyone in my present situation would, I am sure, feel as I do, a very great satisfaction in having been entrusted with the presidency of The Engineering Institute of Canada for the coming year. I am particularly delighted to assume office in the presence of this great company and, in particular, in the presence of Canada's greatest soldier, and of the leaders of engineering in the United States of America.

The Engineering Institute of Canada has built up for itself in the last fifty-five years a magnificent tradition. Dean Mackenzie has been preceded by a long line of distinguished engineers—by the Keefers, whose standing corresponds to that of Telford and the Stephensons in Britain; by Sir Casimir Gzowski, whose name is commemorated in one of our prizes; by Sir John Kennedy; by that fine French-speaking engineer, Ernest Marceau.

These, and many other eminent men, have in their time contributed to the success and the honour of this Institute. It is my hope that I may in my term of office be able to contribute some little measure of addition to that success.

This year we have assuming office a Council which I think will fully maintain the reputation of the Councils that have been responsible for the affairs of the Institute in past years. As is the custom, a number of new members of Council are elected each year. I shall therefore call upon the newly-elected members, and ask them to rise so that the audience may see them in the flesh . . .

Now I am going to ask you to conclude the banquet by the singing of that song that means so much in this part of Canada—"O Canada." And I am going to ask our French-speaking engineers to respond particularly, as they are most capable of doing. Please show our visiting friends from the United States how the French-speaking engineers sing "O Canada."

# Abstracts of Current Literature

## UNDERGROUND PARKING AIDS TRAFFIC HANDLING IN BUENOS AIRES

By F. A. Zamboni, City Engineer, Buenos Aires, Argentina.

From *Engineering News-Record*, OCTOBER 23, 1941

Three years ago the first two municipal underground parking lots in a programme contemplating a total of eight such traffic relief facilities were placed in service in Buenos Aires. These two initial units, with a capacity of 756 cars, have proved a distinct aid in relieving traffic congestion, and their operation, which includes a mechanical ventilation system, has shown that such facilities can be made self-liquidating through a small parking fee (about 15 cents) and rents from sales rooms, repair shops and poster advertising. Because the results have been so satisfactory it is hoped that the entire programme, providing accommodations for 6,770 cars, can now be completed.

The first two subterranean parking garages were built in connection with the widening of the Avenida Nueve de Julio for which a strip of old buildings a block wide and five blocks long was removed; eventually it is planned to extend this tree-lined boulevard completely across the city, but the expense will be large since the work so far completed, including the underground parking garages, cost over \$6,000,000. (U.S.).

The commercial area of Buenos Aires, where traffic congestion is greatest, is located on the rim of the city, rather than near the geographical centre, as is the case in many cities. Subway lines radiate in three directions from this commercial area, and it is on these lines near the limits of this area where the remainder of the parking facilities are to be built. The two existing parking garages, however, are almost in the centre of the commercial area.

Two parking garages are already built. Both are 200' wide. One is 800' long, the other 400'. Ramps, each made up of three 11' lanes, give access to the garages on either side; experience in operation has indicated that two lanes would have given ample capacity. The garage structure is of reinforced concrete, columns with flaring capitals carrying 18" deep flat slab panels 20' x 25' in plan. The ceiling height in the garages is 15'. Although these garages are all on one level, several of two-story type are planned for the future programme.

## U.S. CONCRETE BARGE PROGRAM

From *Engineering News-Record*, OCTOBER 23, 1941

The U. S. Maritime Commission has decided to start its program of building concrete barges somewhat more conservatively than originally intended by limiting the initial construction to fifteen barges—the east, west and gulf coasts to build five each. The commission has developed two alternative types of contract to be used, one a modified form of fee contract, while the other is a lump-sum contract incorporating an escallator clause. Contractors will be offered their choice between the two forms.

The "cost-plus-a-variable-fee" contract is designed to give the contractor the protection of a cost-plus contract, but at the same time to offer him an incentive to hold the costs down. Under this contract an estimated unit cost per vessel is set up. This cost is broken down into estimated monthly payments, divided between labor and material expenditures. Monthly, thereafter, the estimated cost will be adjusted according to the fluctuation of the Bureau of Labor Statistics index of hourly earnings in

## Abstracts of articles appearing in the current technical periodicals

durable goods manufacturing industries and the bureau's index of wholesale metal prices.

As the work progresses, the contractor will be paid his actual costs, including overhead "incident and necessary" to the job. At the completion of each vessel he will receive a fee of 15 per cent of the adjusted estimated cost. If the actual cost plus the fee is greater than the adjusted estimated cost, that is that. If, however, the actual cost runs lower than the estimate, the contractor receives half of the savings. Total of cost savings allotted to the contractor plus bonuses or minus penalties is limited to seven per cent of the estimated cost. A time schedule will be written into the contracts. Liquidated damages of \$50 daily will be charged for failure to meet the schedule, and a like sum will be paid as a bonus if the schedule is exceeded.

The commission may cancel the contract upon payment to the contractor of his actually incurred costs plus ten per cent of the costs or six per cent of the estimated total cost times the percentage of completion achieved at the time of the contract's cancellation—whichever of these two quantities is smaller.

The lump-sum form of contract provides for the establishment of a unit price per vessel to be paid the contractor. This price is to be adjusted for variations in material and labour costs in the same way as is the estimated cost figure in the variable-fee contract already described. Provision is made for liquidated damages, but there is no bonus for early completion. If the contract is cancelled by the commission, the contractor will be paid for work accomplished in terms of a percentage of the contract unit price and will also be paid any cancellation fees he has to pay to his suppliers and sub-contractors.

The contractor's profit under the lump-sum contract is limited to ten per cent of the contract price, and any excess must be turned back to the commission.

## ADAPTION OF MOTOR DESIGN TO CEMENT MAKING

ROBERT WILLIAMSON\*

Cement is a dry, fine powder. It follows that dust is present in the cement works. Motors used in its manufacture must be capable of 100 per cent efficiency in dust-laden atmosphere. Motors of the standard protected type, with self-ventilation by means of a fan, are adequate in dry air but in wet air motors of the totally enclosed, fan cooled type must be used. Nevertheless, with well built works, most drives can be entrusted to standard protected type motors.

Torque determines the type of motor, the highest starting torque being necessary where considerable out-of-balance load has to be overcome and an appreciable mass accelerated.

Other types of drive, where the mass to be accelerated is large, even without excessive friction, also demand a slipping motor.

In large installations, power factor improvement is important. This can be effected by synchronous induction motors for driving one or more of the larger machines. These give a high starting torque, and can be arranged to run at a leading power factor compensating for the lagging current taken by other units.

\* London Correspondent of *The Engineering Journal*.

In one Works, current is taken from 10,000-volt three-phase 50-cycle mains, and stepped down to 440 volts in substations at the main works and the quarry. The quarry substation gives a separate supply for a wash mill plant, the 440-volt circuits being controlled by two G.E.C. industrial pedestal switchboards. One board controls feeders to a chalk excavator and wash mill and to a wet tube mill with its auxiliaries, while the other controls various motor drives.

#### WASH MILLS

Raw material for cement is obtained from "low" and "high" quarries, the first being low carbonate materials, the second, high carbonate materials. These are dug by bucket type electric excavators and conveyed in one yard wagons by diesel locomotives to the washing plant.

Chalk from the "low" quarry is reduced to 4-5 in. lumps and fed into the first wash mill to form "slurry" which is forced through gratings into a sump, and pumped to storage tanks or to the second wash mill where high carbonate material is added. Material put into storage from No. 1 wash mill is used as a standby when No. 1 is not working.

Electrical equipment in this section comprises a 150-hp. 360-rpm. 440-volt G.E.C. synchronous induction motor with liquid starter and oil circuit breaker).

#### SLURRY

The slurry from No. 1 wash mill, and chalk from the "high" quarry, after passing a roller mill, are next mixed in No. 2 wash mill, which has screens. The product of this mill is screened and then passes by gravity to a wet tube mill.

The slurry is then pumped to the storage tanks, which are air-agitated by compressed air at 30 lb. per sq. in. pressure by a rotary compressor direct coupled to a 50 hp. slipring induction motor. The storage tanks have a capacity of 16,000 cu. ft.

#### THE KILN

The slurry is pumped from the storage tanks into a small mixer agitated by a 10-hp. squirrel cage motor and thence it is passed by a three throw ram pump through worm and spur gearing, into a calcinator feeding into the kiln.

The 500-ton kiln is a rotary and consists of a steel tube lined with firebrick and fitted with four cast steel tires running on pairs of rollers. The speed is from 1 rev. in 16 seconds (minimum) to 1 rev. in 55 seconds (maximum). The kiln is driven by a single 85-hp., 440-volt, 3-phase, 60 cycles, variable speed slipring induction motor through triple reduction spur gearing.

The slurry travels slowly down the whole length of the kiln to the "clinkering" zone, being successively dried, calcined, and sintered as the temperature increases from about 100 at entry to about 2,700 deg. F. at the furnace end. Here the clinker is discharged on to a grate cooler. It is next taken by a shaker conveyor and elevator to the coal and clinker store.

#### GRINDING

Next comes the grinding of the clinker (plus gypsum) in the clinker mill house. Preliminary grinding is carried out in two rod mills, driven through gearing from line shafting. The discharges from the rod mills are passed to a large tube mill, driven through gearing by a 400-hp. G.E.C. synchronous induction motor for further grinding.

#### PACKING

The cement is now in its final form and is discharged to a pneumatic conveying system and is taken to storage bins.

The pneumatic conveying systems are supplied with air by three reciprocating compressors driven by slipring motors, two of 45 hp. and one of 70 hp.

Valve type bag packers fill the cement bags at the rate of 35/50 tons per hour.

#### COAL HANDLING PLANT

On arrival the coal is discharged into a receiving hopper, from which it is fed to a vertical elevator leading to a band conveyor, which takes it to the coal and clinker store. From storage it is taken via a magnetic separator and elevators to hoppers leading to an air-swept ball mill, which is gear driven by a 75-hp. slipring motor.

In the coal and clinker store—400 ft. long by 60 ft. wide—wet and dry coal is distributed and the clinker handled by a 5-ton overhead crane fitted with three slipring motors, 25 hp. for hoisting, 12 hp. for longitudinal travelling, and 4½ hp. for cross travel.

The works fitting shop contains a shaping machine, drill, screwing machine, saw, two lathes and two grinders, all of which are driven from line shafting by a 20-hp. motor.

#### MOTORS AND CONTROL GEAR

With the exception of the large synchronous induction motors on the chalk mill and the clinker tube and the kiln motor, all the motors mentioned are standard 440-volt G.E.C. "Witton" induction machines of the protected type running at about 720 or 960 rpm.

#### SIXTY YEARS AGO

##### SUBMARINE ARTILLERY

From *The Engineer* (LONDON), NOVEMBER 21, 1941

On November 14th, 1881, a public trial of Ericsson's torpedo boat, the *Destroyer* took place at New York. The trials were reported to have been in every way successful. The *Destroyer* was an armour-clad torpedo boat, 130' long, 11' deep and 12' wide. She had engines of about 1,000 I.H.P. and her speed was said to be 16 knots. Her novel feature lay in the fact that she carried a long tube on her keelson, the muzzle of which was 6' below water. From this tube there could be discharged elongated projectiles carrying as much as 350 lb. of dynamite. The projectiles were stated to be made of wood and they were propelled out of the submarine gun by steam pressure. Reports received from New York stated that during the trials a projectile carrying a charge of 12 lb. of powder had travelled 600' under water and had penetrated a torpedo net and a target representing the bottom of an iron-clad. In a leading article in our issue of November 18th, 1881, we sought to show that Ericsson's invention had been anticipated in principle by Robert Fulton, who in 1813 carried out experiments to discover what could be done with guns fired under water. He found that a ball fired with 12 lb. of powder from a "columbiad" with its muzzle 2' under water passed clean through a target 3' thick placed 6' from the muzzle of the gun. Following his experiments Fulton designed a ship fitted to discharge a broadside of submarine ordnance, but nothing further seems to have been done with the idea until 1857, when Whitworth made some experiments on submarine artillery. In one experiment carried out at Portsmouth, Whitworth used a 110 lb. Armstrong gun, which was fixed on a platform below high-water mark, loaded when the tide was out and fired when the tide was in. With a charge of 12 lb. of powder this gun sent its projectile clean through a 13½" baulk at a range of 25'. In 1862 Whitworth extended his experiments by firing underwater shots against the side of a wooden hulk protected by six ½" boiler plates. With a conical shot the hulk's side was destroyed over a considerable area. In the same year Forbes, an American, carried out a number of similar experiments and entered into a contract with the United States Government to construct a partially armoured gunboat carrying a submarine gun. The contract, however, was not carried out. Concluding, we referred to some experiments then being made by our own Government, in which a light iron case resembling a fish torpedo in shape was propelled through the water by the discharge of gas at its tail after the manner of a rocket.

## MORALE

Editorial from *Army Ordnance*, Nov.-Dec., 1941

The popular morale of the nation—as distinguished from the military—is its collective mental state affected by such factors as zeal, confidence, spirit, and hope. Our popular morale as regards the all-out effort for arms production is not as high as it should be. Yet, unless that morale is of the highest, the armament production job will fail. We had better diagnose the malady quickly and adopt a remedy at once. For as popular morale goes, so goes everything else—the fighting forces as well as the human machinery of arms production. What are the causes of this low morale, and what are the remedies? Every fair-minded patriotic person will demand that adequate remedies be applied, no matter what the cost.

In seeking the causes one has only to remember the shabby pacifism of the American people during the last two decades. We are now paying the price of that pacifism, and no amount of tall talk can undo the damage done by years of idiocy. And the guilt should not be spread thin.

*The pacifism of the press* did untold harm to the national defense of the United States by its hypercritical denunciations of things military—especially military training and planning. It was the press that fanned to fever heat the stupid crusade against armament manufacture and developed an attitude of mind on the part of the people wherein arms making became synonymous with warmongering.

*The pacifism of the pulpit* all too frequently spoke in derogation of military discipline and training. It helped to inculcate in youth an unrealistic view of the problems of war and peace. It was the pulpit that often misconstrued the cause and effect of war. It was the pulpit—of all places—that frequently branded as unchristian the discipline of the soldier, the dignity of hard work, the thrift of the wise.

*The pacifism of the politician* was exceptionally blatant during those years in its childish crusades against our national-defense machine. Some clumsy politicians did irreparable damage when they turned the technique of smear campaigning upon “munitions makers” and other exponents of military preparedness. Consummate hypocrites, other politicians all but starved the defense forces while wasting billions of dollars on make-believe hard times. It was the cheap politician who misled the people by broadcasting his own ignorance of the national defense at a time when his voice should have been raised in the soundest support of it.

*The pacifism of the pedagogue* was yet more serious. It went to such extreme lengths as to permit an alien visitor to our shores (now safely established in one of our larger universities), to urge the youth of America to renounce arms for the defense of country, thereby striving to indoctrinate our young men with the contemptible treachery of the Oxford Union and the Communist. It was a misguided pedagogue who germinated false doctrines concerning war and peace akin to his other false theories.

What is the remedy? There is only one—sound generalship. Not alone the generalship of the battlefield but the generalship in the factory, on the farm, in the home. We have such generalship in the fighting forces; we do not have enough of it among our civilian leaders. Too many of them are afraid of their shadows! Until leaders come forward in all the respective spheres of action to contest the false doctrines that undermine our national strength, the arms-production programme, and indeed every programme for the welfare of our country, will progress at only a snail's pace. Such generalship, as far as the national defense is concerned, requires a deep knowledge of

the problem. Arms production is a difficult task even for American manufacturing ingenuity. It is a field that has no place for ignoramuses, theorists, or prima donnas. Fearless men in civil life, imbued with a sense of sound generalship, will be the salvation of our armament effort, for they alone can instill the zeal, confidence, spirit, and hope that *are* popular morale. “Free peoples can escape being mastered by others only by being able to master themselves.”

## RUSSIA'S INDUSTRIES

From *Trade and Engineering* (LONDON), NOVEMBER, 1941

During the past month further important manufacturing districts of European Russia have been overrun by Hitler's hordes and hirelings. The U.S.S.R. has suffered grievous losses in consequence, but by steadily pursuing its scorched earth policy it has minimized the enemy's immediate economic gains.

The highly intensive activity of the Donetz Basin, which, during the past three months, has contributed greatly to the Soviet War effort, has come to an end. Operatives have been transferred elsewhere, chiefly to the Urals, where buildings, materials, and machinery have been prepared for them. Kharkov, whose factory equipment has been either removed or destroyed by the Russians, has been a leading centre of machinery manufacture, with one of the largest single plants for producing aircraft, a tractor works, machine tool plants, locomotive works, and electrical engineering concerns in the near neighbourhood.

Rostov has been known for its great agricultural machinery factory. Skilled munition and other workers have been withdrawn from the districts of Kharkov, Moscow, and the Ukraine, and large numbers have taken up employment in factories and mines in the newly developing industrial regions in Asia. From Odessa and other centres important machines, as well as skilled industrial workers, have been moved east.

In Kuibyshev, on the Middle Volga, where all the foreign Embassies and Legations which were in Moscow have been moved, there are new railway repair and carburettor plants, an oil refinery (fed from the “Second Baku” fields between the Volga and the Urals), and many factories producing agricultural equipment and tractors. Kuibyshev is one of the main centres of the great scheme for harnessing the power of the Volga; it has a hydro-electric power station which, when complete, would feed still more new centres beyond the Volga. As headquarters for war the city is important as one of the main junctions between railway and river. Oil coming up from the Caucasus by way of the Caspian and Astrakhan can be transferred from the ships straight on to tank wagons to be sent east or west. Armaments coming by rail could be put on the Volga during the months when the river is free from ice. Round Kuibyshev it is usually blocked by ice between December and April.

In the Ural area there are promising centres of heavy industry, and farther east, near the rich coalfield of Kuzbass, there are others. In Central Asia is the Karaganda coalfield, which produced over 6,000,000 tons in 1940, and there are the other great mining centres which produce over two-thirds of the Soviet lead and zinc and almost the whole of the Soviet chrome, copper, and cotton. Back in the Ural region are the oilfields, the “Second Baku”, based mainly at Ishimbaevo and Makat, which, even in 1938, produced nearly 2,000,000 tons, and were planned to produce nearly 7,000,000 tons by next year.

In these new industrial regions of the east some aircraft and tank factories have been working for years and others have been newly opened, but complete plans of production have not been fully developed.

## POWER SUPPLY IN WARRING COUNTRIES

By H. S. Bennion, Vice-President and Managing Director,  
Edison Electrical Institute.

From *The Electrical Times* (LONDON), Nov. 27, 1941

In our everyday activities so much dependence is now placed on electric service that the following gleanings of information (gathered and surmised from technical journals and a few uncensored reports of happenings in warring countries) are of great importance in considering civilian defence measures.

**RESTRICTED DAMAGE.**—Air bombing appears to be temporarily effective against underground utility distribution systems of all kinds, electricity, water and gas. Overhead electric distribution circuits have proven to be less vulnerable. The effects do not appear to be decisive or permanent, however, since repairs are made promptly either as improvisations or permanent repairs. The duration of outages due to disruption of these facilities grows shorter as operating personnel learn what to expect, how to prepare for it, and how to proceed when it occurs.

In the United States, floods, hurricanes, ice storms, and occasional fires have given the personnel of electric utility companies considerable experience in emergency repairs; and it must be noted that in the case of widespread storms the damage to be dealt with has been vastly more extensive than that which bombing occasions.

The most serious effects of bombing to any utility appears to be the rupture of water mains in conjunction with incendiary bombs, since the means of fighting the incipient fires is thus impaired and they may gain considerable headway. The importance of this feature may be judged by the stress laid upon the desirability of local standing water supplies, such as tanks, pools and other forms of local water storage.

While definite information is lacking, it appears that electric generating stations, occasionally hit and no doubt sometimes damaged, have not been put out of action completely or permanently as a result of enemy bombing, notwithstanding the fact that important generating stations have been among the objectives of bombing attacks. A German article relates that a certain Dutch generating station which had been bombed, and evidently hit, for the removal of a dud bomb within the works was necessary, was "slightly damaged but able to operate." This exhibit of relatively indecisive effect of bombing upon modern, fireproof generating stations appears to be borne out by verbal reports of British experience, and by the record of output there, which could hardly have been maintained at better than the pre-war level if any large amount of generating apparatus had been out of service for any considerable period of time.

**RESTORATION OF SUPPLY.**—Quite a different picture is presented of the effects of large calibre artillery fire, as indicated in a German article describing the restoration of utility service after the occupation of Warsaw in September, 1939. Although primarily a description of the restoration measures that were taken, the article incidentally gives considerable information on the effects of fire.

Although Warsaw had been heavily bombed, the damage to the power plant was specifically ascribed to artillery fire. Warsaw was subjected to artillery fire of all calibres for eight days. As a result at least two turbo-generators in the Warsaw power plant had received direct hits and the remainder showed many hits of a lesser degree. All of the boilers were unfit for service apparently as a result of punctures by shell fire. The German article describes how the boilers were rendered servicable by means of welded patches. The extent of the mechanical damage may be estimated from the following time schedule for restoration:—

0 day.—Station completely inoperative.

5th day.—Two units, aggregating 18,600 kW in service.  
12th day.—Third unit of 15,000 kW in service.  
30th day.—50,000 kW of an original 107,600 kW in service.

Concerning water supply, the article related that a rapid filter had been completely destroyed and chlorinators seriously damaged by artillery fire. The pumping plant was unserviceable because of failure of the power supply. The gas works were badly damaged, in most cases as the direct result of artillery fire. For example, 30-in. pipes and valves were broken, apparently upon impact. Restoration of these water and gas services presented no unusual features beyond the efficiency and expedition with which the work was completed.

**DEMOLITION.**—One German article deals at some length with the demolition methods employed by their adversaries during their retirement from Holland, Belgium and northern France. Reference is made to a Belgian generating station (which had been wrecked by hand) where many parts, such as control instruments, insulators and insulating bushings which could not readily be replaced from any available stock were merely broken. Apparently, this method of demolition was rather efficient. In other cases it was related that essential parts of apparatus were removed by technical specialists among the retiring troops. These acts, however, merely resulted in temporary delays in restoration of service.

**NEW CONSTRUCTION.**—Information as to new construction of power facilities and power output of generating stations has been closely guarded in the Axis countries for the past four years. Recent news stories in this country have indicated prodigious increases in German controlled capacity and output in recent years. So far out of keeping with past performances is this that it seems questionable. At the time of the World War the Germans were given much more credit in such respects than later information showed they were entitled to. The same is probably true at this time, though they did make power gains from 1936 to 1940.

The British have been much freer in publishing information concerning electric power. When the war broke out new installations were stopped and the machinery planned to be installed was sold in the export trade. Information is slow coming out as to output, but the figures for the end of March, 1940, showed output up about 4%, and maximum demand down by 3%. This was an average figure, as might be expected. Certain areas affected by war industries and by the influx of population from the big cities showed substantial increases up to 15% and 20%. It is to be expected that this local variation has happened to a greater extent in Germany because that country has gone to greater lengths in scattering its industries, to make them less vulnerable to bombing attacks.

## SHEFFIELD SALUTES STALINGRAD

ROBERT WILLIAMSON\*

In a steel casket designed by a Sheffield craftswoman greetings have been sent from Britain's steel city to Stalingrad, its opposite number in Russia.

Thousands of Sheffield signatures, from bishops to steel moulders, have been appended to the message in which the British city pledges itself to the people of Stalingrad to play its part in achieving a maximum output and so ensure the fullest use of its resources to speed the victory over Hitlerite Germany.

Produced under the auspices of Sheffield's Anglo-Soviet Union, whose object is friendship between the British and Soviet peoples, the casket containing the greeting bears the City's Arms, flanked by the British lion on one side and the Soviet hammer and sickle on the other, with inscriptions in English and Russian.

\*London Correspondent of *The Engineering Journal*

# From Month to Month

## PRESIDENT'S MESSAGE

A message from the new President of The Institute, Dean C. R. Young, appears on page 127 of this issue. It is recommended that every member read it carefully.

## ANNUAL MEETING

The 1942 Annual Meeting has joined that long list of successful events that go to make up Institute history. For some time it is likely to shine a bit more brightly than the others, but there is no way in which the brilliance of it all can be preserved in perpetuity. To those who were there, it shall remain an outstanding event but to others, less fortunate, there is no choice or grouping of words that will convey any conception of the "feeling" of what actually took place.

It is simple to recount that new records of attendance were established, that the speeches were excellent, that the social events were happy occasions, and the plant visits unusually interesting, but these statements, or any elaboration of them, do not describe the meeting.

Some happy combination of circumstances developed an atmosphere that coloured every minute of the two crowded days. In the first place the registration ran up to almost eleven hundred, which was an inspiration in itself. The presence of the distinguished American delegation also contributed materially. An unusually large number of out-of-town members engendered a spirit of pleasant reunion but above all, of course, was the thrill that came with the announcement Thursday morning that General McNaughton would be present and would speak at the banquet Friday night. All these things, and perhaps others too, combined to give The Institute the happiest event in its history.

It was particularly pleasing to see the large attendance at the professional meetings. In almost every instance the rooms were crowded to capacity and in every instance discussions could have been carried on to much greater length. On two or three occasions many people had to stand throughout the session. The attendance at these meetings ran as high as three hundred and fifty.

The committee was very fortunate in its choice of luncheon speakers. The Hon. C. D. Howe gave the best account of munitions production in Canada that has yet been heard. He spoke without manuscript or notes and it was very evident that he was in a field where he needed no written word to prompt him or to acquaint him with his subject. He has seldom been heard to better advantage. An audience of six hundred and twenty-five gave him a warm reception and expressed in no uncertain terms its appreciation of the work accomplished by his department and of his part in it. A verbatim report of his address is in this number of the *Journal*. It is recommended that it be read by every Canadian.

At Friday's luncheon, James W. Parker, president of The American Society of Mechanical Engineers, spoke on "The Management-Employee Problem for Engineers." This address will be published in the April number of the *Journal*, and readers are again urged to study it. It contains much wisdom that may well be applied to labour situations throughout Canada. The address was recorded by the CBC and broadcast that evening over the Montreal stations. From enquiries received by telephone and mail, it is evident that many persons other than members were interested by it.

No event could be more enjoyable or thrilling than was the banquet Friday night. Almost seven hundred people testified to that. Under the inspired guidance of President Mackenzie, great heights of humour and emotion were reached. Not many people have been privileged to see and hear a more brilliant, adroit and witty chairman. Blest as

## News of the Institute and other Societies, Comments and Correspondence, Elections and Transfers

he is with a keen sense of humour, and a chuckle that absolutely disarms his listeners, he turned in a performance that will be long remembered, and should forever dispose of the theory that the engineer is inarticulate. Dean Mackenzie surely finished up his term of office in a blaze of glory.

A great tribute was paid The Institute in the presence at the banquet of the presidents of the seven leading engineering societies of the United States, and the secretaries of six of them. With these gentlemen present it is doubtful if a more distinguished group of engineers has ever assembled on this continent. The Institute is rightly proud of this tribute, and will long remember the compliment that has been paid it. Each of the presidents spoke for a few minutes and a verbatim report of their remarks is presented in this number of the *Journal*. An excellent photograph of the group also appears on these pages.

The climax of the whole meeting was reached when General McNaughton rose to speak. No finer acclaim of this man's greatness, or of the affection with which he is held by the people of Canada, could be given than was shown in the sincere demonstration of the audience. A less modest man might have been prepared for it, but General McNaughton was taken entirely by surprise. It was with difficulty that he spoke and in his first words he said, "You must forgive me if the reception I have received has made it impossible for me to speak coherently, or to carry any message except that which comes straight from the heart."

He had no manuscript or notes, and he did speak from his heart—and to the hearts of his listeners. There is no need to dwell on the address itself—it was recorded and appears in this number of the *Journal*—except to say that it carried an important, an urgent message to the engineers of Canada. General McNaughton has been on the ground; he speaks with authority, and he brings this message direct to the engineers. The seriousness of the situation was as evident in his words as in his face, and no one who heard him and saw him could fail to grasp the significance of what he said.

General McNaughton's acknowledgment of Dean Mackenzie's accomplishment at the Research Council met a warm acceptance from the audience. He said, "One of the happiest things that has ever been in my mind is the knowledge that the National Research Council and all it stands for, under Mackenzie's leadership, is carrying the mantle of scientific leadership and helpfulness. It is a happy thought for the Dominion of Canada and all those associated in the war effort. . . for this is an engineers' war."

The concluding feature was the induction of the new president, C. R. Young, Dean of Engineering at the University of Toronto. Retiring President Mackenzie gracefully and fittingly introduced him and the new president as gracefully and fittingly replied.

The closing features of the whole programme were the reception and the dance which followed it. Lieut.-General McNaughton and Mrs. McNaughton joined with the Institute officers and their wives in receiving the guests—a gesture greatly appreciated by everyone.

It is still impossible to put a finger on any one thing that made this meeting so outstanding, but there is no doubt in the mind of anyone but that something did occur to lift it out of the realm of the ordinary and place it high in the minds and memory of all who were privileged to participate in it.

# DEAN CLARENCE RICHARD YOUNG, B.A.Sc., C.E., M.E.I.C.

PRESIDENT OF THE ENGINEERING INSTITUTE OF CANADA, 1942

Less than a year ago a distinguished graduate of the University of Toronto was appointed dean of its Faculty of Applied Science and Engineering, an event which was universally approved. This new dean has just taken office as president of The Engineering Institute of Canada for 1942, following in the presidential chair another dean, whose term of office concluded at the recent memorable annual meeting of The Institute.

Like Past-President Mackenzie, Dean Young is a man of many talents and activities. In fact the list of the educational, professional and public questions with which he has been concerned gives ample evidence of his achievements as an engineer, author, instructor, and administrator.

Clarence Richard Young was born near Picton, Ont., and took his bachelor's degree at the University of Toronto in 1905; the degree of C.E. followed in 1914. His professional experience has been largely in the field of structural engineering, his consulting work having also involved many special investigations and reports regarding technical, economic and legal problems connected with civil engineering. He joined the teaching staff of the University of Toronto more than thirty years ago, in 1929 he was appointed professor of civil engineering in succession to the late Peter Gillespie, and in 1941 became dean of his Faculty.

Always a supporter of The Institute, he is a past councillor and has served as chairman of the Toronto Branch. Last year he was chairman of The Institute's Committee on International Relations, and he now represents The Institute on the Committee for Professional Training of the Engineers' Council for Professional Development. He has taken a prominent part in the work of the Society for the Promotion of Engineering Education. He is a Member of the American Society of Civil Engineers and has served on a number of their technical committees. His work as a committee chairman of the Canadian Engineering Standards Association has been notable, particularly in connection with the Specification on Concrete and Reinforced Concrete. In 1937-38 he sat on Mr. Justice Chevrier's three-man Royal Commission on Transportation, dealing with the economics of commercial motor transport in Ontario.

In addition to Dean Young's more strictly technical work in bridge and structural design he was consulting structural engineer to the Ontario government in connection with hospital and prison work; he served on the international board of three engineers who passed upon the original plans of the Detroit-Windsor bridge; he reported on the impact and vibrational stresses in the Victoria Bridge, Montreal; and recently conducted an experimental investigation of the properties of soils to be employed in the Shand earth dam for the control of the Grand river, Ontario.

Dean Clarence Richard Young, B.A.Sc., C.E., M.E.I.C.

The Bulletins of the University of Toronto School of Engineering Research contain reports of many investigations carried out by and under Dean Young, and he has made frequent contributions to technical journals and the proceedings of engineering societies. He is the author of a standard text book on structural problems and of several sections in Hool and Kinne's Structural Engineers' Handbook Library. He is also joint author of a brief but widely used booklet on Military Law.

The Dean's interest in military affairs dates from the formation of the University of Toronto Contingent, C.O.T.C., of which he was one of the original officers. During the last war, Major Young was second-in-command of the Polish Army Camp at Niagara, where over twenty thousand Polish soldiers were trained and sent to France and later to Poland. He was decorated by both Poland and France for his services and is now chairman of the Toronto Branch of the Canadian Friends of Poland.

The esteem in which Dean Young is held by his past and present students, and their appreciation of his work, were evidenced in 1939, when he was awarded the medal of the Engineering Alumni Association of the University of Toronto, for outstanding achievement in engineering.

This estimate of his worth will be endorsed by his many friends throughout the Dominion, who will join in wishing him a happy and prosperous year of office as president of The Institute, and in congratulating the members of that body on the choice they have made.

## "THE PROFESSION OF ENGINEERING IN CANADA"

A booklet bearing this title has just been published by The Institute under the auspices of the Committee on the Training and Welfare of the Young Engineer. It is the result of many months of investigation, study and labour, and represents the combined efforts of all members of the committees.

The purpose of the booklet is to provide guidance to young men who contemplate engineering as a career. It is being distributed without charge to high school pupils across Canada, and to first year students in engineering at all universities. It is intended to assist in leading the proper types of students into engineering and to directing others into those channels in which they are more likely to succeed.

The committee proposes to set up in each branch district, counsellors or advisors to whom the high school student may appeal for advice. The booklet offers this assistance and the committee believes that many competent members will make themselves available for the service.

The first edition runs to ten thousand and it looks as if it would not last a year. Educational officers in every province have spoken highly of the publication, and have assured the committee that it will fill a long felt need. They are assisting in the distribution.

This publication is one of the most difficult undertaken by The Institute and only the perseverance, intelligence and industry of Mr. H. F. Bennett and his committee have made it possible. Not only The Institute but prospective engineers as well owe a great debt to this small group of workers. The distribution and all subsequent developments are in the hands of the committee.

### AN ENGINEER HEADS THE ARCHITECTS

On Saturday, February 21st, at the Cercle Universitaire, Montreal, Gordon McL. Pitts, M.E.I.C., was installed as president of the Royal Architectural Institute of Canada. Mr. Pitts is well known in The Engineering Institute and is equally well known in architectural organizations. It is unusual to find one person so active in two professions, but Mr. Pitts has made valuable contribution to both and is highly regarded by each. Many engineers were present at the ceremony, to pay tribute to a fellow craftsman and

G. McL. Pitts, M.E.I.C.

to share in the pleasure of installing him in an important office.

A native of Fredericton, N.B., Mr. Pitts graduated from McGill University in 1908 with the degree of B.Sc., and in 1909 received the degree of M.Sc. In 1916 he obtained his degree of B.Arch. In 1906 Mr. Pitts was an engineer on construction with the Canadian Pacific Railway Company and in 1908 he was senior draughtsman with the

Trans-continental Railway at Ottawa, Ont. In 1909 he joined the staff of Peter Lyall and Sons Construction Company, Ltd., as engineer and superintendent, and in 1912 he was supervising engineer on the construction of the Montreal High School for the Protestant Board of School Commissioners. In 1914 he joined the firm of Edward and W. S. Maxwell, architects of Montreal, and from 1916 to 1919 he was assistant to John A. Pearson, architect for the Parliament Buildings at Ottawa. Later he became a partner in the firm of Maxwell and Pitts, Montreal, thereby maintaining one of the oldest architectural practices in Canada.

Mr. Pitts joined The Engineering Institute as a Student in 1908 and was transferred to Associate Member in 1914. He became a Member in 1938. He has always been very active in Institute affairs, particularly as chairman of the Committee on Consolidation, and more recently as chairman of the Radio Broadcasting Committee. He is at present a councillor of The Institute representing the Montreal Branch.

Mr. Pitts is a past-president of the Province of Quebec Association of Architects and in 1940 he was one of the recipients of the medal presented to prominent architects by the Association on the occasion of its 50th anniversary. He is, at present, president of the McGill University Graduates Society.

### WARTIME BUREAU OF TECHNICAL PERSONNEL

#### Monthly Bulletin

Since the first of the year the Bureau has been particularly active in matters related to universities. Negotiations with the authorities were carried on for some time with the object of obtaining for certain students exemption from summer military camp. These have resulted in authorization being given to the officer commanding O.T.C. units to give the usual credits to those students who produced evidence to indicate that they had spent at least twelve weeks in a war industry in lieu of the summer camp. This should result in guaranteeing to industry a useful supply of labour for the summer months, and to the student the proper extension of his training.

Military camp usually came at a time that interrupted the student's summer work, frequently causing the loss of a large portion of the vacation period. Under the present arrangements, students should be able to work continuously throughout the time the universities are closed.

The Bureau has undertaken to secure summer work for engineering and science students. Fifteen hundred companies were canvassed to find out how many openings would be available to students. Three hundred and forty-five companies replied indicating that places were available for at least 1600 students. All of these openings have been catalogued and the information sent to the universities, so that students in consultation with university authorities could determine now the work which they are going to do this summer, thereby eliminating the loss of time which ordinarily occurs.

Mr. L. E. Westman, an assistant director of the Bureau is visiting all the universities in order to facilitate arrangements with regard to summer employment both for undergraduates and this year's graduating class. At the same time he will discuss many other matters that have a bearing on employment and university training.

Dr. David A. Keys—scientific personnel officer of the Bureau, has also visited universities in order to assist in utilizing the services of the science undergraduates and graduates. Dr. Key's particular field lies in research work and he has rendered important services to the armed forces, research organizations and industry. His visit with the universities will assist materially in organizing this field for the future.

In the belief that the usefulness of the Bureau would be increased if engineers and employers of engineers knew more about its activities, it was decided to send representatives to the annual meetings of such organizations as

the Canadian Electrical Association; Canadian Pulp and Paper Association; The Engineering Institute of Canada; Association of Municipal Electric Utilities; Canadian Institute of Chemistry; Canadian Institute of Mining and Metallurgy; Canadian Manufacturers Association, etc.

So far the annual meetings of the first four organizations mentioned have been attended; a desk was provided at the registration counter and suitable signs were made to identify the Bureau. The representatives report the experiment to be successful. They found that many engineers discussed their own cases to see if they could be more profitably used elsewhere and that employers discussed in detail their technical personnel problems. This practice will be continued throughout the year.

Arrangements have been made with the Unemployment Insurance Commission to establish at some points regional offices of the Bureau in the same locations as the Commission offices. Several men have been brought in to the office in Ottawa for training and already three have been sent out as regional officers. Mr. S. R. Frost is in charge of the Toronto office; Mr. T. S. Glover the Hamilton office and Mr. G. H. Burdett the Montreal office. Arrangements are under way to establish another district office at Vancouver. These gentlemen are all professional engineers of the executive type, well and favourably known in their own localities, and in almost every instance have obtained leave of absence from their employers; in some instances, a portion of their salaries is being paid by their former employers.

Closer co-operation is developing with the armed services and it is expected that arrangements will be completed, whereby the Bureau can be of greater service in recruiting technical personnel for commissions in all three branches.

About the middle of January the Bureau moved to new premises in the Confederation Building. The expansion of activities made it necessary to obtain additional floor space which was not available in the New Supreme Court Building. The Bureau is now located in the same building and on the same floor as the Department of Labour, under whose auspices it operates. The new location and layout will assist materially in carrying on the business of the Bureau.

#### PRESIDENTIAL VISIT TO WESTERN BRANCHES

President Young plans to visit all the western branches of the Institute during April. Each branch is arranging its own programme, details of which are not yet available at Headquarters. A regional meeting of Council will be held at Vancouver on April 18th. Following is the itinerary:

Lve. Toronto.....	P.M. Tuesday.....	March	31st
Arr. Sudbury.....	A.M. Wednesday.....	April	1st
Meeting with Canadian Institute of Mining and Metallurgy			
Lve. Sudbury.....	A.M. Thursday.....	April	2nd
Arr. Sault Ste. Marie.....	P.M. Thursday.....	April	2nd
Meeting with Branch.			
Lve. Sault Ste. Marie.....	A.M. Friday.....	April	3rd
Arr. Port Arthur.....	A.M. Saturday.....	April	4th
Meeting with Branch.			
Lve. Port Arthur.....	P.M. Saturday.....	April	4th
Arr. Winnipeg.....	A.M. Sunday.....	April	5th
Meeting with Branch—April 6th.			
Lve. Winnipeg.....	P.M. Tuesday.....	April	7th
Arr. Saskatoon.....	A.M. Wednesday.....	April	8th
Meeting with members of Branch at University			
Lve. Saskatoon.....	P.M. Wednesday.....	April	8th
Arr. Edmonton.....	A.M. Thursday.....	April	9th
Meetings with Branch and University			
Lve. Edmonton.....	P.M. Thursday.....	April	9th
Arr. Calgary.....	A.M. Friday.....	April	10th
Meeting with Branch			
Lve. Calgary.....	A.M. Saturday.....	April	11th
Arr. Lethbridge.....	P.M. Saturday.....	April	11th
Noon Meeting with Branch.			
Lve. Lethbridge.....	P.M. Saturday.....	April	11th
Arr. Vancouver.....	P.M. Sunday.....	April	14th
Meeting with Victoria Branch—April 15th.			
Meeting with Vancouver Branch—Friday, April 17th.			
Regional Meeting of Council at Vancouver—Saturday, April 18th.			
Lve. Vancouver.....	P.M. Saturday.....	April	18th
Arr. Regina.....	A.M. Monday.....	April	20th
Meeting with Branch			
Lve. Regina.....	P.M. Monday.....	April	20th
Arr. Toronto.....	A.M. Thursday.....	April	23rd

## CORRESPONDENCE

DEPARTMENT OF NATIONAL DEFENCE

OTTAWA, Canada, 12th February, 1942.

Dear Mr. Wright:

I most deeply appreciate your note of 9th February, 1942, in reference to the annual banquet of the Institute which I was privileged to attend last week.

I feel most deeply that the obligation is the other way round for I had the opportunity to do two things which I was most anxious to carry out—first, to pay my tribute to Dean Mackenzie, both as the president of The Institute and also, and more particularly, as head of our National Research Council; and second, to tell the engineers of Canada through The Institute, of the vital importance which I attach to the use of their members in the development and production of improved weapons and equipments for the forces overseas.

Also, and as a personal matter, it was a great happiness to myself and to my wife to renew acquaintance with so many old friends.

With kindest regards and best wishes,

Very sincerely yours,

A. G. L. McNAUGHTON.

L. Austin Wright, Esq., General Secretary,  
Engineering Institute of Canada,  
2050 Mansfield Street, Montreal, Que.

#### MEETINGS OF COUNCIL

The annual meeting of the Council of the Institute was held at Headquarters on Wednesday, February 4th, 1942, at ten thirty a.m.

Present: President C. J. Mackenzie (Ottawa) in the chair; Past-Presidents J. B. Challies (Montreal), T. H. Hogg (Toronto), and H. W. McKiel (Sackville); Vice-Presidents deGaspé Beaubien (Montreal), K. M. Cameron (Ottawa), and M. DuBose (Arvida); Councillors A. E. Berry (Toronto), D. S. Ellis (Kingston), J. G. Hall (Montreal), W. G. Hunt (Montreal), E. M. Krebser (Border Cities), A. Lari-vière (Quebec), W. R. Manock (Niagara Peninsula), H. Massue (Montreal) H. N. Macpherson (Vancouver), W. L. McFaul (Hamilton), C. K. McLeod (Montreal), G. M. Pitts (Montreal), M. G. Saunders (Arvida), H. R. Sills (Peterborough), C. E. Sisson (Toronto), and J. A. Vance (London); President-Elect C. R. Young (Toronto); Vice-Presidents-Elect J. L. Lang (Sault Ste. Marie), and G. G. Murdoch (Saint John); Councillors-Elect J. E. Armstrong (Montreal), E. D. Gray-Donald (Quebec), T. A. McElhanney (Ottawa), and W. J. W. Reid (Hamilton). Treasurer John Stadler (Montreal), Secretary Emeritus R. J. Durley, General Secretary L. Austin Wright, and Assistant General Secretary Louis Trudel.

The following were present by invitation—Past-Presidents O. O. Lefebvre (Montreal), F. P. Shearwood (Montreal), and George A. Walkem (Vancouver); Past Vice-Presidents Ernest Brown, J. H. Hunter, W. G. Mitchell, J. A. McCrory and Fred Newell, of Montreal, and P. M. Sauder of Edmonton; Past-Councillors Geoffrey Stead (Saint John), and P. E. Doncaster (Lakehead); L. E. Westman, representing the Wartime Bureau of Technical Personnel; H. F. Bennett, chairman of the Committee on the Training and Welfare of the Young Engineer; Fraser S. Keith, a past general secretary of the Institute; F. A. Patriquen, chairman, Saint John Branch; J. A. Lalonde, chairman, and L. A. Duchastel, secretary, of the Montreal Branch; R. C. Flitton, vice-chairman, and G. D. Hulme, member, of the Montreal Annual Meeting Committee; Colonel E. G. M. Cape, Montreal.

President Mackenzie extended a cordial welcome to all councillors and guests, and had each person rise and introduce himself to the meeting.

The general secretary reported that up to January 31st, the amount received from the various branches towards the Headquarters Building Repairs Fund was \$8,076.00, over \$5,500.00 of which had been received from the Montreal Branch. The president again expressed his appreciation of the splendid effort that had been made by all the branches, and by the Montreal Branch in particular. It was of great advantage to the Institute to have had this contribution towards the extraordinary expenses of repairing the building.

Mr. Durley presented the final revised report on Institute prizes and awards, copies of which had been circulated to members of Council and past-presidents. After Mr. Durley had read the complete report, each item was taken separately discussed, and decisions reached.

After consideration of the report on the prizes and awards of the Institute, the sincere thanks of Council were extended to Mr. Durley for his very complete and comprehensive report.

Following the discussions which had taken place at the last meeting of Council on post-war reconstruction, Mr. Cameron advised that there was nothing new to report. Although this question seemed to be in everyone's mind at the moment, our first efforts must essentially be towards helping win the war. However, the Canadian government, remembering the results of the last war, has set up a committee on post-war reconstruction, under the chairmanship of Principal James of McGill University. This committee, with its several sub-committees, is still in the organization stage, and Principal James has not yet made any public statement regarding its work.

Mr. Cameron pointed out that at the Friday afternoon session of the annual meeting, following the address by E. M. Little, Director of the Wartime Bureau of Technical Personnel, Dr. Leonard C. Marsh, research adviser to Principal James' committee, would give a talk on post-war reconstruction. He advised everyone who possibly could do so to hear this address. In Mr. Cameron's opinion, as time goes on, the place of the engineer and the technical man in Canada's post-war programme will clarify itself, and the part which The Engineering Institute can play in post-war planning will also be defined.

Mr. Doncaster was pleased to hear that the matter was going to be discussed, and hoped that it would receive careful consideration. The Lakehead Branch fully realised that the immediate effort should be directed towards winning the war, but was still of the opinion that definite plans should be made for the post-war period. In the opinion of the branch, The Engineering Institute has a definite and distinct responsibility to the engineers of Canada, and should set up its own committee and work with other committees along specific lines which would include the engineering and technical phases of post-war reconstruction.

The president outlined briefly the work which had already been done and which was being done by the government along these lines, most of which could not be made public at the present time. When the proper time comes, he said The Engineering Institute would be able to take a prominent and active part in the reconstruction programme, but he would not like to see the Institute or any of its branches take any unwise or precipitate action at the moment. He suggested that the matter could very properly be referred to the incoming Council for consideration and action, and after some further discussion, it was unanimously agreed that this should be done.

Mr. Bennett, chairman of the Committee on the Training and Welfare of the Young Engineer, distributed to the meeting copies of the booklet which had been prepared by his committee entitled "The Profession of Engineering in Canada." The booklet was just off the press and was being distributed, free of charge, to over one thousand high schools, as well as to universities and Institute branches. Mr. Bennett suggested that after the first free distribution it might be advisable to make a charge of five cents a copy

for additional supplies. The booklet had been very well received. Several service clubs had already called upon the committee for counselling on matters pertaining to engineering.

Mr. Bennett submitted a draft of a letter which he proposed sending to each branch of the Institute asking them to form student guidance and counselling committees. The letter also described the suggested functions of such committees. Mr. Bennett pointed out that his committee had available a great deal of information received through the Engineers' Council for Professional Development, his committee having been in very close touch with the E.C.P.D. Committee on Student Selection and Guidance. Seven members of his committee were present at this annual meeting, and they hoped to get together in a day or so and complete their organization with a view to continuing their work among graduate engineers in their formative years. In Mr. Bennett's opinion, the Institute must take an active interest in these young engineers, particularly those returning from overseas. They must be contacted by the branches to encourage them to continue their membership in the Institute. Mr. Bennett described briefly the contents of the booklet, which included a reference to the other engineering organizations throughout Canada. It also included a list of the cities in which the Institute branches are located.

The president thanked Mr. Bennett for his splendid report, and congratulated him upon the appearance of the booklet. He assured Mr. Bennett that his committee would receive the continued support of Council.

Following some discussion, it was unanimously agreed that the matter of the further distribution of the booklet be left in the hands of the committee, and that it be distributed free as long as the Finance Committee approved. The draft letter to the branches was also approved, and it was unanimously agreed that the letter should be signed by Mr. Bennett as chairman of the Committee on the Young Engineer, and that the ensuing correspondence should be carried on by him.

As chairman of the Committee on Professional Interests, Mr. Challies reported briefly on the progress being made in the various provinces. A very definite step towards the goal of Dominion-wide co-operation had been made by the signing of an agreement on January 12th, 1942, between the Institute and the Association of Professional Engineers of the Province of New Brunswick. This made the fourth province in which there is a co-operative agreement. The agreements now in effect were working out to the mutual advantage of both parties concerned, and the committee felt that they would eventually cover the whole Dominion. Mr. Challies read figures covering new members added to the Institute in the various provinces under the terms of the co-operative agreements.

He then gave a brief outline of the situation in the four provinces in which co-operative agreements are not yet in force. In the opinion of his committee progress is being made towards the desired goal of solidarity of the profession.

The general secretary reported receipt of a communication from Mr. P. B. Motley, dealing with the question of Life Memberships, and suggesting that the matter be discussed by Council and at the annual general meeting. Mr. Wright pointed out that the general question of Life Memberships had been considered by the Finance Committee on several occasions recently.

Under the by-laws, the Finance Committee has considered individually each request for Life Membership and each resignation received from members who appear to qualify for Life Membership under one or more of the conditions, and has made a definite recommendation to Council in each case. In most cases the opinion of the branch executive has been secured. Frequently it had been difficult to reach a decision.

The memorandum from Mr. Motley recommended that Council give consideration to amending the by-laws so that

The Annual Meeting of Council, held in the auditorium at Headquarters

Life Membership would be removed from the section dealing with exemptions and placed in a section similar to that dealing with Honorary Membership, and that it be granted automatically without application from the Member. He suggested the following wording for the consideration of a sub-committee. "Members who have paid thirty annual fees, and have reached the age of sixty-five, shall become, on account of the support they have given the Institute during their best working years, automatically entitled to the grade of Life Membership without further payment of fees, and the secretary shall send them a suitable certificate and letter of congratulation on this occasion."

The General Secretary reported that a search had been made of the records of other societies and it had been found that it was far from common practice to grant Life Membership automatically. In the Old Country there appeared to be no society following the practice. In the United States two large societies granted life membership automatically when a member reached age seventy and had had thirty years of corporate membership or thirty-five years of corporate membership regardless of age. These societies had fees that were approximately double those of the Institute.

In 1940 and 1941, acting on the present system, the Finance Committee of the Institute had recommended, and the Council had granted, sixteen Life Memberships in each year.

Discussion followed, during which the president pointed out that the fundamental point raised by Mr. Motley appeared to be that under the present by-laws the responsibility of asking for Life Membership rests with the member himself. In Mr. Motley's opinion this should be granted automatically and considered as an honour. As the by-laws now stand it is considered as an exemption from the payment of further annual fees, and not as one of the Institute's honours. What the Council has to decide is whether or not the granting of Life Membership should be considered as an exemption or as an honour.

In Mr. Challies' opinion the object of Council in setting up this form of Life Membership had been to deal with senior members who, for various reasons, could not conveniently continue to pay their annual fees. That had been the intention of Council and the by-law had been administered from that point of view. No attempt had ever been made to advertise the availability of this privilege.

Considerable discussion followed, from which it appeared that in the opinion of the meeting no change should be made in the by-law.

Dean Young described a situation with which the University of Toronto was now confronted, and which he believed existed also at other engineering faculties. He did not ask for a formal resolution on the matter, but thought that a general discussion and expression of opinion would be helpful.

He explained that his university had been asked by recruiting officers to release fourth year students with their degrees before the completion of the full term. He informed the meeting that the Wartime Bureau of Technical Personnel had been consulted and had expressed the opinion that in the light of conditions so far disclosed it would be best to carry on normally, giving full instruction and full examination.

He pointed out that the situation was now rather difficult in that the active service units, as well as industry, were interviewing students with the idea of signing them up prior to graduation and then were applying pressure on the faculty to release the students before their courses were completed. This competitive recruiting was resulting in a lot of confusion in the minds of the students and was retarding them in their normal work. He explained that the Ontario Association of Professional Engineers had thought it inadvisable to shorten the courses as the graduates' position in the profession might be prejudiced when they returned to their usual civilian practice.

Past-President Walkem felt that the universities should complete their courses in the normal way, and not be unduly influenced by recruiting officers from the fighting forces.

The general secretary reported that, knowing of Dean Young's interest in this matter, he had suggested that Mr. L. E. Westman, of the Wartime Bureau of Technical Personnel, attend the meeting in order to participate in the discussion. Mr. Westman was handling all university affairs in the Bureau and had been considering this question from the point of view of all the universities. The president called on Mr. Westman for his opinions.

Mr. Westman presented a report which dealt in a general way with university activities under war conditions. He described how the Bureau had gathered opinions from all

the universities in an endeavour to summarize the situation. From these expressions of opinion and from discussions with government authorities the Bureau had reached the conclusion that the universities should continue their courses in the normal way, and that in the senior year the degree should not be given before the full course and all examinations had been completed. Mr. Westman was careful to point out that changes in conditions might very quickly alter the values and make some other arrangement more desirable. He explained that the Bureau was in close touch with all universities and that this subject was up for constant consideration. He also gave a synopsis of several matters affecting university affairs, but preceded his remarks with the comment that many of these matters were confidential and therefore should not be given wide distribution until the final policy had been determined and proper legislation authorized.

The president pointed out to Dean Young the difficulty of answering his question definitely. If the men were vitally needed he thought they should not be held back; yet, on the other hand, the need may not be so great as to justify an incomplete course. He thought Council should be careful not to give public utterance on a question on which it was not particularly qualified to judge and not empowered to act. He thought the deans of engineering would have to keep close to the situation and then make up their own minds as to what should be done.

Mr. Krebsler inquired as to whether or not it would be feasible to have the students recruited and then given leave of absence to complete their courses. Dean Young replied that he had made this suggestion to an officer some weeks ago, but so far had received no reply.

Dean Ernest Brown stated that he endorsed everything that Dean Young had said. Conditions at McGill were very much the same as at Toronto. He thought that there was an inclination on the part of recruiting officers to over-emphasize the need.

He agreed with Dean Young in that the universities wanted to help in any way they could, but thought they must not lose sight of their responsibility towards the students. He stated that at McGill they were carrying on in the usual way and watching the developments very closely. He agreed with the president that the matter was not one on which the Institute was particularly well qualified to offer advice, but he did think that both he and Dean Young would be glad to have the opinions of councillors.

Dean Young again emphasized that he did not want any formal declaration, but was simply seeking expressions of opinion such as he had received.

A number of applications were considered, and the following elections and transfers were effected:

ADMISSION

Student to Junior.....	1

Before adjourning the meeting, which would be the last over which he would have the privilege of presiding, Dean Mackenzie expressed the great pleasure it had given him to be in the chair at these meetings. He had found the Institute Council to be one of the most effective and business-like bodies with which he had had to deal. The experience had been one of the bright spots in his life.

Mr. Hunter also expressed his thanks at having been invited to attend the meeting, which he had enjoyed very much.

Mr. Challies remarked that The Engineering Institute, in honouring Dean Mackenzie, had undoubtedly honoured itself. His connection with research work, now of paramount importance to Canada and the engineering profession, had

lent great prestige to the Institute throughout the Dominion, and he therefore had great pleasure in moving a hearty vote of thanks to Dean Mackenzie for the splendid way in which he had served the Institute during his term of office.

In seconding the motion, which was carried unanimously, Dean McKiel said that everyone realised what the Institute had gained during Dean Mackenzie's presidency, and he associated himself most heartily with Mr. Challies' motion.

The president expressed his thanks and appreciation.

There being no further business, the Council rose at four-forty p.m.

A meeting of the new Council of the Institute was held at the Windsor Hotel, Montreal, on Thursday, February 5th, 1942, at five o'clock p.m.

Present: President C. R. Young in the chair; Past-Presidents C. J. Mackenzie and H. W. McKiel; Vice-Presidents deGaspé Beaubien, K. M. Cameron, H. Cimon and J. L. Lang; Councillors J. E. Armstrong, A. E. Berry, J. H. Fregeau, E. D. Gray-Donald, J. G. Hall, W. G. Hunt, H. N. Macpherson, T. A. McElhanney, G. McL. Pitts, W. J. W. Reid, M. G. Saunders, H. R. Sills and J. A. Vance; Past Councillor C. E. Sisson, and General Secretary L. Austin Wright.

On reading the minutes of the January meeting of Council, Dean Young had noted that it had been decided, subject to the approval of the new Council, to hold the April meeting of Council in Toronto on April 18th, to coincide with a joint dinner to be held that evening by the Council of the Association of Professional Engineers of Ontario and the Toronto Branch of the Institute. As he was to be the guest of honour at that meeting, this had placed him in rather an embarrassing position, inasmuch as he was planning a trip to the western branches and would be unable to leave Toronto before the first of April. It would be more convenient to him if the meeting could be held a week later, as it would crowd things somewhat if he had to be back in Toronto by the 18th.

Mr. Berry thought that although the date had been more or less decided upon by the Association, they would be agreeable to changing it to the 25th, and he also believed that the 25th would be acceptable to the Toronto Branch. After some discussion, on the motion of Mr. Vance, seconded by Mr. Berry, it was unanimously **RESOLVED** to suggest that, if agreeable to the Association of Professional Engineers of Ontario and to the Toronto Branch of the Institute, the proposed joint dinner be held on Saturday, April 25th, instead of April 18th as previously arranged. If that date was not satisfactory to all concerned, it was left with the president to decide upon a suitable date.

The president inquired as to what should be the next step in connection with the resolution from the Lakehead Branch on post-war reconstruction. Would it be advisable to defer action until Mr. Cameron was prepared to report further on the activities of Dr. James' committee?

Considerable discussion followed as to the part which the Institute branches should take in any post-war reconstruction programme. Some of the branches were most anxious to go ahead, but would be willing to do whatever would fit into the plans of Council.

Mr. Cameron pointed out that he was not yet in a position to tell just what the organization of Dr. James' sub-committees would be. His own sub-committee would be meeting very shortly and would set up its own organization. In working on a problem of this kind, cognizance would have to be taken of The Engineering Institute of Canada. If his sub-committee decides to follow along the lines that he has in mind, the twenty-five branches of the Institute would take a very definite part in the regional distribution of the work of the committee.

Dean Young asked if, in the meantime, there were any instructions that could be sent out to the Institute branches in regard to their activities on post-war reconstruction. Mr.

Wright pointed out that the February *Journal* would contain some information about Dr. James' committee, and additional information would probably be secured from Dr. Marsh's address. If Mr. Cameron was able to accompany the president on his western trip, as was hoped and anticipated, he would by then be in a position to give some information on the work of his committee.

In Dean Mackenzie's opinion too much publicity should not be given to any work being done by the Institute branches on this question. He felt that at the present time, the branches should do little more than study the problem and gather information, and be ready to co-operate when they are asked to do so.

After further discussion, on the motion of Mr. Hunt, seconded by Mr. Vance, it was unanimously agreed that it should be left with the president to decide on the action to be taken, it being suggested that the general secretary, after consultation with the president and Vice-President Cameron, might write a letter to the branches explaining the situation.

Mr. Vance inquired as to the possibility of holding a regional meeting of Council during the president's visit to the west. He was very much in favour of such meetings.

The general secretary explained that it had been customary, whenever possible, to hold regional Council meetings when the president visited the branches. In recent years, one had been held in Regina, Halifax, and Saint John, and two in Calgary. On two occasions they had tied in with the signing of the co-operative agreements. It was desirable that such a meeting be held this year either in Winnipeg or in Vancouver.

Members present agreed that it would be a very good thing for the Institute if such a meeting could be held in Vancouver. Although it had already been decided to hold the April meeting of Council in Toronto, in the discussion which followed it was agreed that although it was not usual to hold two meetings in one month, a regional meeting in Vancouver in April would not in any way conflict with the meeting already planned for Toronto. It was finally decided that the April meeting of Council be convened in Vancouver at the time of the president's visit, and adjourned to meet in Toronto on Saturday, April 25th, or whatever date is decided upon for the joint dinner.

Mr. Gray-Donald reported that the Quebec Branch would like to suggest that consideration be given to the possibility of holding the Annual General Meeting for 1943 in Quebec City. No official action had been taken yet but he thought the local committee would look with favour on such a proposal. A formal invitation could be submitted later, but he would like to place the suggestion on record, and hoped it would receive favourable consideration. This tentative offer was received with appreciation to be considered at a later meeting of Council after the branch committee had given to it the necessary consideration.

Mr. Pitts suggested that it might be very desirable at this time if an arrangement could be made with the founder societies in the United States whereby the publications of those bodies could be issued to their members in Canada and to members of the Institute, through the medium of The Engineering Institute of Canada. Dean Young suggested that Mr. Pitts might develop this thought and submit a memorandum which could be considered later by Council.

On the motion of Mr. Sisson, seconded by Mr. Lang, it was unanimously **RESOLVED** that a hearty vote of thanks be extended to the Montreal Branch for their hospitality, and for the very efficient manner in which the Annual General Meeting had been conducted.

On the motion of Mr. Reid, seconded by Mr. Cimon, it was unanimously **RESOLVED** that the thanks of Council be extended to the retiring president and councillors for their efforts during the past year; much valuable time had been given to committee meetings and to meetings of Council, all of which had been very greatly appreciated.

The general secretary reported that Past-President Duggan had telephoned to say that he would like to entertain at his home on Saturday afternoon any members of Council or guests who were able to stay over. Mr. Wright had undertaken to make arrangements, and extended an invitation to all members present.

It was decided that the next meeting of Council would be held at Headquarters on Saturday, March 14th, at ten-thirty a.m.

The Council rose at six-fifteen p.m.

## ELECTIONS AND TRANSFERS

At the meeting of Council held on February 4th, 1942, the following elections and transfers were effected:

### *Members*

**Haven**, Frank Goldie, (Univ. of Minn.), res. engr., civil aviation branch, Department of Transport, Winnipeg, Man.  
**Lewis**, William Milton, B.Sc. (Mech.), (Queen's Univ.), road supt. and engr., Township of Ernestown, R.R. No. 4, Napanee, Ont.  
**Wood**, Ernest William, Lieut. (E), R.C.N.(T), Engr. Officer in Charge, Mechanical Training Establishment, Esquimalt, B.C.

### *Transferred from the class of Student to that of Junior*

**LeBel**, Harry Walter Scott, B.Eng. (McGill Univ.), detailing and design, Horton Steel Works, Ltd., Fort Erie, Ont.

### *Students Admitted*

**Beresford**, Morris Maskew, (Univ. of Manitoba), 428 Ash St., Winnipeg, Man.  
**Chapman**, Harris James, (McGill Univ.), 3582 Durocher St., Montreal, Que.  
**Daly**, Thomas Cyril Norman, (McGill Univ.), 445 Wiseman Ave., Outremont, Que.  
**deHart**, William Gordon, (Mass.Inst.Tech.), M.I.T. Dorms., Cambridge, Mass.  
**Edwards**, Frank Harry, (McGill Univ.), 79 Victoria Ave., Longueuil, Que.  
**Harkness**, Andrew Dunbar, (McGill Univ.), 4315 Melrose Ave., Montreal, Que.  
**Iliffe**, Francis H., (McGill Univ.), 143 Bedbrook Ave., Montreal West, Que.  
**Jeske**, Robert August, (Univ. of Manitoba), 134 Chestnut St., Winnipeg, Man.  
**Macfadyen**, Allan Burt, (Univ. of Manitoba), Box 872, Flin Flon, Man.  
**Martin**, William Stormont, (McGill Univ.), 4260 Beaconsfield Ave., Montreal, Que.  
**McRostie**, Gordon Callander, (Univ. of Toronto), 186 St. George St., Toronto, Ont.  
**Routly**, William James, (McGill Univ.), 8034 Western Ave., Montreal West, Que.  
**Simpson**, Francis W., (McGill Univ.), 1703 Wm. David St., Montreal, Que.  
**Simpson**, William Tyrie, (McGill Univ.), 5207 Trans-Island Ave., Montreal, Que.  
**Solomon**, Julius Denison, (Univ. of Toronto), 17 Madison Ave., Toronto, Ont.  
**Stapells**, Robert Frederic (McGill Univ.), 4888 Dornal Ave., Montreal, Que.  
**Stoppes**, Reginald Edward, (McGill Univ.), 3429 Peel St., Montreal, Que.  
**Turnbull**, John Arnold, (Univ. of New Brunswick), 3 Mount Pleasant Court, Saint John, N.B.  
**Walker**, Adam Stewart, (Sir George Williams Coll.), 204 Hospital St., Room 35, Montreal, Que.  
**Webster**, John Alexander, (McGill Univ.), 141 Kenaston Rd., Town of Mount Royal, Que.  
**Wilson**, William Henry, (McGill Univ.), 510 Main St., Farnham, Que.

# NEWLY ELECTED OFFICERS OF THE INSTITUTE

**Hector Cimon**, M.E.I.C., secretary of Price Brothers and Company, Limited, Quebec, is the newly elected vice-president of the Institute for the Province of Quebec. He is a very active member, having been secretary-treasurer of the Quebec Branch from 1921 to 1924, and councillor representing the Branch from 1930 to 1937. He was born at Rivière-du-Loup, Que., and received his engineering education at the Ecole Polytechnique, Montreal, where he graduated in 1916. Upon graduation he joined the company with which he has remained ever since and was placed in charge of special surveys and later he was in charge of design and supervision of construction of various engineering works for the company. After several years as engineer of the company, he became secretary in 1939.

Mr. Cimon joined the Institute in 1912 as a Student and was transferred to Associate Member in 1919. He became a Member in 1930.

**J. L. Lang**, M.E.I.C., of the firm of Lang and Ross, consulting engineers, Sault Ste. Marie, Ont., is the newly elected vice-president of the Institute for Ontario. He was born at Hyde, England, and was educated at the University of Toronto, graduating in 1907 with the degree of Bachelor of Applied Science. He has been in private practice at Sault

been connected with the construction of most of the water works and sewage systems in his province.

Mr. Murdoch joined the Institute as a Student in 1905. He was transferred to Associate Member in 1911 and he became a Member in 1919.

**E. G. M. Cape**, M.E.I.C., is the newly appointed treasurer of the Institute. Born at Hamilton, Ont., he was educated at McGill University, Montreal, where he graduated in 1898. Shortly after graduation he was an engineer in charge of the plant of the Lethbridge Water Works and Electric Light Company at Lethbridge, Alta. From 1900 to 1902 he was assistant chief engineer of Lake Superior Power Company at Sault Ste. Marie, Ont., and was in charge of the construction of plants, mills, dams, water works and harbour improvements. From 1902 to 1905 he was in private practice at Montreal. In 1905 he was chief engineer in charge of the construction of the shops of the Canada Car Company. In 1906 he was associated with C. E. Deakin, general contractor. In 1907 he established the firm of E. G. M. Cape and Company, engineers and contractors, Montreal, of which he is still president.

During the last war Colonel Cape recruited and commanded the 3rd Canadian Siege Battery and went overseas

Hector Cimon, M.E.I.C.

John L. Lang, M.E.I.C.

G. G. Murdoch, M.E.I.C.

Ste. Marie ever since his graduation, first as partner in the firm of Lang and Keys. In 1910 the firm took the name of Lang, Keys and Ross and a few months later it became Lang and Ross. Mr. Lang served in the last war with the Canadian Expeditionary Force from 1916 to 1919. He has been closely associated with the development of the northern part of the province and at one time he was district engineer of the Northern Development Branch. As a consulting engineer, he has been connected with most of the important engineering projects carried out in his district.

Mr. Lang joined the Institute as a Member in 1921.

**G. G. Murdoch**, M.E.I.C., has been elected a vice-president of the Institute representing the maritime provinces. He was born at Saint John, N.B., and was educated at the local schools. He received his engineering training in the office of his father, William Murdoch, engineer and superintendent of water and sewage for the City of Saint John. After having obtained his certificate as a deputy land surveyor for New Brunswick, he established himself in private practice at Saint John, N.B. in 1895. For several years he was engineer for the New Brunswick Power Company and in this capacity he has designed and constructed many hydraulic structures. As a consulting engineer he has specialized in municipal engineering and has

in 1915. After training in England, he went to France in June, 1916. Colonel Cape was mentioned twice in dispatches after the battles of the Somme and Vimy Ridge. He was awarded the Distinguished Service Order after the latter battle. After the war he organized and commanded the 2nd Medium Brigade, Royal Canadian Artillery. From 1925 to 1930 he commanded the 2nd Regiment, Royal Canadian Artillery, and he is now Honorary Lieutenant-Colonel of the 2nd Regiment, Royal Canadian Artillery.

Colonel Cape joined the Institute as a Student in 1899. He was transferred to Associate Member in 1902 and became a Member in 1909.

**John E. Armstrong**, M.E.I.C., chief engineer of the Canadian Pacific Railway Company, is one of the newly elected councillors representing the Montreal Branch. He was born at Peoria, Ill., and received his education at Cornell University where he graduated in 1908 as a civil engineer. From 1908 to 1912 he was assistant engineer with the Cleveland and Pittsburg division of the Pennsylvania Company at Cleveland. In 1912 he joined the staff of the Canadian Pacific Railway Company at Montreal as an engineer in the office of the assistant chief engineer, and in 1928 he became assistant chief engineer of the company. Since 1938 he has been chief engineer. Mr. Armstrong has been engaged on many important works, including the

Col. E. G. M. Cape, M.E.I.C.

J. E. Armstrong, M.E.I.C.

S. G. Coultis, M.E.I.C.

Quebec joint terminal, the waterfront development at Saint John, N.B., the railway revision during the last war and the construction of the Toronto viaduct from 1924 to 1930.

In 1934 he was president of the American Railway Engineering Association, and in 1940, president of the Canadian Railway Club.

Mr. Armstrong joined the Institute as an Associate Member in 1917 and he was transferred to Member in 1940. He has served on the Finance Committee of the Institute for the last two years.

**S. G. Coultis, M.E.I.C.**, is the newly elected councillor representing the Calgary Branch. He was born at Forest, Ont., and was educated at the University of Michigan where he graduated in chemistry from the class of 1909. He was in the employ of Smith and Leisenring as a chemist from 1909 till 1913, when he went to Calgary as assistant chemist with the city. From 1917 until 1920 he was superintendent of the Southern Alberta Refineries and in 1920 became superintendent of the Royalite Oil Company at Black Diamond, Alta. In 1937 he returned to Calgary.

Mr. Coultis joined the Institute as a Member in 1925.

**G. L. Dickson, M.E.I.C.**, has been elected councillor to represent the Moncton Branch. He was born at Truro, N.S., and received his education at Acadia University where he graduated in 1900. From 1905 until 1910 he was chief electrician with the Pictou County Electric Company and from 1910 to 1916 he held the same position with the Nova Scotia Steel and Coal Company at Wabana, Newfoundland. In the years 1916-1917 he was manager of Chambers Electric Light and Power Company. In 1919 he joined the

Canadian National Railways as general power plant inspector for the Eastern Lines. In 1923 he became electric and signal engineer for the Atlantic Region at Moncton, N.B.

Mr. Dickson joined the Institute as an Associate Member in 1923 and he became a Member in 1940.

**F. W. Gray, M.E.I.C.**, assistant general manager of the Dominion Steel and Coal Corporation, Sydney, N.S., is the newly elected councillor representing the Cape Breton Branch. Born in Yorkshire, England, he was educated at Firth College, Sheffield. In 1904 he came to Canada as assistant to the general manager of the Dominion Coal Company at Sydney. In 1908 he became assistant to the president of the Nova Scotia Steel and Coal Company. From 1919 to 1921 he was editor of the Canadian Mining Journal and Iron and Steel of Canada. In 1921 he became assistant to the vice-president of the British Empire Steel Corporation and in 1923 he was made assistant to the president. In 1928 he was appointed to the position which he now holds. After long residence in the maritimes, he holds an advisory position in one of the most important industries of that region.

Besides being an authority on under-sea coal mining, Dr. Gray is also an author and an artist. A staunch supporter of professional engineering bodies, he is a past-president of the Canadian Institute of Mining and Metallurgy and of the Mining Society of Nova Scotia.

Dr. Gray joined the Engineering Institute as an Associate Member in 1921 and he became a Member in 1924. Last year he was one of the recipients of the inaugural awards of the Julian C. Smith Medal of the Institute.

G. L. Dickson, M.E.I.C.

F. W. Gray, M.E.I.C.

E. D. Gray-Donald, M.E.I.C.

J. Haimes, M.E.I.C.

R. E. Hartz, M.E.I.C.

**E. D. Gray-Donald, M.E.I.C.**, has been elected councillor representing the Quebec Branch. Born at Amoy, China, he received his primary education at Victoria, B.C., and attended George Watson's College, Edinburgh. In 1921 he came to McGill University where he graduated in electrical engineering in the class of 1926. He is also a Master of Science of Laval University, Quebec. Upon graduation from McGill University he joined the Shawinigan Water and Power Company as an apprentice, and in 1927 he was transferred to the Quebec Power Company as an assistant engineer. He became assistant superintendent of the power division in 1928 and was appointed superintendent in 1930. In 1937 he was made assistant general superintendent of the company and in 1939 was promoted to general superintendent, the office which he now holds.

Mr. Gray-Donald joined the Institute as a Student in 1922 and he was transferred to Junior in 1926. He was made an Associate Member in 1934 and was transferred to Member in 1939.

**James Haimes, M.E.I.C.**, is the newly elected councillor for the Lethbridge Branch. Born at Barnsley, Yorkshire, he was educated in the local public and technical schools and served his apprenticeship as a mining engineer in the Wharnccliffe Collieries, Limited, at Barnsley. He came to Canada in 1911 as an instrument-man with the City of Lethbridge, later becoming office engineer. During the last war he served in France from 1916 to 1918. Upon his return to Canada in 1919 he became assistant city engineer at Lethbridge. In 1930 he became city engineer, a position which he still holds.

Mr. Haimes joined the Institute as an Associate Member in 1925 and he became a Member in 1940.

**R. E. Hartz, M.E.I.C.**, is one of the newly elected councillors for the Montreal Branch. Born at Marshfield, P.E.I., he graduated from McGill in 1917 with the degree of B.Sc., and immediately after graduation was employed by the St. Maurice Construction Company at La Loutre, on the construction of the Gouin dam. Later in the same year he enlisted with the Royal Air Force, received his commission early in 1918, and was appointed flying instructor, being demobilized in 1919. In that year he joined the Fraser-Brace Engineering Company, Limited, and was employed on the construction of the Big Eddy dam on the Spanish river. Mr. Hartz became resident engineer at La Gabelle development on the St. Maurice river in 1922, having joined the staff of the Shawinigan Engineering Company in 1920. He was resident engineer on the St. Narcisse development on the Batiscan river in 1924-1925, and in 1926 was transferred to Montreal for investigating preliminary design of hydro-electric developments. In 1927 Mr. Hartz was appointed resident engineer of the Pagan Falls development on the Gatineau river, and since the completion of that undertaking has been connected with the design and construction of different hydro-electric projects. He is now assistant chief engineer of Shawinigan Engineering Company, Montreal. At present he is on loan to the Wartime Merchant Shipping, Limited, where he occupies the position of general manager.

Mr. Hartz joined the Institute as a Student in 1917. He became an Associate Member in 1926 and was transferred to Member in 1933. Last year he was chairman of the Montreal Branch, and it was under his energetic management that the building fund campaign was completed with such success.

W. G. Hunt, M.E.I.C.

E. W. Izard, M.E.I.C.

**J. R. Kaye, M.E.I.C.**

**Nicol MacNicol, M.E.I.C.**

**Walter G. Hunt, M.E.I.C.**, president and managing director of Walter G. Hunt Company, Limited, engineers and contractors, is one of the newly elected councillors of the Montreal Branch. Born at Bury, Que., he was educated at McGill University where he graduated in 1917. For several years he was associated with the firm of Ross-Meagher Company, engineers and general contractors, Ottawa, as engineer and later as general superintendent. In 1926 he came to Montreal and two years later formed the firm of Walter G. Hunt Company, Limited. One of the recent outstanding projects carried out by the firm is the construction of the Sir Arthur Currie memorial gymnasium and armoury for McGill University. More recently his firm has carried out extensions to the tank shops for the Canadian Pacific Railway Company, and construction work at the St. Hubert and Dorval airports, near Montreal. Mr. Hunt is a director of the Stanstead and Sherbrooke Fire Insurance Company and a past-president of the Builders Exchange Incorporated.

Mr. Hunt joined the Institute as a Student in 1916, transferring to Junior in 1919. He was transferred to Associate Member in 1922 and he became a Member in 1932. He has always been active in Institute affairs and he was the chairman of the committee on arrangements for the Annual Meeting in Montreal this year.

**E. W. Izard, M.E.I.C.**, is the newly elected councillor for the Victoria Branch. Born at Wisbeach, Cambridgeshire, England, he received his engineering education at Brighton Technical College and Glasgow University. He served his apprenticeship in shipbuilding with Yarrow and Company in London from 1906 to 1908. Later, until 1911 he was with

John Brown and Company at Clydebank. In 1912 he returned to Yarrow and Company at Glasgow and was employed on the design of turbines and internal combustion engines. He came to Canada in 1914 and was in charge of the dry docking and repairs of passenger, cargo and naval vessels for his company. He is at present works manager at Victoria.

Mr. Izard joined the Institute as a Member in 1937. He was chairman of the Victoria Branch of the Institute in 1940.

**J. R. Kaye, M.E.I.C.**, is a newly elected councillor representing the Halifax Branch. Born at Halifax, N.S., he was educated at Dalhousie and McGill Universities, and graduated in mechanical engineering from the latter in 1924. A few months after graduation he joined the staff of the Montreal Engineering Company and was employed with that firm until 1931, first on maintenance and reconstruction with the Calgary Power Company at Seebe, Alta., and in 1926 he was transferred to the Venezuela Power Company at Maracaibo, Ven. From 1928 to 1930 he was general superintendent at Maracaibo. Returning to Canada in 1931 he later established a consulting engineering practice and is, at present, a partner in the firm Engineering Service Company, Limited, at Halifax, N.S.

Mr. Kaye joined the Institute as a Student in 1924. He was transferred to Associate Member in 1931 and became a Member in 1940.

**Nicol MacNicol, M.E.I.C.**, is the newly elected councillor representing the Toronto Branch. Born at Barrie, Ont., he received his education at the University of Toronto where

**T. A. McElhanney, M.E.I.C.**

**A. W. F. McQueen, M.E.I.C.**

he graduated in 1919. For a few years after graduation he was employed with various firms of consulting engineers, and was connected with the design and construction of several engineering projects. In 1923 he was appointed engineer of Etobicoke Township and in 1931 he became works commissioner for Forest Hill Village, Ont., which position he still holds.

Mr. MacNicol joined the Institute as a Student in 1919 and was transferred to Junior in 1923. In 1935 he became a Member. He was chairman of the Toronto Branch of the Institute in 1940.

**T. A. McElhanney**, M.E.I.C., superintendent of the Forest Products Laboratories at Ottawa, is the newly elected councillor of the Institute representing the Ottawa Branch. He was born in Ripley, Ont., and graduated from the University of Toronto in 1912. After graduation he was connected with the British Columbia government on survey work, and from 1913 to 1917 he was a partner of the firm of McElhanney Brothers, surveyors and engineers. In 1919 he was appointed assistant controller of surveys in the Topographical Surveys branch at Ottawa. In 1923

Gzowski Medal. He was chairman of the Niagara Peninsula Branch of the Institute in 1939.

**A. E. Pickering**, M.E.I.C., has been elected councillor representing the Sault Ste. Marie Branch. Born at Brampton, Ont., he graduated from the University of Toronto in mechanical and electrical engineering. From 1905 to 1912 he was assistant engineer and in 1912-1913 manager and engineer of the Lake Superior Power Company. From 1916 to 1932 he was manager and engineer and from 1932 to date vice-president and manager of the Great Lakes Power Company, Ltd., at Sault Ste. Marie.

Mr. Pickering joined the Institute as a Member in 1921. From 1930 to 1933 he served on the Council as a representative of the Sault Ste. Marie Branch.

**W. J. W. Reid**, M.E.I.C., is the newly elected councillor representing the Hamilton Branch. Born at Oak River, Man., he was educated at the University of Toronto where he graduated in 1924. Upon graduation he joined the staff of Otis-Fensom Elevator Company at Hamilton and in 1925 he was put in charge of electrical manufacture. In

A. E. Pickering, M.E.I.C.

W. J. W. Reid, M.E.I.C.

J. W. Sanger, M.E.I.C.

he was appointed acting superintendent of the Vancouver laboratory of the Forest Products Laboratories of Canada, and in 1938 he became superintendent of the Laboratories at Ottawa.

Mr. McElhanney joined the Institute as an Associate Member in 1932 and he became a Member in 1940.

**A. W. F. McQueen**, M.E.I.C., is the newly elected councillor for the Niagara Peninsula Branch. Born at Lowestoft, England, he graduated from the University of Toronto in 1923 and entered the service of the Hydro-Electric Power Commission of Ontario. For three years he was assistant engineer of tests and for another three years he remained with the Commission in charge of various hydrological and hydraulic investigations. In 1927 he became assistant engineer with H. G. Acres and Company, Ltd., Consulting Engineers, Niagara Falls, Ont., and in 1934 hydraulic engineer, which position he holds at the present time.

Mr. McQueen joined the Institute as a Student in 1920. He was transferred to Junior in 1927 and to Associate Member in 1929. He became a Member in 1939. He is the author of several papers that have been published in *The Journal*. In 1932 he was awarded the Past-Presidents' Prize for a paper on "Engineering Education." In 1938 he was the joint author of the paper "The 18-Foot Diameter Steel Pipe Line at Outardes Falls," which was awarded the

1926 he became assistant construction manager and in 1928 construction manager. He was transferred to the engineering department in 1931 and in 1933 he became works manager, a position which he still holds with that of manager of munitions.

Mr. Reid joined the Institute as an Associate Member in 1929 and he was transferred to Member in 1937.

**J. W. Sanger**, M.E.I.C., chief engineer of the City of Winnipeg Hydro-Electric System and commissioner of the Manitoba Power Commission, is the newly elected councillor representing the Winnipeg Branch. Born at Bristol, England, he received his technical education at Faraday House, London. From 1907 until 1911 he was district superintendent of the Midland Electric Power Corporation at Staffordshire, England. In 1912 he came to Canada as engineer and superintendent of distribution for the City of Winnipeg Hydro-Electric System. In 1915 he became superintendent of the System, and in 1932 he was appointed chief engineer. He became a commissioner of the Manitoba Power Commission in 1931.

Mr. Sanger joined the Institute as an Associate Member in 1921, transferring to Member in 1936. He was chairman in 1939 of the Winnipeg Branch of the Institute. In 1933 Mr. Sanger was president of the Association of Professional Engineers of Manitoba.

## INSTITUTE PRIZE WINNERS

**W. G. McBride**, M.E.I.C., is one of the recipients for 1941 of the additional inaugural awards of the Julian C. Smith Medal "for achievement in the development of Canada."

Twenty-five years after his graduation from McGill University, Mr. McBride was persuaded to leave the copper-mining industry of the west, and return to his old university as head of the department of mining engineering and metallurgy, the position which he occupies today.

During his career in Mexico and Arizona his achievements as mine manager, after overcoming serious technical and labour difficulties, gained for him recognition as a leading authority in metal mining. He has been prominent in the work of professional societies, both in administrative work and as a contributor to technical knowledge. He was president in 1941 of the Canadian Institute of Mining and Metallurgy and is serving his second term on the Council of the Institution of Mining and Metallurgy, London. His services as a consultant have been widely sought. At McGill University he has manifested his great capacity for unstinted service and helpful leadership.

W. G. McBride, M.E.I.C.

W. G. Murrin, M.E.I.C.

E. W. Stedman, M.E.I.C.

**W. G. Murrin**, M.E.I.C., president of the British Columbia Power Corporation Limited and associated companies, has been awarded one of the additional inaugural awards of the Julian C. Smith Medal for 1941. An electrical engineer of wide experience and high standing, Mr. Murrin received his professional training and early experience in England.

During his thirty years' residence in Canada he has been identified with the growth, organization and operation of the great public utility in British Columbia, of which he has been president since 1929. The remarkable development of the electrical power industry which has taken place in that province is in no small measure due to his technical knowledge, energy and leadership. He is prominent also on the directorate of important industrial and financial organizations and in the community life of the city in which he lives.

**Air Vice-Marshal E. W. Stedman**, M.E.I.C., is one of the recipients for 1941 of the additional inaugural awards of the Julian C. Smith Medal.

The career of Air Vice-Marshal Stedman well illustrates the indispensable nature of the services which trained engineers render in aerial warfare. A brilliant student at the Royal College of Science, London, and a Whitworth Scholar, he took up research work in aeronautics at the National Physical Laboratory, Teddington. On the outbreak of war

in 1914 he joined the Royal Naval Air Service—afterwards merged in the Royal Air Force—and was demobilized in 1919 with the rank of Lieutenant-Colonel.

After a period of service as chief of the technical staff of Handley Page Limited, he came to Canada in 1920, on the creation of the Air Board. His distinguished work as chief aeronautical engineer of the Royal Canadian Air Force led to steady promotion in the service; he is now a member of the Air Council, responsible for aeronautical engineering.

A frequent contributor of valuable papers to aeronautical and other journals, he has been honoured by many leading technical and scientific bodies.

**S. R. Banks**, M.E.I.C., has been awarded the Gzowski Medal for 1941 for his paper, "Lions' Gate Bridge, Vancouver, B.C." He was born in Liverpool, England, and received his general education at Liverpool Collegiate School. Studying civil engineering at the University of the same city, he graduated with honours in 1924, and two years afterwards advanced to the degree of M.Eng. His

first appointment was that of junior engineer with the Bridge Stress Committee of the Department of Scientific and Industrial Research, Great Britain. Subsequently he was for some time in the office of Messrs. Rendel, Palmer and Tritton, consulting engineers, of Westminster.

Mr. Banks came to Canada in 1929, and was at first employed by the Dominion Bridge Company at Lachine in the capacity of structural designer and field engineer. From 1932 to 1940 he was assistant engineer with Messrs. Monsarrat and Pratley, consulting engineers, of Montreal. With this firm his duties were closely connected with the design and supervision of erection of the Ile d'Orléans and Lions' Gate suspension bridges, and with inspections of the Jacques Cartier bridge and of the main line bridges of the Newfoundland Railway. For the past two years Mr. Banks has been with the Aluminum Company of Canada, Limited, at Montreal, engaged in the design of works involved in the company's wartime building programme.

Mr. Banks is an Associate Member of the Institution of Civil Engineers, by which body he was awarded a Telford Premium in 1936. He is also an Associate Member of the Institution of Structural Engineers.

It is expected that Mr. Banks' prize-winning paper will be published in the *Journal* starting with the April issue.

S. R. Banks, M.E.I.C.

O. W. Ellis, M.E.I.C.

G. Reuben Yourt

**O. W. Ellis, M.E.I.C.**, is the recipient of the Duggan Medal and Prize for 1941 for his paper, "Forgeability of Metals," presented before the Niagara Peninsula Branch of the Institute and published in the October, 1941, issue of the *Journal*. He was born at Swindon, England, and served an apprenticeship with the Great Western Railway Locomotive Works at Swindon. He came to Canada in 1910 as an educational instructor with the Canadian Pacific Railway Company at Montreal. Returning to England in 1911 he entered the Department of Metallurgy at the University of Birmingham, England, and received his degree of B.Sc. in metallurgy in 1914. During the war 1914 to 1918 he worked as a metallurgist in the Royal Ordnance Factories. In 1916 he received the degree of M.Sc. from the University of Birmingham. At the end of the war he was appointed chief metallurgist at the Royal Laboratory Department of the Royal Ordnance Factories, and in 1920 he was called upon to reorganize all the metallurgical laboratories of the factories. In 1921 he returned to Canada as an assistant professor of metallurgical engineering at the University of Toronto, a position which he retained until 1925. At that date he was appointed an Industrial Fellow at the Mellon Institute of Industrial Research, University of Pittsburgh, where he carried out work on metals for bearings. From 1926 to 1929 he was in the research department of the Westinghouse Electric and Manufacturing Company. In 1929 he was appointed to his present position as Director of Metallurgical Research at the Ontario Research Foundation, Toronto. Mr. Ellis is the author of numerous papers on metallurgical subjects, both ferrous and non-ferrous. He is a contributor to the National Metals Handbook.

Mr. Ellis was awarded the Plummer Medal of the Institute in 1940.

**G. Reuben Yourt, Stud.C.I.M.M.**, is the recipient of the Leonard Medal for 1941 for his paper, "Ventilation and Dust Control at the Wright-Hargreaves Mine."

Mr. Yourt is a graduate of Queen's University where he obtained the degree of Bachelor of Arts. In January, 1936, he became connected with Wright-Hargreaves Mines, Limited, at Kirkland Lake, Ont., as a sampler, later transferring to the engineering department. He is at present ventilation and field engineer of this company.

Mr. Yourt's paper was published in the November, 1940, issue of the *Canadian Mining Bulletin*.

**A. L. Malby, Jr., E.I.C.**, is the recipient of the John Galbraith Prize for 1941 for his paper, "Carrier Current Control of Peak Loads." Born at London, England, Mr. Malby received his education at St. Johns Technical High School, Manitoba, and graduated as a Bachelor of Science in electrical engineering from the University of Manitoba in 1934. Upon graduation he joined the staff of the Canadian General Electric Company, Limited, at Peterborough, Ont., and was engaged on testing and generator erection work. In 1936 he was appointed assistant industrial control engineer, which position he still holds.

Mr. Malby is a past secretary-treasurer of the Peterborough Branch of the Institute.

**Gerald N. Martin, Jr., E.I.C.**, has been awarded the Phelps Johnson Prize for 1941 for his paper entitled, "Character-

A. L. Malby, Jr., E.I.C.

G. N. Martin, Jr., E.I.C.

T. A. Monti, S.E.I.C.

istics and Peculiarities of Some Recent Large Boilers in England" presented before the Montreal Branch of the Institute and published in the June, 1941, issue of the *Journal*. Born at Lachine, Que., he received his primary education at the Mont St-Louis College and he graduated from the Ecole Polytechnique of Montreal in 1934. Mr. Martin joined the staff of the Dominion Bridge Company upon graduation and worked as a designer in the structural and boiler departments. In 1938 he was granted a two years' leave of absence to obtain added experience and to study modern combustion engineering under the Central Electricity Board in London, England. While in England he worked on the design and operation of the highest pressure boiler units in use and was stationed for a time at the Brimsdown Station of the North Metropolitan Power Supply Company. He returned to Canada in the spring of 1940 and resumed his position in the boiler department of the Dominion Bridge Company. A few months later he was loaned to the Aluminum Company of Canada,

Limited, Montreal, where he has since been engaged on design work.

Mr. Martin has been an active member of the Junior Section of the Montreal Branch and at one time he was on the executive committee. He was awarded the Phelps Johnson Prize once before, in 1937, for a paper on "The Elements of Modern Combustion Engineering."

**T. A. Monti**, S.E.I.C., is the recipient of the Ernest Marceau Prize for 1941 for his paper, "Vedette de 40 pieds de Longueur" presented before the Junior Section of the Montreal Branch. Born in Italy, he was educated at the Ecole Polytechnique, Montreal, where he graduated in 1941. During his college vacations he worked for the Northern Electric Company, the Quebec Streams Commission, and the Department of Roads of the Province of Quebec. Since graduation he has been on the engineering staff of the Dominion Bridge Company, Limited, Montreal, in the mechanical design department.

## Personals

**D. E. Blair**, M.E.I.C., general manager of Montreal Tramways Company, has been appointed a vice-president of the company and will combine the duties of this office with his present position.

Mr. Blair, who has been associated with the Montreal Tramways Company for 39 years, was born at Montmagny, Que., and was educated at Quebec High School and McGill University where he graduated with a B.A.Sc., degree in 1897. He started his career in the transportation industry by entering the service of the Quebec Street Railway Company as electrical engineer. In this position he superintended the electrification of the Quebec, Montmorency and Charlevoix, formerly a steam railway. In 1903 he joined the Montreal Street Railway as assistant general superintendent. A year later he was appointed superintendent of

**D. E. Blair** M.E.I.C.

rolling stock and became responsible for the design, construction and maintenance of all street cars used in Montreal. In 1925 he was promoted to the position of general superintendent in charge of operation and maintenance and in 1938 was named general manager.

**H. J. Leitch**, M.E.I.C., has been appointed as assistant to the director-general of the shipbuilding branch of the Department of Munitions and Supply. At the time of his appointment, Mr. Leitch was general sales manager of Algoma Steel Corporation Limited at Montreal and his services have been loaned to the Government by this firm.

## News of the Personal Activities of members of the Institute, and visitors to Headquarters

**A. Duperron**, M.E.I.C.

**Arthur Duperron**, M.E.I.C., has been appointed assistant general manager of the Montreal Tramways Company. He was born at Nicolet, Que., and was educated at Mount St. Louis College and Ecole Polytechnique, Montreal, where he graduated with the degree of B.A.Sc., in 1911. He began his professional career with the C.P.R. Bridge Department and, after spending three years with the company, was associated with the Quebec Streams Commission from 1918 to 1927, becoming assistant chief engineer of this Commission in 1925. He was appointed chief engineer of the Montreal Tramways Commission in 1927.

He joined the Montreal Tramways Company in 1937 as chief engineer, a position which he has occupied until his recent promotion. In 1925 Mr. Duperron was appointed professor of public works at Ecole Polytechnique. In 1930 he served as chairman of the Montreal Branch of the Institute and in 1937-38-39 he was on the Council.

**D. M. Stephens**, M.E.I.C., was recently elected chairman of the Winnipeg Branch of the Institute. He is a graduate in civil engineering from the University of Manitoba in the class of 1931. For two years after graduation he was instructor in civil engineering at the University of Manitoba and in 1933 he joined the staff of the surveys branch of the Department of Mines and Natural Resources at Winnipeg as technical draughtsman. He is at present office engineer in the same department.

**N. B. MacRostie**, M.E.I.C., is the newly elected chairman of the Ottawa Branch. He was born at Metcalfe, Ont., and was educated at Queen's University where he graduated in 1911. In 1912 he was in charge of field work as assistant to the inspector of surveys in Manitoba and Saskatchewan and in 1913 he was employed with J. B. McRae, consulting engineer, Ottawa, as inspector on construction of a dam at High Falls, Que. In 1913 he joined the engineering department of the City of Ottawa, first as assistant roadway engineer and later he became in charge of sidewalks as well as city surveyor. From 1916 to 1918 he was gauge examiner with the Imperial Munitions Board.

**N. B. MacRostie, M.E.I.C.**

In the spring of 1918 he joined the Royal Canadian Engineers and went overseas. Upon his return to Canada in 1919 he became a member of the firm of Lewis and MacRostie, civil engineers and surveyors, Ottawa. Later he was associated with the firm of MacRostie and White. At present he is in private practice on his own account.

**Noel J. Ogilvie**, M.E.I.C., Dominion Geodesist and Canadian International Boundary Commissioner was recently appointed to a committee on aerial surveying and mapping at a meeting in New York of the executive committee of the Surveying and Mapping Division, American Society of Civil Engineers.

**P. A. Lovett**, M.E.I.C., has recently been elected chairman of the Halifax Branch of the Institute. Born at Liverpool, N.S., he was educated at the Massachusetts Institute of Technology and at Nova Scotia Technical College where he graduated in 1928 in electrical engineering. For two years after graduation he followed the apprenticeship course of Canadian Westinghouse Company Limited and in 1930 he joined the staff of the Maritime Telegraph and Telephone Company as assistant engineer. Since 1933 he has been associated as consulting engineer with J. R. Kaye, M.E.I.C., in the firm Engineering Service Company Limited, Halifax.

**F. T. Julian**, M.E.I.C., is the newly elected chairman of the London Branch of the Institute. Born at Brampton, Ont., he was educated at the University of Toronto where he graduated in 1920. During the last war he was with the Royal Canadian Engineers from 1916 to 1919. In the years 1920 and 1921 he was on the staff of the Hydro-Electric Power Commission of Ontario as a junior engineer on the St. Lawrence river investigation. In 1921 he joined the staff of J. A. Vance, M.E.I.C., general contractor, Woodstock, Ont., as a foreman and superintendent. He has been with this firm ever since and has been connected with several construction projects in the field of civil engineering.

**Ross W. Bastable**, M.E.I.C., has accepted a commission as pilot officer in the Royal Canadian Air Force. Previous to his enlistment he was with the Bell Telephone Company of Canada at Montreal. He graduated in mechanical engineering from McGill University in 1922 and spent two years on mechanical design of grain elevators with the John S. Metcalf Company, Montreal. In 1925 he joined the staff of the Bell Telephone Company of Canada and worked on building maintenance until 1928 when he became supervisor of buildings in the western division. In 1930 he was transferred to eastern division. Later he was appointed superintendent of buildings for the company.

**Louis Trudel**, M.E.I.C., assistant general secretary of the Institute, has been appointed member of the Civilian Committee for the selection of French-Canadian officers in Military District No. 4.

**A. A. Swinnerton**, M.E.I.C., has been elected secretary-treasurer of the Ottawa Branch of the Institute at the recent annual meeting of the Branch. Born at Hyderabad, India, Mr. Swinnerton was educated at the University of Toronto, where he graduated in chemical engineering in 1919. He served overseas during the last war from 1915 to 1917. Upon his return to Canada in 1917 he worked as a chemist with British Acetones, Toronto, and in 1919 he was appointed assistant chemist in the Department of Mines at Ottawa. In 1921 he was promoted to chemist in charge of oil shale investigations. Later he was transferred to the fuel research laboratories in the same department. He is at present connected with the Dominion Fuel Board in the Department of Mines and Resources, Ottawa.

**Selwyn H. Wilson**, M.E.I.C., has been appointed maintenance superintendent in charge of the maintenance department of Ottawa Car and Aircraft Limited. He succeeds L. D. Byce who has been loaned to the Government.

Mr. Wilson served with the Royal Canadian Artillery in the last war, winning the Military Cross in action at the Canal du Nord. Returning to Canada, he graduated from

**Selwyn H. Wilson, M.E.I.C.**

McGill University in 1922 and held positions with Consolidated Mining and Smelting Company, St. Maurice Paper Company plant at Hawkesbury, Ont., for three years. In 1928 Mr. Wilson was appointed chief engineer for the Dryden Paper Company and in 1936 and 1937 he was with the maintenance department of St. Lawrence Paper Company. Before joining the Ottawa Car in 1940 he had been mechanical superintendent at the Lake St. John Paper Company plant at Dolbeau, Que.

**F. H. C. Sefton**, M.E.I.C., is now stationed with No. 2 Air Navigation School at Penfield Ridge, N.B. Previous to joining the Air Force he was with the Toronto Transportation Commission, Toronto.

# Obituaries

*The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.*

**Marcel Lamoureux, M.E.I.C.**, who was assistant engineer in the Ottawa district office of the Department of Public Works is now district engineer of the Department of Transport at Parry Sound, Ont. He is a graduate of McGill University and upon graduation in 1932 he worked on the construction of the Lake St. Louis bridge, near Montreal. In the years 1934 and 1935 he was with the Quebec Streams Commission. In 1935-36 he was employed as superintending engineer on road construction with the Raymond and McDonnell Company in northern Quebec. He joined the staff of the Department of Public Works at Montreal as a junior engineer in 1936. In 1938 he was transferred to the Ottawa district branch office as assistant engineer.

**David C. Holgate, Jr. E.I.C.**, has recently been transferred from the Dominion Bridge Company, Toronto, to the Sault Structural Steel Company Limited at Sault Ste. Marie, Ont., where he holds the position of engineer and designer.

**H. O. Wilson, Jr. E.I.C.**, has joined the Royal Canadian Naval Volunteer Reserve as a sub-lieutenant and is at present stationed at Ottawa.

**E. A. Russell, Jr. E.I.C.**, has recently returned to the staff of Defence Industries Limited, and is at present employed as construction engineer in charge of plant extension at Winnipeg.

**Pilot-Officer W. M. Diggle, Jr. E.I.C.**, has recently completed his course at the School of Aeronautical Engineering at Montreal, and has been posted to No. 9 Repair Depot at St. Johns, Que.

**Lieutenant Guy Beaudet, Jr. E.I.C.**, is at present stationed at the Royal Canadian Engineers' training centre at Petawawa, Ont. Previous to his enlistment last August he was city engineer at Thetford Mines, Que. He is a graduate of the Ecole Polytechnique from the class of 1938.

**W. E. Soles, Jr. E.I.C.**, who formerly was with Gaspesia Sulphite Company at Chandler, Que., is now with Anglo-Canadian Pulp and Paper Company at Quebec. He graduated from Queen's University in 1935.

**W. J. Farago, S.E.I.C.**, is now employed with Kelsey Wheel Company Limited at Windsor, Ont. Upon his graduation from the University of Saskatchewan in 1940 he joined the staff of McKinnon Industries Limited at St. Catharines, Ont.

## VISITORS TO HEADQUARTERS

**P. M. Sauder, M.E.I.C.**, director of water resources' Edmonton, Alta., on February 4th.

**P. E. Doncaster, M.E.I.C.**, district engineer, Department of Public Works, Canada, Port Arthur, Ont., on February 4th.

**Thomas M. West, M.E.I.C.**, secretary-treasurer, J. & J. Taylor Safe Works, Limited, Toronto, Ont., on February 7th.

**A. R. Hannaford, M.E.I.C.**, designing engineer, Corporation of the City of Hamilton, Hamilton, Ont., on February 7th.

**D. Hutchison, M.E.I.C.**, Edmonton, Alta., on February 10th.

**Lieutenant O. J. E. Rankin, S.E.I.C.**, Staff Mess, O.T.C., Brockville, Ont., on February 10th.

**Frederick R. Duncan, S.E.I.C.**, Toronto, Ont., on February 14th.

**L. P. Cousineau, M.E.I.C.**, Dufresne Engineering Company, Limited, Dolbeau, Que., on February 18th.

**Edgar H. Davis, Jr. E.I.C.**, Lethbridge, Alta., on February 21st.

**H. A. Ripley, Jr. E.I.C.**, Lethbridge, Alta., on February 21st.

**Pilot-Officer A. L. Denton, M.E.I.C.**, No. 10 Air Observers School, R.C.A.F., Chatham, N.B., on February 25th.

**Archibald Fullarton Byers, M.E.I.C.**, well-known construction engineer, died in the hospital at Montreal on February 9th, 1942. He was born at Gananoque, Ont., on December 18th, 1877. He received his primary education at the local public and high schools, and entered Queen's University at Kingston in 1896. Two years later he left Queen's and went to McGill University, Montreal, where he graduated with the degree of Bachelor of Science in 1900. Following graduation, he was forced to remain inactive for two years on account of ill health and for another two years afterwards he travelled extensively in Europe doing post graduate work.

In 1904 he was employed by Canadian Car Company at Montreal as a draughtsman and a building inspector. In 1905 he was superintendent of construction work for Forest City Paving Company. From 1905 to 1907 he was in the contracting business on his own account. From 1907 to 1913 he was senior partner in the firm of Byers and Anglin, general contractors, Montreal.

A. F. Byers, M.E.I.C.

In 1913 he established the firm of A. F. Byers and Company Limited, construction engineers and contractors, Montreal, and he remained president of the organization until his death. Under his direction the firm has carried on extensive general engineering projects from coast to coast. At the time of his death, Mr. Byers was also president of Aerocrete Construction Company.

Mr. Byers was a great public-spirited citizen and he was closely associated with the development of the Town of Hampstead, near Montreal. He was a member of the Council of the town during the years 1924 and 1925, and he served as mayor in 1932, 1933 and 1934. Much reform and reorganization of the town's affairs were initiated and successfully concluded during Mr. Byers' regime as mayor and he was instrumental in establishing the sound financial and administrative foundation of the town's present organization.

He served for several years on the Hampstead School Board and he was chairman in 1929-30. From 1925 to 1929 he acted as representative of Hampstead, Outremont and Ville St. Pierre on the Central School Board of Montreal.

Mr. Byers was very much interested in conservation. His interest originated in 1925 because of his personal knowledge of speckled trout fishing at Lake Manitou, Que., where he had his summer home. Fishing conditions were poor at that time, and further enquiries on his part led him to believe that the factors responsible for these conditions existed throughout the province.

Mr. Byer's ability to see this and the energy and per-

severance he manifested in securing the attention and interest of the officials concerned, illustrate well his devotion to public welfare. His efforts in securing the interest of government officials, as well as his fellow citizens, was directly responsible for a great improvement and broadening in the organizations occupied with the maintenance of our natural resources, particularly fish and game. For some years he worked closely with the government of the Province of Quebec to encourage research and biological studies of the native game fish. He was an honorary member of the Mastacouche Fish and Game Club and the St. Bernard Fish and Game Club.

He was a member of the Alpha Delta Phi fraternity, the University Club of Montreal, and the Masonic Order, in the Royal Albert Lodge.

Mr. Byers joined The Institute as a Student in 1899. He became an Associate Member in 1906 and a Member in 1911. Since 1936 he had been a Life Member of The Institute.

**Kenneth Thomas Cregeen**, M.E.I.C., died at Montreal on February 8th, 1942. He was born at Montreal on December 31st, 1898 and received his education at the Montreal High School and at McGill University, where he graduated with the degree of Bachelor of Science in 1923. Upon graduation he spent a few months with the Montreal Light, Heat and Power Consolidated in the electrical distribution department. In October of the same year he joined the staff of the Sun Life Assurance Company of Canada as assistant to the building superintendent. In 1924 he became resident engineer in charge of building operations and plant for the company, a position which he occupied until his sudden death.

Mr. Cregeen joined The Institute as a Student in 1921, and was transferred to Junior in 1927. In 1933 he was transferred to Associate Member and he became a Member in 1940.

**Royden John Fuller**, M.E.I.C., well-known structural engineer with the firm of Anglin-Norcross Ontario, Ltd., died suddenly at his home in Toronto, on January 27th, 1942, after suffering a severe heart attack. Mr. Fuller was born in the town of Alliston, Ont., on January 26, 1882, the eldest son of Mr. W. S. Fuller. He attended public and high school in Watford, the Model School in Sarnia and the School of Pedagogy in Hamilton, following which he taught in several schools in Ontario. In 1908 he entered the University of Toronto in the Faculty of Applied Science, and graduated with honours in mechanical engineering in 1911, receiving the degree of B.A.Sc., a year later. He then joined the staff of the city architect in Toronto and specialized in structural engineering. He was successively, chief engineer of the John V. Gray Construction Company, and with the Roy Bishop Construction Company, the Fergusson Construction Company, and, lately Anglin-Norcross Ontario, Ltd.

On the day of his funeral, Mr. Fuller was to have taken part in presenting a paper before the Toronto Branch of The Institute on the "Design and Construction of a Concrete Head Frame for Hollinger Mine," which had been erected by Anglin-Norcross under his supervision.

Mr. Fuller is survived by his wife, formerly Miss Frances M. Telfer, one daughter, Mrs. J. B. Wadland, and one son, Robert Telfer, all of Toronto. He is mourned also by all members of the engineering professions with whom he has been associated.

Mr. Fuller joined The Institute as an Associate Member in 1921 and he became a Member in 1940.

**John Courtenay Mews**, Jr., M.E.I.C., died at Buchans, Newfoundland, on January 19th, 1942. He was born at St. Johns, Newfoundland, on June 30th, 1896 and received his education in local institutions. He was for a number of years with the Nova Scotia Steel and Coal Company at Wabana, Newfoundland. During the last war he was on active service from 1915 until demobilized in 1919. He was

first with the Royal Naval Reserve and later with the Royal Newfoundland Regiment.

After the war he returned with the Nova Scotia Steel and Coal Company at Wabana and in 1927 he joined the staff of the Buchans Mining Company, Limited at Buchans, Newfoundland, as assistant to the construction engineer, later becoming superintendent of surface transportation and construction.

Mr. Mews joined The Institute as a Junior in 1921.

**Thomas Wint Weir Parker**, M.E.I.C., died accidentally at Montreal on February 9th, 1942. He was born at Dumbarton, Scotland, on September 20th, 1885, and received his education at the Royal Technical College, Glasgow. From 1901 to 1906 he was a pupil in the city engineer's office at Glasgow and from 1906 to 1911 he was assistant engineer.

He came to Canada in 1911 as instrumentman for the South Vancouver Municipality. During 1911 and 1912 he was a draughtsman in the city engineer's office at Prince Rupert, B.C., and from 1912 to 1915 he was assistant city engineer.

During the last war he served first with the 3rd Battalion, Canadian Railway Troops in France in 1916 and 1917, and from 1917 to 1919 with the Royal Engineers at Salonica and Caucasus.

Upon his return to Canada in 1920 he spent a few months in the office of A. D. Swan, Montreal, as a designer, and then went to Vancouver on construction of the new harbour works. Later he was with Monsarrat and Pratley, consulting engineers, Montreal, and with the Anticosti Corporation, Montreal. In 1937 he was with Northern Construction and J. W. Stewart Limited at Niagara Falls and the following year at Montreal. In 1939 he joined the staff of Rayner Construction Limited and until his tragic death was employed with this firm on the Shand Dam construction at Fergus.

Mr. Parker had been in attendance at the Annual Meeting of The Institute in Montreal a few days before his death.

He joined The Institute as an Associate Member in 1921 and he became a Member in 1940.

**John Sugden Tempest**, M.E.I.C., died suddenly at his home at Victoria, B.C., on July 1st, 1941. He was born at Keighley, England, on January 11th, 1864 and received his education at South Kensington School of Science, England. Previous to his coming to Canada he spent several years in England with W. H. and A. Sugden, architects and surveyors, Keighley.

In 1896 he came to Sault Ste. Marie, Ont., where he was engaged in farming with his brothers. In 1898 he joined a survey party for the Algoma Central Railway in northern Ontario, and for a number of years was engaged in railway survey and location for various concerns, including three years as locating engineer for the Grand Trunk Pacific Railway north of Lake Nipigon.

In 1908 he moved to the West and located at Calgary, Alta., where he was inspecting engineer with the irrigation branch of the Department of the Interior. In 1910-1911 he was in charge of exploration work at Hudson Bay for the Algoma Central Railway. From 1911 to 1913 he was in charge of railway location for the Edmonton, Dunvegan and B.C. Railway. In 1913 he returned to the irrigation branch of the Department of the Interior at Calgary as hydrometric and inspecting engineer and in 1919 he became supervising hydraulic engineer, reclamation service, Department of the Interior, Ottawa. In 1924 he was made Commissioner of Irrigation and Reclamation for the Prairie provinces and was engaged in this work until he retired in 1934. During all these years he had lived in Calgary, but in 1940 he moved to Victoria, B.C., where he died one year later. He was the father of Frank Tempest, M.E.I.C., of Calgary, Alta.

Mr. J. S. Tempest joined The Institute as an Associate Member in 1907 and he became a Member in 1920.

# News of the Branches

## EDMONTON BRANCH

F. R. BURFIELD, M.E.I.C. - *Secretary-Treasurer*  
L. A. THORSSEN, M.E.I.C. - *Branch News Editor*

The link between the need for oil in time of war and the oil resources of Alberta was described to the Edmonton Branch at its dinner meeting in the Macdonald Hotel on January 31st. The speaker, Mr. W. H. Gibson, who is with the exploration department of the McColl-Frontenac Oil Co., had as his subject **Geographical Methods for Oil Exploration**.

Mr. Gibson explained the fundamental conditions for the formation and accumulation of oil. He emphasized that the hunt for oil was not a search for oil itself, but for the rock structures in which oil can accumulate.

A review of the methods used to locate oil structures formed the body of the address. The earliest method was limited to surface geology but before long underground structures were examined in deep, open cuts and mines. The unexposed structures were later studied by electrical methods based on the potential drop between electrodes driven at different points into the ground. In another method, a delicate, gravity-measuring instrument locates changes in mass distribution of underground rock. Where rocks have magnetic properties a dip compass points to the rock mass. The seismic methods of exploration make use of the time a sound wave takes to travel underground from a point where an explosion is set off to a recording seismic instrument. There are two types of seismic exploration, one in which the sound waves are refracted through the underlying rock, and the other in which the sound waves are reflected from the rock surface. The speaker discussed the ways in which the velocities of sound waves underground are determined, and outlined the advantages and disadvantages of the two seismic methods. He claimed that the reflection method is more popular because the equipment is more centralized and because smaller quantities of explosives are needed. Mr. Gibson described the field procedure in conducting a seismic exploration and showed photographs of equipment as well as actual seismic records recorded in the field. He stated that the seismic method has been used successfully in the U.S.A. and that there is no reason to assume that the same is not true in Alberta. Recently chemical analyses of soil above existing oil fields have shown traces of gases which may have risen from the oil pockets. Mr. Gibson pointed out that these gases may have come from open wells and that the merit of this method will not be known until a new field is discovered by it. He stated that at the present time soil analyses are being taken above regions which a seismic exploration has shown to be possible oil bearing structure.

Mr. Gibson was introduced by the chairman, Professor R. M. Hardy. Following a lengthy discussion, Mr. Hutcheon moved a vote of thanks.

The annual Institute Prize to a third year student at the University of Alberta for scholastic standing in engineering was presented by Councillor J. Garret to Mr. R. McMannus.

## HALIFAX BRANCH

S. W. GRAY, M.E.I.C. - *Secretary-Treasurer*  
G. V. ROSS, M.E.I.C. - *Branch News Editor*

Over two hundred and fifty members of the Halifax Branch, the Association of Professional Engineers of Nova Scotia, and guests gathered at the Nova Scotian Hotel, on January 22nd, for their joint banquet. The popularity of this dinner continues to increase, and many men outside the profession attend every year and look forward to it with as much interest as do the members.

Dr. A. Stanley Walker, Principal of King's College, Halifax, delivered an address which all will remember for a long time. Reviewing the rise and decline of peoples and

## Activities of the Twenty-five Branches of the Institute and abstracts of papers presented

empires during the centuries, he traced a direct relationship between forward movements to greatness and engineering. The ancient civilizations of Egypt, Persia and Rome continued to prosper and expand so long as their people continued to push forward such works as roads, bridges, and communications. Then decline began when their people lost the capacity to continue the works which knit their people together, and moved the products of their labour. The centuries following the fall of the Roman Empire were a time of stagnation, the "Dark Ages," and during this period, engineering works were almost unknown. The British Empire has become great because her engineers have kept up a steady pace of development in industry, transportation, communication and public service.

"After this war we should see to it that the principles of engineering are applied to our problems. The practice of drawing blueprints and experimenting with small things before major plans are attempted will be required if we are to avoid the muddle which followed the last war. If the world would take the gifts which engineers had given and the sense which God had given, and apply them to its problems, it should be able to make a better job of showing the gifts which the world has to offer."

Joint chairmen presiding were Donald Dunbar, Stellarton, N.S., president of A.P.E.N.S., and Percy Lovett, chairman of the Halifax Branch of the Institute.

An interesting feature of the evening was a presentation to Mr. W. P. Morrison. Twenty years ago, the Association of Professional Engineers came into being with Mr. Morrison as secretary-treasurer. He continued to hold that office until the Association and the Institute went into a co-operative agreement in 1940. In appreciation of his services, he was presented with a pipe and humidior and an illuminated address by Mr. Lorne Allen, on behalf of the members of the Association.

Another presentation, that of the Institute Prize, to a junior at the Technical College, was made by S. L. Fultz to H. Rose.

The toast to the services by Col. F. W. W. Doane, was responded to by Captain W. D. Creery, R.C.N., captain-in-charge, Halifax. One to the engineering profession by J. G. Dunlop, manager, Imperial Oil Limited, Halifax, was responded to by Mr. H. C. Burehell, of Windsor, N.S., senior engineer of Nova Scotia. Short remarks were made by Premier A. S. MacMillan, Mayor W. E. Donovan, and Mr. E. C. Kemp, U.S. Consul General. Other guests were Brigadier C. E. Connolly, D.S.O., O.D., M.D. No. 6, and Wing Commander H. D. Carefoot, R.C.A.F.

Harry Cochrane and assisting artists supplied music and entertainment features. Favours were donated by Northern Electric Co., Canada Cement Co., Imperial Oil Ltd., Donald C. Keddy, Canadian Westinghouse Co., Moloney Electric Co., Wm. Stairs, Son and Morrow Ltd.

## LAKEHEAD BRANCH

W. C. BYERS, JR., E.I.C. - *Secretary-Treasurer*  
A. L. PIERCE, M.E.I.C. - *Branch News Editor*

A meeting of the Lakehead Branch of the Institute was held at the New York Lunch in Fort William at 6.30 p.m., January 14th, 1942. In the absence of both the chairman and vice-chairman, Mr. E. J. Davies took the chair.

Mr. J. I. Carmichael introduced the speaker for the evening, Mr. Z. Kryzwoblocki, now with the Canadian Car & Foundry Co. Ltd., of Fort William, Ont. Mr. Kryzwoblocki is a graduate of Lwow College of Engineering in Poland, and has had considerable experience on the design and production of aircraft. He was employed for a time as lecturer in

the Department of Aeronautics at Lwow College of Engineering. On the outbreak of war with Germany, Mr. Kryzwoblocki joined the Polish Air Force as lieutenant-observer, and when Poland was overrun he escaped through Roumania to France. Here he was employed by the Amiot Company on the production of a big bomber. Then France collapsed. He escaped to London and thence to Canada. He is a member of the Polish Military Mission to Ottawa.

Mr. Kryzwoblocki spoke on **The Rocket Wing-Bomb and Rocket Torpedo**. He mentioned that the great majority of people generally are too conservative in their estimation of possible technical developments but expressed the belief that this was possibly due to the fact that any new developments are usually in the hands of a few scientists who do not seem willing to inform the general public of their discoveries. Amongst these experiments now being made were those on the development of rockets and rocket propulsion.

Mr. Kryzwoblocki stated that considerable experimental work and research on the use of rockets and rocket propulsion has already been done in Europe and that possibly most of this information is now in the hands of the Germans. England, of course, and the United States have not overlooked this possible weapon and are also experimenting along these lines.

The great advantage, of course, in the use of rockets, would be the increased range for bombing. If the use of rockets and rocket propulsion could be perfected as a weapon it would give a bombing range of, let us say, 200 miles. It is therefore easy to see how difficult it would be for an enemy to defend an area which would be within a 200-mile radius from the bombing point. Conversely, attacking an objective from such a distance would be much easier and less dangerous to a bombing crew.

Mr. Kryzwoblocki then went on to describe three possibilities of accomplishing this long distance bombing.

- (1) The wing-bomb.
- (2) The rocket-wing-bomb.
- (3) The rocket-torpedo.

The wing-bomb would be located on or under an aeroplane and would be released at a distance from the objective to glide to the target. In order to keep the bomb in flight some means of propulsion would be required, of which rocket propulsion is the simplest method now known. At present the efficiency of such a weapon is low, but with our scientific knowledge increasing along these lines it possesses the greatest possibilities.

The rocket-torpedo is merely a large rocket-wing-bomb launched from the ground instead of from an aeroplane in flight. This type of weapon, stated Mr. Kryzwoblocki, has very great possibilities, and when perfected would be the ideal solution to the problem of bombing from a distance.

Mr. Kryzwoblocki spoke of his associations with various European scientists experimenting along these lines and expressed the opinion that the future would show very interesting results regarding rockets and rocket-propulsion.

### LONDON BRANCH

H. G. STEAD, Jr.E.I.C. - - Secretary-Treasurer  
A. L. FURANNA, Jr.E.I.C. - - Branch News Editor

The annual meeting and dinner of the Branch was held on Wednesday, January 21st, at the Grange Tea Rooms. Dinner was preceded by the annual meeting at which officers for the present year were elected. Dr. S. F. Maine, professor of history at the University of Western Ontario, was the speaker. His subject was the **Rise of the Universities**.

Dr. Maine began his history of the universities back in the days of the Roman Empire. They had their own educational system, but it died with imperial Rome. So between that time and the time of the Crusades, learning was kept alive only within the cloisters of the monasteries. Now, when the crusaders began to arrive in the East, they found that the Mohammedans had a higher civilization than they had themselves. This led to dissatisfaction in Europe and a

desire for knowledge which resulted in schools taught by the Monks. Next, out of these schools came the free-lance teachers who formed the students' guilds. Thus three typical schools arose, one of law, another of arts, and one of medicine. Italy never got away from Roman ideals, and thus Bolonia became the seat of legal learning in medieval times. In the same era, Paris became the centre of learning in arts. The study of medicine also began in Italy, although the early doctors were not Europeans but from the East. At that time, Westerners still worked on the principle of evil possession. However, this new school began to dissect the bodies of animals and of man and as they learned more and more about anatomy, advancement became rapid. This school gradually moved to Palermo to form the beginning of the famous Palermo University.

In the 13th century, Oxford became an offshoot of the Paris school. Also during the same century the Sorbonne in France became the first university to be composed of buildings as well as students. With the Renaissance came the revival of the classics, Latin, Greek and Hebrew. These subjects persisted in the universities until about 100 years ago. It was at that time that the social revolution required the introduction of new subjects, the sciences, and the opening of the universities to more students.

Denominational colleges were the first to rise in Canada. These universities taught science, as well as the other arts, and were the first to open their doors to women. In Ontario, one hundred years ago the first university arose in the east with Queen's at Kingston, next came Toronto in the centre of the province, and seventy years ago Western began in London to the west. To-day these universities are reaching far beyond their walls through the extension and extramural departments.

Concluding the meeting Mr. E. V. Buchanan proposed, and Mr. H. F. Bennett seconded, a vote of thanks to the speaker, Dr. Maine. Also Mr. W. C. Miller was congratulated on his election as president of the Association of Professional Engineers of the Province of Ontario.

### MONTREAL BRANCH

L. A. DUCHASTEL, M.E.I.C. - Secretary-Treasurer  
G. G. WANLESS, Jr.E.I.C. - Branch News Editor

A branch meeting was held jointly with the Institute of Radio Engineers, on January 22nd to hear Mr. E. O. Swan speak on the **Problems Encountered in Erecting Canada's First Directive Broadcast Station**. The chairman was W. H. Moore.

Mr. Swan is a member of the Toronto Section of the I.R.E., and of the Association of Professional Engineers of Ontario. He has been engaged in radio work for over twenty years and for the past twelve has been chief engineer of CKCL, Toronto.

In the early days of radio, a powerful city station would cover several points on the tuning dial, and as more stations were built this condition of jamming became worse. The Havana Conference of 1937 re-allotted the wave lengths and left the then existing Canadian stations crowded in too narrow an area. Mr. Swan described a solution to this problem for a relatively low-powered local station, by means of "directional broadcasting." Beginning March 1st 1940, his station CKCL was the first in Canada to make use of this modern technique.

With old type, long receiving antennae, sets were able to receive signals more effectively in certain directions, which were related to the direction of the antenna wire. This principle is now applied in modern broadcasting stations, and it enables them to send their signals most effectively to the areas of greatest population. It also permits of a minimum of overlapping of other stations, whose field the directional station does not wish to cover. This is accomplished in part by a planned layout of the towers of the broadcasting aerials.

Mr. Swan illustrated his paper with numerous slides showing views of the modern electrical apparatus used in

CKCL. Two reels of movies described the construction of the new station.

Mr. J. T. Dymont, chief engineer of Trans-Canada Airlines, addressed the branch, on January 29th, on **Aircraft Transport Design**. His paper was an extremely interesting discussion of what he believes the purchaser of air transport equipment desires in the way of performance, comfort and safety devices.

Most airlines are obliged to buy standard models, fitting only special equipment of their own specification. Even this may involve as many as 300 modifications to a standard design.

The striking progress of the industry is due in no small measure to existing reciprocal arrangements whereby all lines have access to latest developments in design and safety features. The commercial accident record for the last five years in North America shows only 21 per cent of accidents due to structural failure; all of these were confined to the undercarriage.

Mr. Dymont outlined his idea of the future air liner as follows:

1. *A Stall-Proof and Spin-Proof Plane*. "Boundary layer control"—i.e., minimizing turbulence in the air stream—is required. Diagrams illustrating flight theory showed how turbulence can be reduced by wing design. When the icing problem is solved, wing slots will prevent stalling. Spinning can be controlled by alteration of curvature at wing tips, at slight expense to lifting efficiency. The new Northrup tail-less plane uses an advanced principle of wing design to counteract air turbulence.

2. *Freedom from icing*. The Goodrich pneumatic shoe is the best answer yet, but is not perfect. Some types of "sticky ice" will adhere to the rubber surfaces. Experienced TCA pilots have learned to recognize this and do not use the de-icers under such conditions. It is expected that the use of heat in the leading edge of the wing will provide a more satisfactory solution. Propellers are protected from icing by flowing alcohol through grooves in the leading edge of the blades—a method pioneered by TCA and Goodrich. Windshield de-icing is not adequately solved. Injection type carburetors greatly minimize icing at the air intake.

3. *A full feathering propeller*. To minimize engine damage in case of failure. Electrical and hydraulic types are now well developed.

4. *Ultra high frequency radio beam equipment*. Present beam signals are subject to static and geographical influences, especially in mountainous areas.

5. *An absolute altimeter*. Aneroid types require correction for ground pressures and are inaccurate over mountains. "Terrain clearance indicators" which operate similarly to naval sounding equipment are being developed. At present they are too heavy for most planes.

6. *A radio compass*. To enable the pilot to tune to local stations and be directed to the landing field of that city. Static troubles influence this device at present.

7. *Flight ray indicator*. A cathode ray device which reduces the number of important instruments to be watched by the pilot.

8. *Tricycle landing gear*. With a forward wheel rather than a tail wheel. This permits a "forward center of gravity" which counteracts ground-looping while landing.

9. *Safety fuel*. Boiling range 325-400 deg. F. and flash point of about 105 deg. F.

10. *Safety tires* of the "Lifeguard" type.

11. *Capacity*. About the same capacity as a consolidated B-24 bomber, being capable of carrying 32 passengers by day and 24 by night, with a crew of five. Weight loaded to be about 45,000 lb. In regard to weight reduction, some manufacturers are now pre-stretching the aluminum alloys used, thereby raising tensile strength from 45,000 to 60,000 lb. For fuselage and wing construction, the British geodetic design is the highest ever developed for a fabric-covered plane.

12. *Engines*. Four engines capable of cruising at 50 per

cent of their power, in order to keep maintenance costs at a minimum. Added efficiency is expected from new designs which obtain additional forward thrust from exhausted gases.

Air-cooled designs are preferred. Spark-ignition system engines, weighing about one pound per horsepower, are lighter than compression-ignition engines, but are more complicated. The Bristol sleeve valve engine is promising as a means of reducing the number of parts.

Super-charged ignition systems are desirable to protect insulation.

Supercharger should be of turbo type, two stage, to operate at 9,000 and 18,000-20,000 ft. levels.

Dynafocal type of rubber engine mounts are preferred. Engines need to be arranged for quick changing.

13. *Aerodynamically clean fuselage design*. The present Boeing Stratoliners have achieved a high degree of perfection in this regard.

On February 12th, the Branch was addressed by Mr. C. G. Axworthy, assistant plant manager for Defence Industries Limited, Verdun, P.Q., on the topic **Photoelastic Stress Analysis**. A film illustrating various applications, produced under the speaker's direction at the University of Manitoba, accompanied the talk.

Photoelasticity is based upon the temporary double-refraction produced by stress in certain transparent materials. It is possible to utilize this property in studying the distribution of co-planar stresses by placing the loaded body, usually a bakelite or other plastic model, between crossed polarizers. The light from the first polarizer, vibrating in a single plane, is split up at a point into two components which vibrate along directions coinciding respectively with the maximum and minimum indices of refraction. These directions correspond also to the minimum and maximum stresses, called the principal stresses. The components traverse the model, a plate, at different velocities and emerge out of step. The amount by which the components are out of phase is directly proportional to the principal stress difference or shear and can be observed conveniently by bringing the components into a single plane by means of the second polarizer or analyzer, as it is called. In white light, a multicoloured pattern is observed which is indicative of the stress distribution and which, after calibration of the material, gives quantitative results.

Today most analyses are made in monochromatic light. The stress pattern is of a single colour which, when photographed, gives a series of black lines very easy to interpret. The lines are called "isochromatics" and are loci of equal shear. A crowding together of the isochromatics indicates high stress concentration. Quantitative values are attached to the fringes by calibrating by means of a known stress system, the case of pure tension being the simplest.

Apart from the isochromatics there are the isoclinics or loci of equal inclination of the principal stresses. They correspond to points where the plane of vibration of the incident light is oriented in the direction of one of the principal stresses. Where this occurs the light vibrates on emerging from the model in the same plane as the original plane of vibration and is therefore extinguished by the second polarizer placed at right angles to the first. The isoclinics are consequently black lines. They serve to determine the orientation of the principal stresses. Rotation of the polarizers causes the isoclinics to sweep the stress-field permitting a stress-direction determination for all points. Inclusion of the isoclinics in the monochromatic photograph is confusing. They can be eliminated by the use of quarter-wave plates to destroy the directional qualities of the light by causing it to spin in effect.

Photoelasticity has left the university laboratory to enter the industrial field. This rather recent development has been brought about by the introduction of large field polarizers and the use of highly optical-sensitive plastics, as the model material, in conjunction with the photographic process.

Some interesting applications of the photoelastic method were shown in Mr. Axworthy's film. The study of oscillating, impact and moving loads seems to be particularly within the province of cinematography. The film showed the action of an oscillating load obtained by spring-suspending a weight to the bakelite model: the stresses were actually "seen" to pulsate within the model. The impact loading of an Izod test specimen was also illustrated. Mr. Axworthy seems to have done very original work in using the film to illustrate the action of dynamic stresses.

The photoelastic apparatus used in making the film was designed by and built under the supervision of Mr. Axworthy at the University of Manitoba.

A discussion followed in which was brought up the question of three-dimensional stress which, it is well known, is not within the scope of the conventional photoelastic method.

On February 19th, the Branch was addressed by Mr. N. B. McCreery on the subject of **Plates in Shipbuilding**. Mr. McCreery, who is assistant sales manager, Structural and Plate Division of Carnegie-Illinois Steel Corporation, specialized in the metallurgy of steels at Carnegie-Institute of Technology. His work has included production and testing of armour plate and special alloy steels.

In American practice, a plate is considered as being greater than 48 inches wide, flat, hot rolled (a) from ingots to slabs, (b) cooled for inspection, (c) reheated, (d) rolled from slabs to finished plates. The speaker gave a general survey of types of equipment for production of plates in American mills:

(a) *Three-high shear plate mill*, which has no vertical edge rolls, thus necessitating that the plates be sheared on both sides and ends. With this type of mill especially, orders for small size plates involving much extra cutting can cause a serious bottleneck—even to the point where the mill must be shut down so that shearing operations can catch up.

(b) *Universal mill*, which is a reversing mill, and has vertical rolls to take care of the sides of the plates. It is necessary to shear only the ends of the plates.

(c) *Four-high continuous plate mill*, is a large and high speed operation, co-ordinating the blooming mill, slab mill, reversing mill, automatic descaling equipment, and four finishing stands.

(d) *Continuous hot strip mills*, which were designed for production of light automobile plates.

In the United States, there are 13 shear plate mills which can roll ship plates of 90-inch width and over, but they cannot meet the demand. The 26 continuous hot strip mills are capable of rolling narrower plates, usually up to 72-inch width, which will relieve a substantial part of the bottleneck, if shipbuilders can redesign to make use of these narrower plates. Up to  $\frac{3}{8}$ -inch plates are being so rolled at present, but it is thought by some that it may be eventually possible to roll  $\frac{3}{4}$ -inch plates on these mills.

In regard to structural shapes, considerable relief has already been given to the mills, by reducing and standardizing on a lesser number of items. Carnegie formerly rolled 226 sections to 848 different weights; now they roll 174 sections to only 439 different weights. This permits the mill to carry a small stock of each item and to give more prompt service on small orders.

The shipbuilding expansion programme has made unprecedented demands on the mills. Prior to launching of the programme there were in the United States 83 completed ways and 37 partially dismantled ways, capable of producing sea-going freighters. Now there are 406 ways for such purposes. Steel requirements for the merchant ship building programme totalled in 1940, 132,000 tons per month, in 1941, 247,000 tons per month. The present rate is 500,000 tons and it is expected to reach 700,000 tons per month by the end of 1942. (By comparison there are about 35,000 tons of steel in the Jacques Cartier bridge). It is expected that requirements of the naval building programme may approximate the above tonnages.

An enthusiastic discussion followed the paper. The speaker was heartily applauded for his description of heat treating practice for heavy plates such as are used for bell armour on capital ships.

Once again it was the Branch's good fortune in being able to secure an outstanding speaker. Our appreciation was expressed by Mr. Midgley.

#### NIAGARA PENINSULA BRANCH

J. H. INGS, M.E.I.C. - *Secretary-Treasurer*  
C. G. CLINE, M.E.I.C. - *Branch News Editor*

On January 22nd at the Welland House, St. Catharines, the Niagara Peninsula Branch held a joint dinner meeting with the Niagara District Chemical and Industrial Association, which is a branch of the Canadian Chemical Association. There was an attendance of 60. Messrs. F. C. Rutherford, of the N.D.C. & I.A., and A. L. McPhail, of the Institute, acted as joint chairmen. Mr. W. H. McCartney introduced the speaker, Mr. Douglas Lorimer, president of the Canadian Chemical Association and controller of chemicals, Department of Munitions and Supply. Mr. Lorimer spoke on **Problems of War-Time Control of Chemical Resources**. He mentioned the 12 controllers who meet for consultation as members of the War-Time Industries Control Board, and he outlined the duties and powers of his own office as controller of chemicals. Getting down to particulars, he discussed the supply situation for such chemicals and related articles as: sulphuric acid, soda ash, glycerine, alcohol, bakelite, formaldehyde, creosote, phenol, citric acid, chlorine, aspirin, acetone, lacquer, leather and rubber. The vote of thanks was proposed by Mr. W. R. Manock.

#### OTTAWA BRANCH

A. A. SWINNERTON, M.E.I.C. - *Secretary-Treasurer*

The first noon luncheon of the 1942 term, held at the Chateau Laurier on January 22, was addressed by F. Cooksey, district chief of the Ottawa Fire Department, on the subject of **Incendiary Bombs**. N. B. MacRostie, newly elected chairman of the Branch, presided.

Mr. Cooksey, in connection with his address, exhibited a sample of the usual small incendiary bomb composed of magnesium metal filled with thermite and also the stirrup pump in such general use by the householder in the Old Country for dealing with it.

He began his address with the supposition that an air raid was in progress over the city of Ottawa in which two enemy planes only were involved, each carrying its load of 2,000 incendiary bombs. From these 4,000 bombs, 8 per cent would be effective thereby causing 320 fires to start within a very brief space of time. Even if Ottawa's fire fighting equipment were stepped up to ten times its present strength it would only be able to deal with 40 fires thereby leaving 280 fires to be handled by the population themselves. The necessity for everyone knowing exactly what to do and to have the means at his disposal for doing it is at once apparent.

The small incendiary bomb, he explained, burns with an intense heat for the first 55 or 60 seconds flinging off burning pieces of molten metal for distances up to 30 ft. Attention should be given first of all to these burning pieces and under no circumstances should a stream of water or a fire extinguisher be used against the bomb itself. The bomb, after burning fiercely for the first minute, settles down to a more steady rate when it may be more closely approached. When it falls in a place where it is incapable of doing harm it may burn itself out in about fifteen minutes. If properly fought it may be controlled in a matter of two or three minutes.

It has been learned in the Old Country that merely covering the bomb with sand does not necessarily extinguish it. If the bomb is lying on inflammable material as on a wooden floor gases will be given off which feed the bomb.

The best way is to place a layer of sand alongside the bomb, drag the bomb over it and then cover with sand. A fine spray of water placed in the neighborhood of the bomb assists to prevent the fire spreading. The stirrup pump is fitted with a nozzle through which a spray may be directed or else it may be turned on in a full stream when fighting a fire which has attacked adjacent woodwork or other inflammable material. Eight gallons of water should be able to control a bomb, when used with the stirrup pump.

If every other house in Ottawa were supplied with a stirrup pump, a liberal quantity of sand preferably in small fifteen-pound bags, said Mr. Cooksey, and if Mr. and Mrs. Householder and the children had all had practice and instruction in combatting fires caused by incendiary bombs, then the city would be in a better position than it is to-day to deal with a blitz air raid. At the present time, unfortunately, there is no supply in quantity in Ottawa of stirrup pumps so the garden hose would have to do in the meantime. Also there is a considerable lack of knowledge of how an incendiary bomb acts.

He offered the suggestion that instruction should be available to the population at convenient centres in methods of fighting incendiary bombs and made a special appeal for more of the people to join the auxiliary fire services, which needs 400 for full strength.

J. Leslie Rannie, assistant district warden for the central district, also spoke on behalf of the A.R.P. Warden Service and mentioned the steps that had been taken to educate the wardens themselves more completely in methods of combatting incendiary bombs. He reminded his audience that fire insurance would not protect one in case of loss from this cause so everyone should be prepared.

#### PETERBOROUGH BRANCH

D. J. EMERY, M.E.I.C. - *Secretary-Treasurer*  
E. WHITELEY, Jr., E.I.C. - *Branch News Editor*

At its January 22nd meeting, the Branch learned something of a new technique in training industrial workers. The paper, **Visual Aids for the Industrialist**, had been prepared by Mr. J. Chisholm, of Associated Screen News Limited, but when he was unable to give it, Mr. F. O'Byrne, Ontario manager of the same company, presented it for him.

Actually, the paper was a short introduction to several motion pictures, pointing out the need for every useful aid in training industrial workers for our rapidly growing war industries, and showing how visual aids increase in effectiveness as they make the audience more completely live the experience presented.

One picture is worth a thousand words. Very few descriptions in words only are effective, especially technical ones. One or more simple diagrams will be used, blueprints go one step further, and photographs even more completely convey a story. If now the photograph can be made to move and be accompanied by music, narration, and appropriate sound effects, the audience will absorb the information as effectively as a real-life experience—more effectively even, in some cases. Besides the full use of visual and aural impressions, the motion picture has a great advantage in the fact that the audience, seated in a darkened room, has its full attention concentrated on the scenes which live on the screen before them.

To prove his point the speaker then showed several films. The first dealt with "The Milling Machine," showing the essential functions of the machine. Others showed the use of various gauges. These pictures were some of the series prepared for Industrial Training Programmes by the U.S. Office of Education.

All who were there agreed that Mr. O'Byrne had given them an excellent proof of his thesis, that words supplemented by visual aids can very effectively convey ideas to an audience. The Branch held a technical meeting on February 5th. The speaker, Mr. F. R. Pope, assistant superintendent of the Western Clock Company, presented his paper, **Alarm Clocks—How They Are Made.**

Mr. Pope began by making some observations on the history of time keeping. Time was defined as a system of reckoning duration. There are three chief methods of reckoning time—solar, sidereal and mean solar. Solar is sun time and therefore varies with the length of the day. Sidereal or start time over long periods introduces slight errors in the calendar. Modern time keeping is based on the average day length and is called mean solar time.

The advent of railroad trains made it necessary to have a standard for the whole country. It is a matter of interest that the late Sir Sandford Fleming, a former Peterborough resident, was instrumental in introducing the system of standard time to the world. This involves a common standard and time belts to compensate for differences in longitude.

The first clocks as we know them were introduced by a monk, Gerbert, in the 13th century, and were driven by weights. Galileo developed the pendulum, but the greatest advance was made by Cook in 1660 who invented the oscillating balance wheel.

The essentials of a clock are a source of power, a train of gears for transmission to an indicating mechanism, an oscillating balance wheel and an escapement. The lever escapement, the most accurate devised to date is used in Westclox alarms.

Mr. Pope admitted that from a manufacturing standpoint the problems involved in making high quality clocks for the prevailing low prices are formidable. Extensive tools, fixtures and automatic machine tools are necessary. To justify the large amount of equipment involved, production must be high and the Peterborough plant turns out some 6,000 units per day.

Practically all holes in a clock mechanism are pierced and a few subsequently reamed. Gears are stamped out of sheet. A lubrication problem is obviously present when it is learned that the balance wheel in a Big Ben oscillates about half a billion times in four years—the usual period a clock will run without cleaning and reoiling. Mr. Pope outlined many other manufacturing details, using models and samples for illustration.

We were told that modern clocks are quieter than older ones for much the same reason that modern cars are smoother—rubber mounting and sound deadening applications.

In concluding, Mr. Pope attributed the excellence of Westclox alarms in a great measure to the skill developed by the personnel.

Mr. D. A. Drynan introduced the speaker, and Mr. A. J. Girdwood moved the vote of thanks.

#### SAGUENAY BRANCH

D. S. ESTABROOKS, M.E.I.C. - *Secretary-Treasurer*  
J. P. ESTABROOK, Jr., E.I.C. - *Branch News Editor*

A meeting of the Saguenay Branch of The Engineering Institute of Canada was held in the Arvida school on the evening of the 15th of January.

The meeting was addressed by Dr. D. L. Thomson, head of the Department of Biochemistry at McGill University, speaking on the subject, **Man as an Engineering Miracle.**

Dr. Thomson based his introductory remarks on a general appraisal of man according to engineering standards. The lubrication of muscles and joints and their well-defined hinge action provided the first comparison and this was followed by a study of the human body as an energy converting unit. The efficiency of energy conversion is 30 per cent and on the basis of heat engine performance would require a working range of 1,000 deg. C.

Man can develop and repair damaged structures whereas machines can never do this. This ability to replace cells is done with the assistance of vitamin "C" and it has been found that there is a complete turnover of cells and atoms in the body structure every three or four years. The exceptions in this case are permanent structures such as tooth enamel.

The heart provides a miraculous solution of a difficult hydraulics problem. Here we have a pump working at the rate of five gallons per minute against a six-foot head with a fluid whose viscosity is subject to constant change and with ducts whose elasticity is constantly effecting changes in cross-sectional area. The pulsating motion of the fluid also adds to the complicating factors.

The eye closely resembles a camera in structure, with its shutter, diaphragm, lens and sensitive film. In our human system these are constantly being regulated by what amounts to an automatic exposure meter. In this unconventional system of working, the eye also incorporates the ability to change the shape of its lens at will.

Electrical engineering is represented by the nervous system. Different types of nerves have the task of carrying different sensations and when these are located close together and are operating under stress we can get a short-circuiting effect with a mixed reaction on the senses. An example of this is the well known effect of a blow on the head producing a shock on the optic nerves and causing sensations of light. In recording impressions of the intensity of light, the nerves ordinarily transmit these as a vibrational frequency and they are interpreted in the brain in the form of light intensity.

The speaker's final comparison was that pain is a danger signal in the body system just as vibration is in the engineering sphere of work.

## SASKATCHEWAN BRANCH

STEWART YOUNG, M.E.I.C. - *Secretary-Treasurer*

The Saskatchewan Branch met in the Kitchener Hotel, Regina, jointly with the Association of Professional Engineers and the Saskatchewan Section of the American Institute of Electrical Engineers, on Friday evening, January 23, 1942. The attendance, including the wives and lady friends of members, was 60.

The speaker of the evening, Mr. Ernest Dickinson, gave an illustrated lecture on his experiences from 1936 to 1940 in South America with the Bolivian Power Company, a subsidiary of The Montreal Engineering Company. The lecture, which included numerous still pictures and two reels of moving pictures, one in colour, dealt with life in general in Western South America, the City of La Paz, Bolivia, in particular and the Bolivian Power Company (La Paz) System, a hydro-electric plant in the Andes Mountains. The elevation of the City of La Paz is 12,200 ft. above sea level.

## TORONTO BRANCH

J. J. SPENCE, M.E.I.C. - *Secretary-Treasurer*  
D. FORGAN, M.E.I.C. - *Branch News Editor*

On January 29, a well-attended meeting of the Toronto Branch of the Institute was held in the Debates Room at Hart House. In addition to the members of the Institute, representatives were present from the Canadian Institute of Mining and Metallurgy. The chairman of the Branch, Mr. H. E. Brandon, conducted the meeting.

The speaker of the evening, A. H. Harkness, D.Eng., who is well-known throughout Canada for the many outstanding engineering works which he has designed, was introduced by the chairman. His subject was **Design and Construction of a Concrete Head Frame for Hollinger Mine**. Mr. R. J. Fuller, of the firm of Anglin Norcross Limited, general contractors for construction of the head frame, was to have joined with Dr. Harkness in discussing details of construction. Mr. H. E. Brandon offered regrets of the Institute on the death of Mr. R. J. Fuller, which occurred only two days previous to the meeting. Arrangements were made, however, to have Mr. J. W. Falkner read Mr. Fuller's paper, and to illustrate it with numerous lantern slides prepared by Mr. Fuller.

Dr. Harkness covered in detail the design of the rein-

forced head frame at the No. 26 shaft on the Hollinger Gold Mine's property at Timmins, the only one of its size in Canada. The structure is unique in that, with very simple architectural treatment, it was possible to create a structure most pleasing and monumental in character—quite different to the type of utilitarian structure generally built over mine shafts. It was pointed out that the concrete building, with only few partial floors, would require considerably less maintenance than is necessary for the usual type of structures built for this purpose. At its conclusion, considerable discussion was held, especially with regard to the advantage of using structural steel for head frames which could be removed and re-used elsewhere.

Mr. R. B. Young moved that the thanks of the meeting be extended to Dr. Harkness and J. W. Falkner for the interesting papers presented.

The annual Students' Night of the Toronto Branch of the Institute was held on January 15 in Hart House. There was an excellent attendance, the students having an especially good turnout. The annual Students' Night is one of the most enlightening and beneficial meetings of the year; it was enlightening to the older members in that all student competitors seemed to be experienced speakers and treated their subjects so fluently; it was beneficial to the students as it gave them confidence in themselves. Refreshments were served after the meeting.

The three judges, Messrs. E. A. Stone, J. K. Partridge and W. H. Slinn, had a very hard time making decisions because of the excellent quality of the papers presented.

During the intermission, three comic films were shown, which were thoroughly enjoyed by all.

The winners were as follows:

### JUNIOR SCHOOL

W. O. Cartier—"Frequency Modulation Receiver."

### SENIOR SCHOOL

- 1st—W. S. Glynn, "Prestressed Concrete Construction."
- 2nd—C. B. Livingstone—"On Spinning of Airplanes."
- 3rd—A. B. Extence—"Centrifugal Pumps."
- 4th—C. W. Shearer—"Mercury Arc Power Rectifiers."

The sixth Annual Social Night of the Branch, a gathering sponsored and largely organized by the wives of the members, took place in the Engineers' Club, Toronto, on Saturday, January 10. About 130 attended for dinner and the entertainment which followed. Mr. H. E. Brandon, branch chairman, with Mrs. Brandon, and Dean Young with Mrs. Young, received the guests. It was a most enjoyable evening for everyone.

## VANCOUVER BRANCH

P. B. STROYAN, M.E.I.C. - *Secretary-Treasurer*  
A. PEEBLES, M.E.I.C. - *Branch News Editor*

The first meeting of the Branch for 1942 was held on January 20th in the Medical-Dental building. The speaker was W. D. McLaren, general manager of the West Coast Shipbuilders Ltd., a company engaged in building standard cargo vessels for Wartime Merchant Shipping Ltd. His subject was **Ships: Selection of Type**.

Mr. McLaren first explained the general considerations governing the design of standard cargo vessels now under construction throughout Canada and the United States. They are of a reasonably economical size for war service, and of simple lines to facilitate fabrication. Their speed is sufficient for service in convoy, and their engines and boilers are of a type which can be built without highly specialized plant and machinery. Existing facilities had to be used as far as possible both for engines and hull fabrication. Hence there is some variation in practice among different yards, some using more welding than others, some doing considerable pre-fabrication in shops with a minimum of welding and rivetting on the ways.

(Vancouver Branch, continued on page 198)

**TORONTO BRANCH ANNUAL LADIES' NIGHT**

**Mrs. W. E. Bonn, W. E. Bonn and Mrs. H. E. Brandon.**

**In the group: Nicol MacNicol, Ross Robertson and R. L. Hewitt.**

**In the group: Mrs. W. S. Wilson, Mrs. Otto Holden, Ross Dobbin, Mrs. W. E. Ross, H. E. Brandon, Mrs. W. E. Bonn and E. C. Higgins.**

**From left to right: J. J. Spence, S. R. Frost and H. E. Brandon.**

**Mrs. A. U. Sanderson, Otto Holden and Mrs. J. S. Keenan.**

**D. C. Tennant, Professor R. W. Angus, Mrs. R. W. Angus and H. H. Angus.**

**From left to right: Professor C. F. Morrison, D. C. Tennant, Mrs. and Mr. John Hall, J. S. Keenan and W. E. Ross.**

The trend towards larger ships is explained by the effort to secure a lower size-speed ratio. An increase in length means an increase (usually) in the length-beam ratio, resulting in lessened resistances and a higher relative speed. Other factors have been better engine and boiler efficiencies and performance. The cruiser type of stern serves to lengthen a ship at the water line. In the light of tank experiments the once popular sharp bow has given way to a blunt or more rounded style. In hull design, the high stresses occurring at various points have been met with the use of high strength steels. Since a ship acts somewhat as a bridge, sometimes supported near the ends and sometimes near the center, wide variations in stress occur throughout the members.

In the early days of steamships the size of the engine cylinders practically designed the ship. Later, improvements were made by balancing the engines, but ultimately a limit was reached in bulkiness, and in speed when the piston velocity reached about 1,000 ft. per minute. The invention of the steam turbine made increased speeds and greater power possible. Early difficulties were associated with the gearing, which was reversed from that of the reciprocating engine.

The water tube boiler and oil fuel provided the means for further increases in power and speed. A gradual reduction in weight for the power developed was achieved. The latest step in this advance was brought about by the diesel engine, which also has a much higher thermal efficiency than the steam engine.

After his address, the speaker answered many questions, and several persons added to the information divulged. A vote of thanks was tendered by Dean J. N. Finlayson, on behalf of the 43 members and friends present.

Members of the Branch were guests at one of the largest and most successful meetings ever held in this city. An attendance of nearly 400 indicates the degree of interest in the subject of arc welding at the present time, and the important part which it occupies in war industry.

The meeting was under the auspices of the British Columbia Chapter of the American Society for Metals, a recently formed group which is achieving remarkable success in drawing together those engineers and technicians who deal with metals in any form. A course of lectures is being conducted and over 100 students are taking part. Prof. F. A. Forward of the University of British Columbia is chairman of the chapter.

The meeting opened with a dinner served in the dining-room of David Spencer Ltd., at which more than 200 were present. During dinner, a short talk was delivered by Mr. W. Hanson, Admiralty Inspector from London, England, at present doing work in Vancouver. He reminded the engineers of the Pacific Coast of the necessity for pushing war production to the limit, and indicated that a permanent industrial development would remain in this area after the war.

After dinner, a film was presented showing the principles of the arc welding process, how it should and should not be done.

The principal speaker was Mr. James F. Lincoln, president of the Lincoln Electric Co. of Cleveland, and director of its allied companies in Canada, England and Australia. His subject was **Electric Welding Developments**. The principal theme throughout the address was the need for the use of imagination, knowledge and skill in the creation and adoption of new ideas, new methods, new materials and new products in our industrial system. The speaker illustrated his viewpoint by showing its present results in the field of arc welding.

Arc welding may be classed with tool and alloy steels, for the part which it has played in modern mechanical engineering and shop practice. In its early stages when plain mild steel welding rods were used, results were often unsatisfactory and its application was somewhat restricted. The modern shielded arc, using coated rods to achieve specific results in the weld, have made arc welding a reliable and economical tool in the working of most metals. Welding has already found wide application in the fabricating of structural steel for buildings, in ships, in airplanes, in gun mountings, and in motor vehicles and tanks. So far, however, the welded article has been a close copy of the cast one in size, shape and proportion, and there is a tremendously wide field open in the re-design of such products, whereby the amount of cutting, bending, welding and other operations may be reduced. A wider knowledge of the stresses set up in a structure or machine in service, will make possible changes in the proportioning of parts, resulting in future economy. Slides were shown depicting examples of the replacement of cast parts with welded parts, giving a comparison of weight and cost, both of which favour the welded type.

Following the address, many questions were asked, and much useful information resulted. The practice of bobbing welds has no basic advantage, and in most cases is actually detrimental. In certain circumstances, where a tensile strength is not a governing factor, bobbing may serve to reduce warping of plates without seriously weakening the weld. Stress relieving is necessary for welded pressure vessels for severe types of service, but is ordinarily not required, since internal stresses induced by welding will gradually adjust themselves with time. Welding is not advisable with most non-ferrous metals, though it can be done. The reduction in strength which occurs makes it undesirable in many cases, unless restoration can be effected by heat treating.

Mr. Lincoln stated that the estimated saving to industry which would have accrued from full application of the ideas and methods suggested in the first competition sponsored by the Lincoln Foundation a few years ago, amounted to \$1,600,000,000. A hearty vote of thanks was tendered the speaker by Dean J. N. Finlayson.

## ANNUAL FEES

Members are reminded that a reduction of one dollar is allowed on their annual fees if paid on or before March 31st of the current year. The date of mailing, as shown by the postmark on the envelope, is taken as the date of payment. This gives equal opportunity to all members wherever they are residing.

# News of Other Societies

## DINNER TO HONOUR DEAN YOUNG

To honour C. R. Young, M.E.I.C., recently appointed Dean of the Faculty of Applied Science and Engineering of the University of Toronto, and President of The Engineering Institute of Canada, the Association of Professional Engineers of Ontario and the Toronto Branch of The Engineering Institute of Canada are jointly sponsoring a commemorative dinner in Hart House on April 25th. This dinner will be open to all engineers and will not only be a gala night for the members of the profession, but will at the same time serve to impress upon the public the great contribution that engineers are making in the present conflict.

Arrangements for this dinner are being made by a joint Committee of the Association and of the Toronto Branch of The Institute under the chairmanship of Mr. S. R. Frost.

## A.I.E.E. NOMINATIONS

The National Nominating Committee of the American Institute of Electrical Engineers, consisting of members from various parts of the country, has nominated the following official ticket of candidates for the offices becoming vacant August 1, 1942:

*For President:* Harold S. Osborne, Plant Engineer, Operation and Engineering Dept., American Telephone and Telegraph Co., New York, N.Y.

*For Vice-Presidents:* (North Eastern District)—Karl B. McEachron, Research Engineer, High Voltage Practice, General Electric Co., Pittsfield, Mass.; (New York City District)—C. R. Jones, Eastern Transportation

## Items of interest regarding activities of other engineering societies or associations

Manager, Westinghouse Electric & Mfg. Co., New York, N.Y.; (Great Lakes District)—A. G. Dewars, Manager, System Planning Dept., Northern States Power Co., Minneapolis, Minn.; (South West District)—E. T. Mahood, Engineer, In Charge of Area Engineering Force, Southwestern Bell Telephone Co., Kansas City, Mo.; (North West District)—E. W. Schilling, Professor and Head of Department of Electrical Engineering, Montana State College, Bozeman, Mont.

*For Directors:* K. L. Hansen, Consulting Engineer, Harnischfeger Corp., Milwaukee, Wis.; W. B. Morton, Senior Field Engineer, Philadelphia Electric Co., Philadelphia, Pa.; W. R. Smith, Safety Engineer, Public Service Electric and Gas Co., Newark, N.J.

*For National Treasurer:* W. I. Slichter, Professor Emeritus of Electrical Engineering, Columbia University, New York, N.Y.

These official candidates, together with any independent nominees that may be proposed later, will be voted upon by the membership at the coming election this spring.

## ANNUAL MEETING OF QUEBEC CORPORATION

The annual meeting of the Corporation of Professional Engineers of Quebec will take place on March 28th, at 2.15 p.m., in the meeting hall of The Engineering Institute of Canada, 2050 Mansfield Street, Montreal, Que.

Refreshments will be served at the conclusion of the meeting.

### BOOK REVIEW

#### BRIDGES AND THEIR BUILDERS

By D. B. Steinman and Sarah R. Watson. G. P. Putnam's Sons, New York, 1941. 6 x 9 inches. 379 pages. Illustrated. \$3.75

Reviewed by S. R. BANKS, M.E.I.C.\*

In this book the authors engage to review their vast subject ". . . as a heart-stirring narrative of high adventure and deep dramatic interest." They see in the planning and building of bridges an epitome of human aspiration and achievement; and, in the course of the eighteen chapters, the reader is conducted from a glimpse of a stone-age man crossing a torrent on the uncertain footholds of a fallen tree to the contemplation of Robinson and Steinman's forty-million-dollar proposal for a suspension bridge of 4,620-foot span between Brooklyn and Staten Island.

The triumphal progress of the bridge-builders' art is traced from primitive civilizations, through the times of the Greeks and Romans, through the dark ages when the medieval churchman alone pressed forward, through the Renaissance, and on to the pioneering days of civil engineering and the astounding accomplishments of the twentieth century. Bridges of stone, of wood, and of iron are successively described against the spacious backgrounds of their days, while the tempo of our own age is reflected in the culminating catalogue of span upon longer span of steel. In telling their story the authors rightly eschew the technicalities of the structural engineer, and the reader's attention is stimulated by copious fund of anecdote, biography, and even verse.

It is likely that the layman and the engineer alike will find of greatest interest those chapters that deal specifically with what may

be termed the classic early bridges of steel. The Eads Bridge, the Brooklyn Bridge, and the Forth Bridge are so treated, and in each instance the history of the project is told from its conception to its fulfilment. Of particular value are the occasional excerpts from the papers of the outstanding men through whose vision and courageous effort those prodigious undertakings were guided to fruition.

One or two criticisms occur to the reviewer of this book. In the first place, surely no record of great bridges of the last two decades can be complete without advertence to the disconcerting behaviour of heat-treated wires in the Mount Hope and Detroit bridges, and to the subsequent engineering feats of dismantling the huge cables of those structures and replacing them with wires of the cold-drawn type. Again, while the lessons learned from the failure of Tacoma Bridge undoubtedly represent an advance in knowledge, it does not seem right that "Recent Developments in Bridge Engineering" should be the heading of a chapter which deals almost exclusively with that disaster. With regard to the chapter on suspension bridges, the authors appear to be mistaken in their brief reference to the Lions' Gate Bridge at Vancouver, because that bridge was designed and built in Canada. Lastly, the present review would be incomplete without an expression of regret that the dignity of this otherwise objective survey of bridge engineering should be detracted from by over-frequent reference to the famous partnership of engineers of which one of the authors is a member.

"Bridges and Their Builders" is very readable and will appeal strongly to all who are inspired by the romance and vigour of its subject. The illustrations are good and are well-chosen. It is a pity that no alphabetical index is provided for the reader's convenience.

\*General Engineering Department, Aluminum Company of Canada, Ltd., Montreal, Que.

## ADDITIONS TO THE LIBRARY

### TECHNICAL BOOKS

#### Bridges and Their Builders:

David B. Steinman and Sarah Ruth Watson. N.Y., G. P. Putnam's Sons, (C1941). 6 x 8 3/4 in. \$3.75.

#### Refuse Collection Practice:

Committee on Refuse Collection and Disposal. American Public Works Association, 1313 East 60th St., Chicago, Ill., 1941. 6 x 9 1/4 in. \$5.00.

#### Surveying:

Charles B. Breed. N.Y., John Wiley and Sons, Inc., 1942. 5 x 7 1/2 in. \$3.00.

#### Electrical Illumination:

John O. Kraehenbuehl. N.Y., John Wiley and Sons, Inc., 1942. 6 x 9 1/4 in. \$3.75.

### PROCEEDINGS, TRANSACTIONS

#### Institution of Naval Architects:

Transactions, 1941. volume 83.

#### American Society of Civil Engineers:

Transactions No. 106, 1941. Issued as part 2 of the Proceedings. Vol. 67, No. 8, Pt. 2, October, 1941.

#### Royal Society of Canada:

Transactions, section 3 and 4, 3rd series, vol. 35, meeting of May, 1941.

#### Institution of Mining and Metallurgy:

Transactions, 49th session 1939-40. Vol. 49, 1940.

### REPORTS

#### American Institute of Electrical Engineers—Standard Committee:

Standard for wet tests No. 29, November 1941; Proposed standard for capacitance potential devices and outdoor coupling capacitors, No. 31, December, 1941.

#### American Institute of Electrical Engineers—Committee on Electrical Machinery:

Proposed test code for single phase motors. AIEE No. 502, 1941.

#### Canada—Department of Mines and Resources:

Rapport du Ministère pour l'année financière terminée le 31 mars 1940 et pour l'année financière terminée le 31 mars 1941 accompagné du rapport sur l'établissement des soldats au Canada. Ottawa, 1941. 50c. each.

#### Purdue University—Engineering Bulletin:

Research series No. 83—Report of the research and extension activities for the sessions of 1940-41. Extension series No. 52. Highways then and now by Ben H. Petty.

#### Bell Telephone System—Technical Publications:

Calculation of the Torque on a ferromagnetic single crystal in a magnetic field; Micro-gas analysis methods and their application to research; New microphone providing uniform directivity over extended frequency range; Operation of electrostatic photomultipliers; Spectral and total thermal emissivities of oxide-coated cathodes; Film scanner for use in television transmission tests; Steric hindrance in organic solids; Echoes from near-by short-wave transmitters; The structure of black carbon; Monographs B1297-1302, 1304-05, 09.

#### Ohio State University—Engineering Experiment Station:

Use of washed North Carolina Kaolin as an ingredient of porcelain bodies, by William H. Earhart. Circular No. 42.

#### American Institute of Chemical Engineers:

Directory of officers and members and committee appointments for 1941.

#### American Institute of Steel Construction:

Specification for the design, fabrication and erection of structural steel for buildings, rev. July 1941; Code of standard practice for steel structures other than bridges, rev. Aug. 1941.

#### Electrochemical Society—Preprints:

Solubility of nickel ions in aqueous alkaline carbonate-tungstate solutions; The oxidation of cerous sulfate at a rotating anode; Perborate formation at a rotating anode; Nos. 81-2-4.

#### Quebec Streams Commission:

Twenty-fifth report for the year 1936.

#### Canada—Department of Transport:

Annual report for the fiscal year from April 1940 to March 31, 1941.

#### Canada—Department of Mines and Resources—Geological Survey:

Clérycy and La Pause map-areas, Quebec, by J. W. Ambrose. Memoir 233.

#### Vaillancourt, Emile:

Guillaume D'Orange.

#### University of Minnesota—Engineering Experiment Station:

Comparative performance of four different types of dust counters. Technical paper No. 35.

#### The Converter Process in the Steel Foundry

A 12-page report—Investigation No. 1138—"Some Practical Considerations of the Use of Side-Blow Converters in the Present Emergency," December 24th, 1941. Just issued by the Department of Mines and Resources, Ottawa, draws attention to the advantages of the converter process for the production of light and medium steel castings under wartime conditions. Now that electric furnace capacity is fully employed, grey iron foundries can be readily equipped with side-blow converters, thus releasing electric furnaces for the specific applications for which they are pre-eminently satisfactory.

The side-blow converter equipment is described in some detail, and the technique of its operation discussed. Special mention is made of the control of sulphur and other constituents of the finished product. The limitations of the process are pointed out as well as its advantages.

Copies of the report can be obtained from "The Chief, Bureau of Mines, Department of Mines and Resources, Ottawa."

### BOOK NOTES

The following notes on new books appear here through the courtesy of the Engineering Societies Library of New York. As yet the books are not in The Institute Library, but inquiries will be welcomed at headquarters, or may be sent direct to the publishers.

#### A.S.T.M. STANDARDS ON RUBBER PRODUCTS, prepared by A.S.T.M. Committee D-11 on Rubber Products Methods of Testing, Specifications December, 1941.

American Society for Testing Materials, 260 So. Broad St., Phila., Pa., 1941. 280 pp., illus., diags., charts, tables, 9 x 6 in., paper, \$1.75.

This annual publication gives in their latest approved form the specifications and methods of test adopted by the Society. Among them are several new standards. There are also numerous revisions of earlier ones. There is a useful bibliography on the properties and testing of rubber.

#### ACTIVE CARBON, THE MODERN PURIFIER

By J. W. Hassler. West Virginia Pulp and Paper Co., 230 Park Ave., New York,

1941. 159 pp., illus., diags., charts, tables, 9 1/2 x 6 in., cloth, gratis.

This book constitutes a collection of the existing knowledge regarding the commercial applications of the decolorizing types of active carbon. It presents a general survey of the subject, detailed descriptions of various applications, basic principles for the research chemist and methods of evaluation of carbons. There is a large bibliography.

#### AIRCRAFT TORCH WELDING

By C. von Borchers and A. Ciffrin. Pitman Publishing Corp., New York and Chicago, 1941. 157 pp., illus., diags., charts, tables, 8 1/2 x 5 in., cloth, \$1.50.

This book outlines a training course for aircraft welders based on well-established principles. It deals only with gas welding. Topics treated include equipment, the use of gases, torch and flames, welding technique, jigs and fixtures, inspection methods and repair welding. Review questions accompany each chapter.

#### AIRPLANE DESIGN

By K. D. Wood, 6th ed., Nov., 1941, published by the author at Purdue University Lafayette, Ind., and distributed by the Cornell Co-op. Society, Ithaca, N.Y., pagged in sections, illus., diags., charts, tables, 11 x 9 in., paper, \$4.00.

Practical design procedure covering airplane layout and stress calculations is presented in this textbook. Particular emphasis is laid on the economics of airplane design, and many photographs and diagrams accompany the descriptive material. A large appendix furnishes most of the data necessary for a student to carry a design project through its preliminary stages.

#### AMERICAN SOCIETY FOR TESTING MATERIALS—1941 Supplement to A.S.T.M. Standards including Tentative Standards

Part 1. Metals. 597 pp.

Part 2. Nonmetallic Materials—Constructional. 427 pp.

Part 3. Nonmetallic Materials—General. 641 pp.

A.S.T.M., 260 South Broad St., Phila., Pa., 1941. Illus., diags., charts, tables, 9 1/2 x 6 in., cloth, \$3 for any one part, \$5 for any two parts, \$7 for all three parts.

To keep up to date its triennially published Book of Standards, the American Society for Testing Materials publishes, in the two intervening years, supplements to each of the three volumes of that set. This 1941 supplement gives in their latest approved form the 370 specifications, tests and definitions either issued for the first time in 1941 or revised.

#### ANNUAL REVIEWS OF PETROLEUM TECHNOLOGY, Vol. 6 (covering 1940)

Edited by F. H. Garner, published by The Institute of Petroleum, c/o The University of Birmingham, Birmingham, England, 1941. 318 pp., illus., diags., charts, tables, 9 x 6 in., paper, 11s. or \$2.50 (incl. postage).

Reviews by experts of developments during 1940 are contained in this annual compilation which covers the whole range of petroleum technology; geology, drilling and production, transportation and storage, refining operations, alternative fuels, analysis and testing, road materials, lubrication, etc. In addition to chapter references there is a general review of petroleum literature in 1940, and a chapter on production and commercial statistics is included.

#### ARMS AND THE AFTERMATH

By P. Stryker. Houghton Mifflin Co., Boston, 1942. 157 pp., tables, 8 1/2 x 5 1/2 in., cloth, \$1.75.

The meaning of industrial mobilization is explained, together with the importance of effective mass production methods, and the

results of the change-over and tremendous financing problems for armament are indicated. The purpose is to give the reader a behind-the-scenes view of the causes, functioning and effects of this mobilization of industry for the war effort.

### THE ART OF CAMOUFLAGE

By C. H. R. Chesney. Robert Hale Ltd., London, written in 1939, published in 1941. 253 pp., illus., maps, 8 x 5 in., cloth, 8s. 6d.

Camouflage, "the art of concealing the fact that you are concealing," is thoroughly covered in this book. The first section discusses camouflage as practised by creatures in their natural environment, and presents general considerations upon civil camouflage. The second section discusses the development of military camouflage in the War of 1914-18, and future developments for both military and civil use. Strategic camouflage in military movements is demonstrated in the last section, with examples from campaigns. In this section and in an epilogue the author stresses also the political camouflage which will be used and has been so amply demonstrated just recently.

### BUILDING CONSTRUCTION, Materials and Types of Construction

By W. C. Huntington. 2 ed. John Wiley & Sons, New York, 1941. 674 pp., illus., diags., charts, tables, 9½ x 6 in., cloth, \$6.00.

This book deals with the materials and types of construction used for the various parts of buildings, but not with the structural design except in its qualitative aspects. In the present edition particular attention has been paid to recent developments in our knowledge of soil behaviour, foundations, brick cavity-walls, wood construction and connectors, steel welding, reinforced concrete arches and rigid frames, the protection of wood from termites and the newer structural materials.

### DIESEL ENGINEERING HANDBOOK, Vol. 2

Edited by L. H. Morrison. Diesel Publications, New York, 1941. 574 pp., illus., diags., charts, tables, 9½ x 6 in., cloth, \$5.00.

This volume is intended to supplement both the 1935 and 1939-40 editions. The material contained is either entirely new or an amplification of topics considered in the previous editions. Engine efficiencies, specifications, special installations and various types of auxiliary equipment not previously covered are discussed exhaustively with many illustrations.

### DONE IN OIL

By D. D. Levon. Carleton Publishers, New York, 1941. 1,084 pp., illus., diags., charts, maps, tables, 9½ x 6 in., leather, \$10.00.

The first section of this comprehensive volume covers general petroleum economics, oil reserves and conservation, the international situation and the importance of oil in war. The succeeding five sections deal respectively with finding and producing oil, transportation and refining, financing the oil industry, oil royalty business and investments, and the regulating of securities and markets. Sample leases and deeds, a large glossary of terms and a list of sources of further information are appended.

### EXPERIMENTAL PHYSICAL CHEMISTRY

By W. G. Palmer. MacMillan Co., New York; University Press, Cambridge, England, 1941. 321 pp., diags., charts, tables, 8½ x 5½ in., cloth, \$2.75.

The experiments presented have been chosen among those used in the University Chemical Laboratory at Cambridge, choice having been of those which can be carried out

in customary laboratory periods, with ordinary equipment. Detailed directions are given, and the principles involved are set forth in considerable fulness. There are completely worked examples of most experiments.

### FATIGUE OF WORKERS, Its Relation to Industrial Production

By Committee on Work in Industry of the National Research Council. Reinhold Publishing Corp., New York, 1941. 165 pp., 9½ x 6 in., cloth, \$2.50.

This volume is the complete report of the findings of a committee which made a detailed study of all kinds of variations in working conditions, both physical and psychological considerations were investigated with respect to their effect upon the efficiency of workers. The results of this painstaking study should be of value to employers of all classes.

### FINANCIAL STATEMENT ANALYSIS, Principles and Technique

By J. N. Myer. Prentice-Hall, New York, 1941. 257 pp., charts, tables, 9½ x 6 in., cloth, \$3.75.

Financial statement analysis is considered as a branch of accountancy, and an understanding of such statements and the accounting processes by which they are produced is assumed. The object of the book is to develop sound principles for a technique of analysis and interpretation of the financial statements of business enterprises, and the application of these principles is illustrated in a practical manner.

### Great Britain, Dept. of Scientific and Industrial Research, Building Research WARTIME BUILDING BULLETIN No. 17

His Majesty's Stationery Office, London, 1941. 9 pp., 11 x 8½ in., paper, (obtainable from British Library of Information, 30 Rockefeller Plaza, New York, 15c.).

This pamphlet is based upon an extensive survey of damaged buildings, research data and other information. Damages from explosions above ground, from fire and from ground shock are considered, and tentative recommendations for precautions in design are given.

### Great Britain, Dept. of Scientific and Industrial Research, Road Research Laboratory

#### Wartime Road Note No. 1, RECOMMENDATIONS FOR TAR CARPETS AND SURFACE DRESSINGS. 11 pp.

#### Wartime Road Note No. 2, SOURCES OF NATURALLY-COLOURED CHIP-PINGS IN GREAT BRITAIN. 13 pp.

#### Wartime Road Note No. 3, RECOMMENDATIONS FOR OPEN - TEXTURED ASPHALT CARPETS, 8 pp.

His Majesty's Stationery Office, London, 1941. Tables, 9½ x 6 in., paper, 6d. each. (Obtainable from British Library of Information, 30 Rockefeller Plaza, New York, 15c. each.)

These three pamphlets are intended to assist engineers in dealing with the special problems of road building and maintenance that arise in wartime.

### Great Britain, Dept. of Scientific and Industrial Research, Road Research Laboratory, Wartime Road Note No. 4, SALT TREATMENT FOR ICY ROADS

His Majesty's Stationery Office, London, British Library of Information, 30 Rockefeller Plaza, New York, 1941. 6 pp., tables, 9½ x 6 in., paper, 15c.

Recommendations for the treatment of icy roads with salt-sand mixtures under varying conditions are presented. The purpose of this Road Note series is to assist engineers in dealing with special problems under wartime conditions.

### HANDBOOK OF CHEMISTRY AND PHYSICS, a Ready-Reference Book of Chemical and Physical Data. 25th ed.

Edited by C. D. Hodgman and H. N. Holmes. Chemical Rubber Publishing Co., Cleveland, Ohio, 1941. 2,503 pp., diags., charts, tables, 7½ x 5 in., fabrikoid, \$3.50.

The popularity of this well-known reference work is indicated by the appearance of twenty-five editions in twenty-eight years. The present issue retains the original purpose, to provide accurate data constantly wanted by physicists and chemists in convenient form for quick reference. The present edition has been revised throughout and new matter added where called for.

### (The) HIGHWAY SPIRAL

By G. I. Gibbs. T. D. Toler, Roanoke, Va., 1941. 229 pp., diags., charts, tables, 8 x 4½ in., cloth, \$2.50.

The object of this book is to explain and enlarge upon various formulas, particularly with regard to their practical application to highway alignment. Each of thirteen combinations of tangents, spirals and circular curves is presented separately in chapter form with examples applying formulas to numerical problems. A large section of useful tables is appended.

### HYDRAULICS

By H. W. King, C. O. Wisler and J. G. Woodburn. 4 ed. John Wiley & Sons, New York; Chapman & Hall, London, 1941. 303 pp., diags., charts, tables, 9 x 6 in., cloth, \$2.75.

The fundamental principles of hydraulics are presented, including applications in engineering practice, to provide a text for beginning courses and also to serve as a reference book. The material has been revised in accordance with recent trends of research and practice, expanded treatment being given to the subjects of viscosity, manometers, the energy theorem, laminar flow, compound pipes and non-uniform flow in open channels.

### (The) HYDRAULICS OF STEADY FLOW IN OPEN CHANNELS

By S. M. Woodward and C. J. Posey. John Wiley & Sons, New York; Chapman & Hall, London, 1941. 151 pp., diags., charts, tables, 9½ x 6 ins., cloth, \$2.75.

The theory of the steady flow of water in open channels is presented in concise form, suitable for use in senior and graduate courses and for home study. Backwater curves and flow-profile analysis under varying conditions receive particular treatment. Certain related topics, such as the moving hydraulic jump and slowly varied flow, are also considered.

### (The) INDUSTRIAL CHEMISTRY OF THE FATS AND WAXES.

By T. P. Hilditch. 2 ed. rev. and enl., D. Van Nostrand Co., New York, 1941. 532 pp., diags., tables, 9 x 5½ in., cloth, \$7.50

The aim of this excellent treatise is to supply a concise, connected, logical account of the industries based upon natural fats and waxes. The chemical nature and composition of the fats are considered in the first two sections followed by a description of their transformation for industrial use. Succeeding sections are devoted to edible fats, soap, candles and illuminants, glycerine production, the use of fats and waxes in paints and varnishes, the application of fats to fibers, and fatty lubricants. Each section has a bibliography.

### INORGANIC CHEMICAL TECHNOLOGY (Chemical Engineering Series)

By W. L. Badger and E. M. Baker, 2 ed. McGraw-Hill Book Co., New York, 1941. 237 pp., illus., diags., charts, tables, 9½ x 6 in., cloth, \$2.50.

This textbook is intended to describe current American practise in the heavy chemical

industries from the viewpoint of the engineer. The various processes are presented in the light of present-day understanding of unit operations. Products dealt with include common salt, various important acids, caustic soda, chlorine, sodium carbonate and other miscellaneous salts.

#### IRON HORSES, American Locomotives 1829-1900

By E. P. Alexander. W. W. Norton & Co., New York, 1941. 239 pp., illus., diags., woodcuts, 11½ x 8½ in., cloth, \$5.00.

This book is a pictorial story of the development of the American locomotive from the first engine to run on rails, in 1829, down to the turn of the century. Following a brief historical résumé of the early years comes a chronological series of prints and lithographs, with case histories, depicting typical locomotives of the years covered by the book. An alphabetical directory of locomotive builders of the United States, past and present, is appended.

#### MANUAL OF ELEMENTARY MACHINE SHOP PRACTICE

By E. C. Phillips. Burgess Publishing Co., 426 South Sixth St., Minneapolis, Minn., 1941. 199 pp., illus., diags., tables, 11 x 8½ in., paper, looseleaf spiral binder, \$2.50.

The content of this manual has been written for the use of those making their first acquaintance with the machines, tools and processes commonly employed in machine-shop work. The material consists of operation sheets which give step-by-step procedures for shop operations, and information sheets which simply describe tools and processes, and the necessary computations.

#### METAL—INSIDE OUT

By A. W. Grosvenor, F. Seitz, W. J. Diederichs, L. E. Ekholm, F. B. Foley and A. H. Staud. American Society for Metals, 7301 Euclid Ave., Cleveland, Ohio, 1941. 115 pp., illus., diags., charts, tables, 9½ x 6 in., cloth, \$2.00.

This collection of six lectures presents a description of the fundamentals of metallic structures. The lectures discuss respectively the atom and pure metal structures, substitutional and interstitial alloys with the general rules governing alloying, hardness, microscopic appearance, strength and impurities. The dominant idea of the whole is the development of the crystal and the effect of various influences on its characteristics.

#### MODERN MARINE ENGINEER'S MANUAL, Vol. 1

Edited by A. Osbourne and others. Cornell Maritime Press, 350 West 23rd St., New York, 1941. 1,696 pp., illus., diags., charts, tables, 7½ x 5 in., cloth, \$6.00.

This manual has been written to provide a comprehensive American textbook that will adequately explain the design and operation of all the general types of marine equipment. This first of two volumes covers such fundamentals as mathematics, engineering materials, thermodynamics and combustion, and such equipment as boilers, reciprocating engines and steam turbines, together with certain auxiliaries. Each chapter is the product of a specialist, and simplicity is the keynote.

#### MODERN GUN PRODUCTION

Compiled by and reprinted from "Steel," Penton Publishing Co., Cleveland, Ohio, 1941. 51 pp., illus., diags., 11½ x 9 in., paper, \$1.00.

This pamphlet brings together in convenient form a number of articles which have previously appeared in *Steel*. The principles of gun construction and manufacturing operations as carried out at the Watervliet Arsenal and by the Struthers-Wells-Titusville Corporation are described. There are also articles on the design and production of gun carriages, recoil mechanism, range finders and fire-control instruments.

#### MODERN MARINE PIPEFITTING

By E. M. Hansen. Cornell Maritime Press, New York, 1941. 434 pp., illus., diags., charts, tables, 7½ x 5 in., cloth, \$3.00.

The essentials of marine pipefitting, with particular regard for special conditions, are presented in this textbook for students and apprentices. Emphasis has been laid on what the pipefitter will have to know in each phase of his work, as he follows a job from blueprint to completed installation on board ship. Glossaries of shipbuilding and pipefitting terms are included, and there are many working drawings and photographs.

#### MODERN SHELL PRODUCTION

Compiled by and reprinted from "Steel," Penton Publishing Co., Cleveland, Ohio, 1941. 159 pp., illus., diags., charts, tables, 11½ x 9 in., paper, \$1.50.

The material contained in the first and second handbooks on ordnance production prepared by *Steel* appears again in the present publication, together with new material on the manufacture of cartridge cases, ammunition for small arms, and bombs and fuses. Much practical, up-to-date information is presented, with excellent illustrations and drawings.

#### (The) NATURE OF THERMODYNAMICS

By P. W. Bridgman. Harvard University Press, Cambridge, Mass.; Humphrey Milford, London, 1941. 229 pp., diags., 8½ x 5½ in., cloth, \$3.50.

This analysis of thermodynamics is "operational", in that it examines what physicists actually do when they apply the principles of thermodynamics to concrete situations. It centers about a discussion of the two laws of thermodynamics and the corresponding fundamental concepts. Entirely non-mathematical, the book demands an acquaintance with thermodynamics comparable to that of a college student of physics, chemistry or engineering.

#### NOTES AND PROBLEMS IN BLUE PRINT READING OF MACHINE DRAWINGS

By D. E. Hobart. Harper & Brothers, New York and London, 1941. 105 pp., diags., 11 x 8½ in., paper, \$1.00.

The material presented in this book is the outgrowth of the author's experience in teaching the reading of machine drawings to men taking courses in machine-shop practice. The basic principles for reading both detail and assembly drawings are explained, and a large group of sample problem sheets is appended.

#### OIL WELL DRAINAGE

By S. C. Herold. Stanford University Press, Stanford University, California, 1941. 407 pp., illus., diags., charts, maps, tables, 10½ x 7 in., cloth, \$5.00.

Events and conditions within a producing reservoir are described, and the influence of well performance on the movement of the oil and gas is presented in simple terms. Analogies between artificial and natural reservoirs are considered, the nature of reservoir energy is discussed, and the function of gas in the production of oil is set forth. The chapters are divided into two parts, for two types of wells with distinct features in drainage. Many citations of field examples are included.

#### PETROLEUM REFINERY ENGINEERING

By W. L. Nelson, 2 ed. McGraw-Hill Book Co., New York and London, 1941. 715 pp., illus., diags., charts, tables, 9½ x 6 in., cloth, \$6.00.

The fundamentals of engineering design and processing in the field of refining are presented in this comprehensive text. The composition and properties of petroleum oils, the principles which govern their treatment and the equipment used for the various processes are dealt with at length. The revised edition contains new chapters on rebuilding hydrocarbons,

auxiliaries to processing, and solvent treating or extraction processes. New references have been added to many of the chapters.

#### PLANT PRODUCTION CONTROL

By C. A. Koepke. John Wiley & Sons, New York; Chapman & Hall, London, 1941. 509 pp., illus., diags., charts, tables, 9 x 6 in., cloth, \$4.00.

The maximum production of goods with minimum confusion and expense is the concept dealt with in this book. To this end production control is broken down into its several functions. Each function is treated separately, yet coordinated with the others to show how control of production is obtained for various situations. Review questions and a short bibliography accompany each chapter.

#### POSSIBLE FUTURE OIL PROVINCES OF THE UNITED STATES AND CANADA

Edited by A. I. Levorsen. American Association of Petroleum Geologists, Tulsa, Okla., 1941. 154 pp., diags., maps, charts, 9½ x 6 in., cloth, \$1.50 (to members \$1.00).

The purpose of this symposium is to provide an over-all picture of the undiscovered oil resources of North America, north of the Rio Grande. The separate chapters, prepared by various geological organizations, deal only with outlying areas in which as yet no discoveries of consequence have been made. A map and a section of geology, stratigraphy and structure illustrate each province description.

#### (The) PRACTICAL APPLICATION OF ALUMINIUM BRONZE

By C. H. Meigh. McGraw-Hill Publishing Co., New York and London, 1941. 112 pp., illus., diags., charts, tables, 10 x 7½ in., cloth, \$4.00.

The object of this book is to make available to engineers the results of the experience of a metallurgical engineer who has developed a practical technique in the economic production of aluminium bronzes. Micro-structure, properties and uses are discussed; foundry, hot-working and workshop practices are described; and various faults and failures are explained. Much useful material is appended in tabular form.

#### PRACTICAL MARINE DIESEL ENGINEERING

By L. R. Ford, 3 ed. Simmons-Boardman Publishing Corporation, New York, 1941. 590 pp., illus., diags., charts, tables, 9½ x 6 in., cloth, \$5.00.

Construction, operation and maintenance of marine Diesel engines are explained from the viewpoint of the operating engineer. Latest developments in new types of equipment associated with motorship propulsion, such as couplings, superchargers, etc., are discussed, and there are chapters on methods and requirements for obtaining a motorship license. This third edition is limited to American engines.

#### PRACTICAL PRINCIPLES OF NAVAL ARCHITECTURE

By S. S. Rabl. Cornell Maritime Press, 350 West 23rd St., New York, 1941. 181 pp., diags., charts, tables, 7½ x 5 in., cloth, \$2.00.

This simple introductory volume for the student and practical worker explains first the essential mathematics. It then describes the various steps leading to the construction of the ship: lines, buoyancy, displacement, stability and trim calculations, etc. Launching is discussed, and the later chapters deal with the strength of materials and of floating structures. Ease of comprehension has been emphasized.

## (The) PRINCIPLES OF PHYSICAL METALLURGY

By G. E. Doan and E. M. Mahla. 2 ed. McGraw-Hill Book Co., New York and London, 1941. 388 pp., illus., diags., charts, tables, 9½ x 6 in., cloth, \$3.50.

This textbook aims to supply a unified account of present-day knowledge of metals and alloys, with special reference to their behavior when operated upon in manufacturing. The physics of metals, metallography and metal technology are successively discussed, attention being focussed upon the principles of the behavior of metals as a whole, not of individual metals or alloys.

## RADIO AMATEUR'S HANDBOOK, 19th ed., 1942

Published by the American Radio Relay League, West Hartford, Conn. 552 pp., illus., diags., charts, tables, 9½ x 6½ in., paper, \$1.00 in U.S.A.; \$1.50 in foreign countries; \$2.50 bound.

The latest revision of this widely used handbook has incorporated a new arrangement of the material. The first section has become a non-mathematical presentation of the theory of radio, in which the principles and general matters of design are presented. The second section deals with the practical construction and operation of receivers and transmitters. The work retains the high standard of previous issues.

## RUNNING A MILLING MACHINE

By F. H. Colvin. McGraw-Hill Book Co., New York and London, 1941. 157 pp., illus., diags., charts, tables, 8 x 5 in., cloth, \$1.50.

This simple, well-illustrated introductory book gives a working knowledge of milling machines and shows how they are used. It covers the different kinds of machines, their parts, the kind of work each does, how to operate each kind, proper speeds and feeds, etc., Its practical value is increased if used in connection with actual shop work.

## SURFACE TREATMENT OF METALS

Symposium held during the 22nd Annual Convention of the American Society for Metals, Cleveland, Ohio, October 21 to 25, 1940. American Society for Metals, 7301 Euclid Ave., Cleveland, Ohio, 1941. 427 pp., illus., diags., charts, tables, 9½ x 6 in., cloth, \$5.00.

Fifteen papers by authorities are presented in this symposium on the treatment of metal surfaces. The wide range is indicated by the following sample topics: anodic treatment of aluminum; corrosion resistance of tin plate; diffusion coatings on metals; induction heat-treating; shot blasting; effect of surface conditions on fatigue properties, etc. Discussion of the papers is included.

## SURVEYING

By C. B. Breed. John Wiley & Sons, New York; Chapman & Hall, London, 1942. 495 pp., illus., diags., charts, tables, 7½ x 5 in., cloth, \$3.00.

This book has been prepared to meet the demand for short texts, owing to the current tendency to abridge college courses in surveying. It covers the usual field and office practices in land surveys, leveling, and topographic surveys, discusses aerial surveying briefly, and gives the latest practice in public lands surveys. Attention is also paid to the surveying problems that arise in engineering construction.

## TEXT-BOOK OF ADVANCED MACHINE WORK

By R. H. Smith. 12th ed. rev. and enl. Industrial Education Book Co., Boston, 1940. Page in sections, diags., tables, 8 x 5 in., cloth, \$3.25.

A companion volume to the author's "Principles of Machine Work", this book covers a wide range of machine shop operations. In addition to full descriptions of the tools and processes, schedules of the various operations are given, which provide a complete plan in tabular form of many typical problems in machine construction. These schedules, together with the large number of illustrations, increase the practicality of the book for the inexperienced worker.

## TEXTBOOK OF THE MATERIALS OF ENGINEERING

By H. F. Moore, with a chapter on Concrete by H. F. Gonnerman and a chapter on The Crystalline Structure of Metals by J. O. Draffin. 6 ed. McGraw-Hill Book Co., New York and London, 1941. 454 pp., illus., diags., charts, tables, maps, 9½ x 6 in., cloth, \$4.00.

The physical properties of the common materials used in structures and machines, together with descriptions of their manufacture and fabrication, are presented concisely in suitable form for use as a college textbook. The new edition has an added chapter on plastics, and extensive changes and additions have been made throughout the book.

## THEORETICAL AND PRACTICAL ELECTRICAL ENGINEERING, 2 Vols.

By L. D. Bliss. 5th ed. Bliss Electrical School, Washington, D.C., 1941. Vol. 1, 631 pp., Vol. 2, 671 pp., illus., diags., charts, tables, 9½ x 6 in., cloth, \$8.00 for both Vols.

These two volumes contain a course of lectures given at The Bliss Electrical School upon the principles and applications of both direct and alternating current apparatus. The early chapters discuss fundamental electrical theories, laws and types of instruments. Generators, motors and transformers are treated in detail, and consideration is given in later chapters to telegraphy, telephony, electronic devices, illumination, electric railways and other applications of electricity.

## THERMODYNAMICS

By J. H. Keenan. John Wiley & Sons, New York, 1941. 499 pp., diags., charts, tables, 9 x 6 in., cloth, \$4.50.

The object of this book is to give a simple and rigorous exposition of the first and second laws of thermodynamics. Work, temperature and heat are explicitly defined. The concept of reversibility, entropy, the availability principle, the relations between pressure, volume and temperature, and states of equilibrium are some of the important subjects discussed. Consideration is also given to engines, cycles, refrigeration, air conditioning and other thermodynamic applications.

## TRAFFIC ENGINEERING HANDBOOK

Edited by H. F. Hammond and L. J. Sorenson; published and distributed by the Institute of Traffic Engineers and the National Conservation Bureau, 60 John St., New York, 1941. 296 pp., illus., diags., charts, tables, 9 x 6 in., cloth, \$3.25.

This authoritative guidebook for engineers engaged in the field of street and highway traffic is the product of fourteen specialists in various phases of the work. Concerned mainly with fundamentals and those portions of the field in which well-accepted principles have

been established, its chief purpose is to serve as a day-to-day reference work for those who deal with technical problems of traffic and transportation.

## WATER PURIFICATION FOR PLANT OPERATORS

By G. D. Norcom and K. W. Brown. McGraw-Hill Book Co., New York and London, 1942. 180 pp., illus., diags., charts, tables, 9 x 6 in., cloth, \$2.50.

This is a comprehensive instruction book for filter-plant operators, in which theory and practice are discussed in an elementary way for those without technical education. The structures and equipment used in water purification are described, and operating methods given in full.

## (The) WELDING ENCYCLOPEDIA and the Welding Industry Buyers' Manual

Compiled and edited by L. B. Mackenzie and H. S. Card; re-edited by S. Plumley. 10th ed. Welding Engineer Publishing Co., Chicago, Ill. 712 pp., illus., diags., charts, tables, 9 x 6 in., fabrikoid, \$5.00.

The subject matter of this comprehensive volume is arranged alphabetically, and all relevant illustrations and technical data are to be found directly associated with the definitions and explanations. Some of the principal topics covered are the main types of welding, the most important fields of use, metals and alloys, metal spraying, testing methods and operator training. Company names are included with a listing of the trade names of their products.

## WIRE AND WIRE GAUGES with Special Section on Wire Ropes

By F. J. Camm. Chemical Publishing Co., Brooklyn, N.Y., 1941. 138 pp., diags., tables, 7 x 4 in., cloth, \$2.50.

Each of the standard wire systems of Europe and America is set forth separately in this manual for greater ease in reference. There is also information on wire drawing and on the construction, use and maintenance of wire rope.

## WOOD TECHNOLOGY, Constitution, Properties and Uses

By H. D. Tiemann. Pitman Publishing Corp., New York and Chicago, 1942. 316 pp., illus., diags., charts, tables, 9½ x 6 in., cloth, \$3.50.

According to the author, this is the first book in English to give a comprehensive account of our knowledge of wood, its properties and uses. Written by an authority, in a simple and readable style, the book discusses briefly all phases of wood technology and provides references to more detailed discussions of specific subjects. A large number of photographs and microphotographs are included. The book will be of great value to all users of wood.

## GEOLOGY OF THE WESTERN SIERRA NEVADA BETWEEN THE KINGS AND SAN JOAQUIN RIVERS, CALIFORNIA. University of California, Dept. of Geological Sciences, Vol. 26, No. 2, pp. 215-286, plates 42-46.

By G. A. Macdonald. University of California Press, Berkeley and Los Angeles, 1941. Illus., maps, charts, tables, 10½ x 7 in., paper, \$1.00.

The results of an extensive geological survey of the territory outlined are presented in this publication. Following a detailed description of the characteristic rocks and their distribution, come brief treatments of the economic geology, geologic structure and geologic history of the region.

# PRELIMINARY NOTICE

## of Applications for Admission and for Transfer

FOR ADMISSION

February 27th, 1942.

The By-laws provide that the Council of the Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.—

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

**Communications relating to applicants are considered by the Council as strictly confidential.**

The Council will consider the applications herein described at the April meeting.

L. AUSTIN WRIGHT, General Secretary.

\*The professional requirements are as follows:—

A **Member** shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science or engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A **Junior** shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A **Student** shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An **Affiliate** shall be one who is not an engineer by profession but whose pursuits, scientific attainment or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

**BOURGOIS**—JOSEPH ALFRED ANDRE, of Montreal, Que. Born at Joliette, Que., June 19th, 1911; Educ.: B.A.Sc., C.E., Ecole Polytechnique, Montreal, 1938; R.P.E. of Que.; Summer work—1935, asst. dftsmn., assayer, geologist, Sullivan Gold Mines, 1937, asst. gold ores assayer, Beaucourt Gold Mines, 1938, plant inspector, and 1939, refinery inspector, Quebec Dept. of Roads; Feb. 1940 to date, asst. hydrometric engr., field and office work, Dominion Water & Power Bureau, Montreal.

References: O. O. Lefebvre, T. J. Lafreniere, A. Duperron, J. A. Lalonde, A. Frigon.

**DYER**—WILLIAM ELMER SEIBERT, of Abington, Penna. Born at Philadelphia, Dec. 5th, 1880; Educ.: Private tuition—research in America and Europe; Member, A.S.M.E.; 1908 to date, private practice as consltg. engr. and architect—design, constrn., installn., power plants, factories, equipments, etc.; designed and supervised constrn. of many plants for various lines of mfr. for clients in U.S., Canada and Europe; at present, consltg. engr. to the Algoma Steel Corporation, Sault Ste. Marie, Ont.

References: L. R. Brown, C. Stenbol, J. L. Lang, W. D. Adams, A. E. Pickering.

**GOLDENSTEIN**—ABRAHAM, of 5380 Park Ave., Montreal, Que. Born at Montreal, March 14th, 1915; Educ.: 1930-33, Montreal Technical School (day classes); 1936-39, foreman i/c machine repairs, rebldg., and dftsmn., Ma-Jam Machine Co., Montreal; 1939-41, gen. bench and tool work, Fairchild Aircraft, Longueuil; at present, dftsmn., Defence Industries Limited, Verdun, Que. (Applying for admission as affiliate.)

# Employment Service Bureau

## SITUATIONS VACANT

**MECHANICAL DESIGNING DRAUGHTSMAN**, Graduate preferred, urgently needed for work in Arvida for specification drawings for plate work, elevators, conveyors, etc., equipment layouts, pipe layouts and details. Apply to Box No. 2375-V.

**MECHANICAL GRADUATE ENGINEER** with machine shop experience required for work in Mackenzie, British Guiana, on essential war work. Apply to Box No. 2441-V.

**MECHANICAL ENGINEER** preferred with experience on diesels and tractors, for work in Mackenzie, B.G. Apply to Box No. 2482-V.

**MECHANICAL DRAUGHTSMEN** and engineers for pulp and paper mill work. Experienced men preferred. Good salary to qualified candidates. Apply to Box No. 2483-V.

**ELECTRICAL ENGINEER**, young French Canadian graduate engineer to be trained on work involving hydro-electric plant operation, transmission lines and construction, meter testing and inspection. Good opportunity to acquire first-hand electrical power experience. Apply to Box No. 2487-V.

**GRADUATE DRAUGHTSMAN**, for industrial plant design and detailing. Apply to Box 2497-V.

**MECHANICAL DRAUGHTSMAN**, for piping and general equipment layout work. Apply to Box 2498-V.

**MECHANICAL ENGINEER**, for general maintenance work at Arvida, Que. Apply to Box 2500-V.

**CHEMICAL CONSULTING ENGINEER** experienced in manufacturing methods to advise on efficient

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party. Notices appearing in the Situations Wanted column will be discontinued after three insertions, and will be re-inserted upon request after a lapse of one month. All correspondence should be addressed to **THE EMPLOYMENT SERVICE BUREAU, THE ENGINEERING INSTITUTE OF CANADA, 2050 Mansfield Street, Montreal.**

management of small plant near Montreal, manufacturing synthetic iron oxide for production of colours. Apply to Box 2503-V.

**MECHANICAL ENGINEER** with experience in pulp and paper industry for supervision and maintenance work in large paper mill. Must be experienced in machine shop work and the handling of men. Apply Box No. 2522-V.

## ENGINEER OFFICERS WANTED

Applications are invited for Commissions in the Royal Canadian Ordnance Corps for service both overseas and in Canada as Ordnance Mechanical Engineers. Since it is probable that several new units will be organized in the near future, a number of senior appointments may be open, and applications from engineers with a good background of military experience would be welcomed in this connection. Applications should be submitted on the regular Royal Canadian Ordnance Corps application forms, which can be obtained from the District Ordnance Officers of the respective Military Districts.

## SITUATIONS WANTED

**CIVIL AND STRUCTURAL ENGINEER, M.E.I.C., R.P.E. (Ont.)**, Age 49. Married. Home in Toronto. Experience in Britain, Africa, Canada, Turkey. Chief engineer reinforced concrete design offices, steelworks construction. Resident engineer design and construction munitions plants, and general civil engineering work. Extensive surveys, draughting, harbour and municipal work. Location immaterial. Available now. Apply Box No. 2425-W.

**ELECTRICAL, MECHANICAL ENGINEER**, age 35. Dip. and Assoc. R.T.C., Glasgow, A.M.I.E.E., (Students Premium) G.I. mech. E., M.E.I.C., Assoc. Am.I.E.E. Married. Available after December 22nd. Seventeen years experience covering machine shop apprenticeship, A.C. and D.C. motors, transformers, steel and glass bulb arc rectifiers, design, testing and erection sectional electric news and fineprints paper machine drives, experience tap changers H.V., L.V. and marine switchgear. Apply to Box No. 2426-W.

**MECHANICAL ENGINEER** age 55 years. Married. Available at once. Thirty years experience in draughting and general machine shop and foundry work. Fifteen years as works manager. Considerable experience in pump work, including estimating and inspection. Apply to Box 2427-W.

**ELECTRICAL ENGINEERING** student in third year, age 27, desires summer position starting in April, with view to permanency on graduation. Two summers on design of shop equipment and electrical apparatus. Three years experience on test and experimental work for relays and control equipment. Student E.I.C., and Associate member American Institute of Electrical Engineers. Location immaterial. Apply to Box No. 2428-W.

**ENGINEER ADMINISTRATOR**, experienced in public utilities, shipyard construction, airplane construction, crane construction, general mechanical engineering and inspection work, also sales promotion. Open for appointment. Apply to Box 2429-W.

**GRADUATE ENGINEER** in Electrical and Mechanical Engineering, M.E.I.C., and R.P.E., electric utility experience. Age 30. Married. Transmission line, and distribution, estimating, design, survey and construction three years, (one year acting superintendent), interior light and power wiring design, estimating and supervision one year. Electric meters (AC) six months, electric utility drafting six months, foundation layouts and concrete inspection six months. Steam power plant operation two years. Presently employed but desire advancement. Apply to Box No. 2430-W.

## SALES ENGINEERING WORK IN INDUSTRIAL & ELECTRICAL PLANTS

### WANTED

Man for Sales Engineering work in Industrial and Electrical plants. Engineering and University Training desirable but not essential. Man not subject to Military Service preferred. State experience, training, salary expected, etc., in application.

Apply Box No. 2521-V

## ELECTRICAL DRAFTSMAN

Electrical draftsman or engineer, preferably with knowledge of marine practice, required for shipbuilding work, with sufficient experience to requisition material from plans and specifications and generally to act as liaison between drawing office, electrical foreman and purchasing department.

Apply to Box 2523-V

## PRELIMINARY NOTICE

(Continued)

### FOR TRANSFER FROM JUNIOR

**FULLER—HAROLD ALEXANDER**, of Barranca Bermeja, Colombia, S.A. Born at Carievale, Sask., Jan. 28th, 1915; Educ.: B.Sc. (Civil), Univ. of Man., 1938; 1938 (May-Aug.), driller, International Nickel Co.; 1939 (Jan.-Apr.), asst. to surveyor, Land Surveys Br., Prov. of Man.; 1938 (Aug.-Dec.) and 1939 (May-Nov.), highway constr. engr., Dufferin Paving and Crushed Stone, Toronto, Ont.; Feb. 1940 to date, with the Tropical Oil Company, 1½ years, surveyor, geol. dept., and at present, utility engr., gas plant dept. (Jr. 1939).

## LECTURES AVAILABLE FOR PRESENTATION

A series of six lectures has been made available by the Canadian General Electric Co. Ltd., for presentation before engineering societies, service clubs and similar groups. These lectures are as follows: Lecture No. 1, "Magic of the Spectrum" by J. W. Bateman; Lecture No. 2, "Electricity in Modern Warfare" by G. E. Bourne; and Lecture No. 3, "Plastics" by A. E. Byrne. Requests for further information may be addressed to the closest C-G-E office or to Mr. V. R. Young, Lecture Bureau, Canadian General Electric Co. Ltd., 212 King St. West, Toronto, Ont.

## CLAY PRODUCTS

National Sewer Pipe Co. Ltd., Toronto, Ont., have issued a catalogue which covers the company's many lines of clay products. Copies of this catalogue are being mailed to all engineers, architects, contractors, building supply dealers and municipal offices.

## HIGH-PRESSURE CONDENSATE RETURN SYSTEM

Cochrane Corporation, Philadelphia, Pa., announce the publication of Bulletin No. 3025, four pages, which covers the new Cochrane-Becker high-pressure condensate return system. A typical installation is described in detail with a four-colour illustration showing steam, condensate and makeup lines. A similar drawing illustrates the operation of the jet-loop principle on which the system operates.

## MEEHANITE HANDBOOK

A complete handbook on "Meehanite" castings, describing their manufacture, metallurgy, and engineering properties which has just been published by Meehanite Research Institute of America, Inc., 311 Ross St., Pittsburgh, Pa., contains 47 pages of facts important to engineers, designers, machinery manufacturers, and every user of castings. Although a nominal price of \$1.00 has been established for the "Meehanite Handbook," copies will be sent free to men of industry who can use the data it contains. In requesting a copy please give your title and write on your business letterhead.

## MOTORS

A 34-page bulletin, MU-183, issued by Wagner Electric Corp., St. Louis, Mo., deals with the company's single-phase, direct-current and small polyphase motors. Contains detailed descriptions of the construction of repulsion-start-induction motors, repulsion-induction motors, capacitor-start motors, split-phase motors, direct-current motors, polyphase motors, fan motors, and explosion-proof motors.

## MULTI-STAGE STEAM TURBINES

The Moore multi-stage steam turbines type "S" are described in bulletin 1955 issued by Moore Steam Turbine Div. of Worthington Pump & Machinery Corp., Harrison, N.J. A drawing showing the longitudinal section of a seven-stage turbine is accompanied by a cut-away drawing and illustrations of all important parts. Dimensional drawings are included for non-condensing and condensing turbines.

## NEW MOTOR FOR TUBE CLEANERS

Elliott Company, Tube Cleaner Dept., Springfield, Ohio, have recently issued bulletin No. Y-9. Under the title "Full-Floating Anti-Friction Power for Refinery Table Cleaning with Elliott (Lagonda Type) Double Ball-Thrust Tube Cleaner Motors (1100 Series)" this bulletin describes the newly announced series 1100, double ball-thrust tube cleaner motors, with which any type of Elliott-Lagonda cutter heads can be used. Several heads are illustrated and a graph shows the increased effective power of the new motor.

## Industrial development — new products — changes in personnel — special events — trade literature

GORDON JANES  
President and General Manager  
Canadian SKF Company Limited

## THE 25TH ANNIVERSARY OF THE CANADIAN SKF COMPANY

PRESIDENT GORDON JANES RECEIVES CONGRATULATIONS

On the occasion of this 25th anniversary of the Canadian SKF Company in January, its President and General Manager, Mr. Gordon Janes, was the recipient of congratulations from a host of friends throughout Canada.

On January 1st, 1917, the Canadian SKF Company opened a modest office in Toronto under the general management of Mr. Janes, who for several years prior to that time had been the anti-friction bearing specialist for Canadian Fairbanks-Morse Company. The need for speed and greater production, during the first great war, provided the stimulus to mechanical and electrical engineers' interest in the application of anti-friction bearings to their requirements, in place of old babbit type equipment.

Now, of course, owing to their demonstrated reliability and efficiency, the use of anti-friction bearings is almost universal. They are standard equipment in automobiles, all types of industrial machinery, electric motors, pulp and paper machines, locomotives, freight and passenger cars and all other equipment where anti-friction bearings are practical.

The success of the Canadian SKF Company under the direction of Mr. Gordon Janes, who has been President of the Company since 1934, may be gathered from the fact that, from an original sales and office staff of three people in 1917, the organization now totals eighty. Sales and service offices are maintained in principal cities. Sales in Canada today are seventy times greater than they were in 1917. There are two reasons for this phenomenal growth of business; the remarkable efficiency of SKF bearings, and the twenty-five years of consistent educational publicity and engineering sales effort.

Thus, it may be said that the history of the ball and roller bearing industry has paralleled the Dominion-wide activities of the Canadian SKF Company.

Today the symbol SKF has become synonymous with anti-friction bearings not only in Canada but throughout the world. For the

duration of the war, SKF bearings are on a priority basis. Ninety per cent of the available supply is being used in the priority brackets A-1-a to A-10; about 50 per cent coming in the A-1-a to A-1-c classes.

Mr. Gordon Janes and his associates are justly proud of the results achieved during the past twenty-five years; and particularly of the part their organization is playing in Canada's war effort.

## TRAFFIC OVERPASS

A four-page booklet, published by R. G. LeTourneau Inc., Peoria, Ill., describes and illustrates the company's newly developed overpass, designated as Tournapass. The Tournapass is a portable low-cost overpass designed to eliminate traffic congestion at busy intersections. Photographs, actual time studies and car counts taken at a recent demonstration and trial period are featured and transportation, assembly and construction are explained.

## PIPE AND JOINT COMPOUND

LaSalle Products Limited, Montreal, Que., are distributing a leaflet which contains descriptive information and directions for the use of X-Pando, a pipe joint compound consisting of certain oxides and minerals which, when mixed with cold water and allowed to set, expands slightly and hardens. It is used to repair sand holes or cracks in pipes, castings, etc.

## POWER SUPPLIES

Burlee Limited, Toronto, Ont., have issued a four-page bulletin featuring a variety of equipment, portable and stationary, including engine-generator sets, motor-generator sets, converters, etc., with illustrations of various types.

## STAINLESS-CLAD STEEL

Base prices for sheets and plates of Silver-Ply stainless-clad steel for twelve grades of cladding in proportionate thicknesses of cladding from 5 to 50 per cent. are contained in a 16-page price list issued by Jessop Steel Co. Ltd., Toronto, Ont. A section on standard classification of extras for plates includes tables on machining, shearing and flatness tolerances, estimated weights, and size limits for standard production plates and sheets. The last section contains prices for forming standard or A.S.M.E.A.P.I. flanged and dished heads, elliptical dished heads and machining heads.

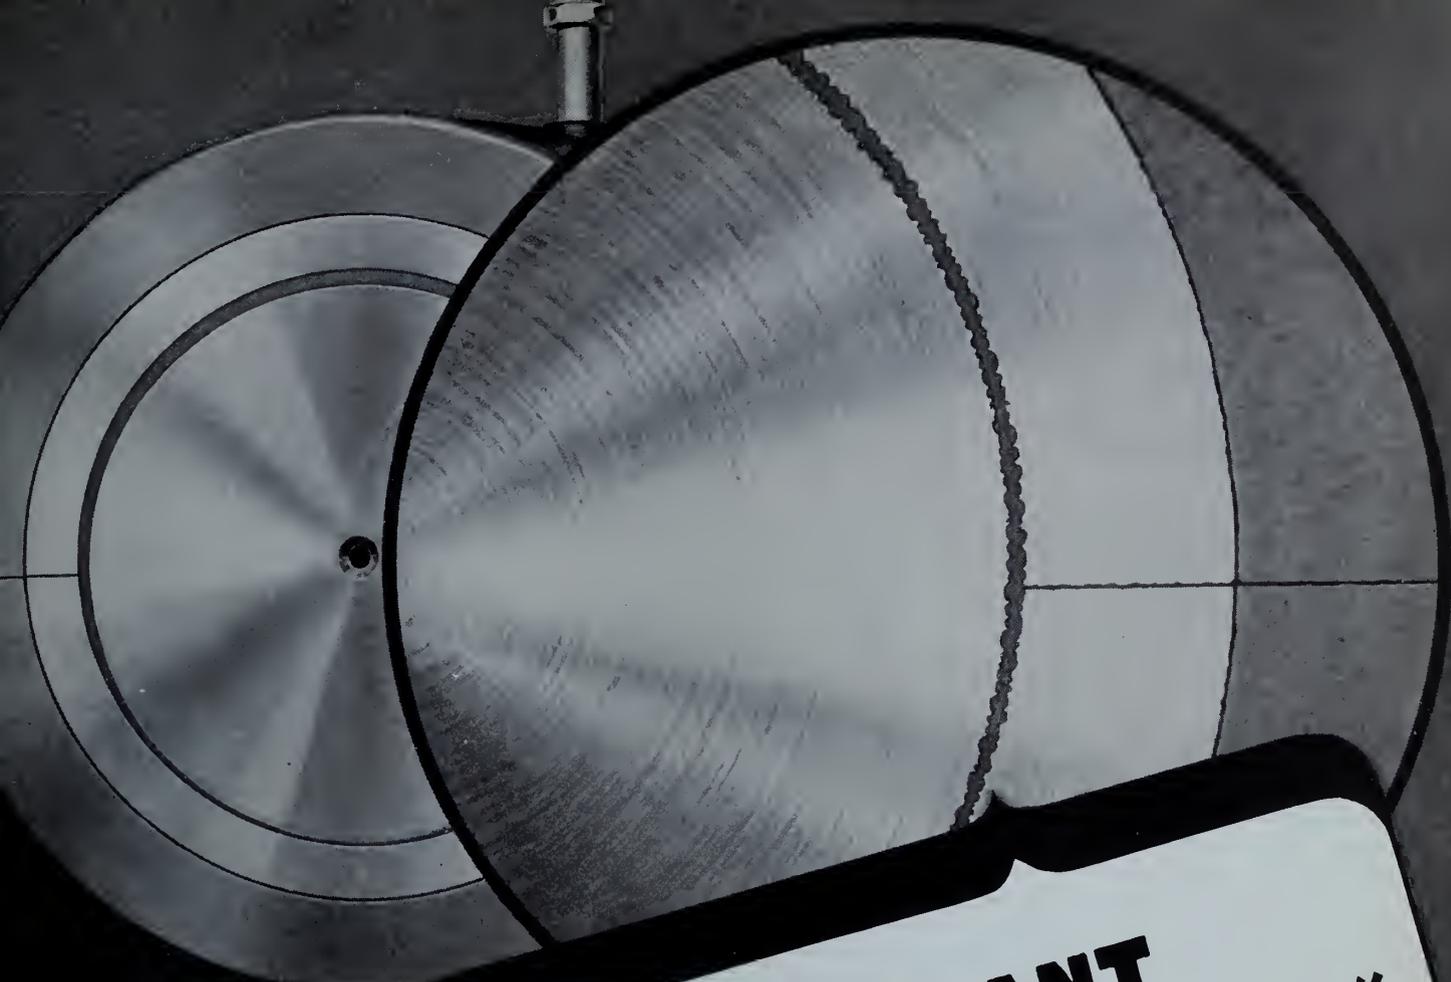

## STEAM TURBINES

Moore Steam Turbine Div., Worthington Pump & Machinery Corp., of Harrison, N.J., have published bulletin No. 1951, featuring types GA and GB of the Moore steam turbines. Combined reduction gears are also featured with sectional drawings and illustrations of all important parts. A dimensional drawing is included with photograph and typical installations.

## TRAINING FOR LEADERSHIP IN INDUSTRY

This booklet, published by Canadian General Electric Co. Ltd., Toronto, Ont., has been prepared for electrical and mechanical engineering graduates of Canadian colleges and is intended to give them a brief survey of the field which they are entering pointing to the opportunities now existing and those being created for the future. It contains a description of the student courses operated by the company with a list of the lectures given and a chart entitled "Experience and Advancement Programme." A large number of illustrations is included showing the company's works. The booklet has 20 pages and is designated as No. 4169A.

(Continued on page 32)

**GARGOYLE  
LUBRICANTS STAND OUT  
AND STAND UP!**

**Cylinder Oil**  
famous for its  
10-year ability  
to maintain a tough,  
oil film on piston  
cylinder walls.

**D.T.E. Oils**  
specially made  
to stand up under  
heat, pressure  
and vibration.

**Voco Engine**  
oil resists wear,  
repels acids; repels  
dirt; efficient in  
both hot and cold.

**Gargoyle D.T.E. Oils**—  
stand up under heat  
and pressure; have un-  
usually long life; are  
used in more than 51%  
of America's major-  
sized steam turbines.

**Gargoyle Vacuoline Oils**  
—combine lubricity and  
stability for circulation-  
oiled machines.

**Gargoyle special oils  
and greases for every  
industrial operation.**

**IN YOUR PLANT  
a "secret weapon"**

Smooth as glass to the naked  
eye—the polished surface of  
a bearing shows its ugly,  
jagged "teeth" under the  
microscope. That's why, in  
all machinery, a film of oil  
must keep moving metal  
surfaces apart.

The oil film must be *tough*  
enough to stand heat and  
pressure—yet *light enough* to  
keep down "drag" and save  
power. Just any oil won't  
do. In Canada's war produc-

tion, nothing must be left to  
guesswork.

If you want to be *sure* of  
your lubrication you'll be  
wise to rely on Gargoyle  
Lubricants. More than 76  
years of experience and more  
than half a million "case  
histories" have taught the  
makers of Gargoyle Lubri-  
cants how to produce an oil  
or grease that does exactly  
what it's supposed to do—  
*without fail.*

Sold throughout Canada and Newfoundland by Imperial Oil Limited

*For Correct  
Lubrication use*

**GARGOYLE LUBRICANTS**

Gargoyle Industrial and Marine Lubricants are made by the makers of Mobiloil,  
the world's quality motor oil.

# I.C.S.

## SPECIALIZED TRAINING

FOR

### THE ENGINEERING PROFESSION

International Correspondence Schools are equipped to provide the non-university man with the specialized training necessary to enable him to study for the examinations of engineering societies and associations. I.C.S. Home Study Courses are of particular interest to prospective applicants for membership in any of these organizations.

I.C.S. courses for examinations are arranged with the object of preparing the candidate for his examinations in the shortest possible time, while omitting no features of his training conducive to thoroughness and diversity of knowledge.

Each candidate will receive the individual attention of a vocational and educational specialist. The candidate's examination courses will be arranged to comply with his individual requirements and his rate of progress will be affected by no other student. He will proceed as rapidly as his ability, his study time and his application will permit. He will be allowed ample time to complete his I.C.S. course and will receive full answers to any questions he may need to ask which come within the scope of his course.

The subjects in which I.C.S. training is available include:

- High School Subjects
- Elementary Physics and Mechanics
- Strength and Elasticity of Metals
- Drawing
- Chemistry
- Chemical Engineering
- Civil Engineering
- Electrical Engineering
- Mechanical Engineering
- Mining Engineering
- Structural Engineering

AN INVITATION—You are invited to send for information about I.C.S. training. You incur no obligation. Just mark and mail the coupon.

International Correspondence Schools,  
Canadian Limited,  
Department H-2,  
Montreal, Canada.

Please send me complete information on I.C.S. training for engineering.

## Industrial News

(Continued from page 206)

### BURNDY CABLE LUG

Canadian Line Materials Ltd., Toronto, Ont., have issued a four-page bulletin for insertion in Burndy Catalogues Nos. 40 to 41. Gives numbers, sizes, cable ranges, weights and list prices, for "Versi" type Burndy lugs, links, tees, and taps. Each item is illustrated.

### CARBOLOY STANDARD TOOLS

Featuring ease of selection and prompt deliveries, the eight-page catalogue CGT-140 of Canadian General Electric Co. Ltd., Toronto, Ont., illustrates ten different styles of tools, each accompanied by dimensional drawings, tables of specifications and prices, and a series of drawings showing "typical adaptations you can quickly grind in these standard tools." A list of carboloy products is also given.

### DISCONNECTING SWITCHES

Through a series of illustrations, dimensional drawings, tables and descriptive matter, the G-E line of disconnecting switches for indoor and outdoor service with silver line-pressure contacts is thoroughly covered in a 28-page booklet CGEA-1907C recently published by Canadian General Electric Co. Ltd., Toronto, Ont.

### FLOOR TREATMENT UNIT

Flexrock Company, Toronto, Ont., are distributing a four-page bulletin entitled "Colorflex-Plus" which describes a new product for the dust proofing and preservation of wood or concrete floors and at the same time provides a lasting dye-like colouring which penetrates deeply into the floor.

### HOW TO MAKE TIRES LAST LONGER

In response to requests for authentic information on the subject, a booklet entitled "How to Make Your Tires Last Longer" has been compiled and issued by The Goodyear Tire & Rubber Co. Ltd., New Toronto, Ont. Dealing with driving speeds, checking tires, retreading, regrooving, and the vital necessity of saving tires, the booklet contains information of real importance to users of tires.

### MOTION PICTURES FOR ADVERTISING

"Showmanship at the Canadian National Exhibition," is the title of an eight-page booklet issued by Associated Screen News Ltd., Montreal, Que., giving a news-picture description of motion pictures at work. It presents a survey of different firms using motion pictures; tells what types of films are being used; what is the purpose behind the use of each; and what other forms of promotion are used to round out the motion picture campaign. The Canadian National Exhibition was the scene of the survey—probably the one spot in Canada where such a diversity of examples would be gathered together in one group.

### MOTORS AND CONTROL FOR PART-WINDING STARTING

Bulletin CGEA-3345, four pages, recently issued by Canadian General Electric Co. Ltd., Toronto, Ont., describes part-winding starting and sets forth the four advantages as: simplified control equipment, continuous circuit starting, low starting current, and multipoint increment control. The part-winding motor design and applications of the method are featured as is also the control equipment.

### NEW CANADIAN HEADQUARTERS

Mine Safety Appliances Co. of Canada Ltd., announce the opening of a new Canadian headquarters at 139 Kendal Ave., Toronto, Ont., where they have acquired a new building to conduct the manufacture and assembly of certain M.S.A. products, at the same time stocking all important items made by the parent company, Mine Safety Appliances Co., of Pittsburgh, Pa. The general manager of the Canadian company, Mr. R. Morris, who

was formerly in Montreal, will make his headquarters in Toronto. The company also operates district offices in Montreal, New Glasgow and Sydney, N.S.

### APPOINTED CANADIAN DISTRIBUTORS

Kahn, Bald & Laddon Ltd., Toronto, Ont., have been appointed Canadian distributors for the Gits Molding Corp., Chicago, Ill., manufacturers of a wide line of plastic gifts, games, novelties and specialties.

### MANUFACTURING STAFF PROMOTIONS

Building Products Ltd., Montreal, Que., have announced the promotions of a number of members of its manufacturing staff. C. E. Turner, Superintendent of the company's paper mill at Pont Rouge, Que., has been appointed Assistant General Manufacturing Manager. J. W. Church becomes Assistant Superintendent at the Pont Rouge Mill. L. J. Newton has been appointed Plant Engineer at the Pont Rouge Mill and W. A. Lawson becomes Assistant to Chief Engineer at Montreal. The company's officers are W. R. McNeil, President, C. P. Cowan and D. P. Hatch, Vice-Presidents and R. C. Crooker, Secretary-Treasurer.

### SNOW REMOVAL EQUIPMENT

LaPlant-Choate Mfg. Co. Inc., Cedar Rapids, Iowa, has issued an 8-page booklet, Form No. A-117-643, entitled "Win Against Winter!" Describes in detail the various models of snow plows for use with "Caterpillar" Diesel tractors. Illustrations show the various types of this equipment at work in the field.

### NEW HIGH TENSION LINES

The Shawinigan Water & Power Company has made application to the Quebec Public Service Board for authorization to proceed with the construction of new high tension lines between Three Rivers and Berthier and Sorel and Hemmings Falls, the project involving a total expenditure of \$1,600,000. It is proposed to commence construction of the Sorel-Hemmings Falls section in the spring and to have the entire programme complete early next fall. The lines will be constructed for 110,000 volts, but will be operated at 60,000 volts pending the installation of complete equipment.

### CARBON TOOL STEEL

Jessop Steel Co. Ltd., Toronto, Ont., is issuing an 8-page Bulletin, No. 741, which features the Jessop "Lion" carbon tool steel and provides descriptive technical data under the headings "Forging," "Annealing," "Hardening," "Tempering," "Applications" and "Tool Design."

### TORONTO PLANT EXTENDED

John Inglis Co. Ltd., of Toronto, is expending \$150,000 for a boiler-testing plant and a heat-treating and stress-relieving furnace in its commercial division. This work is now under way. It is also announced that a two-storey addition to the ordnance division is being erected, the building being of reinforced concrete and flat slab construction and 320 feet long. This will further increase the facilities of the Commercial Division of the Inglis Company which is devoted to the production of machinery for the marine, oil, power, paper, mining, steel, rubber and other basic industries.

### MEEHANITE CASTINGS IN DEFENSE WORK

Entitled "Meehanite Castings in Defense Work," a 12-page bulletin published by the Meehanite Research Institute of America Inc., Pittsburgh, Pa., describes and illustrates "Meehanite" castings used in aircraft manufacture, gun and shell manufacture, machine tool castings, and radio, marine, truck, and steel mill equipment.

# THE LIONS' GATE BRIDGE—I

S. R. BANKS, M.E.I.C.

General Engineering Department, Aluminum Company of Canada, Limited, Montreal, Que.

Awarded the Gzowski Medal\* for 1941

## INTRODUCTION

### GENERAL DESCRIPTION

The Lions' Gate Bridge crosses the first Narrows (popularly named the Lions' Gate on account of the proximity of the two coast-range mountains well-known as the Lions) of Burrard Inlet, at the entrance to the magnificent natural harbour of Vancouver, British Columbia. It satisfies the long-felt need for a more direct means of communication between the city of Vancouver (the population of which, the third largest city in Canada, is 247,000)\*\* on the south side of the Inlet and the rapidly-growing municipality of West Vancouver, together with parts of the city of North Vancouver, on the north shore (see fig. 1). Prior to the bridge construction which is the subject of this paper, all automobile traffic to West Vancouver, to North Vancouver, and to the various coastal resorts along the north shore as far as Howe Sound, had perforce either to make use of the ferry to North Vancouver or, by means of a long detour, to cross the Inlet by the Second Narrows Bridge, the latter service being frequently interrupted by the opening of the lift-span to shipping. The new bridge, the presence of which has already stimulated noticeably the growth of West Vancouver, is expected to play an important part in the residential development by British Pacific Properties Limited of their extensive Capilano Estates, which are commandingly situated on the southern slopes of Hollyburn Ridge. It may also be considered as a preliminary step towards rendering Garibaldi National Park (distant some 50 miles to the north of Vancouver) conveniently accessible by road, and as a general foreshadowing of considerable highway developments on the north shore of the Inlet.

Built, owned and maintained by private enterprise, the project was necessarily subject to the approval of those public authorities whose jurisdiction extends over the site of the bridge and of its ancillary works, and whose permission had to be received before any construction could be undertaken.

In the first place, the promoting company, The First Narrows Bridge Company Limited, is authorized and empowered by provincial statute (Statutes of British Columbia 1926-1927), the Provincial Government being interested in the bridge as an important link in its highway system. Maximum tolls were fixed by this authority, and the provision of a grade separation at the junction of the bridge road with Marine Drive was, at a later date, stipulated. Permission had also to be obtained for the bridge to cross over the presently disused right-of-way of the Pacific Great Eastern Railway.

Secondly, agreement had to be reached with the City of Vancouver regarding a roadway to connect the bridge with that city. Stanley Park, through which such a road must pass, is the property of the Dominion Government but is leased in perpetuity to the City of Vancouver for public park purposes. It is administered for the city by a Board of Park Commissioners, by whom its unique amenities have always been jealously guarded. The agreement between the owners and the City of Vancouver stipulated that the former should at their own expense build

and maintain a 30-ft. hard-surfaced road connecting the bridge-head with the Georgia-Street entrance to the Park, that roadway to be the property of the City. It was also required that the bridge-plans should be subject to the City's approval, and that the structure should be at all times properly maintained. In addition, it was stipulated that the City should have the right, at the end of a period of 50 years, to purchase the bridge in its entirety from the owners. The agreement was made in November 1933.

Finally, it was necessary to obtain general approval of the plans (particularly in regard to site, span, and clearance) under the provisions of the Navigable Waters Protection Act of Canada. That approval was granted by the Governor-General in Council in September 1936.

The setting of the bridge, at the narrowest part of the waterway, is one of outstanding natural beauty. On the south side of the Lions' Gate is the well-wooded peninsula of Stanley Park, terminating in the picturesque eminence of Prospect Point, and justly famous for its care-

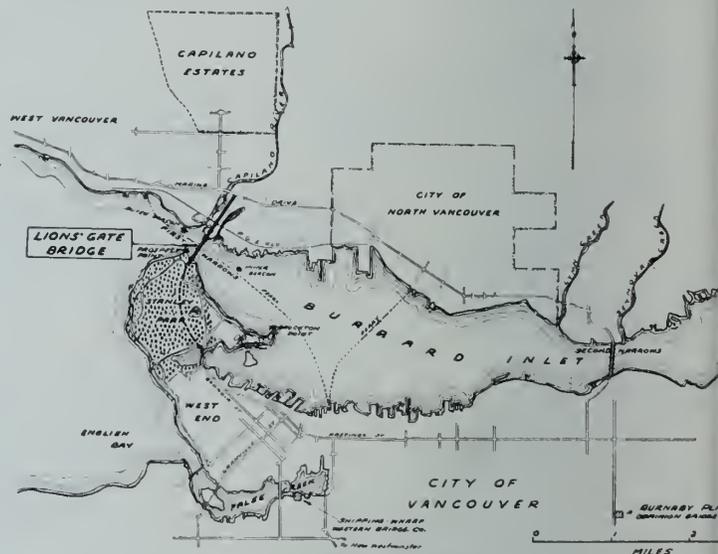

Fig. 1—Map of vicinity.

fully-preserved natural features. Along the north shore, beyond the salt marshes of the Capilano delta and the low-lying terrain of the Capilano Indian Reserve, the land rises within three or four miles to a mountain range of considerable grandeur. Eastwards the harbour, flanked by the waterfronts of Vancouver and North Vancouver, opens out to a width of nearly two miles; and seawards to the west there is an uninterrupted view over the Gulf of Georgia as far as Vancouver Island, some 45 miles away.

Connecting the high ground of Stanley Park a little to the east of Prospect Point with a point on Marine Drive, West Vancouver, a few hundred feet east of the Capilano River, the Lions' Gate Bridge bears in a straight line approximately 31 degrees east of north, the total length of the bridge-works proper being somewhat more than one mile. The distance across the Narrows on the line of the bridge varies from about 1,600 ft. at low water to perhaps as much as 2,200 ft. at extreme high tide, the corresponding tidal range being about 15 ft. Because of navigation hazards in the immediate vicinity of Prospect Point, and

\*The Gzowski Medal is a gold medal provided annually from a fund established in 1889 by Colonel Sir Casimir Gzowski, K.C.M.G., a past-president of the Institute. It is the Institute's senior award.

\*\*Canada Year Book (1931 census)

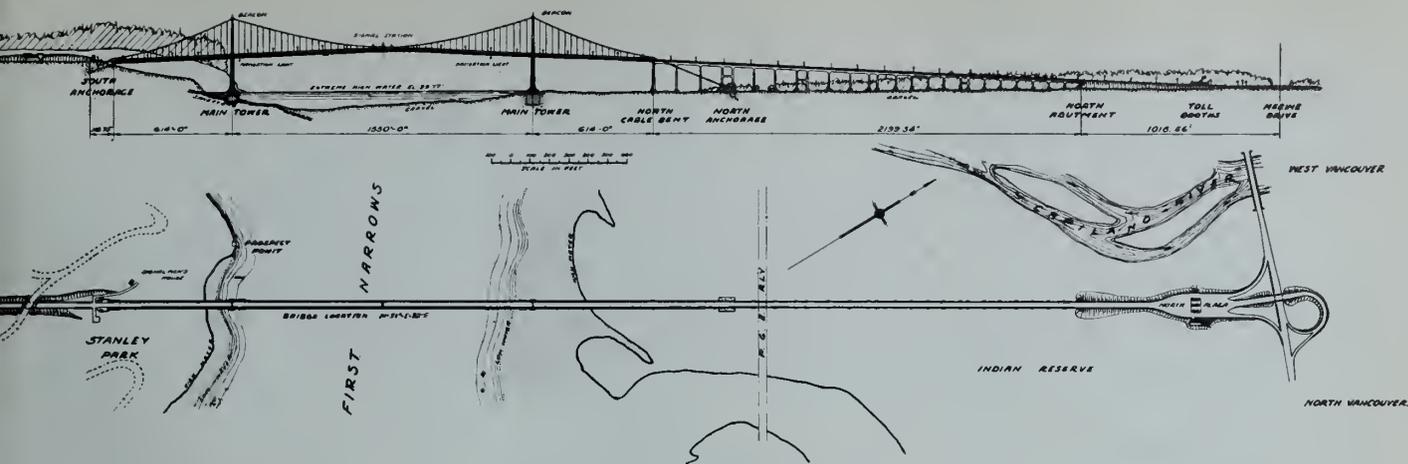

Fig. 2—General plan and elevation.

owing to the constant silting that takes place at the mouth of the Capilano, the navigable channel at present in use (although nominally 1,200 ft.) does not exceed about 1,000 ft. The main span of the Lions' Gate Bridge is of such a length, and the piers are so disposed, that the available channel width is now 1,500 ft—a width that in all probability will never be attained, on account of the enormous dredging programme that would be needed to maintain as well as to establish such a channel. In this connection also, Sir Alexander Gibb, in a report made in 1934, stated that the channel width of the Thames at the busiest part of that river is 1,000 ft., and that the average density of traffic there is more than four times the maximum yet experienced through First Narrows.

The general profile of the bridge, shown in Fig. 2, is dictated by the Dominion Government's requirements regarding the navigation clearance and the length of the main span over the waterway. A suspension bridge was the natural selection for this crossing on account of its intrinsic economy, its aesthetic superiority, and the fact that its erection would entail a minimum of interference with navigation on the busy waterway concerned. The order-in-council to which reference has already been made established the distance between centres of main piers at 1,550 ft., and stipulated a minimum underclearance of 200 ft. for a central fairway of 200 ft. The length of the central span being thus fixed, that of the two flanking side-spans was established provisionally by the distance between the fixed site of the south main pier and the most advantageous location for the anchorage on the Stanley Park hillside. Other factors, chief among which was the necessity for preserving a panel length and suspender spacing that would be adaptable also to the long centre span, led finally to the selection of 614 ft. as the optimum span length.

At the end of the south side-span, where the configuration of the hillside eliminates the need for any approach structure, the bridge roadway traverses an ornamental plaza (built on the upper surface of the large concrete cable-anchorage, which incidentally provides a bearing for the side-span trusses at about 160 ft. above high water), and connects with the new concrete approach highway which, passing in a long easy curve through Stanley Park, meets the western end of Georgia Street at a distance of about 1½ miles from the bridge head.

At the other end of the bridge the conditions are not as favourable. From the shore line to Marine Drive, a distance of about ¾ mile, the land is extremely flat, rising less than 30 ft. from high water level. Considerable approach works are therefore necessary to carry the roadway on a reasonable grade up to the end of the suspension bridge. The first part of these is an earth embankment some 1,000

ft. long, the connection with Marine Drive being made by a "fly-over" junction (to the cost of which the Provincial Government contributed). Situated some 150 ft. south of the convergence of the three roads of the modified "clover-leaf" is the eight-lane toll-collection plaza with four toll booths and a capacious office building. South of this again, the roadway narrows to its normal width, and the fill terminates in a concrete abutment wall which provides bearing for the first of the 25 spans of gradually-increasing length that constitute a 2,200-ft. steel viaduct. At the south end of the viaduct, a steel tower (or cable bent) carries the end-bearings both of the suspended side-span and of the highest of the approach-spans, and at the same time functions as a support for the main cables, which at this point are diverted to a steeper slope, leading downwards to the cable anchorage 388 ft. further to the north.

#### CAPACITY OF BRIDGE

The bridge carries a 29-ft. roadway and two 4-ft. sidewalks. The desirability of the latter provision was evident at once: but the establishment of the former figure as an economical and adequate width of roadway was the subject of much deliberation by all the parties concerned.

On the assumption that the population of Vancouver will be as much as two millions (with a per capita car registration of one in seven), before the bridge is relieved by additional facilities, and neglecting all assistance from the Second Narrows Bridge, from the ferries, and from possible future airway developments, the required total capacity of the bridge was generously estimated as 16½ million vehicles per annum. Comparative traffic figures for a number of similarly-placed bridges and tunnels were adduced in support of this estimate, and two instances may be cited. In the case of the Jacques Cartier Bridge at Montreal (where the situation in regard to tourists and commuters is not dissimilar, and where car registration is about one in 11 persons, with a population of 1,100,000), the annual traffic (not including trucks and buses) is 1,900,000 autos per year. Again, the maximum year's traffic over the four-lane toll-free Manhattan Bridge, which carries the densest traffic of any New York bridge, has been 22 million vehicles; and the daily maximum 61,271 vehicles.

The maximum hourly capacity of a single unobstructed traffic lane has been found\* to be approximately 1,900 vehicles, travelling at a speed of 20 miles per hour, the average spacing of the vehicles being about 60 ft. The possible daily traffic flow (assuming 18 effective hours) of one lane is thus in the neighbourhood of 35,000 vehicles, or, roughly 10 million per year. From this view-

\*Regional Survey of Highway Traffic for New York and Environs.

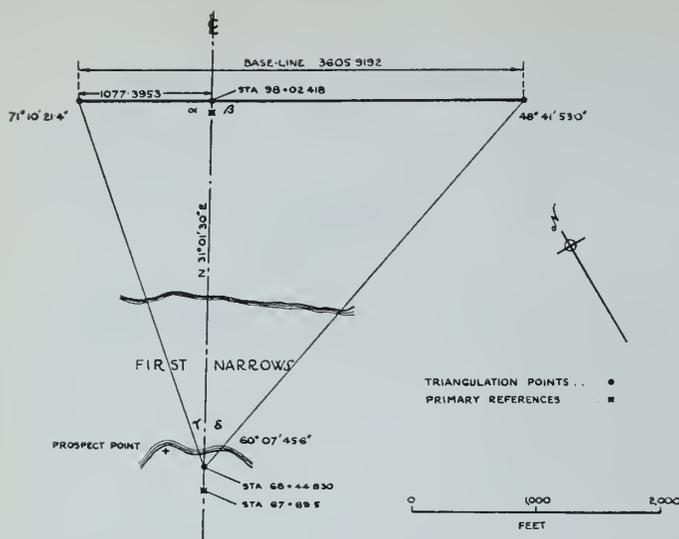

Fig. 3—Triangulation for pier-location.

point it could be argued that a two-lane roadway would provide the capacity required. The engineers, however, recommended the provision of a third lane in view of its value as a relief during short periods of unusually heavy traffic, and also on account of its contribution to the safety of the highway and to the appearance and stability of the structure. Arguments advanced against a three-lane roadway were countered by the fact that the bridge roadway differs from a city street or a country highway in that it is a straight way without any side-turnings, and more particularly in that no stopping is permissible: the road is under supervision over its full length, and obstruction of any part of the road is not likely.

The feasibility of providing a four-lane roadway was also considered, but it was decided that the additional expense involved could not be justified.

The fact that toll has to be collected from all vehicles using the bridge has also an important bearing on its traffic capacity; and, in spite of the provision of eight toll gates, toll taking is probably the governing factor in determining the actual traffic capacity of the bridge. From this point of view, a traffic flow of 1,900 vehicles per hour would mean that cars would be passing through the toll station at the rate of one in every 1.84 seconds. If as many as six toll-gates were in operation in one direction, the time for taking each toll would be 11 seconds. The actual time required for toll taking varies from about two seconds in the case of a commuter to as much as 30 seconds when change has to be given, so that it is probable that the single-lane traffic flow considered above will represent approximately the capacity of the toll station, although it should be possible to deal with a heavier flow for such limited periods as might require the use of two lanes in a single direction.

In the first year's operation of the Lions' Gate Bridge, a total of 1,028,827 vehicles passed over the structure, together with some 2,000,000 persons (including a very large number of pedestrians) apart from the drivers. The maximum week's traffic during the same period was 32,934 vehicles; and the maximum day's traffic (on the first Sunday of operation) was 5,616 vehicles. The largest number of vehicles to cross the bridge in one hour was estimated to have been 2,500. Since the opening of the bridge, the roadway has been divided into two lanes by a line painted on the pavement, and there is no prospect at present of the third lane being put into service as a separate traffic way.

#### THE SUSPENSION BRIDGE

The suspension bridge proper is of particular interest as the outstanding part of the structure, and also in that

it is the longest suspension bridge in the British Empire, or, indeed, outside of the United States of America. The three suspended spans (Fig. 2) have an aggregate length of 2,778 ft. The two cables are 40 ft. apart, 13¼ in. in diameter, and nearly 3,400 ft. in length. They are secured at either end by massive concrete anchorage piers, and each cable is supported by saddles at four intermediate points. Primary support is supplied by the two main towers, which are slender steel structures on granite-faced concrete piers, the main saddles being some 400 ft. above water-level. Secondary saddles are located at the ends of the side-spans, and from these the cables descend to the anchorages in the form of straight backstays.

The riveted stiffening trusses are of the through Warren type, and the batter of the tower legs is so arranged that the ends of the trusses are accommodated conveniently within the tower structure. The trusses are 15 ft. deep, and, hanging in the planes of the cables, are supported from the latter by two-part suspender ropes at 32-ft. 3-in. intervals. The bridge deck is carried on longitudinal stringers framing into floorbeams.

Expansion movements of the trusses and floor system occur at the main towers only, but the lateral system is articulated at each end of each span to permit of transverse wind deflections.

Two somewhat unusual features of the bridge are pedestrian observation platforms cantilevered outside the trusses at sidewalk level, and a marine signal station (replacing that previously situated on the top of Prospect Point) in the shape of a light steel cross-bridge over the roadway at the centre of the main span.

In the detailed description of the bridge works that follows, the subject is treated in its two natural subdivisions of substructure (piers, foundations, and earthworks) and metallic superstructure, the latter being considered under the respective headings of "design and fabrication," and "erection."

It will be noted that occasional reference throughout this paper is made to the Island of Orléans Bridge, Quebec. That suspension bridge,\* with a 1,056-ft. main span, was, prior to the construction here described, the longest in the Dominion. Though of less importance, it may to some extent be considered as the prototype of the Lions' Gate Bridge, and the engineers (as also the superstructure contractors) were considerably assisted by the experience gained in its design and construction.

### SUBSTRUCTURE

#### SURVEYS FOR LOCATION

Preliminary surveying of the site, carried out by Major W. G. Swan, M.E.I.C.,\*\* led to the definite location of the bridge in the position that finally received government approval. The centre line was identified by two hubs, one on either shore, and the position of the south main pier was fixed by a specified chainage from the south-shore hub: the reference of this latter (67+89.5) was accepted as the basis for all chainages.

With the foregoing information as a starting-point, the engineers laid out a base line along the disused P.G.E. right-of-way on the north shore, and on the south shore established a triangulation point (68+44.830) by direct measurement from the primary reference. The base line was measured with a calibrated 300-ft. tape, its length being found to be 3605.9192 ft.; of the several measurements made, none was at variance with that figure by more than 0.0068 ft. Similarly precise chainages tied in the centre line with the base line hubs. The survey (Fig 3) was made in the winter of 1936, and, owing to the

\*The Island of Orléans Bridge, designed by Messrs. Monsarrat & Pratley, has been described by the author (*Journal Inst. C.E.* October, 1936).

\*\*Major Swan was associated with Messrs. Monsarrat & Pratley as their Vancouver partner and representative.

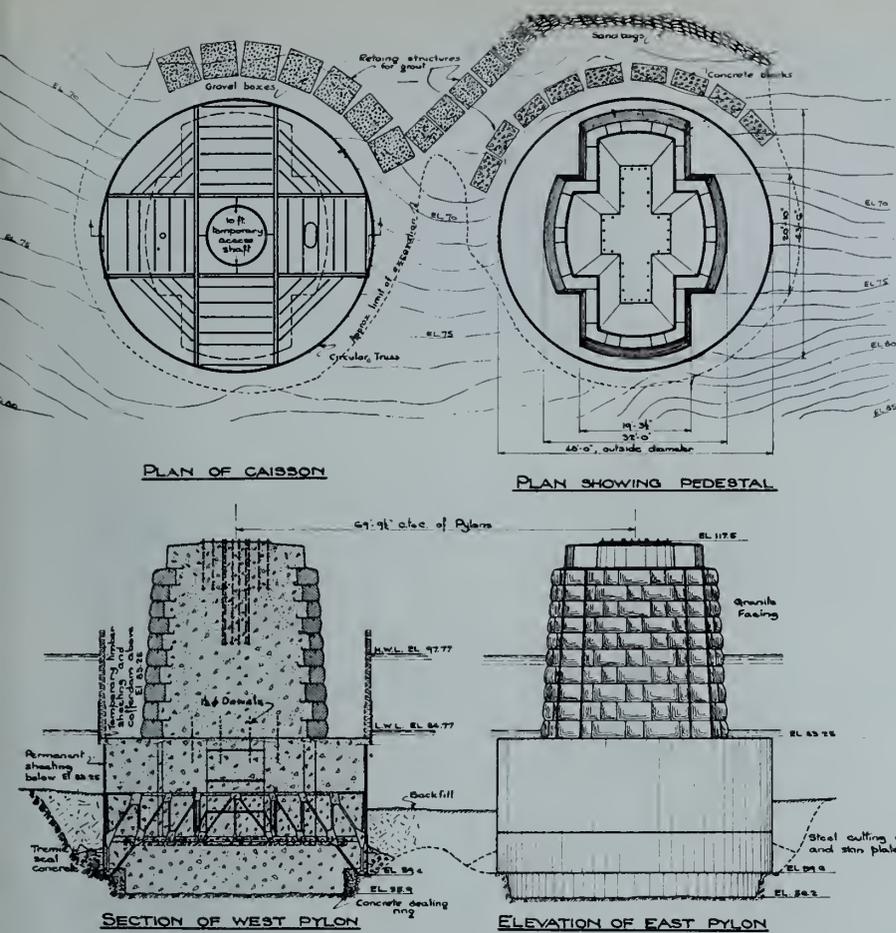

Fig. 4—South main pier.

prevalence of fog at that time of year, considerable difficulty was experienced in making the angular measurements involved. The final and acceptable series of readings was made with a Wild theodolite graduated to single seconds, and the resulting mean readings closed the primary triangle to 3.4 seconds of angle. The adjusted angles are shown in Fig. 3. As a check, the four secondary angles  $\alpha$ ,  $\beta$ ,  $\gamma$ ,  $\delta$  were measured and none of them was found to differ by more than 2.1 seconds from its computed value.

The north piers and viaduct pedestals were located by means of direct chainages from Sta. 98+02.418 (the intersection of the base line and the centre line), a 500-ft. tape being stretched over level crossheads erected at 50-ft. intervals. The location of each point was then carefully referenced by two hubs set on the edges of the right-of-way, out of the way of erection traffic.

Locations on the south shore were more troublesome, on account of the irregular slope of the hillside where the ground rises about 180 ft. in a distance of some 600 ft. Both the main pier and the anchor block were located by direct chainage. In the former case the tape was suspended over the bluff without intermediate support, and corrections for sag and slope (there was a difference in level of about 80 ft. in 130 ft.) were computed. The measurement was checked by running a traverse to the eastward of the line between the two points.

When the piers had been built, a further triangulation was performed by the superstructure contractor to check the relative positions of the two tower bases. A 1,920-ft. base line was laid on the north shore, extending eastward from the main pier approximately at right angles to the centre line of the bridge; and the contractor satisfied himself that the distance lay within  $\frac{3}{8}$  in. of the ideal dimension of 1,550 ft.

After erection of the south tower, a check measurement

of the south side-span length was made by means of a piano wire stretched at deck level, and this disclosed an error of about  $\frac{3}{4}$  in. in the 614-ft. chainage. The error is presumed to have occurred in the difficult measurement down the bluff. No other discrepancies were found.

#### SOUTH MAIN PIER

The south main pier is located about 150 ft. offshore, in a small coastal indentation. The swift (5 or 6 knots) tidal stream of the Narrows is so deflected by the buttress-like outcrop of Prospect Point as to induce a comparatively still backwater around the pier and, consequently, construction problems due to fast water did not arise. However, it was deemed expedient to provide protective rock-filled cribwork to the east and west of the site during the building of the pier.

The bed of the Narrows on this side consists of a soft coarse sandstone which extends some 400 ft. northwards before disappearing underneath a gravel deposit. At the site of the pier the surface of the rock, dipping northwards, lies at an average depth of about 15 ft. below low water level. This material, on exploration by borings to a depth of 40 ft. at the actual pier site, proved to be solid and of uniform consistency except for indications of a thin mud seam or fissure about 15 ft. below the rock surface and of uncertain extent. With such a dense and satisfactory foundation, it was practicable and economical to carry each of the pier shafts on a separate footing. The engineers' drawings therefore called for two rectangular caissons 36 ft. by 48 ft., equipped with steel cutting edges and pneumatic working-chambers. The contractor was later granted permission to substitute open circular caissons of 48-ft. diameter; but, on account of the probable presence of the above-mentioned mud seam, in conjunction with the engineers' insistence on a visual inspection of the bedrock before concreting, the compressed-air features were maintained as a precautionary measure (in case it was found impossible to unwater the working-chambers by pumping). The caissons were made up as shown in Fig. 4, the basis of construction being an 8-ft. circular steel truss supported by four light cross-trusses,

tions of a thin mud seam or fissure about 15 ft. below the rock surface and of uncertain extent. With such a dense and satisfactory foundation, it was practicable and economical to carry each of the pier shafts on a separate footing. The engineers' drawings therefore called for two rectangular caissons 36 ft. by 48 ft., equipped with steel cutting edges and pneumatic working-chambers. The contractor was later granted permission to substitute open circular caissons of 48-ft. diameter; but, on account of the probable presence of the above-mentioned mud seam, in conjunction with the engineers' insistence on a visual inspection of the bedrock before concreting, the compressed-air features were maintained as a precautionary measure (in case it was found impossible to unwater the working-chambers by pumping). The caissons were made up as shown in Fig. 4, the basis of construction being an 8-ft. circular steel truss supported by four light cross-trusses,

Fig. 5—South main pier: caisson-construction on shore.

Fig. 6—South main pier: sinking of caissons.

the lower flanges of which carry steel beams at the ceiling level of the working-chamber. The steel cutting-edge is 5 ft. below the ceiling slab, and the walls of the chamber are lined inside and outside with 3/16-in. plates, which were pierced at intervals to allow tidal water to run in and out during assembly.

The caissons were constructed on a temporary platform a few feet above low water level, and the concrete of the cutting-edge and of the 12-in. ceiling slab was poured before floating into position; and a shell of wood-sheathing of 3-in. planks was carried up some 24 ft. above ceiling level to prevent flooding during that operation (see Fig. 5). While the caissons were being prepared, the rock at the pier site was excavated to make a level landing at Elevation 60 for each cutting-edge. The rock was drilled and blasted from floating equipment, the broken material removed by dipper-dredge, and the bearing-areas then cleaned and trimmed by divers. The caissons were then floated out, and additional concrete was added to the ceiling slab and as a 12-in. wall inside the sheathing, the latter being extended (see Fig. 6) to maintain adequate freeboard. The caissons were sunk on to their beds within 3 in. and 4 in. respectively of their ideal positions, and were sealed to the rock by tremie-concrete placed outside the cutting-edges, this concrete being retained where necessary by a wall of concrete blocks, boxes of gravel, and sand bags on the outside, and by sacks of concrete placed inside.

During unwatering of the caissons, one "blow-in" occurred and was repaired without difficulty. Minor leakages were stopped by grouting, pipes for this purpose having been incorporated into the tremie-seal. A ring of concrete 2 ft. wide was then cast inside and below the cutting-edge to a depth of 3½ ft. The mud seam was revealed under the west caisson, and was entirely removed by complete excavation of the interior to the level of the bottom of the concrete ring, exposing a surface of solid rock at Elevation 56\*, which was tested by a further boring. In the east caisson the solidarity of the rock was proved by sinking a drill hole and test pit after excavation to the base of the concrete ring had been completed, no indication of any imperfection being discovered.

Upon approval of the foundation, each working-chamber was filled with concrete, after which the caisson was concreted solidly to Elevation 83.25, forming a base for the granite-faced pier shaft, which is keyed down by 40 steel dowels 1½ in. in diameter. The granite facing-blocks vary in depth from 2 to 3 ft., and are anchored to the concrete core with steel straps. The courses range in height from 3 ft. 2 in. at the base to 2 ft. 8 in. at the top of the shaft. The stones were all set in cement, vertical joints being grouted up as the work proceeded. The pier

shaft is cruciform in general plan, and terminates in a plain concrete cap or pedestal (4 ft. in depth and set back 2 ft. from the top of the battered granite walls), through the top of which, at Elevation 117.5, protrude the 32 anchor-bolts for the steel tower post. These bolts were set to a steel template and the actual tower seat was bush-hammered to dead level. Small "pilot" areas were prepared, checked, and painted, after which the general area was hammered down to their common elevation. This finished surface was checked by a 12-ft. steel straight-edge equipped with a sensitive level bubble.

The final operation in construction of the south main pier consisted in back-filling around the caisson base, with coarse gravel and stones up to "one-man" size, to the original rock level. The completed pier is shown in Fig. 7.

The handling of all material for the south main pier was effected by means of a timber stiff-leg derrick (100-ft. boom) set up on stone-filled cribwork just shoreward of the pier site. A mixing plant, with a 1½-yd. mixer, a weighing batcher, and suitable storage accommodation, was erected at the foot of the bluff for use in connection with this pier and the south anchorage pier.

Concrete for the cutting-edges, the roof slab of the working-chamber, and for all work on the pier shafts (as distinct from the footings) had a specified strength of 3,000 lb. per sq. in. at 28 days: the mix developed for this contained about 6½ sacks of cement to the cu. yd. The upper part of the footing is built of 2,500-lb. concrete. Seven-sack concrete was used for the tremie-seal, the concrete ring under the cutting edge, and the filling of the working-chambers and around the steel truss-work. To expedite the finishing of the dressed bearing-surfaces of the pier, a high-early-strength cement ("Ceberit") was used for the tops of the pedestals. All mixes were kept reasonably dry, with a slump generally of 3 in. or less (1½ in. for the pedestal tops), though a 6-in. slump was needed for concrete around the truss-work of the caissons. The concrete was vibrated wherever possible. Clean granitic aggregate of excellent quality, obtained from a gravel bank on the shore of Howe Sound, and washed, screened, and graded, was used throughout.

The bearing-pressure at the bases of the pier footings varies from about 4 tons per sq. ft. at high tide and with no live load to about 5.2 tons per sq. ft. under the worst loading conditions, at low water, the figures for the maximum case (for one footing) being as follow.

Pier		
Caisson steelwork . . . . .	95 kips	
Concrete in footing . . . . .	7,522	
Pedestal concrete . . . . .	3,570	
Reinforcing steel . . . . .	56	
Granite facing . . . . .	1,763	
		13,006 kips
Superstructure		
Main tower . . . . .	1,048 kips	
Cable reaction (D.C.T.)**	4,790	
		5,838 kips
Total . . . . .		18,844
Less buoyancy (at low tide) if any . . . . .		2,660
Net total . . . . .		16,184 kips

The base area being 1,810 sq. ft., the unit pressure is thus 10.4 kips, unless the underlying rock is pervious to water,

\*Vancouver Harbour Commissioners datum is referred to throughout this paper.

\*\*D.C.T. indicates the combination of dead load, 'congested' live load, and temperature (see Part II).

Fig. 7—South main pier: completed structure.

in which case the buoyancy reduces this figure to 9.1 kips.

Work on the south main pier was started on April 19th, 1937. Erection of the caissons began on July 5th, and the pier was ready to receive the tower shoes by January 14th, 1938.

#### SOUTH ANCHORAGE

At the south end of the bridge the land rises, steeply at first in the form of a bluff or cliff of very soft sandstone, and then by a more gradual grassy acclivity. At a point about 160 ft. above high water, the new approach road emerges from a cutting some 30 ft. deep through the stiff clay of the hill top, to pass directly over the upper surface of the south anchorage-pier. This pier, shown in Fig. 8, consists essentially of a concrete structure sufficiently heavy to resist the anchorage pull of the main cables, and shaped to take advantage of lateral support from the surrounding earth. The weight is concentrated towards the rear in order to minimize undue toe pressures from the overturning effect of the cable pull: and a heel block extends 12 ft. further into the ground than the remainder of the structure. The conformation of the terrain is such as to render unnecessary any approach structure, and the suspended side-span of the bridge takes its end-bearing on a pedestal at the front face of the anchorage: resting on the same pedestal block are the bases of the two rocker posts carrying cable saddles. While the actual anchor block, being mostly underground, has received no architectural treatment, the extent of its upper surface beyond the requirements for roadway and sidewalks is utilized as a foundation for the various structures pertaining to an ornamental plaza, the weight of this architectural concrete contributing incidentally to the stability of the pier.

The geology of the site presents a glacial deposit of clay containing coarse sand, gravel, and some boulders, the percentage of sand increasing somewhat at lower levels. This formation overlays the sandstone bed (which is gouged into basins by ice action) on which the main pier is founded by varying depths, 80 to 120 ft. of overburden being indicated by wash-borings made on and near the anchorage site. Before any excavation went forward, the findings from those six borings were considerably amplified by the sinking of a test-pit (4 ft. by 6 ft.) for a depth of 50 ft. on the actual site, and the above-described formation was found to extend for the full depth of the hole. The glacial deposit is hard and dense, weighing, in its natural damp state, about 150 lb. per cu. ft.; it resists infiltration of ground-water.

Construction began with the heel block, which took the form of an open cellular caisson with its outer walls poured directly in contact with undisturbed ground. Figure 9 shows the excavation with unsupported sides, for the first 18 ft.; it will be noted that pneumatic spades were needed to cut the material. When excavation had reached a depth of 24 ft., the caisson walls

were poured for that depth, after which excavation continued and the walls were extended downwards by successive 8-ft. pours. Before the 8-ft. sealing-slab at the base of the heel block was laid, 4-in. open-jointed tile drains were laid in a bed of crushed stone around its perimeter, and connected with an 8-in. cast-iron pipe leading to an outfall some 150 ft. away. In view of the impervious nature of the foundation, such drainage was deemed expedient to obviate the possibility of any hydrostatic uplift on the pier, and of any diminution of the friction coefficient due to lubrication.

The concrete of the caisson walls (seen in Fig. 10) and base slab is identified in Fig. 8 as concrete "A," and its placing was followed by the filling of the middle well (and small parts of the outer wells) of the caisson with concrete "B." The two outer wells, which are shaped to accommodate the splayed anchorage forgings, remained open to receive that steel at a later date, suitable openings for its admission being left in the north walls. Excavation for the bifurcated frontal mass of the pier then proceeded, the same policy of maintaining the ground undisturbed being followed. After the concrete "C" of this part of the pier had been placed, the cable anchorage steel was positioned in the outer wells, and incorporated into the pier inside the wedge-shaped concrete masses "E." The junction of this concrete with earlier pours was reinforced, in common with all other important bonding planes, by heavy dowels. Attention was then turned to the building of the pedestal block in front of the anchor pier proper. This, although in contact with the pier, is an independent structure, kept separate on account of possible differences in settlement due to its special loading conditions. Since the hillside falls away at the northeast corner of the site, the eastern side of the pedestal footing (concrete "D") was made correspondingly deeper than the western, and a quantity of backfill was placed about the footing. It may be noted here that the first intention (when the only data available was that from wash-borings) had been to provide added resistance to sliding by means of raking steel piles. In view of the actual soil conditions, however,

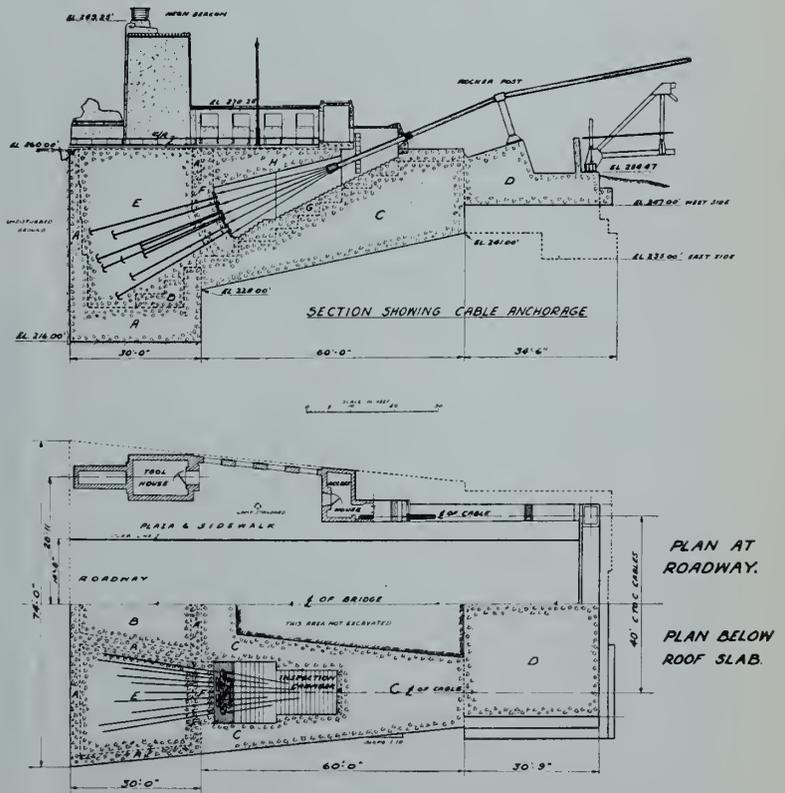

Fig. 8—South anchor-pier.

Fig. 9—South anchor-pier: excavation in stiff clay.

Fig. 10—South anchor-pier: completed walls of heel-block.

it was considered advisable to abandon the piling, and rather to preserve the foundation clay undisturbed. At the same time it became evident that the tougher nature of the soil (in conjunction with the absence of hydraulic effects from tidal water) would allow of the use of a lighter and more compact structure than that necessary on the north shore.

The front pedestal completed, the anchorage remained in its unfinished state, with the cable chambers exposed, until the cable assembly was sufficiently advanced to admit of the placing of concrete "F" behind the anchor buttons, followed by the roof slab "H" and the stairway treads "G." The resulting enclosed inspection chambers were found to be extremely damp during the winter months, owing to condensation, and fans and heaters were therefore installed.

When the "structural" part of the pier had been thus finished, the deck slab and plaza features (see Fig. 11) were taken in hand. These latter are identical in form on either side of the roadway, and are briefly described as follows. At the north end of the anchorage, the main cables each enter (through a battered front wall) into a low box-like structure which is built-on to a small building known as the "access-house," since it provides a means of communication with the inspection chamber that houses the splayed strands. The west access house is provided with toilet accommodation, and either house is available for use by toll-keepers when pedestrian tolls are taken at this end of the bridge. Towards the heel of the caisson are two ornamental pylons, giving architectural emphasis to the entrance to the bridge proper. These are two-storey structures (the spaces within being used for electrical equipment and tool storage), 10 ft. by 15 ft.

at the base and 26 ft. high; and at the top of each is set a specially-designed beacon or cresset, illuminated at night with a soft amber glow by means of concealed neon tubing. Connecting each pylon with the corresponding access house is a screen wall 8 ft. high, pierced with four window-like spaces to break the monotony of its 30-ft. length. Finally, close against the south walls of the pylons are two massive concrete lions, couchant on low pedestals, facing southwards into Stanley Park along the new approach road. A feature of the architectural work is the effective rough finish achieved by bush-hammering the major wall areas to a depth of about  $\frac{1}{4}$  in., thereby giving the work a texture more in harmony with the natural surroundings. The lions (which were pre-cast near the site in carefully-prepared plaster molds, using a high-cement mix with graded granite chippings of small size) received a surface treatment of strong hydrochloric acid, which had the satisfactory result of exposing the granite aggregate in the similitude of natural stone.

After completion of the bridge, the cutting and fill were neatly graded, and, under the direction of the Parks Board, planted with grass and ornamental shrubbery: so that the entrance to the bridge now constitutes one of the formal beauty spots of Stanley Park.

The south anchorage is 90 ft. in length (or 124 ft. inclusive of the front pedestal-block) with a width of 74 ft. at the heel and narrowing to the pedestal width of  $45\frac{1}{2}$  ft. in front. Some 7,290 cu. yds. of concrete are comprised in the structure, and its total weight, including the reinforcing steel (114 kips) and the bedded parts of the cable anchorage (133 kips) is about 15,080 tons.

In reference to the stability of the pier, sliding due to the horizontal part of the cable pull is resisted by the horizontal friction developed between the concrete and the clay foundation; and by positive horizontal bearing on the front pedestal, the battered sides of the bifurcated main structure and of the heel block, and the vertical northern face of the heel block. Assuming a coefficient of friction of 40 per cent, the resistance to sliding developed over the base areas only is just greater than the horizontal component of the cable pull; but when horizontal bearing is taken into account the factor of safety becomes about 1.5. The maximum toe pressure of the pier (occurring under the greatest cable pull) amounts to 4.62 kips per sq. ft. At the rear of the heel block, the greatest pressure took place during construction, before the cables had been assembled, and amounted to 6.51 kips per sq. ft. Under working conditions the heel pressure does not exceed 4.42 kips per sq. ft.

Work on the anchorage was commenced on April 29th,

Fig. 11—South plaza and general view from south.

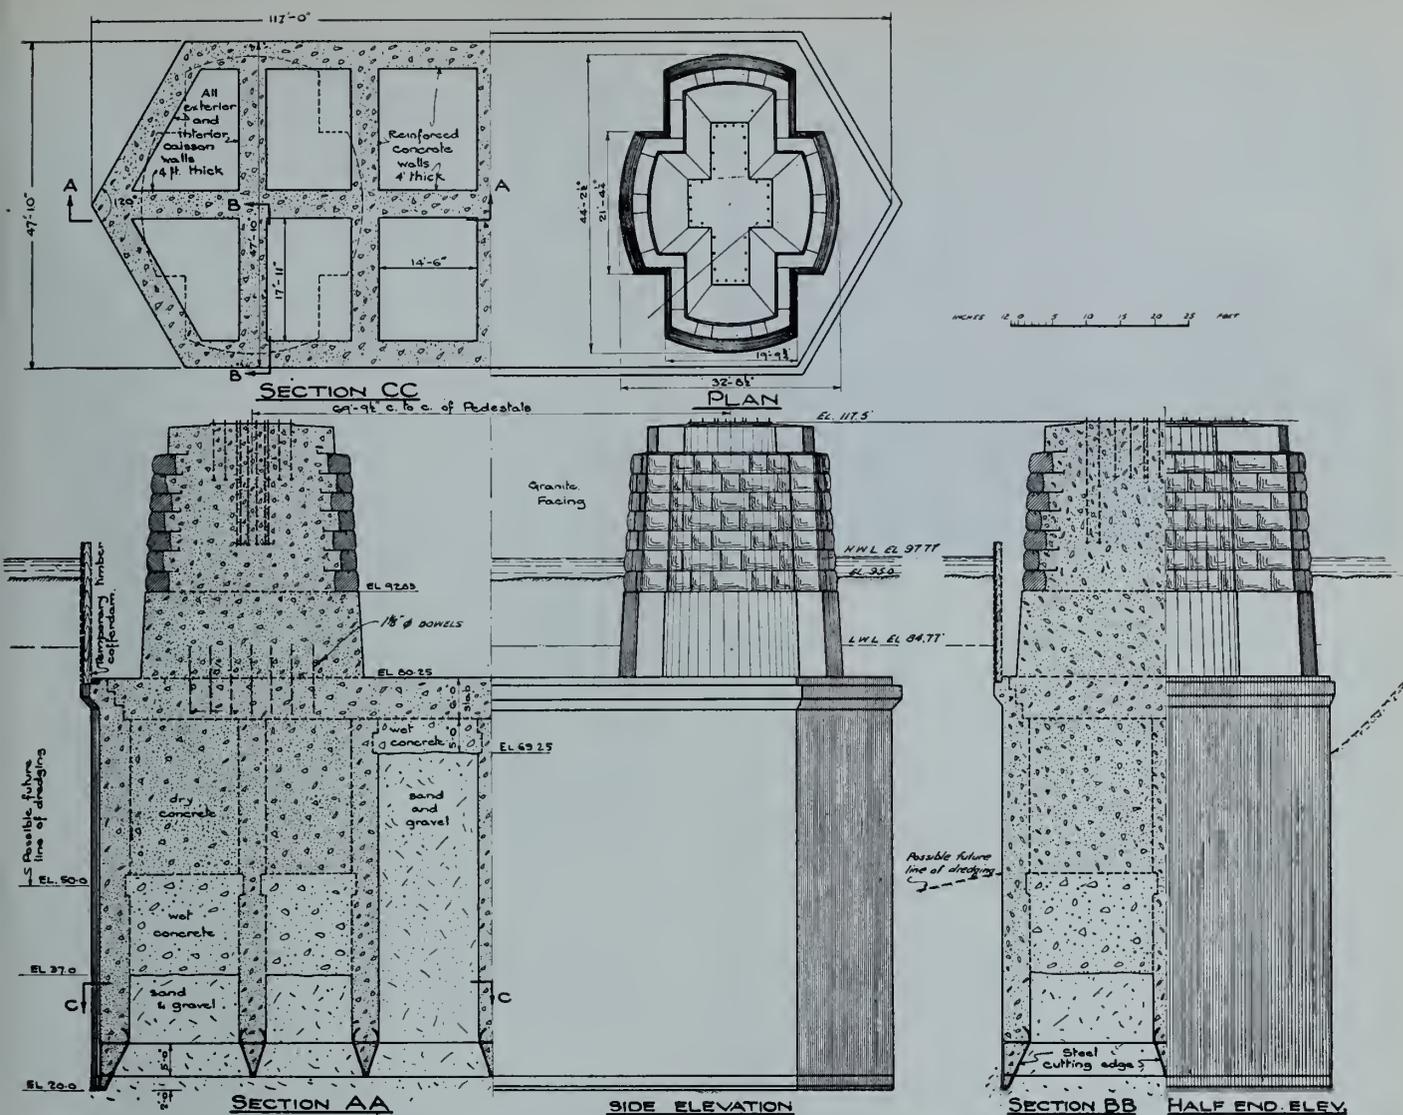

Fig. 12—North main pier.

1937, the excavation proper starting on July 19th of the same year, but the last details of the plaza were not completed until the end of January 1939, some three months after the opening of the bridge to traffic. Concrete for the main part of the pier was hauled from the mixing plant on an inclined railway which passed underground through the bluff at the lower part of the hillside. Later concrete, for the road slab and buildings, was brought ready-mixed from Vancouver. As for other parts of the substructure, a dry mix was always used, and vibrated into place. All concrete for the south anchorage was required to yield a strength of 2,500 pounds per sq. in. at 28 days.

#### NORTH MAIN PIER

The pier which carries the north main tower is situated on shore, above the level of all but high tides. The ground of the north shore is formed of a hard-packed coarse wet gravel, laid down as a deltaic deposit by the Capilano River. This gravel extends to a considerable depth, overlaying the sandstone on which the south main pier rests by about 300 ft., as is evidenced by borings made at the time of construction of Greater Vancouver Water District's pressure-tunnel under First Narrows. The depth and size of this pier were influenced by the extremely remote possibility that the gravel on its south side may be dredged away to Elevation 50 in an endeavour to extend the navigable channel. As the site is at present, scour is non-existent, and the pier is considerably deeper and heavier than is necessary for stability.

The pier footing consists of an open cellular caisson with outside dimensions of 48 ft. and 117 ft. (Fig. 12), the shape being adopted in view of the possible future dredging. The steel cutting-edges (forming the toes of the walls and the partitions, all of which are 4 ft. thick) were assembled on the site after this had been levelled-off at Elevation 92.5; and sinking of the caisson was begun as soon as the reinforced concrete incorporating the cutting-edges had been poured to a height of 7½ ft. The sinking process consisted of alternately dredging inside the pockets (by orange-peel buckets operated by two derricks mounted on piles) and building-up the walls (see Fig. 13) until the cutting-edge had penetrated to the designed level at Elevation 20. A temporary timber cofferdam was built on to the top of the peripheral wall for use during the last stages of sinking and for construction of the pier-shafts in the dry.

The caisson followed the excavation under its own weight for the first 50 ft., after which sinking was accomplished almost entirely by excavating below the cutting-edges and then destroying the skin-friction by the explosion of light charges inside the dredging-pockets, a total of about 200 lb. of 40-per-cent dynamite being used for this purpose. As a matter of incidental record, the skin friction when the caisson was within a few inches of its final set and entirely unsupported by the cutting-edges was computed to be about 450 lb. per sq. ft.; though there is no evidence that this friction would have maintained the pier in its otherwise unsupported condition in-

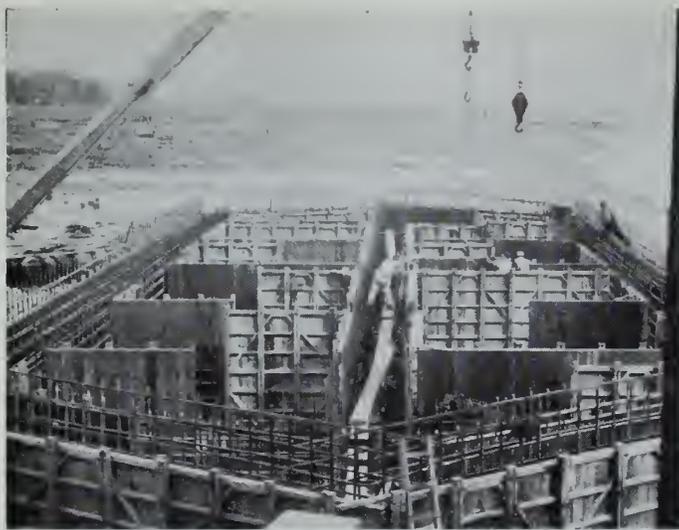

Fig. 13—North main pier; ready for wall-concrete

definitely. The sinking of the caisson occupied a period of three months (August to November 1937), at the end of which the cells were backfilled and concreted as shown in Fig. 12. The operation took place without incident beyond the appearance of several vertical hair-cracks at the top of the 7½-ft. wall, at the first sinking. This condition was rectified by the placing of extra longitudinal wall reinforcement at the bottom of the adjoining pour. The level of the caisson was readily maintained by regulation of the sequence of excavation of the various pockets in accordance with circumstances.

Upon unwatering the timber cofferdam, it was found that the upper 6-ft. rim of the caisson had cracked in a number of places. This top part of the wall, in order to accommodate a solid 6-ft. capping slab, was thinner than the main wall below and was unsupported by the cross-walls; and, since the cracking did not extend into the main wall, it was not considered to be of significance. The cracks were repaired by sealing on the inside with quick-setting cement, and the pier footing was completed by the pouring of the 6-ft. slab over all the pockets, its top surface being at Elevation 80.25.

The pier shafts differ from the south ones only in that they extend 3 ft. deeper and in that the ashlar facing, serving no useful purpose below shore level, is discontinued immediately below that elevation. The elevation of the precisely-dressed caps is 117.5.

Two strengths of concrete were specified. That for the cutting-edges, for the top slab of the footing, and for all work above the footing was required to develop a strength of 3,000 lb. per sq. in. at 28 days; while 2,500-lb. concrete was used for the caisson walls and for backfilling in the pockets. In order to expedite the work towards the end, the pier shafts were capped, as on the south main pier, with concrete containing high-early-strength cement. Slumps varied from 1½ in. for the shaft-tops to 3½ in. for the wall concrete and as much as 6 in. where the concrete had to be worked into the steel of the cutting-edges. Concrete was supplied from a mixing-plant (equipped with two one-yd. mixers with weighing-batchers and a controlled water supply) built nearby, and all material was placed by two timber derricks erected immediately north and south of the site.

Work went forward simultaneously with that on the south side, being started on April 9th, 1937 with the construction of plant. Erection of the cutting-edge began on July 5th, and the pier was finished on February 25th, 1938.

Bearing-pressure under the pier was at first concentrated largely on the cutting-edges. As settlement occurs,

however, owing to the compressibility of the backfill under the concrete plugs of the excavation chambers, the variable pressures at the level of the cutting-edge will tend to reduce to a general average load over the whole base plane; while simultaneously the bearing pressures underneath the concrete plugs of the dredging chambers will increase from a small initial quantity to their final value (which depends on the elevations of the plugs above the bottom of the footing).

From experience of this same gravel-bed at Second Narrows Bridge, six miles further up the Inlet, the engineers anticipated that, during the above-described adjustments of bearing pressures, the pier would settle approximately 1¼ in. over a period of two or three years, and that the greater part of this settlement would occur during the superstructure erection. The pier top was therefore dressed to an elevation higher than the theoretical by that amount. In Fig. 14 the progress of the settlement over the first year has been plotted. Subsequent indications are that the settlement, though rather more than was expected, is tapering off satisfactorily.

Figures for the final average pressure are as follows, the conditions for maximum effect (i.e. low water and greatest superstructure load) being taken. Loads are stated in kips.

Pier:			
Cutting-edge 90, Reinforcing steel 270...	360	kips	
Concrete .....	41,200		
Gravel backfill (wet) in pockets (122 lb./cu. ft.) .....	10,760		
Gravel backfill around pedestals .....	4,840		
Granite facing (170 lb./cu. ft.) .....	2,340		
			59,500 kips
Superstructure			
(D.C.T. as for south main pier) ....	11,670		
			71,170 kips
Total .....			
Less: Resistance from skin friction (on footing only) at 400 lb./sq. ft. ....	6,990		
Buoyancy at low water	19,980		26,970
			44,200 kips
Net total .....			

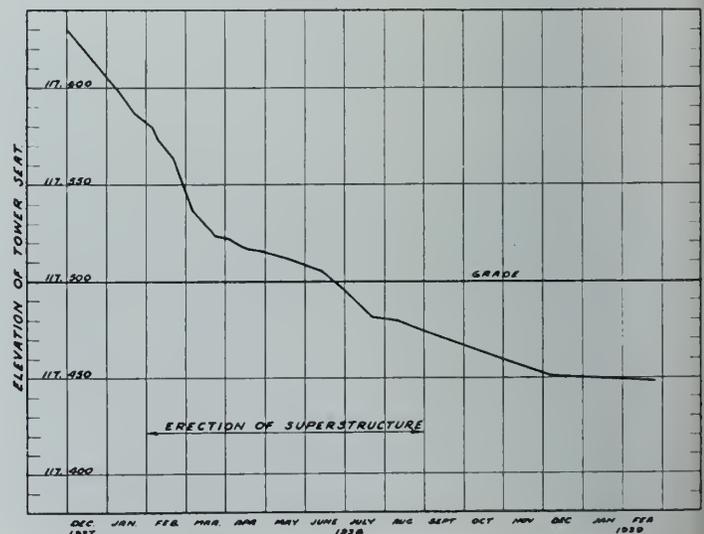

Fig. 14—North main pier; progress of settlement.

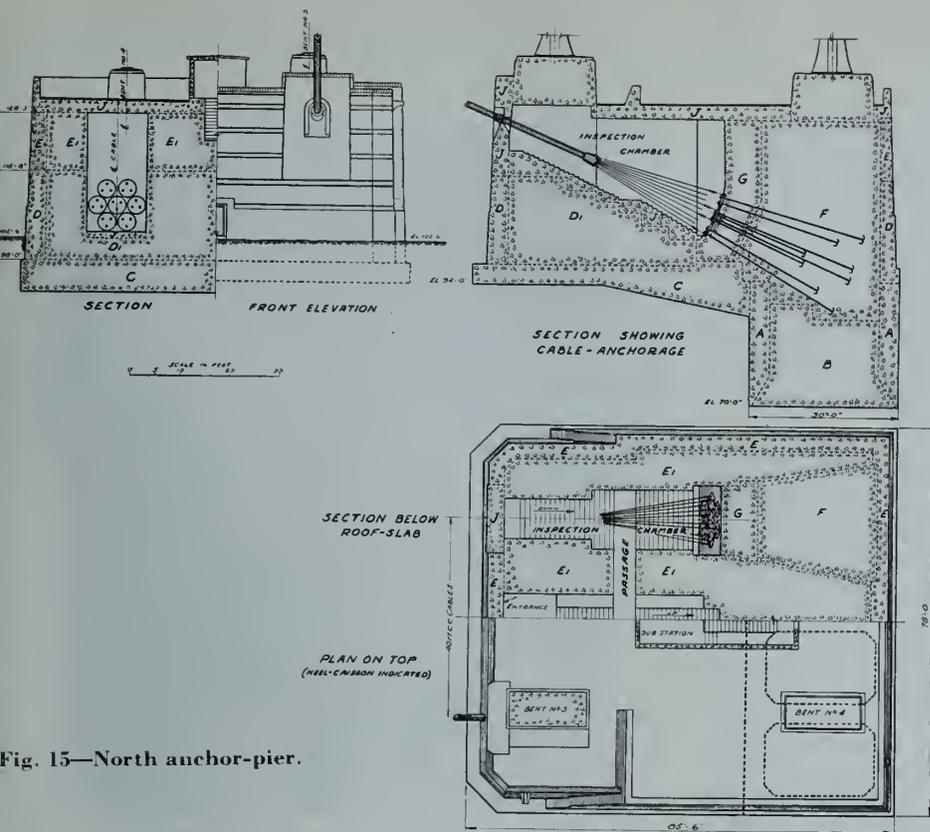

Fig. 15—North anchor-pier.

The base area of the caisson being 4,936 sq. ft., this gives an average bearing pressure over the horizontal plane at Elevation 20 of 9.0 kips per sq. ft.

At the same time, the natural pressure of the gravel on the same plane is made up as follows, figures being in pounds per square foot.

From 11 ft. of "dry" gravel above low water level, 11 x 100 .....	= 1,100
From 64 ft. of wet gravel (with approximately 40% voids) below low water level, with allowance for buoyancy of same, 64 (122 - 64) .....	= 3,712
	4,812

The ultimate "punching" pressure over the area of the base plane is thus 4.2 kips per sq. ft.

#### NORTH ANCHORAGE

Conditions on the north shore, together with the fact that a large structure above ground would not be objectionable (there being no prospect of any development of the low-lying marshy terrain of the delta) led to the choice of a simple gravity-type of anchor-block at this end. The pier is positioned so that it is utilized to support one of the viaduct towers (thus reducing the tonnage of steel in the viaduct and also employing some of its weight as kentledge), while at the same time the slope of the backstay of the main cable is very close to the optimum for economy. The pier is shown in Fig. 15.

Basically, the pier consists of a heavy concrete box containing an anchorage for the main cables together with suitable inspection chambers and means of access. The pedestals for two of the viaduct bents, and also a sub-station whence the electric supply for the bridge is distributed, are carried on the flat roof, which is surrounded by an ornamental parapet wall 4 ft. high. The exterior of the pier is treated architecturally (see Fig. 16), the

dominating features being the provision of a pronounced set-back in each side wall normal to the direction of the cable, and the interruption of the large vertical concrete faces with horizontal rustications. The tops of the parapet walls have a fluted finish, pre-cast gargoyles are provided to throw the roof drainage clear of the walls, and arched niches are employed at the points of egress of the cables. Access to the pier is provided by a door at the bottom of the front face, and a stair connects with the cable-inspection chambers and with the pent-house sub-station, where a door leads out onto the roof. Communication with the viaduct deck may be made by a ladder running up the side of one of the bents. The inspection chambers are ventilated by concrete grilles set low down in the side walls.

At the rear of the pier, and extending over the full 78-ft. width of the structure, is a heel block 30 ft. wide and sunk 24 ft. deeper than the general base of the "box." This was provided in order to concentrate dead weight where it is needed, and also to present a positive resistance to

sliding. Construction began with the laying-down of the cutting edge of a four-pocket open caisson for the heel block. The steel-shod shoes were filled with 3,000-lb. concrete, while 2,500-lb. concrete was used for the caisson walls (denoted by the letter "A" in the figure) and for all other work in this pier. No difficulty was encountered in sinking the caisson, after which the cells (the walls having been roughened to provide maximum bond) were sealed with tremie-concrete to a depth of 12 ft. and built up to the shape denoted by "B." Excavation for the base slab in front of the heel then went forward and this slab "C" was the next to be poured. The outside walls "D" were then built to a construction plane at Elevation 115.67, after which the large mass of concrete "D<sub>1</sub>" was deposited, leaving cavities for the wedge-shaped masses incorporating the anchorage-steel. Then followed walls "E" to the elevation of the bottom of the roof-slab, and the remaining mass-concrete "E<sub>1</sub>" around the anchor cavities. At this stage, the superstructure contractor assembled the cable anchorages, which were then concreted in: the anchor masses "F" each contain about 670 cu. yd. of concrete. Pedestals for the viaduct were then built, those for Bent 3 being carried on shallow concrete beams over the cable chambers. During the building of the pier, all construction joints were thoroughly cleaned of laitance

Fig. 16—North anchor-pier: architectural treatment.

and roughened, important bonding surfaces being heavily reinforced. Vertical wall joints were sealed with copper water stops.

The pier remained in the unfinished state described (i.e. with the roof slab and parapet walls and the upper part of the front wall missing: see Fig. 17) during the assembly of the main cables, the anchorage chambers being open to facilitate unreeling of the strands and assembly of the sockets.

After the cables had taken up their final normal position and the backstays had been wrapped, construction was completed with concrete work "J," which comprises the waterproofed roof slab, parapets, the concrete around the cable entrances, the sub-station, and the stairways. The ground around the pier was backfilled to Elevation 102.5.

Calculations concerning stability were made for all stages of construction, the pours of concrete being so arranged chronologically as to obviate the occurrence of unduly large bearing pressures and dangerous sliding conditions. Sliding resistance was computed separately for the two horizontal bottom surfaces, for the vertical front of the heel block, and for the inclined base of the central slab, the angle of friction of the gravel being taken as  $\tan^{-1}.40$ . The greatest tendency to sliding occurs at high tide, with lateral wind (but no live load) on the approach bents and with maximum cable pull, and for this condition the horizontal component of cable tension is 11,556 kips, while the resistance of the pier to sliding is computed as 24,902 kips. The maximum toe pressure under the pier occurs also with the greatest cable pull, but at low tide and with both live load and wind on the viaduct, and is 6.08 kips per sq. ft. The maximum under the rear edge of the heel caisson took place during construction, immediately before assembly of the cables, and amounted to 7.65 kips per sq. ft. Under working conditions the heel pressure does not exceed 5.40 kips per sq. ft.

The amount of concrete in the pier is about 9,780 cu. yd.; and its total weight, including cutting-edge (13 kips), reinforcing steel (219 kips), and cable anchorage assembly (134 kips), but not including the electrical substation and equipment, amounts to approximately 20,250 tons.

Construction of the pier began on July 6th, 1937, and

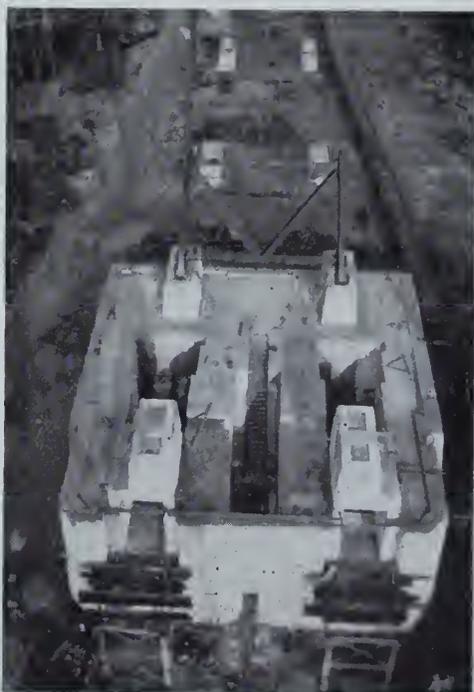

Fig. 17—North anchor-pier; ready for erection of cables.

Fig. 18—Pedestals for north viaduct.

it was ready to receive the anchorage steel in November of that year. The final pour of concrete was made on November 4th, 1938. All concrete was supplied from the mixing-plant near the main pier.

#### VIADUCT SUBSTRUCTURE

The girder-spans of the north viaduct are supported (see Fig. 2) on 24 steel bents, a concrete abutment at the north end, and the cable bent at the end of the side-span. There are twenty-five pairs of concrete pedestals, those which carry Bents 3 and 4 forming part of the anchorage pier, and the remaining 46 being founded on the gravel formation that has already been described. The pedestals have appropriate spread footings which are taken to a depth that depended on the local conditions in each instance. For the footings, 2,000-lb. concrete was specified, and 2,500-lb. concrete for the shafts. The maximum bearing pressure does not exceed 2.6 tons per sq. ft. except in the cases of the most northerly bent (where, owing to the stiffness of the short column, the pressure may attain an extreme value of 3.7 tons per sq. ft.) and of the heavy cable bent (where cable pull and side-winds render 5.6 tons per sq. ft. possible, under the deeper western footing). Anchor-bolts for the steel were set into the concrete, but the bearing surface of the pedestal was not dressed to elevation except for a small central area. On either side of this bush-hammered portion were left 6-in. recesses that were grouted up to the base plates after the bents had been plumbed. In the way of aesthetic treatment, the sides of the pedestals are battered at a slope of 1 in 16, and the upper 8 in. of the sides are set back 3 in., the 8-in. face being painted with black asphaltic paint. A general view of the viaduct pedestals is to be seen in Fig. 18.

The abutment, at the south end of the embankment, consists of a base slab 57 ft. by 20 ft. and 3 ft. thick, on which are carried four columns in the form of longitudinal counterforts (Fig. 19). The two principal columns at 22-ft. centres support the bridge seats, and the two outer columns at 50-ft. centres support the ends of the breast

Fig. 19—Open abutment at north end of viaduct.

wall. This vertical wall is 18 in. thick and 12 ft. deep, suitably reinforced, and serves to retain the fill above a point about 2 ft. below the elevation of the bridge-seats, the remaining depth of the fill being allowed to spill around and through the abutment: the top of the wall is shaped to the profile of the roadway. The height of the abutment from grade to footing is about 40 ft., this figure deriving from study of the comparative costs of embankment and steelwork, and of the permissible weight and lateral extent of the former.

About 3,400 cu. yd. of concrete were required for the pedestals and abutment. This part of the job, including excavation, proceeded concurrently with that of the remainder of the substructure, being started in April 1937 and completed in time to receive the steelwork in November of the same year. No frost was experienced during construction or in the period of curing. Concrete was supplied from the mixer at the north main pier, and distributed by truck.

#### NORTH EMBANKMENT

As may be seen from Fig. 2, the length of the main embankment, extending from the end of steel to the south abutment of the Marine Drive overpass, is approximately 1,000 ft.

For descriptive purposes, it may conveniently be divided into three parts. Over the first section, extending some 340 ft. northward, the roadway continues downward at the grade of the viaduct, and retains its normal 37-ft. overall width. The next section, extending (with a length of 400 ft.) as far as the division of the road into the three traffic ways comprising the junction with Marine Drive, carries the eight-lane toll-collection plaza. A 100-ft. vertical curve reduces the gradient to 0.25 per cent and, in a distance of 220 ft., the roadway widens to the full plaza width of 109 ft. between kerbs, this width being maintained for the remaining 180 ft. of the section (see Fig. 20). Drainage over the plaza is effected by a four-inch parabolic roadway crown,\* assisted by the slight longitudinal gradient; catch-basins and

\*This 4-in. parabolic crown has proved insufficient, the crest of the road being too flat for efficient drainage.

drains are provided. The toll station itself (Fig. 21) consists of three double-lane toll booths, and one single-lane booth on the west side of the road. On the east side stands the administration building which, together with its garage accommodation, covers an area of 31 ft. by 82 ft. The three main toll booths each consist of a small enclosed, heated, concrete building mounted on a concrete "island" 47 ft. long and 9 ft. in maximum width, tapering nearly to a point at each end, where a concrete protection post is set up. The kerbs of these islands are four inches high for the greater part of their length, but increase in height towards the ends to give protection to the booths proper. The two traffic ways between the main booths are sheltered by a common canopy of concrete; but the outer ones, in order to admit high truck loads, are uncovered.

A covered service-trench (for electrical conduits, steam pipes, etc.) connects the series of booths with the administration building; and cavities, covered by removable slabs, have been left in the roadway to permit of the future installation of electro-mechanical traffic-registering gear should the use of such become advisable. The administration building is equipped with water supply, and a septic tank is provided for disposal of the sewage effluent.

The third section of the fill consists of foundations for three diverging roadways. The westerly side-road, forming the inlet from West Vancouver and the popular Whitecliff highway, is 24 ft. in width. That on the east side, being the comparatively little-used outlet towards North Vancouver, is 13 ft. wide as built, but may be broadened in case of necessity. These two outer roads lead directly into Marine Drive on gentle downward gradients. The central road, leading from the plaza on an up-grade of 3.6 per cent, is 24 ft. wide, accommodating traffic both from the east (North Vancouver) and to the

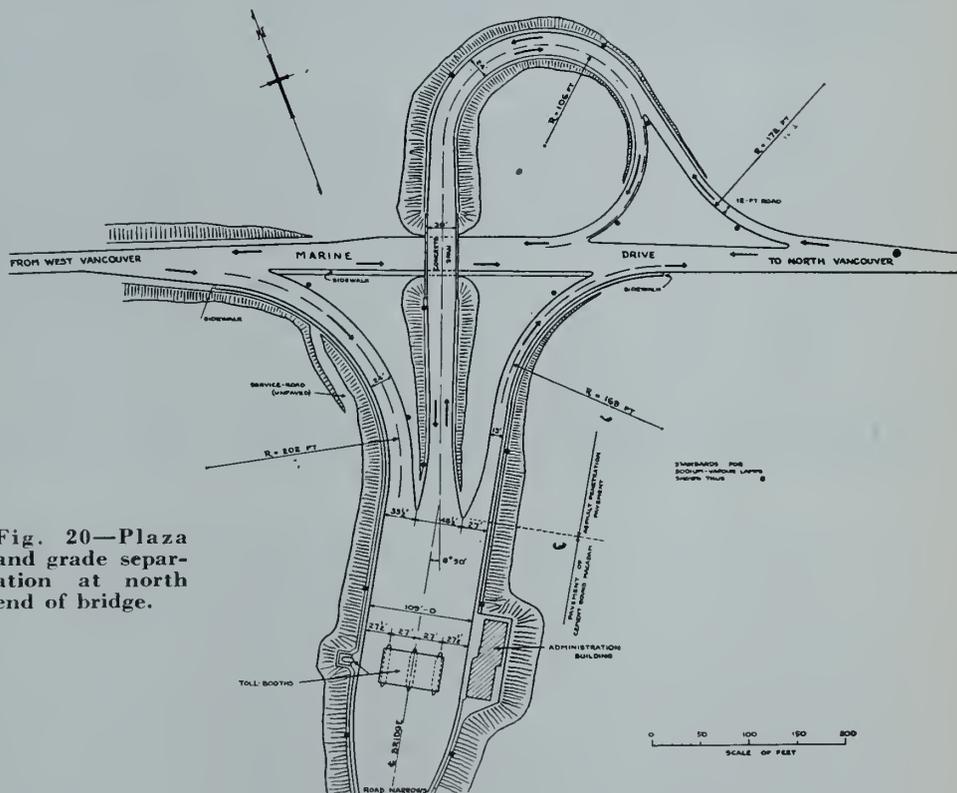

Fig. 20—Plaza and grade separation at north end of bridge.

west. Traversing Marine Drive by a 40-ft. rigid-frame concrete overbridge, this road veers to the east, and, descending on a gravel fill, divides into two single-lane tributaries.

For construction of the embankments, gravel fill of excellent quality was readily obtainable close at hand.

An extensive borrow pit was formed to the east of the right-of-way, on the Capilano Indian Reserve, suitable material being available after clearing the land and removing some 18 inches of top-soil. Although the original specifications contemplated a programme of heavy rolling to consolidate the fill as it was placed, it was found that, provided the gravel were spread in thin layers, consolidation was adequately secured by the heavy traffic incidental to construction. The gravel, which is naturally graded from a sandy soil to boulders of 8 or 9 in. in diameter, bedded down very rapidly and formed an extremely dense, solid and stable embankment, practically impervious to water. The side-slopes throughout were finished to a batter of  $1\frac{1}{2}$  to 1, and the berm-width varies from 2 to 3 ft.

The total amount of fill placed by the contractor was 110,400 cu. yd., of which 45,200 cu. yd. represented additional work involved in the Marine Drive grade separation. Consolidation of this latter fill (placed only a few weeks prior to the opening of the bridge) was expedited by jetting with water as it was dumped. The total unit cost, per cu. yd. in place, including preliminary clearing, did not exceed 30 cents.

Fig. 21—North plaza, toll-booths, and administration building.

The original intention of the engineers had been to provide a temporary pavement on the embankment, to be replaced permanently after a suitable period of consolidation of the sub-grade by traffic and weathering. In view, however, of the remarkably solid nature of the fill, decision was made to proceed at once with the construction of a rigid slab over the main embankment from the end of steel as far as the division of the roadway. It was further decided to use the type of pavement known as "cement-bound macadam," since the prospects were that this could be placed more expeditiously and economically\*

\*Owing to the limited extent of the paved area, and also because of the contractor's lack of experience with this type of pavement, it is doubtful whether any saving was actually effected in time or money.

than a regular concrete slab, while at the same time being of equal wearing-quality. An asphaltic pavement was, however, employed for the three roads of the Marine Drive junction.

Cement-bound macadam consists (to quote from the engineers' specifications\*\*), of "a layer of coarse aggregate over which is poured a Portland cement grout of such fluidity that it will immediately flow through and completely fill the voids"; and the following is an outline of the method used in the construction.

Combined kerb-and-gutter-sections were first constructed of plain concrete, reinforced only by a "Truscon" kerb-bar, to serve as boundaries for the roadway, and the sidewalk slabs,  $3\frac{1}{2}$  in. deep and reinforced with a light mesh, were keyed into them. The subgrade was then levelled-off to profile, and compacted with a 3-ton roller. Expansion joints, both longitudinal and transverse (the latter at 30-ft. intervals), were provided for by one-in. planks laid on edge and extending from just below the subgrade surface to  $\frac{1}{2}$  in. below the finished grade. The coarse aggregate, a clean durable gravel screened to be principally of 2-in. size, was then spread evenly over the subgrade to the specified depth of 6 in., and lightly rolled to smooth the surface without damaging the stones. The grout mixture consisted of  $87\frac{1}{2}$  lb. of cement to 175 lb. of clean natural sand of specified grading, mixed with sufficient water (about 7 gallons per sack) to obtain the required consistency, and its "fluidity" was defined by the time required for the mixture to flow from a vessel of specified size. The grout was poured over the stones by means of a wooden chute perforated with one-in. holes 3 in. apart, distribution proceeding continuously in order to avoid the formation of air-pockets. Thorough penetration was assured by constant supervision. Sufficient grout was applied to leave a thin film over the top of the stones.

The grout was then left undisturbed for one to two hours, and the pavement was compacted by rolling with a 3-ton roller until a hard even surface was obtained, hand-brooms being used to distribute the grout evenly and to remove any excess. Surface irregularities were removed by 12-ft. tamping templates, and excess water by dragging strips of damp burlap along the road. The final finish (Fig. 21) was obtained by transverse brushing with fibre brooms. The total area paved with cement-bound macadam was 1,730 sq. yd., the amount of stone used being approximately 800 cu. yd.

The embankment roadways are bounded by diamond-mesh wire fences 3 ft. high, carried on 8 by 8 in. cedar posts 9 ft. long. The posts extend 4 ft. 9 in. into the fill, being stabilized by underground cross-timbers: all embedded timber received two coats of preservative.

\*\*Based on those of the Portland Cement Association.

*Editor's Note:*—Part II of this paper, which deals with the design of the superstructure, will appear in the May issue.

# PRODUCER GAS FOR MOTOR TRANSPORT

E. A. ALLCUT, M.E.I.C.

Professor of Mechanical Engineering, University of Toronto, Toronto, Ontario

Paper presented before the Hamilton Branch of The Engineering Institute of Canada, on January 9th, 1942

## ALTERNATIVE FUELS

The use of gasoline and other petroleum products for small, high speed internal combustion engines has been so general in North America that few serious attempts have been made to employ other fuels in this field. The convenience and compactness of gasoline and, until recently, its low cost have discouraged competition, but war-time restrictions and transport difficulties have created fresh interest in the search for suitable alternative fuels. Other countries, less favourably situated than Canada is, with regard to supplies of petroleum products, have already explored this field and are able to subsist, at least to some extent, on home-produced fuels.

The properties desirable in a fuel that is to be used for automotive purposes are:

- 1) *Mobility* in the intake manifold, so that the fuel will be distributed evenly to the various cylinders and will mix well with the air supplied for combustion. This points to a gas or vapour—preferably the former.
- 2) *High anti-knock rating*, so that advantage may be taken of the increased thermal efficiency obtainable by using high compression ratios.
- 3) *Complete combustion* in a short time, and absence of deleterious gases in the exhaust.
- 4) *Minimum wear*, corrosion or clogging in the cylinder and valves.
- 5) *No contamination* of spark points or lubricating oil.
- 6) *Flexibility* with variations of speed and load.
- 7) As nearly as possible, the same *mixture strength* for maximum power and best economy.
- 8) *Low cost* and relative *safety*.

The principal objections to gasoline are:—

- a) Its tendency to *knock* with high compression ratios.
- b) *Fire and explosion* risk at ordinary temperatures.
- c) The maximum *power* is obtained with a *rich* mixture and the best *economy* with a *weak* mixture.
- d) The *combustible range* of air-gasoline mixtures is comparatively small.
- e) If power, acceleration and easy starting are required, the exhaust gas contains dangerous quantities of *carbon monoxide*.
- f) The *control* for different speeds and loads is complicated.
- g) *Distribution* is poor on account of the presence of liquid drops in the manifold.
- h) It is *irreplaceable*. Fresh supplies can only be obtained by going further afield, further underground, or both.

The last condition applies to many of the suggested alternatives, but with the practical difference that there may be more of the alternative fuels available and that the depletion of those resources may be proceeding at a slower rate. Alcohol, for example, can be produced rapidly from growing vegetable matter; wood also is growing, but its rate of replacement is slow. Supplies of anthracite coal are few and restricted, but bituminous coals and lignites are relatively abundant.\*①. Synthetic fuels, generated by the

\*Sir H. Hartley states that, at the present rate of consumption, the world's coal reserves are sufficient for about 4,000 years. No estimate has been made of the world's oil reserves, although they are almost certainly much less extensive than coal.

hydrogenation of coal or by the combination of carbon monoxide and hydrogen, ② (produced from coal or coke) cannot be usefully considered at this time because of the high cost of the plant, the time required to build it and its comparative vulnerability to air attack. The hydrogenation process has been used both in Great Britain and Germany, but in these instances the important arguments in its favour were probably its usefulness in war-time and the political and economic necessity of providing employment for the coal miners. Compressed and liquefied gases, such as methane (from sewage), natural gas, propane, butane, coal gas and hydrogen, have been used satisfactorily, but these are probably unavailable at the present time because of

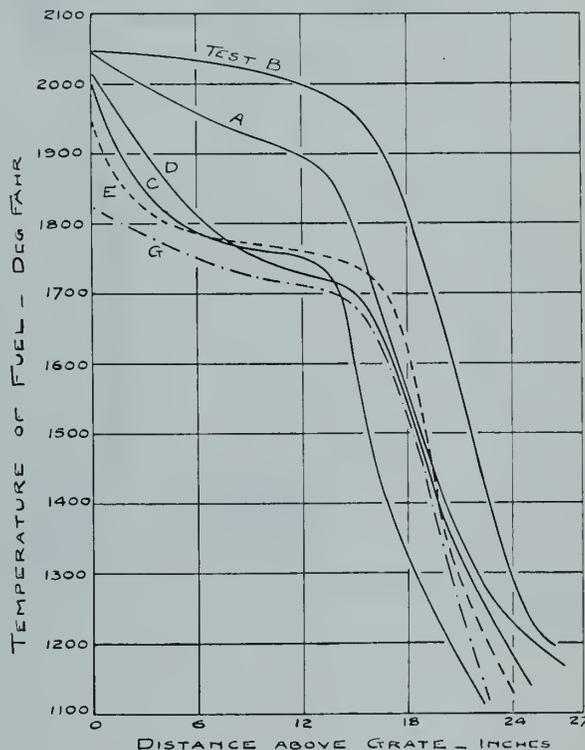

Fig. 1—Fuel temperature in a small up-draft gas producer using anthracite. Water feed in pounds per pound of coal burned: Test A-0.016, Test B-0.232, Test C-0.421, Test D-0.724, Test E-0.718, Test G-1.140.

(1) the difficulty of obtaining compressing plant for gas pressures which may be as high as 3,000-5,000 lb. per sq. in.; (2) the shortage of steel suitable for storage bottles; (3) the lack of the manufacturing facilities necessary for producing light bottles or containers to resist high pressures.\*\* During the First World War, many vehicles were equipped with balloons containing coal gas at atmospheric pressure, the gas being fed to the engines through mixing valves. This arrangement involves a power reduction of about 10 to 20 per cent as compared with gasoline, but in other respects appears to work well. The principal difficulties are, the small radius of action round the filling station (about 20 miles total run) and, at present, the shortage of rubber which is used to make the balloons gas-tight.

Pulverized coal engines have been the subject of extensive experimentation in Germany and it is claimed that a con-

\*\*Storage pressures for propane and butane are comparatively low but, at present, only a small quantity of these gases is available.

siderable measure of success has been obtained with them. The principal difficulties are due to the fouling of the cylinder and oil by ash and tarry matter, together with burning and erosion of some of the surfaces. ② As far as the author is aware, no commercial installations have been made on high speed engines. Numerous attempts have been made to employ acetylene gas with and without the addition of alcohol to suppress knock, but all of these have failed commercially. ③ Benzol, obtained by the distillation of coal or wood, has been used quite extensively in Europe for blending with gasoline. This has the advantage of increasing the knock rating, but the quantity available is small and it has a relatively high freezing point (42 deg. F.).

Apart from petroleum products (which are not being con-

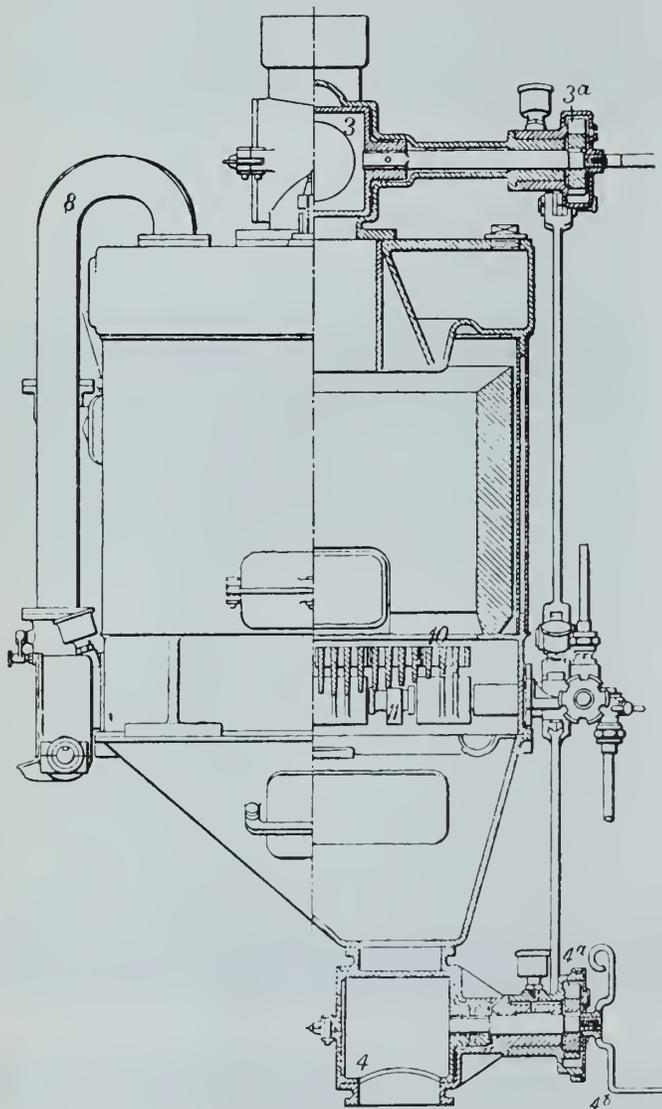

Fig. 2—Early portable gas producer (Col. D. J. Smith) 1919. Grate dia. 12 inches.

sidered here) the only other liquid fuel that is likely to be suitable is alcohol which, before the war, was produced in forty countries at the rate of 200 million gallons per annum. Several European countries had laws making it compulsory to add from 10 to 20 per cent of home-produced alcohol to all imported gasoline. In others, the use of the blend was optional. ④ Bulletins on this subject have been published in Great Britain, ⑤ Australia, ⑥ and Canada. ⑦ In the last paper, it is indicated that the sugar beet is the most attractive source and that, from an economic standpoint, "the expediency of instituting a power alcohol industry in Canada depends on whether the net advantage to agriculture and to the country as a whole outweighs the increase

in cost of the motor fuel." In times of war, however, economic considerations are likely to be disregarded, or to assume a decidedly different aspect, so that these conditions do not necessarily dispose of the matter at this time. Tests ⑧ and practical experience have shown that internal combustion engines can be run satisfactorily on gasoline-alcohol blends, that the power is practically unaffected and that the fuel has a high anti-knock value. Canada has a large surplus of wheat that cannot be used as food and costs money for storage, spoilage and waste. These factors may easily have an important bearing on the power-alcohol situation.

#### PRODUCER GAS

The production of alcohol on a relatively large scale is not likely to cover much more than 10 per cent of our requirements, and the only reasonable remaining alternative appears to be the production of gas as and when it is needed for power production, thus avoiding problems of storage. The gas is usually produced from anthracite, coke, wood or charcoal, though other solid fuels or waste products have been employed. A supply of air, insufficient for complete combustion, is passed through the fuel bed and heat is produced by the reaction:—

$2C + O_2 = 2CO + 4400$  B.t.u. per lb. of carbon consumed. In most instances water or steam is added to the air (or it may be derived from the moisture in the fuel) giving rise to two reactions:

The use of steam, therefore, enriches the gas by the addition of hydrogen and tends to prevent excessive temperatures and the formation of clinkers in the fire. The latter are undesirable because they obstruct the flow of air and tend to cause hollow spots and channels in the fire, with a consequent reduction in the quality of the gas. These reactions and the effect of fire temperature on them were discussed in a paper written by the author in 1910. ⑨ It was there shown, by means of temperature curves (Fig. 1), that, in a small producer, the process of gas generation could be completed with a fire depth of 12 inches or less and that, beyond that point, the superincumbent layers of fuel are useful only as a fuel reserve and are actually detrimental as far as the quality of the gas is concerned. It was found that the best efficiency was obtained when the ratio of  $\frac{\text{water}}{\text{coal}}$  feed was about 0.75, and that about 72 per cent of the water was decomposed into carbon monoxide and hydrogen.

In the case of mobile producers for cars and trucks, it is difficult to provide suitable controls for regulating the water feed automatically, to suit varying loads, speeds and accelerations, and for this reason many of the modern producers have no water supply other than that obtained from the moisture in the fuel, which sometimes is made to flow through the hot fire. In general, the temperature of the fuel bed in an updraft producer using anthracite, should be between 1800 and 2200 deg. F. to give a good gas in the short time available. The composition of the gas varies under different conditions, but it usually has a calorific value of 110 to 140 B.t.u. per cubic foot and contains about 20 to 30 per cent carbon monoxide, 4 to 12 per cent hydrogen, and 55 to 62 per cent nitrogen. The high percentage of nitrogen and poor calorific value make this gas unsuitable for storage purposes, and the presence of carbon monoxide is always dangerous.

It has been stated ⑩ that one of the earliest mobile producers was designed by J. W. Parker who "between 1901 and 1903, ran something like 1,000 miles in Great Britain, at first with a 2½ h.p. car and afterwards with a

25 h.p. car, carrying several passengers." The author tested producers designed by Col. D. J. Smith (Fig. 2) and Mr. Parker (Fig. 3), respectively, on a car, trucks and a motor boat, in 1919-20, and reported that, while encouraging results were then being obtained, the apparatus was not designed and constructed in such a manner as to make it immediately suitable for commercial development. Messrs. Thornycroft of Basingstoke, England, produced one of the earliest commercial designs in 1922, <sup>①</sup> and manufacturers in France, Germany and other countries rapidly followed suit.

These plants proved to be so popular in countries having no petroleum, that in 1937 France had 4,436, <sup>②</sup> Germany about 2,000, Japan and Italy about the same number, <sup>③</sup> and since the outbreak of war these numbers have probably been greatly increased. Russia was expected to produce 16,000 trucks and 9,000 tractors in 1939, and 40,000 and 15,000, respectively, in 1940. <sup>④</sup> Other countries which have been over-run by the Germans are stated to be almost entirely dependent on this type of prime mover.\* A British report <sup>⑤</sup> states that "producer gas can be recommended as a means of maintaining road transport in operation in an emergency," but that, in peace time, at the present stage of development it "is of doubtful economic value for motor vehicles, except in specially favourable circumstances, e.g., for long distance work with vehicles carrying medium or heavy loads." A specially designed equipment was recommended by the Committee for emergency use, and was based on the results of "400 road tests, covering approximately, 50,000 miles, using 9 vehicles, 22 producers of nine different types and over 120 distinct fuels." It is also stated that the "average driver of a petrol-driven vehicle can learn to operate a producer gas vehicle in a few days, though he will continue to improve for a much longer period."

#### DESIGN OF PLANT

The portable producer plant consists of three principal parts, namely, the gas producer or furnace, the arrangements for cleaning the gas and the mixing valve.

The producer may be of the updraft, down-draft or cross-draft types (Fig. 4). The early producers almost invariably had the fuel feed at the top, the air and steam being introduced below the grate. The producer was lined with refractory material and had a built-in boiler or evaporator (which might be at the top, bottom or surrounding the body as a water jacket); the grate was usually of the "shaking" type and the ash was withdrawn from the bottom, either by hand or through a mechanically operated valve (Fig. 2). The gases were taken off at the top of the producer, so that any moisture in the fuel was removed by evaporation and did not produce any appreciable quantity of hydrogen. In these circumstances, the provision of steam was almost a necessity to provide gas of reasonable calorific value. Also, much of the volatile matter in the fuel left as tar, causing trouble in the cleaning apparatus and sometimes also in the engine.

In the down-draft producer, the air and steam are admitted above the fire and the gas is taken off either at the bottom or about half way down the furnace. The moisture and volatile hydrocarbons are thus made to pass through the high temperature zone and are partly decomposed into hydrogen, carbon monoxide and fixed hydro-

\*It is reported that in German occupied countries there were 150,000 producer-gas trucks on the road in the fall of 1941 and that 33,000 more were scheduled to be produced between October 1941 and March 1942. In addition, 20,000 tractors operating on producer-gas were expected to leave the factories in 1942. Sweden had 66,400 vehicles working on producer-gas in August 1941, of which 33 per cent were private cars. About 40 per cent of the total used wood fuel—the others employed charcoal. France now has 50,000 producer-gas vehicles, mostly using charcoal, and Switzerland about 2,000. (*Engineering*, Feb. 6, 1942 and *The Autocar*, Jan. 30, 1942).

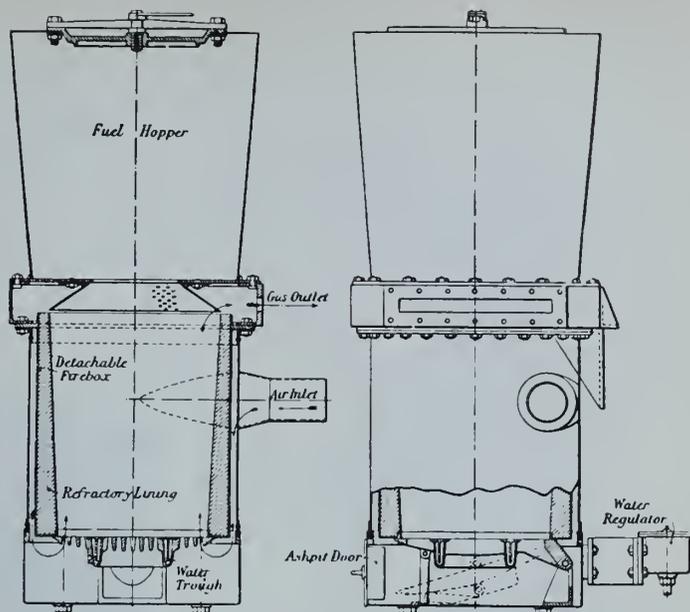

Fig. 3—Early portable gas producer (Parker).  
Grate dia. 11¼ inches.

carbons, which enrich the gas. The latest tendency is to use the cross-draft type <sup>⑥</sup>, in which the air enters through a tuyere or nozzle near the bottom of the furnace, and the gas is taken off through a grid on the opposite side, the flow thus being horizontal. This provides a simple and compact arrangement incorporating the chief advantages of the down-draft principle. The tuyere may be cooled by water from a "radiator tank" and the upper part of the producer is a simple unlined cylindrical vessel, which acts as a fuel storage. One filling usually suffices for a journey of 100 to 150 miles. Where the length of gas travel through the furnace is fixed by the width of the producer, the time of contact between gas and fuel is necessarily small.

Experiments were made at Melbourne <sup>⑦</sup> on a small producer (6 h.p.) with fire lengths varying from 1¾ to 6¼ inches and at 2½ inches a good gas was obtained of net calorific value exceeding 130 B.t.u. per cu. ft. with gas discharges between 3.0 and 6.3 cu. ft. per minute. Water was admitted to the extent of 3.3 lb. per 1,000 cu. ft. of gas generated, giving 6.5 to 10 per cent of hydrogen in the gas. The best gas was obtained with a fire about 4 inches long, and the "transit time" was less than 1/100 second.

Vertical draft producers have relatively deep fuel beds and low air velocities, due to the necessity of protecting the grate and lining from high temperatures and clinker deposits. Horizontal (cross) draft producers have small fire volumes and must necessarily have higher temperatures to produce good gas. It has been shown <sup>⑧</sup> that at 2400 deg. F. the conversion of CO<sub>2</sub> into CO, and of steam and carbon into CO and H<sub>2</sub> is practically complete in three seconds. If the temperature is reduced to 1830 deg. F. the conversions, in the same time, are 6 and 15 per cent complete, respectively. In some cross-draft producers, temperatures as high as 3000 deg. F. are required, to give very rapid and complete production of carbon monoxide. As there is no grate in the cross-draft type, the clinker forms a compact, pan-shaped mass, away from the air and gas connections. The high-temperature combustion zone is small and compact <sup>⑨</sup>, but the exit temperature of the gas is high (Fig. 5). So far, it has not been considered practicable to heat the incoming air at the expense of the outgoing gas, the return not being commensurate with the extra cost and complication of the apparatus. Such regeneration is provided in some vertical draft producers (Fig. 4), but is of doubtful value. Tests made by the author in 1911 showed no considerable advantage when the air was heated to 300 deg. F. One type of producer (Koela) <sup>⑩</sup> embodies a combination

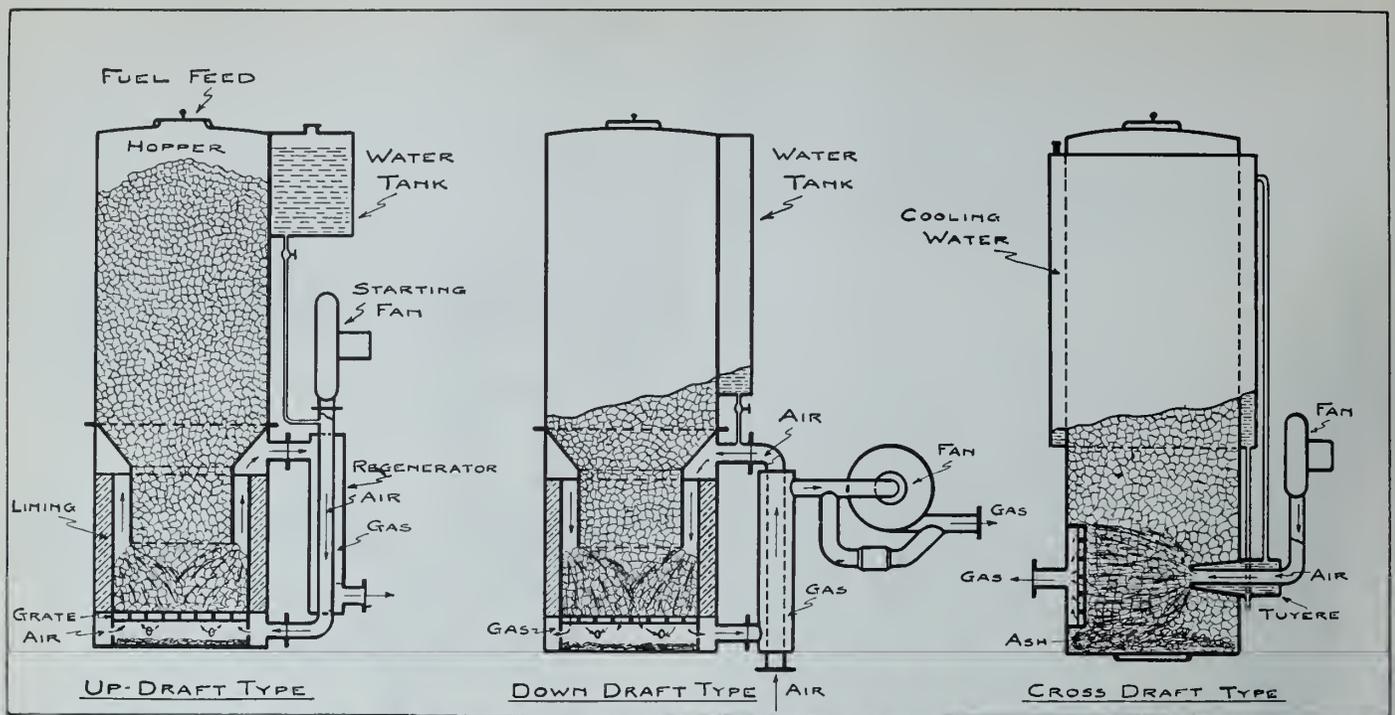

Fig. 4—Up-draft, down-draft and cross-draft producers.

of the updraft and cross-draft principles, and also includes regeneration.

Experiments made on a cross-draft producer with varying water supply <sup>(9)</sup> showed that gas generated without water injection was 12 per cent poorer than the best gas obtainable, corresponding to a decrease of six per cent or more in available engine power. Tests made on an Australian emergency (A E) producer <sup>(10)</sup>, based on the British (B E) design, gave producer efficiencies of 76.4 to 74.1 per cent at engine speeds varying from 750 to 3000 r.p.m. and gas calorific values of 133 to 124.5 B.t.u. per cu. ft. The fire length was 12½ inches, its temperature was about 3000 deg. F. and the diameter of the tuyere was one inch. The air consumption was approximately 5.5 lb. and 83 to 87 cu. ft. of gas were produced, respectively, per lb. carbon burned. The gas temperatures at the mixing valve varied from 80 to 180 deg. F. No water was supplied and the hydrogen in the gas varied from 5.2 to 2.9 per cent, but the carbon monoxide remained constant at 32 to 33 per cent. A similar series of tests was made on the British emergency producer, <sup>(11)</sup> and some of the comparative results obtained are given in Fig. 5.

This shows that the capacity of both producers is about the same at equal air velocities, notwithstanding the fact that the B E tests were made with a blower, and the A E tests with a Ford V-8 engine. The pressure drop across the A E unit is much greater than that across the B E unit, probably because of the greater frictional resistance of the final filter. The temperature of the gas leaving the A E producer varied from 565 to 1000 deg. F., but as these were not final values, <sup>(12)</sup> they have not been plotted on Fig. 5. The temperatures obtained in the B E producer seem to be abnormally high, and it is difficult to understand how burning of the metal is avoided under these conditions.

#### POWER AND ECONOMY

Characteristic power and economy curves for a gasoline engine are shown in Fig. 6. The best economy at full throttle is obtained with a mixture containing from 10 to 15 per cent of excess air, but, as the throttle is closed progressively, somewhat richer mixtures must be supplied. On the other hand, the best power is always obtained with a rich mixture

containing about 20 per cent of excess fuel that cannot be burned. This illustrates the fundamental fallacy of many devices that purport to give both improved power and economy. The conditions that produce greater economy in a gasoline engine almost invariably give less power. Tests made on a single cylinder variable compression engine, <sup>(13)</sup> using producer gas, showed that:—

- (a) The power-mixture strength curve rose to a sharp peak with a mixture containing about two per cent of excess air (Fig. 6). With 30 per cent of carbon monoxide in the gas, this corresponds to slightly less than 50 per cent of gas in the mixture (as compared with about two per cent for gasoline). Good mixture control is therefore essential.
- (b) Compression ratios up to 15:1 may be used without trouble.
- (c) At a compression ratio of nearly 8:1 and a speed of 1500 r.p.m., the combustion period occupied about 40 deg. of crank angle. This indicates the necessity for increased spark advance as compared with gasoline. Alternatively, multiple spark plugs may be used.
- (d) The indicated thermal efficiencies at all compression ratios between 6 and 16 were about 60 per cent of the "air standard" efficiencies. The actual maximum thermal efficiency was about the same as that obtained with gasoline (Fig. 6) and occurred with a mixture about 30 to 40 per cent "weak."
- (e) The net calorific value of the correct producer gas-air mixture is about 70 per cent of that corresponding to the correct gasoline-air mixture. The volumetric efficiency of the engine is also less when gas is used because of the relatively high gas temperature, the absence of the cooling effect derived from the evaporation of liquid fuel and the greater frictional loss of the piping and cleaning apparatus. The mechanical friction in the engine itself is not affected materially by the change from liquid to gaseous fuel and therefore, with the weaker combustible mixture, the mechanical efficiency of the engine falls. For these reasons, the horse power obtainable at low speeds from an engine of a given size, when using pro-

ducer gas, is only 60 to 65 per cent of that obtained on gasoline. The comparison may be still more unfavourable at high engine speeds, as the resistance of the cooling and cleaning apparatus increases rapidly with the speed and may be as high as 30 to 60 inches of water gauge (Fig. 5), particularly if the filters are dirty (16). It is not safe, therefore, to anticipate a maximum power of much more than half that obtainable from liquid fuels. The Australian tests (16) gave a power ratio of 51.5 per cent, and the British report (17) states that a vehicle is "one gear worse" on producer gas than on gasoline. Power ratios of 70 to 75 per cent have been claimed in some instances.

This analysis indicates one of the principal objections to the substitution of producer gas for gasoline in trucks, tractors or marine work where the load factor is high. Most cars work, for the greater part of the time, at less than half of their load capacity, the full power of the engine only being required occasionally, but trucks have to carry heavy loads for long periods and must adhere to definite time schedules. Possible remedies for this difficulty are:—

- (1) The use of larger engines. This is only possible with new vehicles.
- (2) Reduced loads, longer time schedules, or both. These imply a reduction of transport and earning capacities.
- (3) Higher compression ratios (say 8 or 10 to 1). The consequent increase of thermal efficiency will raise the power ratio possibly up to about 70 per cent, but this method introduces difficulties when gasoline is used for starting or emergency operation, though alcohol may perhaps be substituted for these purposes. Moreover, it is frequently difficult to change materially the compression ratio of existing engines.
- (4) Supercharging. This requires a power drive for the supercharger unless exhaust driven superchargers are used. The latter add to the cost, complication and weight of the plant and are of doubtful practicability. Nevertheless, a supercharger of this type has been used by the Brown Boveri Company (18) to put the whole of a wood gas producer plant under pressure. The top of the producer is held down by springs and so acts as a safety valve which blows off at an internal pressure of 7 lb. per sq. in. It is claimed that the test results on this plant indicate that the torque obtained on a Saurer truck at different speeds is equal to that of the same truck driven by a compression ignition (Diesel) engine. The weight of the turbo-charger for 40-150 h.p. engines is 77 lb. Leaky joints or connections would form a considerable hazard in this kind of plant.
- (5) Mixture of producer gas and gasoline. Tests made on a single cylinder stationary engine (19) with a compression ratio of about 5.3 to 1 and a speed of 1500 r.p.m., gave the following comparative results:—

Gasoline, per cent in mixture.....	100	72.1	41.7	22.6	0
Maximum Indicated Mean Effective Pressure, lb. per sq. in.....	137	120	107.5	97.4	93.0
Maximum Brake Mean Effective Pressure, lb. per sq. in.....	117.7	100.5	87.4	76.5	73.5
Power Ratio expressed as a percentage of that obtained with gasoline.	100	85.5	74.3	65.0	62.5

It is impossible to make any categorical statement regarding relative running costs, as so much depends on size, fuel taxation, running conditions, etc., but fuel consumptions of heavy vehicles vary usually from 0.9 to 1.3 lb. of charcoal per h.p. hour. A four-cylinder 12 h.p. car weighing

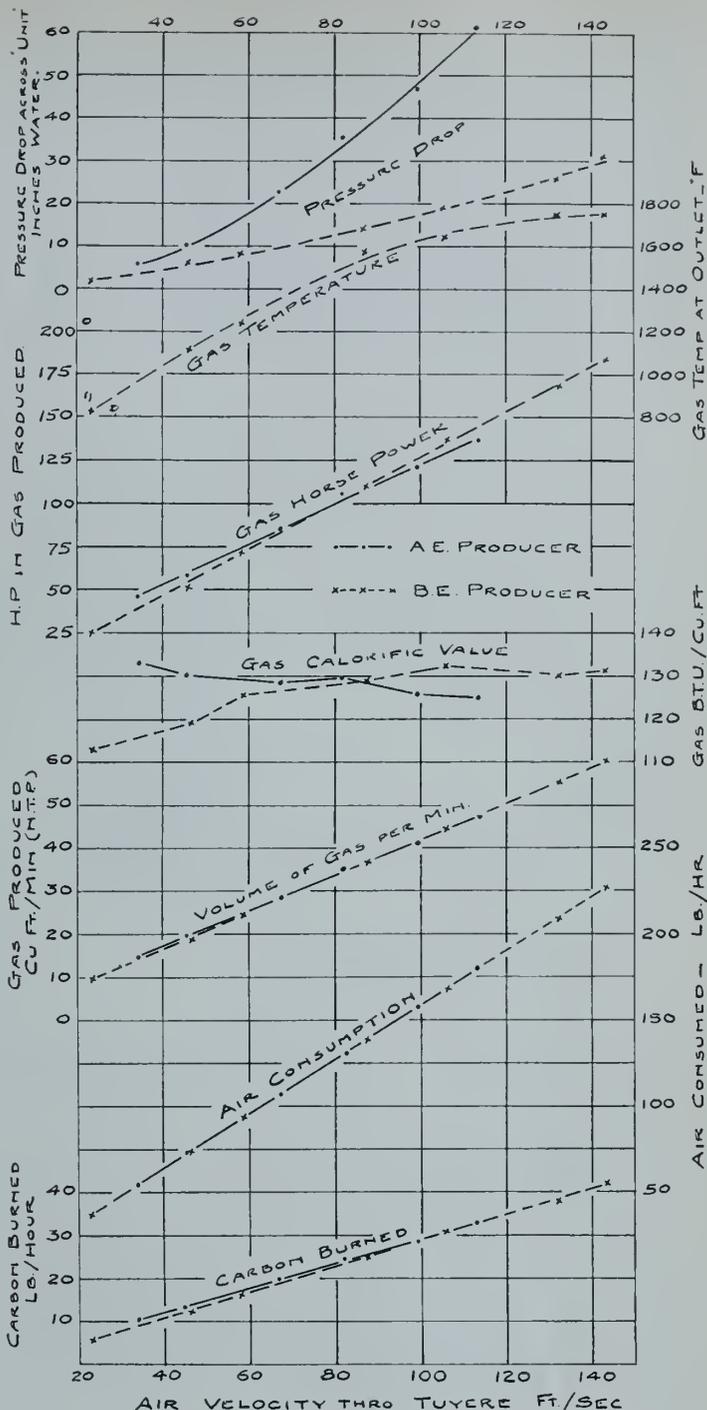

Fig. 5—Comparative test results on the Australian and British emergency cross-draft producers.

2,550 lb. ran for 5,000 miles with an average fuel consumption ("activated progasite") of  $\frac{1}{2}$  lb. per mile, and a continuous run of 100 miles was made on this fuel with a consumption of 0.4 lb. per mile (20). The British report (21) gives the average consumption of anthracite for a vehicle of six tons gross weight as 1.5 to 2 lb. per mile.

Tests made in Australia on the British emergency producer mounted on a trailer (weighing 1,150 lb.) towed by a Ford V-8 utility truck and carrying a load of 550 lb., gave a charcoal consumption of 1.03 lb. per mile. (22) Woods quotes heat consumption figures for trucks ranging from 4,300 to 8,900 B.t.u. per load-ton-mile for pay loads varying from 6.9 to 1.5 tons, respectively, (23) and a test in Great Britain gave a consumption of 4,110 B.t.u. per ton mile for a pay load of 4.6 tons at a speed of 26.3 miles per hour.

Tests made by the French Department of Agriculture (24) indicated that, with an efficient engine, 12 lb. of charcoal (or anthracite) or 22 to 24 lb. of wood (less than 18 per cent

moisture) gave the same mileage as one gallon of gasoline. A comprehensive series of tests was made in Switzerland by Schlöpfer<sup>34</sup>. Various estimates gave comparative fuel costs ranging from one half to less than one third those of gasoline.<sup>35</sup> Comparisons with fuel oil are not so favourable and vary with local rates of taxation on liquid fuels.

As no excess fuel is required in the mixture to produce full power, and as complete mixing of air and fuel are easy, no trouble is experienced with the effects of incomplete combustion or with carbon monoxide in the exhaust gases. The uniform mixture also ensures the generation of equal amounts of power in the different cylinders of multi-cylinder engines.

### FUELS

Producer gas can be made from almost any carbonaceous fuel, but considerations of weight and space occupied by the producer plant and fuel storage play an important part in the final choice. From a gas-making standpoint, the most important property of the fuel is its "reactivity." This is sometimes indicated by its "critical air blast" (C.A.B.) value, which is the minimum rate of air supply that will support the combustion of a graded fuel sample when tested under standard conditions. The lower the C.A.B. value, the greater the reactivity and the more suitable is the fuel for gas-making.

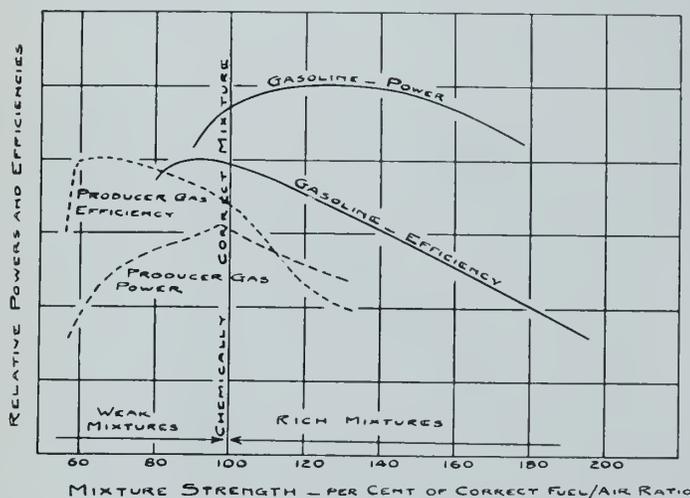

Fig. 6—Relative power and economy curves for producer gas and gasoline with varying mixture strengths. No vertical scale has been given, as the figures are entirely comparative. They are intended to show that the maximum power obtained with producer gas is about 60 per cent of that obtained with gasoline, and that the maximum efficiency is about the same in both cases.

The following typical values are given by Noton:<sup>36</sup>

Charcoal—less than .....	.01
Low temperature coke.....	.01
Bituminous coal—about.....	.02
Anthracite, not less than.....	.035
Gas coke.....	.06
Furnace coke.....	.07

Tests on a cross-draft producer indicated that, for this type of apparatus, the permissible upper limit of the C.A.B. value was .04.

The best results have usually been obtained with wood charcoal, which has the highest reactivity (probably because of its porous structure), and is relatively free from ash and impurities. The provisional specification for Australia<sup>37</sup> describes the principal desirable characteristics and standard methods of testing. The charcoal should be clean, free from "fines," and should not shatter or crumble in service. The size should be between 1/2 and one inch, and the ash should not exceed four per cent of the air-dry

weight of the charcoal. No limit is fixed for the volatile matter, but elsewhere it is recommended that this should be about 10 per cent.

The reactivity is expressed, in some instances, as the volume of carbon monoxide formed by passing 100 cubic centimetres of carbon dioxide over the fuel at a temperature of 1,740 deg. F. and at a rate of five cc. per minute. By this valuation the reactivity of charcoal is about 180, and that of coke 40 to 60; this scale appears to be more open than that of the C.A.B. method, and so is a more practical one. Australian charcoal (air dry) has a calorific value of 12,000-13,600 B.t.u. per lb., and Canadian charcoal of 12,500 B.t.u. per lb. or higher. Canadian hardwood charcoal contains approximately five per cent moisture, three per cent ash and 17 per cent volatile matter. Uniformity of size is desirable to avoid excessive resistance in the fire and the clogging of cleaning apparatus by dust and small particles. The low density of charcoal (about 14 lb. per cu. ft.) makes it necessary to provide a large hopper so that a journey of 100 to 150 miles may be made without refuelling. Charcoal briquettes, with densities up to three times that of coal, have been used in some producers, but their advantage is doubtful, on account of the reduced reactivity of the fuel which probably necessitates a larger fire, less flexibility and longer time for starting. It may be advantageous for using up the finer grades of charcoal.

Many producers have been operated on wood, generally containing up to 18 or 20 per cent of moisture<sup>38</sup> and supplied in pieces approximately 1 1/2 in. by 1 1/2 in. by 3 in. Hard wood is preferable, but soft woods may be used with a greater depth of fire to break up the volatile matter distilled from the wood.<sup>39</sup> If these vapours are not decomposed, they must be removed in the scrubbers, otherwise they will cause trouble in the engine. For this reason, larger and more complicated cleaning apparatus is usually required. With wood fuel, a larger fuel hopper and furnace must be provided, and also there is an increased loss of heat in the water vapour which leaves with the gas. Nevertheless, the large amount of hardwood that is immediately available in Canada forms an important, potential supply of fuel for use in an emergency.

Peat and peat charcoal are possible fuels, but the former is difficult to dry and the latter is inclined to be friable. Peat charcoal, produced by a special low temperature distillation process, was tested on a four-ton truck in Scotland<sup>40</sup> and is stated to have given better results than those obtained on a low temperature coke. Comparative tests made on low temperature coke and charcoal<sup>41</sup> showed little difference between the two fuels, as far as performance and idling were concerned. The coke gave better acceleration after idling, in spite of the fact that the temperature of the plant was higher than that obtained with charcoal, but the clinker formation was much greater with coke. The latter fuel is also stated to give more cylinder wear than anthracite does.<sup>42</sup>

Countries which have access to coal but possess little timber, generally use anthracite or coke. Accordingly, the British emergency producer<sup>43</sup> is designed principally for these fuels, and the specification gives the best grading for anthracite as 1/4 in. to 5/8 in., though somewhat smaller sizes can be used, if necessary. The quantity of volatile matter should be less than seven per cent, and the ash less than four per cent. The principal advantages of anthracite are, that no preliminary processing of the fuel is required, the fuel does not disintegrate when shaken and its density is high (about 55 lb. per cu. ft.) so that a large weight can be carried in a small container.

The size and weight of the plant for a given horse power is influenced considerably by the kind of fuel used, as this governs the size of the fire, the dimensions of the fuel hopper and the kind and size of cooling and cleaning apparatus employed.

The following figures are reasonably representative of current practice:

The Brush-Koela producer for a 2½-ton truck is about 14 inches in diameter by 4 ft. 5 in. high, and weighs 280 to 336 lb., according to the layout employed. 25 The Gohin-Poulenc producers vary from 14 to 20 inches in diameter and from 3 ft. 6 in. to 6 ft. 6 in. high. For a seven-ton truck (empty) the weight is 620 lb. or 3.9 per cent of the pay load. A wood burning producer, for the same service, weighed 1,200 lb. or 7.7 per cent of the pay load. The weight of producer for a 32 passenger bus (53 h.p. engine) is 560 lb., and the hopper contains 510 lb. of coal, sufficient for 200 miles. The British emergency producer, which is mounted on a trailer, is 18 inches diameter by 4 ft. 6 in. high, and the weight of the whole trailer unit is 1,150 lb. The producer and cleaning plant are made entirely of steel pressings and are designed for the rapid conversion of vehicles at a minimum cost.

#### COOLING AND CLEANING THE GAS

The temperature at which the gas leaves the producer, which may be as high as 1,750 deg. F. (Fig. 5), makes it necessary to cool the gas as much as possible before it enters the engine, otherwise the reduction of volumetric efficiency will seriously affect the power obtained. With a gas temperature of 120 deg. F. (air temp. 75 deg. F.) the reduction of engine power is about eight per cent if the gas is dry, or 17 per cent if saturated. It is desirable, therefore, to avoid wet scrubbers if the gas can be adequately cooled without using water.

The presence of dust or ash in the gas is also undesirable, as it contaminates the lubricating oil and causes wear in the cylinders. The amount of dust allowable has not been determined definitely, but it is stated that, with less than 20 milligrams per cubic metre of gas (.0002 oz. per cu. ft.) the cylinder wear is no more than that obtained with gasoline. The following figures were quoted by Burstall 26 from results obtained by Reich on charcoal producer gas cleaned in three different ways. Full details were not given, but the results indicate the order of magnitude of wear and the variation due to the various cleaning devices:—

Group A—.205—.253	} thousandths of an inch cylinder wear per 1,000 miles travelled.
B—.327—.343	
C—.46 —.647	

(For comparable figures on gasoline see Ref. 31 and 32.) The average rate of wear with gasoline is generally in agreement with the figures in Group B.

The velocity of air and gas through the fuel bed, which is controlled by the speed and load of the engine, has a great influence on the amount and grade of dust that must be handled by the scrubbers. Beresinsky obtained the following results on an Australian cross-draft producer with a fire 12 inches long between tuyere and outlet grid:—

Rate of Gasification cu. ft./min.	Speed Miles per hour	Dust M.gm. per cu. metre	Dust in Gas lb./1,000 miles
35	35	650	2.5
50	50	5960	22.4

The relatively low gas velocity through the up and down-draft producers (40 to 80 lb. fuel gasified per sq. ft. grate per hour) probably causes less dust to be carried over than in the case of the cross-draft type.

A method of testing the efficiency of cleaners and scrubbers has been devised by Beresinsky 26, consisting of an aspirator drawing heated gas through a standard filter. This gives consistent results and has revealed the fact that, generally, the most efficient cleaners give the greatest resistances to the passage of gas. In the tests on the "A E" producer, the quantity of dust entering the gas mixing valve was less than one milligramme per cubic metre when tested on the road at 30 miles per hour, but usually the

pressure drops obtained during the road tests were greater than those in the bench tests (Fig. 5), probably because the vibration consolidated the fuel in the producer and the fibre in the filter. 26 The cyclone separator used in the A E producer is efficient for removing large particles, but a filter consisting of layers of sisal fibre, cotton waste and felt, is also used to remove fine particles (Fig. 7). Between the two, are four vertical cooling cylinders with cleaning doors, which also act as a gas storage to meet sudden demands from the engine. European practice appears to favour cloth filter bags, but in some instances wet scrubbers are used, particularly with wood fuel. In the latter case, however, it is stated that neither dry nor wet scrubbers can remove every trace of tar and acetic acid from the gas. Oiled coke, or oily baffling surfaces are sometimes em-

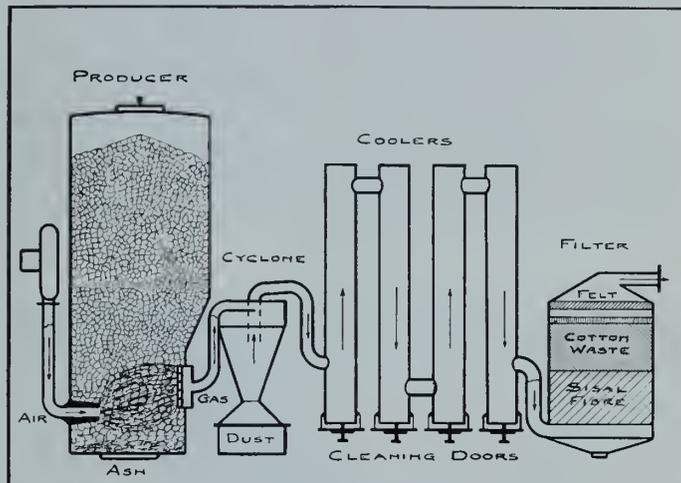

Fig. 7—Diagram of Australian Emergency gas producer plant.

ployed, but are not so efficient as fabric or fibre filters for fine dust separation. The British emergency producer has four horizontal coolers (each 6 in. dia. and 3 ft. 6 in. long) arranged in series, and two filters in parallel, each containing four beds of sisal tow. Regular cleaning is necessary to avoid clogging and excessive resistance, particularly as, if the pressure drop across the sisal filter becomes great, channels may form in the filter bed, reducing its efficiency as a cleaner. In some instances, a flame trap is placed between the mixing valve and the scrubbers. The gas mixing valve and carburettor are connected to a Tee bolted to the intake manifold.

#### OPERATION AND INSTALLATION

The running of a gas producer plant does not offer any great difficulty to the average driver. If water feed is used with hand operation, the rate of water supply controls the temperature of the producer and the quality of the gas, but in most instances this quantity is adjusted automatically to suit the rate of gasification.

Starting from cold is usually performed by running the engine for a short time on gasoline and using the suction to draw a flame into the fuel bed from a torch inserted through the tuyere or other convenient opening. Various starting times, ranging from one to ten minutes, are quoted by different authorities, a good deal depending on the type of producer, kind of fuel and local conditions, but in most instances the fire must be nursed for some time, as full power cannot be obtained until there is a substantial volume of incandescent fuel available for gas making. This period lasts for approximately 20 to 30 minutes after starting. With high compression engines, it may be necessary to use a fan, operated either by hand or electric motor for the purpose of blowing up the fire. In that event, care must be taken to ensure the escape of gas into the open air, and not into a garage, as the 30 per cent of carbon monoxide in the gas is very poisonous.

At the end of the run, or day, the producer is allowed to cool down, after which the ash, clinker, etc., may be removed. Some producers have shaking grates and automatic ash discharges, but these are unusual nowadays, particularly with charcoal fuel. Stops of from one to two hours are possible, but in most instances it is necessary to idle the engine so that the fire may be kept alight. It may also be necessary, on restarting, to run for a short time on gasoline, to re-establish the volume of fire that is required for full load operation.

The necessity of systematically cleaning scrubbers and filters has already been noted.

It is evident from the above, that the gas producer is most suitable for large and heavy vehicles that have been designed specifically for this kind of fuel, although some small plants have been placed in car trunks and on running boards. Buses have the producer enclosed in a special compartment at the back or front, and trucks have them mounted on the side of the chassis. Existing chassis, however, usually have insufficient room for the producers and cleaning plant, so that both the British and Australian emergency producer plants are mounted on two-wheeled trailers that are towed behind the trucks. This increases the wind resistance of the vehicles but gives effective cooling.

#### CONCLUSION

The difficulty of keeping the fire alight during long stops, the dust and dirt encountered when fueling and cleaning, the time taken for starting (particularly if the gas is wet), the difficulty of finding space on the chassis or of manoeuvring in traffic if a trailer is used, and above all, the loss of power and flexibility, make it improbable that gas producers will become popular with the owners of private cars.

Their application would appear to be more directly to trucks or fleets of trucks, where they can be kept in condition by a service staff. Both the British and Australian reports emphasize the necessity of adhering to standard dimensions, and state most distinctly that the design and fabrication of gas producer plants should not be undertaken by amateurs, but should be in the hands of experienced personnel.

The cost of such a plant is in the neighbourhood of \$300-\$500 and the average weight of metal 400-600 lb. This is mostly steel, and assuming an average of 500 lb. of mild steel per vehicle, 25,000 tons would be necessary to equip 100,000 vehicles.\* In addition to this, if trailers are employed, an additional 25,000 tons of steel would be required for the trailers, and 200,000 tires would have to be provided.

The report of the Chemurgic Committee <sup>⑦</sup> states that, in 1940 motor fuel consumption in Canada was nearly 900 million gallons, and it was estimated that 45 million bushels of wheat would be required to replace 10 per cent of this amount by alcohol. Considering 12 lb. of charcoal as equivalent to one gallon of gasoline, an annual consumption of 540,000 tons of charcoal would be necessary for the same purpose.

These factors may be decisive under war conditions.

# TROLLEY COACH OVERHEAD MATERIALS AND DESIGN

L. W. BIRCH

Engineer, Transportation Department, Ohio Brass Company, Mansfield, Ohio, U.S.A.

Paper presented before the Montreal Branch of The Engineering Institute of Canada, on December 4th, 1941

## INTRODUCTION

A vehicle propelled by electric energy collected from a trolley wire system has this advantage, that power is always available. It is not necessary to refill a tank or tender. Trolley coach operation is of this type and is successful because the overhead distribution system is capable of delivering continuous power.

In North America the trolley coach overhead distribution system is part of a \$70,000,000 trolley coach investment which in turn, is part of the mass transportation systems on 50 properties. These systems represent a total investment of \$700,000,000.

## PROBLEMS OF OPERATION AND DESIGN

Primarily a trolley coach overhead system differs from a street car distribution system in that there is no rail return. An aerial negative contact wire replaces the rail. The support and insulation of two aerial contact wires for operation with mobile current collectors present interesting problems. These include:

1. The current collector, itself. Numerous single-pole and two-pole collection equipments have been built and tried on commercial trolley coach routes.
2. Building for operating speeds of 30 to 40 m.p.h. At these speeds the trolley coach may be touring to one side of the trolley wires.
3. Selecting a trolley wire and collector that would prevent excessive wear. Experience with street car current collection demanded that the trolley wire last as long for trolley coach operation as for street car operation.
4. Insulating the positive and negative trolley wire. At both crossovers and turnouts the positive trolley wire crosses the negative trolley wire.
5. Providing a touring range to permit of curb loading, also the passing of other vehicles in traffic. The trolley coach should tour over, at least, three traffic lanes.
6. Automatically selecting the proper path at a turnout point. This necessitates the selection of either turnout or mainline at the will of the operator, and the selection must be made without the operator leaving the coach.

These problems were not solved on the first installations. Our present overhead system is the development of twenty years of experience. The pioneer systems, such as those installed in Toronto, Windsor, Staten Island, Philadelphia,

Baltimore, Rochester and Petersburg, as well as in English cities, were very simple, but they were responsible for many important developments and standards in use to-day. For example, the advantages possible with four trolley wires providing two-way operation rather than two trolley wires providing "single track" operation, were recognized during the early twenties. Furthermore, considerable additional conductivity was made available for the carrying of electric energy.

The selection of 2/0 and 3/0 trolley wire sizes was made on the early installations because the short life of 1/0, and the additional supporting structure necessary for 4/0, were recognized as economically unsound. As early as 1923, the American Transit Association selected a 24-in. spacing between positive and negative trolley wires and recommended a trolley wire height of 18 ft. above the street. These limitations are standard to-day. After many experiments with a

Fig. 2—All metallic collector shoe.

single-pole collector, two individual poles were finally accepted on the Windsor and Staten Island systems as the standard. The general method of insulating the positive from the negative contact wire, the length of insulation and the location of the contact wires with respect to the curb line are other features developed twenty years ago which have helped to secure a well standardized overhead design.

Since 1928, when Salt Lake City installed the first modern 40-passenger, transit type trolley coach, each new installation of trolley coaches has added some new features to the overhead system. These new features have comprised the improvement and development of new devices, the dimensional standards and limitations having remained unchanged. It is an interesting thought that without some of the early standards selected for trolley coach overhead distribution design, we might have had as many different gauges between positive and negative trolley wires as the railroads had track gauges 75 years ago.

## TYPICAL DISTRIBUTION SYSTEM

The standard tangent distribution system, illustrated in Fig. 1, consists of a pole structure, either wood, concrete or steel, which supports four trolley wires with the poles spaced at approximately 100-ft. intervals. The trolley wires are attached to insulated hangers and clamps, and in addition to the insulation placed in the supporting hangers, a secondary insulation, either porcelain or wood, is inserted in the span wire near the pole. The centre line of one pair of trolley

Fig. 1—Standard tangent construction.

wires is usually located 13 ft. from the curb line thus permitting the trolley coach to load at the curb and to tour around double-parked vehicles.

#### DEVELOPMENT OF COLLECTION EQUIPMENT

Early collection equipment included a free-swivelling trolley base mounted on top of the coach, a long trolley pole and a free-swivelling wheel harp for operation under the trolley wire. The trolley base was similar to that installed on street cars, the trolley pole was a lightweight alloy steel pole insulated from the trolley harp and the harp, itself, was a wheel collector similar to an ordinary caster. With this combination the trolley coach could tour on either side of a pair of trolley wires, the limitation to the touring range

Fig. 3—Shoe collector with carbon insert.

being chiefly the length of the poles. This early assembly of equipment is similar to that employed to-day except that the wheel collector has been replaced with a shoe collector. Owing to the point bearing of the trolley wheel and to the swivelling action of the device, the wheel collector was subject to many dewirements when passing through frogs and cross-overs and the milling action of the spinning wheel on the trolley wire, particularly with the trolley coach touring off-centre, was quite injurious. These facts were responsible for the development of the shoe.

With the installation of the larger fleets of trolley coaches and the use of higher accelerations and higher speeds, the wheel collector was abandoned in favour of a shoe collector. The history of the development of the shoe collector is interesting. The first shoe collectors were all-metallic, either malleable iron or forged steel (Fig. 2). The wearing of a groove in these collectors produced a cutting edge that was injurious to trolley wire, particularly round trolley wire that was supported with a trolley ear encircling the wire. Soft nosed or bronze tipped shoes diminished this cutting action but did not prove entirely satisfactory. All of these metallic shoes required lubrication of the contact wires for the prevention of excessive wear to wire and fittings. Usually a graphite lubricant was applied with special roller type lubricator attached to trolley poles mounted on a line truck or a service truck. Five years ago, a collection shoe consisting of a solid piece of carbon permanently embedded in a bronze shoe was installed at Cleveland, Ohio. This was a real step in the right direction but trolley wire lubrication was still necessary since the bronze of the shoe continued to rub the wire. The final step was the development of a collecting shoe consisting of a bronze holder in which is clamped a carbon insert that collects electric energy from the trolley wires and operates in a manner similar to a carbon brush on a commutator (Fig. 3). This small carbon insert is replaced when it is worn to the allowable limit. Lubrication of trolley wire has been completely eliminated since the carbon insert lubricates and burnishes the trolley wire.

#### EFFECT OF SHOES ON TROLLEY WIRE LIFE

When the metallic shoe was first introduced for collection purposes, dewirements diminished, there was less arcing and collector noise disappeared, but on the other hand the cutting effect of the groove worn in the metallic shoe and the wear on trolley wire and fittings was greatly increased.

This wear was controlled by the substitution of grooved trolley wire for round trolley wire. All fittings were attached to the upper lobe of the grooved trolley wire, the lower lobe being free of attachments, thus presenting a smooth underrun to the collector. At this time it was estimated that the life of a 2/0 grooved trolley wire would be 500,000 bus passes. Actual experience showed figures as low as 300,000 bus passes. At the present time the combination of a carbon insert shoe operating on grooved trolley wire has increased 2/0 grooved trolley wire life to figures varying from two million to seven million bus passes. This is equivalent to saying that 2/0 grooved trolley wire might last on the average line from 20 to 70 years. Most installations to-day are being equipped with 2/0 wire. The 3/0 wire is selected only where conductivity demands. Bronze trolley wire, because of its greater life and ability to hold sufficient tension so necessary for good operation, is almost universally used.

#### TROLLEY COACH HANGER

A trolley coach hanger or insulator used for supporting the trolley wires has been developed for this class of two-wire suspension. The hanger carries sufficient insulation with the exception of that placed in the span wires near the poles. However, in some instances a secondary insulator, usually a wood stick, is placed between the positive and negative hangers in the supporting span. Insulation in the hanger is usually a moulded insulation of high dielectric strength

Fig. 4—Segment construction on curves.

and has sufficient resistivity to heat, moisture and mechanical injury to permit of long life. Recently, several installations have been made with a wood stick hanger. This type of hanger provides a longer leakage path than is possible with the moulded insulation hanger. Hangers are built with adjustability in order to properly align the trolley clamps to prevent interference with the collecting shoes.

#### CURVE SEGMENT

The usual conventional curve designed for street railway work requires the frequent installation of pullovers in order to align the trolley wire of the street car with the curvature of the track. This is necessary because of the type of rigid collection equipment normally used on street cars. In the case of the trolley coach, it is not necessary that the vehicle follow beneath the line of trolley wires since the swivelling action of both the trolley base and the harp permit off-centre touring. With this equipment it is not imperative that a trolley wire follow any particular curve except that it must be within reach of the collection equipment.

The conventional curve employing numerous pullovers has been almost entirely replaced by segment construction where the trolley coach does not operate jointly beneath the same trolley wire as the street car. The segment is a large pullover built to provide an easy means of aligning trolley wires over the path of the coach and at the same time eliminate many fittings and cables formerly used on the conventional street railway curve. The segment is built with a comparatively large radius and, of course, connects the several chords on the curve (Fig. 4). An adjustable feature reduces the total number of segments for a given job to a few. This device does not restrict speeds on curves inasmuch as it has been designed to handle the maximum speeds possible for the various curves. It has been responsible for the elimination of some unsightly pullover wires and has contributed to considerably less labour cost during installation.

#### FEEDER SPAN

The frequency of feeder spans for tapping either positive or negative contact wires to aerial feeders is dependent upon electrical loads, cost of annealed trolley wire occasioned by a trolley wire break and the total cost of feed span installation. As a general rule feed spans for the same polarity are located at 800-ft. intervals. This means one negative feed span and one positive feed span in an 800-ft. section. Since tapping of the positive trolley wire requires good insulation in the feed span because of the closeness of the negative contact wires, special equipment has been designed for making these taps. The most recent arrangement uses the copper feed span as a supporting span, direct taps being taken from the span to the trolley ear as illustrated in Fig. 5.

Fig. 5—Feeder span using copper feed span to support trolley wire.

#### SPECIAL WORK FOR INTERSECTIONS

At locations where one trolley coach system crosses another trolley coach system, or where a trolley coach system crosses a street car line, insulated crossovers must be installed. At locations where one trolley coach line leaves another trolley coach line, special turnout equipment is required. In all cases the special equipment includes devices to which a trolley wire is attached. These devices may be for the purpose of crossing two lines or for the purpose of taking one line off another line. In any event, the design of these devices has been made so that the cross-section of the runner pieces, metallic or insulated, is approximately equivalent to that of the trolley wire. This uniform cross-section of trolley wire and fittings reduces bumping and scrubbing and consequent arcing by the collector and also prevents considerable damage and wear. To the trolley coach rider, it is

Fig. 6—Typical crossover using standard insulating unit tips and crossover pan.

Fig. 7—Electrically operated frog installed ahead of a segment.

important because it is responsible for very quiet collection operation. Even the trolley wire splicer is attached to the upper lobe of the trolley wire, itself, in such a manner that there is no obstruction to the passage of the collector.

There are many types of crossovers and turnouts, most of which are constructed with standard parts. For instance, in Fig. 6, similar crossover pans have been used and the same insulation unit occurs repeatedly. The tips for connecting the trolley wire to the devices are the same for the same size of wire. In the case of the turnout, the standard arrangement shown in Fig. 7 is equivalent to that used on all turnouts, the frog pan itself being the only piece that is selected for some particular type of operation. In these illustrations the standard insulating unit, standard tips and crossover pan may be seen. Of course it is understood the degree of turnout may vary the degree of the crossover pan in either a crossover assembly or turnout assembly.

#### INSULATING UNIT FOR TURNOUTS AND CROSSOVERS

The insulating unit used in all crossover and turnout assemblies must withstand the ultimate mechanical loads of the largest sizes of bronze trolley wire. It must provide adequate insulation during the passage of a collection shoe from positive to negative wires and must withstand the repeated arcing caused by the breaking of electrical loads.

Structurally, this unit consists of two phenolic tubes, a tension member and a compression member. The compression member is constructed of insulation only, while the tension member is reinforced with a steel core, properly insulated at the ends, that enables the assembled unit to withstand all mechanical loads transmitted by overhead trolley wires. The unit provides 12 inches of clear insulation between metallic sections, this distance being adequate to prevent the "carryover" of the 600-volt arcs.

### TYPES OF TURNOUTS

Again looking at the standard turnout, a set of ordinary cast trailing frog pans will permit a trolley coach to "trail through" this arrangement from either the main line or the turnout, no additional guiding of the swivelling shoe being necessary. If the direction of operation is reversed, it can be readily seen that further guidance of the shoe is imperative otherwise the shoe may either enter the straight line or the turnout path. Where the trolley coach enters a frog assembly of this type the shoe must be guided.

One type of turnout where the shoe is guided to one path only, is equipped with a spring frog similar to a spring track switch. If the frog is set for the turnout at all times, the shoe will enter and take the turnout at all times. With the spring arrangement it is possible to trail from either the main line or the turnout, the same as a rail car trails through the spring track switch.

The movable runner of this frog, as well as all electrically operated frogs, is of the "double tongue" type. A shoe collector passing through the frog, either over the turnout or over the main line, will travel over one of the runners. Smooth operation of the shoe is accomplished in this way.

There are numerous locations where one trolley coach line branches away from another line. At these locations it is necessary for the operator to select either the main line route or the turnout route. At these locations electrically-operated frogs are usually installed although in some minor cases, frogs operated with pull ropes have been used.

The electrically-operated frog is of two types, the "power-on-power-off" and the Selectric type. In the former type the path at the point of turnout is selected by the operator of the coach by either coasting through the device (power-off) or by taking power (power-on) to actuate the solenoid-operated frog. In this assembly the frog pan is insulated from the trolley wire. It is, however, electrically connected to the trolley wire through a solenoid which operates the frog runners (Fig. 8). If a coach passes through this section with the "power off," the runner remains in the main line position. If, however, the coach passes through this section with the "power on," current passing through the solenoid actuates the frog runner and sets it to the turnout position. Many modifications of this type of frog are in use, however in principle they are similar to this one.

The other type of electric frog depends upon the angularity of the trolley coach body with the trolley coach wires. The electrically-operated frog used with this combination

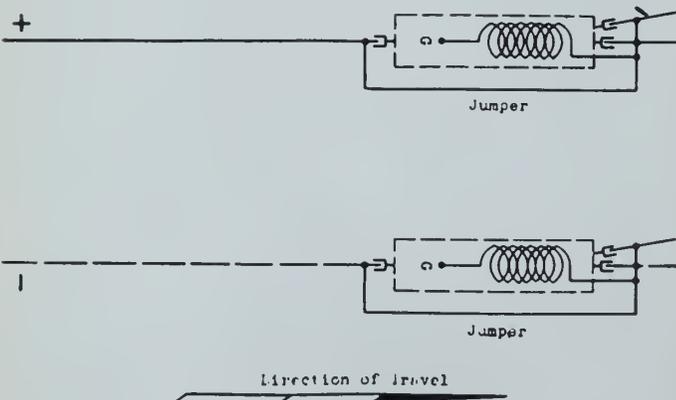

Fig. 8—Wiring diagram of "power-on-power-off" electric frog.

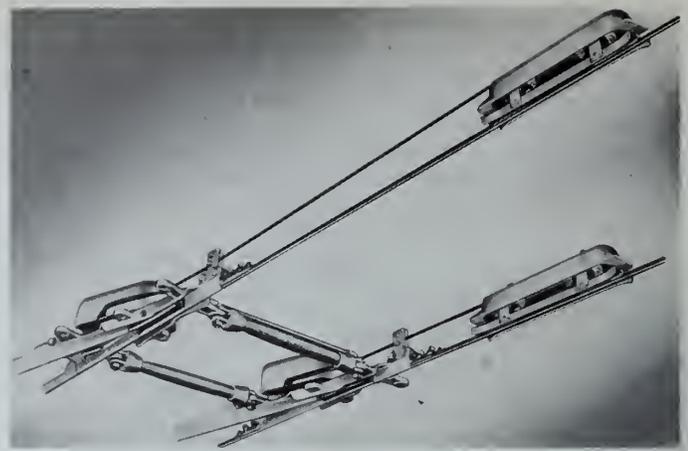

Fig. 9—Location of contactors on trolley wires in front of Selectric frog.

is also equipped with only one solenoid, however, it is also equipped with a mechanical reset. The solenoid actuates the frog runner and after a collector passes through the frog it strikes a trigger and resets the frog to its original position.

Two contactors, one on each trolley wire, are located ahead of the frog. If the two contactors are placed abreast and a trolley coach is continuing over the main line, the collector shoes will be abreast and will strike the two contactors simultaneously. Since these contactors are a part of a circuit to the coil, the frog runner is actuated as the shoes pass beneath them. After the collection shoe has passed through the frog it strikes a mechanical resetting device and throws the frog runner back to its initial position which in this case would be for the turnout. If the coach is to take the turnout, one trolley shoe will lead the other, therefore the shoes cannot strike the two contactors simultaneously and complete a circuit to the solenoid. If the trolley coach is taking a turnout there will be no movement of the frog runner and since the reset position of the runner is for the turnout, the action is positive. See Fig. 9.

Other variations of this type of electric frog are in use, the variations being due chiefly to the locations of contactors. In addition to these variations frequent installations of one-half of an electric frog are used where a street car line either enters or leaves the trolley coach overhead system.

At the present time, an intersection assembly, turnout or crossover, is ordered and shipped as a unit. Previously, the transportation company selected and erected a multitude of small devices, but the confusion caused by this procedure resulted in an effort by all manufacturers to simplify the selection of the proper assemblies for an installation. Unit assemblies are easily identified.

### RESEARCH, AN IMPORTANT FACTOR

The design and development of trolley coach overhead required many laboratory and field tests of materials and assemblies. Impregnated wood beams were first used in crossover assemblies to furnish both mechanical strength and insulation between positive and negative wires. Partially because of bulkiness and weight, but chiefly because of occasional mechanical failures, the wood beam was replaced with a fibre beam. Fibre furnished sufficient insulation for the 600-volt system and provided ample strength but fibre has one inherent feature that was responsible for the discontinuance of its use. Fibre beams warp. As a consequence a straight, smooth under-run was difficult to secure. Variations in moisture even produced warping in stock bins before the devices were shipped. The present tubular, phenolic members of an insulating unit do not warp, have good mechanical strength and furnish excellent insulating qualities over a period of years. Many service tests were necessary during the development of this insulation. The unit is illustrated in Fig. 10.

Life tests on the insulation included repeated collector passages over the runners to determine the deteriorating effect of the arc. An insulating unit is tested with a shoe passing under it at speeds corresponding to the speeds of trolley coach operation in the street. The life of the unit is determined for various values of current at 600 volts. These tests are responsible for the selection of the general design, as well as the selection of materials that will withstand constant arcing. It is to be remembered that the auxiliary load of a trolley coach for lights, heaters and compressor will reach 70 amperes, and this load must be broken at an insulator even when the traction load is cut off.

Fig. 10—Phenolic insulating unit used in crossover and frog assemblies.

The development of the current collection equipment has continued for many years. The first carbon inserts used in the present shoe wore out in less than 10 miles, the next carbon inserts in less than 30 miles and the inserts finally accepted and offered for general use would not last more than 500 miles. The average mileage today for summer and winter, dry weather and wet weather, is considerably over 1,000 miles, and it required four years to secure this mileage. Because of the research conducted by the London Passenger Transport, the present development of the carbon insert collector was no doubt hastened. Similar experiments were carried out in London and in this country. The exchange of data was very helpful in expediting the production of a satisfactory collector.

The usual problems with lightning and radio interference were encountered and satisfactory modifications and improvements were developed to provide the degree of reli-

ability demanded for city transportation service. Today, radio complaints are few and there is no record of damage to the traction motors due to lightning.

#### REDUCTION IN WEIGHT

The weight of the overhead system has always been a problem. A one-pound weight in the overhead system produces from five to eight pounds side load in the supporting structure, either pole or building. The reduction of weight in the overhead system reduces the side loads on the structures and as a consequence, the cost of the system. Substituting 2/0 grooved trolley wire for 3/0 grooved has reduced the weight 20 per cent. The weight of overhead fitting has been reduced 35 per cent since 1934. This weight reduction has permitted the use of many street car poles that formerly supported two trolley wires. Now they support four trolley wires.

#### THE PICTURE OF TROLLEY COACH OPERATION TO-DAY

In addition to the study and development of fittings for overhead design, each new trolley coach installation has required a field study, a study of the application of the materials. To-day, trolley coaches are operating in every climate, almost in every country. They operate at speeds up to 45 m.p.h., accelerate at 4 m.p.h. per sec., collect currents as high as 400 amperes, climb 13 per cent grades, run through subways, through congested streets and over country highways. They do this quietly, swiftly, efficiently, under the overhead distribution system just described.

There are 3,300 trolley coaches now operating in Canada and the United States, 95 per cent of which have been installed within the last ten years. These coaches operating over 1,100 miles of route totalled 100 million coach-miles during 1940, and each coach averaged over 1,000 miles for each trolley pole dewirement.

This is equivalent to saying the trolley coach can run at least five days without a dewirement, a performance that is a measure of the reliability of modern trolley coach overhead.

---

## CHARCOAL HAS WAR-TIME USE

The use of charcoal in making light-weight alloys for aircraft construction has resulted in a substantial increase in the production of charcoal in Canada, reports the Forest Products Laboratories of the Department of Mines and Resources.

Before the war charcoal was used in Canada principally for kindling fires and as a fuel for charcoal cookers. On this continent charcoal was at one time employed in the manufacture of steel but has been largely replaced in that industry by metallurgical coke. In several parts of Europe, in Australia, and in other countries where the price of gasoline is high, charcoal has been used extensively in recent years as a source of producer gas to replace gasoline in the operation of internal combustion engines for buses, tractors, trucks and motor cars. With further

reduction of supplies of gasoline such use may assume importance in Canada.

Charcoal may be made from any species of wood but in Canada it is generally made from the heavy hardwoods—maple, beech, and yellow birch. Two methods of manufacture are employed: charcoal kilns and in steel retorts from which, in addition to charcoal, acetate of lime, methanol, and other by-products are recovered. One cord of air-dry hardwood will produce about 650 pounds of kiln charcoal or about 1,000 pounds of retort charcoal.

The earliest known method of making charcoal was to stack wood in beehive-shaped piles and to cover almost completely with earth. By kindling a fire and regulating the air supply part of the wood is burned, producing sufficient heat to convert the remainder to charcoal.

# THE MANAGEMENT-EMPLOYEE PROBLEM FOR ENGINEERS

JAMES W. PARKER

*Vice-President and Chief Engineer, Detroit Edison Company, Detroit, Mich., U.S.A.*

*President, The American Society of Mechanical Engineers.*

**A luncheon address delivered at the General Professional Meeting of The Engineering Institute of Canada, at Montreal, on February 6th, 1942.**

It is an honour to speak before this meeting of The Engineering Institute of Canada, and a great pleasure to bring you the cordial good wishes of the American Society of Mechanical Engineers. Speaking informally may I say that the views expressed are my own personal views, for my subject is a somewhat controversial one.

Contemplating the world war now in progress, it seems evident that changes in economic conditions after its termination will be momentous, and that the social organization of the nations will differ from that prevailing before this catastrophe.

Many of us feel that the whole issue of the war boils down to a question whether the reorganization of the life of any nation will come from within under leaders of its people's own choosing, or be imposed from without at the hands of a victorious enemy. In either event, the changes will be profound.

When the wave of republicanism swept Europe and America a century and a half ago, and Great Britain eventually emerged successful from the struggle with the French Empire, she found herself free to work out her own scheme of social reform without dictation from the Continent. Reforms took place at last, decades afterward, but in typical British fashion and with the result which you all know. The story would have been a far different one if Napoleon's programme of a new European order had prevailed.

In the United States, changes in the industrial philosophy of the people have been in the making for more than a generation. There are few here who will not remember the time when the purposes of many great corporations were predatory, aimed at the exploitation of both the public and the wage earners.

Those were the days when Theodore Roosevelt used to talk of "malefactors of great wealth." People's consciences were stirred but the way of reform looked long and very nearly hopeless. Yet, since then, the attitude of employers has changed radically. We shall never again see conditions such as prevailed in the days of early steel making in the Ohio Valley. In many ways things have changed for the better. Reasonable hours of work are the rule, good working conditions are general, and the contrast is vast between the conditions under which men work in the great River Rouge plant of the Ford Motor Company, for instance, and those of the steel plants at South Chicago and Pittsburgh in those old unhappy days. The employer has come to have a new concept of the corporation as a great social device and to have a new sense of his three-fold responsibility to the public and to employees, as well as to his shareholders.

It is significant indeed that when the Automobile Labour Relations Board, appointed by President Roosevelt, made its report in 1936, very little had to be said about poor conditions under which men had to work. Indeed, in all the interminable negotiations between unions and manufacturers in recent years, there have been remarkably few complaints about working conditions, and the argument for increased pay has been almost a secondary matter. The issues which arose concerned such matters as membership in unions, representation by collective bargaining agents, and, unhappily, jurisdictional conflict between two types of union organization.

Whether employers or not, there are few thoughtful men who do not believe that in principle, at least, the labour union movement is just, however badly led.

There has, as a matter of fact, been very little of statesmanship in the policies and programme of professional labour leaders. There has, without doubt, been in that leadership an element seeking to inject into the relationship between employer and employee a foreign ideal. It has attempted to arouse class hostility, and has employed the tactics of the European revolutionist; there have been sit-down strikes, and slow-downs, and, I regret to say, much lawlessness.

I do not believe, however, that these alien concepts will take permanent root in America, providing the thoughtful people of the country give constructive attention to this problem. Some industrialists of my acquaintance fear that the labour movement seeks to take over the management and direction of the industrial machine, but it is my own belief that this will never come to pass. My own observation is that wage earners are concerned more with the circumstances which affect their own lives, such as their pay, their conditions of work, or their treatment by the supervisory force, and that they are content to leave to management, as they always have in the past, administrative decisions affecting the conduct of the business.

But the mistakes of management have been many, both in very large manufacturing organizations and in the small 200-man plants. Production men in the automobile companies have repeatedly acknowledged that the unions had chosen stewards from the companies' own employees, who possessed qualities of leadership which management had not discovered.

One hears many stories bearing on this point. A certain manufacturer having a contract with the C.I.O. in his Detroit plant, established a new non-union manufacturing unit at a small city in the northern part of the state. To this arrangement there was immediate objection from the union, and especially from one of his own employees representing his local shop group in Detroit.

My informant, a man of long manufacturing experience who is attempting to establish himself as an industrial relations counsel, talked first to the labour representative and then to the manufacturer, and concluded that the principal cause of disagreement was sheer misunderstanding, rather than a dispute over union membership.

For a time the manufacturer refused to let the shop steward visit the out-of-town plant, and when he finally did consent insisted that the superintendent of the shop accompany the party. Further persuasion was needed before that shop superintendent would permit the shop steward to go freely through that shop. At dinner on the way down from Detroit the shop steward and the shop superintendent sat across the table from each other. My friend hoped they would get talking, but they did not.

When they returned, however, the shop steward had a friendly talk with my informant, and explained that he was pre-occupied because bad management was permitting some work to be done in Detroit which should have been done in the out-of-town plant, and was sending some other operations to the other plant that might better have been carried on in Detroit.

This man had been a trouble-maker in his own shop, but

in regard to what he had seen, his whole attitude was that of an intelligent critic, rather than that of the partisan labour leader that he was supposed to be. I think the incident illustrates a too prevalent inclination on the part of management to withhold confidence from its own employees.

After making allowance for all the pressure to which a man is subjected by union organizers and fellow employees, and for the actual physical coercion which has undoubtedly driven many men into joining a union, there is still another reason which influences men to join unions and to pay dues. They have resented the fact that wage earners have in times past had to deal as individuals with their employers and so have been at a disadvantage. This was not negotiation between equals but rather a suit for relief from conditions objected to, and a decision by a not impartial judge, the employer. The change from this kind of relationship between employee is welcome to almost any man employed.

But, granting the principle, it would be a mistake to conclude that the mere making of a contract with a union will establish a proper relationship with the workers, and between the workers and the employers. Unionized or not unionized, that relationship must be based upon mutual confidence and upon co-operation in meeting problems peculiar to each group—employers and employees alike. It is a result to be studied and worked for unremittingly, as a condition of successful operation, just as merchandisers work for the confidence and good will of the public they serve.

Now, as it happens, engineers play a prominent part in the industrial scene. They and their works are at once the prime cause and product of present day industry, or so we are led to believe. If it is properly in their province to apply the findings of scientific research to the utilization of materials and forces, it is equally their responsibility to deal with the human agencies involved. In the nature of things they gravitate into supervision and administration. Their position is unique, because in their early years of training and experience they have opportunities of forming lasting friendships with the men and the foremen with whom they learn to work.

One of the first questions I have always asked of a junior engineer during his first years in a plant or in a shop is with regard to the workmen—whether or not he has made friends with them and whether or not he likes them. It is a good indication of the boy's worth if he does. One need not ask the workmen whether they like him. If he likes them and admires them it can be taken for granted they have accepted him. Are not such friendships valuable? Out of them come understanding and trust

and they make for success between management and labour in the years ahead.

Men in the ranks look for leadership to the trained, thoughtful men of high purpose with whom they are brought naturally in contact, and if they cannot find it there, they will turn to less worthy sources. The job of management is to maintain a sustained effort to understand and keep the confidence of employees. And it is a job we have too often shirked in the past. Grievances have gone unsatisfied. Men have been offended in ways not even noticed by the supervisory force. I know by experience how dissatisfactions will accumulate in unexpected places, and all under working conditions we had believed as good as it was possible to make them. I believe many an organized demand for wage increases that seemed at the time unreasonable, has been principally the tangible result of neglect on the part of management to treat men with consideration and tact.

I am aware of the uncompromising bearing of some of the labour representatives. But unreasonableness should not be met with unreasonableness, even with the advice of counsel. I have seen too much of that, and, still with advice of counsel, have seen the employer fighting a long-drawn, losing rear-guard action. And, in contrast, I have seen the feeling of the men and even of their organization leaders for such a man as William Knudsen. The job is not one that can safely be delegated to professional labour relations counsel, and then forgotten. That course has been and is still being tried, and the results are not good.

But if the man with engineering training is to prove himself useful in improving these conditions, one may ask what of the unionization of engineers themselves? We hear much about this of late years. I would be the last to deal with the difficult choice often confronting young engineers, in other than realistic fashion. They need the help and advice of older members of the profession, many of them themselves managers and employers of labour. And there are many misconceptions to be removed from people's minds regarding the application of recent labour statutes.

When an engineer makes something of his opportunity to assist in finding solutions for these labour problems, considering it his duty to take that course, rather than one of mere partisanship, the question of unionization within his own profession seems to solve itself. Unionization within a profession is, at best, a contradiction in terms. If a calling is worthy of the name "profession", there must be in it the element of devotion, not for the selfish advantage of some employer or of some self-seeking pressure group, but rather devotion to the interest of the public, in whose service engineers have always done their best work.

# SOME OF THE ENGINEERING IMPLICATIONS OF CIVILIAN DEFENCE

WALTER D. BINGER

*Commissioner of Borough Works, City of New York, and Chairman, National Technological Civil Protection Committee of the United States*

An address presented before the General Professional Meeting of The Engineering Institute of Canada, at Montreal, on February 6th, 1942.

(ABRIDGED)

It is indeed a privilege to bring news of the engineers of England to those of the greatest Dominion.

My one-man expedition to England started from Montreal last September, from whose air-field the bomber flew in a beautiful trip to Scotland with but two hours' stop at Newfoundland.

I have never publicly told of the return trip but it seems fitting to do so here. Montreal was again in our minds on the return journey, which brought us in another very long hop from Scotland to within one hundred miles of Montreal, on what had been a beautiful clear night. About two a.m. some thirty minutes away from Montreal, the plane, without any warning, in view of the fact that the aurora borealis had stilled the radio, suddenly ran into a zone of twelve degrees below zero temperature. Just at the time that the metal of the plane had been cooled to zero, which was about the temperature inside the plane, we encountered a terrific rainstorm, and a phenomenon known as completely frozen rain ensued in which the drops froze so fast that hemispheres of ice built up on the metal. It was estimated that we took on about four tons of ice in a few minutes. There were several inches over the rain-shield.

We still had some distance to go when our altitude dropped to four thousand feet, and kept on dropping at an alarming rate; I understand your hills around here are about twelve hundred feet high. Anyway we were told to put our parachutes on in order to be prepared to bale out. It was dark. It was soon decided to turn around and run away from that ice condition, on the theory that we could always put down on the Atlantic.

We had three rubber boats with us. For three hours we maintained a dead reckoning course back to the east, when suddenly the moon appeared and the navigator found that the storm had been racing toward the North pole, and we were several hundred miles up in Labrador.

We then started south again which was splendid, because we were not only avoiding the danger but we were flying towards the sunlight, and it was a great sight to see the sun try to get through the ice on the windshield. We worked our way south with a failing gasoline supply, and after eighteen hours and seven minutes put down at the Newfoundland airport, still covered with ice and nine hours after we had passed that same meridian in the other direction. So I missed my trip to Montreal altogether, because by that time we were so late we hopped right down to Washington.

I think I should give you some explanation of what took me abroad. About a year and a half ago the American Society of Civil Engineers decided to study the problem of civilian defence. We felt, however, that it was not a task any one institution should undertake by itself, and we suggested to the Secretary of War that he appoint a committee with a member from each of the great American engineering societies—the American Railway Engineering Association, the Institute of Electrical Engineers, the Institute of Heating and Ventilating Engineers, the Chemical Engineers, the Public Health Association, and so on. We took twelve of our outstanding societies and formed a consulting committee, which was empowered to advise the Secretary of War in all things that we thought he ought to know on this subject, and to interpret for him

information which was brought back by military observers from abroad.

Not long after that, Sir Leopold Savile, president of the Institution of Civil Engineers, wrote to the American Society of Civil Engineers, suggesting that a member be sent over there, for, he said, it was impossible to learn this story from reports.

As soon as we felt that we had used all the information we had, we suggested to the Secretary of War that this invitation be accepted, and I was asked to go.

I was sworn in as an expert consultant to the Secretary of War, and attached to the office of the Military Attaché of the Embassy in London.

But the real source of the information I needed was the British Institution of Civil Engineers. They knew what I ought to ask for.

An old professor at the Massachusetts Institute of Technology used to say that in the order of their importance the engineer should be judged, first, by character; second, by judgment; and third, by technical proficiency. And I assure you that the character of the British engineers has a standing fully equal to that of all the other British people.

A striking evidence of this was in the vital decision as to whether or not the repairs made on the public services, such as water supply, gas, and telephone should be of a permanent or temporary nature. With bomb damage occurring many times every night, you can imagine the great temptation, to make temporary repairs. But it was decided that if they did that, then when the bombing was over they would have to tear up their city and do it all over again.

So, in the face of the most terrific air blitz, they made permanent repairs, and when I was in London, some seventy days after the last great air-raid, ninety-five per cent of all the water-mains in London, had been permanently repaired and the streets repaved.

I am in charge of the streets of Manhattan, and when I was over there, the streets of London looked better than the streets of Manhattan. In New York our streets are cut up, owing to a very large amount of new construction going on, whereas at the moment, as you can well realize, there is little new construction in London.

The sewers and the other service lines have also been repaired permanently, but perhaps not to quite as large an extent.

Before I say a few words about water supply, I should tell you that my report was sent back as a sealed document. I was appointed a courier of the State Department, and not allowed to look at it again. The English and the Scotch were not permitted to break the seal under the treaties, and my report was handed in to the Chief of the Intelligence Division of the United States Army. Until that report is finally released as a public document, I am not permitted to divulge any of its contents, nor am I allowed to quote from it. He has, however, already issued one hundred copies of the report, but restricted, so that they are not (under the Espionage Act) permitted to be mentioned in the press, nor passed around without using the greatest discretion.

It is believed that the report will finally be published, but not until the British again have had an opportunity of seeing that there is nothing in it which could possibly injure them.

I carried over with me two hundred questions, prepared by our twelve constituent societies, and brought back the answers to most of them. As I had been working on this subject in all its phases for a year and a half, I was able to discuss it with the British engineers and scientists and officials whom I met, so as to write the report in a give-and-take manner.

The water supply system of London apparently was saved by the fact that it was almost the oldest in the world. According to the chief engineer of the Metropolitan Water Board, the first pipes had been laid in Queen Elizabeth's reign. Of course, they have been renewed many times since, but as the city grew up these water-mains led to street intersections by several different paths. They were not entirely on a rectangular basis, so that in spite of devastating bomb craters which cut many principal mains, there was no district in London he was not able to reach with some line that went another way around.

His message to all American engineers, which I wrote down and I think I may quote, was: Cross-connect, cross-connect, and cross-connect again. Wherever one main meets another, put in a cross-connecting valve, because the time will come when you will need it.

That, of course, does not mean that we in the United States should rebuild our water systems, but it means that those who are designing a water system, which would be good in bombing, would have to bear this in mind.

At this point I should like to say that the Federal and State officials in charge in the United States believe that the time for the expenditure of large sums of money on general protective construction and blackout and air-raid shelters has not yet come, and I agree with this. If we start digging up parks to put in air-raid shelters, or building them in all houses and in streets, and realize that what is done in one city must also be done for others, the expenditure of labour and material would be so enormous that it would really stop first line defence. Obviously, it would be a great error to fall into that frame of mind.

This however, should be the time for intensive planning, not only in general, but in specific cases. A man in control of a big public building should know how he is going to black out that building and which are the safest places in it. It is not intuition that will tell him. It is consulting with qualified engineers who have read the literature of the subject, thought about it, and added what they can themselves.

I think another great mistake would be for us to accept everything that the British have done, because they did not do everything because they wanted to do it. They did a great many things because they had to do them.

For example, take the air-raid shelters in the English cities. Those provided in the streets for pedestrians, are largely built of reinforced brickwork, a horrible kind of construction in which brick is used for what it can give and reinforcing bars are used in such a way that they do not always do the most good.

Statements were made in the United States that the fact that the British were using so much brick was a sign that brick was the best form of protection against blast and splinters. This is not the case. The fact is that when the lumber supplies of Scandinavia were no longer available, the British had not enough foreign lumber to build forms for concrete air-raid shelters. Obviously, since the air-raid shelter is supposed to be a monolithic, homogeneous structure, lying on the pavement, not founded in it, so that in case of a blast the whole structure moves

without collapsing, a reinforced concrete structure is the best.

Another thing that required the most intensive examination and questions was the statement made a year ago in the United States, that no municipal gas holder containing ordinary gas had ever exploded, and therefore that all kinds of gas containers were equally safe, namely, the water-sealed and the waterless type. We did not know whether that was true or not. I was supposed to find out.

There had been a case before the war, where a waterless gas container had exploded in Germany and therefore the British, rightly or wrongly, were afraid that the waterless gas container was a hazard. They therefore withdrew all gas containers of the waterless type from use, so that only water-sealed containers are in use in Britain, with the exception of five individual ones, for which there is no substitute and which are secret. I do not know where they are but they never were hit.

Thus, the answer is that a water-sealed gas container is absolutely safe in any kind of an air-raid, whether incendiary bombs or high explosives, and that is all we can say. We do not know about the others because they have not been exposed.

I mention these things because of the need for going through and beyond statements which are in themselves accurate, but not sufficiently inclusive.

When I decided to look into railways, I went to Mr. E. Graham Clark, the secretary of the Institution of Civil Engineers, and asked him for suggestions. He said that the best man to talk to would be the chief engineer of the most bombed railway. Well, the most bombed railway is one whose name must not be given, but which, while it has only ten per cent of the trackage, has received forty-five per cent of all the bombs. They counted the bombs. Seven thousand five hundred high explosive bombs fell on the right of way of that railway, and tens of thousands of incendiaries. They stopped counting those a long time ago. So you may rest assured the chief engineer of that railway knew all about bombs.

The English use a great amount of brickwork, and are past masters at its use. Their temporary brickwork seems to be better even than our permanent brickwork in New York. They have excellent workmen, which has been a great help to them at a time like this, in repairing the many brick barrel highway bridges which span the two-track railways. One of the railways has a thousand of them. You can repair them simply by bringing down a gang of bricklayers and a few mortar mixers. No plant or complex forms are needed. The result is that they are able to get their lines into use again with remarkable promptness.

Many of the main lines are carried on viaducts of that type. I saw a four-line road on a brick barrel arch system. Large quantities of whiskey were stored under those arches at a point hit by incendiaries. The resulting fire was so hot that the brick actually fused, and ran down, but they had one line in operation in twenty-four hours. They used a very fine system of Royal Engineers' scaffolding, made of steel, very much like our boys' meccano method. You can build it up with any length you want. In a week or so they got the second line running.

It is astonishing to see the way they conserve material. If a barrel arch is destroyed they use every good brick that is left. The result looks like an ancient Tudor construction with new brick fitted in with the old, and concrete put in where they cannot do it any other way.

They have very cleverly built their concrete arches by shovelling concrete into the forms from both sides until they came to a strip eight feet wide in the centre which being immediately overhead could not be shovelled into, and that they repaired with a cement gun.

I had an opportunity of investigating camouflage. That part of my report is marked "secret," at the request of the British, and has been sent to the Army Engineer Board. The British have made great progress in camouflaging things like gas tanks. I am not allowed to say how. It is a clever method and is already available to the American technical people to a considerable extent.

In regard to bombing the British have become fatalists. They know that for practical purposes there is no sure protection against a direct hit. That is not true in case some government department or installation has been buried under many feet of concrete, which might secretly be done. In all other cases a direct hit gets you.

I asked everybody I met in England, taxi drivers and everybody else, where they slept. Practically all of them sleep in their own beds. They have various places they go to when things get pretty hot, but do not imagine that any large percentage of the population use public air-raid shelters as a place to sleep in. At the height of the blitz, and we got the authentic information, only thirty thousand people in London were sleeping in public air-raid shelters. When I was over there there was still a considerable number using the underground railway or tube stations. These tube stations, by the way, are a hundred and fifty feet underground. They are real air-raid shelters. They are not like our subways in New York, where if you did not get killed you would get drowned or asphyxiated because all the gas-lines are directly over your head, supported by a fairly strong roof, but probably protected by only about seven or eight feet of earth.

I found that a thousand people were still sleeping in one of these big stations which had a maximum capacity of 2,500 and they had not had an air-raid in two months or more.

But if you face the fact that it is relatively simple to protect against splinters and glass, and relatively impossible to protect against a direct hit, you have accomplished a good deal, both for your own peace of mind and in knowing what to do.

On the other hand, we shall have to restudy the subject again in the United States, because of the height of the buildings such as we have in our Wall Street area and Radio City.

In such circumstances basement shelters are relatively less useful.

In fact, it seems to be indicated that in streets of high buildings, with frames of steel or reinforced concrete, an air-raid shelter would do better on the third floor, where it would be above the direct blast, and above the action of the massed splinter effect. That would have to be, however, a real air-raid shelter. It would have to be built by bricking up the windows, or making some kind of box inside the room.

Ten per cent of all casualties come from glass splinters and less than two per cent of the casualties are caused by the splinters of the bombs themselves. Of course a large number of the remaining casualties are caused by collapsing of and debris from buildings.

In the case of power stations, protecting the generators from splinters does the greatest amount of good, because the power houses are very big and a direct hit on the generators is unlikely. But splinters can put them out of business. They have developed an excellent system of putting a couple of inches of cork over the casing of the generator and then building a beautiful concrete structure around it, with ring bolts, so the whole thing can be lifted off.

I was shown around the principal power stations by Sir Leonard Pearce, the head of the London Power Company. I said, "There is something delightfully British about building this protection so you can take it off and put it away for another war." He did not answer me, but he showed me where he was going to store it.

You not only get the glass and splinter effect of the explosion, but a remarkable vacuum is created. We have a photograph in New York, in which the whole front of a six-storey wall-bearing building was sucked out into the vacuum of a bomb that never struck it at all. That gives you some idea of what these blows and repercussions are.

In regard to the blackout, which is general throughout England and Scotland, its intensity is unbelievable. I lived in Claridge's Hotel, which was near the Embassy, and every late afternoon the chambermaid came and drew the curtains which were deeply over-lapping, and battened down on the side. Then, when I was ready to step into bed and the lights were out I would pull the curtains apart, and on a moonless night you could hardly see the buildings across the street.

I also travelled by train across the whole of England, starting around seven o'clock, and getting in in the very early hours of the morning, and could see no light anywhere. Every locomotive has a hood between the tender and the cab, of the kind they used to have in the old American covered wagons. All the stoking is done under this and the fireman has a hard time with heat and gas. There are curtains on the car windows and the lights inside are not enough to read by. You do not dare to open the doors from both sides of the English carriages—you do not know whether you are going to step into a ditch or a bridge or where you are. You do not know which side of the station you are on. Men come along with megaphones and call out where you are, and which side you should open up.

The intensity of the lighting in the principal streets is stated to be the intensity of starlight. On a moonlight night London seems comparatively bright, but ordinarily when you come out of a restaurant at night you have to stand still for about thirty seconds before you dare to take a single step. You carry a little flash-light. I carried an American flash-light of the fountain pen type that I kept in my pocket. It had a minute lens, the size of a match-head in the glass. The first night I was there I was stopped by two policemen who told me my flash-light was casting a disk of light on the pavement. This might be seen from an aeroplane, so I had to paste paper over the whole end to get a diffusion of light.

The Americans have been making some experiments of late from aeroplanes and it has been found that blue light is not the least easily seen. A public document will be released within two weeks, giving the concensus of opinion of all the best authorities in the United States, having studied blackouts from all over the world, as to how it can best be achieved. A deep red light is said to be less visible than a blue one.

Those who served in the last war will recall that those blue lights were used in French cities a great deal to protect against air raids. It seems that the principal reason we have all used them since is because the French used them first.

The English extinguish all their street lights on any but main arteries. On the main arteries they have a minute light, very high, covered with a big hood, so that all the light falls downward.

All the railway signal lights are hooded with eighteen-inch cylinders which are apparently perfectly adequate.

The whole theory of blackout, as they have developed it, and it has been proved to be right, is that although it is absolutely impossible to hide a city or even part of a city, you can hide a target, and from the number of bombs that have peppered the neighbourhood of some of those power houses in relation to the relatively few bombs that have hit them, they must be right.

The British have always believed that the first string of bombers are generally the best navigators and you should hide your target from them.

# CONTROL OF TECHNICAL MAN POWER

## THE FIRST STEPS TOWARDS EVEN DISTRIBUTION OF TECHNICAL PERSONNEL IN CANADA

The following regulations became effective on Monday, March 3rd, 1942, and were announced in the House of Commons the following day by the Prime Minister. They are intended to aid in the distribution of those classes of persons in which scarcities have been experienced.

### ORDER IN COUNCIL

P.C. 638

WHEREAS the Minister of Labour reports,—

That having regard to the needs of the armed forces and essential industries there may be a maldistribution of professional engineers, chemists, research scientists, physicists, architects and other technically trained persons in undertakings engaged on essential work;

That the Wartime Bureau of Technical Personnel, which is responsible to the Minister of Labour, was established by Order in Council to organize the placement of technical personnel in the war industries and to co-operate with the Civil Service Commission in arranging for the placement of technical personnel in the Government service; that the Bureau has considerable information concerning such persons, including their qualifications, occupations, the names of their employers and other particulars and that it is desirable that such information be extended and kept up to date;

That there are such persons employed in undertakings not engaged or only partially engaged on essential work and in some undertakings the number employed appears to be in excess of the number required, having regard to their qualifications, the work on which they are engaged and to the national interest at this time;

That after the war, undertakings now engaged on essential work are likely to suffer such a diminution in operations that the number of such persons required in these undertakings will be much smaller;

That there is reason to believe that where such persons are not employed on essential work they would willingly undertake to perform the more arduous duties on essential work if they were so requested by the Minister of Labour and if they were assured that they would be reinstated in their former employment; and

That it is desirable that there should be similarity of treatment in the matter of reinstatement in employment of those who volunteer for service in His Majesty's forces and those who consent to perform services in an undertaking engaged on essential work.

AND WHEREAS the War Measures (Civil Employment Reinstatement) Regulations, 1941 (P.C. 4758), require an employer by whom any person accepted for service in His Majesty's forces was employed when accepted for such service to reinstate him in employment at the termination of that service under conditions not less favourable to him than would have been applicable to him had he not enlisted.

NOW, THEREFORE, His Excellency the Governor General in Council, on the recommendation of the Minister of Labour, and under the authority of the War Measures Act, Chapter 206, Revised Statutes of Canada, 1927, is pleased to make the following regulations and they are hereby made and established accordingly:

### REGULATIONS

1. These Regulations may be cited as the Essential Work (Scientific and Technical Personnel) Regulations, 1942.

2. In these Regulations,

- (a) "Director" means the Director of the Wartime Bureau of Technical Personnel;
- (b) "employer" includes the Crown in the right of the Dominion and in the right of any province;
- (c) "essential work" means work appearing to the Minister of Labour to be essential for the defence of Canada or the efficient prosecution of the war or essential to the life of the community;
- (d) "Minister" means the Minister of Labour;
- (e) "undertaking" includes any branch or department of an undertaking.

3. These Regulations apply to the classes of persons described in the Schedule hereto.

4. Any request made by the Minister, any direction given by him or any notice required to be received or sent by him under these Regulations may be made, given, received or sent, as the case may be, on his behalf by the Director.

5. (a) Any person to whom these Regulations apply may be requested by the Minister to perform, in an undertaking engaged on essential work, such services as that person is, in the opinion of the Minister, capable of performing, being services in the performance of which he should, by reason of his qualifications, in the Minister's opinion, be able to contribute most effectively to the carrying on of essential work.

(b) Notwithstanding any provision in the contract of employment between an employer and any person who is requested by the Minister to perform such services as aforesaid and who consents so to do, it shall be the duty of the employer to release the employee from his contract of employment within thirty days after written notice of the proposed change has been received from the Minister by the employer: provided that during the said period of thirty days the Minister shall consider any written objections made to the proposed change by the employer. The Minister's decision in the matter shall be final.

(c) Notice of the proposed change shall be sent by the Minister to the employer or his agent by post and it shall be deemed to have been received at the time when a letter containing the notice would be delivered in the ordinary course of post and in proving such sending it shall be sufficient to prove that it was properly addressed to the employer's place of business and mailed.

6. It shall be the duty of any employer, who employed a person to whom these Regulations apply immediately before that person at the request of the Minister entered into a contract with another employer to perform services in an undertaking engaged on essential work, to reinstate him at the termination of his contract for such services in a position and under conditions not less favourable than would have been applicable to him had he not consented to perform such services. The provisions of this section shall not apply to the Civil Service of Canada or to the Civil Service of any province of Canada.

7. (a) Where the contract of employment of any person to whom these Regulations apply is to be terminated, or is terminated, it shall be the duty of that person and of his employer each to notify the Director of the proposed or actual termination of the contract.

(b) The notices required by this section shall be given immediately after the party giving notice of his intention to terminate the contract of employment has notified the other of his intention.

8. (a) Any employer who desires to engage a person to whom these Regulations apply must notify the Director of the post to be filled.

(b) Any person to whom these Regulations apply who desires to enter into a contract of employment must notify the Director that his services are available.

9. The notices required by sections 7 and 8 shall give the names of the parties and particulars of the business of the employer, the work on which the employee was, or is, to be engaged, his salary, qualifications, and any other particulars considered by the parties likely to facilitate the proper carrying out of these Regulations. The Minister shall have power to require such further particulars as he may consider necessary for the proper carrying out of these Regulations.

10. After the date on which these Regulations become effective, no contract of employment or arrangement for the services of a person to whom these Regulations apply shall be made until it has been approved by the Minister. Any agreement or arrangement for such services which is made without such approval shall be null and void and where such an agreement or arrangement purports to be for services in an undertaking engaged on essential work, the provisions of section 6 of these Regulations shall not apply.

11. Where a person to whom these Regulations apply enters into a contract to perform services in an undertaking engaged on essential work and the contract is approved by the Minister, such person shall be deemed to have undertaken to perform such services at the request of the Minister and the provisions of section 6 shall apply to such person.

12. In any proceedings for the violation of section 6 of these Regulations, it shall be a defence for the employer who employed a person to whom these Regulations apply before that person agreed, at the request of the Minister, to perform services in an undertaking engaged on essential work, to prove,—

(1) that the person formerly employed by him did not, within two weeks after the termination of his contract for employment on essential work, apply to him for reinstatement; or

(2) that, subject to the provisions of sub-section (1), he failed without reasonable excuse to present himself for employment at the time and place notified to him by the employer; or

(3) that, by reason of a change of circumstances, other than the engagement of some other person to replace him, it was not reasonably practicable to reinstate him or that his reinstatement, in a position and under conditions not less favourable to him than those which would have been applicable to him had he not undertaken essential work, was impracticable and that the employer had offered to reinstate him in the most favourable position and under the most favourable conditions reasonably practicable; or

(4) that he was physically or mentally incapable of performing work available in the employer's service; or

(5) that he was employed to take the place of an employee who had been previously accepted for service in His Majesty's forces or of an employee, being a person to whom these Regulations apply, who, after the date on which they became effective, undertook, at the request of the Minister, to perform services in an undertaking engaged on essential work.

13. Where an employer has reinstated a former employee in accordance with section 6 of these Regulations, he shall not, without reasonable cause, terminate the employment of that employee and, in any proceedings for violation of this section in any case where the employment was terminated within six months of the reinstatement, the

onus shall be on the employer to prove that he had reasonable cause for terminating the employment.

14. An employer shall not terminate the employment of any employee to whom these Regulations apply in the expectancy that the employee, at the request of the Minister, will agree to perform services under another employer. In any proceedings for violation of this section, if the court is of the opinion that there are reasonable grounds for believing that the employment was terminated in violation of this section, the employment shall be deemed to have been so terminated unless the employer proves that the termination was for a reason unconnected with such expectancy.

15. Nothing in these Regulations shall confer on any employer authority to make any contract or arrangement with reference to the period of employment, in any undertaking engaged on essential work, of any of his employees to whom these Regulations apply, and who, at the request of the Minister, consent to perform services in such an undertaking, which he is not authorized to make under any power already possessed by him; but where any employer has entered into an agreement with his employees, being persons to whom these Regulations apply, to restore to their positions employees who undertake to perform services in undertakings engaged on essential work, such agreement shall continue in force to the extent that it is not less advantageous to an employee than the provisions of these Regulations, subject to such interpretation as may be mutually agreed to by the contracting parties.

16. The Minister may make all such orders as he may deem necessary or desirable to carry out the purpose of these Regulations and such orders shall have the force of law.

17. Any person to whom these Regulations apply who fails to comply with the provisions of section 7 or 8 of these Regulations, or of any order made under the authority of these Regulations, shall be guilty of an offence and liable on summary conviction to a fine not exceeding one hundred dollars.

18. Any employer or official who contravenes or fails to comply with the provisions of section 5, 6, 7, 8, 13 or 14 of these Regulations, or of any order made under the authority of these Regulations, shall be guilty of an offence and liable on summary conviction to a fine not exceeding five hundred dollars, and, where the offence is under section 6, 13 or 14, the court shall, in addition, order him to pay to the person whom he has failed to reinstate, or whose employment he has terminated, a sum not exceeding an amount equal to three months' remuneration at the rate at which he was being remunerated by that employer when he undertook, at the request of the Minister, to perform services in an undertaking engaged on essential work.

#### SCHEDULE

1. A person who is normally engaged in the engineering profession in a consulting, technical or supervisory capacity in design, construction, manufacture, operation or maintenance and who has had a regular professional training in practice and in theory as an engineer in any of the following branches of engineering: civil, mechanical, electrical, chemical, metallurgical and mining.

2. A production, industrial or other engineer or chemist who normally holds in any engineering works or manufacturing establishment a position of authority involving responsibility for any phase of executive management or control of any technical function.

3. A person who has obtained a degree at any Canadian or other recognized university and who is normally engaged as a teacher of engineering science or of any branch of science at a university or technical college.

4. A person who has been trained, or who is or has been normally engaged, in the practice of any branch of the science of chemistry but not including a registered pharmacist.

5. A research scientist, that is, a person who, by training or practice, is skilled in the independent search for new knowledge of the properties of matter or energy.

6. A person, other than a teacher, who has obtained a degree at any Canadian or other recognized university in Engineering, Chemistry, Physics, Geology, Mathematics,

Architecture or in any natural science, or who is a technically qualified member of the Engineering Institute of Canada, the Canadian Institute of Chemistry, the Canadian Institute of Mining and Metallurgy, the Royal Architectural Institute of Canada or of any provincial association of professional Engineers, Chemists or Architects.

7. A person, not in the classes described above, who, in the opinion of the Minister, possesses technical qualifications and skill which are needed in undertakings engaged on essential work.

## Abstracts of Current Literature

### REMODELLING THE PLANT OF AN AUSTRALIAN DAILY NEWSPAPER

Extracts from *The Sydney Morning Herald*, OCTOBER 20, 1941

From to-day the *Herald* will be printed on a sheet of a smaller and handier size. The decision to alter the shape of the paper, which was made more than two years ago, was necessitated a large-scale remodelling of the *Herald* building, costing £56,000, and the installation of new presses costing £322,000.

Though the outbreak of war caused anxieties and complications that accounted for the loss at sea of much valuable equipment, the actual work of installation was completed in three months.

Before these changes the *Herald* was equipped with rotary multi-web presses set up in 1922. These have had to be discarded, giving place to a new set of presses able to print the paper on a sheet of a smaller size.

The problem was to install the new machinery while the old presses were still in operation, so that on one night the paper could be produced on the old presses, and not more than two nights later the new machinery could be in full production.

The presses now in operation, plus six more units which are in process of being delivered, will enable the *Herald* to produce 400,000 48-page papers a night. In the chamber underneath the original machine-room there is now space for 24 additional units which would enable the *Herald* to produce one million 48-page papers a day.

#### WORK ON THE BUILDING

There was no space in the machine-rooms as they existed two years ago for more than a few new printing units; at the same time the *Herald* was determined not to transfer its plant to a building elsewhere in the city. It was decided to excavate beneath the existing machines, to underpin them, and to install the new presses below street level. It was therefore necessary to provide for a huge cavern-like sub-basement in hard rock, and at the same time arrange for the plant above to function uninteruptedly.

The overall dimensions for which the builders had to provide were for a chamber 176 ft. long, 27 ft. wide and 34 ft. deep. The chamber was to lie directly under the then existing press-room, and beneath the Scott presses, resting on solid rock 24 ft. below O'Connell Street (These presses weighed about 1,200 tons).

Naturally, at first, the character of the sandstone to be excavated was unknown. What the builders did know, however, was that the proposed chamber would be well below the level of the Tank Stream in Hamilton Street, and also below the highwater level of Sydney Harbor.

The project called for the underpinning of a number of structural columns, the extension of the then existing goods lifts, and, as has been explained, the normal opera-

### Abstracts of articles appearing in the current technical periodicals

tion of the printing machinery during the progress of the operations. The builders were advised that any deflection in the bearings of the presses would be calamitous. A deflection of more than 2/1,000th of an inch would, for instance, seize the bearings and stop the presses!

Another difficulty was the provision of a means of the ingress and egress of all materials, including spoil. In the event this procedure had to be confined to a single opening, only 11 ft. wide, in Pitt Street.

The total amount of rock removed was 150,000 cu. ft. The structural steel used weighed 140 tons.

Ultimately the scheme adopted was the sinking of a shaft 10 ft. deep by 27 ft. in width at the Pitt Street end, then excavating a tunnel of these dimensions—a tunnel somewhat like an underground railway tube. As this tunnel progressed, the machine columns carrying the Scott presses were supported in succession.

Vertical chases were cut in the face of the rock and structural steel columns were inserted under the supports of press No. 4 in the width of 27 ft. Then three-ton structural steel girders, 30 ft. long, were placed under the machine columns.

Great care was necessary to allow for the deflection due to the weight of the presses, 1,200 tons. Each 30-ft. main girder, after being placed in position, was pre-deflected by means of turn buckles and cables anchored to the bottom of the tunnel. This deflection was checked by a dial gauge with an accuracy of 1/1,000th of an inch. Many of the beams, it was found, required half an inch deflection. When the necessary deflection had been obtained, specially prepared steel wedges were driven in, and the spaces were filled with rapid-hardening cement.

This supporting column operation had to be repeated no fewer than 96 times. By then, the whole length and weight of the press-room above, from Pitt Street to O'Connell Street, had been supported on girders, with the new chamber opening below.

The work was successful as no movement could be detected in the press bearings. In short, despite the intricate work going on underneath, the production of the paper continued quite normally.

Where defective layers of stone were removed, strong concrete was inserted under pressure. This was particularly necessary along the northern wall, for the foundations of the heavy building, 190 ft. high, were involved.

The principal structural difficulties were those associated with the underpinning and lengthening of certain columns. Some had to be lengthened by 36 ft., the extended sections each weighing 11 tons. Actually the weight carried by one such column was calculated to be not less than 1,030 tons.

In detail, the procedure adopted was to weld 1½-inch steel plates 8 by 5 ft. on each side of the existing column, to which in turn were welded inclined steel stanchions on concrete foundations.

The bases of the existing columns were then removed and a shaft 36 ft. deep was carried down to the new foundation. The steel extension was thereupon inserted and jacked up.

Extreme care was taken in packing under the new extension columns before the temporary supports were removed. As it turned out, the total compression of each extension did not exceed ½/1,000th of an inch, and no settlement of the building occurred.

Naturally, working conditions were such as to require special ventilation and air-conditioning. Equipment for this purpose was provided as were pumping facilities as the depth of the excavations increased.

Operations were maintained at speed, and during some periods work was continuous for 24 hours. No serious hitch or accident occurred, in spite of the unusual hazards that had to be faced.

The excavation and underpinning took approximately two years to complete, with the men working two shifts, from 7:30 in the morning to 5 o'clock in the afternoon and from 10 o'clock at night to 7:30 a.m.

The work was designed and executed by Stuart Bros., Pty., Ltd., builders of the *Herald* office. They were ably assisted by the advice of Mr. H. R. Smith, of Morris and Smith, their consulting engineers, and had the co-operation of Mr. W. W. F. Denne, the mechanical superintendent of the *Herald*. Under them were a large number of skilled workmen, upon whose proficiency and patience a great deal depended. The excavation called for arduous manual labour, because, although the rock was solid sandstone, no blasting operations could be risked.

#### THE PRINTING EQUIPMENT

Though the essentials of printing have not changed in principle since Gutenberg, nearly five centuries ago, devised a wooden machine modelled on the ancient cheese press (he could print only 20 sheets an hour), the process was revolutionized by the invention of the rotary machine, which made large newspaper circulation possible.

William Nicholson, an English author, school teacher and editor, had, as early as 1790, worked on the idea of printing from type affixed to revolving cylinders, but the problem of attaching the type proved insoluble, and virtually remained so until Robert Hoe, founder of the firm which bears his name, evolved his famous press in 1846.

However, the first machine to print from a continuous reel of paper (instead of sheet paper) was made in 1865 by the American, William Bullock. There were four cylinders—two impression and two plate cylinders—but difficulties arose because the paper had to be cut before printing. Three years later, however, this handicap was overcome in the Walter rotary press used by *The Times*, London, until 1895. From that model the present-day newspaper rotaries undoubtedly developed. It printed reel paper on both sides from curved stereotype plates.

The introduction of electric power, which displaced steam, simplified printing enormously and resulted in a great saving of floor-space. Thus when the *Herald* set up its Scott multi-unit rotary web presses in 1922, the press-room was no longer cluttered up with double and treble decked frameworks, with their mazes of paper, webs and type and impression cylinders. Each of the sixteen units had its own motor and was entirely independent of any other unit. Yet the units could be used in varying combinations. If, for instance, one was thrown out of order, a combination excluding it could be quickly substituted.

These presses, on which until to-day the paper has been printed, could produce 240,000 sixteen-page papers an hour, or half that number of 32-page papers.

Because, however, they did not represent the last word in printing, the proprietors decided in favour of more efficient equipment. Although the war made the change more difficult than had been expected, it has been made successfully and to schedule.

The machinery ordered from R. Hoe and Company, Ltd., London, comprised one 12-unit super-speed line type rotary web newspaper press and one six-unit super-speed line type press.

The double folders and units are so arranged that the following combinations can be speedily selected to meet the varying requirements of the paper:

Six sextuple presses, each consisting of three double-width units and one double folder, to give a total maximum output of 300,000 copies an hour of any size papers from four to 24 pages;

Four octuple presses, four units and one double folder, to give a total maximum output of 200,000 copies an hour of any size papers from 26 to 32 pages;

Three presses, of five or six rolls, to give a total maximum output of 150,000 copies an hour of any size papers, from 34 to 48 pages.

Each of the printing units is chain driven by one 60 hp. commutator type motor, and the electrical connections are such as to enable any motor to be brought in or put out of circuit to suit the various press combinations.

The electrical driving equipment includes a pedestal control station for each sextuple press. These stations are conveniently placed away from the printing machinery, so as to give the operator a clear view over the whole of the presses under his control. To the inexperienced eye each station resembles a complicated high-power wireless set complete with knobs, lights, and handles.

From the station the alignment of the paper as it moves at high speed through the presses, and the automatic tension of each ribbon of paper can be controlled. From it, too, the press is started and stopped.

The presses are equipped with sheet break detectors, consisting of balanced "fingers" supported by the paper web (or ribbon) as it comes from the reel. Should the paper break, these fingers fall and complete an electric circuit which cuts out the motors and applies electromagnetic brakes to each printing cylinder, thus bringing the machinery to a stand-still. In other words, the presses are automatically stopped.

At the same time a knife, operated electrically, cuts the broken ribbon in front of the printing cylinder and in this way prevents the paper from being wound on to the blanket cylinders and causing damage. (The blanket cylinders, it should perhaps be explained, are those which take the impression from the print.)

The paper reels are carried in magazine arms which rotate and, whenever necessary, offer a fresh reel. So that there will be no delay in printing, when the paper from one reel is exhausted an automatic paster cuts the expiring ribbon of paper and joins it to a new reel while the press runs at full speed.

All the driving mechanism, the automatic pasters, and the press control equipment were designed and manufactured by Witton-James Ltd. of Hendon, England.

Actual printing does not, of course, complete the operation, because each paper has to be cut, folded, and delivered to the publishing-room, high above.

Here we have another instance of what can be done by mechanical handling.

Each sextuple press is fitted with an extended delivery, which carries the stream of papers from each folder up through the ceiling of the new machine-room, up again to the ceiling of the old machine-room, over the old rotary presses, and through the floor to the delivery stations in the publishing-room, where an expert staff is waiting to receive them.

One of these deliveries, when filled, carries more than 1,200 copies of the *Herald*.

These masses of papers are automatically counted for distribution.

Every 25th or 50th copy is "kicked" out of the stream in the extended delivery by mechanism in each folder, thus giving a quire count of all copies received in the publishing-room. The paper can thus be collated in lots of 50.

Moreover, special totalisator counters operate electrically with each extended delivery to give the publisher the number of copies from each or all of the deliveries at any given time.

All this time and labour saving equipment was designed and supplied by the Igranic Electric Co., Ltd., of Bedford.

The new presses are served by a new foundry for the casting of stereo. plates. Stereotyping, it should be explained, is the process by which duplicate plates of pages of type and relief printing blocks are obtained. The type and illustrations having been set in the forme, a matrix or mould of the forme is taken in papier mache. The actual printing is done by type-metal castings made from this matrix.

The need for speed and accuracy in newspaper production has brought into general use an ingenious machine called the "autoplate," an American invention, capable of producing such castings very quickly.

The papier mache matrix (on which type and illustrations have been impressed) is fixed into clips and placed in the casting box, which, when closed, is flooded with molten metal, pumped from a large metal pot. The casting box is then opened and the plate is removed from the matrix and cooled by a system of water circulation. The plate is afterwards bored, routed and finished by automatically controlled mechanism. It is then ready for the printing press.

The *Herald's* new foundry consists of three autoplates, three auto-shaving machines, and three routing machines.

This equipment supplies the presses with semi-circular stereo. plates, which are clamped to the printing cylinders, and, when inked by a series of rubber rollers, print on the ribbon of paper as it passes through. Plates are cast at the rate of four per minute per machine.

The 7½-ton pots on each of the machines are fitted with electric heating elements, and the heating is thermostatically controlled to maintain any predetermined casting or stand-by temperature of the stereo. metal. The casting temperature, it should be mentioned, is 580 degrees F., and stand-by temperature—the temperature when the pot is not being used—is 400 degrees.

Directly the stereo. plates are finished they are fed down to the lower machine-room by twin service lifts.

Since the new machine-room is situated, as it were, in the bowels of the earth, and is packed with machinery generating heat, adequate ventilation is a necessity.

To ensure satisfactory working conditions an air-conditioning plant was installed. Clean, fresh air is fed through anemostats in the false ceiling and down vertical trunks to the reel basement. For the benefit of those who may be mystified by the term "anemostats" it should be explained that these are merely circular orifices in the ceiling which give an even spread of fresh air without causing a direct draught.

It will be seen, therefore, that even in this detail the "modern touch" has been applied.

## IT WAVES THE HAIR

### And Also Gives Aircraft Parts to Britain

FROM ROBERT WILLIAMSON\*

A process used in woman's hair-waving is helping to build aircraft for Britain.

\*London Correspondent of *The Engineering Journal*.

It is a form of powder metallurgy, perhaps the greatest innovation in metal-working for thousands of years, in which, instead of using molten metal, articles are made from fine metallic powders and pressed into solid and durable shape.

For ladies' "perms" a metal powder is packed in little sachets of absorbent paper. When moistened, a reaction between the metal and certain chemicals generates the precise amount of heat required, so setting the hair in waves.

In making parts for aeroplanes, guns, ships, tanks and other equipment, powder metallurgy has two great advantages: it is very light and it is self-oiling—that is to say, the metal has fine pores which can absorb oil and retain it almost indefinitely.

The pioneer of powder metallurgy was an Englishman, Mr. W. H. Wollaston, who in 1829 worked out a powder process for platinum because the melting point of this metal was too high for the furnaces then in use. It is being used in Great Britain to-day not only for making metal parts but also for paints, printing inks, metal spraying, soldering and brazing, hardening concrete, dental alloys, fireworks, explosives and diamond tools.

In the near future it may be possible to use it for a ribbonless typewriter in which porous type faces soak up the ink and stamp it on paper.

## INDUSTRY AND INVENTION

FROM *The Beama Journal* (LONDON), DECEMBER, 1941

The proverb telling us that "Necessity is the mother of invention" is a very broad generalization, and by no means always true. Quite often an invention is the result of observation acting upon an acute, alert, and inquisitive mind, eager to learn, but, having learned, content to leave development, application, and financial profit to others. James Watt's first efforts at improving the steam engine were due much more to his awakened interest as he dismantled and examined the Newcomen model that refused to work than to the need of the mining industry for more efficient pumping machinery. Faraday, it is true, had visions of the future of electricity, but no demand for a new motive power directed his brain towards his great discoveries and inventions. Sir J. J. Thomson said that "new ideas on a subject come when one is not thinking about it."

On the other hand, emergencies encourage invention and provide evidence of a basis of truth in the proverb. War brings shoals of fantastic and impracticable ideas to those whose duty it is to sift the wheat from the chaff; but it also spurs on the genuine inventor to effort directed at a definite purpose. Such efforts, however sincerely we may deplore the fact that their ingenuity is generally destructive, are often turned to the aid of industry, transport, and commerce when hostilities cease.

Why are students of science urged to acquire an adequate knowledge of physics, applied mechanics and mathematics, drawing—the tools of their profession? Primarily, that they may be equipped to earn a living. But it is from their ranks, in these days of specialist education, that now and then one man steps out and surprises the world; some moment of close reasoning and logical thinking has acted as a catalyst and precipitated a result that may live in history. Or, it may be, with that same equipment he will produce, at the call of war, a machine, a device, a process, that will influence an entire industry in the direction of speed, of quality, of efficiency. Unknowingly, he may be the leader of that modern phenomenon, so alien to the age of craftsmanship—mass production.

It has been more than once seriously suggested that scientific research should "take a holiday." That idea

will not work. Sir William Bragg, commenting upon it in the presidential address to the British Association in 1928, demolished it. "You cannot prevent interested men from making inquiry," he said. "You cannot prevent the growth of knowledge; you cannot even make a selection of those points of advance which will lead to certain classes of results. No one knows what is over the hill. . . . New applications of scientific knowledge, new ideas, new processes, new machines, must always be in preparation. . . . Nothing in the progress of science, and more particularly of modern science, is so impressive as the growing appreciation of the immensity of what awaits discovery." Here are encouraging words for all workers in the field of industrial invention; and whether their inventiveness is excited by the immediate necessities of war, or is inspired by the mysterious force of unresting thought within them, they will be in the great tradition and acquire merit in that their gifts are for the service of mankind.

### FLEXIBLE PIPE RESEARCH REPORTED

Flexible-pipe culverts made of corrugated metal are able to support the weight of high earth embankments chiefly because of the lateral support of the pipes by the soil in which they are embedded. Such is the report of M. G. Spangler, research engineer of the Iowa Engineering Experiment Station, presented in Bulletin 153 of the Station, which has been issued recently.

Design data for calculating the supporting strength of flexible pipe are developed in the bulletin from both theoretical analysis and field experimentation. The design analysis is a result of an extensive research study, conducted in co-operation with the U.S. Public Roads Administration, which included full-scale field experiments on pipes as large as 60 inches in diameter under earth embankments 15 and 16 ft. high. One of the experiments has been in progress for more than 13 years, and thus furnishes data on long-time increases in pipe deflection.

In addition the study included laboratory tests on full-sized pipes. The bulletin also reports the performance of a flexible-pipe culvert 15 ft. in diameter, installed under a 42-ft. fill in accordance with the design principles presented by Mr. Spangler.

Professor Spangler's study reveals that the thin-ring elastic analysis is valid for calculation of deflections of corrugated-metal pipe. This analysis is used as a basis for deriving a design formula for pipe deflection which evaluates the effect of fill load, pipe size, bedding, properties of the soil, moment of inertia of the pipe wall, modulus of elasticity of the metal, and time of service. Techniques for determining these design factors are presented in the bulletin.

The field experiments show that a corrugated-metal pipe will deflect an additional 25 to 50 per cent after the earth fill over it is completed, although several years may elapse before the maximum deflection occurs. Pre-deformation of large pipes by vertical struts increases the load they will carry without excessive deformation.

The bulletin does not discuss the durability of the various metals used to make corrugated-metal-pipe culverts, nor is the design theory verified experimentally for low heights of fill and large vehicle wheel loads. However, the theory is general and should apply regardless of the load source, Mr. Spangler believes.

The complete research study is reported in Bulletin 153, "The Structural Design of Flexible-Pipe Culverts." Single copies of this 80-page bulletin may be obtained without charge from the Iowa Engineering Experiment Station, Ames, Iowa, U.S.A.

### STEAM RAISING WITH VEGETABLE REFUSE

FROM *Overseas Daily Mail Engineering Supplement*,  
(LONDON), FEBRUARY, 1942

The generation of steam with low-grade vegetable refuse fuels has probably progressed further in the case of sugar factories burning bagasse (cane refuse) than with most other fuels of this kind. This is probably due to the very large quantities of bagasse made each day and requiring disposal, the correspondingly large demand for process steam in the sugar refinery, and the fact that sugar factories are economically of relatively large size and therefore justify the installation of special equipment and furnaces for handling the refuse.

Apart from bagasse, a considerable economy can be effected in many establishments, especially overseas, by the efficient utilization for steam generation of any low-grade vegetable refuse that may be available. This includes, for example, spent tan and a wide range of products such as nutshells, fruit stones, seeds, husks, and skins and cores of soft fruit, as well as materials such as sawdust, shavings, bark, ends and pieces, and similar products from the timber and wood-working industries.

#### RESIDUE FUELS

Another type of low-grade vegetable refuse fuel is the residue after extracting vegetable products of all kinds for tannins, dyestuffs, perfumes, spices, and alkaloids.

During the past twenty years great progress has been made in the design and manufacture of furnace equipment for burning material of this kind, particularly for steam generation. In spite of this, however, in very many cases such refuse material is either not used at all or is burnt more or less with the object of getting rid of a nuisance, even when this applies to the operation of steam boilers. In fact in many cases the methods adopted are so unscientific that not only is no real benefit being obtained from the heating value of the refuse, but it is actually reducing that of the coal, coke, or other fuel that may be used at the same time.

#### GENERAL METHODS

Three general methods can be adopted for burning such refuse fuel. The first is to use handfired forced-draught furnaces, with either steam jets or fans, for the operation of "Lancashire" and other cylindrical boilers.

Another general method is to use water-tube boilers, which may be very small in size if necessary, in conjunction with either inclined step grates, hand or mechanically fed, or travelling grate mechanical stokers, preferably with fan-forced draught and preheated air.

The third method for utilizing low-grade vegetable refuse fuels is to install a small destructor supplying hot water either for process and general heating work or for steam boilers.

Most vegetable refuse fuel of this description has, say, 40 to 50 per cent moisture, with a very low ash content, and a heating value as fired of about 2,000-3,500 B.t.u. per lb. With modern plant it can either be burnt alone or mixed with low-grade small coal or coke breeze.

#### TYPICAL INSTALLATION

An interesting installation at a London works by International Combustion Ltd., consists of a small, inclined tube, water-tube boiler with upper steam and water drum, together with an additional steam drying cylinder and a lower water drum. This burns up to 15,000 lb. per hour of equal parts of coal and of mixed vegetable refuse, which includes wood chippings, sawdust, straw and vegetable refuse from the treatment of cloves and nutmegs.

For this purpose a travelling grate stoker is used, with fan-forced draught, superheaters, air heaters and econ-

mizers on the most scientific lines, the thermal efficiency obtained being stated to average 87 per cent based on the net or lower calorific value of the mixed fuel.

The boiler operates at 450 lb. per sq. in. pressure (725 lb. per sq. in. test pressure), and the normal evaporation is 15,000 lb. of water per hour, with 20,000 lb. maximum, the feed-water being delivered to the boiler at 176 deg. F., while the temperature in the combustion gases at the superheater outlet is slightly over 700 deg. F.

This is a good indication of the fact that the burning of refuse fuels has long since ceased to be a crude and unscientific performance, and that when large amounts of materials are concerned it is just as essential as in the case of coal or other fuel to have a boiler plant operated on the most efficient lines, with high pressures and temperatures if necessary.

#### GROUND-NUT RESIDUE

More and more use is being made of refuse fuels throughout the world, and a typical example of the use of low-grade vegetable refuse fuels is that of ground nuts. These ground nuts are subjected to compression for the production of oil, and the solid residue is made into briquettes and utilized for steam boilers, including those on locomotives.

Before the war this ground-nut residue cake resulting from the compression was used as cattle food, being shipped to France, Finland, Denmark, and Hungary. Now, instead, the residue is briquetted. The heating value of the briquette is 8,000-9,000 B.t.u. per lb. (4,500-5,000 k. cal. per kilo), much higher than the coal hitherto imported, in the ratio of 100:160 by weight.

It is stated, for example, that the Dakar-Niger Railway, which used to burn 5,000 tons of coal per month, will shortly be using 3,000-4,000 tons of these ground nut refuse briquettes per month, the cost of which is less than imported coal.

In addition, even the husks obtained after shelling the ground nuts are being used for fuel, especially in steam boilers for generating steam for driving the machines at the ground nut factories, the heating value of the husks being 6,600 B.t.u. per lb. (3,700-3,900 k. cal. per kilo).

#### BURNING OF WOOD WASTE

Both wet and dry wood wastes form a suitable fuel for steam generation. In up-to-date wood-working establishments the sawdust and chippings from the machines are continuously removed by suction equipment and taken to a central boiler plant, where they are burned either alone or in conjunction with supplementary coal or other fuel.

Dry wood can be satisfactorily burned in many forms of furnace, and refuse of uniform and small particle size can be burned in suspension in conjunction with pulverized coal if necessary.

Wet wood waste is a more difficult matter, depending upon the moisture content; the combustion of all woods must be arranged on the consideration that up to 80 per cent of the (dry) weight of the wood is volatile matter,

and that complete combustion of the resulting gases is of great importance.

For wet wood waste, the only practicable method is to adopt some form of grate set in an extension or supplementary furnace or "Dutch oven," similar to that used in bagasse burning. This arrangement provides sufficient radiant heat to dry the wood waste and then to distil the volatile matter, which is then burned in the main combustion chamber with an ample supply of secondary air. It is general also to arrange for an excess of primary air through the extension furnace or grate to evaporate the moisture and to cool the grate.

The inclined grates in the extension furnaces of advanced designs of furnace are of steel tubes running into headers, forming a water-cooled type of grate.

#### PROSPECTS OF GREATER SHIP PRODUCTION IN SCOTLAND

From *Trade and Engineering* (LONDON), FEBRUARY, 1942

Although production in shipbuilding and engineering reached very high levels in 1941 there are good prospects that new records of output will be established at the Scottish centres in the present year. The urgent need for still greater production is fully appreciated by employers and workers alike throughout all the essential war industries, more especially since the extension of hostilities to the Far East. Shipbuilders and ship-repairers have begun the year with a heavy programme of work on hand, and there will be practically little to limit production except the building capacity of the yards and perhaps also the supply of skilled labour. In the case of new tonnage construction the measure of standardization of design which has been introduced, coupled with the policy of placing repeat orders with individual firms, are aids to the acceleration of work in the yards. Another factor which helps in the same direction is the adequate supplies of steel and other shipbuilding materials available, notwithstanding the heavy pressure on the steel trade from the munition, tank, and aeroplane factories.

An interesting development under war conditions is the return to the use of timber in the construction of vessels of moderate tonnage. This is a branch of shipbuilding which is necessarily limited in extent, but it is understood that a number of useful craft are being turned out, while, so far as labour is concerned, the work makes little demand on those classes of workmen that are skilled in steel shipbuilding. The timber used is to a large extent home-grown. The available plantations are inspected by experts who mark out oak trees suitable for the "knees" and "heels" for the support of keels and decks, but instead of the timber being laboriously shaped by hand as in former times it is ripped up at high speed by the latest types of band saws electrically driven. When completed the wooden vessels bear little resemblance to those of the sailing-ship days, but at a distance are almost indistinguishable from craft built of steel. In most cases the propelling machinery consists of Diesel engines.

# From Month to Month

## NATIONAL SELECTIVE SERVICE

The long awaited plan for man power mobilization was announced by the Prime Minister in the House of Commons on March 24th. The proposal is of interest to all Canadian citizens, and particularly to engineers. The selection of Elliott M. Little as Director of National Selective Service places an engineer in one of the most responsible positions in Canada. It is his duty to implement the legislation already announced and any subsequent Acts which may be promulgated. This appointment is a further demonstration of the oft repeated statement that "this is an engineer's war."

E. M. Little

This development is of additional interest to members of the Institute in view of the fact that the General Secretary — L. Austin Wright—has been appointed Assistant to the Director. Mr. Little and Mr. Wright were responsible for the organization and operation of the War-time Bureau of Technical Personnel, and the experience gained thereby will be of great assistance to them in dealing with the larger field of man power.

The Council of the Institute has given Mr. Wright leave of absence to carry out this important work, but he will be able to retain contact with Institute affairs by attending Council meetings. He will also be available for consultation with Headquarters whenever required.

It has been arranged that the Assistant Secretary, the Secretary Emeritus, and the headquarters staff will undertake additional duties so as to make up as far as possible for the loss of Mr. Wright's services resulting from his new responsibilities.

Members may rest assured that while every effort will be made to maintain the regular Institute activities, occasional delay or inconvenience may prove to be unavoidable. In such case their indulgence will be appreciated, for they will realize that such occurrences result from the assistance given by their Institute to the country's war effort.

—R.J.D.

## News of the Institute and other Societies, Comments and Correspondence, Elections and Transfers

### APRIL TWENTY-FIFTH

On this date Dean C. R. Young is to be the guest of honour at a dinner jointly sponsored by the Toronto Branch of the Institute and the Association of Professional Engineers of Ontario, to celebrate his appointment as dean of the Faculty of Applied Science and Engineering of the University of Toronto and his recent election to the presidency of the Institute. At the same time it is intended to impress upon the public the great contribution that engineers are making in the present conflict.

The committee in charge of the arrangements, under the chairmanship of S. R. Frost, announces that the dinner is open to all engineers. It is expected that representatives from all branches of the Institute, in the provinces of Ontario and Quebec, will be present.

The dinner will take place at Hart House, University of Toronto. In the afternoon the House will be open to all engineers who may care to go and use the facilities before proceeding to dinner at 6.30 p.m. Visitors may use the swimming pool, play squash, billiards and have afternoon tea. After dinner, there will be special entertainment and music.

The Council of the Institute will be holding a regional meeting in the morning, at the Royal York Hotel, while the Council of the Association of Professional Engineers will meet in their own rooms at Bay Street. The two councils will join for lunch at the hotel.

All members are urged to come to this important gathering and pay honour to one of the great men in our profession.

### THE JOURNAL TRIES ANOTHER INNOVATION

The leading paper in this number of the *Journal* has earned the Gzowski Medal for 1941. It is entitled "The Lions' Gate Bridge" and the author is S. R. Banks, M.E.I.C., of Montreal. The work is a very complete description of all phases of design, fabrication and erection and runs to a length much greater than is normally printed in the *Journal*.

The Publication Committee believes that in the absence of Transactions, the *Journal* should be available as the repository of the records of engineering achievement in Canada. Consequently, Mr. Banks' paper will be printed in full, but it will be broken down into sections and spread out through four numbers of the *Journal*. Members who desire to preserve the complete work may put the four sections together afterward, or may keep the four complete *Journals* together.

The paper is one of the best that has been presented to the Institute in many years, and the *Journal* is pleased to be the medium of bringing it before the profession.

### E.C.P.D. GUIDANCE BOOKLET

Following closely on the heels of the Institute's booklet "The Profession of Engineering in Canada," comes a similar booklet from the Engineers' Council for Professional Development. This latter is somewhat more comprehensive and general in nature, but can be used to advantage with the Institute's publication. Its distribution is in the hands of the chairman of the Institute's Committee on the Training and Welfare of the Young Engineer.

This booklet entitled "Engineering as a Career" is planned to help students decide whether they are fitted to be engineers, by giving them a general picture of the

L. Austin Wright, M.E.I.C.

characteristics and requirements common to all branches of the profession and discussing the qualities and aptitudes needed by engineers.

In the first section, "The Scope of Engineering," are included discussions of what engineering is and what engineers do, the functions of engineering, the "engineering method," as well as answers to the question "who should study engineering?", an outline of the necessary preparation for such a career, and a survey of probable opportunities and earnings. The second section presents more detailed accounts of the activities of engineers in the various branches of the profession. The interrelationships among various types of engineering are stressed, and consideration given to the use of engineering training in other fields of activity.

"Engineering as a Career" is intended to give the high-school student, in language that he can understand, the facts he needs to help him choose his career. A list of vocational-guidance books and pamphlets, also primarily concerned with engineering and related vocations, is included. Copies of the booklet may be obtained from Headquarters at ten cents each.

### EMPLOYERS HELP THE UNIVERSITIES

So great have been the demands for technically-trained personnel in recent months that difficulty has been experienced in finding junior instructors in the universities to carry on effectively the regular work of the engineering courses. These difficulties of providing instruction have been enhanced by the increased registration of engineering students.

The University of Toronto was unable to secure a sufficient number of full-time demonstrators to meet its requirements, and, in the emergency, has been assisted by the employers of technical personnel in the city from whom twenty-one men have been made available for periods averaging about two half-days each per week. While assistance of this type is perhaps not so satisfactory in all respects as full-time assistance would be, there is, on the other hand, the advantage that the men who are giving their services in this manner are in nearly every instance more mature and more experienced than the junior instructors generally engaged for this work by the university. Furthermore, the contacts so formed between industry and the university may be expected to work to the advantage of both the university and the organizations assisting in this manner.

The university is indebted in this connection to the Hydro-Electric Power Commission of Ontario, which has supplied eleven part-time demonstrators, to the Bell Telephone Company of Canada, The Canadian General Electric Company, Limited, the Canadian and General Finance Company, Limited, the Canadian National Railways, the Dominion Bridge Company, Limited, and Mr. E. A. Cross, consulting engineer.

### A LANDMARK DISAPPEARS

Following the last great war, the Federal Government announced that captured German guns were available for distribution to municipalities and certain organizations upon application. The Institute had in the last war over one thousand members, mostly officers, and when the piece allocated to the Institute arrived in the form of a battered machine gun, minus most of its parts, the general secretary of that day, Mr. Fraser Keith, considered that this was hardly appropriate, and an immediate search was made for something that would more adequately represent the contribution which the Institute's members had made.

A heavy German field gun, which apparently had no owner, was located by Mr. Keith on a vacant lot on the corner of Cypress and Stanley streets, embedded in mud to the hubs. The Officer Commanding Military District No. 4 was Brig.-Gen. Charles J. Armstrong, C.M.G.,

C.B., an active member and a warm friend of the Institute. He undertook to find out who owned this gun and see if it could be made available to the Institute. Later he telephoned that it had been given to the 199th Irish Rangers, under the command of the Late Lieut.-Colonel Lord Shaughnessy, who graciously agreed to forgo any further claim to it in favour of the Institute.

As soon as this information was received a telephone call went to the late Mr. Archie Byers, of A. F. Byers & Company, with instructions to have the gun brought to the vacant space to the south of the Institute as quickly as possible. This was done and very shortly afterwards a

The gun is taken away by salvage workers.

concrete bed was put in place and the field piece bolted down securely so that the temptation which would otherwise always have been present to McGill students was removed. Thus we received the familiar field piece which has guarded the Headquarters building for over twenty years. At that time it was complete in every detail, but during the years a large part of the mechanism was removed. The mutilation at the muzzle was said to be due to the fact that the Germans had a habit of inserting a shell at the end of the barrel and afterwards firing by means of a long cord, thus rendering it unfit for further use.

The gun is no longer there—but has come to a not inglorious fate, for it has just been presented to the National Salvage Committee, and it is anticipated that it will return to Germany in a form quite different from that in which it left.

### WARTIME BUREAU OF TECHNICAL PERSONNEL

#### Monthly Bulletin

By far the most important development that has taken place in the history of the Bureau is the inauguration of the Regulations that were announced by the Prime Minister in the House of Commons, on March 24th, 1942, as part of the national man power proposal. These Regulations are known officially as the Essential Work (Scientific and Technical Personnel) Regulations—1942 and are covered by Order-in-Council No. 638.

In essence the Regulations require an employer to secure a permit from the Minister of Labour before engaging technical personnel, and to report the cessation of employment of all such persons. Under certain conditions he is also required to release such persons from his employ and to retain their seniority in the organization.

The complete Regulations are printed on p. 241 in this number of the *Journal* and employees and employers alike are urged to study them. It is to be noted that a

fine of one hundred dollars may be imposed for each failure to comply with the law.

The purposes of the Regulations are several. The increased demand for engineers in civilian and combatant occupations, and the decreased supply of competent persons have made necessary a more rigid system of maintaining contact. It becomes necessary to know where every person is; what he is doing and why he proposes changing employment, also why a prospective employer needs a technical person; is the particular person suited to the opening or would he be more useful to the war effort in another occupation?

This information and more is necessary if there is to be any intelligent control over the scarce commodity of technical skill. It is well known to the Bureau that many engineers, though on engineering work, are not being used to the maximum of their abilities, and others are in tasks that have practically no relationship to engineering. It will be difficult to fully correct the present situation—although a great improvement is hoped for—but surely something can be done to prevent further waste of this same kind. The necessity of obtaining a permit before engaging a technically trained person will make this possible.

A better distribution of this type of man power will be possible under the Regulations. Non-essential industries and other industries that have a reserve—and several have—will be encouraged to aid essential industries that are now suffering from a shortage. An employer is required to release an employee if the Bureau so requests and the employee is agreeable to it, and at the same time preserve his seniority. Every attempt will be made to check the relative importance of the work he is doing, with the work which he might do, before any transfers are proposed. It is expected that, when properly informed, employers will release men without the necessity of invoking the Regulations. It is much better that men be given leave of absence with the blessing of their employers than that they should be taken away by force of law.

This legislation is unique in Canadian history. It is the first attempt to apply compulsion to civilian occupation. It is a modified form of conscription that applies to industry and not to the army, and to the employer rather than the employee. Its enactment is based largely on the fact that seventy-five per cent of all persons completing the Bureau questionnaire, stated that they were prepared to transfer to war work if they were so requested by the proper authority. In other words, they were asking to be told. It is to the credit of this profession, that such a large majority puts the needs of the country ahead of their own particular interests.

Such controls are not going to be easy to administer. To avoid complicated and expensive administration, it will be necessary to have the support of employer as well as employee. With such support, everything will be readily possible; without it, the operations will become difficult, expensive and doubtless less satisfactory to everyone concerned. The Bureau is interested only in the successful prosecution of the war. Any attempt to control technical man power has only this objective in view.

The sympathetic support of all parties is sincerely solicited.

### PIONEER IN THE PROFESSION

The following brief notes were taken from a questionnaire of the Wartime Bureau of Technical Personnel which was submitted by Mr. C. A. E. Shaw. They go back into the history of western Canada and touch on many important developments of those days. With Mr. Shaw's permission, they are being printed herewith, for the benefit of other members of the profession. It is particularly interesting to see that Mr. Shaw took over com-

mand of the training camp of the R.C.E. in 1915 when he was sixty-two years of age. He took the officers' training course at the age of sixty-three and retired in 1918 with the rank of major. He is now eighty-nine years old.

Herewith is his letter and the notes:

Mount Tolmie, B.C.,  
February 6th, 1942.

L. A. Wright, Esq.,  
The Engineering Institute of Canada,  
2050 Mansfield Street, Montreal, Quebec.

My dear Mr. Wright,

Your letter of January 30th came to me as a very pleasant surprise. I have been engaged in trying to prepare a record of my past experiences, quite a big undertaking, as it covers about seventy years of a very active life, mostly pioneering. However, even at my age, I have a wonderful memory and already have a considerable portion of it written down, some of it has already appeared in various papers. As you are now in Montreal you could no doubt procure a copy of C.P.R. Bulletin, No. 10, which gives an account of some of my experiences while on various C.P.R. surveys.

Should I ever get this monumental task I am engaged in completed and typewritten, I will be glad to send you a copy.

Very sincerely yours,

C. A. E. SHAW.

Employed by the Government on first survey of C.P.R. from Prince Arthur Landing to Rat Portage (now Kenora) from 1871 to 1874.

Leveller on survey made by Senator A. B. Foster of railway line from the Georgian Bay to Mattawa on the Ottawa River, 1875-76.

Located and built railway from Picton to Trenton, Ontario, for Alexander Manning of Toronto in 1878-79.

Employed as leveller on survey made by the Government of C.P.R. from Selkirk to west boundary of province of Manitoba, 1879-81.

Located and built under General Rosser, in 1881, fifty miles of C.P.R. from a point near where Brandon now is. (C.P.R. Bulletin, No. 10 gives some account of these various experiences).

Took my party with a train of Red River carts to the south Saskatchewan—chose the crossing at Medicine Hat for the C.P.R., ran a trial line from there to Calgary, and made the final location of the C.P.R. from there to Calgary, 1881-82. Employed by General Rosser and later by Van Horne.

Made preliminary survey and final location of C.P.R. from Calgary to Great Divide in 1883. Employed by Sir William Van Horne.

1892-94. Surveying land in south western Manitoba for the Dominion Government.

Private practice as surveyor and mining engineer at Greenwood, British Columbia, also explored line from Point Roberts, B.C. to Rosland for the Vancouver, Victoria and Eastern Railway—now the Kettle Valley Railway 1896-1912.

Employed by British Columbia Government on land surveys 1913-14.

In command of 6th Field Company Royal Engineers, and instructor of engineers at Vernon Training Camp, 1915.

Took officers training course and appointed to command of Morrissey Internment Camp 1916-18, with rank of major.

Demobilized 1918.

Private practice till 1936.

Mr. Shaw is a member of the Dominion, Ontario, Manitoba and British Columbia Land Surveyors Associations—and is a life member of the Association of Professional Engineers of British Columbia.

## MEETING OF COUNCIL

A meeting of the Council of the Institute was held at Headquarters on Saturday, March 14th, 1942 at ten thirty a.m.

Present: President C. R. Young in the chair; Vice-President K. M. Cameron; Councillors J. E. Armstrong, J. H. Fregeau, E. D. Gray-Donald, J. G. Hall, W. G. Hunt, H. N. Macpherson, C. K. McLeod, G. M. Pitts, and J. A. Vance; Treasurer E. G. M. Cape; Secretary Emeritus R. J. Durely, General Secretary L. Austin Wright and Assistant General Secretary Louis Trudel.

The general secretary announced that in accordance with a previous decision of Council the gun which has been standing on the Institute property since 1919 had been handed over to the National Salvage Committee. The story of the gun, together with a photograph of it in the process of removal is published in this number of the *Journal*.

The general secretary read a letter from Mr. Pitts elaborating on the suggestion which he had made at the last meeting of Council, that arrangements might be made with the Founder Societies in the United States for the distribution in Canada by The Engineering Institute of all their publications, both to their own members and to members of the Institute who might desire to receive them.

Discussion followed, all members agreeing that such an arrangement would have many advantages, although it might be difficult to work out the details of distribution and finance. It was finally decided, on the motion of Mr. Pitts, seconded by Mr. Macpherson, that the matter be referred to the Publication Committee for consideration and report.

In the absence of the chairman, the general secretary presented the report of the Finance Committee. The financial statement for the first two months of the year showed that the income was substantially higher than at the same time last year, and that expenditures were slightly increased.

The general secretary read a letter from the Montreal Branch advising that at a recent meeting of their executive committee, a resolution had been passed to the effect that Council be asked to study the advisability of abolishing the class known as "Branch Affiliate."

The branch found that candidates for the class of Affiliate are inclined to apply for admission as Branch Affiliates rather than Institute Affiliates on account of the much lower cost. The former classification does not entitle them to true membership in the Institute; nevertheless, they may receive the *Journal* and are able to attend branch functions.

Mr. McLeod pointed out that it was entirely up to each branch to decide whether or not they had Branch Affiliates. If the Montreal Branch did not want to have such a classification, they did not need to do so. In Mr. McLeod's opinion, the qualifications for an Institute Affiliate were much higher than for a Branch Affiliate. Mr. Vance pointed out that some of the smaller branches had quite a large number of Branch Affiliates, and he thought that all the branches should be consulted before any action was taken.

Mr. Macpherson drew attention to the wide difference in the definition of a Branch Affiliate and that of an Institute Affiliate. The by-laws require that an Institute Affiliate shall be qualified to co-operate with engineers in the advancement of professional knowledge.

In Mr. Pitts' opinion, the higher entrance and annual

fee for an Institute Affiliate may account for the greater number of Branch Affiliates.

After further discussion, on the motion of Mr. Pitts, seconded by Mr. Hall, it was unanimously resolved that this matter be referred to the Institute's Membership Committee for consideration and report.

The general secretary presented a letter from Mr. Robson Black, vice-president and manager of the Canadian Forestry Association, inviting the Institute to appoint a delegate to their Board of Directors.

The president reported that he had discussed this matter with Mr. Black who had called on him in Toronto the previous day, and he felt that the Institute would be well advised to be represented on this Board. It would provide another contact and increase the influence of the Institute. It was unanimously resolved that such an appointment be made, and it was left with the president and the general secretary to name an appropriate representative.

The general secretary announced that the government had offered the position of Director of National Selective Service to a gentleman who, in turn, had asked the general secretary to go with him on the new work. The secretary was not at liberty to disclose the identity of the person selected as final arrangements had not been completed and only a tentative acceptance had been given the government.

Mr. Wright explained that his purpose in bringing the matter before Council now was in order to get some basis upon which a quick decision could be made without calling Council together again in the event that the present proposal went through to completion. He pointed out that to do this important piece of work it would be necessary for him to devote practically all his time to it. As his time was entirely at the disposal of Council he felt that the decision as to whether or not he could accept this appointment should be made by Council.

Mr. Armstrong reported that the matter had been discussed at a meeting of the Finance Committee and it was the committee's opinion that in view of the compulsory nature of the legislation which is pending and the national importance of the work involved, Council should not hesitate to make Mr. Wright's services available. Several of the councillors spoke on the issue, and it was the opinion of all that the Institute should participate in this effort to organize the man power of Canada by making available any services that the government might need.

In view of the fact that a final decision was not required now, it was moved by Mr. Pitts, seconded by Mr. Vance, and unanimously agreed that Mr. Wright's services should be made available if required, and that final details could be determined by the president and the chairman of the Finance Committee.

The general secretary asked whether the Council had in mind any special policies that might be adopted by the Institute in view of changing conditions. Certain things would eventually happen and he wondered if there was anything the Institute could do about them in advance.

Mr. Pitts thought the Institute should continue its efforts to bind the whole profession together. Through the influence of Mr. Wright the Institute had been of great assistance to the Government since the war started. When the war is over and conditions change, it is hoped that the Institute may continue to be of assistance in the reconstruction programme.

The president thought that if there was anything the Institute could do to further its normal activities without hampering the war effort, this should be done, together with any possible planning for the years following the war. He asked Mr. Cameron if he had anything to report on the work of Dr. James' committee on re-construction.

Mr. Cameron thought the Canadian Government was

wise in taking the stand that it should plan for the post-war period in all its aspects. The engineer is more particularly concerned in post-war reconstruction, which is the function of the sub-committee of Principal James' committee, of which Mr. Cameron is chairman. This sub-committee proposes to make certain recommendations to the main committee with a view to formulating some plan which will line up all the projects that will give employment in Canada after the war. Short time works and extended undertakings will be fitted into one complete programme. Mr. Cameron emphasized the fact that this will not necessarily be a public works programme. Private initiative and private industry will take care of such work as far as it is able, after which the Government will step in. This is as far as the committee has gone at the present time. The president thanked Mr. Cameron for his statement.

Following up on a suggestion made at the Annual Meeting of Council in Montreal on February 4th, Mr. Gray-Donald presented a request from the Quebec Branch that The Engineering Institute of Canada Prize of twenty-five dollars be offered each year to undergraduates at Laval University, Quebec. This suggestion had been approved at the previous meeting of Council, and on the motion of Mr. Gray-Donald, seconded by Colonel Cape, it was unanimously resolved that Laval University be included in the list of Canadian universities now receiving The Engineering Institute of Canada Prize.

Mr. Hunt reported that he had just handed back to the general secretary \$300.00 which the Annual Meeting Committee had received from the Council as an advance on the expenses of the recent meeting. The splendid contributions which the branch had received from certain public-spirited firms in the Montreal district had enabled the committee to finance the meeting without the usual assistance from Headquarters. This was noted with much gratification and Mr. Hunt was instructed to convey the thanks of Council to the Annual Meeting Committee. Mr. Hunt reported also that the committee was compiling a very complete and comprehensive report on the whole meeting, making certain recommendations and suggestions which it was hoped, would be of considerable help to future Annual Meeting Committees.

Mr. Gray-Donald reported that the executive of the Quebec Branch had given further consideration to the proposal to have the next annual meeting of the Institute at Quebec. The committee was not yet clear on all points, but expected that a decision would be reached in time to report to an early meeting of Council.

Mr. Hall stated that from discussions with members of the Toronto Branch executive, it appeared that there is some misunderstanding regarding the last sentence of Section 7 of the by-laws relating to the waiving of examinations for admission to full membership in the Institute. The Toronto executive seems to think that Council should take the initiative whereas, in Mr. Hall's opinion, if the branches think that the examinations should be waived in any particular case, they should make that recommendation to Council. He wondered if all the branches gave the same interpretation to that by-law. The president suggested that it might be desirable to write a letter to all the branches regarding this point, but Mr. Armstrong thought it was a matter that could very easily be taken care of by the Institute Membership Committee.

It had just come to Mr. Cameron's attention that Mr. F. P. Vaughan, a past-chairman of the Saint John Branch, a past member of the Institute Council and a past-president of the Association of Professional Engineers of New Brunswick, was retiring from professional work after fifty years of service. On the motion of Mr. Cameron, seconded by Mr. McLeod, it was unanimously resolved that a letter extending the good wishes of Council be sent to Mr.

Vaughan, and that the event be recorded in the *Journal*.

The general secretary read a letter from the secretary of the American Society of Civil Engineers written in response to greetings from the Institute transmitting the following resolution:

"Whereas, the American Society of Civil Engineers has received the friendly sentiments and offers of co-operation as expressed by L. Austin Wright, secretary, in letter dated December 22, 1941, from The Engineering Institute of Canada; and

"Whereas, the Society has always been proud of the genuine kinship existing between our sister organizations and the members of The Engineering Institute of Canada and the members of this Society;

"Now, Therefore, Be It Resolved, that the American Society of Civil Engineers expresses its sincere appreciation of the good will and spirit of friendliness ever evidenced between our organizations and further assures The Engineering Institute of Canada that the feelings are heartily reciprocated and expresses the hope they will always continue and will grow in strength and vigor."

This was noted with appreciation, and the suggestion that it be published in the *Journal* was approved.

A number of applications for admission and for transfer were considered, and the following elections and transfers were effected:

#### ADMISSION

Members .....	17
Junior .....	1
Students .....	32

#### TRANSFERS

Juniors to Members.....	3
Students to Members.....	2
Students to Juniors.....	5

It was noted that two meetings of Council would be held in the month of April, first, the regional meeting in Vancouver on Saturday, April the 18th, to coincide with the president's visit, and, second, one in Toronto on Saturday, April the 25th, to coincide with a joint dinner being held that evening under the auspices of the Toronto Branch of the Institute and the Association of Professional Engineers of Ontario, to honour Dean C. R. Young as president of the Institute and as dean of the Faculty of Applied Science and Engineering of the University of Toronto.

Mr. Macpherson stated that the members in Vancouver were looking forward with a great deal of pleasure to welcoming the president, and hoped that a number of other members of Council would be able to accompany him.

#### COMING MEETINGS

**American Water Works Association, Canadian Section**—Annual Convention at the General Broek Hotel, Niagara Falls, Ont., April 15-17th. Secretary, Dr. A. E. Berry, Ontario Department of Health, Parliament Buildings, Toronto.

**Dinner in honour of Dean C. R. Young**, April 25th, to be held by Association of Professional Engineers of Ontario and the Toronto Branch of the Engineering Institute of Canada, in Hart House, Toronto.

**American Water Works Association**—Sixty-Second Annual Convention at Stevens Hotel, Chicago, Ill., June 21-25th. Executive Secretary, Harry E. Jordan, 22 East 40th Street, New York, N.Y.

## ELECTIONS AND TRANSFERS

At the meeting of Council held on March 14th, 1942, the following elections and transfers were effected:

### Members

**Clark**, Andrew Tudhope, B.Sc. (Engrg.) (Glasgow Univ.), constr. plant and salvage engr., Hydro-Electric Power Commission of Ontario, Toronto, Ont.

**Clixon**, William, asst. to elec. engr., National Harbours Board, Montreal, Que.

**Crowns**, Frank Gordon, B.A.Sc., M.A.Sc. (Univ. of Toronto), heating engr., Defence Industries Limited, Montreal, Que.

**Crechette**, Joseph-Alexis, B.A.Sc., C.E. (Ecole Polytechnique), chief of technical bureau, department of colonization, Quebec, Que.

**Gibson**, Cedric Marold, engineer, Link-Belt Ltd., Montreal, Que.

**Johnson**, Howard, (Durham Univ.), general manager, Midland Shipyards, Ltd., Midland, Ont.

**Keckel**, David Lane, B.Sc., M.E. (Haverford Coll.), consultant to the Algoma Steel Corp., Sault Ste. Marie, Ont.

**Radl**, George, B.S. (Mech.), M.E. (Cooper Union), engr. in charge of design, Canadian Copper Refiners Ltd., Montreal, Que.

**Rice**, Malcolm Mackay, asst. bridge and building master, C.N.R., Port Arthur, Ont.

**Stennie**, Robert, surveyor to Lloyd's Register of Shipping, Vancouver, B.C.

**Wanders**, Lionel John Redvers, (Cornell Univ.), manager, Quebec St. Lawrence Divn., Wartime Merchant Shipping Ltd., Montreal, Que.

**Cott**, Robert Govenlock, B.Sc. (Elec.) (Univ. of Alta), sales engr., Winnipeg Electric Company, Winnipeg, Man.

**Littleman**, Morton S., B.Eng. (McGill Univ.), mech. design, Dominion Bridge Co., Montreal, Que.

**Vagner**, Herbert Louis, B.A.Sc. (Univ. of Toronto), asst. engr., Hydro-Electric Power Commission of Ontario, Toronto, Ont.

### Junior

**Educ**, Rene, B.A.Sc., C.E. (Ecole Polytechnique), lands engr. dept., Consolidated Paper Corp. Ltd., Montreal, Que.

#### *Transferred from the class of Junior to that of Member*

**Wermerson**, Robert Alton, B.Sc. (C.E.) (Univ. of Man.), division engr., Canadian Pacific Railway Co., Brandon, Man.

**Cross**, Hugh Campbell, B.A.Sc. (Univ. of Toronto), testing engr., Hydro-Electric Power Commission of Ontario, Toronto, Ont.

**Ernot**, George Edward, B.Sc. (McGill Univ.), city assessor, City of Montreal, Que.

#### *Transferred from the class of Student to that of Member*

**Hitchell**, William Reginald, B.Sc. (C.E.) (Univ. of Man.), designer and estimator, Canadian Bridge Co. Ltd., Windsor, Ont.

**Vigdor**, Edward Irving, B.Eng. (Elec.) (McGill Univ.), M.Eng. (Elec.) (Renss. Poly. Inst.), resident technical officer for the British Air Comm., Vultee Aircraft, Nashville, Tenn.

#### *Transferred from the class of Student to that of Junior*

**Walderson**, Kenneth Kincaid, B.Sc. (Elec.) (Univ. of Alberta), asst. elec. engr., Trinidad Leaseholds, Ltd., Pointe-a-Pierre, Trinidad, B.W.I.

**Wavey**, Roland Eric, B.A.Sc. (Univ. of Toronto), engr. of works and bldgs., Naval Service, Shelburne, N.S.

**Wardson**, George Ross, grad. (R.M.C.), HQ. 12th Can. Infantry Bde., Sussex, N.B.

**Wohnston**, William David, B.A.Sc. (Univ. of Toronto), sales engr. McGregor-McIntyre Divn., Dominion Bridge Co. Ltd., Toronto, Ont.

Has passed Institute's examinations.

**Sarchuk**, Leon A., B.Sc. (Mech.) (Univ. of Sask.), inspr. of aircraft, A.I.D., R.C.A.F., St. James, Man.

### Students Admitted

**Allaire**, Lucien, (Ecole Polytechnique), 1430 St. Denis St., Montreal, Que.

**Anderson**, Clarence Arthur, (Univ. of Man.), 618 Mulvey Ave., Winnipeg, Man.

**Anglin**, Thomas Gill, (McGill Univ.), 488 Mount Pleasant Ave., Westmount, Que.

**Bennett**, John Robert Gordon, (McGill Univ.), 155 Westminster Ave., Montreal West, Que.

**Bowie**, Ralph Allen, (McGill Univ.), 228-18th Ave., Lachine, Que.

**Cann**, John Alastair Ross, (McGill Univ.), 4277 Western Ave., Westmount, Que.

**Carmichael**, Douglas Alfred, (Queen's Univ.), 194 Stuart St., Kingston, Ont.

**Caverly**, David Sundell, (Univ. of Toronto), R.R. No. 5, Aylmer (West), Ont.

**Chenivesse**, Emile, (Ecole Polytechnique), 366 E Sherbrooke St., Montreal, Que.

**Davis**, Stuart George, B.Sc. (Chem.), M.Sc. (McGill Univ.), 538-12th Street B, North, Lethbridge, Alta.

**Dudych**, Daniel (Univ. of Man.), 178 Spence St., Winnipeg, Man.

**Eisenbauer**, Martin Albert, (Nova Scotia Tech. Coll.), 226 Spring Garden Road, Halifax, N.S.

**Farish**, Frank J., (Univ. of Man.), 260 Ashland Ave., Winnipeg, Man.

**Gabies**, Pierre Maurice, (McGill Univ.), 2407 Coursol St., Montreal, Que.

**Garton**, John McConnell, (McGill Univ.), Boissevain, Man.

**Hamilton**, John C., (Queen's Univ.), Westport, Ont.

**Hopkins**, Herbert Arthur, B.S. (Elec.) (Detroit Inst. of Tech.), 426 Park St., Peterborough, Ont.

**Kerry**, Colin William, (McGill Univ.), 88 Arlington Ave., Westmount, Que.

**Lewis**, George Donald, (Nova Scotia Tech. Coll.), 226 Spring Garden Road, Halifax, N.S.

**Lindsay**, Colin, (Univ. of Man.), 104 Wellington Crescent, Winnipeg, Man.

**MacDougall**, Lorne Wells, (Nova Scotia Tech. Coll.), 331 Spring Garden Road, Halifax, N.S.

**McCallum**, John Francis, (Queen's Univ.), 318 University Ave., Kingston, Ont.

**Nutter**, James Ryan, (Nova Scotia Tech. Coll.), 78 King St., Truro, N.S.

**Ogilvie**, James D. B., B.Eng., M.Sc. (McGill Univ.), 1026 Murdock Road, Calgary, Alta.

**Olynyk**, Alexander, (Ecole Polytechnique), 423 Congregation St., Montreal, Que.

**Parsons**, Robert Lloyd, (Nova Scotia Tech. Coll.), 331 Spring Garden Road, Halifax, N.S.

**Poitevin**, Louis Merrill, (McGill Univ.), 3407 Peel St., Montreal, Que.

**Porter**, William Douglas, (Univ. of Man.), 5 McCulloch Ave., Outremont, Que.

**Pratt**, James Crawford, (Univ. of Man.), 1216 Wolseley Ave., Winnipeg, Man.

**Schafheitlin**, Frederick Blake, (Mount Allison Univ.), 331 Spring Garden Road, Halifax, N.S.

**Thompson**, Alvin Henry, (Nova Scotia Tech. Coll.), Pictou, N.S.

**Tamblyn**, Robert Teudar, (Univ. of Toronto), 80 St. George St., Toronto, Ont.

## MARCH JOURNALS REQUIRED

There has been an unusual demand for extra copies of the March, 1942, issue of *The Engineering Journal* and it would be appreciated if members who do not retain their copies would return them to Headquarters, at 2050 Mansfield Street, Montreal, Que.

**Lieutenant-General A. G. L. McNaughton, C.B., C.M.G., D.S.O., M.E.I.C.,** has recently been elected an honorary member of the Institution of Electrical Engineers of Great Britain, in appreciation of his work on high-voltage research during his presidency of the National Research Council of Canada and for his services in promoting the practical application of science to industry.

**Air Vice-Marshal E. W. Stedman, M.E.I.C.,** was appointed last month to the newly created position of director-general of air research in the Royal Canadian Air Force.

The duties of the director-general will be entirely divorced from routine work of the department and the officer will devote his time entirely to the study of research and development work in close collaboration with the National Research Council. This organization is intended to make possible introduction into service, with a minimum of delay, of new devices and new patterns of weapons.

**Air Commodore Alan Ferrier, M.E.I.C.,** has been appointed a member of the Air Council in the Royal Canadian Air Force succeeding Air Vice-Marshal E. W. Stedman. Air Commodore Ferrier will be responsible for aeronautical engineering. A graduate of McGill University from the class of 1920, he was employed with T. Pringle and Son, Montreal, for sometime after his graduation. In 1922 he was appointed to the staff of the technical branch of the Royal Canadian Air Force at Ottawa and has been in the service of the Government ever since. Before his recent appointment he was chief aeronautical engineer in the Department of Transport.

**Major F. L. C. Bond, M.E.I.C.,** vice-president and general manager of the central region, Canadian National Railways, was in Chicago last month, where he presided over the annual meeting of the American Railway Engineering Association.

**Colonel Arthur L. Bishop, M.E.I.C.,** has been appointed by the Dominion Government to head a new company for manufacturing synthetic rubber. This company, to be called Polymer Corporation Limited, will have its headquarters in Toronto. Born in Brantford, Ont., Colonel Bishop was educated at Brantford Public School and Ridley College, St. Catharines, Ont., and attended the Royal Military College, Kingston, from 1912 to 1914. Colonel Bishop is president of Coniagas Mines Limited, and Consumers Gas Company of Toronto. He is a member of the board of directors of the Consolidated Mining and Smelting Company of Canada Limited.

**A. P. Linton, M.E.I.C.,** has been elected chairman of the Saskatchewan Branch of the Institute for the year 1942. He was chairman of the branch in 1935 and was on the Council of the Institute in 1939. Born at New Hamburg, Ont., he attended the Galt Collegiate Institute and the University of Toronto, graduating from the latter in 1908 with the degree of B.A.Sc. After a few years spent with the Dominion Bridge Company and later with the St. Lawrence Bridge Company, he became, in 1915, chief bridge engineer of the Department of Highways of Saskatchewan, a position which he still holds.

From 1915 to 1919 Mr. Linton was overseas, serving with the 1st Canadian Pioneers, 9th Battalion, Canadian Railway Troops, in France, and commanded the 1st Bridging Company, Canadian Railway Troops, in Palestine. He was promoted to the rank of major, was mentioned in despatches, and received the O.B.E.

**Robert F. Ogilvy, M.E.I.C.,** has recently returned from St. Thomas, Virgin Islands of the United States, where he has been employed with the Aluminum Company of Canada since the summer of 1941. He is now connected with the same company as resident engineer on construc-

tion of the concrete storage dam on the Peribonka river, a hundred miles north of Lake St. John, Que.

**L. M. Howe, M.E.I.C.,** is now with the Bolivian Power Company, La Paz, Bolivia. Since 1930 he had been with the Saskatchewan Power Commission, Regina, Sask., where he had held the position of district superintendent of the rural transmission system, for the past six years.

**R. W. Willis, M.E.I.C.,** formerly associated with the Canadian Bridge Company at Walkerville, Ont., has accepted a position as designing engineer with the Standard Steel Construction Company at Welland, Ont. He had been with his previous employers since his graduation from Queen's University in 1937.

**J. E. Dion, M.E.I.C.,** formerly with the Wartime Merchant Shipping Limited, Montreal, is now with United Tool Engineering and Design Limited, in their Montreal office.

**T. A. Lindsay, M.E.I.C.,** who is with the Canadian Telephone and Supplies, has been transferred from Winnipeg, Man., to their office in Ottawa. He has been with the firm since his graduation in electrical engineering from the University of Manitoba in 1933.

**H. F. Bennett, M.E.I.C.,** district engineer for the Department of Public Works of Canada at London, Ont., and chairman of the Institute's Committee on the Training and Welfare of the Young Engineer, visited the maritime branches of the Institute during the month of February.

At the regular dinner meeting of the Saint John Branch on February 24th, Mr. Bennett spoke on the development in the scheme on vocational guidance for prospective engineers promoted by his committee and its possibilities for local high school students. On February 25th, he spoke on the Great Lakes Waterway System before the Moncton branch of the Institute. Mr. Bennett spoke on February 27th to the Halifax Branch on The Engineer of Tomorrow and stressed the need for increasing co-operation between engineering colleges and employers. In Sydney on March 2nd, he met with the executive of the branch and discussed the work of his committee and the organization in the branch of a students' guidance committee.

Mrs. Bennett accompanied her husband.

**Professor G. Ross Lord, M.E.I.C.,** of the Department of Mechanical Engineering, University of Toronto, was elected councillor in the mechanical branch of the Association of Professional Engineers of the Province of Ontario for the year 1942, being one of the youngest members to be so honoured.

Born in Peterborough, he graduated from the Faculty of Applied Science and Engineering of the University of Toronto in 1929 with the degree of Bachelor of Applied Science. In 1932, he was granted the Master of Science degree from the Massachusetts Institute of Technology. In 1932-33, he was the Freeman Scholar sent to Germany by the American Society of Mechanical Engineers, where he studied at engineering colleges in Berlin, Munich, Karlsruhe. He was awarded the Ph.D. degree from the University of Toronto in 1939 for his original research on cavitation in hydraulic turbines. Since 1934, he has been on the mechanical engineering staff of the Faculty of Applied Science, University of Toronto.

**S. G. Coultis, M.E.I.C.,** has been elected president of the Association of Professional Engineers of Alberta at the annual meeting held last month. Mr. Coultis is also a councillor of the Institute representing the Calgary Branch.

## NEW BRANCH CHAIRMEN

**H. J. McEwen, M.E.I.C.**  
Calgary Branch

**F. T. Julian, M.E.I.C.**  
London Branch

**A. S. G. Musgrave, M.E.I.C.**  
Victoria Branch

**H. J. McEwen, M.E.I.C.**, is the newly elected chairman of the Calgary Branch of the Institute. Born at Brantford, Ont., he received his early education at Brantford Collegiate and his engineering training at the University of Toronto where he graduated in 1911 as Bachelor of Applied Science in electrical engineering. Upon graduation he joined the staff of the Canadian Westinghouse Company, Limited, and went to Hamilton, Ont., where during two years he followed the shop engineering course. In 1913 he was appointed as sales engineer for the company at Calgary, Alta. He later became in charge of the sales of the company in the province, and in 1919 he was appointed branch manager of the company at Calgary. He is at present the district manager. Mr. McEwen is a member of the Association of Professional Engineers of Alberta.

**B. Snape, M.E.I.C.**, has now returned to Jasper, Alta., where he is resident engineer of Jasper Park. For the past five months he had been with the Works and Buildings Department of the naval service at Halifax.

**Alph E. Williams, M.E.I.C.**, has accepted a position with the Demerara Bauxite Company, Mackenzie, British Guiana. He was previously assistant engineer on construction of the cordite plant of Defence Industries Limited at Winnipeg, Man. Since his graduation from the University of Toronto in 1934, Mr. Williams has had extensive construction experience both in the United States and in Canada.

**George N. Richards, M.E.I.C.**, manager of Lee & Nash, consulting engineers and land surveyors, Brantford, Ont., has been appointed city engineer of Brantford. Born in England, he was educated at Derby and he served in the last war with the Royal Canadian Naval Volunteer Reserve. He served his apprenticeship as an engineer with the firm of Lee and Nash of Brantford. From 1924 to 1931 he was employed with Warner and Warner, registered engineers, Detroit, Mich. Since 1933 he has been manager of the firm of Lee & Nash of Brantford.

**E. Armand Dugas, M.E.I.C.**, has accepted a position with R.C.A.F. No. 3 Training Command, Montreal, as assistant electrical engineer in the Works and Buildings Division. He was formerly with the Montreal Light, Heat & Power Consolidated. He is a graduate of the Ecole Polytechnique of Montreal, from the class of 1932.

**Robert A. Kerr, Jr., E.I.C.**, who resigned his position as assistant electrical superintendent at the Montreal Cottons Limited, Valleyfield, Que., is now with the Nichols Chemical

Company as works engineer of the sulphuric acid plant at Valleyfield.

**A. S. G. Musgrave, M.E.I.C.**, municipal engineer at Oak Bay, B.C., is the newly appointed chairman of the Victoria Branch. Born in Cork, Ireland, he was educated at Trinity College, Dublin, where he graduated with the degrees of B.A. and B.C.E. From 1914 to 1919 he was with the Canadian Engineers, 4th Field Company, and later with the Royal Engineers as a captain. From 1919 until 1935 he carried on a private practice as civil engineer and land surveyor at Victoria, B.C.

**P. B. Motley, M.E.I.C.**, has recently been made a Life Member of the American Society of Civil Engineers, as well as Life Member of the Engineering Institute. In 1937 Mr. Motley retired as engineer of bridges for the Canadian Pacific Railway after forty-five years of service with the company.

Born in Calcutta, India, Mr. Motley completed his general and engineering education in England, and joined the engineering department of the Canadian Pacific Railway Company at Montreal in 1892. He occupied the positions of draughtsman and inspector of bridges both in the shops and during erection until 1903 when he became assistant engineer in the department. In 1908 he was made assistant engineer of bridges and on June 1st, 1911, received the appointment from which he has since retired. Among the more important bridges for which Mr. Motley has been responsible may be mentioned the Lethbridge viaduct, the Edmonton City bridge, the crossings of various large rivers on the prairies such as at Saskatoon, Outlook, Nipawin and Winnipeg, besides the bridge at Galt, Ont., and the bridge over the St. Lawrence river near Montreal, which was reconstructed to allow for double tracks, and the Saint John, N.B., cantilever bridge. There were many others of lesser magnitude though of difficult construction, particularly in the Rocky and Selkirk Mountains and on the north shore of Lake Superior.

**Frank P. Vaughan, Hon. M.Sc., M.E.I.C.**, consulting electrical engineer and contractor of Saint John, N.B., has recently retired after a professional career of fifty years. Born at Liverpool, England, he was educated in primary schools and Regent College. His education was completed by extensive lecture courses at the Massachusetts Institute of Technology, Boston. He began his career in 1891 in Vancouver, B.C., where he was engaged with the local telephone corporation, through which he was connected with other British Columbian telephone interests. In 1895 he went to Yarmouth, N.S., with the Yarmouth Street Railway Company. In 1896 he became connected with the

Northern Electric Works at Saint John, N.B. From 1897 until 1900 he was employed with three of Boston's largest electrical engineering firms. From 1900 to 1902 he was in the testing department of the General Electric Company at Schenectady, N.Y. In 1902 he returned to Saint John, N.B., and entered private practice as an electrical engineer and contractor. In 1906 he founded the firm of Vaughan Electric Company, Limited, electrical engineers and contractors at Saint John, N.B., from which he has just retired.

Besides his interest in the electrical contracting business, Mr. Vaughan has been a pioneer in experimental investigation in wireless telegraphy and telephony and high potential high frequency currents. He was granted the first license issued from Ottawa for experimental wireless telegraphy in 1904, and in 1908 talked a distance of three miles by wireless telephone. Mr. Vaughan has read a number of papers before the Institute and other scientific societies and has been a contributor to magazines. As manager of the Vaughan Electric Company Limited of Saint John, Mr. Vaughan was consulting electrical engineer during construction of the Saint John drydock.

Mr. Vaughan has been an active member of the Institute since he first joined in 1919. He was chairman of the Saint John branch, as well as a member of the Council. He is a past-president of the Association of Professional Engineers of New Brunswick.

**D. H. Parker**, Affiliate E.I.C., has enlisted for active service as engineer lieutenant with the R.C.N.V.R. This is Mr. Parker's second term of service with the Navy, since during the last war he was artificer with the Royal Navy. For the past sixteen years he has been mechanical superintendent and production manager with the *Montreal Daily Star*.

**Wm. P. Nesbitt, Jr.**, E.I.C., formerly with the Consolidated Paper Corporation, Limited, at Grand'Mère, Que., has accepted a position with the Howard Smith Paper Mills, Limited, Cornwall, Ont. Since his graduation from Queen's University in 1935 he has been in the paper industry successively with the following firms: Alliance Paper Mills, Merritton, Ont., Fraser Companies, Edmundston, N.B., Canadian International Paper Company, Hawkesbury, Ont., Consolidated Paper Corporation, Limited.

**Charles S. Gorowski**, Jr., E.I.C., who was formerly with Canadian Associated Aircraft Limited, Montreal, as engineer in the modifications department, is now with the National Steel Car Corporation Limited in their aircraft division at Malton, Ont., where he holds the position of electrical engineer in the production engineering department. He was graduated in electrical engineering from the University of Manitoba in 1934.

**Flying Officer Pierre A. Charest**, Jr., E.I.C., is at present stationed at No. 9 Bombing and Gunnery School, R.C.A.F. at Mont-Joli, Que. Previous to his enlistment he was with Fraser Companies Limited at Edmundston, N.B.

**Captain R. C. Lane**, Jr., E.I.C., who was stationed at Camp Borden with the 6th Armoured Regiment (1st Hussars) is now overseas. Previous to his enlistment he was on the staff of International Harvester Company at Toronto.

**Major Alexandre Dugas**, Jr., E.I.C., who returned from overseas a few months ago, is at present stationed at the Officers' Training Centre at Brockville, Ont. He is a graduate of the Ecole Polytechnique in the class of 1933. Previous to his enlistment for active service at the outbreak of war, he was with the Quebec Public Service Board at Montreal.

**Fernand Lecavalier**, S.E.I.C., is now employed at the National Research Council at Ottawa. He graduated from Ecole Polytechnique in 1939.

**A. I. Mendelsohn**, S.E.I.C., is now serving overseas as a captain with the Royal Canadian Ordnance Corps. He graduated in mechanical engineering from McGill University in 1929.

**Captain A. J. E. Smith**, S.E.I.C., is now located at Winnipeg, Man., with No. 10 detachment, Royal Canadian Engineers.

**H. A. G. Kingsmill**, S.E.I.C., has left the Aluminum Company of Canada at Arvida, Que., and is at present with the Royal Canadian Ordnance Corps at Barriefield, Ont.

**Herbert F. Coupe**, S.E.I.C., who was formerly with the Saguenay Power Company, Limited, Isle Maligne, Que., is now with Aluminum Company of Canada, Limited, on construction of the storage dam on the Peribonka river, north of Dolbeau, Que.

**F. R. Park**, S.E.I.C., has joined the National Research Council of Canada, Radio Branch, Ottawa, as junior research engineer. He was formerly with the Northern Electric Company at Calgary, Alta.

**Roger Lessard**, S.E.I.C., who was graduated last spring from the Ecole Polytechnique, Montreal, is now on the staff of Milton Hersey Company, Limited, on construction of the storage dam on the Peribonka river, north of Dolbeau, Que.

**Paul A. Verdier**, S.E.I.C., who formerly was with the Dominion Engineering Works at Longueuil, Que., has taken a position in the engineering department of the Allied Brass Limited, Montreal.

#### VISITORS TO HEADQUARTERS

**F. G. Green**, M.E.I.C., National Research Council, Ottawa, Ont., on February 20th.

**G. A. Sutherland**, Jr., E.I.C., National Research Council, Ottawa, Ont., on March 3rd.

**H. F. Bennett**, M.E.I.C., district engineer for the Department of Public Works of Canada, London, Ont., on March 5th.

**H. Balmforth**, M.E.I.C., Vancouver, B.C., on March 10th.

**Hector Cimon**, M.E.I.C., Secretary, Price Brothers and Company, Quebec, Que., on March 10th.

**J. P. Henderson**, M.E.I.C., Dominion Observatory, Ottawa, Ont., on March 13th.

**W. J. Thomsen**, M.E.I.C., Arvida, Que., on March 17th.

**Adolphe Clairmont**, S.E.I.C., Singer Sewing Machine Company, Thurso, Que., on March 17th.

**Donald Ross**, M.E.I.C., Foundation Company of Canada, Limited, Otter Creek Contract, Mont Laurier, Que., on March 23rd.

**G. G. Murdoch**, M.E.I.C., Saint John, N.B., on March 26th.

**W. A. Ketchum**, M.E.I.C., chief chemist, Fraser Companies Limited, Edmundston, N.B., on March 26th.

**A. E. Tyson**, Jr., E.I.C., Rayner Construction Company, Limited, Geraldton, Ont., on March 26th.

**Ernest F. Brown**, Jr., E.I.C., mechanical engineer, Royal Canadian Mint, Ottawa, Ont., on March 27th.

**D. P. Urry**, M.E.I.C., Dominion Bridge Company, Vancouver, B.C., on March 28th.

# Obituaries

*The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.*

**William Gamble Boyd, Jr.**, E.I.C., died at his home in Kingston on February 5th, 1942. He was born at Teddington, England, on February 10th, 1897, and came to Canada at an early age. He received his education at St. Alban's School and the Toronto Technical School. In 1915 he joined the Signal Section of the 74th Battallion and later followed a course with the Officers' Training Corps at the University of Toronto. He later joined the Royal Flying Corps and was demobilized as a Flight Lieutenant. After the war he joined the staff of the Canadian General Electric Company at Toronto. In 1921 he went with the Northern Development Branch of the Province of Ontario. In 1931 he was general engineer of the Canadian National Carbon Company, Limited, at Toronto. He joined the staff of the Aluminum Company of Canada at Toronto as draftsman in 1935. In 1940, he was transferred to the Kingston plant of the company as safety engineer and security officer.

Mr. Boyd joined the Institute as a Junior in 1922.

**Edward Preston Johnson, M.E.I.C.**, died in Toronto on February 28th, 1942. Born in Ottawa on November 13th, 1873, the son of Edward V. Johnson, inspector for the Department of Railways and Canals, he attended McGill University in the Faculty of Applied Science. From 1901 to 1903 he served as resident engineer, Algoma Central Railway, and assistant engineer in charge of dam construction on the Rideau Canal at Smiths Falls. From 1904 to 1916 he was assistant engineer in charge of Port Colborne harbour improvements, and resident engineer, Section 8 and 9, Welland Ship Canal. In 1917 he was chief field engineer for the Foundation Company of New York, on construction of the International Nickel Company plant at Port Colborne, and on construction of a bag loading plant at Tullytown, Pa., U.S.A. In 1919 when work was resumed,

he returned to the Welland Ship Canal as division engineer, Section 1, then until 1923 he was division engineer, Section 5, and in charge of surveys, Sections 6, 7, 8 and 9. In 1923 he was transferred to Welland as divisional engineer over Sections 5, 6 and 7, where he resided until moving to Toronto in the spring of 1936. As resident engineer during that period he was responsible for all construction work on the canal from Allanburg to Humberstone, including the siphon

**E. P. Johnson, M.E.I.C.**

culvert at Welland, an undertaking of some magnitude involving the carrying of the Welland river under the canal, and requiring several years to complete. He was employed by the Department of Railways and Canals for thirty-five years.

Mr. Johnson joined the Institute as a Student in 1900 and was transferred to Associate Member in 1909. In 1940 he became a Life Member of the Institute. He was chairman of the Niagara Peninsula Branch and in 1927 he represented the branch on the Council of the Institute.

## News of the Branches

### BORDER CITIES BRANCH

J. B. DOWLER, M.E.I.C. - *Secretary-Treasurer*  
W. R. STICKNEY, M.E.I.C. - *Branch News Editor*

Mr. James Livermore of the Engineering Department of the Detroit Edison Company was the guest speaker at the February meeting of the Border Cities Branch held on Friday, February 20 at the Prince Edward Hotel, Windsor. Mr. Livermore, who was introduced by Mr. E. M. Krebsler, is a graduate of Cornell University and is a member of the American Society of Heating and Ventilating Engineers, Michigan Chapter. He has previously given papers on the subject of Air Conditioning and his subject for the evening was **The Adaptation of Air Conditioning to an Existing Office Building**, accompanied by lantern slides.

The speaker pointed out that to establish an air conditioning system in an existing office building involves many problems which are not met with in a new building designed for air conditioning. An example of the former was the installation of an air conditioning system in the existing General Office Building of the Detroit Edison Company, and of the latter the completion of the air conditioning system in their new Service Building. Both of these are located in Detroit, and, as the Detroit Edison Company maintain their own construction department, the design, drawings and installation of both systems were carried out by themselves.

### Activities of the Twenty-five Branches of the Institute and abstracts of papers presented

The new six-story Service Building, has brick walls and glass bloc in place of windows, and in which a mixture of shop and office work is done. The first and second floors are devoted to appliance repairs while the remainder are for clerical and drafting work, but the type of air conditioning is essentially the same for each. Since there are no windows in the building, it may be compared to an automobile exposed to the sun with its windows closed, and therefore air conditioning is absolutely necessary.

To design an air conditioning system it is necessary to estimate the capacity of the equipment required to cool the building in summer and to heat it in winter. This is done by making a balance sheet of the heat sources, internal and external, which affect the building. The external sources are heat from the sun on the glass bloc, and in summer heat from the outside air drawn in to replace loss through doors and openings. The internal sources are illumination and sensible heat of the occupants, and this means that regardless of the season of the year, heat has to be removed from the central portion of the building, at all times. Therefore, the air conditioning equipment must be flexible and able to supply heated and cooled air at the same time to locations where control is required. This is done by what is called the double duct system—two large

fans in the room supply heated and cooled air through hot and cold air ducts as required to maintain room temperature, regulated by a thermostatic control valve. These ducts are installed in what might be termed a false ceiling on each floor of the building and an ingenious arrangement of recessed lights allows the air to be distributed to the room below through perforated acoustic tile board in the ceiling between the lights. This was found to be the best method for eliminating drafts. The air is withdrawn through grills near the floor and taken back to the circulating fans in return ducts, being filtered each trip around the circuit. Heating of the air, when required, is done by passing it over steam coils, and cooling is done by passing the air over coils containing a refrigerant.

The installation of an air conditioning system in the Main Office, an existing ten-storey building, required more than two years to complete since all work had to be done at night, although a cooling system had previously been installed in the basement and on the first floor where the office cafeteria is located.

In the usual commercial installations in old buildings a system of zoning is used, i.e. the temperature for certain sections of similar exposure is controlled by one thermostat in each section, but in this case each office was partitioned off so a means of controlling each one was sought.

For cold weather the heating could be done by existing radiators in each office, but after some experimentation it was found that better results could be obtained by cutting down the capacity of these radiators to about fifty per cent of the heat loss through windows, etc., and supplying heat by warm air from a duct system. Fortunately, in this building there existed a means of drawing off air from the ends of the corridors to the roof, so means were available for establishing a circulatory system.

This led to the installation of a double-duct system again so that dual control of air would be available to each enclosed office. In this case, however, it was necessary to run the hot and cold air ducts beside each other along the top of the corridors and install mixing dampers at openings in the ducts opposite each partitioned office. These mixing dampers are the heart of the double-duct system. They are operated by a small air cylinder which is controlled from a pneumatic thermostat. As the temperature in the office changes, compressed air is fed into or released from the cylinder which operates the damper regulating the supply of hot or cold air as required. The pressure in the ducts is kept slightly higher than room pressure to ensure proper working of the dampers. In this way, the quantity of air supplied to the room is constant and only the temperature of that air varies. These damper boxes had to be well made to prevent leakage of air and ensure accurate control of temperature.

Since air was forced into the offices or rooms from the top, it had to be drawn off somewhere and this was not done by having open windows but by putting openings or outlet ducts in the doors leading to the corridors and drawing the air back to the circulating fans from the ends of the corridors. After several trials it was found that the best position of the thermostats was in these outlet ducts in the doors.

The problem of diffusion into each room required some experimentation and was finally solved by installing ducts from the mixing dampers along the top of each partition and having adjustable openings in these ducts. To prevent drafts the openings were made with perforations similar to those in the new Service Building.

As in the Service Building the equipment consists of two large fans with hydraulic couplings. Thermostats control the supply of water to the cooling coils and also the supply of steam to the heating coils. These thermostats are installed in a control panel in the fan room which enables

the operator to control practically everything from there. It is very necessary to have well trained, competent operators to keep the systems under proper control and secure best results. In conclusion, Mr. Livermore stated that the expense of these installations was well justified by the resultant comfort afforded their employees.

Some discussion took place after Mr. Livermore's talk and a vote of thanks was proposed by Mr. C. M. Goodrich. Mr. H. L. Johnston, Branch Chairman, presided and there were thirty-six members in attendance.

### CALGARY BRANCH

K. W. MITCHELL, M.E.I.C. - *Secretary-Treasurer*  
F. A. BROWNIE, M.E.I.C. - *Branch News Editor*

Mr. Max W. Ball, petroleum engineer, addressed a meeting of the Calgary Branch on **Anglo-American Responsibilities**. Since the topic was non-technical and many visitors were present, the chairman, Mr. J. B. deHart, introduced the speaker, postponing any business until the next meeting.

Mr. Ball, who is a graduate of the Colorado School of Mines in engineering, and of the National University of Washington in law, has served ten years with the United States' Geological Survey and has spent a number of years in exploration work. More recently he came to Alberta, where in 1930 he started the Abasand Oils Ltd., developing Alberta tar sands. Consulting practice, however, frequently takes Mr. Ball across the border, giving him an excellent opportunity to observe public opinion and international developments.

With a strong conviction that the Allies will emerge victorious from the struggle in which they are now engaged, Mr. Ball outlined American and British responsibilities if world peace and order were to be maintained.

Referring to the attitude of the American people, the speaker said.

"Remember Pearl Harbor" is not a slogan, it is a promise and a resolve."

Mr. Ball analyzed our attitude towards war during the period from the last Armistice until the recent invasion of Poland, pointing out that the minds of the Democratic Nations were permeated with pacifism, cynicism, and sentimentality, making this period between the wars more tragic than the wars themselves. In conclusion, the speaker pointed out that our early mistakes must not be repeated, and the English speaking "United Nations" must, united in one spirit, shoulder the responsibility of preserving honest peace in the world after the present conflict.

An interesting paper by a young civil engineer, Mr. B. A. Monkman, J.R.E.I.C., was presented before the Calgary Branch on January 29th, 1942, entitled **Cascade Project**. Projections of sketches and photographs were used to illustrate the progress of construction in its various stages.

An earth filled dam across the Cascade River Canyon will raise the level of Lake Minnewanka 65 ft. providing some 200,000 acre feet of storage in the 30 ft. lake regulation. Water will be conducted along the 2½ mile side hill canal into a 200 ft. length of wood stave pipe, terminating in a surge tank and a steel penstock. The power plant situated at Anthracite, just below the surge tank, will consist of a 20,000 kva. vertical generator driven by a 23,000 horse power reaction turbine, operating under a 325 ft. head. The plant will be operated on base load during winter months and at other times as standby. Large additional amounts of power required by war industries and particularly the Ammonia Plant near Calgary, have necessitated this development, which has the advantages of speed and economy.

Towards the close of the meeting the Ford Motor Co., showed a film entitled "Tools for the Job."

## EDMONTON BRANCH

F. R. BURFIELD, M.E.I.C. - *Secretary-Treasurer*  
L. A. THORSSEN, M.E.I.C. - *Branch News Editor*

The Edmonton Branch held its February dinner meeting in the MacDonald Hotel on February 24th. R. M. Hardy, the branch chairman, conducted the meeting.

The speaker for the evening, Mr. B. A. Monkman, Jr., E.I.C., field engineer, Calgary Power Company, spoke on the company's new power development on the Cascade River in Banff National Park.

Mr. Monkman introduced his topic by mentioning the company's present developments, and showing how the new project tied in with the existing system. He then pointed out the speed with which extra power had to be developed, that together with economic considerations, made it imperative that the Cascade site be used, rather than other proposed sites.

In his paper, the speaker outlined the location and design of the various structures making up the entire plan. These structures included the earth fill dam on the Cascade River, at the outlet of Lake Minnewanka, a spillway structure concrete control dam, two miles of canal, wood-stave pipe line, surge tank, penstock, power house and tailrace. In his discussion of the separate structures, Mr. Monkman described the various problems of design and methods of construction, as well as difficulties encountered during construction. In conclusion he described the method of operating the control dam and canal in the interval between the high and low water levels in Lake Minnewanka.

Mr. Monkman's most interesting paper was well illustrated by lantern slides and was followed by an excellent discussion. Mr. H. R. Webb, chief field engineer for the Calgary Power Company during the summer of 1942, moved a vote of thanks to the speaker.

## HALIFAX BRANCH

S. W. GRAY, M.E.I.C. - *Secretary-Treasurer*  
G. V. ROSS, M.E.I.C. - *Branch News Editor*

Mr. H. F. Bennett, M.E.I.C., of London, Ontario, chairman of the Institute Committee on the Training and Welfare of the Young Engineer, addressed the Halifax Branch on February 27th, at the Halifax Hotel. Mr. Bennett's talk, **The Engineer of To-morrow**, was a review of the work done by his committee and the plans made for future work. The objects are to place before interested high school students the requirements of the profession, the studies that will be met with in college, the branch of engineering most closely related to the field in which the student's interest lies, and to assist the young engineer in shaping his early career.

Considerable work along these lines has been done by various bodies in the United States, and the Institute committee has worked in close harmony with several of these bodies. Increasing co-operation between the colleges and employees of engineers, also between members of the profession and young engineers in another field in which the committee has begun studies.

Mr. Bennett is a former member and chairman of the Halifax Branch, and well known to many members. His enthusiasm for this work seems to know no bounds and everyone hearing his talk was impressed by the great amount of time and study that he and his fellow committee members have devoted to their task.

Dr. H. F. Munro, Nova Scotia Superintendent of Education, and Hon. J. D. MacKenzie, Nova Scotia Minister of Highways, were guests of the branch and spoke briefly.

The branch has grown in membership until it is now the fourth largest in Canada and entitled to representation on

Council by two members. John R. Kaye has accepted the appointment to this office.

R. L. Dunsmore gave a brief outline of the highlights of the recent annual meeting in Montreal.

About fifty members were in attendance with P. A. Lovett as chairman.

One hundred and sixteen members of the Halifax Branch and the Professional Association, attended a special dinner meeting at the Halifax Hotel on March 11th.

The speaker was Professor F. Webster, formerly of the University of Rangoon. He is at present a member of the Research Experimental Staff of the Dept. of Home Security, London, England, and has been engaged in the study of bombing as it affects the design and construction of buildings. His talk was illustrated by a film.

Professor Webster is in Canada on a special mission and this was his first address to any Canadian organization.

The regular March meeting of the branch was held in the auditorium of the Nova Scotia Technical College on March 20th, when a motion picture film entitled **Photo-elastic Stress Analysis** was shown. This film explains the use of polarized light in the analysis of stresses in plastic models of machine parts and structures under load.

A large number of models of various shapes are shown under concentrated, rolling and impact loads and by means of polarized light the distribution of the stresses become visible.

The film has been prepared in the laboratory of the University of Manitoba under the direction of Prof. A. E. McDonald, Dean of Engineering.

## HAMILTON BRANCH

A. R. HANNAFORD, M.E.I.C. - *Secretary-Treasurer*  
W. E. BROWN, JR. E.I.C. - *Branch News Editor*

Professor E. A. Allcut, M.E.I.C., was the guest speaker on the occasion of the branch Annual Meeting held in the Royal Connaught Hotel on January 9th. In discussing his subject **Substitute Fuels for Gasoline**, he not only pointed out the need for a satisfactory substitute due to the present emergency, but also because of the diminishing supply of petroleum. Professor Allcut reviewed the various substitutes which have been tried such as, alcohol from wheat, and compressed gasses such as methane, propane, hydrogen and producer gas. While much work has been done on the question, particularly in Great Britain and Europe, as yet no fuel has been found as economical and as satisfactory as gasoline. J. S. Glover, introduced the speaker and W. L. McFaul, moved the vote of thanks.

We were happy to have the General-Secretary as our guest, his genial presence always adds to the pleasure of a meeting. He gave a very concise and informative report to the members on some of the things that are being done in the interests of the Institute and the country, particularly with regard to Wartime Personnel and post war problems.

The business meeting was short and to the point and when the formalities were concluded our retiring chairman, W. A. T. Gilmour, had the pleasure of installing the new chairman, Stanley Shupe. The meeting was then declared closed.

The American Society for Metals (Ontario Chapter), American Institute of Electrical Engineers (Hamilton Group) and the Hamilton Branch of the Engineering Institute, held a joint meeting in the Westinghouse Auditorium, on February 10th. The chair was held jointly by H. Thomasson, J. T. Thwaites and S. Shupe, chairmen of the three societies respectively.

Dr. H. B. Osborn, Jr., research and development engineer, Tocco Division, Ohio Crankshaft Company, Cleve-

land, Ohio, addressed the meeting on the subject **Surface Hardening By Induction**. Dr. Osborn made it very clear that the surface hardening by induction is not new, but the application and control is new.

Induction hardening means that the core of the material remains the same, by inducing a thermal transformation in the surface a metallurgical change is obtained. The induction involves the use of high frequency current and three sources are available, spark-gap oscillators, motor-generator sets and vacuum tube oscillators. At present the motor-generator is the most satisfactory for the purpose and is therefore used.

Basically the process involves placing the steel article to be hardened within a magnetic field of rapidly changing polarity. The molecules of iron resist this change of polarity and the resultant hysteresis brings about heat in the steel. The temperature rises till the material becomes non-magnetic. At the same time eddy currents flow through the material and cause even greater heat than that due to the change of polarity.

The higher frequency current concentrates on the surface and thus the hardening takes place on the surface where it is required and ductile core is left within the material to withstand impact stress as in gear teeth. When hardening to a greater depth is required, lower frequency current is used and longer time to allow the heat to be conducted towards the centre of the material.

The equipment used involves a motor-generator set either within the unit or one set serving several installations. The unit has an inductor block of suitable design for the material. Part and parcel of the inductor block, there is a system of water spray jets. The heating and quenching cycle is controlled electrically and both are a matter of a very few seconds. Incidentally the time of the piece in the unit is so short, that the feed mechanism becomes quite a problem itself.

Induction hardening for a given carbon, gives slightly higher hardness. The structure for this type of hardening is more finely grained and, therefore, more homogeneous.

The possibilities of this method of hardening are unlimited. Already it is serving the war industry of the United States and Canada, speeding production.

#### MONCTON BRANCH

V. C. BLACKETT, M.E.I.C. - *Secretary-Treasurer*

**The Great Lakes System** was the subject of an address delivered at a branch meeting held on February 25th. The speaker was H. F. Bennett, B.Sc., M.E.I.C., district engineer, Department of Public Works, London, Ont. F. O. Condon, chairman of the branch, presided.

The Great Lakes, together with the canal system connecting them, constitute the greatest international waterway in the world. The volume of traffic is greater than the normal peacetime traffic of the Panama, Suez, Manchester and Kiel Canals combined. Forty million people are dependent on shipping operations in the Great Lakes. The most important freight movement is that of iron ore. 83 million tons are transported annually from the Lake Superior region to ports connecting with industrial centres in Canada and the United States. As the war continues, this figure will probably advance to 90 million tons. Second in importance is the shipment of coal, which in one year amounted to 40 million tons. Stone used in the steel industry and in road building comes third in volume of freight carried. Grain is fourth. Last year 359 million bushels of wheat, mostly Canadian, passed through the Great Lakes. Each year, some 50,000 automobiles are transported from the Detroit area westward. In 1941 this number was cut in half, and this year the movement will probably stop altogether.

Mr. Bennett spoke briefly on the history of the canal system, and referred to some of the physical characteristics of the Great Lakes. Certain weather conditions produce a very considerable tide in Lake Erie, the difference in level at the two ends sometimes being as great as eight feet. Lesser tides occur in Lake Superior, and in the other lakes, the tidal movement is very small.

The speaker related a very curious incident connected with the widening of the channel in the Saint Clair river. It was necessary to cut into the shore of a small unceded island, which was owned by the Indians and did not belong to either Canada or the United States. Before operations could be commenced, he and an American official had to meet with a council of the Indians, obtain their permission and arrange for compensation. Mr. Bennett stated that a number of similar unceded islands existed in the Great Lakes.

A vote of thanks to the speaker was moved by H. J. Crudge and seconded by B. E. Bayne.

#### MONTREAL BRANCH

L. A. DUCHASTEL, M.E.I.C. - *Secretary-Treasurer*  
G. G. WANLESS, J.E.I.C. - *Branch News Editor*

On February 26th, a lecture was given on **Subcontracting** by Mr. F. L. Jeckell, director-general of the Industry and Subcontract Co-ordination Branch of the Department of Munitions and Supply.

The "Bits and Pieces" programme of subcontracting originated in England as a means of decentralization to reduce dislocations from bombing. It was discovered, however, that it also served another very valuable service by making use of the skill and workmanship available in the small shops of the nation.

In Canada, the "I and S.C." Division is efficiently organized to give service, with branches and engineering personnel in principal cities. Among other things, it performs the following services:—

1. It has assembled and keeps revised, cross-indexed files on plant equipment throughout the country. With this, it is in a position to advise prime contractors of companies who may be in a position to accept subcontracts.
2. It has available on request, a manual on munitions subcontracting, giving its recommendations on procedure.
3. It considers applications for capital assistance for new machine tools—which are allowed only if no other comparable equipment is available in any other plant in the country.
4. It offers engineering service from its regional offices to expedite subcontracting and final delivery of the goods.
5. It is devoted to the job of producing as much war material as possible in the shortest time and not to worrying about the consequences of economic post-war dislocations.

From the Division's experience in granting prime contracts it has concluded that a prime contractor should set up a separate department to handle the job. The manager must be competent and on an equal footing with heads of other departments in the company. He must have his production, follow-up, and technical supervisors. The latter must give real engineering assistance to the subcontractor, who should be treated as though he were part of the organization.

Out of the sudden expansion programme, Mr. Jeckell sees a serious management problem, which deserves the serious concern of members of the Institute.

The following points came up during the discussion:—

1. At present, due largely to steel shortages, there are more sources willing to accept subcontracts, than can be given work.

2. At first, generally speaking, sub-contractors' costs run about the same as those of prime contractors, but as experience is gained, lower costs usually result, due to smaller overhead charges.

3. Subcontracts cannot be placed like purchasing requisitions for stock items; instead the prime contractor must co-operate by supplying engineering service. When this is done, percentage rejections run lower, as a rule.

4. It is the responsibility of the prime contractor to follow up the sub-contractor re schedules. If necessary the Division helps out.

5. Where possible the prime contractor is given a unit job; i.e. the Division itself does not usually farm out the components as sub-contracts.

6. There are two types of contracts:—

(a) Fixed price prime contracts.

(b) Cost plus prime contracts. In this latter case, the sub-contracts come under the direct supervision of the Division.

7. Among the most needed machine tools are the following:—

Milling machines

Turret lathes

Cutting tools

Presses, 1,000-ton capacity and up

Large size planers

Broaching machines and honers

External and internal grinders

8. The sub-contractor carries the same allocation and preference rating as the prime contractor. It is up to the latter to help the sub-contractor locate materials and it is advisable for him to supply raw materials to the sub-contractor—thus maintaining a better control over the complete operation.

Mr. Busfield thanked the speaker and suggested that our management committee might take concrete action in response to Mr. Jeckell's request.

On Thursday, March 5th, Dr. R. S. Jane delivered a comprehensive lecture on **Synthetic Rubber**, which was most timely in relation to the present emergency.

Dr. Jane did much of his graduate school work on rubber, and has made a continued study of developments in his and in the synthetic rubber field, in Europe and America. He is presently research chemist of Shawinigan Chemicals Limited, Montreal.

Chemists have for generations sought to produce synthetic rubber by the classical research method of synthesizing and polymerizing isoprene, which is the basic unit of natural rubber. No commercial successes have resulted. After the first World War, Britain abandoned her efforts and emphasized development of her far eastern plantations. Germany, being in less favourable circumstances, was encouraged to continue the synthetic researches, which had produced about 2,000 tons of inferior methyl rubber during the war. About 1930, the development of chloroprene rubber in the United States indicated a new approach to the problem through the polymerization of materials whose structures resemble but are not identical with isoprene. Fruitful results of this work in Germany, Russia, Poland and the United States has given the following general types of synthetic rubbers:—

(a) *Polysulfide rubbers*: (as from condensation of ethylene dichloride and sodium polysulfide)—a class of materials low in tensile strength, but excelling in oil resistance, and therefore desirable for gasoline hose tubes, etc.

(b) *Chloroprene rubbers*: (from polymerization of an acetylene derivative containing a high proportion of chlorine). Tensile strength is quite good, resistance to oil swelling and heat aging is outstanding. It is widely used in mechanical goods but will not likely be used for tire treads.

(c) *Koroseal*: (plasticized vinyl chloride). Really a rubber-like thermoplastic material, low in tensile strength, but of outstanding value in cable insulation.

(d) *Buna S*: (from copolymerization of butadiene and styrene). In Russia and Poland it is produced from by-product alcohol; in Germany from lignite coal; in the United States from petroleum refinery gases. This type is not oil resisting, but is said to equal natural rubber in tire tread performance. It will no doubt be produced on the greatest scale during this emergency.

(e) *Buna N*: (from copolymerization of butadiene and acrylic nitrile). An oil resisting type of Buna. Modifications of this basic type are known as Hycar, Ameripol, Chemigum.

(f) *Vistanx*: (from polymerization of isobutylene—a refinery by-product).

(g) *Butyl Rubber*: (from copolymerization of butadiene and isobutylene). This development is of more recent origin and probably resembles natural rubber most closely in processing characteristics. Coming as it does from refinery by-products, it is a bright hope in the synthetic field.

Following the emergency this range of synthetics, each excelling in one or more properties, will supplement natural rubber on a greater scale. During the emergency it is expected that they will have to supply the major proportion of our requirements, as our rubber stock-piles decrease. America's normal requirements are about 600,000 tons per year, (about 2½ per cent of this is now produced synthetically), and that of all the United Nations is estimated at about 1,000,000 tons per year. The petroleum resources of this continent can supply the necessary raw materials easily, but the production of the chemical plant equipment is a gigantic task which will sorely tax the steel industry. We will be hard pressed for rubber before this synthetic production is achieved.

On March 12th, an address on the subject **An Engineer Looks at Music** was given by Mr. S. T. Fisher, development engineer for Northern Electric Company, Limited. The chairman was Mr. P. B. Motley.

In conjunction with his work on Canadian production of Hammond electric organs, Mr. Fisher has made a study of physical basis of music and harmony, and he believes that such electrical musical instruments provide a means for perfecting the musical scale of keyboard instruments.

As we all know, certain combinations of sounds (chords) are pleasing to the ear (consonant) and others are not (dissonant). Pythagoras observed that the frequency ratios of consonant chords must be small integers. Helmholtz, who did exhaustive research on this subject, also found that these simple ratios were the only ones tolerable to our ears. For the seven major intervals of the octave, these ratios are: 1, 9/8, 5/4, 4/3, 3/2, 5/3, 15/8, 2. If these ratios are applied to the key of C major, the "just" (perfect) scale of C major is obtained, as seen in Fig. 1. It will be observed that the major chords C.E.G., F.A.C., and G.B.D., are all in the ratio 4/5/6 which is essential if they are to be perfectly in tune. But if one attempts to play the scale of D major on this same just scale it will not be in tune, as the ratio A/D will not be 6/4 as required, but instead 426.5/288. Thus it is, that a keyboard string instrument can only be correctly tuned in the perfect (just) scale of one key at a time.

	C	C*	D	D*	E	F	F*	G	G*	A	A*	B	C
<b>Just Scale:</b>													
Ratio to Tonic .....	1		9/8		5/4	4/3		3/2		5/3		15/8	2
Vibrations per sec. ....	256		288		320	341.25		384		426.5		480	512
<b>Tempered scale:</b>													
Ratio to Tonic .....	(Each semitone = previous one $\times \sqrt[12]{2}$ )												
Vibrations per sec. ....	256	271.2	287.3	304.4	322.5	341.7	362	383.5	406.3	430.5	456.1	483.2	511.98

Fig. 1

To overcome this difficulty of retuning keyboard instruments, the composer Bach popularized a scale which was developed in Europe and known as equal temperament. Probably this is the best compromise for a string keyboard instrument, but as can be seen from applying the ratio 4/5/6 to the major chords in the tempered scale, the intervals are not perfectly in tune.

In the new electric organs, the sounds are produced by radio equipment which can be instantaneously readjusted as to pitch. It is conceivable, therefore, that an instrument can be built in which the whole keyboard can be readjusted from one just scale to another just scale, every time the music changes key. This will increase the complexity of playing such an instrument, but the technical difficulties are believed to be not insurmountable. The result would be a perfectly tuned keyboard instrument.

Mr. Fisher illustrated his lecture with some electrical sound-generating equipment and an oscillograph, and was able to demonstrate to the eye and ear, the imperfections of the present tempered scale.

Several ladies were present among the large audience of musicians and engineers. All were keenly interested in the possibility of an improved musical instrument, and an enthusiastic discussion followed. Mr. J. B. Stirling moved the vote of thanks to the speaker.

#### NIAGARA PENINSULA BRANCH

J. H. INGS, M.E.I.C. - *Secretary-Treasurer*  
C. G. CLINE, M.E.I.C. - *Branch News Editor*

The Niagara Peninsula Branch held a dinner meeting in Niagara Falls at the General Brock hotel on February 26th, with an attendance of 50. Mr. C. G. Cline presided, in the absence of the Branch Chairman, Mr. A. L. McPhail. Mr. L. P. Rundle introduced the speaker, Mr. J. P. Skillen, and his assistant Mr. C. Vrooman, both of the Canadian Westinghouse Company. His subject was **Application of Relays and Meters for Industrial Substations and Plants**, and it was illustrated by lantern slides.

Mr. Skillen discussed first the special kinds of relay protection required at different parts of a substation. For a single incoming feeder, no extra protection is needed in addition to that provided by the power company but where there are two feeders in parallel, relays are needed that will clear the line on which a short has developed without tripping the line that is still in good working order. If the transformers are small, they can be protected simply by over-current relays but if they are large, a set of differential relays is warranted. On the out-going feeders, the relay system must be arranged to clear only that feeder on which a fault has occurred and only as much of it as may be necessary to remove the fault. Here again, additional complications occur when there are two feeders working in parallel. Each motor served must be protected against overheating but the extra current required momentarily for starting induction motors should not be interrupted. Synchronous motors require elaborate protection. Throughout this part of the address, various

types of relays suitable for use in each location were shown on the screen as well as explanatory wiring diagrams.

Mr. Skillen concluded by showing various types of meters and meter mountings suitable for use in industrial substations. After an interesting question period, the vote of thanks was moved by Mr. Robert F. Cline.

#### OTTAWA BRANCH

A. A. SWINNERTON, M.E.I.C. - *Secretary-Treasurer*  
R. C. PURSER, M.E.I.C. - *Branch News Editor*

R. E. Hayes, M.E.I.C., of Ottawa, gave an address entitled **Earth Moving Takes Wings**, at the noon luncheon at the Chateau Laurier on February 19. It was illustrated by slides and motion pictures. T. A. McElhanney, immediate past chairman, presided in the absence of Chairman N. B. MacRostie.

Carryall scrapers up to a capacity of 60 cubic yards, costing \$45,000, almost half of which was made up in the cost of the huge rubber tires on which they travel, were some of the items described. They represent a tremendous advance from the methods of former days where manpower with pick and shovel had to do the job. They go a long way, even, from the equipment in use only a few years ago. For highway construction and for the levelling off of airport landing fields they speed up the work and keep the cost down.

Instead of digging into the earth as was the case with the old-time steam shovel, the earth is now shaved off the surface in successive layers and the operation of dumping, or "spoiling," the earth is simplicity itself, taking only a few seconds. The earth load may be transported to its place of deposition at a speed up to 18 or 20 miles an hour and spread, as it were, "on the fly," that is while the whole outfit is moving forward. City streets may readily be negotiated if required and the entire outfit is operated by one man.

In line with this method of treatment there are other modern outfits in which the tractor, a mobile power plant in itself, is an integral part. These include tractor shovels for digging smaller quantities, tractor cranes in which the crane is mounted on the same chassis with the tractor, and various designs wherein power taken off from the tractor is used.

**Engine Testing Tribulations** was the subject of a noon luncheon address on March 5 by M. S. Kuhring of the National Research Council. Mr. Kuhring, after considerable experience in aircraft design and construction, joined the staff of the National Research Laboratories in January, 1930, and has been in charge of the Engine Testing Laboratory there since it was first organized.

Inasmuch as the engines that come up for test may from time to time embody new and radical ideas in design or construction, the laboratory is confronted with a more difficult problem than the ordinary engine manufacturer who need not be prepared for such a wide variation in types. Sometimes, before the tests can be satisfactorily undertaken, adaptations to the mounting have to be provided for, additional parts have to be made

up, and even tools for overhauling and taking the engine apart have to be designed. These latter are often awkward to produce rapidly and it is not unusual for them to cost as much or more than the engine itself. Variations between British and American engine types and parts is another problem, as well as differences in threading and in types of mounting.

Electrical gadgets also cause their share of trouble, stated Mr. Kuhring, who characterized them as "the bane of the engine tester's existence". Differences in voltage have to be taken into account for fear of blown fuses.

Air scoops, exhaust rings and other parts normally supported by the engine cowling often present a problem inasmuch as it is preferred to run the engine test without the cowling. Ingenuity therefore has to be displayed to develop a bracket to hold these parts. Other difficulties that beset the engine tester's work were also described by the speaker.

"It requires a peculiar combination of ability and temperament to carry on efficient tests of airplane engines these days", concluded Mr. Kuhring. "The engine tester must be able to handle any and every type of engine as it comes along. He must instantly be able to detect anything that might vitiate the engine itself. And he must be able to cruise over the engine installation with a pair of binoculars, keeping his eye on all parts at once to see that no particular part is working loose."

### SASKATCHEWAN BRANCH

STEWART YOUNG, M.E.I.C. - *Acting Secretary-Treasurer*

The new president of the Association of Professional Engineers and the Saskatchewan Branch of the Engineering Institute is A. P. Linton, bridge engineer, Department of Highways, Regina. Mr. Linton replaces R. A. McLellan, Saskatoon, now attached to No. 4 Air Training Command, R.C.A.F., Calgary, Alta.

Mr. Linton was elected at the annual meeting of the bodies held in Hotel Saskatchewan, Regina on Friday, February 20th. A. M. Macgillivray, Saskatoon, district engineer of the Canadian National Railway, was elected vice-president and members of the new council are J. G. Schaeffer, Regina, F. C. Dempsey, Regina, and N. B. Hutcheon, assistant professor of mechanical engineering, University of Saskatchewan, Saskatoon.

In attendance at the meeting was G. L. Parkinson, lecturer in civil engineering, Saskatoon. Mr. Parkinson is secretary of the Saskatoon section of the Association and the Institute.

One of the main items of business of the meeting dealt with a scheme to place before high school students a method of approach to their entering the field of engineering. A resolution was passed ordering council and executives to form a committee to take action in approaching principals of collegiates in the larger sections of Saskatchewan to give information to students regarding personal requirements and possibilities of engineering and to advise them.

It is not too early for us to give some serious consideration to the post-war period, said Mr. McLellan in his retiring presidential speech. Engineers were not organized at the end of the first Great War as we are to-day, and little or no interest was taken in the young engineer after he was demobilized. Practically all our graduating engineers to-day are being absorbed in some branch of the

war effort. Some undergraduates are joining up before the completion of their courses. We have a very definite responsibility towards these men in the years immediately following this war, he said.

This study naturally is linked with the future of the profession in Saskatchewan. Unless agriculture can be lifted from the bottom of the heap, or new developments made, our future does not appear very bright. We should, therefore, be vitally interested in making every possible contribution towards the solution of this problem. Apart from our own professional interest, perhaps no greater opportunity exists to enhance the usefulness and determine the necessity of this association in the minds of the public and of the leaders of our national life, said Mr. McLellan.

Seventy or more members of the Association and the Institute attended a banquet in the Hotel Saskatchewan on Friday evening. The speaker was S. J. Latta, commissioner of the Bureau of Publications, Regina. His subject was **Our Way of Life**.

The Saskatchewan Branch, jointly with the Association of Professional Engineers, held their regular monthly meeting in the Kitchener Hotel, Regina, on Tuesday evening, March 10, 1942, with an attendance of 44. The meeting was preceded by the usual dinner.

Two films were shown, one in colour depicting the **Manufacture and Use of Plywood** and the other **Copper Mining and Refining in Arizona**.

Mr. F. C. Leroux explained the various stages in the manufacture of plywood from British Columbia fir giving an outline of the uses to which it is being put and the possibilities for further extension of the field of application. The picture, by courtesy of the British Columbia Plywoods, Ltd., was provocative of considerable discussion, a hearty vote of thanks being tendered to Mr. Leroux.

The second film by courtesy of the Canada Wire and Cable Company, through the local manager, Mr. F. Heseltine, traced the production of copper from discovery and development of the mine to the manufacture of pure copper for industrial purposes. A hearty vote of thanks was tendered Mr. Heseltine.

### SAULT STE. MARIE BRANCH

O. A. EVANS, J.E.I.C. - *Secretary-Treasurer*  
N. C. COWIE, J.E.I.C. - *Branch News Editor*

The branch held its second general meeting of the year on February 28th in the Windsor Hotel. Members and guests numbering fifteen were present.

The speaker of the evening was Fred A. Becker, M.E.I.C., field engineer for Canadian General Electric Company. The subject of his address, **Some Recent Trends in Industrial Applications of Electricity**, was well illustrated with slides showing how utility, flexibility, beauty and conservation has affected the trends in the design of electrical equipment.

At the conclusion of his address, the speaker was thanked by N. C. Cowie, and by the chairman, L. R. Brown, for his inspiring address.

It was announced that at the March meeting of the branch an address would be given on Ferro Alloys by Mr. Udy of the Chromium Mining and Smelting Company.

# News of Other Societies

## QUEBEC PROFESSIONAL ENGINEERS ELECT NEW OFFICERS

J. A. McCrory, M.E.I.C., vice-president and chief engineer of the Shawinigan Engineering Company, Limited, Montreal, was elected president of the Corporation of Professional Engineers of the Province of Quebec, at the annual meeting held at the Headquarters of The Engineering Institute of Canada, in Montreal, on March 28th, 1942.

Mr. McCrory graduated from Pennsylvania State College in 1907 with the degree of B.Sc., in mechanical engineering, and, coming to Canada in 1910, located in Toronto, where he was engaged on the design and construction of the London Hydro sub-station and in general building work. In 1912 he moved to Montreal, and for four years was employed on the design and supervision of reinforced concrete construction. Mr. McCrory joined the staff of the Shawinigan Water and Power Company, in 1916 as designer, and on the formation of the Shawin-

J. A. McCrory, M.E.I.C.

igan Engineering Company, Limited in 1918, was appointed office engineer. He was subsequently engaged on the investigation and design of a large number of hydro-electric developments for the Shawinigan Water and Power Company and others, and in 1935 he was appointed to his present position.

He has been a member of the Corporation since 1923 and has also taken an active interest in the affairs of the Institute since he became an Associate Member in 1921. He was transferred to Member in 1926 and in 1929 he was elected chairman of the Montreal Branch. He represented the branch on the Council of the Institute during the years 1930-1935 and he was a vice-president of the Institute from 1937 to 1940. He is at present a member of the Finance Committee.

Other officers on the Council of the Corporation for the present year are: Vice-president: A. O. Dufresne, M.E.I.C., deputy minister, Department of Mines, Province of Quebec; Secretary-treasurer: C. C. Lindsay, M.E.I.C., consulting engineer of Montreal and member of the Montreal Tramways Commission, Montreal; Councillors: Brian R. Perry, M.E.I.C., consulting engineer, Montreal; J. Omer Martineau, M.E.I.C., assistant chief engineer, Roads Department of the Province of Quebec, Quebec City; P. E. Poitras, M.E.I.C., mechanical engineer, The Steel Company of Canada, Montreal; A. D. Ross, M.E.I.C.,

## Items of interest regarding activities of other engineering societies or associations

manager, Canadian Comstock Company, Limited, Montreal; Adhémar Laframboise, M.E.I.C., chief engineer, Eastern Canada Steel and Iron Works, Limited, Quebec City.

## CANADIAN INSTITUTE OF STEEL CONSTRUCTION OPENS NEW OFFICE

The Canadian Institute of Steel Construction has opened a new Ottawa office at 213 Laurier Avenue, West.

Due to the many regulations which have been brought about by the war, the General Executive of the Institute has decided that an Ottawa office is necessary so that a closer contact can be established with various Government Departments.

The Toronto and Montreal offices of the Institute have been closed, and the staffs have been moved to the new consolidated office.

These new offices will be in charge of Ralph C. Manning, M.E.I.C., formerly of the Toronto office, who is at present engaged in special work for the Director of Engineering Services, Department of National Defence. Ernest S. Mattice, M.E.I.C., formerly of the Montreal office of the Institute, will assist Mr. Manning.

It is hoped that all persons interested in obtaining handbooks or other information on structural steel will continue to make use of the services offered by the Institute.

One of the main objects of the Institute during the present period will be to conduct technical research with a view to more efficient use of steel in construction. This research will cover a wide field including the possibilities of combining structural steel with aluminum, stainless steel and the various types of modern insulating materials.

It is felt that efficiency will be the keynote of construction when the war is over. Many of the older methods of construction using heavy walls and massive interior members will give way before the speed and light weight of newer materials which are being used in large quantities for war purposes. After the war, the vastly increased production for these materials will seek outlets into normal peacetime markets of which the construction field is one of the largest. It is with this in mind that the Canadian Institute of Steel Construction has established a Research Committee consisting of the most widely known engineers of its various member companies to study these problems.

## AN OPPORTUNITY FOR ENGINEERS

The inaugural address of Warren C. Miller, M.E.I.C., president of the Association of Professional Engineers of the Province of Ontario, carries an important message to all engineers. It was delivered at the annual banquet of the Association, at the Royal York Hotel, Toronto, on January 17th, and it is reproduced herewith for the benefit of those who were not present:

"Mr. Chairman, Distinguished Guests, and Members of the Association: For your expression of confidence, I am deeply grateful. To be elected president of a professional body is an appreciated honour that should be repaid by a renewed effort on behalf of one's professional colleagues. This effort I trust that I may be able to give.

"It would be idle at this time to make any extended pronouncement on our Association's affairs or its particular policies. Any work that we may do is so greatly overshadowed by our larger obligation. Our first job is to make whatever contribution our professional attainments permit toward a complete, all-out war effort. We must be prepared, without sacrificing fundamental principles, to

ide our time and be content with a somewhat liberal interpretation of our obligations and our privileges, in the light of their effect on defence production and defence effort generally. This war is being waged by our enemies without the restrictions imposed by laws or rules.

"We must take care that a too-strict insistence on rules is not essential at this time shall not give our enemies any advantage. We are called on to make many sacrifices. This is one for which we must be prepared.

"Some of us may feel that such delays in our programme of public protection and professional advancement are irksome. We may sometimes feel that we are accomplishing little. A great Englishman once said, 'They also serve, who only stand and wait.'

"We engineers have another duty, another opportunity to place our skill at the disposal of our Country and Empire, as so many of our members have already done. Out of this war is going to come a different world, a world so different from that of the 1920's as they were from the 1900's. Necessary war expenditures are going to be of such an order that our existing economy will be strained to the limit, if it manages to survive at all.

"The post-war period is more than ever going to be one where, of necessity, fact and reason must dominate public decisions. Our learned friends of the legal profession already operate in this field, particularly within the realm of those laws, gradually 'broadened down from precedent to precedent,' which are the creation of human agencies at the behest of human nature. We of the engineering profession share with the bar the duty of collect-

ing and evaluating factual evidence and of arriving at conclusions therefrom.

"But we work with the administration of those immutable laws of Nature that are derived by patient investigation and research from the Creator Himself, directly. If His natural laws do not suit our purpose, there is no court where we may argue and persuade that a new shade of meaning should be given to the law of gravity in keeping with changed conditions of modern aerial transportation. We cannot go to a friendly legislature and have Boyle's Law amended.

"Our unique function as engineers is the search for facts and the basing of logical decisions on those facts. We use our specialized study of natural laws and forces to aid us in interpreting facts, evaluating evidence, drawing conclusions and translating the results into physical structures, materials and machines that serve mankind. An appreciation of the fundamental natural laws and their application to the problems of humanity will be of paramount importance when man-made laws of conduct and human relations have of necessity been distorted, possibly out of recognition, by the urgency of the conflict to preserve our rights to live at all.

"This will be a great opportunity for engineers. In rising to meet the country's needs at such a time, our profession, slowly advancing as it has been in the past, with a little acceleration in recent years, will, I am satisfied, find its proper place in the sunlight of a tired but victorious democratic world. It should be one of our principal objectives for the present to prepare for it."

## Library Notes

### ADDITIONS TO THE LIBRARY

#### TECHNICAL BOOKS

##### Continuous Beam Structures:

*Eric Shepley, London, Concrete Publications Ltd., 6½ x 9½ in. 7s. 6d.*

##### American Standards Association:

*List of American standards for 1942. (This list will be sent free of charge to anyone writing in for it. Requests should be addressed to the American Standards Association, 29 West 39th St., N.Y.C.)*

##### Canadian Engineering Standards Association, Specifications:

*Standard specification for alkali sulphate resisting cement, A72t; Construction and test of industrial control equipment for use in ordinary locations (2nd ed.) C22.2—No. 14; Construction and test of receptacles, plugs and similar wiring devices (2nd ed.) C22.2—No. 42.*

#### PROCEEDINGS, TRANSACTIONS

##### Junior Institution of Engineers:

*Journal and record of transactions for the year 1940-41.*

##### National Council of State Boards of Engineering Examiners:

*Proceedings 22nd annual meeting, October 27-30, 1941 and Year book 1942.*

##### Canadian Good Roads Association:

*Proceedings of the 26th annual convention, October 7-9, 1941.*

#### REPORTS

##### American Institute of Chemical Engineers:

*Directory of officers and members and committee appointments for 1942.*

### Book notes, Additions to the Library of the Engineering Institute, Reviews of New Books and Publications

##### Cornell University, Engineering Experiment Station:

*The buckling of compressed bars by torsion and flexure by J. N. Goodier. Bulletin No. 27; Flexural-torsional buckling of bars of open section by J. N. Goodier. Bulletin No. 28.*

##### Ohio State University Studies, Engineering Series:

*Surface and underground waters of Ohio. Engineering experiment station circular No. 43.*

##### Engineering as a Career, a message to young men, teachers and parents:

*Engineers Council for Professional Development.*

##### U.S. Department of Commerce, National Bureau of Standards:

*Report of the 31st national conference on weights and measures. Miscellaneous publication M170.*

##### British Trade and Industry:

*A survey of past achievement and future prospects published by Country Life.*

##### Electrochemical Society:

*Electrolytic polishing of silver. Preprint 81-5.*

##### New C.E.S.A. Electrical Standards

The Canadian Engineering Standards Association has just issued the following ten approvals specifications under Part II of the Canadian Electrical Code, the requirements of which must be met in order to obtain CESA approval of the electrical devices concerned. These standards were prepared in collaboration with interested manufacturers and industrial associations and are based on laboratory tests and record in service.

Copies of these standards may be obtained from the Canadian Engineering Standards Association, National Research Building, Ottawa. The prices are quoted below.

##### C.E.S.A. No. C22.2

##### No. 5—1942 Service Entrance and Branch-Circuit Breakers. 2nd. ed.

*This specification covers the construction and test of circuit breakers rated at not more than 600 amperes or 600 volts, designed to provide service-entrance, meter-service, or branch-circuit protection, in accordance with the rules of Pt. 1 of the Canadian Electrical Code. It does not cover circuit-breakers rated at more than 600 amperes or 600 volts, or switches, or so called "breakers" provided only with overload devices and intended to be protected by overcurrent devices. This specification is effective as of April 30, 1942 for new production. 60c.*

##### No. 9—1941 Electric Fixtures. 2nd ed.

*This specification applies to electric fixtures intended for use in non-hazardous locations, both indoors and outdoors, and for connection to lighting circuits of not more than 250 volts between conductors, in accordance with the rules of Pt. 1 of the Canadian Electrical Code. It includes recessed fixtures and show-window and show-case fixtures, having incandescent and/or electrical-discharge lamps. It does not include troughs exceeding 10 ft. in length, outline lighting, or fixtures of the so-called "vapour-tight" and "explosion-proof" construction or high-voltage gas-tube fixtures (i.e. tubes containing inert gases). This specification is effective as of March 31, 1942 for new production. 75c.*

**No. 11—1942 Fractional-Horsepower Electric Motors for other than Hazardous Locations. 2nd ed.**

This specification applies to fractional-horsepower (electric) motors for use where ordinary conditions prevail and also for use in other locations, except hazardous locations as covered by Section 32 of Pt. 1 of the Canadian Electrical Code where it may be necessary to protect the motor windings, etc., with regard to the atmospheric or other conditions surrounding the motor. It applies particularly to the following types of motors as defined by types of enclosures:—1 open; 2 protected; 3 enclosed; 4 drip-proof; 5 splash-proof; 6 water-tight. It applies to electric motors of fractional horsepower rating, whether self-contained or forming a part of a piece of electrical equipment and whether portable or otherwise, for potentials up to 600 volts inclusive and for either a.c. or d.c. or both. It should be noted that electric clock motors and electric motors built into and forming a part of domestic appliances, fans, dental equipment, and hair dressing equipment are not covered by this specification. It is effective as of April 15, 1942, for new production. 50c.

**No. 21—1941 Cord Sets. 2nd ed.**

This specification applies to cord sets designed to be employed in accordance with the rules of Pt. 1 of the Canadian Electrical Code on circuits operating at not more than 125 volts. This specification is effective as of March 31, 1942, for new production. 50c.

**No. 54—1942 Integral Horsepower Electric Motors for other than Hazardous Locations**

This specification applies to integral-horsepower electric motors for use where ordinary conditions prevail and also for use in other locations (except hazardous locations as covered by section 32 of Pt. 1 of the Canadian Electrical Code) where it may be necessary to protect the motor windings, etc., with regard to the atmospheric or other conditions surrounding the motor. It applies to electric motors of integral-horsepower rating from 1 to 200 horsepower for potentials up to and including 2,500 volts between conductors on ungrounded systems and 4,500 volts between conductors on grounded-neutral systems and intended to be employed in accordance with the rules of Pt. 1 of this code. This specification is effective as of April 30, 1942, for new production. 50c.

**No. 55—1942 Snap Switches**

This specification applies to manually operated snap switches rated at not more than: (a) 60 amperes and 250 volts; (b) 30 amperes and 300 volts and (c) 2 h.p. and 600 volts; and designed to be employed in accordance with the rules of Pt. 1 of the Canadian Electrical Code. It does not cover: (a) Snap switches rated at less than 50 volts unless such rating is used in conjunction with a rating of 125 or 250 volts; (b) Snap switches forming parts either of electro-thermal appliances e.g., "heater switches" or automatic temperature-responsive switches; (c) Slow make and/or slow break switches; (d) So-called "mercury-switches" and (e) Switching mechanism built into lamp-holders. This specification is effective as of April 30, 1942 for new production. 50c.

**No. 66—1942 Specialty Transformers**

This specification contains three sections covering three different types of specialty transformers as follows; 1. Miscellaneous and General Purpose Transformers applies to dry-type, air cooled transformers (including auto-transformers and primary circuit reactors) for use with; mercury

vapor lamps; power operated radio devices (other than the original and authentic transformer designed by the radio manufacturer for his particular radio device and so identified); signalling and control circuits; and high reactance transformers (incapacities of one kva. and less and for primary and secondary potentials of 750 volts and less) intended to be employed in accordance with the rules of Pt. 1 of the Canadian Electrical Code. It does not include transformers intended for the following purposes; testing electrical insulation, electric welding, electric soldering, bell ringing, toys, luminous tubes, oil burner ignition systems, instrument transformers and fluorescent lighting. 2. Bell ringing transformers, applies to dry type, air cooled bell ringing transformers for potentials of 250 volts or less between conductors, and designed to be employed in accordance with the rules of Pt. 1 of the Can. Elec. Code. 3. Toy Transformers applies to dry type, air cooled toy transformers for potentials of 150 volts or less between conductors and designed to be employed in accordance with the rules of Pt. 1 of the Can. Elec. Code. This specification is effective as of April 30, 1942, for new production. 75c.

**No. 67—1942 Portable Electric Vacuum Cleaners.**

This specification applies to domestic and commercial vacuum cleaners of the portable motor operated type for potentials up to and including 250 volts between conductors designed to be employed in accordance with the rules of Pt. 1 of the Can. Elec. Code. This specification is effective as of April 30, 1942. 50c.

**No. 68—1942 Motor operated appliances—Domestic and Commercial (Fractional Horsepowers).**

This specification applies to motor operated appliances both stationary and portable for potentials up to and including 250 volts between conductors designed to be employed in accordance with the rules of Pt. 1 of the Can. Elec. Code. It applies to both domestic and commercial appliances using fractional horse-power motors such as electric shavers, hair clippers, vibrators, massage machines, and food preparing machines (e.g., food and cake mixers, juice extractors, meat slicers, bread slicers, food choppers, peelers, coffee grinders, etc.) It does not include any specific appliances which are covered by individual specifications, e.g., blowers, floor surfacing and cleaning machines, washing machines, vacuum cleaners, hairdressing equipment and tools. This specification is effective as of September 30, 1942 for new production. 50c.

**No. 73—1941 Electrically Equipped Machine Tools.**

This specification applies to both stationary and portable machine tools which may or may not have certain portable parts, having electrical equipment mounted thereon and designed to be installed and employed in accordance with the rules of Pt. 1 of the Can. Elec. Code. It does not apply to: 1. The mechanical features of such machine tools except as these affect the electrical equipment used in connection with such machines; 2. wood-working machines; 3. tools for automobile works (e.g., cylinder borers, valve seat grinders); 4. Small portable tools (e.g., electric drills tappers, grinders, hammers, screw drivers); 5. Welding or gas cutting machines. It should be noted that the approvals laboratory will at its discretion use this specification in the approval of other types of machines not specifically covered by other individual Approvals Specifications of Pt. 11 of the Can. Elec. Code in so far as its requirements may be applicable. Also the CESA Approvals division will con-

sider upon request, any deviations from this Specification if such are due to war conditions. This specification is effective as of December 31, 1941 for new production. 50c.

**BOOK NOTES**

The following notes on new books appear here through the courtesy of the Engineering Societies Library of New York. As yet the books are not in the Institute Library, but inquiries will be welcomed at headquarters, or may be sent direct to the publishers.

**ELECTRICAL ILLUMINATION**

By J. O. Kraehenbuehl. John Wiley & Sons, New York, 1942. 441 pp., illus., diags., charts, tables, 9 x 6 in., cloth, \$3.75.

The principles underlying the specification and design of electrical lighting for commercial and industrial buildings are presented as an elementary course for architectural and electrical engineering students. Maintenance and economic factors are discussed, and there are special chapters on floodlighting and novelty lighting. A bibliography accompanies each chapter.

**ADVANCES in COLLOID SCIENCE, Vol. 1**

Edited by E. O. Kraemer in collaboration with F. E. Bartell and S. S. Kistler. Interscience Publishers, New York, 1942. 434 pp., illus., diags., charts, tables, 9½ x 6 in., cloth, \$5.50.

The series which this volume begins is intended to publish recent significant discoveries and advances in our knowledge of colloids, in a more comprehensive and unified form than is possible in periodicals. The present volume contains twelve contributions by well-known workers in this field, each accompanied by a useful bibliography.

**AERIAL BOMBARDMENT PROTECTION**

By H. E. Wessman and W. A. Rose. John Wiley & Sons, New York; Chapman & Hall, London, 1942. 372 pp., illus., diags., charts, tables, 9½ x 6 in., cloth, \$4.00.

This book is primarily devoted to a detailed discussion of those measures which can and should be undertaken to make building construction resistant to the effects of bombing, at reasonable cost. Characteristics of bombs, air raid shelters, evaluation of shelter zones and camouflage are other topics considered. A brief statement of other engineering problems related to aerial bombardment is also included. The material has been developed with particular regard for American structural and architectural practice.

**AEROPHOTOGRAPHY and AEROSURVEYING**

By J. W. Bagley. McGraw-Hill Book Co., New York and London, 1941. 324 pp., illus., diags., charts, tables, 9½ x 6 in., cloth, \$3.50.

Broad in scope, logical in arrangement and up to date, this new text covers the fields of standard and exploration mapping. The chief aim of the book is to deal with Aerial photographs, standard laboratory practice and the various methods of utilizing aerial photographs for making standard and exploratory maps, mosaics and engineering surveys.

**AMERICAN HIGHWAY PRACTICE, Vol. 1**

By L. I. Hewes. John Wiley & Sons, New York; Chapman & Hall, London, 1942. 459 pp., illus., diags., charts, maps, tables, 9½ x 6 in., cloth, \$5.00.

This first volume of a two-volume text on current rural highway practice in the United States presents in logical order the topics of highway survey, roadway and landscape design, and grading practice. Succeeding chapters deal with sand-clay, macadam,

avel and intermediate bituminous surfaces. Higher types of surfaces will be covered in the second volume.

#### **AUTOMATIC ARMS, their History, Development and Use**

By M. M. Johnson, Jr., and C.T. Haven. William Morrow and Co., New York, 1941. 344 pp., illus., diags., tables, 9½ x 6 in., cloth, \$4.50.

The five principal sections of this authoritative work deal respectively with the history and development of automatic arms, working principles, requirements for efficient operation, employment in combat, and various miscellaneous considerations. A table of characteristics of the various types and diagrams of operating parts are appended.

#### **DICTIONARY OF RADIO AND TELEVISION TERMS**

By R. Stranger. Chemical Publishing Co., Brooklyn, N.Y., 1941. 252 pp., diags., tables, 9 x 5½ in., cloth, \$2.50.

This dictionary is designed to provide quick reference for students of radio and television. In addition to radio and television terms, a number of scientific terms allied to these subjects are also included. Helpful diagrams and illustrations accompany many definitions.

#### **DIE DESIGNING AND ESTIMATING**

(Based on "Die Designing" by C. Bohmer and "Die Estimating" by G. Dannes). 2 ed. American Industrial Publishers, Cleveland, Ohio, 1941. 160 pp., illus., diags., charts, tables, 9½ x 6 in., cloth, \$3.00.

The operation, uses and basic principles of design of various kinds of dies are described. In the second section procedures are given for estimating the cost of several dies, with tables of time values for necessary operations in die construction. A section of practical points in die design and construction is appended.

#### **EASTERN PHOTOELASTICITY CONFERENCE, 13th SEMI-ANNUAL PROCEEDINGS**

Held under the auspices of the Department of Mechanical Engineering at the Massachusetts Institute of Technology, Cambridge, Mass., June 12-14, 1941. (Copies may be obtained from W. M. Murray, Room 1-321, Massachusetts Institute of Technology, Cambridge, Mass.) 130 pp., illus., diags., charts, tables, 11 x 8½ in., paper, \$2.00.

Contains the eighteen papers presented. These discuss various applications of the photoelastic method of stress analysis, and some results obtained.

#### **Great Britain, Dept. of Scientific and Industrial Research**

#### **WATER POLLUTION RESEARCH, Technical Paper No. 8.**

#### **THE TREATMENT AND DISPOSAL OF WASTE WATERS FROM DAIRIES AND MILK PRODUCTS FACTORIES**

His Majesty's Stationery Office, London; British Library of Information, New York, 1941. 125 pp., illus., diags., charts, tables, 10 x 6 in., paper, \$1.20.

The results of an intensive investigation of this problem are presented in this report. Methods of reducing the quantity of milk carried away were also investigated. Large-scale experimental plants were constructed and the results obtained, with the conclusions and recommendations derived from them, are given in this report.

#### **Great Britain, Dept. of Scientific and Industrial Research, Building Research, Wartime Building Bulletin No. 18, FIRE STOPS FOR TIMBER ROOFS**

His Majesty's Stationery Office, London, 1941. 13 pp., illus., diags., tables, 11 x

8½ in., paper, (obtainable from British Library of Information, 30 Rockefeller Plaza, New York, \$3.00).

This bulletin describes simple devices that can be erected to check the spread of fire along existing roofs of wood or other combustible materials. Four types are described, and the results of tests given.

#### **HEAT IN THEORY AND PRACTICE ESSENTIAL TO REFRIGERATION AND AIR CONDITIONING**

By S. R. Cook. Nickerson and Collins Co., Chicago, Ill., 1941. 228 pp., diags., charts, tables, 9½ x 6 in., cloth, \$2.00.

The fundamental facts and theories of heat are presented in a simple manner for the student interested in refrigeration and air conditioning. The intent of the volume is to give information essential to the solution of problems which may arise in the study of refrigeration and air conditioning, whether from a text or from actual handling of refrigerating and air conditioning machinery.

#### **HIGHWAY ECONOMICS**

By H. Tucker and M. C. Leager. International Textbook Co., Scranton, Pa., 1942. 454 pp., illus., diags., charts, maps, tables, 8½ x 5 in., cloth, \$4.00.

A considerable range of topics is covered in this book, from financing methods, in which the subject of taxation is particularly important, to technical discussions of power requirements for and the performance of motor vehicles under varying conditions. Equipment rental, the allocation of highway costs, and traffic and accident considerations are other topics dealt with at some length.

#### **HORIZONS UNLIMITED, a Graphic History of Aviation**

By S. P. Johnston. Duell, Sloan and Pearce, New York, 1941. 354 pp., illus., 10 x 6½ in., cloth, \$3.75.

The story of man's conquest of the air is told in words and pictures. The great experiments are described; struggles and desires, successes and failures are discussed; and consideration has been given to the human elements and social consequences of the development of the means of flight. Brief discussions of meteorology and aerodynamics are included.

#### **HOW YOUR BUSINESS CAN HELP WIN THE WAR**

Compiled by the Staff of Industrial Specialists of the Conover-Mast Periodicals, and edited by H. W. Barclay, with an introduction by D. M. Nelson. Simon and Schuster, New York, 1942. 111 pp., charts, maps, tables, 11 x 8 in., paper, \$1.00.

This book is designed to show business men what the government wants to buy, how to bid, and how to get contracts and sub-contracts for government orders. It also shows ways in which time and money can be saved and red tape cut in dealing with government offices.

#### **Industrial Relations Digests**

#### **XI. METHODS OF TRANSMITTING INFORMATION TO EMPLOYEES**

Princeton University, Princeton, New Jersey, January, 1942, 8 pp., 10 x 7 in., paper, \$2.00.

This digest of current practice in methods of keeping employees informed on company policies, mainly through printed material, has been prepared for use in companies facing rapid expansion owing to defense orders. It is based on material received currently from representative companies.

#### **MARINE ELECTRICAL INSTALLATION**

By J. F. Piper. Cornell Maritime Press, New York, 1941. 308 pp., illus., diags., charts, tables, 7½ x 5 in., cloth, \$2.50.

This manual is intended to aid the inexperienced workman to obtain practical insight into electrical marine work. The tools and materials used; the laying out of work; wiring methods; power, lighting and communication systems are described in detail in a practical way and without undue use of technical language.

#### **MATHEMATICS FOR ELECTRICIANS AND RADIOMEN**

By N. M. Cooke. McGraw-Hill Book Co., New York and London, 1942. 604 pp., diags., charts, tables, 9½ x 6 in., cloth, \$4.00.

This book presents a course which is intended to provide adequate mathematical background for solving practically all electrical and radio problems. Elementary algebra through quadratic equations, logarithms, trigonometry, elementary plane vectors, and vector algebra as applied to alternating-current circuits are included. The text follows an electrical rather than a purely mathematical arrangement.

#### **(The) MATHEMATICS OF THE SHOPS**

By F. J. McMakin and J. H. Shaver. D. Van Nostrand Co., New York, 1942. 444 pp., illus., diags., charts, tables, 9 x 5½ in., cloth, \$2.50.

A text for use in vocational high schools and apprenticeship classes. The fundamentals of arithmetic, algebra, geometry and trigonometry are explained in simple language, after which basic problems are discussed which arise in the building trades and in electrical and machine shops. Special consideration is given to acceptable trade and technical practices.

#### **MECHANICAL PROPERTIES OF MATERIALS AND DESIGN**

By J. Marin. McGraw-Hill Book Co., New York and London, 1942. 273 pp., illus., diags., charts, tables, 9½ x 6 in., cloth, \$3.50.

The primary purpose of this book is to furnish a survey of the mechanical properties of engineering materials and to show how a consideration of these properties modifies design procedure. With this end in view, the author attempts to bridge the gap between books on engineering materials which deal with the manufacture, testing and properties of materials, and those dealing with the stress analysis of machine and structural members.

#### **OPERATION OF WATER-TREATMENT PLANTS**

By W. A. Hardenbergh. International Textbook Co., Scranton, Pa., 1942. 307 pp., illus., diags., charts, tables, 7½ x 5 in., cloth, \$3.10.

General considerations of water-supply systems are first presented, including distribution practice. The requirements with respect to quality of water are stated, and analytical methods for the determination of water quality are fully covered. The last half of the book describes details of plant operation and the types of equipment necessary, with a final section which presents typical data and records for a rapid sand-filtration plant.

#### **PERSONAL LEADERSHIP IN INDUSTRY**

By D. R. Craig and W. W. Charters. 2nd ed. McGraw-Hill Book Co., New York and London, 1941. 245 pp., tables, 8½ x 5½ in., cloth, \$2.50.

Practical methods are given, based on experience, for executives, supervisors and foremen who want aid in managing men. Qualifications and character traits essential to successful personal leadership are described, and the text shows how to use these qualities in getting the right kind and right amount of work done with the least disturbance and friction.

# PRELIMINARY NOTICE

of Applications for Admission and for Transfer

FOR ADMISSION

March 31st, 1942.

The By-laws provide that the Council of the Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

**Communications relating to applicants are considered by the Council as strictly confidential.**

The Council will consider the applications herein described at the May meeting.

L. AUSTIN WRIGHT, General Secretary.

\*The professional requirements are as follows:—

A **Member** shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupillage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science or engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A **Junior** shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A **Student** shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An **Affiliate** shall be one who is not an engineer by profession but whose pursuits, scientific attainment or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

ALLEN—CHARLES HARRY, of 5553 Queen Mary Road, Montreal, Que. Born at Wells, Somerset, England, Jan. 13th, 1908; Educ.: 1922-27, night classes in engr., Hamilton Technical Institute; with the Canadian Westinghouse Company as follows: 1923-27, student on elec. training course; 1927-30, electric mechanic on install. of elec. machy. and equipment in vertical lift and rolling lift bridges over Welland Ship Canal, also 500 ton capacity electrically operated floating gate-lifter, electrical sub-stations, etc.; 1930-37, foreman, and later engr. in charge of various large electrical installns. incl. major developments at the Ontario Hydro Leaside Sub-station, Queenston plant, H.E.P.C., Chats Falls Power Plant, H.E.P.C., Rapide Blanc Power House of Shawinigan Water & Power Co.; July 1937 to date, sales engr., Montreal office, chiefly concerned with industrial control and secondary switchgear.

# Employment Service Bureau

## SITUATIONS VACANT

**MECHANICAL DESIGNING DRAUGHTSMAN**, Graduate preferred, urgently needed for work in Arvida for specification drawings for plate work, elevators, conveyors, etc., equipment layouts, pipe layouts and details. Apply to Box No. 2375-V.

**MECHANICAL ENGINEER**, preferred with experience on diesels and tractors, for work in Mackenzie, B.G. Apply to Box No. 2482-V.

**MECHANICAL DRAUGHTSMEN** and engineers for pulp and paper mill work. Experienced men preferred. Good salary to qualified candidates. Apply to Box No. 2483-V.

**ELECTRICAL ENGINEER**, young French Canadian graduate engineer to be trained on work involving hydro-electric plant operation, transmission lines and construction, meter testing and inspection. Good opportunity to acquire first-hand electrical power experience. Apply to Box No. 2487-V.

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party. Notices appearing in the Situations Wanted column will be discontinued after three insertions, and will be re-inserted upon request after a lapse of one month. All correspondence should be addressed to THE EMPLOYMENT SERVICE BUREAU, THE ENGINEERING INSTITUTE OF CANADA, 2050 Mansfield Street, Montreal.

**CHEMICAL CONSULTING ENGINEER** with practical experience to advise on efficient management of small plant manufacturing pigments and dry colours for paint and rubber production. Apply to Box No. 2503-V.

**MECHANICAL ENGINEER** with experience in pulp and paper industry for supervision and maintenance work in large paper mill. Must be experienced in machine shop work and the handling of men. Apply to Box No. 2522-V.

experience. Age 30. Married. Transmission line, and distribution, estimating, design, survey and construction three years, (one year acting superintendent), interior light and power wiring design, estimating and supervision one year. Electric meters (AC) six months, electric utility drafting six months, foundation layouts and concrete inspection six months. Steam power plant operation two years. Presently employed but desire advancement. Apply to Box No. 2430-W.

## ENGINEER OFFICERS WANTED

Applications are invited for Commissions in the Royal Canadian Ordnance Corps for service both overseas and in Canada as Ordnance Mechanical Engineers. Since it is probable that several new units will be organized in the near future, a number of senior appointments may be open, and applications from engineers with a good background of military experience would be welcomed in this connection. Applications should be submitted on the regular Royal Canadian Ordnance Corps application forms, which can be obtained from the District Ordnance Officers of the respective Military Districts.

## SITUATIONS WANTED

**MECHANICAL ENGINEER** age 55 years. Married. Available at once. Thirty years experience in draughting and general machine shop and foundry work. Fifteen years as works manager. Considerable experience in pump work, including estimating and inspection. Apply to Box 2427-W.

**ENGINEER ADMINISTRATOR**, experienced in public utilities, shipyard construction, airplane construction, crane construction, general mechanical engineering and inspection work, also sales promotion. Open for appointment. Apply to Box 2429-W.

**GRADUATE ENGINEER** in Electrical and Mechanical Engineering, M.E.I.C., and R.P.E., electric utility

## FOR RENT

### Desirable Location For Engineering Office

Entire ground floor about 30 ft. x 80 ft., 4 large rooms and one small. Suitable for consulting engineering office or similar private professional practice. Garage in back yard.

3425 University St.  
(Opp. Pulp & Paper Laboratory)  
MONTREAL

Apply at above address or telephone  
MA. 2975

## WANTED IMMEDIATELY MECHANICAL ENGINEERS

as managers of divisional offices of corporations handling sub-contracts for war emergency programme.

—to supervise production of machinery and equipment, including direction of staff and relations with contractors. Must have experience in production control, machine shop and foundry practice—preferably in heavy industry. Give credentials, present salary. Do not apply if already engaged in war work.

P. O. Box 170, Station B,  
MONTREAL

## PRELIMINARY NOTICE

(Continued)

### FOR TRANSFER FROM STUDENT

**GIAUQUE—LOUIS FREDERICK**, of Hamilton, Ont. Born at Elbow, Sask., June 25th, 1914; Educ.: has completed 3rd year engrg. and expects to graduate July, 1942 at Univ. of Sask. with degree of B.Sc. (Mech.); 1941, design engr., B. Greening Wire Co. Ltd., Hamilton, Ont., at present on leave of absence, completing engrg. course. (St. 1941).

References: R. A. Spencer, I. M. Fraser, G. D. Archibald, C. J. Mackenzie, W. L. Lovell.

**HARRIGAN—MAYO ARTHUR PERRIN**, of 244½ Barrington St., Halifax, N.S. Born at Halifax, Jan. 19th, 1907; Educ.: B.Sc. (Elec.) 1932, B.Sc. (Mech.), 1933, N.S. Tech. Coll.; 1929, student asst., Geol. Survey; 1931, inspr. of concrete, City of Halifax; 1934-39, marine engr. i/c of watch at sea on govt. and cable ships; 1939-40, shift engr., Canadian Industries Ltd., i/c of elec. and mech. repair (C.I.L. Consolidated and Alkali Works, Shawinigan Falls); 1940, chief engr's staff, at present asst. to the chief engr., H. M. C. Dockyard, Halifax, N.S. (St. 1930).

References: S. J. Montgomery, H. R. Theakston, A. E. Flynn, R. P. Donkin.

**LEROUX—FRED CLEMENTS**, of Vancouver, B.C. Born at Weyburn, Sask., June 13th, 1913; Educ.: B.Sc. (Agric. Engrg.), Univ. of Sask., 1939; 1940-41 (intermittently), Univ. of Miss., preparing for Master's Degree; 1934-36, J. H. Early Motor Co. Ltd., Saskatoon; 1937, serviceman and repairman, J. I. Case Co.; 1939, head of a small survey at the Scott Experimental Station; 1939-40, instructor of mechanics, Extension Dept., Univ. of B.C.; 1940-41, research asst., Dept. of Agric. Engrg., Univ. of Miss., on American Cyanamid Fellowship; 1941 to date, field and agric. engr., B.C. Plywood Ltd., Vancouver, B.C. (St. 1939).

References: I. M. Fraser, C. Neufeld, S. G. Talman.

**NORMAN—RONALD LEE**, of 1 Prince Arthur St., Halifax, N.S. Born at Westville, N.S., July 15th, 1914; Educ.: B.Eng. (E.E.), N.S. Tech. Coll., 1935;

1935, pavement inspr. (junior), and 1935-37, senior inspr., Milton Hersey Co., Ltd., for N.S. Dept. of Highways—asst. to res. engr., i/c of staff inspecting materials, mixing and laying of bituminous pavements; 1937-39, sound engr., Dominion Sound Equipments Ltd., Halifax, N.S.; 1939-40, constr. engr., Fundy Construction Co., Halifax; at present, meter engr., i/c gen. mtce., installns., etc., of metering and control equipment, Imperial Oil Refinery, Imperoyal, N.S. (St. 1932).

References: W. P. Copp, S. W. Gray, P. A. Lovett, I. M. Fraser, R. L. Dunsmore.

**READ—FREDERICK CYRIL**, of Montreal, Que. Born at Cobalt, Ont., Aug. 1st, 1914; Educ.: B.A.Sc. (Chem.), Univ. of Toronto, 1939; with Hollinger Cons. Gold Mines, Timmins, Ont., 18 mos. prior to University, and three summer vacations—10 mos. labour, 8 mos. assaying, and 12 mos. ore dressing lab.; 1939-40, Marks & Clark, patent attorneys, Ottawa; 1940-41, sulphite pulp grader, Spruce Falls Paper & Paper Co., Kapuskasing, Ont.; Sept., 1941 to date, research asst., Dominion Tar & Chemical Co., Montreal, Que. (St. 1938).

## BLUE PRINT READING

The Lincoln Electric Company, Cleveland, Ohio, have issued the second edition of their 146-page book entitled "Simple Blue Print Reading with Special Reference to Welding." This book is written in simple, practical language, and it is intended that welders, mechanics and others will be enabled, by a few hours' sparetime study, to learn print reading which otherwise might take many months to learn. The text gives the students a clear understanding of symbols used in drawing various types of welded joints, including butt, corner, fillet, lap, etc. The illustrations contained in the book include practical examples of drawings of a number of machine parts, pipe connections, general construction, tanks, etc. A list of questions and answers allows the student to test his knowledge.

## CONSERVATION OF TIRES

"Valuable Hints on How To Make Your Tires Last Longer" is the title of a 12-page booklet recently published by Dominion Rubber Co. Ltd., Montreal, Que. This timely publication is filled with important information on the subject, illustrated with photographs and drawings. Among the subjects treated are: how retreading and re-grooving add mileage; how to "cross-switch tires"; how to guard against blowouts; and many other recommendations and tips.

## ENGINEERING STANDARDS

Bulletin Vol. 15 No. 4, published by Canadian Engineering Standards Association, Ottawa, Ont., gives list of publications, and description of matters dealt with at the 19th ordinary general meeting, and at meetings of committees on steel construction, small rivets, distribution transformers, Canadian Electrical Code parts II and III, and new CESA Standards. Amendments to CESA Standards, committee appointments, report of chairman of approvals division, A.I.S.I. manuals and New British Empire Standards, are also covered.

## EXTRA CARBON TOOL STEEL

Jessop Steel Co. Ltd., Toronto, Ont., are distributing an 8-page Bulletin No. 941 which describes this cold melt electric furnace steel made from the best domestic base. It is this manufacturer's "intermediate" grade of carbon tool steel, being less expensive than "Special" grades, yet of better quality than "Standard" grades. It is intended for applications where both price and service requirements must be considered, and where a tough core with hard surface is desired. Typical applications, with recommended tempers for each, are listed.

## INDUSTRIAL RUBBER PRODUCTS CONSERVATION

The first four of a series of six pamphlets on "How to Get the Most Service Out of Industrial Rubber Products" have just been published by The B. F. Goodrich Rubber Co., Akron, Ohio, and are prepared in a vest-pocket-size format so that they can be easily carried. The series is designed to assist in the tremendous programme of rubber conservation now made necessary by war developments. All four of the first series of pamphlets deal with belting—No. 1 "Transmission Belting," No. 2 "Conveyor Belting," No. 3 "V-Belt Drives," and No. 4 "Belt Salvage." Each of the subjects is subdivided into chapters dealing with the various angles of the topic, and is written in non-technical language so that all can understand how to best maintain and conserve the precious rubber products now in their plants. The company will supply copies of these booklets free upon request. If no figures are given as to the number of copies desired, the company will send only one on each request.

## Industrial development — new products — changes in personnel — special events — trade literature

### THE GEOLOGISTS' PARADISE

The province of Nova Scotia is the geologists' paradise because all ages of rocks from Mesozoic down to Precambrian are predominately displayed within a relatively small area.

Fossil ferns and stems found in the coal measures are the palaeo-botanists' delight.

Pitching anticlines, synclines and anticlinal domes are prominently displayed in the Precambrian sediments.

The rock exposures around Minas Basin are the museum curators' favorite hunting ground for zeolites.

Shortage of gasoline and tires may curtail your proposed motor trip—but come just the same—the province is well served by the two largest railway systems on the North American continent, and interconnecting bus lines.

### THE DEPARTMENT OF MINES HALIFAX, NOVA SCOTIA

L. D. CURRIE                      A. E. CAMERON  
Minister                              Deputy Minister

## CONTROL AND TRANSFER SWITCHES

Booklet No. CGEA 1631D, 20 pp., issued by Canadian General Electric Co. Ltd., Toronto, Ont., describes and illustrates control and transfer switches, type SB-1, for circuit breaker rheostat and governor control, or for instrument transfer. Illustrations of construction show styles of fixed contacts and common uses. Tables give interrupting ratings in amperes. Diagrams are given showing dimensions, specifications, weights, etc., and 10 pages of contact diagrams are included.

## CUTTING TOOLS

Effective January 26, 1942, an 8-page Catalogue CGT-140, made available by Canadian General Electric Co. Ltd., gives specifications, numbers, prices, and illustrations, for various styles of "Carboly" standard tools. Each style of tool is illustrated and a series of drawings show typical adaptations that can be quickly ground in these standard tools.

## DE-HYDRATING HYDRO-BIN

Allen-Sherman-Hoff Co., Philadelphia, Pa., describe de-hydrating hydro-bins for handling ashes, coke, or other materials, which can be hydraulically conveyed, in their 12-page Catalogue No. 1240. Methods for use are fully described, and many illustrations show typical installations. This company is represented in Canada by F. S. B. Heward & Co. Ltd., Montreal, Que.

## DIACTOR REGULATORS

A 16-page Bulletin CGEA-2022D, published by Canadian General Electric Co. Ltd., Toronto, Ont., describes type GDA diactor generator-voltage regulators for alternating current machines, with pictorial diagram of regulator connections, descriptions and diagrams covering methods of mounting, general descriptions of construction design, auxiliary apparatus, accessories and operation. Connection diagrams, tables of dimensions and vector diagrams showing effect of cross-current compensation on voltage are included.

## ENGINEERING PROGRESS—1941

Entitled "Engineering Progress—1941," booklet S.P. 2270A, 40 pp., issued by Canadian Westinghouse Co. Ltd., Hamilton, Ont., contains illustrated articles on hydro-electric power, steam turbine studies, transformers voltage regulators, capacitor potential devices, power factor correction, steel mill developments, dynamometers, mine locomotives, refrigeration, X-rays, fluorescent lighting, sun lamps, electric ranges, and many other subjects.

## FLY ASH ELIMINATION

Precipitation Company of Canada, Ltd., Montreal, Que., have issued a 24-page bulletin which contains illustrations, diagrams and dimension sheets, as well as tube calculation charts, tables of collection efficiencies and other valuable information on the collection of fly ash. While ash cannot be prevented even by the most careful firing, by the installation of a "Multiclone" assembly between the boiler and the stack, all solid particles down to the lower micron brackets are automatically collected with minimum draft loss. Simple duct arrangements minimize installation and operating costs. Automatic volume controls ensure efficiency under all conditions.

## GRINDING CEMENTED CARBIDE TOOLS

Norton Company of Canada Ltd., Hamilton, Ont., have available a 52-page booklet which describes, with illustrations and diagrams, and 14 pages of tables, the construction of and uses for "Norton" green crystalline wheels and "Norton" diamond wheels. Recommendations are given as to types most suitable for various operations and directions for use are included.

## OVERCURRENT RELAYS

A 20-page Booklet No. CGEA 3553, issued by Canadian General Electric Co. Ltd., Toronto, Ont., describes induction-time overcurrent relays type IAC, single-phase and three-phase. Applications are described, with illustrations and connection diagrams. Four graphs of settings, showing characteristics are given, also a table showing volt-ampere burdens for various sizes. Construction and operation are fully described with illustrations. Tables of ratings, dimensions and specifications, and directions for ordering are also included.

## PARTS FOR MAGNETIC SWITCHES

Description of parts, catalogue numbers and quantity per switch, of renewal parts required for CR-7006, size 3, A-C magnetic switches, with an illustration of each part, are given in a 4-page Folder 3008 published by Canadian General Electric Co. Ltd., Toronto, Ont.

## PROLONGING LIFE OF RUBBER PRODUCTS

The B. F. Goodrich Rubber Co., Akron, Ohio, are distributing mimeographed reprints of the text of an article on the subject "Don't Abuse Rubber—How to Prolong Its Life" which was originally published in "Factory Management and Maintenance" and is reproduced with the magazine's permission.

## WIRING DEVICES

Catalogue No. 41WD, 76 pp. and cover, recently issued by Canadian General Electric Co. Ltd., Toronto, Ont., gives tables showing catalogue numbers, capacities, weights, and prices for various wiring devices including lampholders, switches, plates, caps, plugs, connectors, outlets, etc. Typical illustrations are given for each type, with descriptions.

# SYNTHETIC RUBBER

DR. R. S. JANE

*Department of Research and Development, Shawinigan Chemicals Limited, Montreal, Que.*

Paper presented before the Montreal Branch of The Engineering Institute of Canada, on March 5th, 1942, and before a joint meeting of the St. Maurice Valley Branch of the Institute and the Shawinigan Chemical Association at Shawinigan Falls, Que., on April 22nd, 1942.

During the past few months our attention has been focused on the East Indies, now completely overrun by the Japanese. While the threat to India, Australia and New Zealand is uppermost in the minds of most of us, those responsible for supplies of vital raw materials for carrying on the war look upon the Eastern catastrophe from another point of view altogether. When one considers that 97 per cent of our crude rubber is imported from the East Indies, the seriousness of our position with regard to this vital raw material is at once apparent. The gravity of the situation is reflected in the action of our Government in placing rubber and rubber products under control in order to conserve the supplies of crude rubber now in this country, and at the same time to build up a reserve against the threat of a complete stoppage of shipments from the Orient. This, as we now realize, is only a stop-gap measure and eventually, in the not too distant future, we shall be compelled to develop to gigantic proportions our small but rapidly expanding synthetic rubber industry.

Naturally technical men throughout the country are very much concerned over the rubber situation and are wondering where the supply for industry and commerce is to be obtained during the next few years if this war continues, as it is almost certain to do.

The uncertainty of this situation naturally gives rise to a number of questions, the answers to which are a matter of some importance to those of us engaged in industry where rubber in some form or other is a vital material. For instance, among the questions which immediately come to mind are the following:

1. How is synthetic rubber made?
2. Approximately how much synthetic rubber is now being produced on this continent?
3. What raw materials are being used to produce synthetic rubber and are these available in sufficient quantity to enable the existing plants to expand?
4. To what extent can synthetic rubber be used to replace natural rubber?
5. How long will it take to build synthetic rubber plants to satisfy our numerous demands?
6. What is to be the cost of plant and production for large scale operation?

In the following paragraphs an attempt is made to answer these questions as far as the answers can be found in the current literature on the subject.

In order to get a clear picture of the present status of the synthetic rubber situation it is necessary to review briefly the developments of the industry in this and other countries.

Even before the time of Goodyear's historic discovery of the vulcanization process, chemists were searching for a synthetic substitute for rubber. Faraday analysed crude rubber and found it to be a hydro-carbon having the empirical formula  $C_5H_8$ . Greville Williams, another Englishman, later in 1860 subjected rubber to destructive distillation and obtained a water-white liquid of the same composition as rubber which he called isoprene. Later still a Frenchman, Boucharat, converted isoprene into a rubber-like mass which while like rubber in appearance was very much inferior to the natural product in physical properties.

During the decade prior to the first World War, British and German research groups worked feverishly for the honour of being the first to obtain a satisfactory synthetic product. The wide fluctuation in price of crude rubber in this period spurred them on, but all attempts to obtain a product comparable to natural rubber resulted in failure.

The British soon lost heart and concentrated their efforts on building up the efficiency of production in the plantations in the East Indies. The Germans too were more or less discouraged and did not take up the search again until they were forced into it by the British blockade in 1915. Faced with a critical shortage of rubber in Germany they built a plant in Cologne to produce 150 tons of synthetic rubber per month based on dimethyl butadiene or methyl isoprene from acetone derived from calcium carbide and acetylene. The product turned out from this plant was definitely inferior to natural rubber and consequently its production was discontinued immediately after the armistice.

After the war the British introduced the Stevenson Restriction in order to raise the level of crude rubber prices. While this arrangement no doubt materially aided plantation owners and probably saved the industry in the East it had the effect of reviving the search for a synthetic substitute in Germany and also this time in the United States. The search continued until 1931 when the DuPont Company announced the first successful synthetic rubber which they called polychloroprene. In chemical composition polychloroprene is different from natural rubber in that it contains 40 per cent chlorine, but in its physical properties it is more nearly like the natural product than many of the synthetic rubbers discovered before or since. When announced by the DuPont Company the new rubber was called Duprene but it has since been called Neoprene, the name which it still bears.

A year later, in 1932, Thiokol, the polysulphide rubber, was discovered and this was followed by the Goodrich Koroseal, which is a plasticized polyvinyl chloride. In 1935 the I. G. Farben Company, in Germany introduced a series of Buna rubbers based on butadiene, styrene, and acrylonitrile. The year 1938 was an important one for synthetic rubber when Hitler rolled the German army into Austria on Buna tires, a performance which convinced the world that synthetic rubber was no longer a laboratory curiosity but an industrial product that had come to stay.

The spread of the war in 1940 and 1941 with a possibility of the East being involved sooner or later finally caused the United States to become concerned over its supply of crude rubber. As if in answer to our second question above there followed announcements in quick succession that the Goodrich Rubber Company, the Goodyear Tire and Rubber Company, the Firestone Company and the Standard Oil of New Jersey were building or had already built educational plants to produce new variations of the butadiene type rubbers. This then brings the development up to the beginning of this war and well into 1940.

Now to go back to the first question, how are the synthetic rubbers made? First let us consider the German Bunas. Everyone is more or less familiar with the name Buna as being the trade name for the synthetic rubbers developed in that country during the last decade. Buna S, the most important one, is a copolymer of butadiene and styrene. Buna N, another synthetic rubber, is made in a similar manner by copolymerizing butadiene and a compound called acrylonitrile, or vinyl cyanide. The process of copolymerization is a German invention whereby mixtures of butadiene and other hydrocarbons of the same family are brought together under certain conditions to form rubber-like masses which they call copolymers.

The theory is that certain hydrocarbon molecules link up into long chains attached end to end forming what is called a macromolecule. When a substance is composed of

macromolecules of this type it generally possesses plastic or elastic properties more or less resembling natural rubber. Apparently when butadiene and styrene are linked up into long chains (copolymerized) the resulting product is extremely like natural rubber in its behaviour. However our knowledge of the macromolecular structure of natural and also synthetic rubber is far from complete and consequently the picture of these polymers in the form of chains of various complexities may not be entirely a true one.

In Germany all these materials are made from acetylene derived from calcium carbide and from coal tar derived from distillation of coal. The sequence of steps that is used in manufacturing these materials is shown in Chart I.

### CHART I

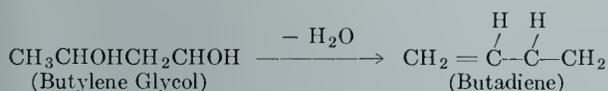

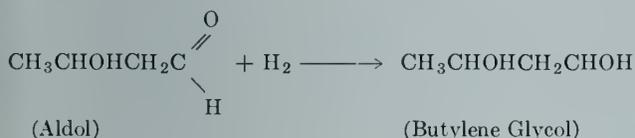

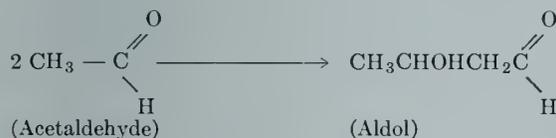

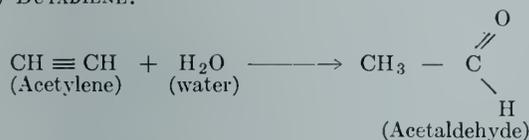

#### THE GERMAN BUNAS

Buna S: Butadiene + Styrene (Copolymer)  
(20%—40%)

Buna N: Butadiene + Acrylonitrile (Copolymer)  
(20%—40%)

Method of Manufacture of:

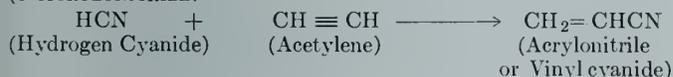

(1) BUTADIENE:

(2) STYRENE:

(3) ACRYLONITRILE:

American Bunas are similar in composition to their German counterpart but on this continent the raw materials or their manufacture are quite different. The butadiene, styrene, etc., can be made from crude petroleum and petroleum refinery gases much more cheaply than from carbide and acetylene as is done in Germany. Chart II is a summary of the methods used in the United States for the manufacture of butadiene, styrene and acrylonitrile from petroleum.

It is seen from this chart that most of the raw materials for the American Bunas stem from petroleum. The Butyl rubber of Standard Oil Development Co. which is the subject of much comment in the daily press at present, is a copolymer of isobutylene and butadiene with the isobutylene comprising the greater part of the copolymer. Since isobutylene is a cheaper material than butadiene it is reasonable to assume that Butyl would constitute a lower priced rubber than Buna S or N. However, little has yet been published regarding the price and properties of Butyl and in the absence of such data it is difficult to make comparisons.

### CHART II

#### THE AMERICAN BUNAS

Buna S: Butadiene + Styrene (Copolymers)  
The Buna S of Standard Oil and Firestone (under license from German I. G. Farben).

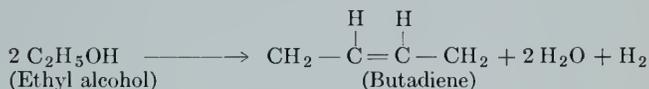

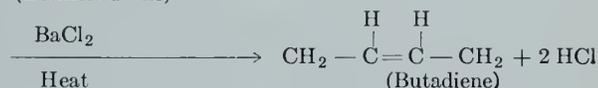

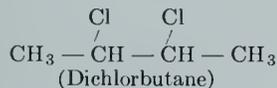

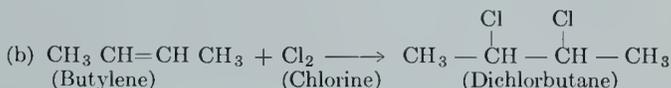

Buna N: Butadiene + Acrylonitrile (Copolymers)  
The Buna N of Standard Oil and Firestone.  
The Hycar or Ameripol of Goodrich.  
The Chemigum of Goodyear.

Butyl Rubber: Isobutylene + Butadiene (Copolymers)  
Standard Oil Development Co.

Method of manufacture of:

(1) BUTADIENE:

(a) Petroleum + special cracking  $\longrightarrow$  5—12% Butadiene.

(2) STYRENE:

(3) ACRYLONITRILE:

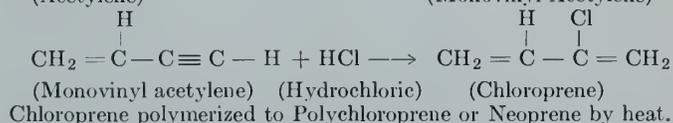

It is worthy of note that in spite of the fact that the search for a suitable synthetic rubber was pursued for more than thirty years in Germany, the first synthetic rubber worthy of the name was discovered and developed on this continent. The DuPont Neoprenes were among the first synthetics to be put on the market in the United States and since that time their outstanding properties have won for them a wide acceptance in industry even before the present crisis arose. The method of manufacturing the Neoprene is shown in Chart III.

### CHART III

#### THE DUPONT NEOPRENES

Several types are on the market each having its own industrial application.

Method of manufacture:

Neoprene like the German Bunas is made from acetylene gas but, as will be noted from the chart, by a very much

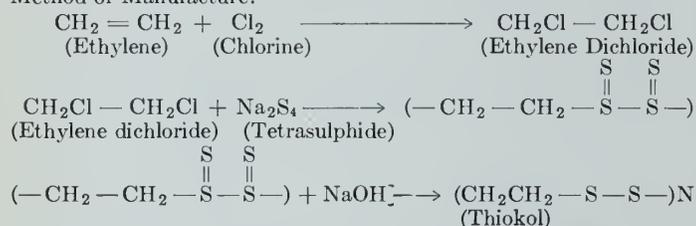

simpler process. If acetylene could be produced readily from petroleum or refinery gases, producers of Neoprene like the producers of American Bunas would look to the oil industry for their raw material. Up to the present however, calcium carbide seems to be by far the cheapest and most suitable source of acetylene gas.

Another important synthetic rubber which is used to replace rubber in certain applications is the organic polysulphide known on this continent as Thiokol. Its method of manufacture is shown in Chart IV.

CHART IV  
THE THIOKOLS

ORGANIC POLYSULPHIDES—THIOKOL CORP.

Method of Manufacture:

In addition to its many interesting properties which will be shown later in this paper, Thiokol is probably the simplest of all synthetic rubbers to produce. The equipment is simple and inexpensive and the separating and treatment of the product is not involved.

One of the most interesting developments in the field of rubber substitutes is that of the thermoplastic substance called polyvinyl chloride. As it is made polyvinyl chloride is a hard, horn-like material, having not a vestige of rubber-like properties, but when plasticized or softened (elasticised is more appropriate), it possesses many of the excellent qualities of vulcanized rubber. Its method of production and raw materials involved in its preparation are set out in Chart V.

CHART V

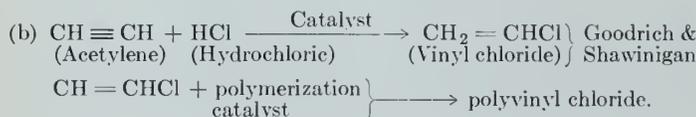

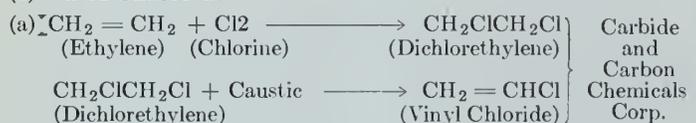

KOROSEAL AND THE VINYLITES

KOROSEAL: polyvinyl chloride + plasticizer — Goodrich.  
(Tricresylphosphate)  
(20-40%)

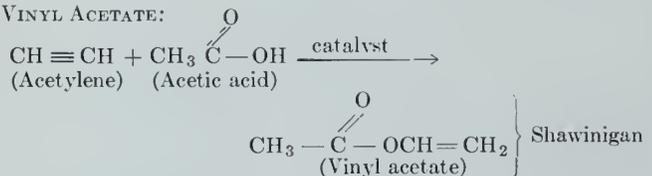

VINYLITES: polyvinyl chloride + polyvinyl acetate (Copolymers)  
+ Plasticizer. (Carbide and Carbon Chemicals Corporation).

Method of manufacture:

(1) VINYL CHLORIDE:

(2) VINYL ACETATE:

#### PROPERTIES AND APPLICATIONS

It is beyond the scope of this paper to describe in detail the numerous properties and applications of the synthetic rubbers. There has accumulated over the last ten years an extensive literature on the subject to which the reader must be referred for a complete treatise on properties.

The properties of the synthetics, like natural rubber, depend to a large extent on their response to compounding—that is, the art of selecting the kind and quantity of the various ingredients added to rubber in order to vulcanize it and impart to the product specific desired properties. In the case of the Bunas, natural rubber compounding practice is followed fairly closely. Sulphur is used for vulcanization but much less amount is necessary in order to give satisfactory properties. So far the existing organic accelerators have met with fair success but more active ones may yet be demanded. The usual rubber anti-oxidants are not so effective as with rubber because synthetics themselves are quite resistant to oxidation. The customary reinforcing agents (for example, carbon black) are even more effective in the case of the Bunas. On account of the hard and tough internal structure of the Bunas, a very considerable proportion of oils, plasticizers and softening agents are required in order to process them. Because of their resistance to oxidation and cross-linked type of structure, they do not soften or break down on milling to the same extent as rubber, and consequently it is more difficult to disperse in them pigments, fillers, etc. Plasticizers are added to overcome this deficiency, but the physical properties of the resulting product suffer correspondingly.

Neoprene is unique among the butadiene type rubbers in that sulphur is not required for vulcanization, the application of heat being sufficient. Magnesium, zinc and lead oxides function as vulcanization agents and sulphur as an accelerator. Some rubber accelerators exhibit the same effect in Neoprene; others have a retarding action; while still others are efficient plasticizers. The usual reinforcing powders increase the elasticity but not the tensile strength of Neoprene.

Thiokols can be made to undergo a change similar to vulcanization in spite of the fact that one would not expect it from their chemical structure. As in the case of Neoprene, the metallic oxides act as vulcanizing agents and sulphur as an accelerator. Reinforcing agents, particularly carbon black, are required to bring about the maximum tensile strength.

Koroseal does not vulcanize. The optimum properties of polyvinyl chloride can be brought out only by suitable plasticizing. It is possible to use plasticizers which themselves may be vulcanized and thus impart to the Koroseal some outstanding properties.

Extensive experimental work, involving road tests has been done on synthetic rubber in tires. In Germany the Buna S type has been used almost exclusively. In this country satisfactory tire tread stocks have been developed from all the Buna types and Neoprene. The wear resistance of synthetic tire treads in road tests has been comparable with the best natural rubber and in some cases superior to it. Two major difficulties with synthetic still remain:

- (1) The unvulcanized synthetic rubber—carbon black stocks cannot be processed without using excessive amounts of softeners.
- (2) The use of synthetics in the carcass of the tire has not proved satisfactory on account of poor adhesion.

How serious these two defects are is difficult to ascertain from authorities in this field. There is no doubt that difficulties of varying degrees have been encountered. But it is certain that the rubber processors will find a way around these difficulties in the course of time.

Chart No. VI, taken from Dr. Greer's excellent paper on "Elastomers in the Nation's War Program" published in the January issue of *Chemical Industries*, contains an extremely clear and simple summary of the properties of a number of synthetic rubbers now being used to an increasing extent on this continent. The chart is self-explanatory and requires no comment.

#### ECONOMICS OF SYNTHETIC RUBBER PRODUCTION

The prime consideration in discussing the economics of synthetic rubber is the cost and availability of raw mate-

rials. Since the Buna types will most likely be used extensively for tire treads, the availability of butadiene is obviously the critical factor. This turns our attention to the petroleum industry, where the butadiene and styrene are produced. What is the position of the petroleum industry in this respect? Before answering this question we must ask another—what quantity of rubber do we require per year on this continent for the duration of the war? It is difficult to get reliable data on the point at the present time, but from recent press reports it will require upwards of one million tons per year to supply the demands of the United Nations.

If then we need one million tons of crude rubber per year, is the petroleum industry able to supply the raw materials? The answer is definitely in the affirmative. Few of us realize the tremendous extent of the petroleum industry on this continent. It seems almost incredible, but is true nevertheless, that the United States refines over 200 million tons of crude oil per year, from which is produced 90 million tons of gasoline. The steel industry in the United States, which is generally described as gigantic, has a capacity of only 80 million tons. Dr. Egloff, Director of Universal Oil Products Laboratories, states that the United States petroleum industry could supply raw materials to produce butadiene and styrene at the rate of 85 billion pounds per year—that is, approximately 40 million tons—without lessening production of any of their other products required for peace times or national defence. This completely dwarfs the one million tons of rubber that the United Nations require per year. Even two million tons of rubber would not seriously affect our raw material supply.

The cost of plants to produce one million tons of synthetic rubber per year is a more serious matter than the raw materials but it is by no means hopeless. Rough estimates have been made by reliable people for 400 thousand tons capacity amounting to approximately a half billion dollars. This cost while obviously out of the reach of private enterprise is well within the range of a government expenditure. Apparently neither the availability of raw materials nor the cost of plant need be considered a deterrent to our synthetic rubber programme, but to obtain the equipment necessary to put these plants in operation from our already overburdened equipment industries is entirely another matter. Those of us who are building war plants at the present time know a little of the difficulty of procuring the ordinary mechanical and chemical equipment. What the situation will be like when there is superimposed on the present chaotic condition another billion dollar chemical project, is beyond prediction.

As for production cost, small-scale plants are turning out butadiene for 20c to 25c per lb. and styrene for about the same. The cost of the polymers being produced from these monomers is correspondingly high. When the industry gets into large tonnage production it is reliably estimated that butadiene will be produced for 10c to 15c with the finished rubber at 20c to 25c per lb.—which is comparable with natural rubber at 23c per lb. In Chart VII, taken from Cramer's excellent paper in the February 1942 issue of *Industrial and Engineering Chemistry*, the present prices of several synthetic rubbers are given, and for comparison the prices at which these synthetics must be sold in order to compete with rubber at 23c per lb., are also included.

CHART VII  
SYNTHETIC VS. NATURAL RUBBERS—PRICE COMPARISONS

	August, 1941		Equivalent Price
	Price	Density	
Natural Rubber.....	\$0.23	0.92	\$0.23
Neoprene S.N.....	0.65	1.24	0.17
Buna S.....	0.60	0.96	0.22
Perbunan.....	0.70	0.96	0.22
Thiokol.....	0.45	1.38	0.15
Vistanex.....	0.45	0.90	0.24
Koroseal (30% Plasticizer) ..	0.60	1.33	0.16
Hycar OR.....	0.70	1.00	0.23

Whether or not the synthetics will be able to compete with natural rubber particularly after the war is a question that cannot be answered completely at the present time. Up to the present, manufacturers of rubber goods have regarded the synthetics as supplementary to, rather than competitive with natural rubber. It would seem that this is the most reasonable attitude to take when considering the future of the synthetic rubbers in this country.

The question of present and future synthetic rubber production on this continent can best be answered by referring to Charts VIII and IX reproduced also from Cramer's paper.

CHART VIII  
SYNTHETIC RUBBER PRODUCTION

CAPACITY		
1939	All types.....	2,500 long tons
1940	" ".....	4,000 " "
1941	" ".....	17,000 " "
1941 Production broken down:		
	Buna types.....	4,000 long tons
	Neoprene.....	6,500 " "
	Thiokol.....	1,500 " "
	Polyvinyl chloride types.....	5,000 " "
TOTAL.....		17,000 long tons

CHART IX

PRESENT AND PROJECTED PRODUCTION OF SYNTHETIC RUBBER IN THE UNITED STATES

(Data in long tons)

	July, 1941	January, 1942	January, 1943
Buna types.....	5,000	10,750	60,000
Neoprene.....	6,500	9,000	19,000
Thiokol.....	1,750	1,750	2,650
Polyvinyl Chloride...	5,000	6,000	18,000
TOTAL.....	18,000	27,500	99,650
Percentage of normal requirements.....	3%	4.6%	16.6%

It is seen from Chart VIII that considerable progress has been made between 1939 and 1941, an increase in production of almost 800 per cent. The projected production for January 1943 of nearly 100,000 tons, representing almost a four-fold increase over January 1942, is another tremendous advance when considered in terms of normal peace time industrial growth. But faced as we are with a complete stoppage of crude rubber imports, this figure of 100,000 tons per year, large as it is, is not at all reassuring. The projected capacity for January 1943 is only 16.6 per cent of our peace time requirements and only 10 per cent of the estimated war time consumption.

However, more encouraging are recent reports that a 400,000-ton project is now under consideration in the United States, and in Canada our own situation is to be improved to the extent of approximately 20,000 tons of synthetic rubber, probably Buna S.

It has been estimated that to complete the 400,000-ton project will require at least three years. This does not mean that no synthetic rubber from this particular project will be available for three years. Super plants will no doubt be erected at strategic locations from the standpoint of raw materials, and after approximately one year has elapsed these plants will come into production one by one depending on local conditions, until the project has been completed. From information available at the present time it appears that the economic plant has a minimum capacity of approximately 25,000 tons per year, but as the engineer will readily appreciate, time and experience may alter this figure considerably.

With strict civilian conservation which is now getting into full force, and with the help of 200,000 to 300,000 tons of reclaim rubber capacity in the United States which can be used in the fabrication of many forms of rubber goods as well as up to 50 per cent in tires, the outlook is reasonably bright for future supplies of rubber, for war purposes and vital industries.

# SUBCONTRACTING IN CANADA'S MUNITION INDUSTRIES

F. L. JECKELL

*Director-General of the Industry and Subcontract Co-ordination Branch of the Department of Munitions and Supply, Ottawa, Ont.*

**An address presented before the Montreal Branch of The Engineering Institute of Canada,  
on February 26th, 1942.**

This is a welcome opportunity to give to engineers an explanation of the work which the Industry and Subcontract Co-ordination Branch performs in aiding Canada's war production. Actually, subcontracting is no new thing in Canada. In its essentials, it has been practised, widely, in the automotive industries.

Before the organization of the I.S.C. Branch by Mr. Howe, several of Canada's war industries were subcontracting large numbers of parts. Methods of administering subcontract departments were, however, of widely varying types, while methods of discovering sources for the manufacture of these parts were equally varied. When the "Bits and Pieces" programme was inaugurated last October, we undertook to co-ordinate subcontracting in Canada's munition industries. Since then we have been through the period of defining our task, breaking it down into workable units and finding the men to do the job.

It is now possible to tell you what the Industry and Subcontract Co-ordination Branch is, what it does and how it can be used. This is essential information for all organizations engaged in the production of war materials because the "Bits and Pieces" programme is now an integral part of our war production system.

The Industry and Subcontract Co-ordination Branch, which for brevity will be referred to as the I.S.C. Branch, is a service organization. It was organized by the Minister of Munitions and Supply to assist the production and purchasing branches of the Department and also all manufacturers. Its purpose is to speed the manufacture of all war materials by obtaining the maximum use of Canada's facilities.

The policy of the I.S.C. Branch is one of help and co-operation, governed by eight guiding principles which are named in the following paragraphs and are all based on the necessity for making as much war material as possible—as soon as possible.

With this main purpose in mind, we undertake to see first that, when efficiency can be maintained, all available machines are put to work before more of the same type are recommended for purchase.

Second, it is important that, when feasible, plants which have been shut down due to war restrictions should be put into war production as rapidly as possible.

Further, whenever possible and advisable, we try to have contracts broken down into sizes to suit the production units available.

Next, whenever possible, shops are recommended for work similar to that to which they are accustomed and for which their machines and tools are adapted.

We also see that good machines with skilled operators under experienced direction are employed before work is given to less efficient organizations.

We keep watch to see that shops are not overloaded when idle capacity is available and we encourage modern and efficient methods of production.

Our last principle, which is not the least important nor the easiest to carry out, is this:

Every possible service must be rendered with the utmost despatch and with a minimum of formality.

If it can be shown that any one in the I.S.C. Branch is violating these principles, prompt action will be taken on the information.

It must be noted, however, that we interpret our ruling

principle ruthlessly and without friendship. We must make as much war material as possible—as soon as possible. Everything else is secondary.

Now a word about our organization. The I.S.C. Branch is organized on a nation-wide scale. The head office is in Ottawa.

District offices are maintained in Saint John, N.B., Montreal, Toronto, Winnipeg and Vancouver. Wherever necessary in highly industrialized areas sub-offices will be set up.

Our Head Office organization in Ottawa co-ordinates the activities of the district offices and it maintains a constant liaison with the Production and Purchasing Branches of the Department of Munitions and Supply and all Government departments.

Through this service we know in advance approximately what is going to be purchased and so we are able to accumulate up-to-date information regarding production facilities about to be required.

Each district office is fully equipped to give complete service. In this part of our organization the engineer plays a leading role.

He interprets blueprints in terms of the machines required to produce the wanted article. When these machines are located field engineers check their condition and availability.

When a subcontractor goes into production one of our engineers often helps to promote efficiency and quality.

So well equipped are these offices that they have produced one very interesting result. It is now unnecessary for manufacturers to travel to Ottawa for the purpose of offering their facilities or to obtain service. All of our services are based on the information which we have at our disposal.

We have in our files complete surveys of practically every machine shop and factory in Canada. This information is classified as to type, grade and location of facilities. The shops themselves as a whole are also graded.

This information has been cross-indexed and we can locate quickly any machine or facility that is available in Canada.

A great deal of this information is constantly being worked over. It is being brought up-to-date by interviews with shop and factory owners and it is also brought up-to-date by "checking" surveys which are made before we make any recommendation to a prime contractor or a Government department.

In fact our files are live files and the more use that is made of them the better they become.

Through experience and reports from prime contractors and Government departments we have also accumulated a great deal of information as to the management and financial condition of these organizations. In the district office nearest you, this information is available and the staff of the district office is at your service at all times. Should you call upon one of our district offices to get some service, you will get that service promptly and the information given you will be reliable. If we cannot supply your demand, we will tell you so promptly.

We do not wish to convey the impression that this is a perfect organization. We make mistakes of course—but we are getting work done. We welcome constructive criticism and sincerely want our mistakes pointed out to us—so that they will not be repeated.

We have spent a great deal of time in investigating the various ways for handling subcontracts by a prime contractor and we have arrived at certain conclusions, which may be of interest to those of you who are responsible for the administration of the affairs of manufacturing companies holding Government prime contracts.

These conclusions have been checked by able and experienced heads of businesses who are themselves skilled in subcontracting.

Here then, are some of the conclusions in question:

First, if the subcontracting effort is to be of any size and importance, it is essential that a separate department be set up to handle subcontracts.

The manager of this department should be on a level in authority with the purchasing department, the planning department and the plant manager, and should be in direct communication with the general management of the company.

This subcontract-manager has a tough job. He not only has to reconcile the differences of interests between the various departments of his own company, but he also has to get production out of a group of small and large shops that vary widely in their conceptions of the ways of doing business. So this man should be one who is not afraid of responsibility and one with plenty of patience. He should have no fear of the unorthodox nor should he be a worrier. He should be diplomatic enough to obtain co-operation from the other department heads. Once you have picked this kind of a man hang the responsibility around his neck and leave him alone to work it out.

One of the problems that he has is maintaining liaison with the I.S.C. Branch but fortunately this has been formalized to such an extent that it is only one of his minor troubles.

Now in the large type of subcontract department, the subcontract manager should have under his direction three supervisors—one in charge of technical operations, one in charge of pricing and the other a follow-up supervisor. The duties of these three men are obvious from their titles.

The technical supervisor should be a top-grade practical production man. He need not be an engineer, but if he is, so much the better. He is the man who is primarily responsible for the selection of subcontractors. This includes the making of shop surveys. He studies tooling requirements, sees that proper jigs and fixtures are made and maintains a record of them. He also reports if the subcontractor needs the odd machine to round out production. Operation and tool records, progress sheets, rejections, raw material changes and quality are all his responsibility.

He must anticipate delays or raw-stock shortages and must prevent the subcontractor from taking more work than he can handle efficiently. He must act as the interpreter between the subcontractor and the subcontract manager. In an expanding operation the technical supervisor may employ shop layout men, machine tool experts, tool designers and jig and fixture designers. The net of all these duties is, that the prime contractor treats the subcontractor as if he were a part of his organization and thus obtains efficient production in outside shops.

In dealing with a large number of manufacturing plants of all sizes, some astonishing variations in cost accounting methods are met with. As one of the problems of subcontracting is obtaining accurate costs, it is easy to see that the task of the pricing supervisor is one requiring a certain amount of ingenuity. Very often he will find that he has to go right to the beginning and establish a simple cost system in the shop itself in order to have an accurate record of the hours.

In large operations he will probably have under his direction other men whose purpose it is to increase the efficiency of the shop from a cost standpoint. These are

such types as time-study men and experts on shop practices. In smaller operations these men can be employed from organizations who specialize in rendering this type of service.

Now we come to the man who keeps the whole thing moving. He is the follow-up supervisor. He has only one job and that is to see that the work is delivered to the prime contractor on time.

When anywhere from fifty to two hundred items are being subcontracted in fifty to a hundred different shops, it is easy to see that this man must be one who can keep his head under pressure, who has infinite patience and one who will not take "No" for an answer. At the same time he should not be a bully.

Two things should be maintained as a guide to the follow-up man and as a check on his operations.

One is a card file on each subcontractor which will carry a history of deliveries made by this subcontractor. This, as it grows, indicates whether the shop is reliable in its deliveries or whether it has to be watched all the time.

The other, and this is most essential, is a big wall chart with every part plotted on it and its exact delivery status and its raw material position shown up prominently. This chart has the effect of keeping the whole subcontracting organization on its toes because, as time goes on, the items that are behind schedule become more and more conspicuous and are harder and harder to explain. This wall chart also enables the subcontract manager to see at a glance how his organization is functioning.

With these three divisions manned by the right type of individuals the subcontract department can handle a large amount of material and do it promptly and efficiently.

The I.S.C. Branch is rapidly establishing its contracts with prime contractors. Naturally, it has its best contracts with those prime contractors whose subcontract departments are functioning in a systematic manner.

Some of the services which the I.S.C. Branch is set up to render are these:

We can provide verified information regarding idle machine capacity of the type desired, if it is available.

We can assist greatly in placing subcontracts. We can assist in organizing subcontract departments. For this purpose we have prepared a manual entitled "Subcontracting in Canada's Munition Industries" which gives the essence of all the results of our investigations about subcontracting methods.

Copies of this manual may be obtained by persons interested, on request through the general secretary of the Institute.

Another service that the branch can give to prime contractors is helping them to avoid placing subcontracts with poorly managed shops. We think that we have discovered most of them. It is of no help to Canada's war effort to let a whole programme bog down on account of one inefficient subcontractor.

We keep in touch with prime contractors on another point and that is the overloading of any subcontractor. Sometimes a subcontractor is a little over-ambitious and takes on subcontracts from several different prime contractors. He soon finds himself in a jam and cannot make deliveries on any of his subcontracts. We are getting records of all subcontracts placed by all prime contractors and so we can watch this situation and notify the subcontract managers concerned if necessary.

It is another of our functions to prevent the placing of subcontracts with shops which have not all of the necessary machinery when there are complete shops available.

On the other hand we examine applications from subcontractors for machines to round out production and make such recommendations as the situation calls for.

Another service that we are very often called upon to

render is to furnish technical assistance in getting subcontractors into production.

These services, naturally, are rendered most effectively when a close liaison is maintained between the subcontract manager of the prime contractor and the nearest district office of the I.S.C. Branch.

Much depends on the degree of reliability of our recommendations of possible subcontractors. Here is what happens.

When you send us a blueprint and state that you want to find a shop that can make some particular part, we first uncover all of the possible sources and check them on the telephone to make sure that they have the time available. Those that appear to be available are then checked in person by a field engineer to make sure that everything is all right.

Then, and only then, do we advise the prime contractor that this is a recommended source for the part he wishes to have made. We do not tell the subcontractor who the prime is.

Another important matter is the responsibility of the branch as regards the purchase of additional machinery, involving what is commonly referred to as capital assistance.

When a manufacturer wishes to increase his production and he decides that he needs additional equipment to execute the programme, he may make an application for capital assistance to the Department. This application is then checked by the I.S.C. Branch to make sure that equipment is not available to do the job.

If the I.S.C. Branch finds that equipment is available that will do this sort of job satisfactorily and efficiently then we recommend that the application be denied and that subcontracting be resorted to in its stead. The reasons for this course are obvious to all.

At this point let me leave the subject of subcontracting for a moment, and draw attention to a situation that is affecting our whole war effort. The point is that Canada has a serious management problem.

Apparently the tremendous expansion of our production machine has not been accompanied by a corresponding expansion in our production brains.

Here is an example of what is happening.

A firm that was doing a nice, comfortable business of about 250,000 dollars a year now has orders on its books running into three to four million dollars. Instead of one shift, the plant is operating three shifts, seven days a week. Four times as many machines are working.

All the problems of management are correspondingly greater, but those in charge have failed to make a bold onslaught on them. Timidity and fear of the unknown have made cowards of the men at the top.

Take the case of a purchasing agent whose job is more than ten times as big as it was in peace time. He has not been able to rise to the responsibility. He is becoming a nervous wreck.

Yet the management of this concern hesitates to put a senior man over him who could handle the job—difficult organization problems would result and reorganization would be troublesome after the war.

In another instance, the works manager's job has increased out of all recognition, but he has risen to the demands of the job magnificently. He has grown as fast as his responsibilities.

Yet the management has hidden behind the wage legislation and refuses to raise his pay. Of course he is not feeling very pleased with this situation.

In this case, it came out that if he were paid a salary comparable with that of other works managers doing similar work, he would be getting more than the general manager. That was regarded as impossible. But there's another firm that places a proper value on him—and he will move.

This is not the spirit that wins wars. We must have courageous management that will go forward. We must eliminate the small men in the big jobs. We must give the doer his day.

Our desperate ills demand a speedy cure. Our time is short and our obligations infinite. Long contemplation of the post-war effect of our actions to-day cannot be tolerated.

We have single-purpose machines and we must have single-purpose management, whose only purpose is to make as much war material as possible as soon as possible. Must Canada have long casualty lists before we wake up?

This management problem is brought before you in the hope of receiving some assistance in the matter from the influence of your organization.

Are these good men at the top of many medium sized organizations to be crushed in health and in spirit by this great machine that war has raised up, or is there a way to educate them, give them courage and a place in the great plan?

There are dozens of ways in which the I.S.C. Branch can serve industry in this time of stress and strain. Speaking not as an engineer but as a business man who has spent a great deal of time studying the subcontract method of increasing production, I have tried to give you some of the background of our operations and to leave you with the feeling that the entire I.S.C. organization is devoted to anything that will accomplish our purpose, which is to get more production as quickly as possible.

## SUPERSTRUCTURE: DESIGN AND FABRICATION

### CLEARANCES, GRADIENTS AND ELEVATIONS

The terms of the Order-in-Council prescribed 200 ft. of clearance over a central fairway of 200 ft. (Fig. 22). Computations, continually revised as the design progressed, established the maximum central-span deflection as 8.14 ft. (to which the temperature-contribution is approximately 2.25 ft.), and the corresponding figure for the critical points 100 ft. from the centre at 8 ft. The final roadway-elevation at span-centre was derived as follows:

Elevation of highest tides . . . . .	97.77
Stipulated clearance . . . . .	200.00
Calculated maximum deflection (at 100' from span-centre) . . . . .	8.00
Vertical distance from crown of roadway to bottom of lowest rivet-head . . . . .	4.34
Rise of roadway in 100 ft. from critical point to span-centre (based on final profile) . . . . .	1.98
	<hr/>
	312.09
Arbitrary allowance for contingencies . . . . .	2.91
	<hr/>
Elevation of crown of road at centreline . . . . .	315.00

The level of the roadway at the outer ends of the suspension-bridge, while not susceptible of equally precise determination, was nevertheless set within narrow limits by the conditions obtaining at these points, and by the symmetry of the two side-spans. At the south end of the bridge, limits were imposed by the restricted choice of a suitable anchorage-site, while at the north end of the bridge, the viaduct-grade was the ruling consideration. The elevation finally chosen, as a satisfactory compromise between the several requirements, was 262.00, applying to the crown of road at the two points that are located 614 ft. shoreward of the main towers.

For the general profile of a suspension-bridge, the usual procedure is to provide a constant side-span gradient, with a parabolic transition across the central span. In the present case, however, it was decided to provide a camber in the side-spans, sufficient to prevent the occurrence of unsightly sag in warm weather; and therefore a single continuous curve was employed over the entire extent of the suspended roadway. The requirements to be met by such a curve were; that it should have the above definite elevations at points 100 ft. and 1,389 ft. from the highest point (at bridge-centre); that its tangent should be horizontal at mid-span; and, finally, that its maximum slope should present a reasonable roadway-gradient.

That maximum slope was based on the arbitrary selection of five per cent for the ruling gradient under any ordinary conditions. The general effect of uniform live loading is a reduction in gradients, but such reduction, amounting to about one per cent, is evidently not significant. Under conditions of non-uniform loading, however, (as, for example, when the central span and one side-span are loaded, the other side-span being empty; or when the central span is loaded over half its length only), local upward deflections may take place, causing increases of gradient; but the occurrence of such loadings in any appreciable magnitude is extremely unlikely, and in any case the adverse effects are of a transitory nature. Further, those effects are much

more pronounced in the central span (in which the cable-polygon is comparatively sensitive to load-variations) than in the stiffer side-spans (where the cable-curvature is slight); whereas it is in the latter, where the normal gradient is steepest, that they have the greater significance. For the above reasons, the effects of live-loading were neglected.

Temperature-variations, on the other hand, set up definite changes in the geometry of the structure. Deflections from this cause are, similarly to those due to live-loading, greatest in the central span, but are only of significance in conjunction with the steeper gradients in the side-spans. The deflection of the side-span at the specified extremes of temperature is plus or minus 0.26 ft., and the corresponding change of end-gradient amounts to approximately 0.2 per cent. The maximum normal roadway-gradient, occurring at the shoreward end of the side-spans, was consequently established at 4.8 per cent, thus giving the final requirement for the profile-curve.

In the search for a continuous curve that would meet the said requirements it was found that none of the conic sections was adaptable to the purpose. The semicubical parabola came more nearly to meeting the case, and this fact led to the adoption of a modified parabola possessing the formula  $y = 0.00625x^{1.25}$ . This curve has its origin at the centre-line of the bridge, and yields a maximum slope of 4.79 per cent at the ends of the side-spans. The camber in the side-spans amounts to approximately six inches, and their resulting appearance is good. In the case of the central span (with a camber, incidentally, of 25.6 ft.), the appearance of the profile in general is also satisfactory, though a foreshortened view of the rapidly-changing gradient near the bridge-centre gives the effect of rather too rapid a transition in that vicinity (Fig. 11). The phenomenon, however, is not apparent from points of broader view.

In the case of the north viaduct, the necessity for an adequate stretch of level roadway at the toll-collection plaza, together with that for bringing the roadway to the desired height at the end of the suspension structure, dictated that the maximum permissible gradient should be employed. The gradient was therefore set, with due deference to considerations of detail, at 4.836 per cent over the whole viaduct.

The roadway-profile having thus been settled, that of the cables was established therefrom. The relation of span to sag for the central span is a more-or-less arbitrary quantity that may vary considerably without serious effects upon either economy or appearance. A sag of 150 ft. was adopted in the present instance, and the consequent ratio of 10.33 is in accord with the modern trend towards securing additional vertical and lateral stiffness by exceeding the commonly-accepted ratio of 10.

Depending on the cable-diameter, on the shortest practicable length of a suspender-rope, and on the depth of truss and floor beam, the elevation of the centre-line of the cable at the mid-point of the central span was established at 331.5 ft. above datum; and the elevation of the intersection of cable-tangents at the main saddle became accordingly 481.5. The top of the tower was then fixed (at elevation 478.0) in accordance with the height of the saddle-assembly.

The elevation of the cable-intersection at the north cable-bent, also established at the lowest practicable level, is 276.0, and that at the saddles of the cable-posts at the south end is 272.0, the latter figure deriving from the former in order to preserve symmetry in the suspender-lengths of

\*Part I of this paper, dealing with the substructure, appeared in the April issue of the *Journal*.

the two side-spans. The side-span sag, depending upon the central span sag and upon the relations of dead loads and spans, is approximately 21.6 ft.

### SUSPENSION-BRIDGE LOADING

For the main carrying-members of the suspension-bridge (i.e., the towers, the cables and anchorages, and the stiffening-trusses except insofar as the latter are affected by local concentrations of load), two classes of live loading, termed "normal" and "congested" respectively, were established. These loadings were arrived at by a study of the actual weights and spacings of vehicles likely to occur. Thus the normal loading (referred to by the letter N, used as a suffix in the calculations) of 470 lb. per linear ft. represents, for one side of the bridge only, the effect of three lanes of three-ton vehicles at 30-ft. spacing, with 20 lb. per sq. ft. on each sidewalk, together with a general allowance of 5 lb. per sq. ft. to take into account the effect of a light snowfall. For the congested loading (C) the figure adopted was 615 lb. per linear ft., representing the same vehicles spaced at 20 ft., together with a heavier sidewalk-loading.

In the case of members (such as floorbeams, stringers, suspenders, and truss-web members) that receive loads directly, the design was made on the assumption of a concentration consisting of three conventional 20-ton trucks (C.E.S.A.) abreast with impact, together with a sidewalk load of 100 lb. per sq. ft.

The basic wind-load (W) considered was 500 lb. per linear ft. of the bridge. This load, which represents a pressure of about 25 lb. per sq. ft. on the exposed area of trusses, deck, and vehicular traffic, was assumed to be capable of application over any continuous length of bridge up to 600 ft. For longer lengths, it was arbitrarily reduced to 380 lb. per linear ft. Lateral loads considered in the design of the towers are referred to on p. 294.

Temperature effects (T) were based on a range of 120 deg. F. with an assumed normal temperature of 60 deg. F. The maritime climate of Vancouver is very equable, and extremes of temperature such as occur in other parts of Canada are unknown.

Stresses due to dead-loading are referred to by the symbol D.

### LIGHT-WEIGHT DECK

The weight of the floor-system is of prime importance in view of its effect upon the size and cost of the main supporting members of the bridge. In the present case it was clear from the outset that general economy would derive from the use of a "light-weight" slab even though the latter might cost more than one of reinforced concrete. Numerous grid-floors are on the market, and the choice of the engineers, supported by satisfactory previous experience, was the Truscon Steel Company's "Teegrid" composite slab. The steel grid therein employed involves no riveted connections, contains none but simple sections, and is well adapted for fabrication in a structural-steel shop. Also, the grid-sections themselves are extremely rugged and are not likely to be damaged during handling. The finished slab presents an armoured non-skid surface to traffic, and is opaque and solid in appearance. In the latter connection, the use of an open grid was deemed inadvisable for so long and high a roadway, in a location, moreover, where heavy pedestrian-traffic obtains.

The construction of the Teegrid slab is shown in the accompanying isometric view (Fig. 23). The steel grid which forms the basis of the slab was shop-fabricated in panels 29 ft. 3½ in. long and approximately 4 ft. wide. Each ordinary panel consists of 16 structural tees (3 by 3 in., and 1.38 sq. in. in area) in contact, with stems upward, the flanges being welded together at 16½-in. intervals. The tops of the stems, punched for the purpose, are connected by a series of half-round ½-in. bars, at 4-in. centres welded at every intersection. The ends of the grid-sections are closed by ¾-in. plates welded to the tees. The material is

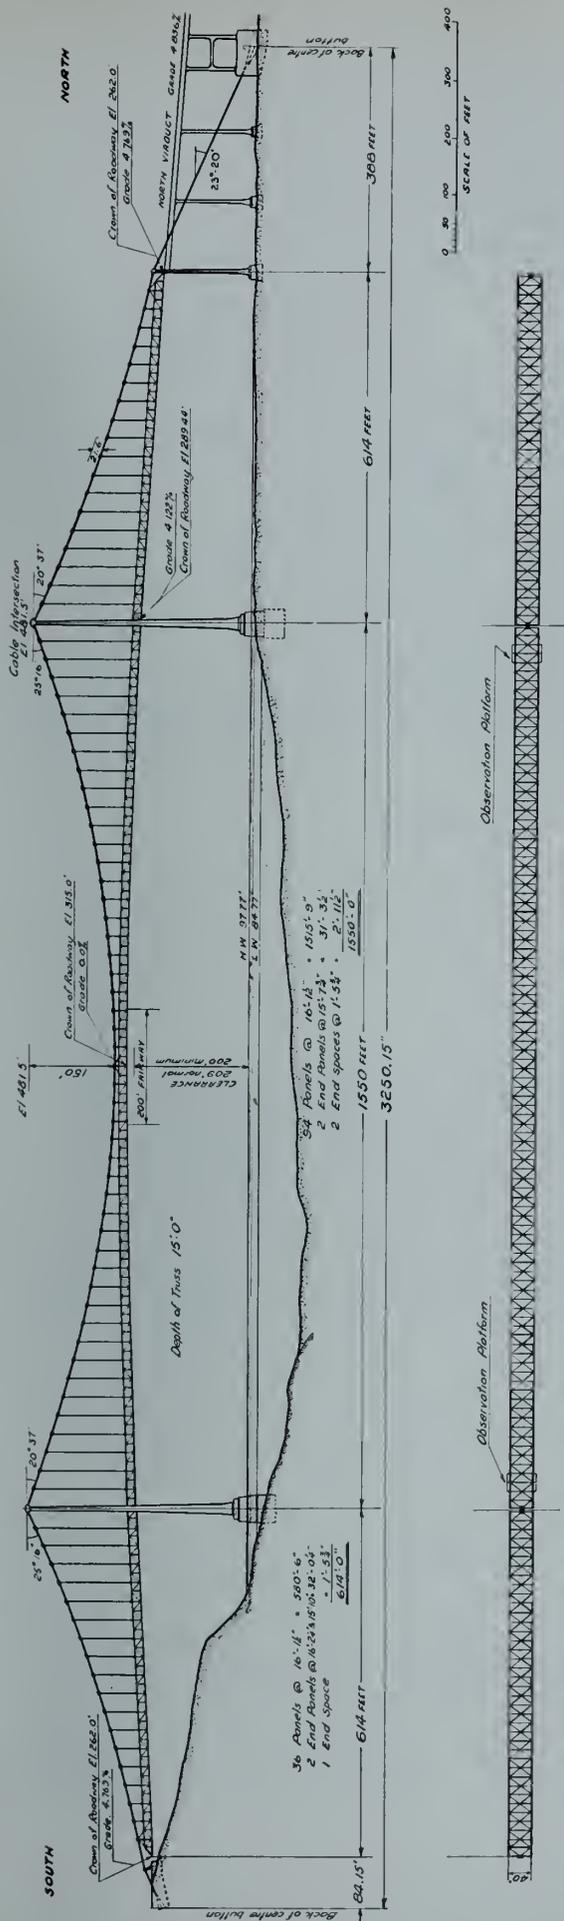

Fig. 22—General diagram of suspension bridge.

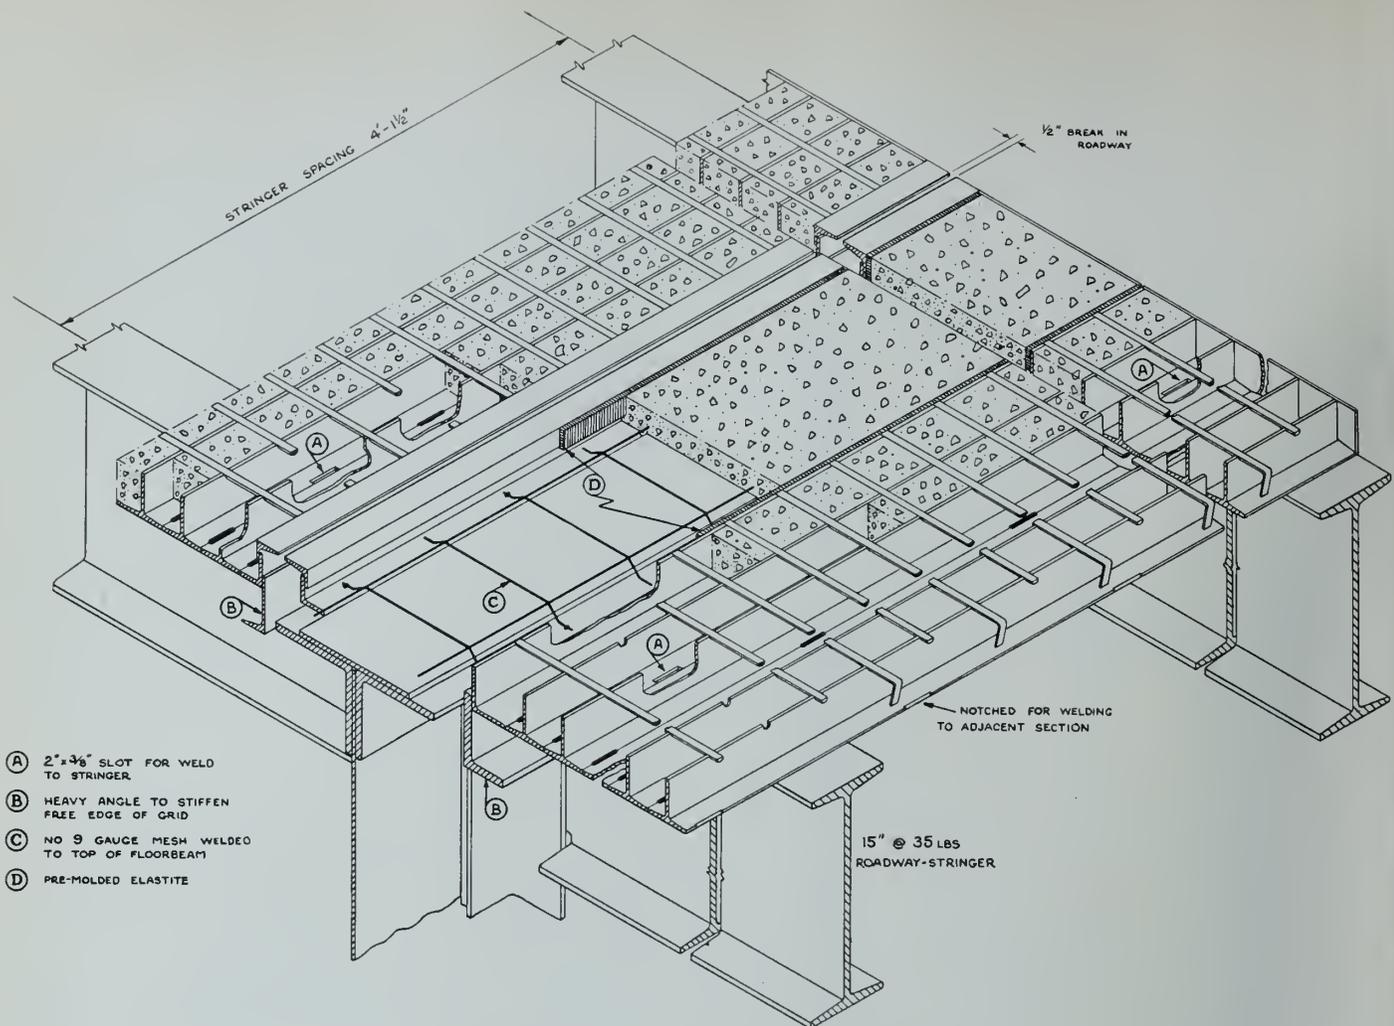

Fig. 23—Isometric view of Teegrid slab.

medium-carbon steel (C.E.S.A. S-40) with a copper-content of 0.25 to 0.30 per cent.

The grid-sections (weighing 2,000 to 2,600 lb. each) lie athwart the roadway and rest directly on the stringers, each section being welded in three places to each stringer and, at 16½-in. intervals, to the contiguous sections. The cross-bars are not continuous at the junctions of the sections, but alternate ones are bent down as indicated in the figure. The weight of the Teegrid slab after receiving its concrete filling is 52 lb. per sq. ft., whereas that of an ordinary concrete deck would be 80 to 90 lb. A valuable incidental advantage of the Teegrid slab is that the grids, before concreting, are capable of supporting considerable traffic-loads without damage, so that a roadway suitable for the passage of erection-equipment becomes available as soon as the steel sections are in place, and prior even to their welding to the stringers. Another advantage is that, since the grid itself acts as a container for the fresh concrete, a good deal of what might well be hazardous work in the placement and removal of forms is avoided.

As shown in Figs. 23 and 24, the Teegrid is not continuous over the floorbeams, the top flanges of which are ½ in. above the stringers. The pavement of the floorbeams consists of a 2⅞-in. depth of concrete, reinforced by steel mesh welded to the flange. To avoid cracking of this slab at its junction with the adjoining grids it is separated therefrom by a ⅜-in. pre-moulded filler ("Givantake") cemented to the grid before pouring the concrete. The figure also shows the arrangement whereby (at intervals of approximately 97 ft.) the continuity of the deck is deliberately broken to prevent its participation in the action of the stiffening-trusses to the detriment of the latter. Such breaks occur at every sixth floorbeam, and the stringers

at those points are provided with sliding-connections.

The sidewalk is constructed of a similar slab, known as "Anglgrid," the steelwork of which consists of a series of ¼-in. angles, 1½ in. deep, welded together in the same fashion as the tees of the roadway-grids, and similarly reinforced (but at 6-in. intervals) with half-round bars. It was fabricated in sections 4 ft. wide and 16 ft. 1½ in. long, one section (weighing approximately 600 lb.) thus providing the sidewalk between two adjacent floorbeams. The sidewalk-grids are field-welded to transverse tees located immediately over, and midway between, the floorbeams. These tees are carried on brackets riveted to the outer stringer of the roadway and to an 8-inch sidewalk-beam which rests on pedestals riveted to the floorbeams. The continuity of the sidewalk-slabs is, like that of the roadway-slab, interrupted at intervals.

The fabrication of the grid-sections was successfully accomplished in the Dominion Bridge Company's structural-steel shops in Vancouver, the chief problem encountered being the selection of welding-rods best adapted for use in the confined spaces presented by the grid-assembly. The tee-grid-sections were built without camber, and were sufficiently flexible to bed down to the camber of the roadway. The Anglgrid-sections were found to warp during welding, but were satisfactorily straightened in the plate-rolls. Slight variations (within the rolling-tolerance) in the depths of the tees and angles were accommodated by punching the half-round holes with reference to the back of the section.

#### FLOOR-SYSTEM AND ROADWAY

The floorbeam-and-stringer system on which the deck rests is, in the main, of conventional construction, as may be seen from the typical cross-section shown in Fig. 25.

The floorbeams, spaced 16 ft. 1½ in. apart, are hog-backed to suit the camber of the roadway: and, for the same reason, the 15-in. I-beam stringers, which frame into the floorbeams immediately below the top flange-angles, are variously inclined to the vertical. The floorbeams are necessarily normal to the changing roadway-grade, and their end-connections accordingly make varying angles with the truss-verticals into which they frame. The end-connections are designed to resist distortion of the bridge cross-section due to unequal loading of the two sides of the deck. End-moment stress of the bottom flange is transferred to the truss-chord (and thence to the vertical) through a horizontal tie-plate, and the complementary top-flange stress passes through a vertical gusset into a welded insert in the truss-vertical.

The 29-ft. roadway, having a 3-in. elliptical camber (giving a four per cent drainage-slope at the gutter), is bounded by steel kerbs, 10 inches high, and the sidewalks have a drainage towards the kerb of one in. in their 4-ft. width. The kerb, consisting of a tee made by halving a 15-in. British standard beam, derives its support from the same brackets that carry the sidewalk cross-tees. The 6-in. back of the tee slopes away from the side-walk at an inclination of one in five and its upper edge forms the boundary of the sidewalk-slab. The 4-in. space between the roadway-surface and the lower edge of the tee performs the function of a continuous open scupper, simplifying cleaning and drainage of the roadway and obviating any need for catch-basins (see Fig. 24). The kerb-tees are discontinuous at every sixth floorbeam.

Fig. 24—Grid deck before concreting.

Owing to the proximity of the comparatively heavy and continuous steel-work of the trusses (which, together with the high kerb, presents an effective obstacle to prevent a vehicle from falling overboard), there is no necessity for heavy fences. The fence (Fig. 28) consists of galvanized 2-in. diamond wire-mesh of No. 6 gauge. The mesh for each 16-ft. panel of fence is woven onto a frame of 1¼-in. channels and is bounded top and bottom by 1½-in. pipe, to which the longitudinal channels are bolted. The height of the top rail above the sidewalk is 3 ft. 8 in., the fence proper having a depth of 3 ft. 4 in. The fence is supported by welding the pipe-rails to angle-posts which themselves are welded to the trusses. The end-channels of adjoining fence-panels are connected with galvanized bolts. The weight of each fence, including posts and brackets, is approximately 17 lb. per ft.

The steelwork of the suspension-bridge deck was fabricated in Vancouver. All the stringers, together with a number of floorbeams, were fabricated by Western Bridge Company, while the majority of the floorbeams, together with the sidewalk-supports, kerbs, and fence-posts, were made by Dominion Bridge Company.

#### STIFFENING-TRUSSES: DESIGN

The function of the stiffening-trusses is to distribute local live-loading amongst all the suspender-ropes, so maintaining the parabolic shape of the cable, and eliminating uneven roadway-gradients such as would occur if the cable were the sole restraining influence. In comparison with that of the loaded cable, however, the stiffness of the long truss is comparatively small, and deflections in general are but little affected by its presence. The stiffening-trusses are thus of hardly any assistance as load-carrying members (the cables taking something more than 95 per cent of live-loads) except insofar as they span between adjacent suspenders. Chord-stresses are thus to all intents and purposes directly related to the moment of inertia of the truss, and it would seem that the optimum truss-depth is therefore the minimum consistent with efficacious control of deflections. On the other hand, however, it is increasingly apparent (and particularly since the lamentable failure of

Tacoma Bridge) that the use of an unduly light and limber truss is likely to be attended by dangerous oscillations of the structure. In the present state of knowledge there is no clear ruling for establishing truss-depth, and the engineer is perforce guided by past experience, the trends of current practice, and by the circumstances of the project in hand.

In the present case, an examination of the span-depth ratios of various existing bridges led to the selection of a depth of 18 ft. between chord-centres

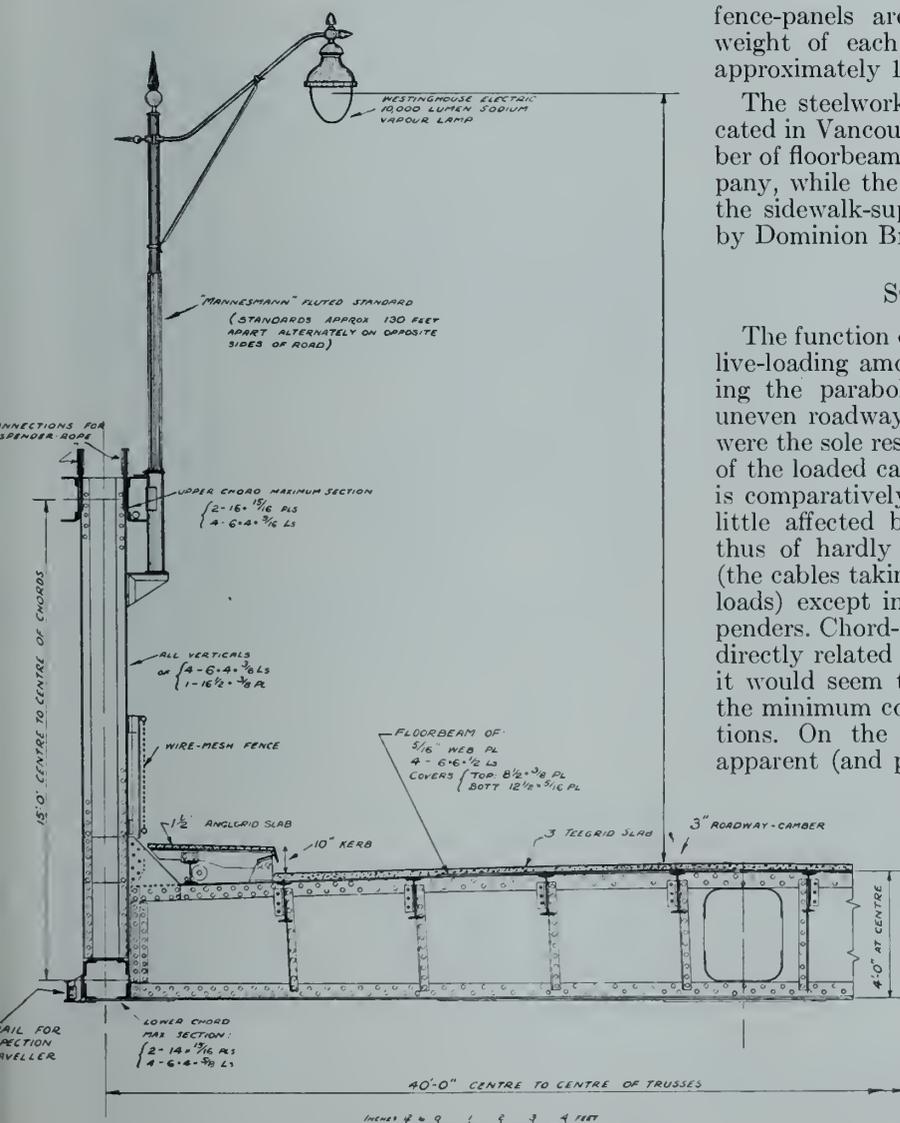

Fig. 25—Typical cross-section of suspended spans.

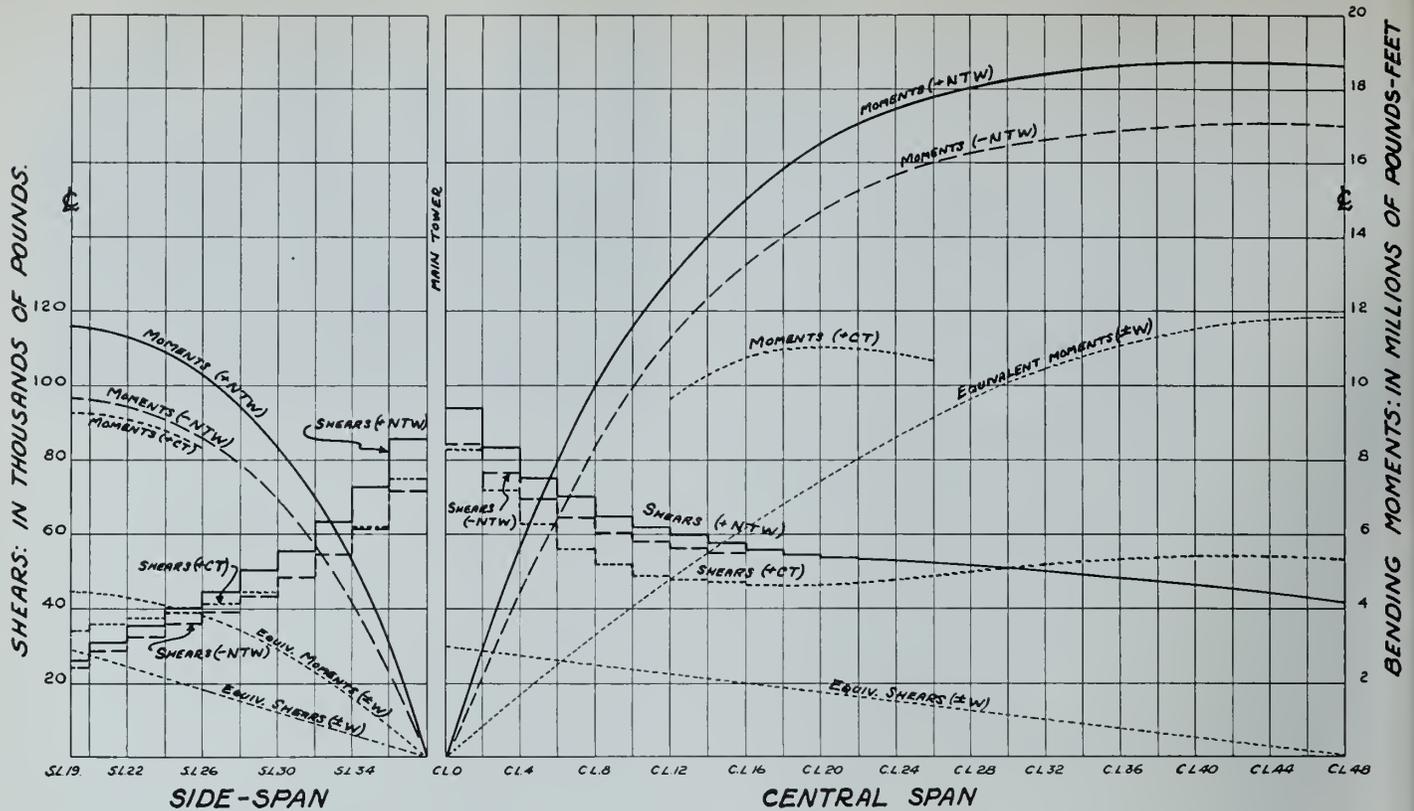

Fig. 26—Bending-moments and shears in stiffening-trusses.

as a preliminary figure, the span contemplated at that time being 1,500 ft. The depth was subsequently reduced to 16 ft.; and ultimately a depth of 15 ft. was adopted, for the 1550-ft. span.

Contributing to this decision were studies of panel-length, suspender-spacing, and of overall-sizes and weights for shipment and erection. The spacings chosen are seen in the general diagram of Fig. 22, the panel-length being 16 ft. 1½ in. (varied slightly in the special cases of the end-panels), and suspenders being located at alternate panel-points. The web-system is of the Warren type, with a vertical member at each panel-point, the diagonals being sloped at approximately 45 deg. The trusses are two-hinged, but for aesthetic reasons the physical discontinuity at the towers has been largely concealed by the extension of the upper chords as far as the ends of the trusses. The trusses, 40 ft. apart, hang in the planes of the cables, and lateral X-bracing is provided between the lower chords.

With regard to stress-computations, theories have been advanced for direct solutions by approximate methods,\* but it is by no means certain that accurate results are available any more swiftly thereby. While an approximate method is of great value in setting up initial assumptions, the author believes that the continued use of the "deflection" theory thence onwards until accord is reached between assumption and result, is the most satisfactory routine to follow. This latter procedure was employed in the present instance, use being made of Mr. L. S. Moisseiff's stress-analysis. Maximum bending-moments and shears were evaluated (involving the theoretically-worst distributions, in any pattern of discontinuity, of the specified live-loadings), at frequent intervals throughout the spans; and curves of the maxima were prepared (see Fig. 26) for the governing conditions of loading. The usual assumptions, of uniform dead-loading and of an equivalent mean truss moment of inertia, were made.

In dealing with resistance to lateral loads, the participation of the upper chords was recognized, and wind-

pressures were translated into equivalent vertical loads in the trusses. Furthermore, in the case of the central span, the lateral wind-unit of 380 lb. per linear ft. (together with an assumed unit of 36 lb. per ft. on the cables) was divided between trusses and cables by use of the ingenious method of Messrs. Moisseiff and Lienhard\*\*, the resulting lateral load on the trusses amounting to 210 lb. per linear ft. For the side-spans such a distribution is not operative, and the full lateral load of 500 lb. per linear ft. was applied to the trusses.

The following are the properties of the interacting truss-and-cable system that finally emerged from the design-calculations:

Truss-depth.....	15'-0" c. to c. chords
Cable-area.....	71.1 sq. in.
Total dead load—central span.....	2,300 lb. per lin. ft.
Total dead load—side-span.....	2,104 lb. per lin. ft.
Truss M.I. —central span.....	5,250 in <sup>2</sup> ft <sup>2</sup>
Truss M.I. —side-span.....	2,900 in <sup>2</sup> ft <sup>2</sup>
Lateral M.I. —central span.....	83,000 in <sup>2</sup> ft <sup>2</sup>

From the following tabulation it will be seen that the actual weights of the suspended structure exceeded those

Item	Total weight (kips) suspended from one cable	
	Estimated	Actual
Cable, wrapping, fillers.....	788.88	783.866

<b>TOTAL.....</b>	<b>5,955.22</b>	<b>5,980.152</b>

\*Preliminary Design of Suspension Bridges: Hardesty and Wessmann. Trans. Am. Soc. C. E. Vol. 104: Discussion.

\*\*Volume 98. Trans. Am. Soc. C. E.

estimated by 0.40 per cent. In determining the geometry of the cable-polygon, loads were computed separately for each suspender, and the range of error in these individual weights was from  $-0.32$  per cent to as much as  $+1.17$  per cent.

The subsequent addition of four observation-platforms and of the signal-station (the weights of which were not anticipated in the estimated figures), however, increased the dead load in several of the suspenders. That of the central suspender (the most severely affected) became 14 per cent in excess of the design-load; but, as will be seen

Fig. 28—Arrangement of observation-platform.

by reference to Part III, the safety-factor was not appreciably reduced. Correspondingly the general overrun of total suspended dead load increased by 1.13 per cent, but, in view of the ample provision for live load, it was not necessary to make any changes.

#### STIFFENING-TRUSSES: WORKING-STRESSES

Comparatively high unit-stresses are permissible in the stiffening-trusses. The reason for this is two-fold. In the first case, each member is designed to resist forces that are set up by the most severe arrangement of live-loading possible for the member in question. It is highly improbable that such peculiar patterns of live loading will ever obtain, while the possibility of their occurrence in conjunction with high wind and extreme temperature may be discounted altogether. Secondly, as has already been pointed out, the trusses are not primary supporting-structures, and truss-members could sustain relatively severe damage without jeopardising the safety of the roadway.

The trusses are built of medium-carbon steel, and the basic unit-stresses adopted were as follow:

Tension: 20,000 lb. per sq. in.

Compression:  $\frac{20}{18} (18,000 - 60 \frac{L}{r})$  lb. per sq. in. (maximum 16,200).

In proportioning the chord-members, these units were used for stresses due to D or W alone. They were increased in the ratio 25/20 for cases DW or DNT, and in the ratio 30/20 for DCT or DNWT. For the upper chord, the compressive units were arbitrarily reduced by 2,000 lb. per sq. in. For vertical members, the basic units were specified for all cases not involving W, and were increased in the ratio 25/20 when effects due to W were involved. The same increased units were employed for all cases of loading in the truss-diagonals. The basic shear-unit for shop rivets was 13,500 lb. per sq. in., and, for field rivets, 12,000 lb. per sq. in.; and these were increased respectively to 15,000, 17,000 and to 13,000, 14,000 in accordance with the tensile and compressive units. Rivets were manufactured to comply with C.E.S.A. specification S-42.

#### STIFFENING-TRUSSES: DETAIL

Typical details of the trusses are given in Figs. 25 and 27. The chords each consist of two vertical web-plates and four flange-angles with horizontal legs turned outwards

in the case of the upper chord and inwards in the lower. Double lacing is used for the upper chord; but for the narrower lower chord, single-lacing becomes obligatory and, for the heavier sections, wider bars with two-rivet connections are necessary. The 16½-in. width of the truss was determined mainly by the exigencies of the suspender-connection.

All vertical members of the trusses are truly vertical under "normal" conditions, and are of the same built-up H-section throughout. The governing loading occurs in the case of the hanger-vertical, and this member, as well as being designed for the maximum direct tension from the suspender, is calculated to withstand bending-stresses from the floorbeam-connection and also to provide lateral stiffness for the upper chord in addition to that deriving from the suspender-pull. Connection of the truss to the suspender is made directly to the hanger-vertical, as shown in Fig. 43.

The diagonals, except for the end-posts (which are of double-channel section for stiffness and for connection to the chords), consist of two angles the backs of which are braced together with batten-plates and the toes with light welded angles. These members, receiving stress from live-load, temperature, wind, and from local loadings between suspenders, are of varying cross-section, becoming lighter towards the centres of the spans. Lateral-bracing members, apart from those in the end panels, consist each of a pair of angles with the shorter legs downstanding and riveted in contact. Connection to the trusses is made through gusset-plates riveted to the undersides of the lower chords. Gussets at the intersections of the braces are riveted to the bottoms of the floorbeams, and additional support is given to each member by a 7/8-in. rod-hanger which hangs from the lower flange of the appropriate roadway-stringer. Studies indicated that greater economy of material was effected by such a tension-system than by one of K-bracing.

The lateral system terminates, at either end of each of the three suspended spans, with two heavier latticed-channel members (designed for compression as well as tension), through which the whole wind-reaction is delivered into a suitable "nose" detail.

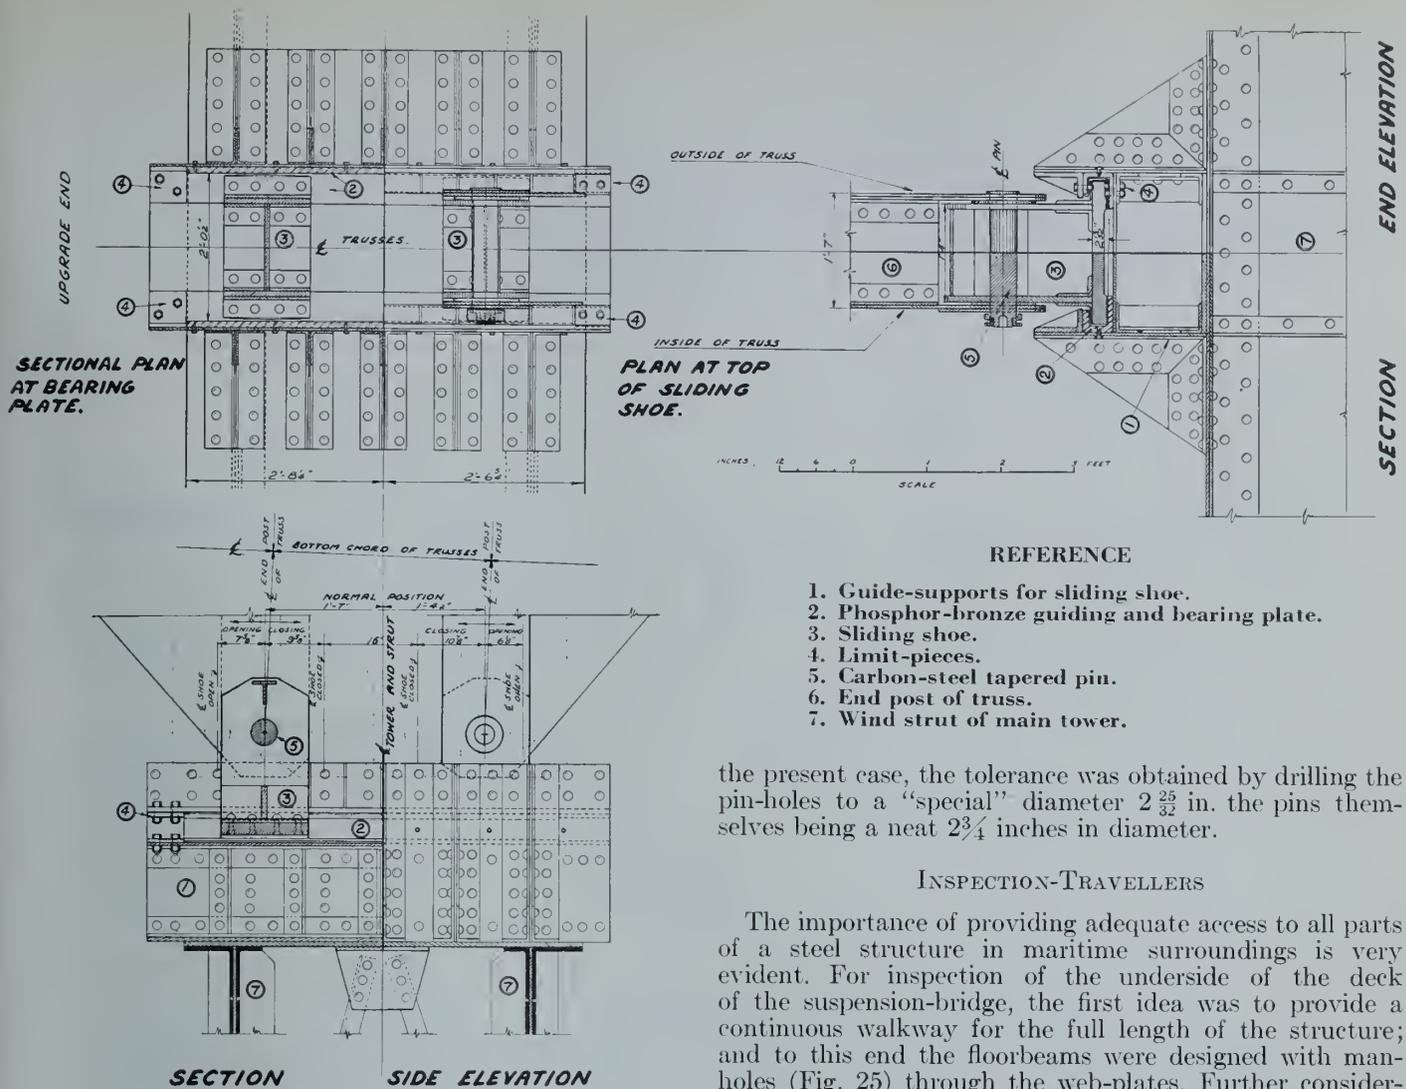

Fig. 29—Signal-station: Steel structure.

The trusses and bracing are riveted with 7/8-in. rivets. The C.E.S.A. highway-bridge specification was referred to for workmanship and detail.

#### STIFFENING-TRUSSES: FABRICATION

In order to achieve the anticipated balance of interdependence between cables and trusses wherein the latter are unstressed under dead load at normal temperature, it is essential that the field-geometry of the structure shall conform closely to the theoretical dimensions. The lengths of cables and suspenders were obtained very accurately, and every effort was made to attain equal precision in the profile of the long trusses.

The contractor made complete detail drawings of the trusses from the end of the side-span to the middle of the

the present case, the tolerance was obtained by drilling the pin-holes to a "special" diameter  $2\frac{25}{32}$  in. the pins themselves being a neat  $2\frac{3}{4}$  inches in diameter.

#### INSPECTION-TRAVELLERS

The importance of providing adequate access to all parts of a steel structure in maritime surroundings is very evident. For inspection of the underside of the deck of the suspension-bridge, the first idea was to provide a continuous walkway for the full length of the structure; and to this end the floorbeams were designed with man-holes (Fig. 25) through the web-plates. Further consideration, however, led to the adoption of movable underslung platforms, giving convenient and safe access to all underneath parts. The three travellers each consist of two light welded trusses, spanning the full width of the bridge. The trusses are braced apart by 4-in. cross-channels welded under the lower chords, the channels functioning also as supports for a plate platform, 4 ft. wide. The top angles of the trusses (which are 3 ft. 6 in. deep) constitute handrails for the walkway, while the truss-webs form protective fencing. At each end is a widening of the platform (to 7 ft. 6 in.), from which a crank can be operated for moving the traveller by hand. The cranks at the two ends of the traveller operate on a full-length shaft, from which the manpower is transmitted at each end by a chain-gear to one of the wheels. The two wheels at each end are spaced 6 ft. apart and, double-flanged, run on the flange of a standard 7-in. I-beam which is supported from the lower chord of the truss at every panel-point. The travellers are equipped with hand-brakes, and there are safety-bolts which lock into holes punched at 4-ft. intervals in the webs of the rail-beams. The primary purpose of these travellers is for regular maintenance of the bridge, but they were found invaluable during construction for work that otherwise would have necessitated the use of elaborate scaffolding. Each traveller weighs approximately  $4\frac{1}{2}$  tons.

#### OBSERVATION-PLATFORMS

At the instance of the owners, four observation-platforms for the use of pedestrians were incorporated into the structure of the central span. These are steel structures, sustained, at sidewalk-level, on cantilever-brackets outside the trusses. Each is about 6 ft. wide and 32 ft. long, extending between panel-points 2 and 4 (i.e., about 30 ft. from the

central span, and each section was fabricated individually. On account of the constantly-changing gradient of the suspended structure, the only repetitive details were those of the vertical members. The engineers required accurate facing of the ends of chord-members at all splices, and the varying angles of these members necessitated extremely precise workmanship. As an instance, the bevel to which one of the lower-chord splicing-faces was successfully machined is stated on the detail drawing to be  $\frac{9}{32}$ -in. in 4 ft.

The trusses were fabricated in sections of approximately 48 ft. in overall length, each shipping-piece comprising two adjacent vertical members, two diagonals, and two panels of each chord. Upper chord splices were made midway between suspenders, the faced ends of the material being at the panel-point. The lower chord splices were made a little to one side of the alternate panel-points, so that adjoining sections might be bolted together in the field without complicating the subsequent connection of the floorbeam.

The trusses were built in the Burnaby plant of the Dominion Bridge Company. They were shop-assembled, four at a time, and bevels and dimensions were checked before reaming or riveting took place. The main production-problem encountered was that of so ordering the sequence of fabrication of the 170 pieces as to anticipate the shipment-programme and to avoid as far as possible any unproductive sorting in the yards.

A recommendation made by the fabricating-shop was that pin-holes (for suspender-lugs) should be made to suit a standard drill, since it is simpler to allow for the necessary fitting-tolerance in the diameter of the machined pin. In

main tower in each case), and commands an extensive view of the surrounding scenery. The platforms are floored with chequered plating and are protected by stout fences 4 ft. 6 in. high. Uninterrupted access is obtained from the sidewalk, two openings in the fence (Fig. 28) being provided for each platform. Fixed steel benches are also furnished.

The signal-bridge and the observation-platforms were fabricated in Vancouver by Western Bridge Company and Dominion Bridge Company respectively.

#### SIGNAL STATION

In accordance with a stipulation of the Federal Government, provision was made for the replacement of the marine signal-station on Prospect Point by a new structure situated at the middle of the bridge. This new station was put into operation on January 15th, 1939, and its location affords a considerably more extensive view both seawards and into the harbour.

The steel structure consists of a light cross-bridge over the roadway at span-centre, giving a 20-ft. clearance over the roadway-crown. The  $\frac{1}{4}$ -in. chequer-plate deck of the "signal-bridge" is supported on 5-in. channels (spaced 2 ft. 9 in. apart) which in turn are carried on two light welded trusses, 10 ft. apart and of such depth (4 ft. 6 in.) as to permit of their functioning as handrails. The trusses are supported by framework built onto the stiffening trusses, and the signal-bridge deck, with an overall length of 48 ft., is cantilevered out at either end, where suitable railing is provided. A steel stairway connects the east end of the signal-bridge with a small platform at sidewalk-level, access to that platform being given by a gate in the fence.

The signal-bridge carries two cabins (9 by 8 ft. in plan, and 8 ft. high), one near either end (Fig. 29), and a 36-ft. steel mast with 10½-ft. cross-arms is set in the middle of the deck. The cabins are of welded construction, with walls of No. 12 gauge steel plate lined with 5-ply wood veneer. The ceilings are finished with "Masonite" and the floors are of oak. Generous window-space is provided. The western cabin serves as office and control-room, and the eastern contains batteries, machinery, meters and switch-gear, storage-space, and toilet accommodation, the soil-pipe from the latter discharging directly over the water. Water is provided by an insulated copper pipe from the south bridge-head.

Ancillary to the signal-station (but not comprising part of the main contracts as administered by the engineers) is a cottage-dwelling built near the south anchorage, for the resident personnel.

#### PROVISIONS FOR EXPANSION

In the case of the main suspension-system, thermal and elastic variations in the lengths of the cables are self-accommodating. The cables are free to adjust themselves by alterations in sag, and the cable-saddles are also to all intents and purposes free to move within the limited ranges involved.

Provision is essential, however, to cater for changes in the long horizontal length of the truss-and-deck system of each span, and for angular end-movements both lateral and vertical.

The linear movements are provided for at the points where the trusses take their end-bearing on the two towers, the outer ends of the side-spans being "fixed." This arrangement, although it has the disadvantage of concentrating the expansion-movement of the whole 2,778 ft. of structure at only two points, was resorted to in order to avoid the effects of flexure on the shorter suspender-ropes and rather to make use of the freer support of the very long ropes in the vicinity of the towers.

The other movements, caused by lateral or vertical deflections, demand articulation of the suspended structure at each end of each span. The lateral-bracing system in all cases terminates in a central intersection at which the

reaction is delivered. At the shoreward end of the south side-span this intersection is connected by a vertical pin to a wind-anchorage secured into the front face of the pedestal; and, in the case of the north side-span, to the cable-bent. Thus at these two shoreward ends of the bridge the trusses are fixed in regard to longitudinal movements (excepting those due to deflections of the cable-bent) but are free to deflect laterally by rotation of their ends about the wind-pins. The accompanying small to-and-fro movements of the truss-ends are accommodated by sliding details, the trusses bearing on horizontal pins that permit of angular movement due to vertical deflections but which restrict vertical movements to the small clearance needed for sliding. Expansion-details at the south end of the bridge are shown in Fig. 27, while those at the north end are discussed in connection with the cable-bent (p. 296).

At the towers, provision is made for similar movements, and, in addition, for longitudinal expansion of the suspended spans. The wind-reaction of each truss is delivered through a sliding "nose" (riveted to the end floorbeam at the intersection of the terminal lateral-members) which can move longitudinally between phosphor-bronze guides mounted on the top of the wind-strut immediately under the roadway. The rubbing surfaces of those bronze guides are curved to a radius of 3 ft., and are spaced to give  $\frac{1}{16}$ -in. clearance for sideways motion of the nose.

The possible extent of movement of the ends of the trusses at these expansion-points is considerable, such movements emanating from various sources. Thus, at the north tower, the side-span truss, in addition to its alteration in length owing to stress-and-temperature-variations, moves bodily with deflections of the cable-bent, to which it is fixed. At the same time the northerly half of the central span contracts and expands, with its natural fixed point at span-centre. Furthermore, wind-loads, in bowing the spans sideways, cause rotation of the end floorbeams about the wind-pins, so that the leeward truss-ends of adjacent spans approach each other, while the windward ends retreat. Further, there is to be considered the elastic deflection of the tower itself due to displacement of the saddle on account of cable-adjustments. Movements at the south tower are smaller in extent, but the same expansion-assembly is provided in both cases.

The arrangement of the truss-shoes at the main expansion-joint is shown in Fig. 30. The end of each truss is pin-connected (with a 4½-in. horizontal pin) to a sliding shoe which moves between upper and lower bronze guides. In this manner no resistance is offered to longitudinal movements or to vertical angular motion, but the truss-end is constrained against movement due to positive or negative reaction. Weather-protection for the shoes is afforded by light articulated steel frames with canvas covers.

Traction-forces in the suspended structure are transferred from the trusses into the main cables at the low points of the latter. In each span, as shown in Fig. 27, two points of the upper chord (some 30 ft. apart) are connected to the lowest cable-band, which is specially adapted for the purpose, by a pair of 1⅞-in. high-tensile rods. The lengths of these are adjustable by turnbuckles, and their outer ends are forged and bored to receive 2½-in. pins. Each of the six assemblies is designed to withstand a traction-force (see Part III) of 51 kips. In this manner the three spans are severally prevented from bodily movements longitudinally, and expansion of the central span is constrained to take place equally at both ends.

#### EXPANSION-JOINTS IN ROADWAY

The engineers' drawings in the first place called for a conventional type of expansion-finger joint: such a detail comprises two sets of narrow steel bars set on edge, attached respectively to the ends of the adjoining deck-slabs, the bars of one set meshing with those of the other. Owing, however, to the large movement to be accommodated, the

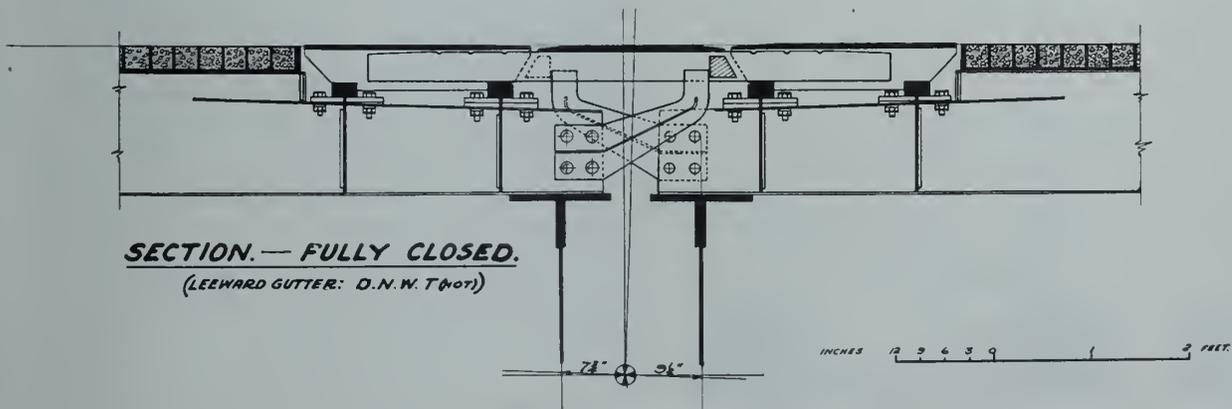

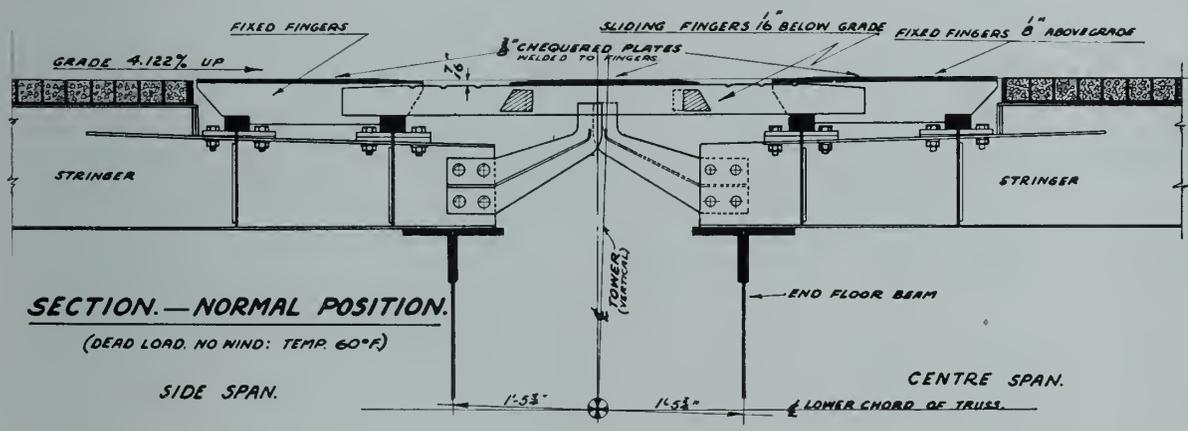

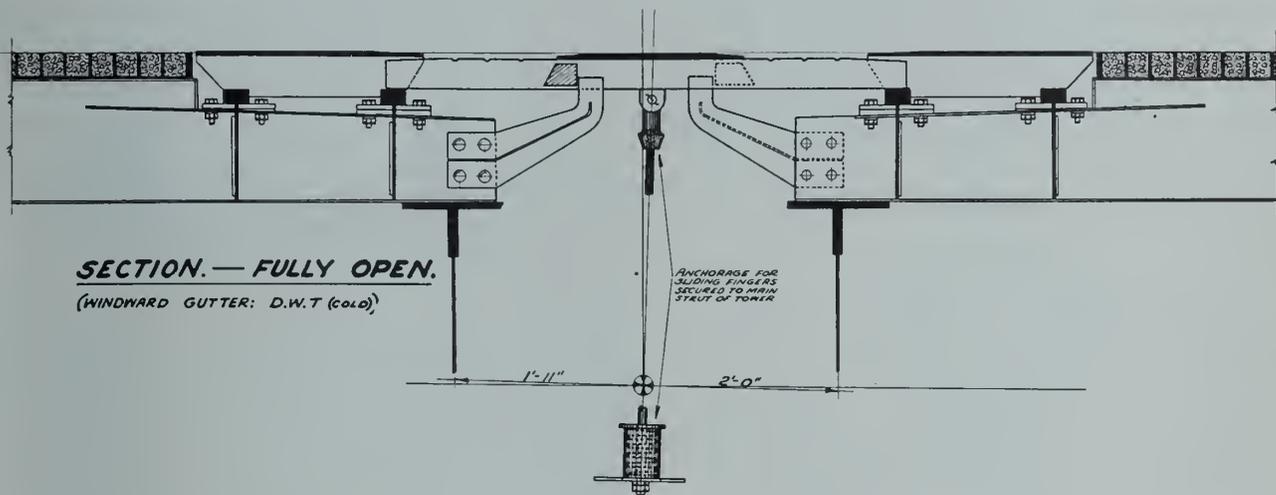

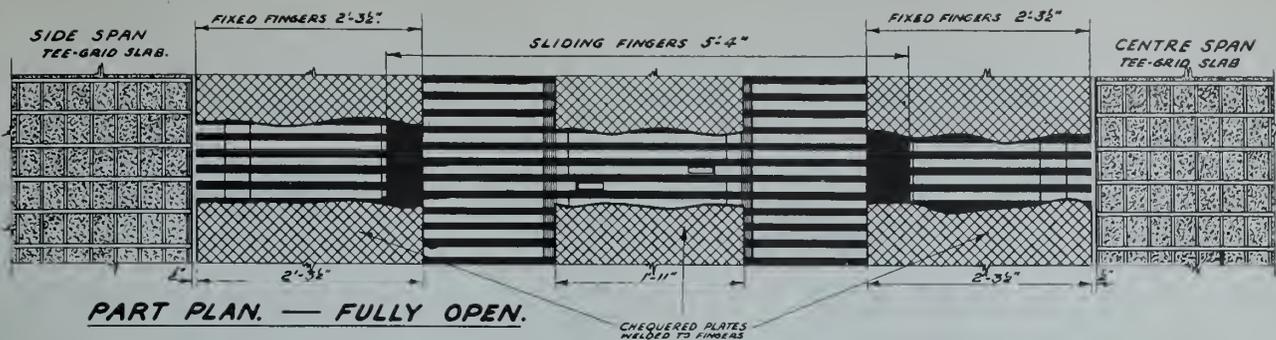

Fig. 31—Main expansion-joint for roadway.

consequent abnormal overhang ( $17\frac{3}{4}$  in.) and depth (6 in.) of the fingers, and the wide finger-spacing needed to prevent binding due to rotation of the span-ends, the contractor suggested an alternative in which the total movement is divided into two parts that occur at separate finger-meshings. This amended design utilised smaller bars for the fingers, eliminated the cantilever feature, and offered certain

advantages in fabrication. In spite of additional complication, the design was accepted by the engineers on account of its superior qualities of stability and rigidity, and the details were duly approved.

The joint is shown in Fig. 31. Rigidly attached to the end-stringers of the adjacent spans, and thus forming in each case an extension of the deck-slab proper, are two "fixed" sets of  $5\frac{1}{2}$  by  $\frac{13}{16}$  medium-steel fingers set up on edge at  $1\frac{15}{16}$ -in. centres. The fingers of each set are welded to two transverse supports (each made up of a 3 by 2 bar welded to a  $9\frac{3}{4}$  by  $\frac{3}{8}$  web-plate) that span between the stringers, the latter being cut down and strengthened to receive them. The supports are curved so that the top surface of the finger-assembly, which extends across the road, follows the roadway-camber. A third set of fingers ( $4\frac{1}{2}$  in. deep and tapering in thickness from  $\frac{13}{16}$ -in. at the top to  $\frac{7}{16}$ -in. at the bottom to prevent accumulation of road-debris), spaced similarly to those of the "fixed" sets and welded with spacers to form a single cambered unit, intermeshes with the two fixed units, and bears and slides on the outer supporting-bars of the latter.

In Fig. 31 are shown the relative positions of the three sets of fingers under normal conditions and also when the gap between the two adjoining deck-slabs is at its maximum and its minimum. It will be noted that the anticipated range of movement at the edges of the roadway amounts to as much as 30 inches. It will also be seen that the central (or "sliding") fingers are free, except in the extreme cases (when their movement is controlled by "stops" which, connected to the stringer-ends, engage with choeks welded between the fingers), to move independently. The weight of the sliding-fingers is probably sufficient to prevent any vertical movement or "chattering," but, as a safeguard, they are held down positively by two one-in. steel rods whose lower ends are secured to the main tower-strut. The rods are pin-connected, and tension is maintained by coil-springs.

In order to maintain an unbroken roadway-surface as far as possible, both sets of fixed fingers, together with the central portion of the sliding fingers, are covered over with welded chequer-plating. Also, to accommodate angular movements due to deflections of the spans, the sliding fingers are set at a lower level than the fixed ones, and the latter are sloped slightly downwards. The sliding-surfaces of the support-bars are rounded for the same reason.

A conventional assembly, of two intermeshing sets of fingers, is provided at the cable-bent, where relative movement of side-span and viaduct may amount to 9 in. At the south end of the bridge there is no provision for expansion, but a sliding-plate assembly is furnished to take care of deck-movements due to rotation about the wind-pin.

#### MAIN TOWERS: DESCRIPTION

The two main towers are shown in outline in Fig. 32, and pictorially in Fig. 33. Each tower, which is 364 ft. in height from the top of masonry (elevation 117.5) to the theoretical intersection of the cable-curves, consists of a pair of slender columns carrying the main cable-saddles and thus providing primary support for the suspension-system. The tower is braced to resist transverse loads, and derives its longitudinal stability from the fixity of its base and from the restraint afforded at the top by the cables themselves: the saddles are attached positively to the towers. The two columns of each tower are battered at 1 in 24, the cable-saddles being 40 ft. apart and the centres of the pier-shafts 69 ft.  $9\frac{1}{2}$  in.

The importance of the appearance of the towers was realized from the outset, and every effort was made by the engineers to render these dominating structures pleasing to the eye. To this end the form and arrangement of the tower-bracing were carefully considered, the X-type being deliberately selected as possessing those satisfactory aesthetic qualities which normally derive from a "functional" design.

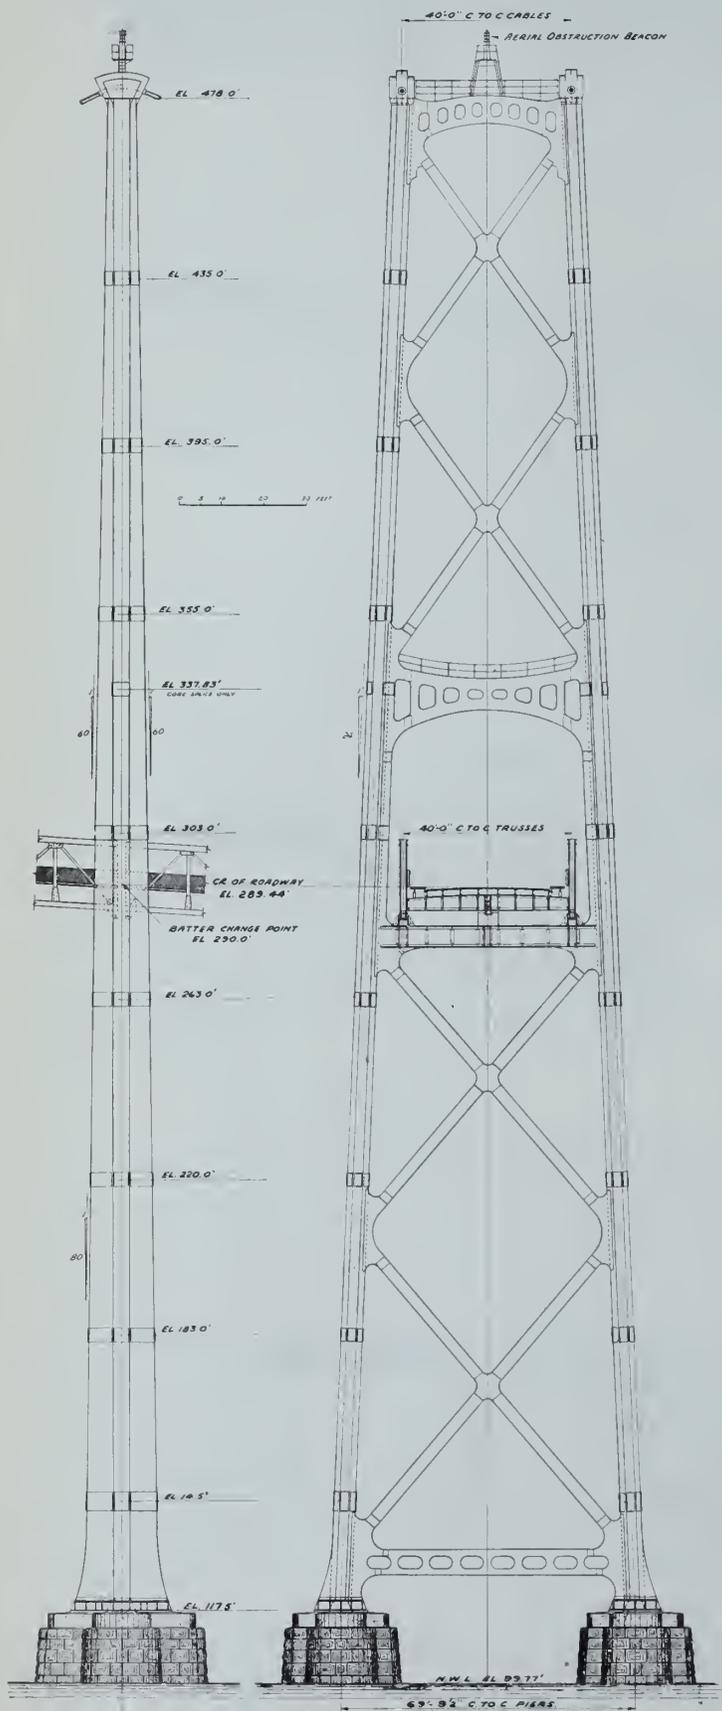

Fig. 32—Main tower.

Fig. 33—South main tower.

The bracing is continuous except for the portal-opening through which the roadway passes. Each diagonal is built up of four angles and two vertical webplates, and is braced with two planes of angle-latticing. The gusset-plates at all bracing-intersections and connections are rounded, and the three visible cross-struts (at the top and bottom of the tower, and over the roadway-portal), which would otherwise be oppressive in appearance, are "lightened" by a series of carefully-spaced piercings of the web-plates. The crown- and portal-struts are also shaped in a manner as to emphasize the functions which are implied by their locations. The fourth strut, which receives the wind-reactions from the suspended spans and on which the sliding end-bearings of those spans are mounted, is rendered inconspicuous by its position immediately below the deck of the bridge, and consequently did not receive any special architectural treatment.

The cross-section of the tower-column (Fig. 34) is governed principally by structural requirements. Cruciform in general outline, and built up of plates and angles, it consists of a rectangular core flanked by two symmetrical wings.

The core-section is of constant size and material throughout. Stiffening-diaphragms, with a vertical spacing of about 6 ft., consist of peripheral angles only, leaving a clear central shaft 4 ft. by 2 ft. 6 in. This shaft is large enough to accommodate an electric elevator in the event, at one time probable, of a signal-station being required at the top of the tower. The two wing-sections are also rectangular. They are of constant width, but their depth increases (apart from the entasis introduced by a change in the side-batter from 1 to 60 in the upper part of the column to 1 in 80 from the roadway downwards) regularly from the underside of the cable-saddle to a point about 19 ft. above the masonry. Below that point the wing-sections are flared out in order to accentuate the appearance of stability of the fixed base. For the greater portion of its length, each wing is subdivided into two parts by a latticing-system connecting two vertical angles, the whole tower-column thus comprising five separate chambers. The wing-sections are stiffened by U-shaped diaphragm-angles, the spacing of these being as for the core, again leaving clearance for continuous access. The material of the wing-sections is also, as far as possible, constant throughout.

An inspection-ladder is provided in each chamber of the tower-column. These ladders (there are ten to each tower)

are continuous for the full length of the chambers, and manholes give access from one chamber to another at various levels. Entrance to the interior of the columns is effected by doors (equipped with locks) at roadway-level and at the base of the tower. Other doors are located at the tops of the columns, and also at every bracing-connection, the latter connecting with the ladders that are provided inside all of the diagonal members. There are also fenced walkways along the tops of the crown-strut and portal-strut. Electric lighting is installed in all the chambers, the controlling switches being situated near the principal points of entrance.

#### MAIN TOWERS: DESIGN

Under any condition of bridge-loading, the cables assume a position of equilibrium so that the horizontal component of tension is constant throughout the system. Since, however, the reaction-pressure of the cables on the main saddles is sufficiently great to preclude cable-slip at those points, and as in any case it would be undesirable to permit such sliding to occur, any balancing-movements are accommodated by longitudinal displacements of the tower-tops. The range of these displacements being of definite and limited

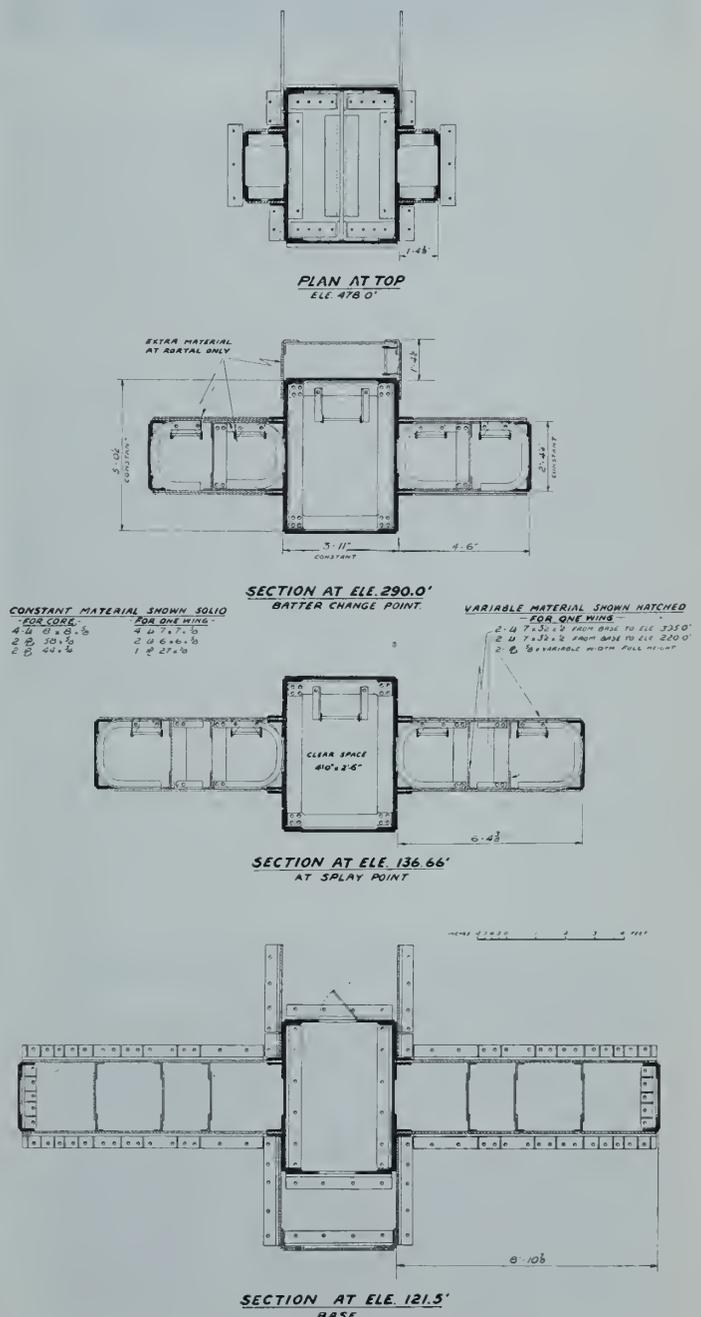

Fig. 34—Cross-sections of tower-column.

extent, it has, in modern practice, been found\* both convenient and practicable to provide for them by invoking the inherent flexibility of the tall tower-columns, assuming that the latter are free to adopt any position dictated by the pull of the cables.

The conditions of loading which govern the design of the towers are apparent from inspection. Thus, the heaviest cable-reaction will occur when all three suspended spans

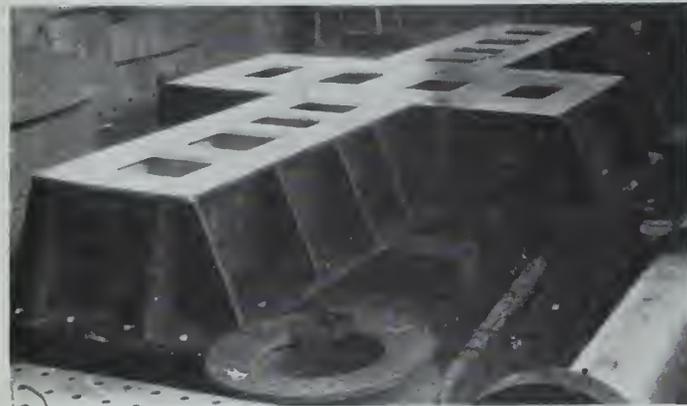

Fig. 35—Main shoe.

are fully loaded and minimum temperature obtains. The greatest saddle-movement, however, will take place when the central and far-side spans are loaded, and at maximum temperature. The latter case, together with wind-loading, was found to control. It may be noted here that, owing to the greater length of the north back-stay, deflections are larger at the north tower, which is thus the more severely loaded. The towers were, however, made identical in structure, being designed for the worse case.

For each condition of loading investigated, the amount of the cable-reaction at the saddle, and its simultaneous displacement, were first determined. The cable-reaction bears a fixed relation (approximately 82 per cent) to the horizontal component of cable-tension, which latter is arrived at by the relevant deflection-theory computation. The displacement of the saddle, or departure of the tower from verticality, is obtained from consideration of the changes in length and shape of the cable between the saddle and the nearest anchorage. For the case of DCT (as given in the tabulation below), for instance, the total riverward movement is comprised of 0.454 ft. due to thermal elongation of the cable, 0.606 ft. due to elastic lengthening of the cable from stress, and 0.460 ft. due to upward deflection of the unloaded side-span.

The first step in design was the assumption of a suitably-tapered "trial" column, capable of withstanding the loading from the cable with the saddle in its deflected position. The physical properties of cross-sections about 20 ft. apart were evaluated, and the elastic curve due to a hypothetical unit load acting horizontally on the saddle was computed, establishing the relation between the horizontal load and the movement of the saddle. In the final design, the deflection of the top of the column due to a load of 1,000 lb. was calculated to be 0.0564 ft.

The second step was the assumption of an elastic curve for the column when subjected to a particular loading and simultaneously deflected by the appropriate amount (first and second columns of the tabulation). With this assumption, the stresses in and deflections at the various sections were figured, and it was naturally found that the top deflection differed, one way or the other, from the original amount, owing to the moments caused by the eccentricity of the vertical loads. That original amount, however, which is a definite quantity, is entirely independent, for all practical

\*The first use of fixed flexible towers with immovably-connected saddles was in the Manhattan Bridge, built 1909. Such towers have since been invariably used for bridges of long span.

purposes, of the dimensions of the column. Accordingly, the next step was the evaluation (from the unit-load deflection previously obtained) of the induced horizontal load necessary to maintain the status quo. The elastic curve due to this induced load was then superimposed on that due to the vertical loading-condition, and the resulting composite curve gave the required actual saddle-deflection but did not necessarily agree throughout its length with the assumed curve. New assumptions for the curve were then tried until such agreement occurred. The stresses over the various sections were then inspected, and suitable alterations in size and disposition of metal were made. The argument was then repeated to determine the new elastic curve. Similar computations were performed for all important loading-conditions including those involving longitudinal wind-loads, which set up a cable-pull in addition to the above induced load.

The tabulation given below summarizes the cable-reactions, saddle-offsets, and induced cable-pulls for the principal conditions of loading, applied to the column finally adopted.

TOWER LOADINGS AND DEFLECTIONS

Loading	Vertical Load (Kips)	Deflection of Saddle Riverward (feet)	Induced Horizontal Load (Kips)
DNT.....	4,582	1.249	+ .286
DCT.....	4,790	1.520	- .648
DNTL (offshore).....	4,582	1.249	+2.151
DNTL (onshore).....	4,582	1.249	-1.581
DNTW.....	4,582	1.249	-1.623

NOTE:—Figures are for high temperature (120°).

The bracing of the tower, which is stressed only by lateral loads, was designed independently (except insofar as the rigid-frame moments around the portal influenced and were dependent on the column-sections over that length) as a simple framework. The determining factor, however, was that of appearance, the members in question being in general of considerably heavier section than is necessary to fulfil the minimum requirements. An approximate estimate of stresses in the bracing due to its participation in the main function of the tower-structure indicated that such were not of significance.

#### LOADING AND WORKING-STRESSES

The loadings D, N, C, T, which are described on p. 283, were used also for the towers. The lateral load  $W$  was extended to include the effect of  $1\frac{1}{2} \times 30$  lb. per sq. ft. of vertical projection of the tower. A longitudinal wind load  $L$  of 300 lb. per ft. of height on each column was also considered, this being effective either off-shore or on-shore; and a further wind-load  $W_1$ , of  $1\frac{1}{2} \times 50$  lb. per sq. ft. of column, operative on the unloaded tower, was the controlling factor in the bracing-design.

The normal compression-unit, for medium-carbon steel (C.E.S.A.: S-40), was specified to be  $\frac{20}{18} (17000 - \frac{240h(358-h)}{358r})$  lb. per sq. in., with an upper limit of 16,222 lb. per sq. in., where  $h$  is the height above elevation 120 of the section in question, and  $r$  is its radius of gyration. This formula is an adaptation of the common mild-steel formula  $f_c = (17000 - 60\frac{l}{r})$ . It was designed to permit higher working-stresses near the restrained ends of the column, and the units are also increased in accordance with the higher quality of the material. The upper stress-limit corresponds to a "cut-off" at  $\frac{l}{r} = 40$ .

The above unit was used for stresses due to D, W, DW, or DNT, and a 15-per-cent increase was permitted in the

case of DCT, DNTW, or DNTL. It was found that the column-section up to roadway-level was governed by loading DNTW, and thence to the top by loading DNTL (on-shore) except for some 30 ft. of the portal, where the effects of DNT preponderated.

The bracing was designed to a working-stress of 20,000 lb. per sq. in. in tension and  $\frac{20}{18} (17000 - 60 \frac{l}{r})$  in compression.

The unit-stresses for rivets throughout were 15,000 lb. per sq. in. for shop-rivets and 13,500 for field-rivets, the rivet-material according with C.E.S.A. specification S42.  $\frac{1}{8}$ -in. rivets were used.

#### TOWER-SHOES

Satisfactory experience with this type of fabrication for the Island of Orleans Bridge, together with the fact that the contractor possessed complete and modern facilities (including stress-relieving furnaces of adequate size) for such work, led the engineers to adopt without hesitation an all-welded construction for the base-pedestals of the towers, although these members are considerably heavier than were those of the earlier bridge.

The tower-shoe (seen in Figs. 32 and 35) is built up entirely of heavy plates of medium steel. In plan it is shaped to conform with the outline of the base of the column, its overall dimensions being 23 ft. 7 in. and 12 ft. 1 in. The top and bottom slabs which provide the bearing-surfaces are respectively  $1\frac{1}{4}$  and  $1\frac{1}{2}$  in. thick after machining, the former being smooth and the latter rough-planed. The bottom slab is horizontal, to rest on the dressed concrete, while the top slab is inclined to match the 1-in-24 batter of the tower-leg. The central depth of the shoe is

Fig. 36—Main saddle.

2 ft. 6 in. The slabs each consist of three sections (corresponding with the core and wings of the tower-column) which are heavily butt-welded together, and openings are provided in the top slab for access during fabrication.

Separating the bearing-slabs is a series of transverse and longitudinal vertical webs of mild steel. Of these, the heavier ones (2 in. thick) supply direct support under the main material of the column; while lighter ones ( $1\frac{1}{2}$  in. thick) function as subsidiary supports and as stiffeners for the former. Semi-circular drain-holes, 2 inches in diameter, are cut at the bases of the webs to prevent accumulation of water inside the member. The shoe is fabricated with  $\frac{1}{2}$ -in. fillet welds throughout (apart from the heavier welding of the butt-joints to which reference has been made) and the whole assembly was stress-relieved before bearing-surfaces were planed. The weight of each shoe is 18 tons.

The tower-column is riveted to the shoe with fifty-two  $\frac{7}{8}$ -in. rivets and sixty-two  $1\frac{1}{4}$ -in. rivets to resist wind-loads during erection, and the shoe is anchored to the pier by twelve  $2\frac{1}{2}$ -in. bolts 18 ft. 6 in. long and twenty  $1\frac{1}{2}$ -in. bolts 9 ft. long. The anchors functioned during erection only: under working-conditions there is no uplift.

The cable-saddles for the towers are also all-welded. The bearing-surface for the strands is a billet of medium steel 19 in. wide,  $9\frac{1}{2}$  in. deep, and approximately 10 ft. long. Its top surface is at the level of the centre-line of the cable, and is curved to a radius of 10 ft. 4 in. The billet is machined out to receive the lower half of the cable, and the bottom and sides of the cut are grooved to seat the individual strands (Fig. 36). The billet is supported from a base-plate (2 in. thick and of the same plan as the top of the tower-column) by two main longitudinal webs 2 in. thick and battered inwards to give lateral stability: five transverse 2-in. webs are also provided (Fig. 61). Continuous  $\frac{1}{2}$ -in. fillet-welds are employed except in the connections of the main webs to the base-slab and to the saddle forging, those joints being made with  $\frac{5}{8}$ -in. continuous reinforced fillet-welds. There are no caps (such as are necessary at the cable-bent saddles) for the main saddles since the frictional component of the cable-reaction suffices to prevent slipping; but six "keepers" are provided to obviate the possibility of the upper strands of the cable being displaced from any cause. Each saddle is secured to the tower by thirty-four  $1\frac{1}{4}$ -in. rivets, and each assembly weighs six tons.

#### FINIALS AND AERIAL-BEACON SUPPORTS

Three purposes are served by the finials which surmount the tops of the main-tower columns. Weatherproof protection is afforded to the important saddle-and-cable assembly; a satisfactory architectural termination is provided for the tower-column; and the aesthetically-awkward conjunction of the slender tensile lines of the cable with the comparatively heavy profile of the post itself is adequately masked.

The column-finial, seen in detail in Fig. 37 and as part of the tower-assembly in Fig. 72, is a light welded box of simple outline, fabricated from  $\frac{1}{4}$ -in. mild steel. The top plate is curved to a radius struck from the centre of the saddle-curve, and the planes of the end plates through which the cable passes are normal to the respective cable-tangents. The open bottom of the "box" fits neatly over the saddle-base, and the outline of the core-section of the tower is continued to form a buttress on either side of the finial.

The finial stands six ft. high above the top of the column, and has a door that gives access from the top strut of the tower. Zinc flashings with painted canvas gaskets are provided at the points of entrance of the cable. The weight of each of the four finials is 2,900 lb.

In accordance with a requirement of the Department of Transport, aerial-obstruction beacons were placed on the tops of the towers. To elevate the lights above the top of the finials, a structural-steel support, 13 ft. 6 in. high (weight 1,100 lb.), and comprising a small platform carried on an A-frame made of two light stairs, is riveted to the crown strut of each tower (Fig. 32).

Fig. 37—Finial over main saddle.

The towers, each containing some 1,000 tons of steel, were fabricated by Dominion Bridge Company. The welded saddles and bases, together with the three lower sections of each column (Fig. 32), were made up in Lachine, but the greater part of the fabrication was done in Vancouver; the company's Burnaby shops were supplied with a detailed programme of the operations entailed, and the major machinery was overhauled prior to the start of work.

In view of the importance of precise alignment of the tower-columns to ensure their verticality when erected, great care was taken in the fabrication of the 112 pieces (not including bracing and struts) involved. Facing of material was done with the utmost precision and every joint was shop-assembled for checking and for reaming splice-holes. In the course of joint-assembly at Burnaby, some difficulty was encountered owing to "growth" of the main angles of the wing-sections (which had been assembled and milled with the core-sections) relative to the core material, during riveting. The growth, partly due to temperature-variations in the shop and partly the effect of riveting, did not, however, exceed a few thousandths of an inch, and was rectified by filing the angles flush where necessary. That the accuracy achieved in the shop-work was of a very high order was borne out by the subsequent speed and facility of erection.

The length of the tower-columns as detailed and fabricated was  $1\frac{5}{16}$ -in. longer than the theoretical, that amount representing the normal compressive strain when in service. The long and relatively light braces, however, were built to uncambered dimensions, and their assembly under the necessary slight tension presented no difficulty.

An interesting feature of the lower sections of the towers is that the contractor obtained from the engineers permission to use cold-driven rivets. This was the first use of this comparatively new process on major bridge-work in Canada, and it was successful in all particulars.

#### NORTH CABLE-BENT

This structure serves the dual purpose of supporting the cables and the suspended-span bearings at the end of the

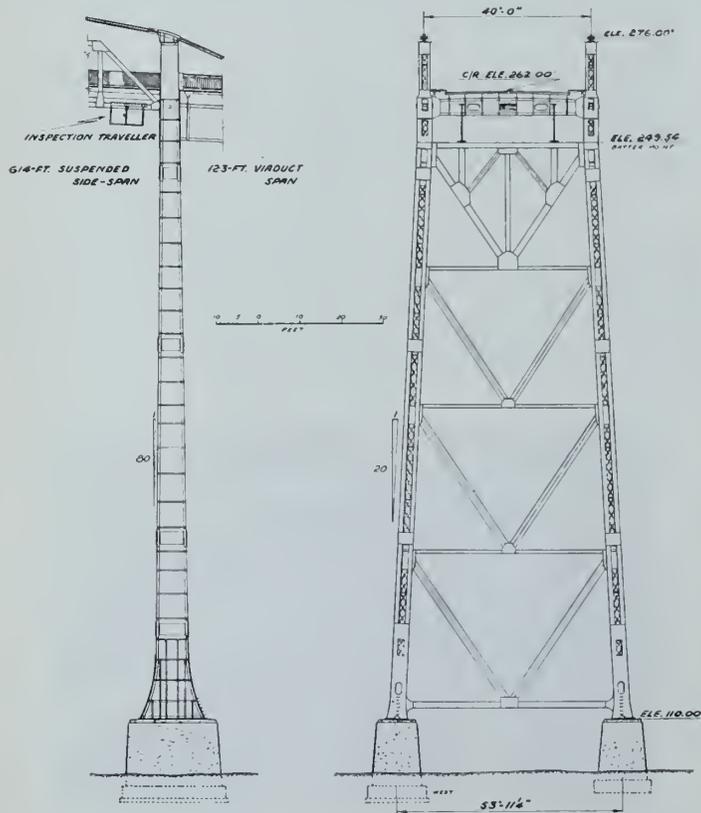

Fig. 38—Cable-bent.

side-span, and of providing bearing for the expansion-end of the most southerly of the approach-spans. Support for the cables is required at this point in order to deflect them towards the anchorage at a slope approximating to the maximum inclination already established near the tower-saddles.

The cable-bent (Fig. 38) has a height of 166 ft. from the pedestal-concrete to the cable-intersection. Below the level of the approach-span bearings, the two columns are connected by lateral K-bracing (harmonizing with that of the viaduct-bents), and are battered at a slope of 1 in 20, that batter being selected as midway between the 1-in-24 of the tower-legs and the 1-in-16 of the viaduct-columns. Above that level, however, the columns are vertical and 40 ft. apart centre to centre, the final 12 ft. of each column being self-supporting.

Two load-bearing cross-struts (Fig. 39) are provided. The lower of these receives the heavy reactions (amounting to 246 kips from each girder under full load) from the 123-ft. viaduct-span, and is stiffened by incorporation into a truss-system which includes the upper members of the K-bracing. The upper strut, situated below the roadway, functions as an end-floorbeam for the suspended span and also supports the vertical pin which receives the wind-reaction of the suspended span. The upper strut has substantial connections to the columns, designed to resist lateral forces from the cable-saddles.

The lower chords of the stiffening-trusses are each pin-connected to a pair of bronze slabs which can slide horizontally (the end of the span rotating about the wind-pin) inside the column of the cable-bent. The ends of the trusses are thus free to move to accommodate both vertical and horizontal rotations of the span, though they are restrained against vertical movements. The reaction at either pin may range between a maximum of 95 kips and a minimum of -77 kips. Movements of the end-stringers of the side-span are permitted by sliding shoes on the floorbeam-strut.

The cable-bent saddles, like the main saddles, are of all-welded construction and are rigidly attached to the supporting columns. Subjected to much smaller loads (the maximum reaction to one saddle is 1,463 kips) however, they are smaller than the tower-saddles, the overall size of the  $1\frac{1}{2}$ -in. base-plate being 4 ft. 1 in. by 3 ft. 6 ins., and the length of the grooved billet being 5 ft. 2 in. In order to prevent slipping of the cables and consequent forward-movement of the bent (the reaction-friction being insufficient for that purpose, on account of the relatively small change in cable-direction), the saddles are equipped with heavy curved covers which are bolted down with sixteen  $1\frac{1}{4}$ -in. high-tensile bolts each. The complete saddle weighs three tons, and is shown in Fig. 66. (Part IV.)

Each of the two cable-bent columns is composed of a pair of plate-girder sections braaced together by two planes of heavy latticing, the lattice-bars being connected to four longitudinal angles, two of which are riveted to the inside of each main web. The girders are spaced 2 ft. 8 in. apart throughout; and the distance between latticing-planes is 3 ft. The width of the girders, which is presented in a side-view in Fig. 38, increases (with side-batters of 1 in 80) from 4 ft. under the cable-saddle to 7 ft. 8  $\frac{1}{2}$  in. at the top of a basal flare that is modelled from the formula used for the viaduct-columns. The sectional area of the column varies from 121 sq. in. at the top to 299 sq. in. at the base. Horizontal diaphragms are located at approximately 6-ft. intervals throughout the length of the column, and each is flanked by a pair of stiffening-angles on the outsides of the main webs. The outstanding legs of the stiffeners are dished to facilitate drainage. The central space of the column is uninterrupted except where the truss-bearings are housed, and contains an inspection ladder, access to which is gained from the ground or from the roadway. Other ladders, and platforms, are provided for inspection of the various articulated connections. Each column bears on a steel slab 16 ft. 6 in. by 5 ft. in extent and planed to

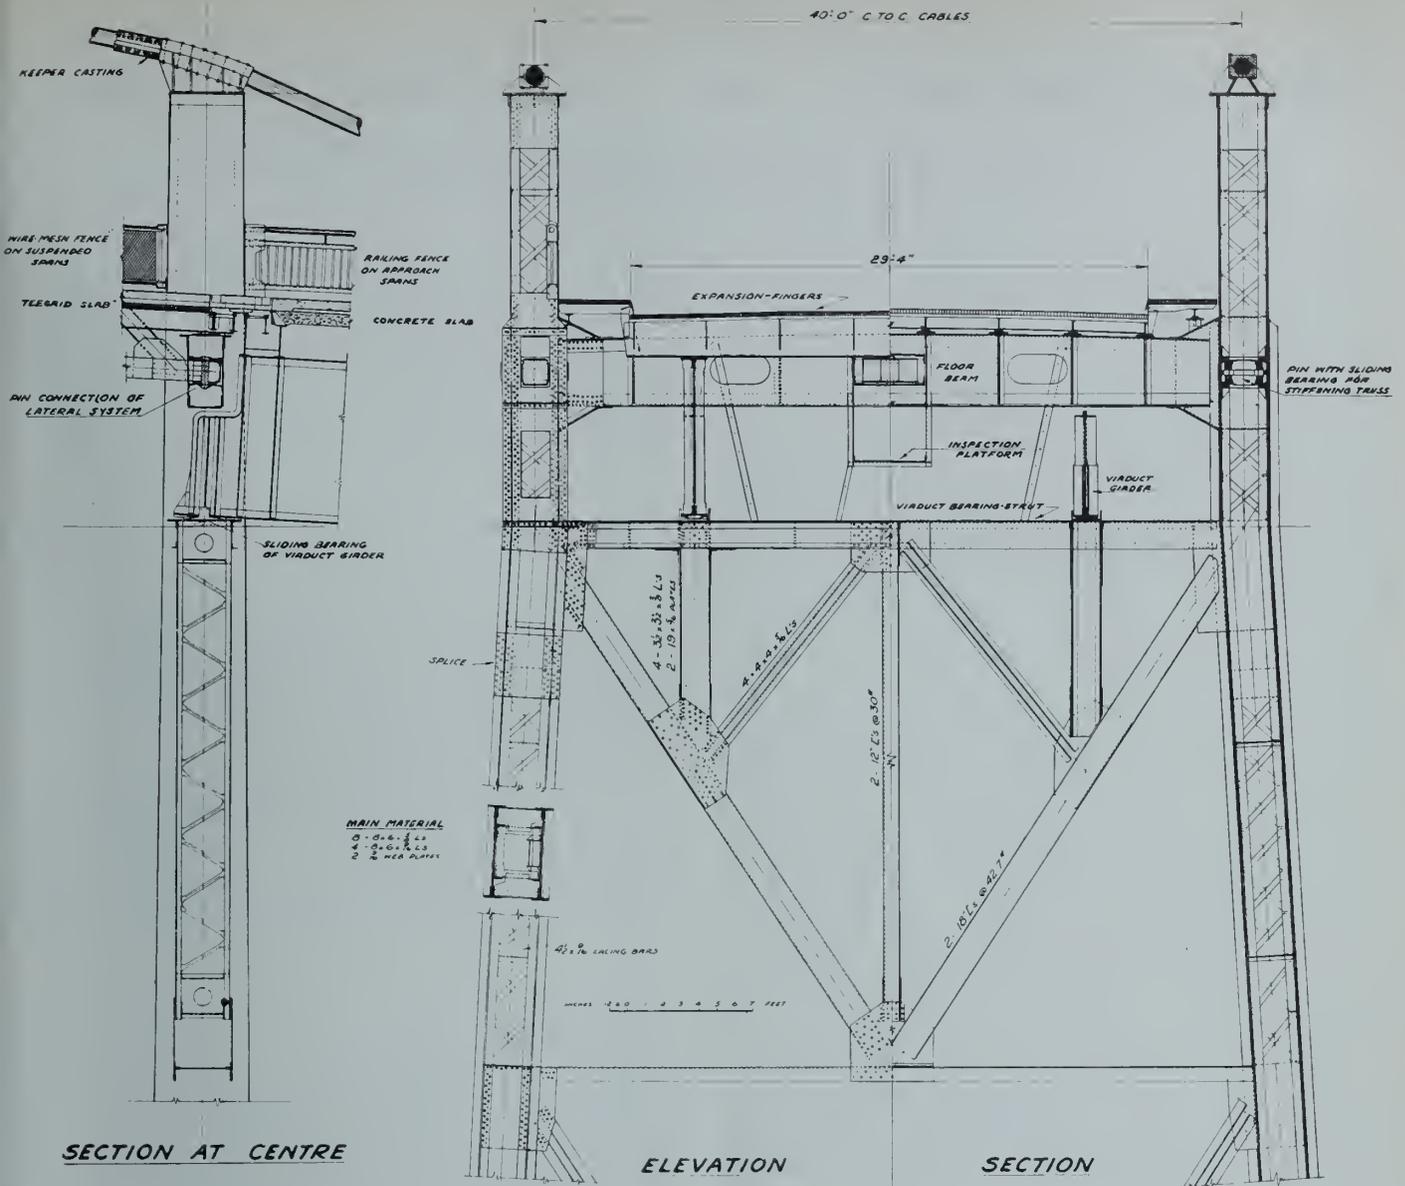

Fig. 39—Cable-bent: detail of upper part.

the appropriate batter from an original thickness of  $4\frac{1}{2}$  in. The column is anchored by sixteen  $1\frac{1}{2}$ -in. anchor-bolts. There is no uplift of any part of the base under service-conditions.

The cable-bent, fixed at the base and subjected to known loadings simultaneously with known saddle-movements, is susceptible to the same analytical process of design as the tower. Saddle-movements, being influenced by the backstay-length alone, are small, the range of movement being  $5\frac{1}{2}$  in. from normal. Loading-conditions, on the other hand, are more complicated, owing to the presence of the sliding-bearings of the approach-girders, and to the horizontal friction-force developed by these under the influence of expansion-movements. The governing case of loading for the lower part of the posts is that due to D.N.T.W.; while, for the upper part, the same loading, but with the addition of the frictional force due to contraction of the girders, produced the worst stresses. For the former case, the basic unit-stresses were increased by 15 per cent; and for the latter, by 25 per cent.

The material is medium steel, and permissible stresses were similar to those for the tower, the compression-formula being adapted to suit the shorter length of the column.

The cable-bent was fabricated at Burnaby, and was joint-assembled for reaming the connection-holes. The planing of the base-slabs from  $4\frac{1}{2}$  in. to a thickness varying from 4 in. to 1 in. proved a costly procedure, but it is doubtful whether alternative base-details could ensure equally efficient bearing for these important members.

#### SOUTH CABLE-POSTS

At the south end of the bridge the cables are deflected to the backstay-gradient by means of saddles carried on short rocker-posts which bear on a pedestal in front of the anchorage-pier. The cable-reaction to each post amounts to 1,234 kips under the severest loading-conditions. The post is inclined (at 17 deg.) in order to equalize the tension on either side of the saddle, and thus there is no need for special anchoring of the cable such as is essential at the vertical cable-bent. The small cable-movements at the saddle, due to changes in the backstay-length of 68 ft., are accommodated by the 6-in. pin at the foot of the post. The cable-saddle, (Fig. 67), which, like the other saddles, is weld-built, is a relatively small structure, the size of its 1-in. base-plate being 2 ft. 2 in. by 2 ft.  $2\frac{1}{2}$  in. Together with its cast-iron cover, which is protective only and does not bear on the strands, its weight is 1,600 lb.

EDITOR'S NOTE:—Part III of this paper will appear in the June issue.

# DISCUSSION ON THE MANUFACTURE OF THE 25-POUNDER IN CANADA

Paper by W. F. Drysdale<sup>1</sup>, M.E.I.C., published in *The Engineering Journal*, January, 1942, and presented before the General Professional Meeting of The Engineering Institute of Canada, at Montreal, Que., on February 5th, 1942.

W. D. BLACK,<sup>2</sup> M.E.I.C.

A mechanical analysis such as Mr. Drysdale's on the 25-pounder gun is both timely and significant. It points to the fact that engineering in Canada has entered a new phase in its development.

History and Hitler have brought about an era when the first requisite of Canadian life is a virtually unlimited supply of complicated mechanisms, lethal and otherwise. The day of the mechanical engineer has arrived. The fourteen acre plant at Sorel producing 25-pounders is one of many huge new establishments in which the engineering problems to be solved are almost exclusively of a mechanical nature.

It is to be noted, however, that gun designers are largely guided by military and ballistic considerations in originating ordnance. Such study as is devoted to speed and facility of production (there is undoubtedly some) is a secondary consideration. This can be seen by comparing the component parts of any considerable artillery piece with those of a commercial mechanism designed for quantity production. The complexity, and, from an operational viewpoint, the greater all-round difficulty of the gun parts are immediately apparent. Further, there is the fact that, due to the high stresses to be provided for, the use of materials having high physical properties beyond the range of ordinary commercial machine shop practice is necessary. If the gun is of an automatic type, the permissible manufacturing tolerances for much of the assembly will be such as to demand the best of any commercial shop, however well-equipped and manned it may be. These are some of the difficulties connected with the problem of producing modern guns with the available equipment and with labour that may be ninety per cent lacking in any previous mechanical training, as was the case at Sorel.

In his final paragraphs, the author alludes to some aspects of the Sorel project that are not, in the technical sense, engineering matters. But, to-day, such questions as employee training, housing hostels, morale, and other human factors have to be dealt with. It is regrettable that Mr. Drysdale could not take the additional space to enlarge somewhat on these important problems, as encountered at Sorel. We may hope that he will take a future occasion to do so, for the size, success and peculiar circumstances of the project would render such a discussion of exceptional interest.

It is a matter of common report that the housing provided at Sorel is of a high standard. Some description of this would have been of interest to many, like myself, who feel much of our wartime housing, designed on the assumption that it is entirely temporary in character, will in fact have to be used for a long period. If the occupants of this housing are to be dispossessed after the war, other accommodation must be found for them. There is nothing to indicate that the field of low cost housing will be any more attractive to private enterprise after this war than it was previously. Consequently, the betterment of mass housing which must ultimately come, will prob-

ably have to be undertaken on a community basis. Without criticizing the excellent work done under great pressure by the Wartime Housing Board, I am of the opinion that, at least in the cities, our wartime housing should be recognized and accepted as permanent and designed accordingly. For this reason information concerning the housing provision made at Sorel would be of exceptional interest.

At this time it seems impossible to plan any large scale manufacturing project apart from the personnel and labour relations problems which it involves. When we consider the peculiar circumstances of Sorel Industries, with its bi-racial and bi-lingual problems, its importation of supervisory personnel and the almost complete absence of local skilled labour, we may safely assume that personnel and employee relations required a high degree of judgment and discretion. I, for one, should certainly like to hear more of this phase.

Employee training is another element of war industry that must have been of exceptional consequence in the production of the 25-pounder. Behind the author's brief intimation that not more than ten per cent of employees had previous mechanical training, there must lie a story of employee training under emergency conditions. Let us hope we may have a future opportunity of hearing it.

JAMES CRONE<sup>3</sup>

It is a great pleasure to receive an invitation from your Institute to join in this discussion. It gives me an opportunity to extend hearty greetings as a member of the Institution of Mechanical Engineers of the United Kingdom. Having had a fairly long experience connected with armament production, I would like to state how proud I am to be associated with the progress that has been made in Canada, generally, with particular reference to Sorel. Mr. Drysdale's paper, so ably presented, is a full record of a great Canadian accomplishment. May I pass a few general remarks, which, although not directly concerned with the production of 25-pounder equipment, are applicable to such a project.

The manufacture of a gun and carriage has always been regarded as embracing work requiring the highest technical skill. In times of peace we, in the Old Country, have always had available a plentiful supply of highly skilled mechanics. It has been very illuminating to help in this case of successful production of high class equipment by practically unskilled labour. That success has been due to very efficient jiggging and tooling, whereby complicated machining operations are reduced to those of a repetition nature, and here I will stress the point referred to by the author, viz:—that something in the region of 90 per cent of the workers at Sorel were unskilled and now can probably be classed as semi-skilled. The aptitude with which these employees have learned to perform intricate operations is creditable and speaks highly for Canadian initiative, and enterprise, and, in this connection, tribute must be paid to the great Canadian family of the Simards, particularly to my good friends, Messrs. Joe and Edouard Simard, without whose initiative the Sorel plant would not exist.

<sup>3</sup>Special Adviser to the Minister, Department of Munitions and Supply, Ottawa, Ont.

<sup>1</sup>Director-General of Industrial Planning, Department of Munitions and Supply, Ottawa, Ont.

<sup>2</sup>President, Otis-Fensom Elevator Co. Ltd., Hamilton, Ont.

The author has drawn attention to the hearty co-operation and efficient service given to this development by the Chrysler Corporation, who have, to a great extent, introduced automobile production methods in gun and carriage manufacture. This is particularly noticeable in the arrangement of the machine tools in the shops. Each major component has its own special machine tools allocated and congregated around the production of that component. This method of layout is perfectly correct and leads to efficiency in cases where, as at Sorel, a particular equipment is being manufactured in large quantities, but is not so suitable in a plant engaged on work of a general nature. Having been trained and associated with shops of the latter class it has been very pleasing to note the increase in efficiency resulting from the system adopted at Sorel. Although a large office technical personnel is required, the ultimate cost production figures will justify the methods that have been introduced. After all, the test is in the number of guns on the assembly line and this line is daily increasing in length.

There is no doubt that the introduction of this and other work of a similar nature will improve manufacturing technique in Canada. Such was undoubtedly the case in the Old Country after the last war. Changes in production methods in the general engineering industry are taking place due to the efforts of the automobile, aircraft and other similar industries. The old-fashioned ideas, practised in general engineering, are now giving way to ideas based essentially on mass production practice.

To maintain position in the markets of the world economic production is a necessity and production, without system, will not attain cheap manufacture. To take an example, consider the many firms here and elsewhere which have been built up on the production of specialties. A firm of this type, if successful and in operation for a number of years, finds itself in the position of having a minimum number of executives and an efficient workshop staff who, in many cases, can be classed as the equivalent of working foremen. The development staff is neglected and dwindles in numbers, which fact becomes very apparent when a new proposition is submitted for the firm's consideration. Without labouring this point I would sum up by pointing out the danger of such a state of things and stress the importance both of the maintenance of a full engineering staff, capable of tackling any class of manufacture, suitable for the plant, and also the necessity for the introduction of system methods to effect cheap manufacture.

COLONEL F. M. GAUDET,<sup>4</sup> M.E.I.C.

Will the author add to the value of his interesting paper by giving information on the following points:—

- (1) What is the life of the inner tube in rounds?
- (2) What is the action of the recuperator.
- (3) What are the physical properties of the steel in the finished inner tube?
- (4) Describe the heat treatment and normalizing of the steel.
- (5) Describe the sighting arrangements of the gun, and the range of elevation provided.
- (6) What is the rate of fire?

CHESTER B. HAMILTON, JR.,<sup>5</sup> M.E.I.C.

I should like to ask for a little more explanation on the application of the straight line production method—the use of specific machines for specific operations on only one kind of part as it moves along. With a production of only fifty units per month, or about one per twelve-hour

shift, this arrangement is not at all easy for the many short operations. How is it accomplished without idle machine intervals or much changing over of machines from one operation and set of jigs to another different set up.

COLONEL J. B. HOWARD<sup>6</sup>

There appears to be little to add to Mr. Drysdale's paper. With characteristic modesty, however, he has not mentioned the part he and his associates of the Department of Munitions and Supply, and of the Ministry of Supply in England, have had in bringing about this important achievement.

It may be that the difficulties involved in initiating gun and carriage manufacture in Canada are not realized by those who have not been concerned with that phase of armament manufacture. The most exacting material specifications must be met, to begin with. These specifications were, in many cases, based on British materials and practice; consequently, materials to meet them had to be specially produced, or alternatively, the specification amended to permit the use of what was available here.

On the machining side, close tolerances must be maintained to ensure satisfactory performance of the weapons. Any laxity in this respect can only lead to functioning failure.

Mr. Drysdale has mentioned the advantages of the loose barrel type of gun construction as compared to the wire-wound guns. In the former case, the allowable clearance between the exterior of the barrel and the interior of the jacket is very small, since the latter takes up part of the firing stresses. This entails precise finishing of that part of the barrel inside the jacket. This finish was unnecessary with wire-wound or built-up guns.

Many other difficulties were encountered, the details of which are probably of less interest. The fact that they have all been met successfully is a tribute to the teamwork shown by all who had to do with this project.

As far as quality is concerned, it is certain that the guns and carriages which reach the service from the hands of our French-speaking Canadian workmen of Sorel are fully up to standard, and wherever they meet the enemy, they will give a good account of themselves.

J. G. NOTMAN,<sup>7</sup> M.E.I.C.

Mr. Drysdale in his paper mentions the fact that the barrels of 25-pounder guns made from steel having a yield point in the neighbourhood of 40 to 45 long tons per sq. in. are auto-frettagged. I heard this word during the early months of the war and my curiosity was aroused when our firm, Dominion Engineering Works, Limited, was called upon to make up the intensifiers for converting triplex pump pressure into the necessary pressures for auto-frettage work.

It is known that pressure in the internal bore of heavy walled cylinders will set up stresses in the walls, having their maximum intensity in the innermost layers and gradually reducing towards the outside, and that when pressure is applied which will exert in the innermost layers stresses beyond the elastic limit of the material that is being used, the mere addition of extra thickness does not help. Therefore, one of three alternative methods must be adopted: either the built-up method, where one tube is shrunk on to another, or wire-winding, or auto-frettage.

Auto-frettage may be defined in general terms as the process of automatically setting up the effects of shrinking a number of infinitely thin hoops on one another to make

<sup>4</sup>Deputy Inspector General, (Canada).

<sup>7</sup>Manager of Manufacturing, Dominion Engineering Works, Limited, Montreal, Que.

<sup>5</sup>Canadian Car Munitions Limited, Montreal, Que.

<sup>6</sup>President, Hamilton Gear and Machine Company, Toronto, Ont.

up the wall thickness of a cylinder or tube in such a manner that when the internal pressure is removed the inner layers are in a state of residual compression and the outer layers in a state of residual tension. These effects are produced in a monobloc cylinder or tube by the application and release of a radial pressure (auto-frettage pressure) on the bore, which pressure during its application sets up over-tension in some or all of the layers in the wall.

Each layer of steel from the bore to the exterior being subjected to tensile stress set up by the radial bore pressure will behave in accordance with the stress-strain relationship of the class of steel used, that is, as the internal pressure applied increases continuously from zero, the bore layer will, in turn, be stressed in the elastic range through the slip and yield ranges into the semi-plastic range. The layer next to the bore layer will in its turn be stressed in these ranges but here the permanent deformations will be less than in the bore layer. Layers in sequence more remote from the bore will be over-tensioned to graduated lesser degrees until a layer or diameter is reached where the stress set up is just equal to the elastic limit of the steel. Layers more remote from the bore than this particular layer will be stressed in the elastic range of the steel.

When the auto-frettage pressure is removed the steel in the inner layers is left in a state of residual compression while the outer layers are in tension, and show some residual expansion.

In the auto-frettage process, 0.025 strain of the bore layer under load has been considered the limit for the manufacture of guns, closed vessels, etc. The selection of this degree of over-tension was also made from consideration of impact qualities which were practically unaltered after 2.5 per cent over-tension, whereas after a greater over-tension they were markedly lowered.

Formulae have been developed which enable radial pressures, stresses and strains set up at any diameter in the wall of a monobloc steel cylinder to be determined within a limit under load of 0.025 strain at the bore.

To produce stability, low temperature heat treatment is a part of the auto-frettage process. In general, the effect of low temperature treatment on a cylinder which has been subjected to auto-frettage pressure is to increase the elastic limit of the material.

In the application of the auto-frettage process to gun construction, three gun steels have been considered: nickel, nickel-chromium and nickel-chromium-molybdenum.

Cylinder experiments show that provided the compressive stress in the bore layer after the first auto-frettage does not exceed 15 tons per sq. in., one low temperature treatment in producing new tensile elastic limits and restoring compressive elastic limits insures that the cylinder is elastic for a bore pressure equal to the auto-frettage pressure.

If the compression is between 15 and 20 tons per sq. in. after the first auto-frettage, the first low temperature treatment must be followed by reapplication of the pressure equal to the auto-frettage pressure and a second low temperature treatment.

If a second application of auto-frettage pressure and second low temperature treatment does not produce stability for this pressure, the requisite elastic strain range must be obtained by subsequent applications of the auto-frettage pressure and low temperature treatments.

If for any practical reason it is necessary to remove metal from the bore of the stabilized cylinder or tube, the requisite treatments must be based on the compression in the finished bore.

The test for stability is the reapplication of a pressure

equal to the auto-frettage pressure. If the cylinder or tube is stable (a) the pressure expansion curve of the exterior of the cylinder is a straight line graph, (b) the expansion of the exterior diameter is the same each time the pressure is applied, (c) there is no alteration in the bore or exterior diameters as shown by measurements taken before and after test.

Low temperature heat treatments are carried out at temperatures ranging from 250 degrees C. to 400 degrees C., allowing a soaking time of two hours after the piece is up to heat.

Commercial glycerine has been found to be the most suitable liquid for applying auto-frettage pressure. At pressure of 42 long tons per sq. in., the compressibility of glycerine is approximately 10.7 per cent.

I am indebted to Major General A. E. Macrae and to his book for such limited knowledge as I may have of the subject.

P. E. POITRAS,<sup>8</sup> M.E.I.C.

The subject treated by Mr. Drysdale is of great interest to all engineers—and in particular to industrial engineers.

Of the many recent developments mentioned by him, one of the most notable is the auto-frettage of the gun barrel. By this operation the metal is pre-stressed so that in action the strain of the explosion is distributed over the entire cross section of the barrel.

By this auto-frettage operation, the manufacture of a gun barrel shows important economics in time, labour, and materials, and the use of single forgings. Furthermore, the increased elastic strength enables the weight of the piece to be reduced, thus offering greater mobility for a given service.

The recuperator is an important component of the gun that requires very accurate machining and specialized workmen for its fabrication. A brief description of the hydraulic principle used in the recuperator would be appreciated.

Noting the author's remarks about the distribution of work to different sub-contractors for the manufacture of some 700 different components, was it really necessary to have a Rolling Mill installation in Sorel Industries? Saving in waste of crop ends from the ingots and the ability to get at wish stock bars for bolts, studs and small forgings must have been the dominant points in the recommendation of such an installation. Would Mr. Drysdale give us some information on the size and capacity of the projected Rolling Mill installation?

Thanks are due to him for his tribute to the French-speaking Canadians of Sorel who, like all other Canadians, will never shirk their responsibilities, and will always answer the call of their country.

HAROLD J. ROAST,<sup>9</sup> M.E.I.C.

The author should be complimented on the clarity of his presentation and the pertinence of his illustrations. Undoubtedly the Sorel people have done a marvellous job in this connection and their success is a tribute to the 85 per cent of labour which was French-Canadian, and 75 per cent of which had had no mechanical training beforehand.

In the ramifications brought about by distributing work to the 80 sub-contractors, I am glad to know that in a very modest way I was able to assist the production of gun parts in one plant as their consulting metallurgical adviser.

<sup>8</sup>Mechanical Engineer, The Steel Company of Canada, Limited, Montreal, Que.

<sup>9</sup>Vice-President, Canadian Bronze Company, Limited, Montreal, Que.

The opportunity of discussing Mr. Drysdale's excellent paper is particularly appreciated by me as I am now connected with an ammunition filling project which produces the finished ammunition for this particular gun. The paper points out that actual operational work had to be performed by untrained labour on very fine machine tools to the limit of accuracy which the machines are capable of producing. This somewhat paradoxical condition had to be faced by training the labour available and providing the necessary jigs and gauges to ensure the accuracy and speed of production required. Mr. Drysdale has been very modest in his treatment of this phase of the Sorel operation.

In an operation of this kind, the rapid assembly of such a fine piece of precision equipment as a gun, it is necessary that the accuracy of preceding machining operations is assured. It should be remembered that the designer of the gun has decided on the type of fit which any two mating parts require, which fits may be push, drive, running or shrinkage and each type of fit has its own definite clearance. It should also be remembered that it is practically impossible to turn or bore a piece to mathematically correct dimensions so that the machined parts must be gauged by limit gauges. These consist of—

Snap gauges for outside diameter checking.

Plug gauges for inside diameter checking.

Thread gauges, both internal and external, for sizing.

Thread gauges for form (usually now checked by comparators).

Receiver gauges for locating a number of holes in different planes in a machined forging or casting.

Length, ring, profile, depth and many other types.

The material to be assembled is checked by the British inspectors, whose gauges are set to the limits shown on the drawings; it follows that the manufacturers' gauges must be set to even closer limits in order that the individual parts will pass the final British inspection.

When the Sorel plant was first started I was concerned with the manufacture of several hundred snap and plug gauges for use in the gun shops, which gauges, of course, had very small differences between the "go" and "no-go" dimensions; that is the tolerances of the parts gauged were very close. Thus the dimensions of the "go" and "no-go" gauges themselves had to be held within much narrower limits, the permissible error in the gauges being of the order of approximately .0001 inch. Before these gauges could be used they had to be checked by the standards of the National Research Council at Ottawa.

When it is considered that each gun has such a large number of pieces and that each piece may require as many as a dozen different types of gauges, the magnitude of the task is evident.

Anyone associated with the production of large quantities of parts to very close dimensions will fully understand the difficulties which can well be encountered if proper gauges and jig facilities are lacking. The management of Sorel and its associate, The Chrysler Corporation are to be commended for the splendid manner in which they jointly have mastered the situation.

#### THE AUTHOR

The mechanical engineering of manufacture began to develop in Canada about forty years ago. The majority of our designs had to be imported and also the mechanics to carry out the instructions contained in the specifications. There were exceptions, but at that time most large engine, electrical, mining and other machinery

<sup>10</sup>Executive Assistant to General Manager, Canadian Car Munitions Limited, Cherrier, Que.

manufacturers dealt chiefly with the replacement and repair of imported parts; apart from certain types of slow reciprocating engines, locomotives, marine reciprocating engines, very little original design and manufacture was done in Canada. With the advent of hydro electric power, and the motor car, and the use of internal combustion engines, a limited programme began, and it was to the nucleus of mechanical engineers then starting that we went when, in World War I, we undertook to make shells, cartridge cases, and fuses. Canada then found herself as a manufacturing nation. Development was rapid in the twenties, but came to an abrupt stop which lasted through the thirties.

When World War II started a certain amount of preparatory work was commenced. However, in May, 1940, an intensified programme of manufacture of aerial bombs, aeroplanes, and guns was started. This period is the cycle of Canadian engineering to which Mr. Black refers. Two large operations on shell and guns were soon underway, largely due to the initiative of certain manufacturers who anticipated a demand which came in volume many months after they started.

When a demand came for skilled help at Sorel, employee training received attention. Night classes were started and elementary training in use of chisel and hammer, filing, scraping and surfacing, reading drawings, were given in the shops. Elementary as this was it helped to familiarize the youths with the general idea of the handling and processing of metal. From then on progress has been rapid and we have developed and trained a large percentage of our skilled and semi-skilled help.

Housing was a serious problem from the start, and will continue to be as the work expands. A separate and interesting paper could be prepared on that alone. Briefly it may be said that the management, in close co-operation with the Government, decided to provide accommodations of three classes:

1. Single men's accommodation,
2. Married men's accommodation,
3. Inspectors' accommodation.

Old warehouses were converted, new extensions made to existing facilities, and new structures with communal dining accommodations were provided, so that 2,500 men and their families could be accommodated in existing and recently constructed buildings.

It did not make matters easier when we had to bring skilled English-speaking help, into an area where French only had been spoken for many years.

The cottages put up in a plot adjoining the city are of a type, which although low in cost, are intended for permanent occupancy; and as Sorel is located in a strategic commercial situation, we have every reason to believe that after the war is over these buildings will not only be used, but will, in the meantime, have set a style which will, if emulated, raise the standard in adjoining parts, and emphasize the importance to health and happiness of ample air, small garden plots, and sanitation.

The management has made a point of giving talks to the workers, with an occasional party. The various contacts of the Simard Brothers with their help have been close and democratic. The good relations established over many years between Protestants and Catholics remain excellent, and we trust this will set a good example to other similar localities in building up a united community truly Canadian in the broadest sense.

Mr. Crone has been of inestimable value in the Sorel effort. Having a lifetime of experience in armament manufacture, he has encouraged us from the start. It is a great satisfaction to know that his confidence was well placed and that we have been able to deliver the goods. We reached and exceeded our production goal this month of February, 1942.

Answering Colonel Gaudet's questions:

(1) The normal life of an inner tube varies between 2500 and 3000 rounds, this, however, depends entirely on the rate of fire, and varies according to the charge being used.

(2) The object of the recuperator is to control the recoil of the gun when fired. In a 25-pdr. gun the recuperator is provided with four bores—air cylinder, buffer cylinder, recuperator cylinder and the storage tank, which is also a cylinder designed to receive the recoil dampening liquid when the gun is fired. The recuperator block is submitted to a hydraulic pressure test. Test pressures on the various cylinders range from 3000 to 5000 lb. per sq. in., except for the storage tank which is only tested to 40 lb. per sq. in. The buffer cylinder is rifled, the grooves having a slight helix angle, and serving to operate the valve mechanisms.

(3) Cannot answer.

(4) Taking barrels for example. After forging, these are normalized. They are then rough turned and bored, following which they are heat treated and annealed. The barrels are then machined for auto-frettage. After auto-frettage they are submitted to a low temperature treatment. This completes the heat treating operation.

(5) Cannot answer.

(6) Cannot answer.

Referring to Mr. Hamilton's query as to lining up specific machines for specific operations on a single component. I may say that when laying out the machining operations a ten-hour, two shift basis was established.

In selecting the machine tools required for the different operations the actual machining times were so broken down that each machine is fully occupied. Where several identical operations are involved the work returns to the same machine twice and in certain cases, three times.

For instance, in machining the breech block, the first operation is a milling operation requiring a vertical milling machine, the second a grinding operation, the third a lathe operation, the fourth a milling operation on a horizontal miller. The fifth operation is a further milling operation executed on the same vertical milling machine as the first milling operation. The sixth is a plano-milling operation and the seventh a further milling operation requiring a vertical miller so that the work returns to the first machine for the third time.

The machines have, of course, been laid down in sequence of their operations and so as to reduce handling to a minimum. Thus one can safely say that no machine is ever idle.

For the machining of the breech block there are 16 machines, at least eight of which perform more than one operation.

It is a great satisfaction to note Colonel Howard's

appreciation of the many difficulties encountered and successfully overcome.

Regarding the team work to which he refers and which enabled us to achieve success, I wish to take this opportunity of paying tribute to the wonderful co-operation of every one associated with the enterprise. By their united work and unswerving loyalty they did their best to bring the plant to early production without sacrificing quality.

The comments of Mr. Notman are well timed as the art of pre-stressing metals has not been used as much on this Continent as has been the case in Europe.

His qualitative description of auto-frettage follows substantially that of Major General A. E. Macrae's book, "Overstrain of Metals" (His Majesty's Stationery Office, 1930).

It may be of interest to know that the cost of manufacturing the twenty-five pounder gun barrel is being further reduced and production rate increased at Sorel by a concession on the part of the Government Inspection Board, who are now willing to eliminate auto-frettage provided the quality of the steel is raised to 60 tons per sq. in. yield point.

Re auto-frettage, I would call Mr. Poitras' attention to the discussion on this subject contributed by Mr. J. G. Notman, which is a clear exposé of the method enabling us to use a 40-ton steel to do the work of the more expensive and difficult 60-ton steel.

The recuperator operation has been described in answering Colonel Gaudet.

The rolling mill is a great advantage at Sorel, particularly as it enables us to speed up delivery of rounds and square bars made of special steel which is produced at Sorel. We are installing a 16 in. roll with two 3 roll stands and one 2 roll stand. Also we have in operation a 14 in. roll with one 3 roll stand.

This will enable us to reduce from an 8 in. x 8 in. billet to 1½ in. on the large roll and from 2 in. x 2 in. to ⅝ in. on the smaller roll.

The sub-contractors of Ontario and Quebec have contributed greatly to the success of Sorel's operations, saving skilled men, machines, and housing. Sub-contracting systems developed here have been used as a pattern for the enlarged Canadian sub-contracting effort.

Mr. Whitcomb has pointed out the size of the task of providing the shop gauges for the inspection of the 25-pdr. parts. What this means can more easily be appreciated when one considers that for the gun, 150 different gauges are required, and for the carriage, more than 300.

It must be further borne in mind that some of the gauges are of a complicated type, such as the gauge for checking blow and concentricity of striker, and the turn-over gauges for measuring the bore and depth of rifling. His tribute to the management will be appreciated.

# DISCUSSION ON THE JUSTIFICATION AND CONTROL OF THE LIMIT DESIGN METHOD

Paper by F. P. Shearwood,<sup>1</sup> M.E.I.C. published in *The Engineering Journal*<sup>2</sup> June, 1941.

W. P. COPP,<sup>3</sup> M.E.I.C.

It is a fact that in fabrication and erection many parts of structures are strained beyond the elastic limit. I remember in my experience of years ago certain I-beam stringers which were badly bent when used for erection purposes. They were condemned but because they were needed immediately in the permanent structure they were straightened for temporary use and placed in position. As far as I am aware they are still there, carrying the same loads as the stringers which were not damaged. However, these stringers, no doubt, would be stressed beyond their elastic limit at local points only, while, if I follow Mr. Shearwood's reasoning, the whole outer flange layers would be stressed to the elastic limit at least, if designed by the limit design method. An overload therefore would stress these outer layers beyond their elastic limit. It would be interesting to know what would be the distribution of stress on the next application of a severe load and whether a designer could compute the strains with any feeling of security under these conditions. At the end of his paper Mr. Shearwood states that the limit design method is less safely justifiable for structures supporting their full load or those subjected to severe vibration, but might properly be used to the design of structures which will probably seldom or never be loaded to their designed capacity and to those carrying an immovable load. It seems to me that for such structures the mistake is not in designing by the elastic theory but in the choice of loadings that are altogether excessive.

With respect to fatigue it is common knowledge that material will fail at stresses far below the elastic limit, after many repetitions. Except in limited cases it seems to me impossible always to restrict uniformly the strain as suggested in the paper and thus avoid fatigue failure in every part of a structure. I remember at one time observing a swing bridge in the process of being dismantled. When one of the end diagonals was cut free at its top it had not enough strength to support its own weight and failed by bending near its bottom connection, presumably from fatigue stresses set up during the years of service. At the time it seemed fortunate that there were unused paths along which the stress must have acted since it would appear evident this particular diagonal could not have functioned for some time. In a case of this kind would the limit design method result in these other paths being able to carry extra stress without serious damage?

From Mr. Shearwood's paper I gather that some members of a structure would be designed by the limit design method, while others would be designed by the elastic theory method depending upon whether or not there were portions of the members that could not be stressed fully until other parts had been overstressed. Would not this somewhat complicate the design?

For some time it has appeared to me that in many cases steel designers are excessively cautious in their choice of loadings and factor of safety, particularly in the case of static loading. It would seem that to design by the limit design method while using excessive loadings would result in many cases in members being strained elastically only

<sup>1</sup>Consulting engineer, Dominion Bridge Company, Limited, Montreal, Que.

<sup>2</sup>The paper as it appears in the June 1941 issue of the *Journal* was laid out with two galley's interchanged with the result that the continuity is badly broken. Corrected copies have been made and are available at Headquarters.

<sup>3</sup>Professor of Civil Engineering, Dalhousie University, Halifax, N.S.

since the loads used with the large factor of safety are so greatly in excess of actual conditions. The use of more practical loads and the elastic theory of design would accomplish the same end, namely saving of material.

The thanks of the Institute are due Mr. Shearwood for his paper because it represents a real effort to avoid a waste of material by suggesting a line of study and research to that end. No doubt models could be made and tested by modern methods to show the stresses and strains suggested in the paper. The fact that an engineer with the experience and prestige of the author suggests a study of the limit design method is proof to the writer that it deserves careful thought and consideration.

HARDY CROSS<sup>4</sup>

It is not at all difficult to recognize the mathematical theory of elasticity as an intriguing, highly skilled, and frequently illuminating field of study. It is doubtful whether any structural engineer in America ever thought that steel structures—or concrete structures either for that matter—fail elastically. We have always recognized that plasticity was an important element to be taken into account. I have always, I believe, emphasized that evidence from the theory of elasticity is merely some of the evidence to be considered in judging structural parts and is often not the most important source of evidence.

It is important to point out that there are two objectives of what is called structural theory. One objective is to predict action of structures as they exist, each structure being to some extent a different problem. The other objective, which some seem to think is the only purpose, is to set up specifications or their equivalent so that not too much judgment is left to the individual designer. The author has recognized this and has tried in a practical way to set up some "acceptable tests" for a structure based upon conditions at failure. He has also clearly recognized that this is very difficult to do. It is perhaps unfortunate that our specifications in the past have been directed primarily to structures which were statically determined. We all hesitate to break abruptly with our traditions in regard to such matters because our experience and the experience of the profession is correlated with these traditions.

I do not differ from the author in our ideas in regard to these questions. I have been a little annoyed, I confess, by the suggestion that the idea of considering structural action beyond the elastic stage originated on the continent of Europe in recent years. Certainly we built enough Whipple trusses and double intersection trusses in pioneer days in this country. It is, I suspect, the concept of structural engineering as a branch of mathematics which has come from the continent of Europe.

EDWARD GODFREY<sup>5</sup>

The subject of the paper is a matter that has interested me for many years. It is epitomized in the statement, "Steel must be recognized as a material not perfectly elastic." There are many cases where this fact can be taken advantage of and where perfectly safe design can be effected—cases where perfect elasticity in the steel would mean sure failure.

A few years ago, Prof. J. A. Van den Broek called my

<sup>4</sup>Chairman, Department of Civil Engineering, Yale University, New Haven, Conn., U.S.A.

<sup>5</sup>Civil Engineer, Pittsburgh, Pa., U.S.A.

attention to the fact that a publication of the Royal Institute of Engineers of the Hague, The Netherlands, consisting of specifications for steel structures, refers specifically to an article of mine in *Engineering News Record*, May 13, 1920, which deals with the subject and emphasizes the paucity of information and instruction on the benefit derived from a knowledge that steel is ductile as well as elastic.

The author, in his paper, cites some cases where the property of ductility in steel is an advantage in the matter of safety of design. One case is in pins for pin-connected structures. In girders, particularly continuous girders, doubtless advantage could safely be taken of ductility, if experimental tests could be devised to determine to just what extent rules could be relied on.

In the author's hypothetical example of several rods of different lengths taking the same load jointly, it would be hazardous to let the stress of one of these approach near the elastic limit, unless the load were to be permanently static. For such load the condition would resemble a bent rod carrying a static load. I have more than once found that loading, releasing and reloading rods, where loads approach the elastic limit leads to disaster. Static loads do not produce this effect.

If several rods carried the same dynamic or oft-repeated load, and one were stressed near the elastic limit by reason of its shorter length, that rod might fail by fatigue and thus put added stress on the others.

Recently a paper was published which aimed to show that punched holes in riveted plate girders do not weaken the girder, and the method of design which uses the gross section is therefore justifiable. It was stated that stresses beside the holes in excess of the elastic limit of the steel serve to raise the elastic limit and thus the strength of the steel. This is false reasoning, for it is only when the subsequent applications of stress are much less than that which exceeded the elastic limit that integrity is assured. Fatigue is almost sure to follow repeated loads of the same intensity as those that permanently stretch the steel.

C. M. GOODRICH,<sup>6</sup> M.E.I.C.

The author, in his discussion of the limit design method offers interesting examples, in particular the one of the three rods. The points wherein one agrees are many, those wherein one differs are few; but the differences offer ground for discussion.

He proposes (a) to consider the sum of all resisting paths at normal unit stresses when treated independently; (b) to stress no path above the elastic limit when treated elastically. The writer would prefer to examine what happens when the structure as such is loaded increasingly, to determine as limit that point where something detrimental to the appearance, integrity, or use of the structure occurs, and to take such a portion of the loading as safe loading as may be consonant with the duty of the structure. The limit may be strength as such, it may be deflection, it may be appearance, it may be the psychological effect on the user of too much shake; other elements may enter as well, such as the very important one of reversal of stress, which in many cases would be the determining factor.

In certain mill buildings in the United States, stiffness has been secured by adding weight, while comparable buildings of half the weight and of greater stiffness have been built, by designing to this end. This, in the writer's opinion, is limit design; the limit here is a matter of stiffness.

Most telephone and telegraph lines, and many transmission lines as well, are supported on wood poles. Every year stretches of them are blown down. Yet we continue to build them. Presumably we think that practice economically

<sup>6</sup>Consulting engineer, The Canadian Bridge Company, Limited, Walkerville, Ont.

correct; and in many instances this is true, while in others it is untrue. It depends on a good many factors. Mr. Shearwood's criteria do not apply.

Take the case of the three rods of different lengths supporting a vertical load. If the load is suddenly applied and released, there would be an unpleasing sight to see if the longest rod shook and shuddered too violently. If the load were a steady load that would not happen. In that case, if deflection were not objectionable, there is no reason the short rod should not be allowed to stretch.

In the case of the beam fixed at both ends, if the loading is from one side only, let the fibres stretch if they want to do so; the centre deflection will be smaller in any normal case than that of the alternative simple beam. If the loading is reversed, then one should stay inside the elastic limit.

There are in existence structures where a stiff bent is guyed with ropes. Here it often happens that the guy will stretch say ten times as far, before it is doing its figured duty, as the stiff bent will deflect before it is in trouble. Here one may say that the limits have not been properly correlated.

In many cases it would cost more to figure stresses in a frame, or in certain of its parts, than it would to make it amply strong. Here the limit is set by the cost of the design work.

Limit design invites us to face all the facts we can gather together, and then throw away those we believe non-essential, employing the least amount of design work economically consistent with the character and importance of the work in hand, and producing a result which will be adequate to all its uses.

KENNETH W. LANGE<sup>7</sup>

What has been referred to in recent papers as limit design has been used by engineers for a considerable time. Mr. Shearwood's paper is of value as it reopens discussion of many problems of importance to structural engineers.

It occurs to the writer that any discussion of limit design also should involve careful consideration of what is meant by factor of safety. Without discussing here what the factor of safety against failure should be, and why it is provided, it can be said that many older structures are in use to-day because the safety factor used in their design renders them useful under present day overloads.

Many of our existing structures, designed by the so-called elastic theory, when analyzed by the method outlined in this paper, will show usefulness under loads considerably in excess of those for which they were designed. Had these same structures been designed by the principles of limit design, the useful loads which they could withstand would be proportionately less. The same result might be achieved by raising the allowable stresses and continuing to design under the elastic theory, which is in effect what some writers on the subject propose to do.

It is interesting to note that the hanger of Fig. 3 will withstand a load of some 110 kips or more when analyzed by the theory of the paper. Elastic analysis at design stresses with a safety factor of three permits a load of 36.7 kips. Actually then the factor of safety is  $\frac{110}{36.7} = 3$ . By allowing a load which will induce yield point stress (or strain) in one member, the capacity of the hanger is 55 kips with a safety factor of  $\frac{110}{55} = 2$ . In any case, the failure of the hanger will follow the rupture of the shortest bar.

In the design of concrete slabs, it has long been recognized that any reasonable distribution of reinforcing steel across a section is satisfactory, so long as the amount of this reinforcing is sufficient to withstand the statical moment on this section. Tests have shown that generally a slab so

<sup>7</sup>Research engineer, Chicago Bridge and Iron Company, Chicago, Ill.

designed will not fail until all of this reinforcing has been stressed beyond the yield point.

The accepted practice of proportioning foundations for some average bearing pressure, presupposes that before any one region of the soil under the foundation fails completely, the remaining part will act to resist the applied load.

The design of steel structures without regard to locked up rolling, fabricating and sometimes welding stresses, recognizes and utilizes the ductility of steel.

It is intended to point out here that the philosophy of limit design is not new in engineering. Perhaps the use of a formal theory of limit design will lead to some revisions in current practice. The contemplation of such a theory requires a reconsideration of the reasons for some of our present design requirements.

I. F. MORRISON<sup>8</sup>, M.E.I.C.

In this paper there appears to be a certain amount of misunderstanding especially of fundamental facts, which has led the author to present his argument perhaps not quite so soundly and clearly as might have been the case. To be sure, the paper is purely theoretical, based on hypothetical thinking, but it is intended that its method could be applied to practical design. This being so, one is led to question the propriety of applying an hypothesis beyond the point at which it comes into conflict with natural phenomena. After all, nature does not recognize hypothesis.

In order to make clear the discussion that follows, it is proposed just to set down in review certain well established facts. Whatever theories we may propose and put to use, these facts must not be disregarded and any application of our theory must not lead to results contrary to them.

In Fig. 9 is shown the usual graph based on the results of a tension test on a bar of mild steel. The characteristics of this graph to which the writer wishes to direct attention are as follows:

1. The curve rises as a straight line from 0 to some point F after which it bends over slightly to point A.

The unit stress—load divided by the original cross-sectional area—at F is called the proportional limit because for stresses larger than it the load-stretch relationship is no longer linear, i.e., Hooke's law ceases to exist. This linear relationship is assumed by the author to hold for all stresses with utter disregard of the existence of a proportional limit.

2. At A, which is called the upper yield point, there is a sudden yielding. If the load be of the reaction type, a decrease will take place and a considerable amount of stretch will follow until it rises again to B due to the strain hardening of the material. On the other hand, and this is extremely important in what follows, if the load be of the gravity type the complete stretch takes place continuously, with no diminution of load, from A to B and its advance cannot be checked at any intermediate point between A and B, i.e. when a unit stress corresponding to point A is attained a large unit strain of amount AB is suddenly developed. The author disregards this fact or fails to recognize the horizontal portion A-B of the stress-strain graph. He assumes that the process of stretching under a gravity load will stop at some strain lying between A and B. This is contrary to the fact as established by experiment.

3. After the point B is passed, a region of gradually increasing load is experienced until the maximum load corresponding to point C is attained. During this region of loading the entire specimen has gradually increased in length and decreased in diameter by the process of plastic deformation.

4. At the load C, a constriction at some point along the specimen starts to develop and continues to do so through the region CD. At D, fracture takes place. If the load be of

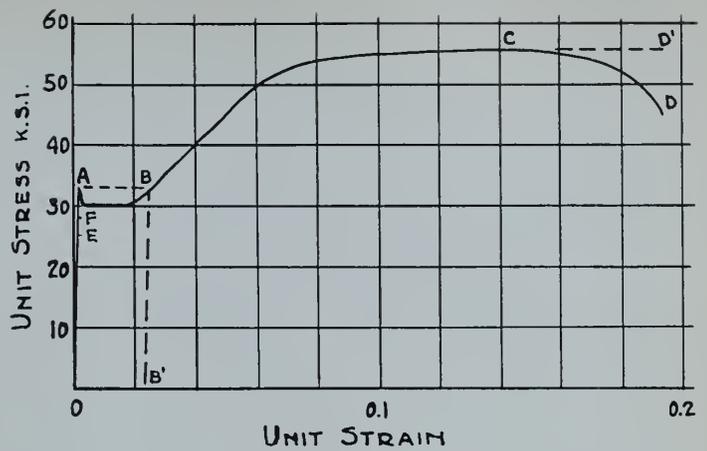

Fig. 9

the gravity type, when point C is reached the fracture process goes forward continuously to point D' and it cannot be stopped between C and D'. The total unit stretch of the piece up to point D is by definition the "elongation."

5. At some point E on the graph the material passes gradually from the elastic to the plastic state. It must be recalled that the concept of elasticity demands that the specimen return to its original size and shape whenever the stress-causing loads are removed. To determine the position of E is a difficult and time consuming process, which depends on the sensitivity of the instruments used to measure the stress and the strain. Some doubt may be cast on the actual physical existence of such a change point. The unit stress corresponding to the point E is called the "elastic limit." This term is often misused and confused with the proportional limit. It appears to be so misused in the paper.

6. If, when the unit stress corresponding to point B is attained, the load be subsequently released and then reapplied the graph retreats to B' and returns to B along the straight line B'B. In this way B becomes the new yield point and also the proportional limit.

These, then, are the physical facts. Let us see now how some of the statements in the paper compare with them. In order to build up a theory, certain hypotheses must be made and in the present case these are concerned primarily with the relationship between unit-stress and unit-strain of the material. This is done by the usual process of abstraction and the results may best be shown by the graph of Fig. 10 in which the corresponding points are similarly lettered. The line OA is straight, i.e., the material obeys Hooke's law for the stress range OA. The points F and E now coincide with A, i.e., the proportional limit, the yield point and the elastic limit now have the same numerical value. The meanings of these terms however, are still quite

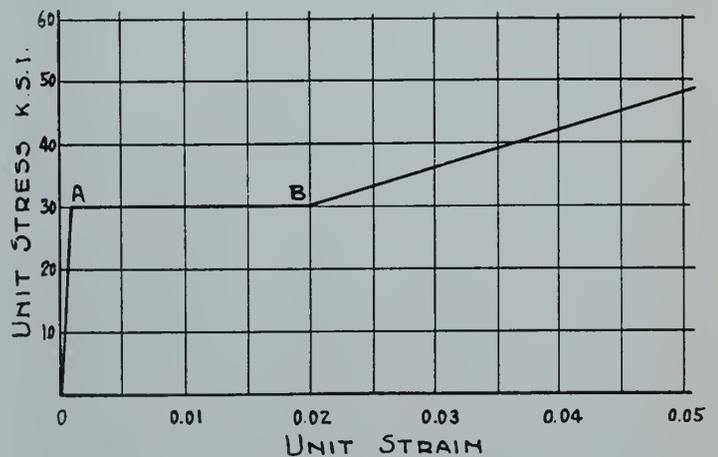

Fig. 10

<sup>8</sup>Professor of Applied Mechanics, University of Alberta, Edmonton, Alta.

different and in any rational argument cannot be interchanged indiscriminately. The load is assumed to be of the gravity type.

In order to confine this discussion within reasonable limits, it is proposed to discuss only the first part of the paper. Figure 11 corresponds to Fig. 3 of the paper redrawn for the sake of simplicity. Three steel rods, all of the same unit cross-sectional area, support a gravity load,  $W$ . The lengths are  $l_1 = 100$  in.,  $l_2 = 200$  in.,  $l_3 = 300$  in. A load  $W = 36.7$  kips is applied. The total stresses and, therefore, also the unit stresses, in kips per square inch, in the rods then are  $p_1 = 20$ ,  $p_2 = 10$ ,  $p_3 = 6.7$ , computed on the basis that each rod behaves according to Hooke's law. Assuming  $E_s = 30 \times 10^6$  lb. per sq. in., the amount of stretch is 0.067 in. for all rods. Now suppose that  $W$  be gradually increased, a value will be reached at which the unit stress in rod No. 1 will correspond with the yield point, A of Fig. 10, not the elastic limit<sup>9</sup>, i.e.  $p_1 = 30$  kips. The value of  $W$  for this condition will be not less than 55 kips and the stretch will be 0.1 in. As the load increases from 55 kips, a value will finally be attained at which the unit stress in rods Nos. 1 and 2 is 30 kips per sq. in. respectively and the minimum value of  $W$  is 90 kips, and the stretch will be 0.3 in. Any load  $W$  greater than 90 kips will cause a sudden, and rather disconcerting total stretch of 2.0 in. Such a performance would cause alarm on the part of the most ardent proponent of the limit design process.

It will be noted that the combination of  $p_1 = 35.25$  kips,  $p_2 = 22.9$  kips,  $p_3 = 15.25$  kips, as shown in the paper (Fig. 3c), is not possible if we are to be consistent with the load stretch curve shown in Fig. 10, for these values are based on the incorrect assumption that Hooke's law holds beyond the physical yield point of the material.

It is apparently anticipated, in the limit design process as set forth in the paper, that the limiting carrying capacity will be 90 kips and that for design purposes the safe load would be obtained by applying a factor of safety, although no indication is given of what a reasonable value for it would be in this case. Let us suppose, however, the factor to be 1.5. Then with the load at 60 kips, the total stresses will be  $p_1 = 30$  kips,  $p_2 = 18$  kips and  $p_3 = 12$  kips with total stretch of 0.12 in. This does not agree with Fig. 4b. The numerical values given in that figure are inconsistent with the facts as determined by test. If the stretch of 0.12 in. is satisfactory the design might be accepted as quite safe.

A little careful consideration, along with Fig. 10, will convince the reader that such combinations of stresses as shown in Fig. 4e are quite incompatible until the second rising part of the load stretch curve has been reached

and therefore only after a considerable amount of stretch has occurred. The impracticability of basing any design on such figures is at once apparent.

If the factor of safety were taken at 1.8, then  $p_1 = 27.3$  kips,  $p_2 = 13.6$ ,  $p_3 = 9.1$ . This would be equivalent to assuming a maximum allowable unit stress of 27.3 kips per sq. in., and we are simply back to the classical theory with a higher than usual allowable stress. If limit design leads back to the customary process, why not simply adopt higher allowable stresses?

One can hardly give serious consideration to such remarks as are found on pages 3 and 4 of the paper to the effect that "medium steel specification calls for an elongation of 22 per cent or equivalent to a stress of 6,600,000 lb. per sq. in." Such astronomical flights of the imagination find no place in such a paper and can add nothing to it. The author has apparently overlooked the technical meaning of the

<sup>9</sup>The tone elastic limit lies slightly below A and it is relatively important in this discussion.

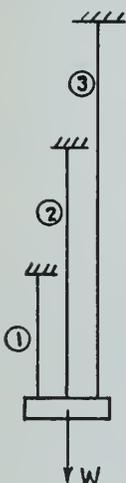

Fig. 11

word "elongation" as applied to the standard test, as well as the facts as set forth in Fig. 9 of this discussion.

The writer must confess he is surprised at the author's remarks under the heading of Fatigue. The most striking single fact concerning fatigue is that it takes place without plastic straining of the metal. The cause of a fatigue failure is not "progressive creep," which is a different phenomenon in no way related to cyclic stressing. Just why a restriction of the strain should inhibit fatigue failure is most certainly not clear.

THE AUTHOR

The general principle of limit design is the recognition that yield can be safely counted on to equalize the distribution of stresses in steel frames. Many claim that this has already been in use which is, no doubt, true (sometimes deliberately or more often by accident). It is not, however, an accepted standard practice to allow for the influence of yield when designing new structures.

Mr. Goodrich very rightly emphasizes the fact that the designer should always consider the character and importance of the work in hand, but the first and the absolutely essential condition which must be fulfilled in all cases is that of adequate strength. Other items which he mentions require supplementary consideration. In order to simplify this discussion it must be confined to the essential requirement.

There was not in the paper any intention to advocate the discarding of elastic computations, but rather to suggest a more perspective use of them in conjunction with the effect of deformation, and to realize what an extremely minute adjustment of strain is being pursued by these intricate and laborious calculations, and to judge whether simpler computations giving perhaps less theoretically exact distribution of strain (interpreted as stress), would not actually provide as safe a structure.

The stress equivalent of the elongation requisites of standard specifications (22 per cent) was referred to in order to show that the ratio of strain to stress varies so greatly as it reaches the ultimate strength and that such a very minute portion of the specified deformation can insure advantageous readjustment of the stresses.

Fatigue is referred to by nearly all those discussing the paper. It is of course an all important matter for structures supporting intermittent forces, but with quiescent loading repetition does not occur and therefore, fatigue cannot affect the main question.

The discussion by Professor Morrison is very welcome, since it views the problem from the testing laboratory angle, whereas the author may have been too greatly influenced by his observations in the erection and fabrication of steel work.

Professor Morrison claims that there is a long flat portion in the stress-strain diagrams of structural steel. This is generally true of small test coupons but may not be the case with shapes in which the yield point may vary throughout their section, and with built up members which generally have some assembling inaccuracies. The exact length of the straight portion and as to whether it is exactly horizontal appear to be somewhat doubtful.

The error or difference in the stress-strain ratios used on Figs. 2, 3 and 4, does not materially alter the comparisons of these examples. The intention was to compare the strengths as calculated by the elastic theory and the limit design method of a hanger having no unequally strained rods (Fig. 2) with one having unequally strained rods (Figs. 3 and 4). Professor Morrison takes no notice of these comparisons and only compares Fig. 4 with Fig. 3.

Revising the stresses given in Figs. 2, 3 and 4 for the stress-strain conditions given by Professor Morrison's Fig. 9, the working value of the member with equal lengths (Fig. 2) when computed by either the elastic or by the limit design methods is 60 kips. The member having three rods of different lengths has a working value of 36.7 kips

(Fig. 3) when computed by the elastic theory and of 55 kips (Fig. 4) when computed by the tentative method of this paper. If these loads are increased by 50 per cent, the rods of Fig. 2 will all reach the yield point, and, according to Professor Morrison, a sudden deflection of four inches will take place, certainly rather alarming! In the case of Fig. 3 only one rod will reach the yield point and the deflection will be limited to 0.2 in. because of the elastic resistance of the other two rods. The load in Fig. 4 will be 83 kips and the two shorter rods will reach their yield point, but the longer rod is still within its elastic stage and it will limit the deflection to 0.23 in. If the working loads are doubled the deflections will be about as follows:—

Fig. 2.....	about	7 in.
Fig. 3.....	“	0.26 in.
Fig. 4.....	“	4.8 in.

If the stresses and distortions of the hangers having equal and unequal length rods are compared, it is evident that any partially unstressed material should add to their strength and possibly justify the values given in Fig. 4 being nearer the relative safety than those given by Fig. 3 when compared with the standard given by Fig. 2.

Professor Morrison states that fatigue occurs without plastic straining (i.e. yield) but many tests have shown that it takes a repeated stress greater than the yield stress to produce a fatigue failure (see Morley's "Strength of Materials" and others). Therefore, if deformation only occurs after the yield point is reached, there must be some deformation when a repeated stress is applied which is great enough to fracture the metal.

Mr. Godfrey points out that perfect, i.e. the complete elasticity would mean sure failure in many cases. It would certainly bring trouble to the fabricating shops, since they could not straighten any steel without fracturing it. This must prove that much of the material in steel structures has been strained beyond its yield point, and yet can function as if undamaged.

Professor Copp and some others infer that it is a good practice to neglect any strength not shown by the primary elastic computations and use it as an extra means of meeting possible future increase in loading or abuse. This would be a

very inconsistent provision; e.g. in a simple span structure there would be no excess strength, while in many other types the excess might be as much as 30 per cent.

To merely increase the unit stress and use the elastic theory would not achieve the same objective as the limit design method because that would merely reduce the figured margin of safety, instead of taking credit for the proportionately greater participation of under stressed paths coming into effect as the primary paths yield, which must happen before there is any danger of failure.

Mr. Lange points out that failure will probably be in the shortest rod (Fig. 3) but owing to the changes in the modulus of the rods as they pass their yield point, the distribution of stress between the rods will be constantly more nearly equalized after the yield point of the shortest rod is passed, and the loading is increased.

Mr. Lange's remarks regarding locked up stresses (strains) are certainly important in these days when plates and shapes are being bent, formed and welded so frequently during fabrication and so generally put into use without stress relief. These everyday practices must indicate that the small amount of yield required to redistribute the stresses as called for by the limit design method can be accomplished without harming the material at least for those structures which support quiescent loads.

Professor Hardy Cross has aptly drawn the author's attention to the fact that the modern specifications, which so autocratically govern most of the commercial designing were originally written for simple or assumedly simple structures, but are now rigidly applied to all steel structures, whether they have all their strength in one brittle path or in several ductile ones.

The discussion as a whole is rather non-committal but while admitting that yield cannot be avoided during fabrication and has often secured the safety of many severely over-stressed structures, there is a reluctance to count on it officially in designing new work. It was to assist in correcting these inconsistent conditions that this paper was written.

The author wishes to thank those who have contributed to this purpose.

## Abstracts of Current Literature

### TORPEDO AIRCRAFT

From *The Engineer*, (LONDON), MARCH 20, 1942

There was healthy rivalry in the days before the war between those in the Royal Air Force who flew bombers and the crews of torpedo aircraft. Which form of attack upon hostile warships would prove the more effective? Many practical exercises were carried out to throw light on this question. The bombers relied on the use of heavy bombs of high penetrative power and flew at the greatest possible height they could to ensure that the striking velocity of the falling bomb should be high enough to be effective, as much as 20,000 ft. of altitude being necessary. Such high-altitude flying led, of course, to an acceptable lessening of the danger from A.A. fire, but there was the risk lest it should nullify accuracy of aim. If it be admitted, as it must, that doubling the height is likely to halve the accuracy, other things being equal, it must be remembered that careful training can go far to reduce bombing errors and that at the worst a battleship is always a satisfactorily large target. Moreover, the bigger the ship the slower will it be in taking avoiding action, although such action at the best of times is not found to be a grave hindrance to the bomb aimer. Low-height bombing, on the other hand, is most risky to the

### Abstracts of articles appearing in the current technical periodicals

aircraft, and if it has to be done at all it had better be on the dive than by a level attack. The dive sometimes produces very remarkable accuracy, even when carried out in the face of active defence; on the other hand, it can never give high striking velocity, hence the penetration will be slight. Nevertheless, it can disorganize A.A. fire, and by doing so enable its fellows, the torpedo bombers, to have a better opportunity to dash in to the attack. Unless they have assistance of this kind torpedo aircraft have a difficult and dangerous task. They have to fly very low to release their torpedoes and they must come in close to the target if they are to get accurate aim. They have, of course, a far better chance both of success and of survival when they attack in numbers and from various directions, since the A.A. guns, even when they are not being attacked by bombers, cannot deal with numerous torpedo craft all at once and a single torpedo hit may prove disastrous to the ship. A single torpedo, it is true, is hardly likely to sink a modern warship, but it may easily wing it and so render it a prey to other forces.

The damage done by missile attack on a ship is of two chief kinds: damage to the effectiveness of its means of

propulsion and damage to its buoyancy. The armour penetrating bomb aims at the former; the bomb which just misses the ship—the “near miss”—may achieve the latter if it detonates closely alongside, but it is the torpedo which is much the most effective weapon, since it explodes in actual contact. But whether by “near miss” or by torpedo the mechanism of the resulting damage is much the same. The exploding mass creates two things: a great sphere of very high-pressure gas, and in the sea an intense pressure wave of the water hammer variety. The bomb may detonate too far from the ship for the blast of the explosive gases to reach it, but the compression wave in the water rushes outwards at a speed of over a mile a second and may smash its way right into the hull of the ship unless the latter is of such carefully chosen construction as to prevent any great degree of damage from resulting. In the case of the torpedo attack both gas blast and detonation wave act together and very precisely thought-out defence measures are needed if this powerful combined effect is to be neutralized.

The first constructional step in the direction of defence against torpedoes was made long ago by the addition of the so-called “bulge,” since absorbed by the methods of construction used in initial design. The traditional remedy, and it has a scientific basis, against any fiercely sudden attack is the interposition of a cushion of some sort. The fiercer the attack the more effective must be the cushion. Our naval architects are second to none in the world and we have in our councils, potentially at any rate and we hope actually, scientific men who are expert in hydrodynamic phenomena and who can advise as to the nature and amount of these impulsive pressures and of the probable lessening of the damage they can do when suitable precautionary actions are taken. These are matters which cannot be probed in public, but we hope, as we little doubt, that the authorities are fully alive to the position. One has an impression that the German warships have proved themselves able to stand up well to punishment, and it is up to us to show that we can do still better.

## WAR OUTPUT UP 2,000 PERCENT

FROM ROBERT WILLIAMSON\*

Output of shell fuse cases in a British munitions factory was increased twenty-fold after industrial psychologists had suggested improvements in methods of working.

The job required careful hand-soldering of seams, and as the factory had lost most of its experienced solderers the weekly output was only 1,000 good cases, with several thousand rejects. But after various changes of which the most important was a systematic training scheme, based on careful study of hand and body movements, the output was raised to 20,000 cases a week, passed by the inspectors.

This is only one of the cases in which trained psychologists from Britain's National Institute of Industrial Psychology have helped to speed up production in Britain's war factories. Although the results are sometimes startling there is no particular magic about their job. It is based rather on a careful study of the physical movements entailed, on proper methods of instruction, and above all on interesting the trainee in the work.

Hours of wasted time have been saved by getting the trainees into the habit of arranging their tools around them in an orderly way and replacing them after use. More subtle are devices whereby both hands can be used instead of one. For example, if a screw has to be placed on either end of an article, instead of holding it in one hand and then transferring it to the other it is held in

\*London Correspondent of *The Engineering Journal*.

a vice and both screws are put on simultaneously. Then to save the trouble of picking it up a foot pedal may come into operation and drop it into a box.

Training is made interesting by interspersing hand-work with general instruction so that trainees understand how their work fits into the general scheme. In weaving, for example, they are told about the types of thread used, the use of the cloth which is being woven, and so on. In tank factories they not only see their particular part assembled into the completed job, but are shown the tank in action.

Coil winding operatives trained by these methods were found to reach a standard of proficiency in only five days which previously had taken five weeks. Moreover, this was not achieved at the expense of output, for a 65 per cent increase in the average output of good pieces was obtained, while the scrap rate fell from 5 to 2 per cent.

Apart from this, the psychologists have increased production by suggesting improvement in working condition amenities and by investigating and smoothing grievances.

## SAND IN THE GEARS

EDITORIAL COMMENT

FROM *New Equipment News*, (MONTREAL), MARCH, 1942

There is a substantial undercurrent of gossipy criticism of our government, the country's war effort and, in fact, almost anyone or anything connected with any part of the war activities of Canada and the Empire. This situation is not serious in itself but it is undoubtedly affecting our unity of effort and, if permitted to gather momentum, it will pave the way for disunity within this country and even within the Empire itself. It is not the idle talk of really ignorant persons but the growing theme of conversation of educated people to whom we should look for “all out” (in its truest sense) support and personal effort.

Much of this criticism is based upon what might be termed apparent facts—things that have actually happened—things that are happening—conditions that exist—decisions and rulings of the government—actions and orders of government departments and boards—appointments to war organizations—selection of army recruits—government administrative expenses—and a thousand other major and minor subjects. These are general subjects but more specific items of conversation include: lack of production in some war industries, overstaffing of government war-time offices, excessive expenditures in newly established boards, absence of co-ordination of effort in special war-time organizations, and many others. In fact, there are few, if any, of the war activities that are not ruthlessly pulled to pieces, and at times even ridiculed, in these conversations. And, remember, this endless stream of gossipy criticism is the theme of conversation of “educated people.”

“Educated people”—but thoughtless ignorant people—who perhaps think it is smart to “know it all.” Thoughtless, because they do not realize the damage they are doing. Ignorant, because obviously they cannot know what is really happening, or the reason for things, or the wider plan and strategy, which are the reasons for the “apparent facts” they so carelessly discuss. Their greatest sin is “thoughtlessness.”

All this does not emanate from any particular centre. It is not an organized effort in any sense. It may be fostered or encouraged by enemy propagandists but, if so, there does not appear to be any evidence to that effect. Certainly not among the people to whom the above statements are attributed. In fact, these Canadians are, in their hearts, among the most loyal of our citizens. But, through their ignorance and their carelessness, bolstered

by their egotism and their superiority complex, they are playing into the hands of the enemy and leading to the one goal—disunity. They talk of “an all-out war effort” but apparently do not know the real meaning of the phrase, otherwise they would support, rather than discredit, the endeavours of those guiding and carrying on Canada’s and the Empire’s plans to defeat the enemy.

We have witnessed an untimely political flurry in Ontario and Quebec, when much was said in the heat of the campaign. That’s over—it’s time to discard politics for the duration. Now it is urgent that the people of Canada, from coast to coast be cemented into one single unit with only one motto—“no effort in thought, word and deed that will help the cause of freedom shall be left undone until the enemy is vanquished.” Anything less than this is criminal negligence.

Never in the history of Canada—never in the history of our Empire—has there been a time when it was so vitally important for us to all stand together—work together—and face the enemy with a solid united front. Never were the minutes passing more quickly—to-day we can cast aside all selfishness and save all—to-morrow it may be too late.

This is not a message from our government, or our churches, or any group of our leaders. It is not for the purpose of supporting any political party, any creed, any race, or any of our special war efforts. It is a plea to every Canadian, whether he be in a position of authority, or in some important war work, or simply performing his regular daily duties, to face the facts and to do his little bit to prevent the terrible catastrophe that is so steadily and rapidly moving towards us.

What the individual is doing, or can do, at this critical time depends very largely upon circumstances and to some extent upon opportunity. It is not possible to marshal millions of individuals in a few short months and allocate some obviously important duty to each. But each, on his own initiative, can make a contribution of inestimable value to our cause by standing back of those in authority; by refraining from idle chatter and gossip; and above all, by openly squelching that simple but dangerous fool, the “scandal monger”—the “know-it-all.”

## BRITISH AIRCRAFT PRODUCTION

From *Engineering* (LONDON), FEBRUARY, 1942

Addressing a press conference in London last February, Lieut.-Colonel J. T. C. Moore-Brabazon, then Minister of Aircraft Production (in which position he has now been succeeded by Colonel J. J. Llewellyn, M.P.), gave some indication of the changes that were being gradually effected in the output of bombers. Construction of the Hampden and Whitley types was being reduced and would eventually cease, the productive capacity thus released being devoted to increasing the output of long-range four-engined machines. The Wellington would remain in production, however; it had proved to be a most serviceable machine, especially for medium-range work, and would still be used in considerable numbers. The Minister recalled that questions had been asked in the House of Commons last year, before the United States came into the war, regarding the delays caused by the various modifications required by the Royal Air Force to American machines. Experience had shown the American manufacturers the wisdom of these alterations, and they were now being incorporated in the designs; the output of American machines, in operationally complete form, would thus be appreciably accelerated, apart from the speeding-up that would result from the full mobilization of the vast motor-car industry of the United States. Machines were coming from Canada also, at a rate which

was most gratifying, and their quality was fully comparable with that of the machines constructed in this country. Supplies of aircraft to Russia continued on a considerable scale; under the agreement made at Moscow, they were not to fall below the figure then promised, though that figure might be exceeded. Developments in aircraft engines were progressing satisfactorily. The Rolls-Royce Merlin engine was still the best liquid-cooled engine manufactured anywhere in the world, but the types at present in operational use did not represent the last word; new models were in hand which would certainly provide the enemy with some surprises. The production of fighters had been speeded up by simplifying manufacturing processes and so reducing the number of man-hours required per machine; in the case of one type, the total of man-hours had been halved. The American fighters which were now coming into service in useful quantities were in the forefront of their class, and in this connection Colonel Moore-Brabazon mentioned particularly the Mustang and Kittyhawk machines. In conclusion the Minister stated that the formation of works committees, which were helping materially to increase the production of aircraft and engines, was being pressed forward throughout the industry; but he pointed out that the change-over of factories to the construction of new types must always involve a certain amount of idle time for the relatively unskilled labour now being employed in large numbers, which could not be rapidly switched on to unfamiliar work without further training in the new processes thus rendered necessary.

## CONCRETE ARCHED AEROPLANE HANGARS

From *The Engineer*, (LONDON), MARCH 20, 1942

Among the numerous types of hangars built for the aeroplane services of the American Army and Navy are concrete barrel arch hangars, springing from the ground level, with a span of 294 ft. and a height of 81 ft. at the centre. They are built in pairs, side by side, with a single central footing, the narrow space between the two arches being utilized for repair shops. The arched roofs are built in sections, separated by expansion joints. Each section consists of two arched ribs with a thin roof between them and a stretch of thin roof cantilevered on each side. The edges of these cantilevered stretches are thickened and are stiffened by small ribs in which the expansion joints are formed. Brackets on the outer sides of the arch ribs carry longitudinal beams and framing for two-storey offices and quarters. On the inside, or intrados, the roof is smooth and unbroken, the ribs rising on the outside. For the foundations, where rock cannot be reached, the vertical arch reaction is taken on wood piles, while the horizontal thrust or tension is taken by tie bars composed of steel cables, each member having eight strands of 1 1/16 in. diameter. These ties are anchored in the footings and the cables are pre-stressed, so that under dead load the horizontal thrust is taken by the ties and the footings take only the vertical reaction. The arch ribs are designed as two-hinged arches, with hinges of the Mesnager type. Each hinge consists of thirty-two vertical 1 1/4 in. steel bars and twenty bars of one in. diameter arranged in fan shape to take the horizontal reaction. In order to resist overturning moments, such as might be caused by earthquakes, bars of high yield point strength are used at the outside of the hinges. In construction, a timber falsework was used, long enough for one section, and mounted on rollers so as to be moved to each section in turn. When in position it was adjusted and supported by screw jacks and blocking. The concrete, designed for a strength of 3,500 lb. per square inch, was prepared in two mixers, which fed a double pump having two 8 in. pipe lines that discharged directly into the forms.

## REVERSIBLE MAGNETIC COUPLING DESIGNED FOR USE IN MARINE ENGINES

From *Overseas Daily Mail*, (LONDON), OCTOBER 25, 1941

Magnetic couplings have been employed in geared oil-engine installations for marine use, and they have several advantages. The couplings act as a truly flexible and resilient member between engine and gear, for there is no mechanical connection between the engine and the pinion shaft of the gear drive.

This benefits design in several ways, especially as regards fluctuations of the engine speed being transmitted to the gears, misalignment, and torsional oscillations between engine and pinion shaft, which may, unless damped, lead to severe wear on the gear teeth. The engine can be started under no load, and speeded up, when torque is applied gradually by exciting the coupling.

During reversal the coupling is de-excited, the engine reversed under no-load, and the coupling excited again to pick up the torque.

In the ordinary non-reversing type of coupling one member carries a squirrel-cage winding and the other a salient-pole magnet wheel—it is immaterial to the principle whether the squirrel-cage winding is attached to the engine or the pinion shaft or whether it is the inner or outer member of the coupling.

More usually the salient-pole magnet wheel rotates with the engine shaft around the squirrel-cage winding which is attached to the pinion shaft. The salient-pole magnet wheel is excited by D.C. current.

The rotating field produced by the D.C. magnet wheel drags round the rotor after it; there is a little slip, very similar to that between the rotating field and the rotor in a squirrel-cage motor.

To reverse the propeller, it is necessary to reverse the rotation of the D.C. field, and this can only be done by reversing the engine. This reversal is, in fact, more easily permitted because, as stated above, the load may be disconnected at the coupling and the engine reversed under no-load conditions.

None the less, it remains that reversal of the propeller means reversal of the engine, and this in turn, means complications in engine design, and especially the provision of ample compressed air equipment and storage.

A design has been proposed and patented by The General Electric Co. Ltd., in which it is possible to effect reversal of the propeller without reversal of the engine, if necessary at full torque. The basis of this design is to use D.C. operation in the normal way for forward running, but to substitute three-phase A.C. current to excite the rotating field member in such a way as to produce a rotating field in the opposite sense to the engine rotation.

The frequency of the three-phase exciting current is double that corresponding to the engine speed so that the field rotates backwards at twice the engine speed with regard to the engine member. As the latter is rotating "forwards" at engine speed, the net result is that the speed of the rotating field in space is the normal speed backwards. The propeller, therefore, is reversed and runs at normal speed astern.

To enable this to be done the exciting winding must be designed to be suitable both for D.C. excitation when running ahead, and A.C. excitation when running astern. The magnet wheel with salient-poles is therefore replaced in the reversing coupling by a laminated core with star-connected three-phase winding.

In ahead running the exciting winding is fed by D.C. current through two phases in series or through two phases in parallel and the third in series, in either case producing alternate poles as with a salient-pole design.

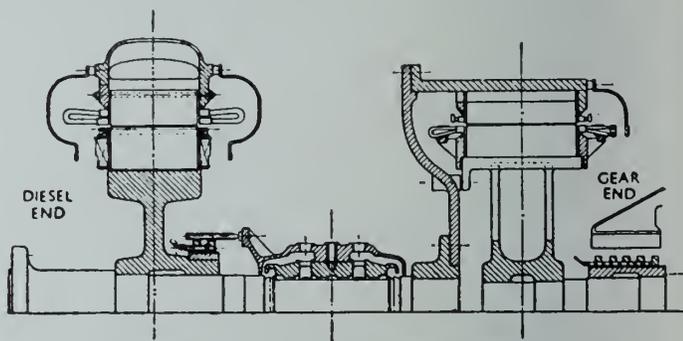

It is also necessary to provide a supply for the A.C. excitation for running astern, and this may most con-

veniently be obtained from an alternator incorporated in the coupling. The alternator takes the form of a salient-pole rotor with a three-phase stator surrounding it, the rotor being excited with D.C., and the stator then producing A.C. which is used to excite the winding of the coupling.

Since the frequency of the alternating current required is double the normal frequency the number of poles in the salient-pole alternator is double those in the exciting winding. Consideration will show that there will be an inner circulation of power resulting in the alternator having to supply twice the full power of the engine. It might be thought that this would call for a disproportionately large and heavy alternator, but this is not so severe a limitation as might be assumed, because the duration of full torque reversal is usually very limited and an alternator designed for a very short time rating can be used.

The reversing coupling described consists, therefore, of the alternator and the coupling proper, which behaves very much like an induction motor. It may very well be asked what advantage this has over the ordinary form of Diesel-electric propulsion where generators and motors have to be provided in much the same way.

The reply to this is that the alternator required, though it has to carry twice full load power for astern running at full power, is of very short-rated design, since these conditions are infrequent and of short duration. During ahead running the alternator is completely idle.

An arrangement of G.E.C. reversible magnetic coupling for geared Diesel vessels.

The efficiency for ahead running is exactly the same as for a simple magnetic coupling—not less than 98 per cent., and considerably higher, therefore, than a Diesel-electric scheme. The amount of switchgear is at a minimum as only two field switches and two regulators are required, none of which is required to carry heavy currents owing to the special arrangements described below.

In starting and ahead running, the control is precisely the same as with the non-reversing magnetic coupling. The engine is started and runs up to speed under no-load, when the D.C. exciting current is switched on and the propeller picks up to a speed corresponding with that of the engine, which can then be set to run at any required speed.

In reversing, the D.C. excitation is switched off, the engine speed reduced, and the alternator stator winding connected to the exciter winding, the alternator rotor-winding being itself excited with D.C. The coupling then reverses and the vessel moves astern, the engine speed being as required, but the engine still running in the forward direction.

Since power has to be transmitted by this method between the two windings and heavy-current switches would be necessary, special methods of connection have been devised which avoid this difficulty. These include the division of the exciter winding into two separate parts, one permanently connected to the alternator stator winding, and the other carrying the D.C. excitation for forward

running. When running ahead, the part connected to the alternator stator carries no current.

In running astern, special precautions are taken to avoid a voltage being induced in the exciter winding by the rotating field produced by the A.C. This refers particularly to a design of coupling whereby the alternator is mounted on the outside of the coupling, the order of the windings from the outside being then: alternator stator, alternator salient-pole rotor attached to the engine, coupling exciting member attached to the engine, squirrel-cage rotor attached to the pinion shaft.

This arrangement is apt to be of large overall diameter, and an alternative arrangement is to arrange the alternator separately on the engine shaft by the side of the coupling, introducing a bearing if necessary. The squirrel-cage member can be attached to the engine shaft if necessary, and the exciter winding to the pinion shaft; this arrangement reduces the overhanging weight, and is the one illustrated in the diagram.

It has been assumed in the above that the ratio of poles in the alternator to the coupling is 2 to 1. Special advantages may be obtained by departing slightly from this ratio, say 1.8 to 1 or even 1.6 to 1, according to the reversal torque required when the ship is still moving at full speed ahead at the moment of reversal.

In the case of these fractional ratios, the reversed coupling acts as a reduction gear between engine and propeller; with a pole ratio of 1.8 to 1 the gear ratio is 1 to 0.8; with a pole ratio of 1.6 to 1 the gear ratio is 1 to 0.6. With a normal pole ratio of 2 to 1 the gear ratio is 1 to 1, and in forward motion the ratio is always 1 to 1, apart from the slight slip in the coupling.

### LARGER WELDING ROD

From *Mechanical Engineering*, (NEW YORK), APRIL, 1942

If instead of continuing arbitrarily to use the smaller diameter rods, industry would employ just one size larger, there would be a tremendous increase in speed of welding and, consequently, much faster production of vitally needed welded war products, according to J. F. Lincoln, president of The Lincoln Electric Company. For example, every welder working to-day who would start using 1/4-in. electrode in place of the 3/16-in. size, could, in six hours, do the same amount of welding he now does in eight. The total saving in man-hours, if only half the 200,000 welding operators were to make this change on only 50 per cent of the war welding jobs being done to-day, would be equivalent to 25,000 welders. This army of workers would thus be made immediately available for other, or additional work.

Electrodes of larger diameter, says Mr. Lincoln, make for faster welding because they deposit more metal in a given time than the smaller sizes. Larger electrodes simply "pour" the metal into the weld faster than small ones.

Not only would adoption of larger electrodes give industry a new and vast army of skilled welders, but it would relieve a threatened bottleneck in electrode production. According to Mr. Lincoln, it takes just as long to produce small-size electrodes as it does large ones. The controlling factor is the application of the coating which allows the modern electrode to produce the much higher quality of weld than was possible with old-type uncoated rods. If the welding industry could concentrate on producing larger size electrodes the availability of electrode metal would be greatly increased, since the larger sizes contain proportionately more metal for welding than the smaller.

### TO-MORROW MAY BE TOO LATE

C. D. Howe, Hon.M.E.I.C., Minister of Munitions and Supply

From *Industrial Canada*, APRIL, 1942

These are dangerous days. Never before in the history of mankind has there been such universal havoc. The proportions of this bloody battle are beyond the comprehension of peace-loving citizens who have spent their lives creating a new world where men could look forward with confidence to a future of comfort.

This war has rudely upset all of our calculations. Yet an alarmingly large proportion of our citizens cannot even yet realize that we face now, to-day, at this very hour, the awful crisis in our history.

It is not a question for armies or navies or airmen to decide. It is not within their sole power to turn the tide of battle. The crisis rests right on the shoulders of the average citizen—the workers in the plants, the women in the homes—the executives who control the productive capacity of our industries big and little.

To-morrow it may be too late to discover the ways and means of speeding up production, and then our future is an uncertainty too awful to contemplate.

Is it then too much to expect that every man in Canada who has productive capacity at his command, will forget self and profit, will overlook rights and privileges and turn his whole thought to the production of the war materials so sorely needed by those who face the enemy on none too distant battle fields and on oceans shockingly near our own shores?

This is the story that the Department of Munitions and Supply has been endeavouring to bring home to the citizens of Canada in the daily press, in the magazines and by the radio during recent weeks. Shall Brave Men Die Because YOU Faltered?

### THE R.A.F.'S TWENTY-FOURTH BIRTHDAY

From *The Engineer*, (LONDON), APRIL 3, 1942

Twenty-four years ago, on April 1st, 1918, the R.A.F. was first officially formed, under the terms of the Air Force (Constitution) Act of 1917. The amalgamation of the R.F.C. and the R.N.A.S., recommended by the Air Organization Committee under General Smuts, became an accomplished fact, Britain's two air arms being merged into a single fighting Service. An Air Council had been set up in January, 1918, under the first Air Minister, Viscount Rothermere. He was succeeded, on the creation of the R.A.F., by Viscount Weir. Shortly afterwards, in January, 1919, Mr. Winston Churchill became Secretary of State for War and Air, a post he held for two years. The Chief of the Air Staff at the time of the R.A.F.'s formation was Major-General Sir Hugh (now Viscount) Trenchard. Following the creation of the Force, Major-General Sykes took over for a year; then in April, 1919, Lord Trenchard again became C.A.S., holding the post for ten years—the longest tenure of any holder of that key position in the Empire's defence. At the time of the Armistice Britain's R.A.F. comprised 188 operational squadrons with a first-line strength of 3,300 aircraft. Altogether, the R.A.F. possessed 22,647 aeroplanes, 103 airships, and had a total personnel strength of 291,175, including over 27,000 officers, of whom more than one half were trained pilots. This mighty force was backed by the world's greatest and most efficient aircraft industry, with an output of about 3,500 airframes a month, and an even larger output of aero-engines. To-day, the R.A.F. faces the greatest test of all. With a strength now equalling that of its most powerful enemy, the German *Luftwaffe*, it is fighting offensively on several air fronts.

## ARE ENGINEERS INARTICULATE?

It would be interesting to trace the origin of the idea held by some that engineers as a class are inarticulate; a statement which unfortunately is even heard from engineers themselves. The dictionary tells us that the term implies inability to speak distinctly or even inability to speak at all. Thus an inarticulate person is presumably one who is unable to give effective expression to his ideas, even if he has any, and the circulation of the statement is certainly not a compliment to our profession.

Perhaps as a class, engineers do not like talking about subjects on which their knowledge does not qualify them to speak, or on which they have nothing to say. In this respect they differ entirely from, shall we say, certain types of professional politician. But engineers as a class are able and willing to express themselves, both in writing and orally, on subjects with which their training enables them to deal. As a rule they do not care for speeches or written communications which carry no definite message and employ a multitude of words in doing so. Few engineers are orators in the politician's or lawyer's sense of the word.

The engineer usually has to address hearers or readers who, like himself, wish to base their conclusions on ascertained facts and reasoned argument, not on impassioned appeals to sentiment, emotion, or prejudice. There are persons in all walks of life who seem to think that the announcement of a fact taking five hundred words is ten times as forceful as the same statement made in fifty words, but not many of these people are engineers. It may even be that the legend of the inarticulate engineer was put forth in an attempt to explain why so few engineers are given to the outpouring of words.

Bodies like the Engineering Institute have as one of their main purposes the encouragement of communications by and between their members. As a matter of fact the professional publications—or literature—of the engineer compare very favourably in quality and amount with the corresponding output of sister professions. If a criticism is permissible at this point, it would be that too many engineers are silent because they do not realize that their own individual work or experience covers much which would be of interest to their fellows, and that therefore they have a message to deliver.

In addition to the preparation of papers, and taking part in spoken or written discussion on professional matters, the average engineer is occasionally called upon to address a professional or social gathering, sometimes without time for preparation. Those of us who have had the opportunity to attend Institute and branch meetings in various parts of the Dominion, and over a period of years, cannot fail to have been struck with the large number of Institute members who can think on their feet, take an active part in debate, preside at meetings, and prove effective—in some cases even brilliant—as extempore speakers.

There were outstanding examples of the last named ability at our recent annual meeting. No one who had the privilege of seeing and hearing General McNaughton when he delivered his address without manuscript or notes, to Canadian engineers at this year's annual dinner will forget that stirring call to the Canadian people, the eloquence of its words, or the sincerity and deep emotion of the speaker.

On the same occasion the speeches of the outgoing and incoming presidents of the Institute were noteworthy. Dean Mackenzie's efficiency as a presiding officer was evident throughout the evening and everyone was delighted by the agility with which he glided over a momentary check by suddenly awarding an "honorary" doctorate to an American guest whose turn had been omitted. Dean Young's happy

## News of the Institute and other Societies, Comments and Correspondence, Elections and Transfers

address on his induction as president for 1942 was a model. Brief and to the point, it shed light on the traditions and history of the Institute, touched on the part played by our French-speaking members, and gracefully welcomed our distinguished guests.

Surely a series of speeches such as these—and there are many other examples—should finally dispose of the rumour or legend that the engineer is inarticulate.

## PRESIDENT'S TRIP TO THE WEST

An account of the president's visit to the Sault Ste. Marie and the Lakehead Branches is published in the News of the Branches section of this *Journal* and it is expected that detailed reports from other branches will appear in the next issue. In the meantime, it may be of interest to present a general outline of the presidential tour to the western coast.

Dean Young left Toronto on March 31st and returned on April 23rd after having visited all branches from Sault Ste. Marie westward, a total of eight. In addition, he was the guest speaker at a meeting of the Sudbury Branch of the Canadian Institute of Mining and Metallurgy on his way west.

The presidential party, up to Winnipeg, included Vice-Presidents K. M. Cameron of Ottawa and J. L. Lang of Sault Ste. Marie, and Past Vice-President R. L. Dobbin of Peterborough. At Winnipeg, the president was also accompanied by Past Vice-President Fred Newell of Montreal who joined him again at Vancouver. The general secretary, who had expected to accompany Dean Young on his tour, was detained at Ottawa by his new duties in the National Selective Service.

Dinner meetings were held at all branches except at Winnipeg where the function was a luncheon. In his addresses, the president described the responsibilities of the engineer in the war and reviewed the active part played by the Institute in the national effort. He outlined also the duties which would fall on the profession in the reconstruction of a new world.

At Vancouver, on April 18th, a regional meeting of Council was held and was attended by several councillors representing the western branches. Among past officers present were, Past-Presidents G. A. Walkem and E. A. Cleveland of Vancouver and Past Vice-President Fred Newell of Montreal. In the absence of an official from Headquarters, the secretary-treasurer of the Vancouver Branch, P. B. Stroyan, acted as secretary of the meeting. The proceedings were recorded in a very able manner and the minutes which appear in another column show that most of those present took part in the discussion. This is further evidence of the wisdom of the policy established in recent years of holding regional meetings of the Council; they afford an opportunity for an exchange of views with branches away from Headquarters and stimulate the interest in Institute affairs.

Besides meeting with branches of the Institute during his trip, Dean Young addressed groups of the University of Toronto Alumni Federation in all cities where he stopped.

The fact that the president now contemplates visiting the Quebec and the Maritime Branches during the summer is the promise of another brilliant year in the records of the Institute.

## BIG WEEK

A fortunate combination of events in Toronto made the week of April 20th outstanding in Institute history. First there were three days devoted to the Webster lectures, then a regional meeting of Council and a concluding event in the form of a tribute to Dean C. R. Young.

### THE WEBSTER LECTURES

For some time the Institute has wanted to give assistance to various parts of the country in the matter of civil defence. It was felt that many phases of this topic were entirely engineering, and therefore lay directly in the path of Institute interests and policy. Certain approaches to government officials has not produced encouraging results, and for some time it appeared as if little could be done.

It was, therefore, a great pleasure to have the Institute's proposal to give a series of lectures, accepted by Professor Fred Webster, Deputy Chief Engineer of the Ministry of Home Security, who is in Canada temporarily — on a special mission. Prof. Webster has made a study of the effects of bombing on structures, and is the outstanding expert on these matters in the British Empire. No more competent person exists, and it was a wonderful piece of good fortune that he was available in this country at this time. The Institute is indeed proud to be the means of bringing such valuable information to the Canadian people.

The lectures occupied three days — April 22, 23, and 24th, and consisted of a two and a half hour session each morning and afternoon. There is no description that will do justice to the value of the information distributed by Professor Webster. Only those who attended have any conception of its volume and importance, but the following time-table will indicate the breadth of field that was covered.

#### APRIL 22ND:

*Morning* —The background—Bombing action and its effects.

*Afternoon*—Air Raid shelters in general.

- (a) Trenches.
- (b) Surface shelters.
- (c) Semi-sunk shelters.

#### APRIL 23RD:

*Morning* —Shelters and protected working spaces within buildings.

The strengthening of floors above basements and other floors.

The problem of the multi-storeyed building.

General discussion on shelters.

*Afternoon*—(a) Bomb-proof tunnels.  
(b) Bomb-proof structures above and below ground.

#### APRIL 24TH:

*Morning* —(a) Fire protection.  
(b) Protection of buildings against high explosive effects.  
(c) Window protection.  
(d) Factor in design in new buildings for war-time purposes.

*Afternoon*—(a) Factory protection.  
(b) Protective walls for machinery and assembly line protection.  
(c) Public utilities.

*Evening* —General discussion.

Invitations to attend were sent by the Institute to those persons or organizations proposed by the branches, al-

though in all instances it was not possible to include the full list. It was felt that the lectures would be of most benefit to organizations such as public utilities, public works, municipalities, transportation companies, war industries, active service units, structural steel firms, architects and consulting engineers.

These lectures were given without charge to anyone, and were not restricted to members of the Institute. Employers were told to send their best man, irrespective of whether or not he was a member. In matters of such great national importance, the Institute did not think it wise to restrict the dissemination of the knowledge to its own members. The Royal Architectural Institute of Canada was also invited to send representatives, and did avail itself of the opportunity.

It was the opinion of many people that the Institute has never rendered a greater service to the profession or to Canada than was given by these lectures. One hundred and eighty engineers are now aware of the damage that can be done by bombs, and of methods of protecting people, buildings and production from the devastating effects. The information given by Professor Webster is official—it's new, it's specific, and it's largely confidential. It does not just come out of books, but out of field experience and laboratory tests, and from a man whose chief duty it has been to study such matters day and night in all parts of his own country.

The only condition attached to the lectures was that each person would act as a consultant, so that others who could not attend, and who needed the information, could secure it in their own locality and with little difficulty. To this end, those who heard the lectures are being formed into committees right across the country, not only to be consultants but to adapt to local conditions those things which they learned at Toronto, and to study methods by which the greatest use can be made of the material which is now available.

Professor Webster deserves the thanks of every member of the Institute—in fact of every Canadian citizen. He was not sent here to give lectures, and yet he undertook this arduous assignment, as well as certain other lectures at Institute branches, solely to give the Canadian people that information which he knows will aid in the preservation of life and property.

His audience was very appreciative of what they were privileged to see and hear. No one missed a single lecture, and no one left before each lecture was concluded. At the final lecture they presented Professor Webster with a wrist watch suitably engraved and a purse of money. The latter was turned over to the High Commissioner to purchase chocolate and milk for English children. Professor Webster was greatly affected by the unexpected presentation, and afterward said it was one of the most pleasing things that has happened to him in a long time.

The lectures were held principally in the theatre of Hart House at the University of Toronto, and luncheon was served in the Great Hall. People were there from all over Canada—from coast to coast, and from Washington, D.C. It was indeed an important occasion, a great privilege, and a real experience.

### REGIONAL MEETING OF COUNCIL

The Webster lectures had brought to Toronto several members who had been at one time or another active in Institute affairs. Following the established practice they were invited to the regional meeting of Council on April 25th and a very representative attendance resulted. Among those who had come from distant branches were Vice-President J. L. Lang of Sault Ste. Marie, Past Councillor D. A. R. McCannel of Regina, who is also president of the Dominion Council of Professional Engineers, Past

# TESTIMONIAL DINNER TO DEAN C. R. YOUNG

HART HOUSE, TORONTO

Professor R. W. Angus addresses the meeting. On the right is M. B. Hastings, president of the Toronto Alumni Federation.

President Warren C. Miller speaks for the Association of Professional Engineers of Ontario in praise of Dean Young.

First graduate in engineering, Dr. J. L. Morris, presents the illuminated address to Dean Young. Past President F. A. Gaby looks on.

Below: William Storrie makes an excellent chairman. On his left is President H. J. Cody, on his right Dean Young and Warren C. Miller.

From right to left, Dean Arthur L. Clark of Queen's, Professor F. Webster of London, England, General C. F. Constantine, Dr. Cody and Mr. Storrie.

General picture of the group before entering the Great Hall.

Chairman Storrie leads the cheering for the guest of honour. Left to right, Messrs. Morris, Gaby, Miller, Young, Storrie and Cody.

### TAKEN AT THE JOINT LUNCHEON

President C. R. Young presents the Duggan Medal to O. W. Ellis

From left to right: Past President F. A. Gaby, D. A. R. McCannel, Dean C. R. Young, Warren C. Miller and I. P. MacNab.

Councillor Ira P. MacNab of Halifax and D. R. Smith, vice-chairman of the Saint John Branch.

The discussion of the items on the agenda developed to a point where it was necessary to adjourn for lunch and reconvene immediately after. When the meeting concluded in the afternoon it was nearly five o'clock. Coming one week after another regional meeting held in Vancouver, the Toronto meeting allowed comparison between the views of members from different sections of the country on matters of importance to the membership at large. The president who had been present at Vancouver was able to interpret the sentiments of the western branches and it was felt after the meeting that the decisions arrived at were well representative of the opinion of the membership in general. The usual report of the proceedings will appear in the June *Journal*.

Members of the Council of the Association of Professional Engineers of Ontario joined with the Council of the Institute for lunch. At the end of the luncheon Dean Young presented the Duggan Medal of the Institute for 1941 to O. W. Ellis, Director of the Department of Engineering and Metallurgy, Ontario Research Foundation.

#### TRIBUTE TO DEAN C. R. YOUNG

Three hundred and fifty friends and admirers of C. R. Young gathered in the Great Hall of Hart House on the evening of Saturday, April 25th, to do him honour. The Association of Professional Engineers of Ontario and the Toronto Branch of the Institute combined to arrange a banquet which would be the medium by which engineers could acknowledge and celebrate his election to the Deanship of Engineering at Toronto, and to the Presidency of the Engineering Institute of Canada.

William Storrie was in the chair, and very acceptably filled the office. The speaker list included C. M. Goodrich, Professor R. W. Angus, M. B. Hastings, Warren C. Miller and F. A. Gaby. D. A. R. McCannel read the illuminated address, which was later presented by J. L. Morris to C. R. Young. The address, which was bound in a tooled leather jacket, the handiwork of A. E. Berry, reads as follows:

CLARENCE RICHARD YOUNG  
B.A.S.C., C.E.

WE the Members of the Toronto Branch of The Engineering Institute of Canada, and of the Association of Professional Engineers of Ontario, extend Greetings and Best Wishes on your accession to the Presidency of The Engineering Institute of Canada, and to the Deanship of the Faculty of Applied Science and Engineering, University of Toronto.

Your friends and fellow engineers gathered here in the Great Hall of Hart House ask you to accept our Sincere Congratulations. We acknowledge with appreciation the Honour that we share in your appointment to these high offices.

W. C. MILLER,  
President, Association of  
Professional Engineers of Ontario.

W. S. WILSON  
Chairman, Toronto Branch,  
The Engineering Institute of Canada.

Toronto, April 25th 1942.

Dean Young spoke of his trip to the west coast and of his splendid reception at all branches of the Institute and at the Alumni luncheons. He dwelt on the engineers' part in the war and in post war reconstruction, pointing out the greater responsibility that now lies before the profession because of its special training and its assumption of responsibility in carrying on the war.

After the dinner there were special features to entertain the guests—displays in the pool and feats of legerdemain, music, dancing and so on. It was a great day, thoroughly enjoyable. Everyone was happy to participate in a demonstration of affection and respect for the guest of honour.

#### ENGINEERING AND ENGINEERS

Warren C. Miller, M.E.I.C., president of the Association of Professional Engineers of Ontario, was the guest speaker at the meeting of the Border Cities Branch of The Engineering Institute of Canada held on March 13th.

Taking as his topic "Engineering and Engineers," he defined engineering "as a system of logical reasoning based on established facts with a definitely practical application to the effective production and distribution of materials, machines and structures."

Mr. Miller was of the opinion that the engineer is primarily an economist rather than a technician. His technical training and experience is for the purpose of enabling him to establish definite facts that will form the basis of economic decisions. While his particular field in the first instance is the production and distribution of materials, machines and structures, the engineering approach to the solution of this type of problem can be applied effectively to a wider field.

The substance of Mr. Miller's address appears in this issue under the News of the Branches heading.

## PUBLICATIONS OF AMERICAN ENGINEERING SOCIETIES

From time to time announcements have appeared in the *Journal* regarding the exchange arrangements which exist between The Engineering Institute of Canada and the founder engineering societies of the United States, whereby members of the Institute may secure the publications of the American societies at special rates which in most instances are the same as charged to their own members. A list of these publications with the amounts charged is given below, and subscriptions may either be sent direct to New York or through Headquarters of the Institute.

	Rate to E.I.C. Members	Rate to Non- Members
<b>AMERICAN SOCIETY OF CIVIL ENGINEERS</b>		
Proceedings, single copies.....	\$ 0.50	\$ 1.00
Per year.....	4.00*	8.00†

### BRITAIN'S EXPORT TRADE

The maintenance of British overseas trade under war conditions is a matter of prime importance, for the export of British products has to furnish as far as possible the foreign exchange which is required to pay for food and materials which she must import. The situation has been somewhat relieved by the generous action of the United States in passing the Lend-Lease Act of 1941, although this arrangement has necessarily had the effect of limiting the export from Britain of certain lines of manufacture.

We are so accustomed to think of Britain's constantly increasing production of munitions of war, and the complete change in industrial conditions which her war effort

has involved, that it is almost a surprise to find that the total war effort has not put an end to her export trade, although no doubt her enemies hoped it would. The necessities of war production, especially as to the distribution of labour and the allocation of available materials, of course override all other requirements, but within the limits thus imposed, customers abroad are being served with goods whose quality fully maintains British traditions as to craftsmanship and reliability. This is in spite of the restriction of manufacturing space, the enforced shifting of population, the rationing of supplies of almost every kind and the action of the King's enemies.

It is true that in some industries, production for export has had to be suspended owing to lack of shipping space or labour shortage. But in others, especially in products such as textiles or dyestuffs, the exports permitted are of great value to the country—wool, for example, is not a lease-lend material—pottery and glass ware exports are among those strictly controlled and allocated.

A recent publication—"British Trade and Industry"\*—has come to the Institute which gives an absorbing picture of the growth of industrial Britain, and—what is of even greater interest just now—of the present activities of the industrial organization in the beleaguered island. Its advertisements are as interesting as its wealth of illustrations, and (perhaps looking forward to post war developments) the letterpress is in English and Spanish. The book is lavishly produced: its articles cover twenty-two of the main divisions of British industry and are written by acknowledged leaders in each field.

The advertising matter seems to be prepared with the general aim of stating what the industry is prepared to supply, either now or after the war, and giving a clear idea of the advertisers' status and resources. A characteristic attitude is taken by one company which simply names the various wars which the concern has survived. Its business began at the time of the War of the Austrian Succession in 1740 and is now affected by the war of 1940!

As an example of British foresightedness and craftsmanship the publication is both interesting and unusual. "British Trade and Industry is a record of creative effort, eagerly initiated and long sustained. It is a reminder of what British enterprise has done to unlock for all the treasure-house of the earth's bounty. It can need no other justification for appearing now, when the powers of Order and Anarchy, as we see them, are clenched in the bitterest struggle of all time."

### REGIONAL COUNCIL MEETINGS

The policy of holding council meetings away from Headquarters as often as possible has been followed for some years past, and the results have been so satisfactory that its continuance seems assured. Last year half the total number of council meetings were of the regional type; thus enabling many members to take part in the debates of Council who would otherwise have been prevented from doing so, unless they could attend the sessions at the Annual General Meeting. This year two such regional meetings have already taken place.

Regional meetings plus the general council meeting at the time of the Institute annual meeting, have thus replaced the plenary meetings of council which were held annually from 1927 to 1937. These plenary meetings had the disadvantage of involving the Institute in considerable expense and did not bring out so clearly the decentralized nature of the Institute's organization as regards zones and branches.

The effective working of a body whose most easterly and westerly branches are more than three thousand miles

\*British Trade and Industry—a survey of past achievements and future prospects. By various authors. Published by *Country Life*, London. 332 pp. illus. advts. 14½ x 9¼ in. paper. 21s.

apart gives rise to many problems which can only be solved satisfactorily by regional action. This has been the case, for instance, in the negotiations leading to agreements with the several provincial professional associations, and in other questions where diversity of outlook and differences in local conditions have had to receive special consideration. Regional council meetings meet these conditions, and also enable practically all councillors to become more familiar with the details of management and administration of the Institute; giving them also an opportunity to observe at first hand the results of the work of the headquarters staff, particularly as regards correspondence, committees, finance, and the admission and transfer of members.

Probably few of our members realize the amount of work undertaken by councillors in the interest of their branches and the Institute as a whole. It must be remembered that these duties are performed by men who carry at the same time the burden and responsibility of their own particular jobs. Attendance at regional meetings means increased demand on their time but, as council records show, this is willingly met by practically all councillors who can travel to the meetings. They realize that their participation in such sessions helps them to obtain that general knowledge of the Institute's work and activities which they need in explaining Institute problems to their branch committees and branch members.

Another feature of such meetings is that they enable past councillors to keep in touch with activities and to lend the benefit of their experience to new Councils. It is important that the interest of active members be maintained even after they leave office. The regional meeting is ideally suited to such purposes.

## CORRESPONDENCE

Toronto, Ontario, April 14th, 1942.

The Editor,  
The Engineering Journal.

Dear Sir,

### POST WAR RECONSTRUCTION

In the February issue of the *Journal* it was intimated that the Council of the Institute had been asked to enquire as to the progress made by a Committee appointed by the Federal Cabinet to consider the problems of reconstruction after the war. As a result of this request the Council of the Institute arranged for an interview with Dr. Cyril James, the Chairman of the Committee, and a "release" was furnished and printed in the *Journal* to publicize the establishment and work of the Committee.

In May last I addressed an enquiry to a Deputy Minister of the Federal Government to ask if the problem of post-war immigration, and in particular rural settlement, would be considered by this Committee. I was advised that "as Crown lands are now vested in the Provinces, the matter is somewhat outside Dominion jurisdiction." From the "release" published in the *Journal* it does not appear that immigration had up to that time been considered either by the Advisory Committee, or by the two supplementary committees appointed later, which it is stated are composed of ranking civil servants.

Shortly after the Confederation of the Dominion the surveyors of that time, who were also the engineers of the country, were commissioned to survey the prairie provinces and subdivide the land on a system of square miles, with road allowances at stated intervals, very similar to that adopted by the United States. This system greatly facilitated settlement on the land and the granting of homesteads. As the population increased trading posts developed into towns which were subdivided into rectangular parcels or lots to fit within the square miles already established by the survey. On this land pattern policies both of rural and

urban settlement have been based, and for long years were considered to be satisfactory, but now it is seen that there is need for a radical revision.

This is an engineering problem of the first order far too great to be left in the hands of ranking civil servants in Ottawa however able they may be, and "as Crown lands are now vested in the Provinces" is one that must be considered by the Provinces, whereas immigration policies will be determined by the Dominion government.

National planning is now a subject of much concern in Great Britain, and some of the best minds are working on a new "Ground Plan for Britain." A new Minister has replaced Lord Reith in the Ministry of Works, and Lord Portal is now in charge of the Ministry of Works and Planning. But before this change took place Lord Balfour of Burleigh, the Chairman of the 1940 British Council, presented to Lord Reith a series of maps on which to base a National Plan. The letter which was transmitted with this gift is perhaps too long for your columns, but the latter half is, in my opinion, well worth serious consideration by the engineers of the Dominion and all interested in planning for a better Canada. The last paragraph clearly indicates that a Central Planning Authority must seek information from many sources and secure co-operation by taking the people into their confidence. Extracts from the letter follow.

Yours truly,

ARTHUR G. DALZELL, M.E.I.C.

Extracts from the letter to Lord Reith from Lord Balfour, in reference to a suggested new Ground Plan of Britain:

"You may say, perhaps, that the maps provide you with a chess-board on which the pawns can be moved to suit the game, but planning is not a game of chess and the pawns are not inanimate chessmen. They are flesh and blood, living organisms, of tender and vigorous growth, deep-rooted in soil, tradition and daily rounds. The area of the chessboard is not neatly squared out. It is a lovely countryside, on which the development of the past has sprinkled small towns, and in more recent years has spilled congested cities and sprawling suburbs bound together by the steel and concrete chains of transport.

These represent some of the capital that has been put into the country to assist its growth. If we have accepted national planning, it is because we are aware that this capital has not, in the past, been laid out in such a manner as best to serve the needs of the population, that our towns are not what they should be as dwelling places for citizens, that much of our countryside has been despoiled, that our industry is not able to give a balanced living to its work-people, nor is the soil able to support them. We must organize it to give freedom for work, for home, for leisure and for movement.

If future development is to be organized, it must spring from knowledge of the land, of how it is now used and how it might be used, of its industries and of the needs, habits and desires of those who live on it.

Not only is knowledge necessary, there must also be co-operation between industrialists, agriculturists, economists, sociologists and planners in all walks of life before a national scheme can be evolved. Planning means Direction, it does not mean Dictation. Planning will develop in relation to the intensity of search and sharing of experience. There will never be one final completed national plan. There must be flexibility to meet changing circumstances. The plan will develop as a result of patient co-operation, careful experiment and just administration, based on a knowledge and understanding of the facts.

Time may well be short. The concept of planning has hardly yet touched the main body of the public, and it is important that the assembly of greater knowledge and greater experience in planning matters be considered at the first opportunity. One of the most urgent tasks of a Central Planning Authority would be the collection of a body of

information flowing to it from the experience of all concerned, affording a set of values by which the full effect of plans and proposals can be judged and their repercussions analysed. In this manner, there would arise a form of co-operation between Government and people, between administrators and administered, which would savour not of control or restriction, but of welcomed initiative and shared experience."

### VANCOUVER MEETING OF COUNCIL

A regional meeting of the Council of the Institute was held at the Hotel Vancouver, Vancouver, B.C., on Saturday, April 18th, 1942, convening at ten o'clock a.m.

*Present:* President C. R. Young (Toronto) in the chair; Councillors S. G. Coultis (Calgary), I. M. Fraser (Saskatoon), J. Garrett (Edmonton), J. Haimes (Lethbridge), and H. N. Macpherson (Vancouver). There were also present by invitation—Past-Presidents E. A. Cleveland and G. A. Walkem of Vancouver; Past Vice-President Fred Newell of Montreal; Past-Councillors I. C. Barltrop (Vancouver), P. H. Buchan (Vancouver), A. R. Greig (Saskatoon), H. J. MacLeod (Edmonton), W. H. Powell (Vancouver), and A. S. Wootton (Vancouver); W. O. Scott, chairman, W. N. Kelly, vice-chairman, P. B. Stroyan, secretary-treasurer, H. Fitz-James, member of executive, J. N. Finlayson and C. E. Webb, past chairmen, and T. V. Berry, immediate past secretary-treasurer of the Vancouver Branch.

In the absence of the general secretary, Mr. P. B. Stroyan, secretary-treasurer of the Vancouver Branch, was appointed acting-secretary of the meeting.

The president explained that in accordance with the usual practice, invitations to attend this regional meeting of Council had been sent to all past-presidents, to past-vice-presidents and past councillors in the western zone, to members of the Vancouver Branch executive, and to other members who had been active in Institute affairs.

He welcomed all councillors and guests, and asked each person present to rise and give his name, place of residence and Institute affiliation. He invited everyone to take part in the discussion. The opinions of non-members of Council would be very helpful to the Council in reaching decisions.

The secretary read a letter from the acting-secretary of the Association of Professional Engineers of Saskatchewan suggesting amendments to the Saskatchewan agreement which would make the provisions of the agreement applicable only to members while resident in the province of Saskatchewan.

Following some discussion, on the motion of Mr. Macpherson, seconded by Mr. Fraser, it was unanimously resolved that this meeting of Council approve the principle of the proposed amendments, and that the Committee on Professional Interests be authorized to conduct the necessary negotiations with the Association of Professional Engineers of Saskatchewan.

There was a discussion about the possibility of giving wider distribution to Institute members of the publications of the Founder Societies.

At the March meeting of Council a letter had been presented from the Montreal Branch suggesting that Council study the possibility of abolishing the class of membership known as "Branch Affiliate." Following discussion, the matter had been referred to the Institute's Membership Committee for consideration and report. That committee hoped to present its report to the Council meeting to be held in Toronto on April 25th, but the chairman had indicated that in the meantime any suggestions received from the members attending the Vancouver meeting would be well received by the committee.

Letters were read from the Calgary and Edmonton

branches requesting that the decision as to whether or not there should be Branch Affiliates be left with the individual branches. The Calgary Branch was desirous of retaining the classification.

Speaking on behalf of the Lethbridge Branch, Mr. Haimes endorsed the requests made by Calgary and Edmonton. The Lethbridge Branch could not carry on without its Branch Affiliates. They experienced great difficulty in obtaining speakers, and unless they could have an audience of at least twenty or twenty-five people, it was not worth while getting speakers.

As councillor from the Calgary Branch, Mr. Coultis pointed out that the number of Branch Affiliates had increased considerably during his term of office as chairman, principally due to the efforts of the Membership and Attendance Committees. They had had a number of good speakers and had an excellent attendance of Branch Affiliates which was the means of bringing together in the west those who were interested in engineering but who do not have the same opportunity as those in the east of contacting other engineers. These Branch Affiliates are not permitted to vote on any matters pertaining to by laws, election of officers, etc., but it was felt that Institute members could transmit certain knowledge to these men who could not become full members. The fee is \$3.00 without the *Journal*, or \$5.00 if they desire to subscribe to the *Journal*. No complaints had been received from the regular members of the branch. If a Branch Affiliate does not pay his fee promptly he is not carried any further.

Mr. Scott stated that the Vancouver Branch had only four Branch Affiliates, who were charged only for the *Journal*. Like the Calgary Branch, the Vancouver Branch also desired to have a large attendance at their meetings, particularly when they had an out of town speaker. He was unable to see any reason for a change at the present time.

In response to an inquiry from the president, Mr. Newell stated that he had no knowledge of the discussions which had taken place in Montreal on this subject. He was in sympathy with the speakers who had presented the views of the various western branches. The Montreal Branch probably did not realise the difficulties under which the smaller and outlying branches operated. He was of the opinion that if the branches could bring into their organization as Branch Affiliates men who are in some way connected with the engineering profession, but who have not the qualifications to become full members of the Institute, they were doing a good thing. He considered that the professional engineer could learn a lot from these men, and they, in turn, could learn a lot from the professional engineers. He would be very sorry to see the classification of Branch Affiliate abolished.

It was moved by Mr. Garrett, and seconded by Mr. Haimes, that it is the opinion of this Council meeting that the classification of Branch Affiliate be retained. This was carried unanimously.

The President pointed out that in addition to being carried unanimously by Council, the amendment covered the unanimous opinion of those present other than councillors. It was also supported by Past Vice-President Newell of the Montreal Branch.

The president reported that at the last meeting of Council in Montreal the Canadian Forestry Association had asked that the Council appoint one of its members to their Board of Directors. This organization has for its objects the general promotion of the forest welfare of this country. The Council had appointed as its representative, Mr. John Stadler, of Montreal, who, last year, was treasurer of the Institute, and who is well acquainted with the forest reserves of the Dominion. He believed Mr. Stadler would be a very creditable representative of the Institute. This was noted.

The president reported that post-war reconstruction had been discussed at several meetings of the Council. Proposals had been made from time to time that the Institute branches should take an active and leading part in the planning for post-war reconstruction. This whole matter is under consideration by a government committee under the chairmanship of Principal James of McGill University. In the opinion of Vice-President K. M. Cameron, the Institute should work very closely within the frame-work set up by Principal James' committee. The Institute's interest centres largely around the work of a sub-committee on post-war reconstruction projects, of which Vice-President Cameron is chairman, and to which other members of the Institute have been appointed, including President Young and Vice-President Beaubien. This is a very complicated problem involving financial, economic and other considerations.

Past-President Cleveland felt that all members of the Institute were vitally interested in this question, and he favoured the most active support and co-operation on the part of the Institute in helping to solve these tremendous problems.

Mr. Coultis asked if the branches would be kept posted on all activities and advised of any service they could render in their particular districts. The President assured the meeting that from time to time communications would be sent to all the branches which would keep them informed as to the policy of the Council on this important question.

The financial statement to the end of March had been examined and approved, and showed that income was higher than for the same period last year. Although there was also an increase in expenditure, the net result indicated a substantial improvement in position.

The Finance Committee cannot recommend to Council the acceptance of the proposal contained in Serial Letter No. 45, dated April 7th, 1942, from the Canadian Chamber of Commerce, regarding the collection of personal income tax at the source. It was the opinion of the committee that the multitude of deductions already being made from payrolls by employers was a sufficient burden without adding to it by the deduction of income tax. The Institute's interest in the proposal would come simply as an employer, and the committee felt that it would not be justified in supporting a recommendation that affects other employers. This was noted, and the secretary was directed to so advise the Canadian Chamber of Commerce.

As a member of the Finance Committee, Mr. Newell asked permission to speak on the committee's report. During the past few years the financial condition of the Institute had been improving very steadily. He regretted that owing to other activities it had not been possible for the general secretary to visit all the branches during the past year. He did not know whether it would be possible for Mr. Wright to visit the branches this year, but in his opinion, it was vital to the life of the outlying branches that either Mr. Wright or the assistant general secretary should visit some, if not all, of the branches. It would be a good thing for the Institute, and particularly so from the financial point of view. It is realised that the work Mr. Wright is now doing is for the benefit of the country, and that is why the Council has granted him leave of absence. It may be necessary to slow down on some of the Institute activities, but personally he did not wish to see the interest in the Institute lowered in any way. For that reason he was anxious that either the general secretary or his assistant should visit the branches.

The president explained that at the Council meeting held in Montreal on March 14th, Mr. Wright had given preliminary information with respect to the position he now occupies, that of assistant to the director of National Selective Service. Council was then asked whether or not

it would be prepared to release Mr. Wright for practically full time service in this capacity. Council very generously approved of the proposal, feeling that it was one way in which the Institute could render a very valuable service to the country. Detailed arrangements had not yet been completed, but it has been agreed that Mr. Wright will be able to attend Council meetings in central Canada at least, and give such general guidance and assistance as he can. The president hoped to have Mr. Trudel accompany him on his visits to the branches, particularly in Quebec and the Maritime provinces.

The secretary read a memorandum on the question of life membership which had been presented to the annual meeting of the Institute by Mr. P. B. Motley, and which had already been discussed at one meeting of Council. The matter had been referred to the Finance Committee for consideration and report, and the Finance Committee had requested that the matter be discussed at the Vancouver and Toronto meetings so that the committee might have the benefit of any opinions expressed.

Following some discussion, it was agreed that the opinion of this Council meeting is that some steps should be taken to place life membership in the category of an honour rather than a concession. It was hoped that this expression of opinion would be of some assistance to the Finance Committee in dealing with the matter.

The president outlined the events which had led up to the Institute sponsoring a series of lectures on the effects of bombing to be given in Toronto on April 22nd, 23rd and 24th, by Professor F. Webster, Deputy Chief Engineer of the Ministry of Home Security of Great Britain. The officers of the Institute had felt that it would be a distinct contribution to the war effort if the Institute would sponsor these lectures, and he asked for an expression of opinion from the meeting as to whether or not Council approved of this action on the part of its officers.

On the motion of Mr. Macpherson, seconded by Mr. Garrett, it was unanimously resolved that the officers of the Institute be commended for their prompt action in sponsoring the lectures to be given by Professor Webster. The president thanked the meeting for the resolution.

The secretary read a progress report from the chairman of the Committee on the Training and Welfare of the Young Engineer. It outlined the progress which had been made in distributing the booklet "The Profession of Engineering in Canada," and also reported that counselling committees had already been appointed in several of the Institute branches. The reaction to the booklet had been most encouraging. Many favourable comments had been received. The report was noted with interest, and on the motion of Mr. Coultis, seconded by Mr. Haines, it was unanimously resolved that the thanks of Council be extended to Mr. Bennett and his committee for their splendid work.

As the consideration of applications was largely a routine matter and need not take up the time of non-members of Council, it was decided to adjourn for lunch and ask members of Council to reconvene afterwards in order to consider the applications.

It was noted that the next meeting of Council would be held in Toronto on Saturday, April 25th, 1942.

Mr. Webb expressed his personal appreciation of being able, for the first time, to attend a regional meeting of Council. He considered Vancouver had been honoured in having been chosen as the meeting place.

Mr. Kelly also expressed his appreciation at being invited to attend the meeting.

Mr. Coultis expressed the thanks of the visiting members for the kindly care and entertainment that had been tendered to them by the Vancouver Branch.

The president stated that it had also been a source of great pleasure to him that the visiting members had been

so well looked after by the Vancouver Branch. To those who had come from distant parts it had been an inspiration and a revelation, and they would return to their homes with renewed enthusiasm for the work of the Institute. They were all very grateful to the Vancouver Branch.

The meeting adjourned for lunch, and reconvened in the afternoon, with the president in the chair.

A number of applications were considered, and the following elections and transfers were effected:

#### ADMISSION

Members .....	7
Affiliates .....	4
Students .....	11

#### TRANSFERS

Juniors to Members.....	3
Student to Member.....	1
Students to Juniors.....	5

The Council rose at three thirty p.m.

### ELECTIONS AND TRANSFERS

At the meeting of Council held in Vancouver on April the 18th, 1942, the following elections and transfers were effected:

#### Members

**Allan**, George William, (Tech. Coll., Glasgow), president and mgr., Canadian Sumner Iron Works, Ltd., Vancouver, B.C.

**Bourgeois**, J. A. A. Paul, B.A.Sc., C.E. (Ecole Polytechnique), asst. hydrometric engr., Dominion Water & Power Bureau, Montreal, Que.

**Dyer**, William E. S., constltg. engr., Algoma Steel Corp., Sault Ste. Marie, Ont.

**Geddes**, Alvin Brooks, B.Sc. (Elec.), (Iowa State Coll.), sales engr., Canadian Westinghouse Co. Ltd., Calgary, Alta.

**McDiarmid**, Frederick John, B.Sc. (Queen's), field engr., asst. to W. E. S. Dyer, constltg. engr., Sault Ste. Marie, Ont.

**McIntyre**, Vernard Howard, B.A.Sc. (Univ. of Toronto), president, V. H. McIntyre, Ltd., Toronto, Ont.

**Tubby**, Allan, B.Eng. (Civil), (Univ. of Sask.), mgr., Ottawa Branch and Plant, Currie Products Ltd., Ottawa, Ont.

#### Affiliates

**Auger**, J. B. Gerard, School of Engineering, Milwaukee, chief operator, rectifier stn., Aluminum Co. of Canada Ltd., Shawinigan Falls, Que.

**Goldstein**, Abraham, dftsman., Defence Industries Ltd., Verdun, Que.

**Key-Jones**, Gilbert, mgr. and owner, The Key Agencies, Calgary, Alberta.

**Roberts**, John David, sales engr., Farand & Delorme Ltd. Divn., United Steel Corp. Ltd., Montreal, Que.

#### Transferred from the class of Junior to that of Member

**Fuller**, Harold Alexander, B.Sc. (Civil), (Univ. of Man.), engr., Tropical Oil Co., Barranca Bermeja, Colombia, S.A.

**Leroux**, Jacques, B.A.Sc., C.E. (Ecole Polytechnique), res. engr., air services branch, Dept. of Transport, Mont Joli, Que.

**Ryder**, Frederick James, B.Sc. (Civil), (McGill Univ.), sales engr., i/c Toronto office, Canadian Bridge Co. Ltd., Toronto, Ont.

#### Transferred from the class of Student to that of Member

**Sentance**, Lawrence Crawley, B.Eng., M.Sc. (Mech.), (Univ. of Sask.), mech. engr., Canadian Westinghouse Co. Ltd., Hamilton, Ont.

#### Transferred from the class of Student to that of Junior

**Cuthbertson**, Wellington B., B.Sc. (Elec.), (Univ. of N.B.), instr'man., Dept. of Transport, Moncton, N.B.

**Fraser**, Frederic Walter, B.Sc. (Civil), (Univ. of Sask.), civil engr., Sault Structural Steel Co. Ltd., Sault Ste. Marie, Ont.

**Sicotte**, Jean, B.A.Sc., C.E. (Ecole Polytechnique), asst. mgr., Armand Sicotte & Sons, constrtg. engrs., Montreal, Que.

**Wallman**, Clifford George, B.Sc. (Elec.), (Univ. of Man.), B.Eng. (Mech.), (McGill Univ.), mech. engr., Canada Starch Co. Ltd., Cardinal, Ont.

**Weber**, Peter Albert, B.Sc. (Civil), (Univ. of Sask.), instr'man., Land Surveys Dept., C.N.R., Toronto, Ont.

#### Students Admitted

**Bain**, Frederick Archibald, (McGill Univ.), 4644 Oxford Ave., Montreal, Que.

**Beckett**, Donald Russell, (Queen's Univ.), 327 S. Mark St., Fort William, Ont.

**Bogert**, Frank Godard, (McGill Univ.), 103 Drayton Road, Pointe Claire, Que.

**Hudson**, George Waugh, (McGill Univ.), Montreal, Que.

**MacAulay**, Roy D., (Nova Scotia Tech. Coll.), 174 South St., Halifax, N.S.

**Mason**, Vere K., (McGill Univ.), 2101 University St., Montreal, Que.

**Newman**, Frederick Herbert, (Univ. of Toronto), 1 College St., St. Catharines, Ont.

**Norton**, Howard William, (McGill Univ.), 4165 Marcell Ave., Montreal, Que.

**Rogers**, Frank K., B.Sc. (Univ. of Man.), (McGill Univ.), c/o Shawinigan Chemicals, Ltd., Shawinigan Falls, Que.

**Scott**, Richard, B.A.Sc. (Univ. of Toronto), 471 St. Clements Ave., Toronto, Ont.

**Timms**, Reginald Harold, (Univ. of Toronto), 66 Randolph St., Welland, Ont.

At the meeting of Council held in Toronto on April 25th, 1942, the following elections and transfers were effected:

#### Members

**Bentley**, William Alexander, (Univ. of Toronto), struct'l. designer, Dominion Bridge Co. Ltd., Toronto, Ont.

**Grey**, Noel William, (Regent St. Polytechnic, London), gen. supt., gasoline dept., and chem. engr., Lobitos Oilfields, Lobitos, Peru.

**Harisay**, Vito, B.Sc. (Mech.), (Royal Hungarian Polytechnicum), mech. designer, Longueuil plant, Dominion Engineering Works Ltd.

**Harris**, John Thomas, (Battersea Polytechnic, London), plant engr., Sorauren Ave. Plant, Dominion Bridge Co. Ltd., Toronto, Ont.

**Holsten**, Alfred, (Trondheims Tekniske Skole), electrical chief operator, Hudson Bay Mining & Smelting Company, Flin Flon, Man.

**Maclaren**, William Officer, asst. director of aircraft production factories, Ministry of Aircraft Production, London, England.

#### Juniors

**Miles**, Charles William Edmund, (Grad., R.M.C.), asst. to chief works officer, Eastern Air Command, Halifax, N.S.

**Padley**, Gilbert, B.Sc. (Elec.), (Queen's Univ.), asst. elec. engr., Trinidad Leaseholds Ltd., Pointe-a-Pierre, Trinidad, B.W.I.

#### Affiliates

**Honde**, J. Oscar, cost and quantity analysis, Shawinigan Water & Power Company, Montreal, Que.

**Josslin**, James Alexander, asst. chief dftsman., Ont. Divn., Dominion Bridge Co. Ltd., Toronto, Ont.

**McKerlie**, Jardine, (Royal Tech. Coll., Glasgow), mgr., Ontario-Great Lakes Divn., Wartime Merchant Shipping Ltd., Toronto, Ont.

#### Transferred from the class of Student to that of Junior

**Hobbs**, George Hugh, B.Eng. (Elec.), (McGill Univ.), elec. engr., Defence Industries Ltd., Nobel, Ont.

#### Students Admitted

**Buhr**, Richard K., (Univ. of Man.), 2nd-Lieut., R.C.C.S., Officers' Training Centre, Brockville, Ont.

**Flay**, Alfred David, (Queen's Univ.), 386 Sunnyside Ave., Ottawa, Ont.

**Fraser**, William Mitchell, (N.S. Tech. Coll.), 331 Spring Garden Road, Halifax, N.S.

**Skelton**, Eric Tudor, (Univ. of N.B.), 2112 Vendome Ave., Montreal, Que.

### COMING MEETINGS

**Canadian Electrical Association**—52nd Annual Convention at the Log Chateau, Seigniory Club, Que., on June 11-12, 1942. Secretary, B. C. Fairchild, Room 804, Tramways Building, Montreal, Que.

**Eastern Photoelasticity Conference**—Fifteenth Semi-Annual Meeting at the University Club, 40 Trinity Place, Boston, Mass., on Saturday, June 20, 1942, Chairman, W. M. Murray, Room 1-321, Massachusetts Institute of Technology, Cambridge, Mass.

# Personals

The recent announcement of the formation overseas of a Canadian Army of two corps has been received with enthusiasm by all Canadians. It is of particular interest to note that several members of the Institute have received high appointments on the staff of the Army Headquarters under command of **Lieutenant-General A. G. L. McNaughton**, C.B., C.M.G., D.S.O., M.E.I.C.

**Major-General G. R. Turner**, M.C., D.C.M., M.E.I.C., has been promoted from the rank of brigadier and appointed to the army staff. He was born at Four Falls, N.B., in 1890 and was educated at Andover, N.B. He enlisted at sixteen in the 3rd Field Company, Royal Canadian Engineers, and served in France as a sergeant and sergeant-major, being commissioned in September, 1915. He was promoted to captain a year later.

His subsequent appointments included regimental and staff service and in May, 1918, he was promoted to major. He was mentioned in dispatches, awarded the Distinguished Conduct Medal and the Military Cross and bar.

## News of the Personal Activities of members of the Institute, and visitors to Headquarters

In 1918 he was placed in command of the 2nd Field Company, Royal Canadian Engineers, with the rank of major, and in 1926 he was made lieutenant-colonel, commanding the non-permanent engineers. At the end of his tenure of command he was transferred to the reserve of officers in 1930.

At the outbreak of this war he went overseas as officer commanding 1st Divisional Engineers and was promoted to the rank of brigadier and made chief engineering officer at Corps Headquarters.

General Hertzberg has acquired a very wide experience in the construction field with the Trussed Concrete Steel Company of Canada and the Bishop Construction Company. He has been a member of the firm of James, London and Hertzberg, consulting engineers and he is at the present

**Major-General G. R. Turner,**  
M.E.I.C.

**Major-General C. S. L. Hertzberg,**  
M.E.I.C.

**Brigadier J. E. Genet,**  
M.E.I.C.

In 1920 he was appointed to the permanent force with rank of captain, and studied at the School of Military Engineering, Chatham, England. Returning to Canada, he became an instructor in military engineering at the Royal Military College, Kingston. In 1924 he attended the Staff College at Quetta, India, and in 1927 he was appointed district engineer-officer of Military District No. 10, Winnipeg, Man. In 1929 he became assistant director of engineer services, National Defence Headquarters, Ottawa, Ont. In 1938 he attended a course at the Imperial Defence College, London, England, and on his return in 1939 he was on the General Staff at M.D. No. 11 Headquarters, Esquimalt, B.C.

At the outbreak of this war he went overseas as general staff officer, grade 1, with the 1st Division. He was promoted to colonel and later brigadier, and on formation of the Canadian Corps was appointed deputy adjutant and quartermaster-general of the corps.

**Major-General C. S. L. Hertzberg**, M.C., V.D., M.E.I.C., has been promoted from the rank of brigadier and appointed to the army staff. He was born at Toronto in 1886 and received his education at the University of Toronto where he graduated in 1905.

During the first world war he served overseas with the 7th Field Company, Royal Canadian Engineers. He was wounded in January of 1917, a month after winning the Military Cross at the Somme, and was invalided to Canada. In October, 1918, he joined the Canadian Expeditionary Force to Siberia, serving there until June, 1919, and winning the Czecho-Slovakian war medal for valour.

time a partner of Harkness and Hertzberg, consulting engineers of Toronto.

**Brigadier J. E. Genet**, M.E.I.C., has been promoted from colonel and appointed to the Army Staff. He was born at Brantford, Ont., in 1891 and was educated in the local schools. He served four years in the ranks of the 38th Regiment before being commissioned in that N.P.A.M. unit in 1912. In 1915 he went overseas as a lieutenant and served in France and Belgium with the 2nd and 1st Canadian Divisional Signal Companies. He was promoted to captain before the war ended.

In 1924 he was appointed to the Royal Canadian Corps of Signals, permanent force, after serving with the Princess Patricia's Canadian Light Infantry and for a period was district signals officer at Headquarters of M.D. No. 2 (Toronto). He was promoted to major in 1932 and became chief instructor, Royal Canadian School of Signals, Camp Borden, Ont. In 1935 he was appointed superintendent of the Northwest Territories and Yukon Radio System for the Canadian Government and was stationed at West Edmonton, Alta. In 1939 he was promoted to lieutenant-colonel and attended the Senior Officers School at Sheerness that year. Shortly after the outbreak of the present war he was appointed officer commanding the 1st Division Signals and in July, 1940, was appointed chief signal officer of a corps with rank of colonel.

**Brigadier J. L. Melville**, M.C., M.E.I.C., has been promoted from colonel and is posted at Corps Headquarters in England. He was born at Glasgow, Scotland, in 1888 and came

to Canada in 1913. In the last war he went overseas with the engineers as lieutenant and was promoted to captain in May, 1918. He served in France and Belgium from August, 1916, to April, 1919. He was in command of the 3rd District Engineers from 1934 to 1936 after which he was transferred to the Corps Reserve of Officers, Royal Canadian Engineers. In 1941 he was promoted from lieutenant-colonel when appointed to command R.C.E. Headquarters Corps Troops.

At the outbreak of the present war Brigadier Melville had resigned his position as commissioner on the War Veterans Allowance Board in the Federal Department of Pensions and National Health to command the 1st Canadian Pioneer Battalion, Royal Canadian Engineers, C.A.S.F.

Word has just been received that the 1st Canadian Armoured Divisional Ordnance Workshop C.A. (Reserve) has been organized with the following members of the Institute as officers: Officer Commanding, Captain Charles E. Garnett, M.E.I.C.; Captain George H. N. Monkman, M.E.I.C. Lieutenant Ralph R. Couper, M.E.I.C.; and 2nd Lieutenant Charles W. Carry, M.E.I.C.

H. W. Lea, M.E.I.C.

H. W. Lea, M.E.I.C., has been appointed director of the Wartime Bureau of Technical Personnel at Ottawa, succeeding E. M. Little who was recently made director of National Selective Service. Mr. Lea had joined the staff of the Bureau last summer and was its chief executive officer.

Born at Victoria, P.E.I., in 1898, he received his early education at Charlottetown and at the age of eighteen he joined the Canadian Expeditionary Force and served in England and France until 1919. He also served with the Royal Air Force during the last war. Returning to Canada in 1919 he entered McGill University at Montreal and graduated in civil engineering. He spent several years in Montreal working on design and construction for the Montreal Sewers Commission. At various periods he has also been employed with R. S. and W. S. Lea, Montreal, on hydraulic investigation and preparation of reports on hydro-electric power projects.

In 1937 he joined the Phillips Electrical Works Limited at Brockville, Ont., later being transferred to Montreal as district manager of the affiliated company, Canadian Telephones and Supplies Limited. Mr. Lea was granted leave of absence from this company last year to join the Wartime Bureau of Technical Personnel.

L. E. Westman, M.E.I.C., former assistant director of the Wartime Bureau of Technical Personnel, has been transferred to National Selective Service as assistant to the director, E. M. Little. Born at Granton, Ont., he was educated at the University of Toronto. During the last war he was employed by the Dominion Government on

Air Commodore Alan Ferrier, M.E.I.C., who succeeds Air Vice Marshal E. W. Stedman, M.E.I.C., as member of the Air Council in the Royal Canadian Air Force.

chemical control work and inspection. In 1918 he returned to the University of Toronto as chief demonstrator in the Department of Chemistry and was charged with the training of undergraduates for war industries. In 1919 he became editor of the *Canadian Chemical Journal* now *Canadian Chemistry and Process Industries*, which position he still holds. He was secretary of the Canadian Institute of Chemistry from 1921 to 1936.

I. S. Patterson, M.E.I.C., industrial control specialist with the Canadian General Electric Company, Limited, at Montreal, has been loaned to the Wartime Bureau of Technical Personnel at Ottawa. Born at Thomson, N.S., he received his education at the Nova Scotia Technical College where he graduated in electrical engineering in 1928. Upon graduation he joined the Canadian General Electric Company at Peterborough and after a period of training in Peterborough, Toronto and Schenectady, N.Y., he was appointed in 1930 to the Montreal office of the company as sales engineer.

Mr. Patterson will be missed from the Montreal Branch where he was particularly active, having been on the executive for the past few years.

H. N. Macpherson, M.E.I.C.

H. N. Macpherson, M.E.I.C., has been appointed regional representative of the Wartime Bureau of Technical Personnel in the Vancouver area. Mr. Macpherson is particularly well equipped to carry out these duties in British Columbia, where war industries have been expanding rapidly during recent months. Though born and raised in Ontario, Mr. Macpherson has obtained most of his business

experience in the West. An honour graduate of the University of Toronto in engineering he obtained his first position with the Saskatchewan Department of Highways.

During the Great War Mr. Macpherson served with the Imperial Ministry of Munitions at Moose Jaw, Sask., Edmonton, Alta., and at Montreal. After the war he spent a short time in Quebec as chief engineer for a road construction firm, but returned to the West and Regina in 1924. In 1927 he moved to Calgary as engineer and sales manager for the Alberta Wood Preserving Company and five years later started his own company, Permanent Timber Products Limited, at Vancouver. He is at present councillor of the Institute for the Vancouver Branch.

**Professor L. M. Arkley**, M.E.I.C., is retiring from Queen's University after acting as Head of the Department of Mechanical Engineering for twenty-two years; besides service at Queen's he was nine years in the Mechanical Engineering Department of the University of Toronto and one year at McGill, five years at Swarthmore College in Swarthmore, Pa., and five years as Director of the School of Machine Design at the Franklin Institute of Philadelphia, Pa.

**J. J. Spence**, M.E.I.C., has retired from the office of secretary-treasurer of the Toronto Branch of the Institute after having served for the past five years. He is a graduate of the University of Toronto from the class of 1909. For three years after graduation he was with Smith, Kerry and Chace, consulting engineers, Toronto, and from 1912 to 1923 he was plant manager of Woodturning Products Limited, Toronto. In 1923 he became demonstrator in the Faculty of Applied Science at the University of Toronto and has been on the teaching staff ever since. He is now a lecturer in engineering drawing at the University of Toronto.

**S. H. de Jong**, M.E.I.C., is the newly appointed secretary-treasurer of the Toronto Branch. He was educated at the University of Manitoba where he received his degree in civil engineering in 1931. For three sessions after graduation he was employed as a demonstrator at the University of Manitoba. In 1935 he was draughtsman and office manager with Fort Garry Motor Body and Paint Works Limited at Winnipeg. The following year he was a night school instructor with the City of Winnipeg School Board and Department of Education of Manitoba. He went to Ottawa

**Lieutenant-Colonel W. S. Wilson,**  
M.E.I.C.

**S. H. de Jong, M.E.I.C.**

**Jules Archambault, M.E.I.C.**

He was graduated as a B.Sc. from McGill University in 1900 and as an M.Sc. in 1910. Besides the teaching experience mentioned, Professor Arkley has had about ten years of practical experience in designing and operating steam power plants and has written many reports and papers on engineering subjects.

He joined the Institute as a Student in 1899 and has been a member ever since. He is also a member of the Association of Professional Engineers of Ontario and a member of the American Society of Heating and Ventilating Engineers.

Professor Arkley expects to live in Toronto.

**W. S. Wilson**, E.D., M.E.I.C., is the newly elected chairman of the Toronto Branch of the Institute. Born at Louise, Ont., he received his education at the University of Toronto where he graduated in 1921. In 1921-1922 he was engaged on estimating and supervising construction work with Wilson and Falconer, and in 1922-1923 was estimator with Dowling-Williams Limited. From 1923 until 1926 he was demonstrator in the Department of Engineering Drawing, University of Toronto, and in the following year was with R. W. H. Binnie, general contractor, as estimator. In 1927 Mr. Wilson was appointed secretary of the Faculty of Applied Science and Engineering of the University of Toronto, which position he still holds, along with that of assistant dean.

During the last war Mr. Wilson was overseas with the Canadian Expeditionary Force from 1915 to 1919, holding the ranks of lieutenant and captain. He is now a lieutenant-colonel, and is the officer commanding the Training Centre Battalion of the University of Toronto C.O.T.C.

in 1937 as compiler in the Topographic and Air Surveys Branch of the Department of Mines and Resources. Since 1940 he has been a demonstrator in the Department of Civil Engineering at the University of Toronto.

**Jules Archambault**, M.E.I.C., has recently been appointed associate transit controller with the Department of Munitions and Supply. He was educated at McGill University, Montreal where he received his engineering degree in 1926. Upon graduation he went with the Aluminum Company of Canada at Arvida as technical assistant. In 1927 he was transferred to the Duke-Price Power Company as engineer. In 1929 he joined the Bell Telephone Company of Canada at Montreal as an engineer in the transmission and foreign wire relations division. He became district manager at St. Hyacinthe in 1935. In 1937 he received the appointment of chief engineer of the Montreal Tramways Commission, a position which he still holds.

**E. M. Proctor**, M.E.I.C., is now head of the scrap rubber division of the Department of Munitions and Supply at Ottawa. Previously he was representing the Canadian government on the Bureau of Industrial Conservation at Washington, D.C. Mr. Proctor is president of the firm James Proctor and Redfern Limited, consulting engineers, Toronto.

**A. G. Graham**, M.E.I.C., city engineer of the City of Nanaimo, B.C. for the past twelve years, has been granted leave of absence by the city council and has taken up engineering duties under the chief works officer of the Western Air Command with headquarters at Victoria, B.C.

**Dugald Cameron**, M.E.I.C., formerly vice-president of John T. Hepburn Limited, Toronto, has joined the staff of the Citadel Merchandising Company, a government-owned company, and is in charge of the Toronto office. He has also been appointed secretary of a Technical Advisory Committee to Citadel.

**Flying Officer J. M. Walker**, M.E.I.C., engineer and designer with Gore and Storrie, consulting engineers, Toronto, has been granted a commission as flying officer in the R.C.A.F. and is at present stationed as works and building engineer officer at No. 31 Operational Training Unit, Royal Air Force Station, Debart, N.S.

**Sarto Plamondon**, M.E.I.C., has recently been appointed engineer in the Division of Industrial Hygiene of the Department of Health of the Province of Quebec, at Quebec. He was educated at Mount Saint Louis College and Ecole Polytechnique of Montreal, where he graduated in 1936. He joined the staff of the Department of Health on his graduation and became assistant sanitary engineer at Amos, Que. He left this position to accept his new appointment.

**Major J. P. Carrière**, M.E.I.C., of the Royal Canadian Engineers, has recently returned from overseas to attend the Staff College at Kingston, Ont.

**Norman D. Wilson**, M.E.I.C., prominent consulting engineer of Toronto, has been elected a councillor for the Civil Branch of the Association of Professional Engineers of the Province of Ontario for the year 1942.

**Major G. W. F. Ridout-Evans**, M.C., M.E.I.C., who was formerly stationed at M.D. No. 5, Quebec, Que., has been on the staff of the Inspection Board of the United Kingdom and Canada for several months past.

**Flying-Officer Ronald G. Archer**, M.E.I.C., has been commissioned in the R.C.A.F., Works and Buildings Branch and is at present stationed at Charlottetown, P.E.I. Previous to his enlistment he was assistant engineer of the Works Department, City Hall, Toronto, Ont.

**Hugo B. R. Craig**, M.E.I.C., has joined the staff of the Fraser-Brace Engineering Company, Limited, in Montreal. Before coming to Montreal he had been with the Hydro-Electric Power Commission of Ontario in Windsor.

**E. V. Gage**, M.E.I.C., is the new president of A. F. Byers Construction Company, Limited, Montreal, formerly known as A. F. Byers and Company, Limited. He fills the position held by the late A. F. Byers, M.E.I.C. Born at Peareton, Que., Mr. Gage attended McGill University and graduated in civil engineering with the degree of B.Sc., in the class of 1915. Upon graduation he joined the organization of which he is now president.

**William M. Harvey**, M.E.I.C., who for the past year has been on the staff of Rhokana Copper Corporation at Nkana, Northern Rhodesia, has returned to Canada and is now with the Aluminum Company of Canada at Arvida, Que.

**Henry M. Howard**, M.E.I.C., has accepted a position with the Eldorado Gold Mines, Limited, Port Hope, Ont., manufacturers of radium and uranium products. He was formerly with E. Long Limited, Orillia, Ont., as metallurgical sales engineer. Mr. Howard graduated from the University of Toronto with the degree of B.A.Sc., in the class of 1940.

**R. A. McLellan**, M.E.I.C., is now attached to No. 4 Air Training Command, R.C.A.F., at Calgary, Alta. He is the recent past-chairman of the Saskatchewan Branch. Before joining the R.C.A.F. he was a partner in the firm of Underwood and McLellan, Saskatoon, Sask.

**Sidney Phillips**, M.E.I.C., has received a commission in the R.C.N.V.R., as engineer lieutenant. Born in England, he came to Canada in 1940 from Talara, Peru, where he had been employed since 1933 by the Lobitos Oilfields as assistant electrical engineer and later as chief electrical engineer.

**L. G. Scott**, M.E.I.C., has been given leave of absence from the Hudson's Bay Company and has been appointed plant engineer at Boeing Aircraft in Vancouver, B.C. Mr. Scott graduated in electrical engineering from the University of Manitoba with the degree of B.Sc., in 1932, and joined the Hudson's Bay Company in the autumn of the same year.

**W. Grey Stuart**, M.E.I.C., of Vancouver, has accepted a position with the Demerara Bauxite Company, Mackenzie, British Guiana.

**L. A. Wilmot**, M.E.I.C., is with the Commodity Prices Stabilization Corporation Limited at Ottawa, having joined the Foreign Exchange Control Board in 1940. Before the war he was customs consultant at Toronto.

**Edgar H. Davis, Jr.**, E.I.C., who has been in Guayaquil, Ecuador, S.A., for the past two years with the International Petroleum Company as party chief, has returned to Canada and has accepted a position as designing engineer with the Canadian Dredge and Dock Company, Limited, at Toronto.

**Lieutenant W. A. Nelson, Jr.**, E.I.C., is now attached to the Royal Canadian Ordnance Corps and is stationed at Campbellford, Ont. Before his enlistment, Mr. Nelson was sales service engineer with the Bailey Meter Company, Limited, Montreal. He graduated from Queen's University with the degree of B.Sc., (Hon.) in the class of 1937.

**G. G. Wanless, Jr.**, E.I.C., has recently accepted a position in the National Research Council laboratories at Ottawa. He was educated at the University of Alberta and at McGill University where in 1934 he graduated with the degree of B.Sc. with honours in chemistry.

Upon graduation he returned, as an assistant chemist, to the Dominion Rubber Company, Limited, where he had been previously employed during his college vacations. Until 1937 he was in charge of a group of development workers on latex rubber. The following year he was transferred to the mechanical department in the Montreal office. He also spent a few months in the Winnipeg and the Vancouver offices of the company, returning to Montreal in 1940.

Until his transfer to the Capital, he was on the executive of the Junior Section of the Montreal Branch of the Institute, as well as the Branch News Editor.

**N. J. Paithouski**, S.E.I.C., is a lieutenant with the Royal Canadian Engineers and is attached to the training centre at Brockville, Ont. Before his enlistment, Mr. Paithouski was with the Canadian Kellogg Company in Sarnia, Ont. He graduated in civil engineering from Queen's University with the degree of B.Sc., in the class of 1940.

#### VISITORS TO HEADQUARTERS

**Rosaire Saintonge**, S.E.I.C., Consolidated Paper Corporation, Limited, Port Alfred, Que., on March 30th.

**Frank O. White**, M.E.I.C., chief engineer, Fraser Companies Limited, Edmundston, N.B., on April 1st.

**J. W. Wright**, S.E.I.C., Toronto, Ont., on April 4th.

**Sarto Plamondon**, M.E.I.C., Ministry of Health, Department of Industrial Hygiene, Quebec, Que., on April 8th.

**Gustave St. Jacques**, M.E.I.C., Public Service Board, Quebec, Que., on April 14th.

**Ira P. MacNab**, M.E.I.C., commissioner, Board of Commissioners of Public Utilities, Halifax, N.S., on April 20th.

**D. R. Smith**, M.E.I.C., director of works, Saint John, N.B., on April 20th.

**J. W. Sanger**, M.E.I.C., chief engineer, Hydro-Electric System, Winnipeg, Man., on April 20th.

**J. W. Porter**, M.E.I.C., chief engineer, western region, Canadian National Railways, Winnipeg, Man., on April 20th.

# Obituaries

*The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.*

**Robert McDowall, M.E.I.C.**, died in Toronto on March 29th, 1942. He was born on June 8th, 1864 in the township of Sydenham, Ont., and received his early education at Owen Sound Collegiate Institute. He entered the School of Practical Science at Toronto in 1885, having previously taught in public schools from 1883 to 1885. Graduating in 1888, he was employed for a year as an engineer by the contractor on the construction of piers and abutments of the bridges for the Canadian Pacific Railway entrance to Toronto, down the Don river valley. In 1889 he entered private practice as a civil engineer in Owen Sound and the following year he was commissioned as an Ontario land surveyor.

During the period from 1890 to almost the present time Mr. McDowall has acted as engineer for Owen Sound, Collingwood, Meaford, Wiarton, Chesley, the counties of Grey and Bruce, and many villages and townships. His engineering work included sewers, waterworks, bridges, pavements, grading, harbour works, dams, tunnels, and many minor works. As a pastime he constructed the framework of the first aeroplane ever seen in Owen Sound, and would have flown in it if he could have had a little financial help to complete the machinery. His surveying activities embraced railways, subdivisions in cities, towns, and waterfronts, mining claims in Rainy river, and many other assignments. Mr. McDowall received the degree of C.E. from the University of Toronto in 1901.

Mr. McDowall was one of the oldest members of the Institute having joined as a Student in 1887, the year of

its foundation. He was transferred to Associate Member in 1892 and in 1935 he became a Life Member.

**John Palmer, M.E.I.C.**, died in the hospital at Montreal on April 20th, 1942. Born in London, England, on June 20th, 1881, he received his education at the University of London where he was graduated as a Bachelor of Science in engineering in 1909. Before taking the engineering course at the University he had been for several years an articled pupil with the firm of Messrs. Johnson and Phillips, electrical contractors, London, England. He came to Canada in 1910 and joined the Canadian Westinghouse Company as erecting engineer. In 1912 he became district engineer at Calgary.

When war broke out he enlisted with the 102nd Infantry Battalion and became an officer and went overseas in March, 1916. After service in England and France he returned to civil life in October, 1919, and resumed his duties as district engineer of Canadian Westinghouse Company at Calgary. In 1920 he was transferred to Montreal, also as district engineer, a position which he held at the time of his death.

Mr. Palmer joined the Institute as an Associate Member in 1923 and he became a Member in 1940.

**Russell Henry Swingler, S.E.I.C.**, died as a result of an accident at Ottawa on March 21st, 1942. Born at Port Arthur, Ont., on June 4th, 1913, he received his primary education at the local technical school. In 1933 he went to Queen's University and was graduated in mechanical engineering in 1937. In the fall of the same year he joined the Civil Aviation Branch of the Department of Transport at Ottawa as junior engineer, a position which he held at the time of his death. During his stay in Ottawa, Mr. Swingler had been active in the Ottawa Sea Cadets and at the time of his death he was commanding officer.

Mr. Swingler joined the Institute as a Student in 1937.

## News of the Branches

### BORDER CITIES BRANCH

J. B. DOWLER, M.E.I.C. - - - Secretary-Treasurer  
W. R. STICKNEY, M.E.I.C. - - - Branch News Editor

The March meeting of the Border Cities Branch was held on Friday, the 20th at the Prince Edward Hotel. The guest speaker, who was introduced by J. Clark Keith, was Warren C. Miller, city engineer of St. Thomas and recently elected president of the Association of Professional Engineers of the Province of Ontario, who spoke on the subject **Engineering and Engineers**.

Mr. Miller, who has been a member of both The Engineering Institute of Canada and the Association of Professional Engineers for many years and has been on the council of both bodies, has had a better than average opportunity of appreciating that these two organizations are not competitive but complementary. Each has its own field and in some provinces agreements for joint membership have been reached. Up to the present it has not been possible to do this in Ontario, but there is no reason why the Institute and the Association should not work together in harmony and complete co-operation.

One of the most active Association committees is the Publicity Committee. Their work deals with publicity of two kinds: publicizing among its own members the work of the Association, and, through press releases publicizing the work and position of the engineer insofar as his work creates news that reacts to his professional benefit.

A great many people, including a minority of our own profession, have a very narrow idea of engineers and engineering. This conception seems to indicate that the engineer is only a technician—one step ahead of a skilled mechanic—who puts into operation the ideas of the executive. In the past there have been short-sighted gradu-

ates of the university who looked on it as a glorified trade school and went out into industry believing they were indeed technicians. Such men do not see any value in professional organizations, they think that if we used trade union methods we would get further; in general such men do not advance in station and they help contribute to the fiction that lawyers, financiers and business men are the only ones from whose numbers executives are selected. We should all be engaged in our business or profession for the ultimate purpose of making some contribution towards improvement in our way of life. This is our duty as members of the society in which we live, and we are only able to make a contribution to the general good so long as we think and act as one member of a great social fabric.

Engineering may be defined as "a system of logical reasoning based on established facts with a definitely practical application to the effective production and distribution of materials, machines and structures." This is what the professional economist considers his field, but there is a distinction based in the four words—"Based on Established Facts." Such men have been known to produce erroneous answers to industrial problems because they did not start from established facts.

Now in order to evaluate the evidence of established facts, sometimes to establish those facts themselves, and in order to reason logically from those facts, an intimate knowledge of the forces of nature is essential. Facts are elusive things and evidence is often conflicting, so a knowledge of natural law helps us when we are sorting out the facts from the guesses and opinions. An engineer, however,

must not be misled by assuming that because he works with facts his work is an exact science. He must keep in mind that his profession, while based on established fact, is engaged always in the solution of problems that involve human judgment and all his computations must be corrected by the human coefficient.

The engineer must realize, if he has a conception of the very fundamentals of his profession, that he is first, last and always an economist, with his feet firmly planted on solid ground, the ground of established facts. What then does the engineer, whether in training or practice, owe to society and how shall he repay to society the great part of the expense of his education that his fees do not cover?

The engineer's debt may be considered a fourfold obligation that is due to himself, his professional colleagues, his clients and society generally. He must prepare himself by observation, application and continual study for his life's work. If he is to be able to exercise that sound judgment that should characterize the engineer he must have a firm grounding in the essential mathematics and practical sciences that are the distinguishing marks of the engineer. He must not only know how but why; he must never cease studying to keep step with new methods and a changing technology. He should keep in mind at all times that his engineering training and experience can make a real contribution to administration and management, but if he expects to become a part of management he must not only know engineering as it is applied to the problems of business, but he will have to have in addition a working familiarity with the function of all other branch departments, and to understand in a general way what they contribute to the enterprise as a whole.

Secondly he has a duty to his professional colleagues. They have made it possible for him to have the benefit of their experience in orderly fashion. He owes it to them to practice his profession in accordance with the golden rule as explained to him in the code of ethics. Gentlemen do not need a code to define their duty but codes do give the public a knowledge of how engineers interpret the golden rule in their relations to one another. The code of ethics enables the young engineer to see how his older confreres with a high sense of ethical values act in a given situation.

He has another obligation to his fellow engineers. Just as he himself in his education has profited from their experience in the text books, the technical press and in the proceedings of technical societies so he in his turn has a duty to contribute to the general knowledge by a similar presentation of papers and articles on work in which he has had special experience. He should in addition contribute to the intelligent discussion of the papers of his fellows before meetings of engineers, and make, when he can, an intelligent contribution to the matters under debate. Such a participation in proceedings of this kind are among the distinguishing marks of the professional man. When two men each have a dollar and exchange them they still have a dollar each. However, if each has an idea and they exchange them then each has two ideas.
