Dr. Simeon Snell, an eminent eye surgeon, and, shortly before his death, President of the British Medical Association, had propounded the theory that miners' nystagmus was caused by a strained position of the eye-ball of the miner in the operation of "holing" or undercutting the coal by the handpick. Dr. Snell's persistence in his theory, and his acknowledged eminence in his profession, for a good many years led to its general acceptance, but Dr. Court, as the result of painstaking researches pursued underground, and the examination of underground and surface workers of all grades employed in naked-light mines and in safety-lamp mines, obtained convincing evidence that nystagmus was the result of deficient and partial illumination, and that the steady growth in the number of cases reported was the result of the increasing substitution of the oil-flame safety-lamp for torches and candles. Later Dr. Court had the satisfaction of having his resources confirmed by an exhaustive investigation, carried out by Dr. Leonard Hill, under the direction of Dr. John Haldane of the Home Office, and the medical profession has now for some years ascribed nystagmus to defective illumination. The definiteness with which this fact has been established is in large measure due to Dr. Court's first-hand and early investigation of the matter under actual working conditions, and has had as a result the installation of electric hand-lamps in English collieries on a large scale in substitution for the oil-flame safety-lamp.

Confirmation of Dr. Court's researches is to be found in the appearance of miners' nystagmus in Nova Scotia since the general introduction of safety-lamps about 1904. Up to that time no cases of nystagmus had been recorded in Nova Scotian collieries.

Dr. Court has been good enough to state that he has found many nystagmus cases suffer from the glare of the white light of the electric lamp, and for their relief he has advised the use of light-amber coloured glass in front of the electric bulb, or the use of Crookes' glass. Very satisfactory results have been thus obtained.

Another ailment of miners to which Dr. Court directed early attention was Ankylostomiasis, a variety of what is known on this side the Atlantic as the hook-worm disease. A series of articles on this disease was contributed by the writer to the "Journal" shortly after its appearance in present form in 1907. The disease had only one outbreak in Britain, namely at the Dolcoath Tin Mine, and suitable precautions have so far kept it out of British collieries, although should conditions of deep mining and compulsory watering of the roadways ever bring about the necessary predisposing conditions of heat and moisture in British mines, its re-appearance might be anticipated.

Canadian collieries, in their present stage of development are usually too cold to breed this parasite, or, if they are hot, they are usually dry. The disease is undoubtedly present in the southern States, but so much is now known about the habits of the parasite, and the necessary precautionary measures are so elementary, that with due care, the "miners' worm disease", as it was termed in Europe, should be easily eradicated from any American mines in which it may have obtained entrance. Prophylactic measures are entirely those of ordinary sanitation.

Dr. Court is a representative of a fine school of men, namely, the "colliery doctor." Earlier in his career his theories seemed to conflict with the financial interests of colliery owners, and were used to some extent by miners' leaders to oppose the introduction of safety lamps. He has had the pleasure of seeing his work commended by both miner and coal-owner, as the result of a painstaking and undeviating search for facts, and in this fashion has earned that recognition which is the crowning reward of the scientist. —Ed.

FATIGUE OF THE VISUAL ORGANS IN COAL MINERS: (La Fatigue de l'Appareil visuel, chez les Ouvriers Mineurs). By Dr. M. Stassen, Liege, Belgium.

Dr. Stassen's volume reviews the history of miners' nystagmus, describes the conditions of work underground, and assembles the conclusions indicated by statistics obtained during a comprehensive survey which comprise all the mines in the Province of Leige, and all the cases coming under observation of the nystagmus clinic at Mines Hospital at Liège. Dr. Stassen undertakes as the result of his investigations to establish the cause of miners' nystagmus—a disease of which the most prominent symptom is oscillation of the eyeballs—as *the result of a pronounced fatigue of the entire apparatus of vision*. He examines also the connection of nystagmus with the occurrence of accidents at work. The preventative and curative measures to be adopted are discussed, and also the principle of workmen's compensation in cases of nystagmus.

Medical writers on nystagmus have been sharply divided into two schools, namely, those who ascribed the cause of the disease to a strained position of the eyeballs at work, and those who attributed it to a deficiency of illumination and the fatigue arising from an attempt to see in the dark. The supporters of these two viewpoints are found in Britain, Belgium, France and Germany, and Dr. Stassen reviews with authority and in an interesting manner the progress of the medical literature on the subject. The large amount of attention given to this disease by British authorities is evident from the bibliography and the nomenclature associated with the disease.

Dr. Stassen discusses at great length the conditions of the coal miners' work, which he has observed under actual conditions, having, as he says, many times followed the miner from the daylight to the working place and back again. His studies have convinced him that *the work of a coal-miner imposes upon his visual organs a general fatigue, such as no other profession is exposed to*.

The miner descends in the cage, his eyes being adapted to the sunlight; the pupils, the visual ac-

commodation, and also the pressure upon the labyrinth of the ear being such as required by the atmospheric pressure and light conditions of the surface. In descending the shaft all these change abruptly, setting up reactions that irritate and tire the visual apparatus, and the nerve centres of both eye and ear, which are particularly to be observed in collieries having deep shafts with rapid hoisting time. Further adjustments of the visual apparatus are necessary before proceeding to the working place, known to miners as "getting the eyesight." The illumination underground is insufficient to enable the miner to distinguish objects clearly, and the visual apparatus is again strained in the endeavour to use the adaptation powers of the eye to their fullest and to an unnatural extent. During a prolonged stay underground the glare and the flickering of the miners' lamp exert a further irritating effect, and rapid changes are needed to regulate the admission of light to the retina. In coming out of the mine, into the daylight, reverse adaptations of the visual apparatus and the inner ear are caused. Dr. Stassen names many other circumstances of the miners' work that he considers to be the source of fatigue of the visual apparatus, but generally, he appears to prove that it is not one circumstance, but a combination of many, that causes nystagmus. All the causes, however, seemed to be included in the conditions of deficient illumination obtaining in coal-mines underground.

Dr. Stassen states that after examining many miners, suffering from varying forms of eye-trouble, by a process of elimination, he has found but one cause of nystagmus, and consequently but one mode of amelioration, namely, *that a sufficient and necessary cause of nystagmus is the deficient condition of coal mine illumination.*

The standard types of miners' lamps, oil and spirit-flame safety-lamps, and electric lamps, are discussed at length as to their effect upon the causes of nystagmus.

Dr. Stassen finds that nystagmus tends to increase the number of accidents, to lessen the value of men as workers; and he also finds that accidents to men afflicted with nystagmus intensify the trouble under certain conditions. He denies, however, that nystagmus can ever be a traumatic consequence of injuries, but is essentially "a professional malady, engendered by an accumulation of causes of irritation and fatigue of the eyes occasioned by bad conditions of lighting."

Prevention of nystagmus is possible only in one way, namely, by the improvement of the illumination underground. Not only should the amount of illumination be greater, but its diffusion must be improved, and the light provided should be steady, without glare and shadows as far as possible. The use of suitably tinted glass, or glass with a ground or "mat" surface, is recommended. Good results have been obtained at the Hasard Collieries in Belgium by glasses tinted a yellowish-green.

Dr. Stassen mentions that his investigations and the proposals for ameliorating lighting conditions in Belgian collieries, were interrupted by the war, but will be immediately resumed. This is a typical instance of Belgian fortitude, and calls to mind that in Liège many additions have been made to the world's knowledge of how to combat the dangers of the coal mine.

**COST OF MINING BITUMINOUS COAL IN THE UNITED STATES.**

Figures for January 1920.

Reports received by the Federal Trade Commission from 1,589 bituminous operators in various parts of the country, covering the month of January, show that the average cost of production in that month was \$2.32 per net ton. This compares with an average of \$2.04 for the year 1918.

The figures do not include interest, selling expense tax and certain other items which enter into the cost of mining and marketing soft coal.

Of the total production cost per ton in January by far the largest item was labor, amounting to \$1.74, as compared with \$1.49 in 1918. The largest production cost reported—\$3.52—was in Arkansas.

The increase in the average cost of production in 1920 as compared with 1918, the statement said, was attributable to two causes—the higher wage scale put in effect in November, 1919, and a small decrease in the January output as compared with the monthly average in 1918.

The average sales prices for January was \$2.78 per ton, as compared with \$2.60 in 1918, in the case of 1,272 identical companies. This gave a gross margin of 46 cents a ton in January, as against 56 in 1918, from which selling expense, interest, excess profits tax and other charges not included in cost of production, as reported, must be deducted to give the operators' net profit.

The reports were submitted in response to the Federal Trade Commission's order of January 31, which the Supreme Court of the District of Columbia has decided is not enforceable.

Average cost of production, per ton, in various bituminous districts during the month of January, 1920, is reported as follows by the Federal Trade:

ILLINOIS.

District No. 1 .. . . . .	\$2.84

**IMPROVEMENT IN WATER-SPRAYING DEVICE FOR HUMIDIFYING MINE AIR**

Considerable interest attaches to the "Daniel Wakall" improved water blast, an appliance designed by Mr. J. Daniel, of the Government Mining Areas Company, on the Eastern Rand, for the purpose of better allaying dust and deleterious gases in mine air, by utilizing water under pressure causing it to split into fine particles by striking solid surfaces, and subsequently atomized by compressed air. The device consists of an outer shell or casing, fitted internally with a plug valve, with two passages, one for the airway and the other for the water. In the air passage a non-return ball valve is placed. The airway connects with a cylindrical sleeve admitting the compressed air to an inner chamber through slots at the back end. Within the chamber is fixed an air regulating spindles, with cone-shaped face, forming a valve with the inner front head cone surface of the sleeve, acting as a valve seat. The extension of the spindle beyond the valve face is a distributing cone. The water passage connects with an annular chamber surrounding the front head of the sleeve, which has a cone face forming a valve with the outer casing as a valve seat. The screwed spindle is rotated within the sleeve, and the screwed sleeve carrying the spindle rotates with the casing. The plug valve is operated by a removable key.

The functions of the device are as follows:—Compressed air and water under pressure are connected to the device by the usual pipe fittings. The key operating the plug valve is rotated through a quarter of a turn, admitting the air and water into their respective chambers. The screwed sleeve is rotated back to form the required aperture between the casing and the sleeve to determine the quantity of water used. The spindle is similarly adjusted within the sleeve, controlling the quantity of air used. The water under pressure issues from the chamber in a cone-shaped jet, and, striking the spindle, is split into fine particles. The compressed air issuing from the centre behind the water immediately projects the fine particles of water on to the head of the spindle, which deflects the atomized water into a cone-shaped stream, the degree of atomization being controlled by the adjustable apertures of both the air and water. The non-return valve placed in the air passage of the plug is to prevent the back pressure of water entering the com-

pressed air mains when the air pressure fails, or, for economic saving, is cut off after the blast has been in operation for a certain length of time. The removable key operating the plug valve can only be separated from the casing when the blast is turned full on. As the device is placed in direct connection with the air and water services, without any intermediate valves between the mains and the devices, the return of the key to an official is a direct proof that the water blast has been put into operation. The claims for the device are as follows:—(1) The adjustable sleeve regulating the quantity of water used. (2) The adaptability for clearing the water aperture in the event of its being choked, by rotating the screwed sleeve in the casing and flushing the aperture clear. (3) The regulating spindle allowing any quantity of compressed air to pass. (4) Any desired combination of quantities of air and water producing every degree of atomization from a dry fog to the state in which the particles of water rapidly fall out of suspension. (5) The retaining valve in the air falls to atmospheric pressure, thereby ensuring the inability of any back water pressure entering the air mains. (6) The inability to remove the key except when the water blast is in operation.

**THE HUFF ELECTROSTATIC SEPARATOR.**

At the recent meeting of the American Electrochemical Society in Boston, opportunity was given to the members to visit the testing and demonstration plant of the Huff Electrostatic Separator Company at Arlington Heights, near Boston. The Huff separator uses electric current of high voltage and low amperage to separate mixtures of dry materials having different electrical conductivities, either by repelling part of the material vigorously, or allowing part of the material to be electrically released more quickly than the rest when passed over an electrode.

Some of the materials shown to the visitors in original form, and as concentrates and tailings, included garnetiferous sands, fine anthracite coal mixed with sand and dirt, graphite ore, micaceous rocks, molybdenite ore, abrasives, aluminum slag, barytes and lead ore, and, amongst other things a mixture of ground automobile tires separated into rubber and cotton particles.

While the electrostatic separation process has admitted limitations there would appear to be a wide field for its use because of the exactness and nicety of the separation, the small and inexpensive plant required, and the comparatively small power cost. For the separation of graphite the process seems excellently well adapted, as a comparison of the flaky and unctuous-feeling product of electric separation with Ceylon "chip" revealed. For separation of minerals contained in sands the process is well adapted, as it is also for the separation of abrasives from sands, or from the dross of artificial abrasive manufacture.

The usefulness of this method of separation in connection with any given natural or artificial mixture of materials cannot be determined with any exactness except by actual testing, but trial with a small sample will enable an opinion to be given as to the suitability of the method in each case, and the Huff Company state it has not been required to dismantle, as yet, any plant which was recommended for ore-dressing by its engineers as the result of tests.

## PROBLEMS OF PROSPECTING AND STAKING IN THE YUKON.

Progress is being experienced in the field of prospecting as well as in all other fields of human endeavor. The world stands still in no respect.

Time was when prospecting was confined to the picturesque individual who roamed the hills and vales with pick, shovel and pan. He served his day well, and to a large degree his kind have yet a large field and a large service to render the world. While recognizing his economic position in the mining world of yesterday and of today, recognition also must be given to the fact that a new form of prospecting has come into vogue with the innovation of modern mining equipment the last few years.

The new equipment has made it possible to work properties of low grade which the earlier individual miner could not touch. Wholesale methods are now contrasted with those of the individual sphere. Any business conducted on a vast scale reduces costs to the minimum and brings within workable range many low grade propositions which are thus made to yield their wealth to the world.

Keystone drills, diamond drills, and other new methods of testing make it possible to sink and determine values accurately now on ground which years ago could not have been touched. Dredges, hydraulics and other big operating equipment and, in the Arctic, the new cold water thawing process have brought grounds which formerly were considered hopelessly low grade into the desirable range. On the vast low grade areas, however, the individual operator is not prepared to proceed. A number of individuals must band themselves together in order to combine their financial strength to make it large enough to acquire capital to obtain the necessary equipment. When they do so they become co-operative prospectors and miners, or in other instances may be denominated companies.

Where the individual would have to leave large areas untouched, the company or co-operative mining enterprise can proceed. When such low grade grounds are made productive, the company is not alone the beneficiary. Operation of low grade properties first calls for labor. The first earnings of a mining company go into labor. That is the first dividend from the enterprise. The law recognizes the bill of the laborer or worker for service as the first that must be paid.

Large companies operating in the Yukon the last twelve years have taken millions from the ground which could not have been extracted profitably by individuals. Had there not been a way provided for the large concerns to handle this low grade property on the large scale on which they did work, Klondike would have been a dead camp years ago. Millions of yards of auriferous gravel have been turned over by dredges and hydraulics on which individuals had to cease operations prior to the coming of the gold ships.

Now the gold ships have worked out scores of miles of placers of known dredge values in Dawson and vicinity. One company's fleet already has been reduced from nine to only two working dredges for this season. That company will ship the dredges from the camp if it does not obtain new ground of workable values. Some of its dredges already have gone. Another is to leave Iditarod this season, and work of dismantling it will begin at once. When the dredges leave, the pay rolls diminish and men no longer reap

any returns from ground which is too low grade for individual operation.

It appears there are many low grade properties in the territory which under the cold water thawing should prove profitable to work. Dredge companies now want, it seems, to test some of those tracts, and, if proved satisfactory, start operation on them.

The proposition has been advanced that five-mile tracts be allowed to be staked by large companies and that they first be permitted to prospect the tracts. It would be a shame for any large company to get privilege to close any virgin creek carrying original values in the garden spots such as Eldorado, Bonanza, Hunker and similar Klondike creeks, and no steps should be taken which would thus deprive the individual in any such possible new field. And it is to be hoped every precaution will be taken against such contingency arising.

On the other hand, it would be a poor business to drive dredges from this region because the people willing to test low grade ground could not have the opportunity. It is well known that in the past some large concerns tried to acquire good sized tracts by individual staking, and that parlor prospectors and chair-warmers staked claims here and there in the tracts with hopes of getting good prices. They did not stake the ground until the large companies started to prospect or move in that direction, and after the large companies moved off the individuals in most, if not every instance, moved away.

It also is to be remembered that on some of the creeks in this territory practically hold-up methods blocked some of the largest dredge operations of this camp, and that several miles of good placers on two or more creeks where dredges attempted to undertake work now lie idle because one or two individuals on each of those creeks intervening with small strips of ground.

The hold-up staker and the parlor prospector have been quite as much of a detriment to the pay roll and production totals of this camp as the concessionaire who held the ground from the individual operator. Both deserve the condemnation of this camp. The genuine prospector who gets into the hills, the man who punches the hills and valleys full of holes, the big companies willing to risk their investments in order to open this country and create employment, all deserve encouragement.

Surely Yukon is going to do her best to find the solution for keeping the old-time individual mining going in every suitable district and the new class, modern large operations, also humming.

Where there is a will there is a way.—Dawson Weekly News.

## Nova Scotia Notes

### Dominion Coal Company to re-open Morien Colliery.

The decision of the Dominion Coal Company to re-open the Morien district for coal production has been a foregone conclusion for some time. Mining operations in this locality have witnessed many vicissitudes although time was when Morien was the business place in Cape Breton, and in the front rank as a coal producer. As the successor to the Boston and Morien Coal Company, which in its turn succeeded the Gowrie and Blockhouse Company, the Dominion Coal Company became possessed of the very extensive submarine field of the Morien Basin, and by purchase from the Cumberland Railway and Coal Company the Dominion Steel Company acquired the land areas of the basin, which were later turned over to the Dominion Coal Company, who in 1911 opened the collieries now known as Nos. 21 and 22, designed to extract a tongue-shaped area of shallow coal which is the remnant of the rather sharp synclinal basin that finds its apex about five miles inland from Morien, and extends seawards in a fan-shaped extension.

It is interesting to note that Mr. Belloni, a pioneer coal operator in Cape Breton, who formerly operated the Blockhouse Seam at Morien, is still alive and in good health in New York.

The Dominion Coal Company owns a branch line to Morien, connecting with the Sydney and Louisburg Railway, and for some time has run workmen's and passenger trains enabling some of the workmen at Collieries Nos. 21 and 22 to reside at Morien in the colliery houses there.

When the Morien Colliery was operated by the Gowrie and Blockhouse Colliery, vessels were loaded by means of an aerial conveyor which connected with a loading pier standing out in deep water in the Bay. This arrangement has long been dismantled, and will not of course be used again, as there is now rail connection.

Between Morien Basin and the Glace Bay Basin lies in the course of a pronounced anticlinal ridge which can be traced by the folded and broken outcrop of the Millstone Grit across country to the neighborhood of Sydney. Presumably a wide tract of barren rock intervenes between the seaward continuation of the Glace Bay and Morien Basins, but under the waters of Morien Bay itself it may be expected that a large body of workable submarine coal exists. The identity of the Morien seams with relation to those of the Glace Bay side is not determined, but it is surmised that the Blockhouse Seam at Morien is the equivalent of the Hub Seam at Glace Bay.

## Manitoba Letter

By Chas. A. Millican, Winnipeg.

One thousand pounds of ore, taken with a view of having a fair sample, so that a reasonably accurate and representative assay value could be obtained was shipped recently from the Bingo Mine to Ottawa. Mr. Myers has received word that this sample has produced at the rate of four and one fifth ounces of gold or about \$100.00 per ton at present values. Mr. Myers expresses great satisfaction at this return. He expects to have a Mill run of from 30 to 40 tons early this summer run through the Mill on the Rex property, which adjoins.

Extensive underground work is being undertaken on the Rex Mine this year. Towards the latter part of the season the Company intends to treat all rock taken out. The Mill has a capacity of 80 tons per day.

Over one hundred men are engaged on preliminary work on the Flin Flon Mines and \$85,000 has already been spent for machinery. Work is being rushed ahead. The Longyear Co. of Chicago has the contract for sinking on two shafts and are reported to be making good progress.

A regular air passenger and parcel freight service is to be established during the coming summer between Winnipeg and the Rice Lake gold fields by one or more of the Winnipeg Aviation Companies. The Winnipeg Aereo, Limited, are contemplating taking moving pictures from the air of all mining camps, water routes and other transportation channels. The present intentions are to have these pictures exhibited locally in connection with the Province's natural resources, and later, released in other parts of the Dominion. The Aereo Company's aerodrome is located at River Park, Winnipeg.

The matter of Provincial police protection in the different mining areas will receive the attention of the Provincial police Commissioner. Heretofore there has been a sad lack of proper protection for those camps may have been temporarily idle, and the unwritten miners' laws that usually prevail in mining camps have been, on several occasions, very severely offended against. It is hoped that, from now on, miners and prospectors may feel a greater sense of security in these districts.

Incorporation has been granted by the Provincial Government to Angus McDonald Mines, Limited (Non Personal Liability), a mining concern with an authorized capitalization of \$3,000,000. Provisional directors named in the charter are: Frank M. Ruggles, broker; William Martin, Jr., broker; G. C. McTavish, barrister, and others.

The head office of the company is to be in Winnipeg and powers granted the company are wide enough to permit it to enter into any kind of business connected with mining, development, brokerage or otherwise for the flotation of companies.

The division of the stock is to be 600,000 shares at \$5.00 each.

### SOVEREIGN PROFITS \$16,872

#### Annual Meeting of the Company Shows Satisfactory years Operations.

At the annual meeting of the shareholders of the Sovereign Porcupine Mines, Limited, held in Toronto on April 22nd, the financial statement showed that during the period ending January 31st, 1920, \$16,872.43 was expended in exploration and development. President Moodie, in his address to the shareholders, stated that over 4,000 feet of diamond drilling was carried out on the company's property, which lies adjacent to the Hollinger Consolidated. Mr. Moodie also stated that the operations on the north claim were discontinued owing to the existence of forest fires and work transferred to the south claims, where a considerable amount of trenching and stripping was carried on, with the result that an excellent vein, heavily mineralized, was uncovered.

## Northern Ontario Letter

### THE SILVER MINES.

The fourth week of April will be remembered in Northern Ontario, particularly in the precious metal mining areas, as marking the commencement of the turn in the tide of the post-war readjustment of economic conditions. The ticker all week carried a message of uneasiness in the stocks of the big industrial concerns, which have literally wallowed in prosperity since the late war began. At times, quotations for these shares declined almost precipitately, thus reflecting the fact that they may now be entering upon a period of re-adjustment to normal, and that the voyage from artificial prosperity to normal may not be altogether smooth sailing.

In the North, actual enthusiasm has been manifest. Precious metal is in great demand. The difficulty has been that it has cost a lot to produce it. The messages from the south which tell of the downward movement in the industrial stocks, as well as an actual break in the price of provisions, including corn, pork, etc., carry hints at least of cheaper material, and offer some promise of actual curtailment of work in many centres to the end that men must seek employment elsewhere. It is here, that the belief is entertained that the exodus from centres of industry created by war's necessity will be to the centres of such basic industry as the precious metal mines of Northern Ontario.

Meanwhile, the quotation for commercial bar silver remains at a figure well above the average for any previous year in the North's history, while as is well-known, the price of gold must inevitably remain unchanged—it is the standard of value, the yardstick of the monetary status of the nations.

The embargo on freight between Canada and the United States has caused a temporary curtailment of ore shipments across the border. Much of the ore which ordinarily goes to smelters in the States to be treated, is being held in Cobalt. In the meantime, however, no serious consequences result, for the reason that the greater volume of the ore is treated in Canada, and that going to the United States is but a certain class of ore of small quantity which is found difficult to treat, and its deferred shipment does not interfere in any way with the operations of the mines.

Bullion stored at the mines is believed now to amount to more than at any previous time in the camp's history. It is thought, however, that the delay in the expected upward trend in prices may cause at least a limited quantity of this bullion to be marketed at a reasonably early date.

According to an official statement, the Chambers-Ferland mine of the Aladdin-Cobalt Company, shipped ore steadily during the month of March to the Dominion Reduction plant for treatment, and realized a comparatively large net profit. The average content of the ore approximated 20 ounces of silver to the ton. Shipments are continuing during April at the rate of between 30 and 40 tons daily. In the meantime, underground work is being centered on a new ore shoot in a vein which appears to bear relation to the old vein No. 15. This ore shoot is stated to be about four inches in width and has been drifted on for upwards of fifty feet, showing values ranging from \$5 to \$4,000 to the ton.

At the annual meeting of the Trethewey-Cobalt Company, it was stated that the Castle property of the

Trethewey, in Gowganda, had produced upwards of \$50,000 to date, this amount having been contained in two shipments sent out since the beginning of the year. Another shipment is forecasted for late June. Some \$40,000 was produced from a drift just 70 feet long at the 100-ft. level, at which point some 250 feet of drifting has been done. A prosperous future is predicted by the manager, I. S. McReavy.

An unofficial report in Cobalt intimates that Stuart M. Thorne, who was manager of the Trethewey prior to enlisting for overseas service during the late war, will again resume his former duties, it having been generally understood that he would be re-instated immediately after his return from overseas. Concerning Mr. McReavy, it is general knowledge that his work at the Trethewey mine has been highly efficient, and that as a result of his two year's of activity in the Cobalt camp he has been singled out as perhaps one of the most successful of the rising young engineers.

The Mining Corporation of Canada is stated to have decided to take up bonds which it recently obtained on the Yankee Girl mine in Ymir, B.C. It is stated that instructions have been issued to prepare the mine for operation, the sum involved being estimated at \$400,000.

Proposed amendments to the Mines Act of Ontario are having a more or less rough passage through the Ontario House, at least in the case of the proposal to alter the schedule of recording fees. The Minister of Mines is endeavoring to change the recording fee from \$10 to \$5 for each claim staked and recorded by a license holder for himself, but would increase the fee from \$10 to \$15 in the case of where one license holder stakes claims on behalf of another license holder. The contention is being put forward by prospectors that such an alteration would be harmful to the mining industry. It is pointed out that the great majority of prospectors in the field are kept active through being grub-staked by business men and mine workers, the prospectors agreeing to stake claims on behalf of those grub-staking them. It is also shown that as was the case with such mines as the Hollinger Consolidated and the Dome Mines, they were located by prospectors working on a grub stake arrangement. It is thought that although the bill has passed its second reading, the above proposed alteration of fees will be omitted before it is given its third reading. As regards the other amendments, they appear to have met with fairly general favor.

Robt. Lyman, manger of the Seneca Superior mine at the time of its successful and spectacular career, has secured a lease on the Rochester mine and proposed to carry out a comprehensive development campaign. Work, when commenced, will be carried on through the shaft of the adjoining Lumsden mine.

At the Oxford-Cobalt property the work of development is well under way. The contractors are at work on the shaft which is being driven from surface to the 200-ft. level. At the time of writing, the shaft is down 20 feet. Two machines are employed.

Authentic information received today is to the effect that the formation of the Bailey Silver Mines having been completed, and with the Bailey mine officially estimated to contain upwards of half a million ounces of silver ore in sight, arrangements have been made to commence work at once, and that by June it is hoped to have a carload of high grade ore ready for shipment.

The Bailey Silver Mines was formed for the purpose of purchasing the old Bailey-Cobalt Mine as well as the plant of the Northern Customs Concentrator, both purchases of which have now been completed, the above mentioned concentrator to now be known as the Bailey Mill.

Ore at the Bailey is estimated to amount to 23,186 tons containing 510,294 ounces of silver, which consists of actually developed ore, and does not take into account that contained in the dumps, and in further probable ore in the mine. The property, though closed down on account of litigation since 1914 is regarded as one with a big future. In addition to this, it is stated that the concentrator taken over is making net profits at the rate of \$75,000 a year from customs work done for other companies.

Directors of the new company include the following: A. J. Young, of Toronto, is president; Alex. Fasken, Toronto, Treasurer; and J. R. Booth, of Ottawa, Vice-President, with F. J. Bourne as General Manager.

### Ore and Bullion Shipments.

During the week ended April 23rd, three Cobalt companies shipped an aggregate of seven cars containing close to half a million pounds of ore, the Mining Corporation being the heaviest shipper, with one car a day, as announced in advance recently in these columns.

Following is a summary:

Shipper.	Cars.	Pounds.
Mining Corporation . . . . .	5	345,909
La Rose . . . . .	1	84,660
O'Brien . . . . .	1	60,075
Total . . . . .	7	496,644

During the corresponding period, the Mining Corporation sent out 99 bars containing 100,004.90 fine ounces of silver bullion. This is the first heavy shipment of bullion to go out in several weeks, the tendency being to hoard up the output with the expectation of another upward move in quotations for the metal.

### THE GOLD MINES

The gold miners' view with equanimity the gyrations of quotations for shares in the big industrial concerns in the more thickly populated centres to the south. The general impression exists that the present is the beginning of the post-war era of readjustment which is to spell for the gold mining industry perhaps the most prosperous period in history.

The important announcement is made this week officially to the Canadian Mining Journal correspondent that the Cassel Cyanide Company of Glasgow has made application for the incorporation, under Dominion and Provincial charters, of a company to be called the "Cassel Cyanide Company of Canada, Limited," to handle the Canadian business of the Cassel Cyanide Company, of Glasgow, Scotland. The directors of the Canadian company will be Sir George Beilby, F.R.S., Glasgow; Colonel Sir Edward Allen Brotherton, of Bart, M.P. for Leeds; William Neill, Glasgow; Rupert G. Bruce Toronto; Major Fred A. Peacock, Montreal, and William Evan Simpson, Boston Creek. It is proposed to establish head office in

Montreal, and to have Northern Ontario headquarters located at Timmins, in the Porcupine gold district.

It is unofficially reported that the Hayden-Porcupine mine may resume work this year on a large scale. The property is situated in the township of Ogden, some three or four miles south from the Hollinger mine. In the period prior to the shortage of labor caused by the war the property was explored in a fairly big way, and the developments are stated to have been sufficiently encouraging to warrant continued work.

The Hollinger, McIntyre and Dome, as well as the Porcupine Crown all continue to work on a fairly uniform scale, with indications of conditions improving gradually. It is thought that the improvement taking place will be found to be permanent, and that the end of this year will witness all the producers working at full capacity.

During March, the Lake Shore mine at Kirkland Lake, produced \$45,133.18, making a total of \$130,687.92 for the first quarter of the year, or at the rate of well over half a million dollars a year. The total output from this mine in its as yet, short career amounts to \$809,271.97. Mill heads have averaged approximately \$25 a ton for every ton of ore handled since the mill started operation, thus winning for the mine the reputation of being the highest grade gold mine among the important gold producers in Canada.

With the Lake Shore setting such a pace, and with the Kirkland Lake Gold Mines now also said to be producing value in excess of costs, the gold mining industry of Kirkland Lake is steadily taking on added importance. In addition to this is the actual construction of the large Wright-Hargreave mill now under way with the likelihood of the Tough-Oakes mine resuming work next month. Added to this, also, are a number of other important properties where work is resulting favorable. These include the Ontario-Kirkland where the shaft is now being driven from the 300-ft. to the 450-ft. level, and where considerable commercial ore has been developed. Another is the Bidgood where the work of sinking a central shaft from surface to a depth of 300 feet is now underway.

At Boston Creek the Miller Independence Mines has turned on electric power and is now in a position to carry out its big development programme with the maximum of speed. While cross-cutting is being done at the 500-ft. level to open up the downward continuation of the main orebody, work is also being done in the incline shaft along the rich deposit known to occur there. Specimens of ore sent from the Independence to the Toronto University were found to contain "calverite," as in these columns from time to time. Confirmation of the occurrence of this, the highest grade gold telluride known is regarded as being significant, in that it occurs in such spectacular quantities.

Prospectors just in from the Skead township district declare that the prospectors and miners in that district have commenced the work of cutting a road to the railway by way of Boston Creek. Failure of the government to grant the assistance has resulted in the property owners themselves taking the matter up. It is still hoped to induce the government to finance the construction of a bridge over the Blanche river. The distance to the railway over this route is only about twelve miles as compared with some 25 miles over the old road to Englehart.

## British Columbia Letter

### Alice Arm, B. C.

A tunnel that has been driven on the Muskateer Mineral Claims by A. McGuire for J. D. Meenach, of Seattle, Wn. It is reported that this work disclosed some high-class ore.

Satisfactory results are said to have been obtained by the diamond drilling which has been in progress on the Tiger Group for some time.

### Prince Rupert, B. C.

Attention has been drawn by the Prince Rupert Board of Trade to the limonite ore deposit of the Copper River District situated near Copper City and in proximity to the city of Prince Rupert. In this connection reference is made to the coal fields of that locality, it being claimed that these contain the finest coking coal of the Province. The business men of Prince Rupert fear that the Provincial Government and individuals or corporations, in their investigations of the iron and steel possibilities of British Columbia will overlook that these resources, together with "water powers and all necessary fluxes," are to be found in the northern section of the Province.

### Princeton, B. C.

The Horn Silver Mining Co., situated in the Similkameen District, is operating again after a period of idleness, weekly shipments of from 45 to 50 tons being sent to the Tacoma (Wn.) Smelter. The lessees are working on a vein varying in width from eighteen inches to six feet, the ore of which contains considerable gold and silver values. An aerial tramway carried the ore from the mine to the bunkers whence it is transported by wagon to the railway.

### Grand Forks, B. C.

It has been officially announced that the Granby Consolidated Mining and Smelting Co. will dismantle its mine plant at Phoenix, where the mines have been idle for some months. Those parts that can be used either at the Company's collieries, Cassidy, Vancouver islands, or at the copper smelter, Anyox, will be shipped. Some sections will be disposed of on the ground and the remainder will be stored at the Grand Forks Smelter. Not since the mines of Phoenix ceased to be worked last June have the people of the district given up hope of seeing them resume operation. Authorities have given it as their opinion that there are 3,000,000 tons of ore available still, of which several thousand tons is of good grade. The establishment of a concentrator for the treatment of the remainder has been talked of but the plan clearly now has been abandoned. Phoenix thus will become one of those phantom mining towns not infrequently found in mining sections of the American continent. Its streets, its houses, and its places of business will continue practically deserted and no longer will the clear mountain air of what was the town of greatest altitude in British Columbia re-echo the clang of industrial activity. The Phoenix properties were opened more than twenty years ago during which time there have been shipped about 13,000,000 tons of ore to the Grand Forks Smelter, which ore is estimated to have had a gross value of about \$56,000,000.

### Rossland, B. C.

The surface equipment of the White Bear Mine was destroyed by fire recently. Flames first were seen bursting from the compressor house. This soon was wiped out after which the mine shaft and some un-

occupied houses were reduced to ruins. The transformer house was saved by packing snow about it.

### Slocan City.

That a stringer of ore has been opened up on the fifth level of the Ottawa Mine, near Slocan City, which assays from 800 to 3,000 ounces of silver per ton, is the effect of a report from this camp. The showing was observed during the cleaning out of a drift and it was thought that it contained about a sack of ore. Development, however, appears to have disproved this as 10 cars already have been taken out and what is now referred to as "one-sack slope" has been exposed for 20 feet with a width up to 18 inches.

### Trail, B. C.

The British Columbia town of Trail, smelter centre of the Consolidated Mining and Smelting Company of Canada, proposes introducing daylight saving this summer without regard to what action may be decided upon elsewhere. The Company's clocks were set ahead an hour at midnight on the 15th of April. Employees in and around the smelter expressed a preference for this arrangement and the management acquiesced.

Ore receipts at the Trail Smelter for the week, April 1st-7th inclusive, were 4,588 tons, making the total for the year to date 77,834 tons. The independent shippers were the Donohus, Nicola, 35 tons; the Emerald, Salmo, 41; the Josie, Rossland, 172; the North Star, Kimberley, 86; the Ptarmigan, Athlamer, 25; and the Spokane Trinket, Ainsworth, 46. The Sullivan Mine, Kimberland, contributed 3,978 tons of zinc and 205 tons of lead ore.

### Victoria, B. C.

When Hon. D. T. Pattullo, Minister of Lands in the Provincial Government, asked the Provincial Legislature to endorse a vote of \$25,000 to continue the investigations inaugurated last year by Prof. Gwillims into the oil possibilities of the Peace River District of British Columbia he stated that the explorations up to date encouraged the belief that oil would be found in quantities in this section. The government's policy, he asserted, was to see that this oil wealth, if it existed, should accrue to the whole people. A reserve had been declared on oil on the crown lands of that district and if oil was discovered the government would consider the advisability of itself going into the oil producing business, using the profits to pay off the provincial debt. The vote was passed although several private members expressed the belief that private enterprise would make a more thorough exploration and that it would be the wiser policy to let those wishing to do so undertake the work, it being understood that a royalty would be payable to the government on anything that might be discovered.

The Minister of Justice, Ottawa, has announced that there would be no disallowance of the Dolly Varden Act of the British Columbia Legislature under the terms of which the Taylor Mining Co. acquired possession of the Dolly Varden Mine, Alice Arm, certain mining equipment, and a line of railway from tide-water to the property, the latter at the time of the change of ownership being within a short distance of completion.

Immediately this information was received R. T. Elliott, K.C., legal representative of the original Dolly Varden Mines Company, took the necessary steps to have the validity of the Provincial Legislation, and the title of the Taylor Mining Company to the property, tested in the British Columbia courts.

Mr. Elliott has issued two writs, one asking for a series of declarations setting aside the Act and all proceedings taken under its provisions and the other asking for damages for alleged trespass and for payment to the plaintiff of all money realized from ores produced at that Mine.

The Ward-Hopp litigation, a struggle for possession of the Bullion Mine Property which was carried through all Canadian Courts and even to the Privy Council of the Empire, is nearing its finish. R. T. Ward and his associates have been declared the winners of this long-drawn out legal battle and now there is before the Provincial Legislature a special Bill, entitled the "Cariboo Hydraulic Mining Company Amendment Act, 1920" which renews and extends for a period of thirty years the placer leases of the Company. Mr. Ward, however, evidently has not seen the last of his legal troubles for, as soon as the Legislative Assembly re-establishes the Company's title to the property, he must defend himself in court against an application made by a group of his associates for his dismissal from the position of trustee of the Bullion Mine and for a declaration by the judge of the respective interests of Messrs. Ward et al in the property.

**Vancouver, B. C.**

There is still hope that the Dominion Government will establish the long promised Ore Testing Plant in British Columbia. Some years ago \$300,000 was placed in the estimates to meet the necessary outlay but so far no steps have taken place towards installation. Assurance, however, has been received that the money will be re-voted this year and that action may be looked for.

**Dawson, Y. T.**

That the placer laws of the Yukon Territory should be amended for the express purpose of encouraging companies wishing to engage in dredging operations is the opinion of the Yukon Development League, which has placed its ideas before the Dominion Government. Such companies, it is maintained, should be permitted to prospect and work low-grade placer areas, former worked by individual miners and now abandoned without molestation. They are hampered and interfered with at present to the point of hopeless disgust by persons who, as soon as they begin to prospect, stake all around and proceed to hold up the companies for excessive prices. Several large dredges representing millions of dollars of an investment are likely to be shipped out of the country if further low-grade placer ground cannot be secured. The League believes that the individual miner should be allowed permits to prospect exclusively on one-mile tracts on virgin creeks for one year with the privilege of first choice in the staking of a discovery claim within that tract. The League also recommends the abolition of the royalty on gold, arguing that as gold has lost half its purchasing power the maintenance of the gold mining industry in the Yukon is threatened.

The Provincial Assayers' Association Board has just completed a special examination of seven candidates who recently completed a five month course of study at the British Columbia University under the auspices of the Soldiers' Civil-Re-establishment Board. Four of those who wrote were successful and will receive certificates entitling them to practice their profession

in this Province. They are E. D. Beilby, V. R. Thirkel, T. J. Laing, and F. W. Broughton. The percentage of passes reflects credit on the efficiency of the course laid down for the benefit of returned soldiers as the standard could not and has not been lowered in their favor.

**The Collieries.**

There has been a marked falling off in the coal production of the Crow's Nest Pass Coal Field of late largely for the reason, no doubt, that comparatively little is required for coke making in comparison with the demands of previous years. At present the ovens at Fernie are idle, those of Michel alone being active. The importance of this change in conditions can be better understood when it is pointed out that in 1918 the coke production of Michel and Coal Creek combined approximated 18,000 tons a month necessitating the consumption of something like 30,000 tons of coal. The explanation of the slackness of the coke market as far as the Crow's Nest is concerned lies in the closing down of the smelters at Greenwood, Canada Copper Corporation, and at Grand Forks, Granby Consolidated Mining and Smelting Company, as well as the fact that the latter Company now is in a position to produce from Vancouver Island coal, and by the use of its by-product coking plant, the necessary fuel for its Anyox smelter. There may be other reasons behind the condition at Coal Creek and elsewhere in that district, where the men have been working little more than half time, but those given may be accepted as chiefly responsible.

On Vancouver Island the situation is different, although there was a period following the strong demand of the winter during which the trade fell off sufficiently to affect to some extent the operation of the mines. During February the Canadian Collieries (D) Ltd. kept their men at work at the three Comox mines for 17 days, at Extension for 22½ days, and at South Wellington for 23 days. The Canadian Western Fuel Company operated its properties at Nanaimo, Harewood, Reserve and Wakesiah for 24 days in February. This also applies to the collieries of the Granby Consolidated Mining and Smelting Co. at Cassidy's, the Pacific Coast Coal Mines, the Nanose-Wellington Collieries, as well as the Coalmont Collieries in the Nicola-Princeton Field. What the forthcoming season is going to bring to coal operators in the bunker business remains to be seen but it is feared that the exchange conditions are likely to have such an effect on the mercantile trade of the Pacific that the collieries of this Province will find the market unpleasantly quiet. However, the output figures for the Island collieries for the month of March indicate that the market has become brisker and that the production has jumped. This is particularly evidenced in the output of the Pacific Coast Coal Mines and it also is worthy of note that the production of the Cassidy Collieries, Granby Consolidated Mining and Smelting Company, also shows a substantial advance.

The British Columbia coal output for the month of February was as follows:—

CROW'S NEST PASS DISTRICT.		Tons
Crow's Nest Pass Coal Co., Coal Creek . . .		34,672
Crow's Nest Pass Coal Co., Michel . . . . .		22,427
Corbin Coal and Coke Company . . . . .		9,954
Total . . . . .		67,053

NICOLA-PRINCETON DISTRICT

	Tons
Middlesboro Collieries . . . . .	8,930
Fleming Coal Company . . . . .	3,446
Coalmont Collieries . . . . .	280
Princeton Coal Company . . . . .	2,633
Total . . . . .	15,289

VANCOUVER ISLAND DISTRICT

	Tons
Canadian Western Fuel Company, Nanaimo . .	56,813
Canadian Collieries (D) Ltd., Comox . . . .	28,515
Canadian Collieries (D) Ltd., Extension . . .	18,377
Canadian Collieries (D), S. Wellington . . .	6,450
Pacific Coast Coal Mines, Extension . . . .	8,752
Wellington-Nanoose Collieries . . . . .	2,488
Vancouver Nanaimo Coal Company . . . . .	1,441
Granby Consolidated Mining & Smelting Co.	14,419
Total . . . . .	137,255

PRINCE RUPERT DISTRICT

	Tons
Telkwa Collieries . . . . .	325

The production returns for March are available only for Vancouver Island which follow:—

VANCOUVER ISLAND DISTRICT

	Tons
Canadian Western Fuel Company, Nanaimo . .	55,769
Canadian Collieries (D) Ltd., Comox . . . .	32,587
Canadian Collieries (D) Ltd., Extension . . .	19,277
Canadian Collieries (D) Ltd., S. Wellington . .	7,219
Pacific Coast Coal Mines, Limited . . . . .	10,338
Wellington-Nanoose Collieries . . . . .	1,849
Granby Consolidated Mining & Smelting Co.	17,566
Total . . . . .	144,605

Victoria, B. C.

The Lignite Utilization Board of Canada is expected to make important advances this year in the development of the Saskatchewan Lignite Coal fields and the furnishing of the people of the prairie provinces of the Dominion with cheaper and better fuel. One of its definite objects is to place the briquetting business on a commercial basis. For the use of the Board there has been appropriated the sum of \$400,000 by the Dominion, Manitoba and Saskatchewan Governments. The former is to contribute one-half of the amount while the two latter put up one-quarter each.

Coal lands situated adjacent to the old "Jingle Pot" mine, which recently ceased to produce, are being developed. This property is situated close to the town of Nanaimo. A shaft is being sunk and it is expected that coal will begin to be taken out in a short time. The new company, whose personnel is not yet generally known, has purchased the machinery of the Jingle Pot mine and is making use of it in its development operations.

A dispute as to the title to some 1222 acres of Vancouver Island coal lands was ventilated before a select committee of the Provincial Legislature at the session

which has just concluded. This property at present is held by the Canadian Collieries (D) Ltd. It originally belonged to the old Baynes Sound Coal Mining Company and has been developed to a considerable extent, production having been maintained years ago over a lengthy period. In 1904 when the Provincial Government of that day reached an understanding with the Esquimalt and Nanaimo Ry. Co., by which coal rights within the Island Railway Belt were secured for a number of old-time settlers or their descendants in return for which the company was granted further lands in the north-eastern section of the Island, operations had ceased at the Baynes Sound Collieries. The property of the latter came within the limits of the supplementary E. & N. Land Grant. It was found, however, that the latter company did not obtain possession of these holdings, as the Baynes Sound Company's leases still were in good standing at the time of the transfer from the Government to the Railway Company. Thereupon, so it is alleged, representatives of the Railway Company proceeded to stake the property which subsequently had become open. From them it came into the hands of the E. & N. railway and later was transferred to the Wellington Colliery Co. and thence to the Canadian Collieries (D), Ltd. It is the contention, however, of Messrs. E. T., C. H. F., and E. A. Carew-Gibson and E. Priest, that the company's representatives did not stake the land accurately and that they are the only ones who complied fully with the law following the lapse of the Baynes Sound Coal Company's leases. On this ground they are asking for possession. The Legislative Assembly's special investigating committee is understood to have refused this demand, but the claimants assert that they are to carry their case if necessary to the court of last recourse.

Some trouble has been experienced of late in the coal fields of the Province of Alberta because of the government's ruling that only miners acquiescing in the "check-off" for payment of dues to the United Mine Workers of America shall be permitted to work. This order was issued last January, but at first was not strictly enforced by the operators. Recently, however, the Minister of Labor agreed to accept responsibility for the regulation. This brought about an effort at its enforcement, with the result that the miners left work at two camps at Coleman, Alta., and at Blairmore and Canmore.

**WHAT CANADA CAN DO BY DEEPENING THE ST. LAWRENCE-GREAT LAKES WATER ROUTES.**

- Can construct the greatest waterway in the World.
- Can made every Lake Port an Ocean Port.
- Can place Western Canada 1,500 miles closer to the markets of Europe and of Eastern Canada and the United States.
- Can develop electric energy that will make Canada the workshop of the World.
- Can enable Nova Scotia to send coal to Ontario.
- Can open up the coalfields of Alberta by providing the Western Provinces with the cheap transportation facilities which are essential to her development.
- Can forward the day when Alberta will be the greatest industrial and manufacturing province of Canada.

**CORROSION IN WIRE ROPES**

Experience has shown that wire ropes of compound-construction, subjected to corrosion influences, are likely to deceive engineers as to the strength remaining in them, says a circular issued to managers of mines on the Rand, South Africa. Where reduction of diameter or circumference of the rope has taken place, not accounted for by the evidence of wear, the part of the rope under examination should first be fully loaded and then relieved of the load. Any noticeable difference in circumference under these circumstances and the slackening of the outside wires when the load is off will indicate that internal corrosion has taken place. The extent of corrosion inside the strand can only be estimated by the slackness of the outside wires. The corrosion between the strands can be further examined by nutwisting the rope or displaying the strands sufficiently with a marline spike.

Engineers are apt to imagine that reduction in the size of a rope may be due to some collapse of the hemp core. In a test at the mines department mechanical laboratory of a 1.28 in. diameter rope, the hemp core was entirely removed for about 5 ft. of the length. The specimen was gradually loaded up to 30 tons, but beyond a slight increase of the lay from 10½ to 11 in., subsiding after test to 10¾ in., there was practically no alteration in the shape or size of the rope.

In some recent tests of corroded ropes, the following results were obtained:

Original diameter, in.		Original breaking load, lb.	Diameter at test, in.	Breaking load at test, lb.
Rope.	Wires.			
1.50	0.099	222,208	1.41	191,960
1.50	0.099	222,208	1.40	166,660
1.50	0.099	222,208	1.30	137,260
1.50	0.099	222,208	1.23	66,880
1.50	0.102	220,000	1.22	97,260
1.25	0.115	148,700	1.23	137,660
1.25	0.115	148,700	1.00	78,920

In all the above-mentioned cases the outside wires were less than half worn, but the internal corrosion was excessive. The wires were brittle also. Experience has shown that the remarks concerning corrosion on the certificate of biannual tests are taken as merely applying to the test specimen and not considered as having a bearing on the state of the rest of the rope.

**THOMAS'S DIRECTORY OF AMERICAN MANUFACTURERS.**

The eleventh edition of the Thomas' Register of American Manufacturers, dated January 1920, has just been published, in which more than 300,000 names of United States manufacturers of products classified under over 70,000 headings are listed. It weighs 17 pounds and contains 5,980 advertisements, said to be the largest number of advertisements ever printed in a trade publication.

The register is divided into three main sections with an index totalling 176 pages. The classified section (3,340 pages) furnishes a complete list of the makers of every known United States product, classified according to the article, eleven pages alone being devoted to the single item of acids. A capital rating is also given of each manufacturer, showing the amount of capital invested and the approximate size of the concern. About 800 pages are devoted to two other main sections listing the trade name or brands of manufactured products, and to a continuous list of the names of manufacturers in alphabetical order from A to Z, also giving the addresses of head office, branches, names of officers, etc., of the concerns listed.

Thomas' Register lists all names absolutely free of charge and irrespective of advertising support. The purchasing agent and buyers for nearly 25,000 important business houses use it, several hundred of these being Canadian concerns which find it indispensable when buying United States products.

An international trade section, listing exporters and importers, is included in the eleventh edition, together with a directory of banks, commercial organizations and trade papers in the United States and Canada.

The Thomas' Publishing Company, New York, are represented in Canada by the Canadian Buyers' Register Company, 92 Constance Street, Toronto, from whom specimen pages, etc., can be obtained. The price of Thomas' Register in Canada is \$17.50, all charges prepaid.

**TURNING THE SCREWS ON CANADA.**

The United States railway companies have served notice that freight rates on shipments of American goods must be paid in American currency from the point of shipment to any destination in Canada. This arbitrary ruling takes an extraordinary advantage of the exchange situation, since the American roads declare they will not permit reshipment at the border, where Canadian currency could be used at full value for part payment of the freight charge.

The possession of a strangle-hold upon the Dominion permits American business men to indulge in this sharp practice. Canada's dependence on the United States for coal is the root of the whole trouble. It encourages exploitation of the Canadian market with no limit except the forbearance of the exploiter. It permits the foreigner to levy a tax upon the Canadian public which, in the present case, will amount to ten per cent and over.

Here at last is the economic third degree. Question may be raised if any more striking illustration could be imagined to proclaim the meaning of Canada's needless fuel disability. And it happens to come at the very moment when Senator Underwood of Alabama is urging Washington to tighten the coal grip on Canada's throat so that our pulpwood resources may be utilized regardless of our own needs and in the interests of American paper manufacturers.

Foreign exploitation faces Canada allied with Winter. This menace will cast its shadow over the land, and work its repeated hardships, until the people of Canada, led by a vision of national self-sufficiency, utilize the enormous coal deposits of their own Dominion. The very soil of the nation cries out against this self-inflicted shame and offers snecor in full abundance.—Montreal "Star" April 29th.

## THE HAND THAT ROCKS THE CRADLE RUNS THE "JACKHAMER".

By F. A. McLEAN.

The accompanying photographs taken in the Buxton Limestone Works quarries in England during the war, serves to illustrate the remarkable way in which the women of the Old Land so nobly answered the call and "carried on" when their men folks marched off to "Flanders' Fields." For many years it has been customary to employ women for certain kinds of light factory work such as in textile mills, and electrical works where it was found that their temperament made them of much more value for certain kinds of monotonous routine work than men.

With the coming of the war and its accompanying scarcity of man power, however, women were given employment at various tasks for which it had been long considered that only men were suitable. Thus there were few industries in which female help was not tried out with varying degrees of success. Women doing various forms of office work that was usually done by man, operating elevators, street cars, motor trucks and machine tools in munition plants, were a sight more or less familiar to us all, two or three years ago. So well did some of these women perform their allotted tasks, that in many industries they will probably continue to be employed on work for which it would have been once thought that only their fathers, brothers or sweethearts could properly handle.

WOMEN AT WORK IN BUXTON LIMESTONE  
QUARRIES

In England, due possibly to the fact that they were stronger than in this country, or to the more incessant demand for labor, women were given much heavier kinds of work than they were in the United States or Canada. Thus, perhaps, it was only natural that women should be used to operate large cranes in shipyards and steel mills, erect and paint structural steel, load trucks and cars, handle heavy timbers, load and tram heavy muck in mines and collieries, excavate for foundations and so on, ad lib., all of which are forms of work that are usually associated in the minds of most people with good strong men.

This photograph also lends emphasis to the wonderful progress that has been made in the development of power rock drilling equipment during the last decade or two. With this idea in mind it is interesting to speculate on what would be the sensation of the immortal shades of the late J. J. Couch and Joseph W. Fowler, were they allowed to visit the earth again and witness the transformation that has taken place in

their clumsy drill of the early forties through the ministrations and inventive genius of such men as Sergeant Waring, Halsey, Githens, Ingersoll and Leyner.

What a far carry it is from Couch's ponderous drill with its big steam boiler from the invention of which mining methods practically date, to the little "Jackhammer" weighing only a fraction as much and having many, many times the drilling speed and yet withal, so easy to operate and control that even women can run them if necessary without undue fatigue or physical strain.

## A VOICE FROM THE NORTH-WEST.

Hyder Miner: The voice of the wildcatter will soon be heard in the land.

Already we read in outside papers glowing descriptions furnished a too gullible press by companies unknown to the North, with claims unheard of outside of the recording office.

A mining man recently returned from Vancouver told "The Miner" that promoters were thicker in the lobby of the Vancouver hotel than second-growth spruce saplings on an old burn. And if this is true of Vancouver, where there is less interest taken in mining than in any city of its size west of the Rocky mountains, what must be the situation in other cities where a real interest is manifested in the country's greatest industry!

We have heard the remark that every mine was, at initial stage of its existence, a wildeat. This is not true. It is true that every mine was at some time a prospect, but there is a vast difference between a prospect with well defined surface showings of ore, which intelligent development may prove to extend to depth, and a wildeat with its few acres of country rock, whose owner staked it because some prospects in the district were showing up well, and whose promoters foist it upon the public with the full knowledge that not a dollar's worth of ore will ever be extracted from it.

However, we are inclined to pity the public with too great a pity. Anybody who will invest his money in mining stocks because of a high-sounding name or glowing prospectus, and without making such inquiries as to any ten-year-old child should have brains enough to make, is not entitled to pity.

There is only one good thing about a wildeatter. The money he extracts from the public he generally puts back into circulation with both hands. As a rule his easiest victims are people who are so tight they wouldn't buy a cheese sandwich for a starving orphan but who pull their money out of the banks when told by some suave gentleman that they can easily double it with no other effort on their part than signing checks.

Many of the companies now organizing are being formed in good faith and the money turned over to them will be expended honestly. Such companies are public benefactors. They undertake mine prospecting and development work which the individual, unless he belonged in the multimillionaire class, could not undertake. If they fail, no one is hurt much because no one has invested much. But if they develop a mine, the money taken from the ground is distributed among the many shareholders, people of moderate means, to whom an augmented income is of some benefit.

# A MARSH HOIST

## IS MADE THE RIGHT SIZE FOR YOUR MINE

and in either Steam Power or Electric Power

This shows one of our Electric Mine Hoists. We make many other types. Send for our catalogue of Mine Hoists, Cars, Cages, Buckets, etc., and see what we offer you. It will repay you.

From the little 10 Horse Power size for prospectors or small mines to the massive 50 Horse Power size, one of our 7 sizes should be just right for your mine.

We are specialists in the building of Hoisting Machinery of all sorts. For nearly a quarter of a century we have been designing and building Hoists, and have developed a Hoist that we are really proud of—proud because of the record of good work they have done, and are doing in mines, quarries, and other classes of work from one end of Canada to the other.

## MARSH ENGINEERING WORKS, Limited

ESTABLISHED 1846

BELLEVILLE, ONTARIO, CANADA

Sales Agents:—MUSSENS, LIMITED, Montreal, Toronto, Winnipeg and Vancouver

### ONTARIO DOES NOT PROPOSE INCREASE IN IN MINING TAXES IN 1920.

Hon. Harry Mills, Minister of Mines, has stated in the Legislature that he is of the opinion that there will be no change in the Ontario Mining Act this session. The statement was made in reply to a question by Hon. G. Howard Ferguson, who said that he had received several letters from which he had gathered that it seemed to be the general impression that there would be an increase on the tax on mines this year. He thought an announcement would have a good effect on the general public interested.

## Miners' Nystagmus

A paper was recently read before the Illuminating Engineering Society in England by Dr. Llewellyn on "Lighting Conditions in Mines with Special Reference to the Eyesight of Miners." The discussion which followed was taken part in by eminent eye specialists and authorities on the occupational diseases of the coal miner. Dr. John S. Haldane summarised the causes of nystagmus in words understandable by the laymen when he said it "was fatigue of some sort connected with the miner trying to see in the darkness", in which opinion he was supported by Dr. Shufflebotham, who congratulated the Illuminating Engineering Society on their joint endeavours with the Royal Society of Medicine to combat this nervous disease resulting from deficient illumination.

Dr. H. S. Elworthy suspected that some incurable cases of nystagmus were connected with rays from the violet end of the spectrum, and he gave figures intended to show that the incidence of nystagmus was greater in pits where owing to the colour of the coal there was a large amount of blue reflected from its surface. In this connection the occurrence of nystagmus cases in zinc mines, as noted by Dr. Stassen, is interesting.

Figures were given by Mr. Turner, of the Stafford Coal and Iron Company, showing that with the very best types of clean safety lamps the illumination at the face is only a small proportion of the candle-power of the lamp. In some instances, lamps over eight feet away from the coal-face gave an illumination of less than 0.01 foot-candle on the coal-face.

Dr. Llewellyn thought the miners' lamp of the future would be the electric lamp, and he directed special attention to the cap type of electric lamp, the alternative to which he said was an increase in the lighting power of the ordinary electric lamp to 3 or 4 candle-power, compared to an average of about one candle-power in standard types now on the market.

One speaker stated that the collieries with which he was connected had purchased 10,000 lamps of the "Ceag" type, which had been in use since 1912. He had noticed three things resulting from their use, first, a reduction of nystagmus, secondly, a reduction

in accidents, and thirdly, the men were able to get away more quickly from the coal-face.

Mr. E. F. Fudge, speaking as Secretary of the Home Office Committee now enquiring into the question of miners' lamps, said that with the present form of construction there was no royal road by which the candle-power could be increased to the extent sufficient to prevent nystagmus. This applied both to the electric lamp and to the oil-safety lamp. He suggested more white-washing of the face and roads in the mine.

Is it not possible that makers of safety lamps are slavishly following older types, much as in the early days of electric lighting the manufacturers of lighting fixtures followed the design of Victorian gas fixtures? It is only recently that electric-light fixtures have shown signs of emancipation from the influence of gas-tubing. Dr. Llewellyn's remarks on the cap-type of the portable electric lamp show a hopeful tendency. In the United States and in Canada lamps of this type have proved to be excellent and safe instruments. They avoid the sensations of shock, and the effects of the vacillating flame that Dr. Stassen insists are so fruitful a cause of the nervous irritations that combine to cause nystagmus. Dr. Llewellyn stated that the chief symptoms of nystagmus, particularly the backward inclination of the head, were a result of the attempt to get the eyes in a position of maximum stability, convergence and depression, and at the same time to direct the line of vision forward. The cap-type of lamp would seem to admirably suit these requisite conditions of vision, and to supply all the deficiencies of which these symptoms are the proof. In fact, they might almost be quoted as a description of the characteristics of the cap-type of electric lamp with conical reflector.

The very general attention now being paid to the causation and remedy of nystagmus, and the combined efforts of illuminating engineers, eye-specialists and mining engineers above noted, should lead shortly to the removal of an occupational disease of miners that has not received any really concentrated attention in years gone by. We may hope, with Dr. Llewellyn, that "in this twentieth year of the twentieth century the long-continued supremacy of the farthing dip will be finally ended."

## The British Steel Corporation, Limited

The progress of the negotiations for a consolidation of a number of coal, iron and water transportation enterprises of Eastern Canada has now proceeded to a point where it is proper to make public comment on a proposal that has been adumbrated for about a year. It is understood the consolidation will include the Dominion Coal Company, the Dominion Iron and Steel Company, and the associated undertakings attached to these two main subsidiaries of the Dominion Steel Corporation, and the Nova Scotia Steel and Coal Company with its subsidiaries and controlled interests, that include the Acadia Coal Company and the Eastern Car Company.

By the inclusion of the Canada Steamships Lines, which company it is understood controls the Century Coal Company of Montreal, Toronto, Port Colborne, Sarnia and Sault Ste. Marie, there is added a network of water transportation and coal distributing facilities that will very much broaden the scope of the Dominion and Scotia Companies' operations, themselves almost as much transportation companies as they are coal miners and steel manufacturers.

It is also stated that the Halifax Shipyards, the Davis Shipbuilding Company of Levis, the Port Arthur Shipbuilding Company, the Collingwood Shipbuilding Company and other smaller interests are to join the consolidation.

The scheme is vast, comprehensive, but we believe quite logical, and is—although we think it quite possible that few will agree with our viewpoint—but a resumption of the natural evolution of industries having coal as their base that was interrupted when the consolidated operation of the coal seams of Nova Scotia by the General Mining Association was abandoned in 1857 for the experiment of independent operation.

We have always believed that whatever financial stability attaches to the coal companies of Nova Scotia is a testamentary benefit conferred by the General Mining Association, and we ventured about five years ago to suggest that the only hope of settled prosperity in the Nova Scotia coal trade lies "in the development of strong corporations, with adequate financial resources."

The base of the imposing fabric of the "British Steel Corporation, Limited," so far as Canada is concerned—and for that matter so far as any other plans its promoters may have overseas are concerned—is built upon coal. On that foundation has been reared the acquisition of ore bodies, the manufacture of iron and steel, and all that implies, the acquisitions of lumber areas, and the coastwise and inland water traffic of Eastern Canada and the St. Lawrence waterway, and the assembly of all these activities under one head is but the family reunion,—with the added vitality that union always gives,—of the children of coal.

It is as a coal-mining consolidation that the merger of these various enterprises holds most significance, and we believe further holds out most hope for financial success for its promoters and real impetus to the industry of Canada. The aggregate production of the Dominion Coal Company, the Nova Scotia Steel and Coal Company and the Acadia Coal Company comprises ninety per cent of the coal production of Nova Scotia and probably ninety-five per cent of the capacity of the collieries of Nova Scotia for production.

It is interesting to note that the coal areas which are controlled by the associated companies are precisely those chosen in 1857 by the representatives of the General Mining Association when that Company relinquished its monopoly of the minerals of Nova Scotia, namely the areas at Springhill Mines, at Stellarton, Sydney Mines and Glace Bay.

It is not within the province of the "Journal" to comment on the propriety or otherwise of the far embracing, but we would repeat, essentially logical consolidation of interests that has been sketched for the public information in the newspapers, but as to the desirability of a consolidation of the operations of the Dominion Steel Corporation and those of the Nova Scotia Steel & Coal Company, there is in the minds of those who are best qualified to judge not the slightest doubt. The only regret that such a consolidation could occasion was that it had not been undertaken many years ago.

The attitude of the "Journal" as to the necessity of an agreement between the Dominion and Scotia Companies for a re-allotment of the submarine areas has not been in doubt. We have always contended that the best interests of both companies were to be served by an amicable agreement, based on consideration of technical operation, a condition that, as we stated in our issue of December 31st last, "will speedily become apparent if a scientific, impartial and complete survey of the problem is undertaken by competent persons." Such a survey has apparently been made, with a result that was a foregone conclusion. There was no escape from the conviction of any competent and unprejudiced group of men who examined the undersea coal area problem that continued independent operation of the undersea coal areas, with continued failure to come to agreement, would in time have spelled disaster to both rival companies.

The consolidated operation of the undersea coal areas off Cape Breton will not by any means remove all the problems that have to be overcome in the future of this unique field, but it will simplify them as no other single occurrence could possibly do, and it will enable concentration of expenditure and technical direction on the problem, in lieu of duplicate expenditure and the raising of man-made difficulties in the operation of a coalfield that is essentially one con-

tinuous deposit, requiring for its most perfect exploitation one continuous management.

We would commend to those who have the direction of the policies of the new Corporation the suggestion that coal is the base of every activity of the thousand and one departments that will require attention, and that it is at the collieries where intensive capital expenditure to improve the capacity of the mines for output is most urgently required.

### CANADA RANKS SECOND AS MINERAL PRODUCER IN EMPIRE.

Commenting on the mineral production of Canada in 1919, the "Mining Journal" of London, Eng., states:

"In common with practically all other mining communities, Canada experienced a general decline in its mineral output last year. Allowing for the great expansions which took place in Canada during the war, and arising directly from the war demand, the falling-off was relatively less than in other parts of the Empire, and today Canada undoubtedly stands second only to the United Kingdom in the importance of its mineral industry. Not only so, but the Canadian industry is very diversified, and in many directions has prospects of expansion which promise to increase her lead over the other Dominions and Dependencies. The extent to which Canada is supplanting Australia as the premier white mining community overseas is very marked. South Africa is, of course, unapproachable as a gold producer, while India has a big lead in coal and manganese, but Canada, while possessing certain special features of her own, such as nickel and asbestos, has an all round strength which is the best guarantee of regular prosperity."

The day is coming when Canada will produce much more coal than Great Britain, and may be relied upon to overtake India in this regard. Great Britain's coal reserves was in 1913 estimated at 189,533 millions of tons, including Ireland. Canada's reserve is 1,234,269 millions of tons. India's reserve is only 79,000 million tons, and is mostly coal of poor grade. There is therefore little doubt that Canada will one day be the mineral producer of first rank in the Empire, as it is now constituted.

It was only in the quinquennial period between 1895 and 1900 that the United States passed Great Britain as a coal producer. It is difficult to realize that 25 years ago the annual coal production of the United States was only 177 million tons, and that it is now in the neighbourhood of 700 million tons. Canada's rise as a coal producer may be commensurately rapid. Why not? We have more coal in Canada than in the whole of Europe, and next to the United States, we have more coal than any other single country in the World.

There are those who argue that Canada should use United States coal, as such a practice will tend to conserve Canadian resources. If it is intended that Canada should wait until the reserves of the United States are exhausted, then the matter ceases to have any interest for this generation, seeing that the coal reserves of the United States are estimated at 3,838,657 million tons. In the meantime, if our own coal reserves remain undeveloped, Canada occupies the position of not having any resources of domestic coal supply, because non-utilization of natural resources is equivalent to their non-possession for every practical purpose. It will be possible to gauge Canada's material growth by watching the curve of coal production, and just now, most unfortunately, Canada is not progressing, but is slipping backwards steadily and without immediate hope of recovery in the rate and tonnage of coal production.

How much longer will we submit to be, as a contributor to the "Journal" on the availability of anthracite recently remarked, the "last applicant at the final source of fuel" in the United States; where, as our contributor further remarked, Canada "can only ask for consideration, has no voice in any proposals developing or conserving production for her future necessities, no control over efforts to expand, no means to compel any change in policy, and no authority to force her needs." Who can doubt the correctness of his further statement, namely, that "the future fuel supply of Canada is a subject large and important enough to justify the continued attention of the Government, and should not be taken up and sidetracked as crises from varying causes rise and disappear. It is a problem greater and more Dominion wide economic importance than much of the work now being undertaken by numerous Government departments."

### NIPISSING MINES ANNUAL MEETING

Shareholders of the Nipissing Mines held their meeting in Toronto on Monday and listened to satisfactory reports concerning the years operation. During the meeting the question was raised as to why the dividend was not higher than 20 per cent. in view of the large surplus of the company, now standing at \$4,372,952, an increase of nearly one million for the year. President E. P. Earle of New York, replied that a good deal of the surplus was in the form of investments in Victory and Liberty Bonds, amounting to \$1,375,000 in the former and \$340,000 in the latter, and that, having regard to the bond market, the company was inclined to pay heed to a feeling of the Government and hold the bonds for some time rather than throw them on the market and to that extent, further depress prices. Further dividend disbursements would be made as soon as possible. It was stated in regard to the company's oil lands that in the Texas field, drilling had reached 2,800 feet and the Ranger sands occur at about 3,400 feet. The former board of directors were re-elected.

# SAFETY LAMP GAUZES

By JAMES ASHWORTH, Livingstone, Alberta

It is now more than one hundred years since Sir Humphrey Davy experimented and produced the well known safety lamp which still bears his name. Its construction has for all practical purposes never varied. The confidence of mining men in its safety and utility in mines has been unaltered through all these years, and even at the present day there are scores of miners who would enter the most dangerous gassy and dusty coal mines and use it with the utmost confidence.

It is, however, a fact that some of the warnings of its inventor were not heeded at first, and, moreover, the later warnings of observant mining men who detected some of its weaknesses, have not been heeded either; thus Sir H. Davy said, that the gauze needed shielding from strong air currents, but some time elapsed before the lamps of this type were fitted with tin shields, for the whole height of the gauze but more generally for only part of the height. In time the tin shield was partially replaced by a cylindrical glass shield in this form and called the "Jack Lamp." Almost contemporaneously the Stephenson and Clanny types of lamp came into use, but they were never regarded with the same degree of confidence as the Davy, because the glass parts were looked upon as being dangerous; and not even the improved lighting value of the Clanny has been able to entirely displace the Davy.

Explosions, however, began to occur where Davy lamps were in use, and various committees and individual men commenced to make experiments, ALL of which showed that the Davy was not as safe a means of lighting a mine, as was popularly thought. Amongst the doubters was a Mr. Darlington (1852), and previously also Dr. Priara (1833) whose energies resulted in the Upton & Roberts safety lamp. The last named safety lamp was a thoroughly well shielded Davy Lamp, but it was very much heavier than the Davy and had not any better lighting value than the Stephenson (Geordie).

The North of England Institute of Mining and Mechanical Engineers appointed investigating committees and experiments were also made by some of its members from time to time, and still nothing definite resulted.

However about 1878-79 following the explosion at Haydock, near St. Helens, Mr. Smethurst of the Garswood Hall Collieries, Wigan, England, erected a testing gallery at one of the collieries where pure methane was piped up one of the shafts from the Six Feet mine, and being joined by the writer commenced experimenting on all safety lamps then in use. The results of these experiments were reported from time to time to the North of England Institute of Mining and Mechanical Engineers, the Secretary of which was Mr. Theo. Wood Bunning. This gentleman was deeply and practically interested, and he induced his Council to arrange to call a meeting of representatives from all the British coalfields to consider what ought to be done to improve the safe lighting of Collieries, and to ask the Government to take up the matter with a view to legislation. After this meeting had been arranged and just before it was to have been held, the Government took a very unexpected move and astonished the whole mining community by appointing the Royal Mines Accident Commission. This Commission com-

menced its investigations with the apparatus used by Messrs. Smethurst and Ashworth, and its report, which is known all over the world, was published in 1886, and so far as safety lamps were concerned, they selected four which seemed to them to have given the best results, viz., the Marsaut, (3 gauzes), the Gray, the Evan Thomas No. 7, and the bonneted Mueseler; all of which were bonneted lamps. But none of these lamps excepting the bonneted Mueseler are in use to-day.

Since then hundreds of patents have been taken out for new patterns of safety lamps, and for various small improvements in safety and lighting value, and yet here we are in 1920 still struggling with the question of a safe safety lamp. Just to show that the matter is considered of great importance it may be interesting to note that the British Government have an official Committee now engaged on a fresh investigation of miner's safety lamps.

It is a remarkable fact that although fine coal dust has often been suspected of reducing the safety value of miners lamps, yet as a factor in experimental tests it has been neglected, and may be said to be so still.

The writer whilst conducting safety lamp tests for the North Staffordshire Institute of Mining and Mechanical Engineers safety lamp committee 1879, made an accidental discovery; thus, it was proposed by the committee to commence the tests with an explosive mixture of coal gas, (town lighting gas), and air, having a velocity of ten feet per second, but as the volume of gas was insufficient, it then seemed as if tests would have to be abandoned until a larger connection could be made with the gas mains. On looking around a sack of fine Eight Feet Bambury coal-dust was noted, which had been specially collected from the roadway of a mine (where there had been at least two explosion disasters), for another committee which had been engaged in making tests with explosives and coal dust. A small handful of this dust was placed on the floor of the lamp testing gallery, on the windward side of the Davy lamp under test, whilst a low velocity of current of 370 feet per minute, consisting of air with 4½ per cent of gas, just licked up what is best described as a normal percentage of the dust. The result was startling, as the lamp quickly showed the effect by becoming red hot near the top of the gauze, and exploded the surrounding atmosphere in eleven seconds. This experiment was repeated many times and the flame passed at times in as little as ten seconds.

This experimental result was communicated to the North of England Institute of Mechanical Engineers, and of course to the North Staffordshire Institute of Mining and Mechanical Engineers, and the records are to be found in the transactions of both Institutes, in the 1879-80 of the former.

The writer does not know of any other experiments having been made in England with the same combination, and why it was not taken in hand by the Government when the Mines Accidents Commission commenced to test safety lamps it is now impossible to say. The next English Royal Commission which was appointed to investigate explosions from coal-dust, did not touch the subject of safety lamps at all, and thus we have now reached the year 1920, after a lapse

of forty years before the subject seems to have awakened mining men to its great importance.

Possibly a real awakening is now in prospect, something comparable to the early morning sun peeping up on the eastern horizon, as there is actually a Miners' Lamp Committee, composed mainly of officials connected with the British Home Office Department, making an investigation.

In 1919, Mr. T. J. Thomas, of Porth, South Wales, contributed to the "Colliery Guardian," of London, a series of articles on safety lamp gauzes. These articles were spread over many months, and whilst reporting the work of those who have in the past devoted their time and energies to the safe lighting of coal mines, show minute thought, and the sound reasoning on which he has based his conclusions.

He commences from the earliest period, beginning of course with Sir Humphrey Davy's work on wire and wire gauzes, and in this regard has deduced facts which demonstrate most clearly that the Davy wire gauze (composed of 28 iron wires of 0.0148 diameter (28 S.W.G.), with 784 apertures of 0.0209 diameter to the square inch), is in all respects superior to any of the Continental standard-gauze meshes. Sir H. Davy's rule was that if a wire gauze could be improved it would be by increasing the radiating or cooling area, and not as was the rule of the late M. Marsaut, by reducing the size of the aperture and using finer wire than that of Davy, and showing that he attached less value to the radiating surface than to the area of the apertures.

The standard wire mesh of France, Belgium and Germany in 1912, had a diameter of wire of 0.3 m/m.; mesh 14; apertures per square cm. 196; diameter of the apertures 0.5 m/m. (0.01969); total surface of wire in one cm. 2.06 and the total open space in one cm. 0.4096.

In none of the gauzes tested by Sir H. Davy (1/40 to 1/60 of an inch), did the diameter of the aperture equal its depth. The nearest size was 28 B.W.G. (0.020 mesh wire), with 24 mesh (578 aperture per square inch wire). It is curious that no one has experimented with a 25 mesh, made of wire of 0.020 diameter, which would give an aperture of 0.020 diameter. This is smaller than the aperture in our standard mesh, and practically equivalent to the aperture in the Continental standard mesh of 0.5 m/m or 0.01969 inch. A gauze made of 25 B.W.G. 0.020 inch diameter (1/50th), of 25 mesh would give 625 apertures per square inch, with the same open space as the standard gauze, of 784 apertures per square inch.

The Continental standard wire for gauzes is made of wire of No. 30 S.W.G., and is 0.0124 inch diameter, or 0.0024 less in diameter than the British.

Sir H. Davy to get as much useful effect out of his safety lamp as was possible, made it 8 to 10 inches high, and 2 to 2½ inches diameter, to give good lighting value, he further proposed a gauze cap on the top of the main gauze, and also a tin shield. This possibly was the origin of the Scotch gauze or Blantyre miners lamp 3 inch diameter by 10 inches high, but the Davy lamp as generally used was only 1½ inches diameter by say 4½ inches high.

In Sir H. Davy's day the air currents in coal mines were of low velocity, and the air impure in comparison with today, and hence both the Davy, the Stephenson and the Clanny proved to be safe and reliable under the then circumstances. But when ventilation became more efficient, and with higher velocities, the confi-

dence in the lamps did not decrease, and they became like heirlooms handed down from father to son with all their traditions. As before noted, possibly Dr. Darlington was the first, or one of the first, to call attention to what he thought was a danger of the lamps from the presence of coal dust in the air. This was in 1852, at which time Dr. Darlington thought that the danger arose from coal dust in a state of incandescence flying off red hot gauzes.

Before mining men began to suspect that the Davy Stephenson and Clanny lamps, were unsafe in their early form of construction, suspicion fell on blasting because explosions were caused under certain conditions when coal dust alone was present, and when no detectable percentage of fire damp (methane was found in the ventilating current. Following this suspicion a great many private experiments were made to demonstrate without a shadow of a doubt, that coal dust was, when very fine and mixed with the ventilating current, an explosive which could wreck a mine much more effectually than a mixture of air and methane. And yet in spite of these demonstrations of the danger attached to the very fine coal-dust found in most coal mines, only a very few persons recognized that the arguments might at the same time be applied to all means of lighting collieries. In addition to this information re coal dust, various savants, Professor B. Phillips Bedson for instance, proved that coal dust was not merely very finely divided coal, but that when fresh it contained occluded gases which helped to make the very fine dust float in the air. Thus we always have a very finely divided solid carried along in its own balloon of gas.

Mr. T. J. Thomas, who has been referred to before and from whose work many quotations will be made, says in one of his articles, "what we are evidently trying to do in our mines today is to resist the passage of the flame from the inside to the outside of a gauze in a safety lamp, with a mesh which will not resist for longer than two minutes the passage of an inflammable mixture of methane and air in the proportion of about the lowest inflammable mixture, having a velocity of only 7 feet per second. It is obvious that if fine coal dust is coming into contact with a reated gauze there must be an evolution of coal gas from the dust. **This is the explosive mixture of unknown composition**, varying in composition, which increases the inflammability as the temperature of the gauze rises, and yet we are trying to resist it with this standard mesh. Our aperture of 0.0209 inch is greater than half the diameter of the mesh which passes flame when strongly heated, and in our standard mesh the absorbing and radiating surface is increased by 0.2 square inch,—these meshes were safe when cold, but will pass the flame when strongly heated, or when subjected to any motion.

Mr. T. J. Thomas again remarks, "It is remarkable that lamps with double gauzes should only have been submitted to test with 8 per cent of coal gas by the Royal Mines Accidents Commission at Woolwich Arsenal. (See the report of the experiments published in the 1886 report). What value these tests have in showing the resistance of the mesh to the flame of fire-damp and air in a Marsaut lamp, Mr. Thomas finds it difficult to discover. It is known that if we throw a quantity of fine coal dust on to a metal plate at a dull red heat, we shall get an evolution of coal gas, and it is evident that we get a certain amount of

coal gas produced when coal dust comes in contact with a safety lamp gauze which is at a dull red heat. Enrique Hauser ("Researches on Firedamp" *Transactions of the American Institute of Mining Engineers* 1916), states that he obtained ignition of a mixture of coal gas with a limit of inflammability of 8.5 by using five parts mixed with 4.5 parts of firedamp, the illuminating gas forming therefore 54 per cent by volume of the two inflammable gasses. This ignition was obtained by the fusion of a ferro-nickel wire of 0.3 in diameter.

We are trying to prevent the flame passing, in possibly a mixture of this kind, with a mesh which will not resist the action of the lowest explosive mixtures of methane and air for any length of time.

A mesh of 900 apertures per square inch made of S.W.G. wire (0.0148 inch in diameter), 30 meshes per inch gives an aperture in diameter of 0.01853 with a wire surface of 2.788 square inches and a total open space in each square inch of 0.320 inch. Mr. Thomas thinks that with two superposed gauzes it could not be used in an ordinary safety lamp. The apertures of this mesh would be smaller than the mesh in use on the Continent.

Mr. T. J. Thomas expresses the opinion that we have long passed the limit when gauze can be relied upon for safety in fiery dusty mines. Thus when there is a continuous flame of burning firedamp in a miner's lamp in a coal mine, which has fine coal dust floating in the air the lamp ceases to be a safety lamp that can be carried about.

Probably the products of combustion when passing through a heated gauze may become decomposed and affect the result.

We are quite certain that the safety of a safety lamp is also affected by the air pressure in which it is being used, thus, take the case of the Viviers Reunis mine, at Charleroi, in France, with the barometer standing at 30 inches on the surface the pressure of the air is increased to 33.9 at a depth of 3500 feet, and thus would naturally increase the lighting power of a safety lamp, but of the effect of this extra pressure on the safety value of the lamp we practically know nothing.

Mr. T. J. Thomas calls attention to another point which would seem to require careful investigation, viz., as to what is the most suitable metal to use for miners' safety-lamp wire gauzes, thus, he gives reasons why steel wire ought NOT to be used, and why we should retain the iron wire as having been distinctly specified by Sir Humphrey Davy. He is also of opinion that a copper wire gauze is not as safe to use in a fiery mine as is iron wire. In this regard probably most mining people will agree with him, his argument being that copper occludes oxygen and therefore is one of the most dangerous substances to use in a gauze, and further that Sir H. Davy preferred brass wire.

Naturally, the force of an explosion within a safety lamp gauze or gauzes affects the safety of the lamp.

Mr. Thomas frequently uses the expression "internal detonation" and therefore assuming that detonation can take place under certain conditions, then we have another possible danger to provide against, seeing that the speed of such an explosion may be more than 3,000 feet per second.

Then again we know as a definite fact that the word firedamp covers many other gases besides methane, such as ethane, propane, and hydrogen, and

therefore even a small percentage of any one of these gases will greatly increase the danger of lighting a fiery mine. For instance, the failure of a perfectly sound double gauze Marsaut (Wolf gasoline pattern), caused an explosion at No. 3 mine Michel, B.C., as soon as the miner reaching his working place had hung his lamp. (See paper on "Firedamp" in the February, 1920, *Canadian Mining Institute Bulletin*).

Another suggestion which Mr. Thomas throws out is based on his reasoning that as one, two or three, superposed gauzes do not make a safety lamp safe in a fiery dusty coal mine, that some other construction should be adopted in which the gauze part is only exposed to the minimum of danger from the ignition of firedamp within the lamp. This does not seem feasible at first sight, but he quotes the Hailwood Combustion lamp, in which, as it is of the Mueseler type, there is only the disc gauze exposed to an explosive flame, in which case the flame is probably passing away from the gauze and therefore does not impinge on it and cannot dangerously heat it.

The Mueseler type of safety lamp is not, however, entirely immune from a certain amount of liability to fire the outside atmosphere, and therefore it is well to examine and find out if possible what are its weak points. Undoubtedly, the most likely part to show its weakness is through the open chimney, thus if the current of air and gas through the lamp becomes reversed, and does not extinguish the wick flame on ignition, or gas continues to burn under the disc gauze at the foot of the chimney, the explosion within the glass part of the lamp may be sufficient to carry the flame through the large gauze covering the top part of the lamp. The other risk is that the explosion of gas and dust within the glass part may carry the flame through the disc gauze at the foot of the chimney and into the top truncated or cylindrical gauze and thence into the mine atmosphere. Another danger arises from the fact that in a brisk ventilation if the gas continues to burn under the disc gauze after the first explosion at the wick flame it may continue to burn on the windward side and pass the products of combustion out through the same gauze on the lee side of the chimney, in which case the chimney may become a downcast and ultimately be the means of carrying the flame up and out through the main gauze. In the failures of this type of lamp it is very difficult to make sure how the failure occurs because as a general rule burning gas and the wick flame are both extinguished by the first explosion within the glass part. The writer has always considered the chimney to be the weakest part of the Mueseler, and therefore when making an improved Mueseler safety lamp he added a protection to the top part of the chimney to stop the possibility of a down-draught, and also a small circular truncated conical shield to cover the disc gauze, with of course a space between, to prevent any double current, that is, from the windward to the lee side, as referred to above.) (See paper on the Davy and Mueseler types, 1879-80, *Transactions of the N. of E. I. of M. & M. E.*)

The Mueseler type of safety lamp has been unfavourably received because of its almost certain extinguishment if thrown over or placed very much outside its perpendicular position, and hence the Clanny and the double gauze lamps have taken the lead. But even with this disadvantage the type is undoubtedly coming into favour again with the additions of what amount to small alterations in construction. One of the

best known of these is the Hailwood in which a high lighting value and, of course, a better combustion at the oil wick flame has been attained, by adding a small cylindrical glass to the base of the chimney and extending it down to the level of the wick flame, also with a cowl or protection to the top of the chimney to protect it from any down-draught current. Like many other modern designs, that of the Hailwood Combustion lamp is not entirely new, but presumably it is the combination and difference in the dimensions of the parts which constitute the patent; and, judging from the writer's practical and experimental experience he would expect to find that gas might be ignited and continue to burn under the disc gauze between the two glasses.

Another modification of the Mueseler type has also been patented by the Patterson firm of safety lamp makers, and is called the Patterson.—In this lamp the alterations are a combination of the Mueseler and Gray types.

There are also some other alterations in the details which do not materially affect its safety value. A higher lighting value is claimed for this lamp than for the Hailwood, and that there is only one glass for the light rays to pass through, and also that the glass part is less liable to become fouled by smoke from the wick flame. The gauze ring below the glass part of the Gray is replaced by a perforated brass ring one-eighth of an inch thick. In regard to this perforated ring it is to be noted that the Prussian Safety Lamp Commission, 1880-1887, decided that perforations through a metal plate were not as safe as standard wire gauze, but as the lamp has received the approval of the British Home Office it has evidently passed safely through the Eskmeals testing station. It may be observed, however, that the tests made at Eskmeals are made to pass the lamps through a fixed series of tests so that all safety lamp tests are made to one standard, and not to find out any particular weakness of design or construction.

There is, however, one notable claim for the lamps points of excellence which is extremely novel, viz., that of passing the inlet air twice through the same gauze, to double the resistance to the passage of flame, whereas the only practical effect is to increase the friction of the incoming current of air. A deflector plate is also fitted inside the shield touching the cylindrical gauze about half way up the height of the shield, which thus to some extent separates the ingoing and return air currents. Some value is claimed for the lamp as a gas detector, but the section shows that it does not permit the atmosphere to be tested to enter at any point nearer to the roof than any ordinary lamp, and in this regard is a long way behind the lamps of the true Gray type, neither is there any arrangement to save the wick flame from extinguishment from excess of gas, by admitting gas-free air at the lower end of the inlet air tubes, as in all Gray and Ashworth-Gray patterns.

Whether or not this pattern of safety lamp is immune from the possibility of a down current in the chimney is a point which could be ascertained by experiment, but like the true Gray patterns it has a very limited space within which the ignition of an explosive mixture of air and firedamp can take place.

Having thus called attention to the main points of these two safety lamps, both of which have been specially designed to give an excellent light to the miner whilst at work, one being of the true Mueseler type and the other one mostly like the last pattern of

Major Gray, the patentee of the original Gray, it remains to refer to the latter as well as to the Ashworth-Gray patterns.

All of these have a deflector plate around the wick flame to bring the incoming air for combustion into intimate contact with the wick flame, and thus improve the lighting value; some patterns have the chimney inside the gauze part as in the Patterson pattern, but lamps of the true Gray type have the gauze part inside the chimney—the difference in practice being that no coal dust can settle on the gauze when placed inside the chimney, and also it cannot become red hot. Therefore the lamps at this point are secure from the dangers which Mr. T. J. Thomas has called special attention to. The glasses of all patterns of Gray may be either cylindrical or conical—the original Gray having a cylindrical glass and most of the Ashworth-Grays, truncated conical glasses. The practical difference is that the latter form is stronger than the cylindrical, has smaller cubic contents and gives a superior roof light. All patterns of the Gray type have been specially designed for firemen and firebosses use, as the best detectors of firedamp and at the same time to give a superior illumination with less than an ordinary expenditure of oil or spirit or whatever illuminant is preferred by the firm using them. The outstanding features of the Gray type are (1), that it is impossible to make any gauze part red hot; (2) that the ventilating current within the lamp cannot be reversed when an ignition of firedamp occurs inside the lamp; (3) that if the lamp wick flame is not extinguished along with the gas the gas flame can only burn out of contact with the gauze ring, and thus it is impossible to overheat this gauze.

Another advantage of the Gray type of safety lamp is that the whole of the air entering the lamp is exposed to the wick flame and consequently the products of combustion become a really extinctive gas. A still further advantage is that it is the only type of safety lamp in which the air necessary for combustion, and the products of combustion, both pass through openings of standard size and therefore there is no danger of an excess volume of explosive current entering the lamp.

The patent rights of the Gray and the Ashworth-Gray constructions of safety lamps have long since expired, and therefore as there are no royalty charges these lamps ought to be supplied at very reasonable price, though at the time the patents were in effect, the sale of them was made almost impracticable in competition with bonnetted Clanny lamps selling at such prices as one dollar to a dollar and a half each.

Both the Hailwood and the Patterson are as expensive to manufacture as either the Gray or the Ashworth-Gray, and hence the prime cost does not seem to enter into the controversy, and consequently only the lighting values and safety points need to be taken into account. As regards safety in particular, it may be assumed without question that all the above named lamps are safe, as they have passed the British Home Office tests at Eskmeals.

It would make very little difference to the lighting value of any of the modern lamps named above if the new and more resistive gauze mesh suggested by Mr. T. J. Thomas were adopted and therefore the sooner it becomes the standard size the greater will be the margin of safety.

Since the partial introduction of electric lamps into dangerous mines, it has been impossible to carry out the rules of the Acts of Parliament in regard to the

testing for methane, and other gases, and therefore the safety lamp makers have been vigorously struggling to perfect oil safety lamps of higher lighting values than the electric, which can be used for testing for inflammable gases and also conform to the rules for keeping a mine safe. The makers claim that these high powered oil lamps give a better all-round light to the miner, are also better for his eyes, and therefore that they will enable a miner with nystagmus eyes to continue at work underground. What causes nystagmus has been debated for a score of years, and is still an unsettled question, but the majority of doctors and others incline to the insufficient light as the reason—others say it is "glass glare." Both these possible causes have now been provided for, thus, all the newest safety lamp designs provide for increased lighting power, and such lamps as the Hailwood Combustion lamp are shielded by the frame which carries the inner glass; all of the Gray type lamps may have one single flat air tube instead of two or four round ones, the same with the Patterson. The flat tube arrangement also permits it to act as a reflector, or white enamelled glasses (which the writer patented many years ago), might be applied to the Patterson or any other type. If the English Home Office Committee take up the question of gauze versus perforated metal, and decide in favour of the perforated metal, then we can have these safety lamps made entirely without gauze parts, and in this way replace Sir Humphrey Davy's gauze with George Stephenson's perforated metal plate. The writer thinks, however, that the majority would prefer the gauze and the higher powered oil lamp rather than the electric lamp, or at any rate until the electric lamp can be used for gas testing purposes.

In concluding these notes, the writer would impress on every one vitally interested, that no matter what our personal prejudices may be, we should *make* "Safety the First Consideration," and in this practical way do something towards minimising such fearful disasters as colliery explosions.

#### CONSOLIDATION OF INDUSTRIES BASED ON COAL A LOGICAL HAPPENING.

Abstracted from a Review of the Steel Industry since the Armistice by the Editor in the Christmas Number of the "Grain Growers' Guide".

It is in the logic of events to anticipate a consolidation of interests, including coal mines, iron-ore deposits, steel plants, and steel-ship building yards, along the lines that have been so successful in Britain, where it is often stated that the ore comes in at one gate and the steel ship goes out at another. It is possible by a consolidation of such allied interests, which are all founded upon coal and the heat that comes from coal when burned, to utilize that heat more completely and scientifically when all the surplus gasses, and the by-products of combustion are concentrated in a compact area, enabling process to follow process without loss of time or heat, and facilitating what is today known as straight line production. If such consolidations take place in the future, they should not be looked at askance, or regarded as undesirable, but should be recognized as the only way in which our basic industries of coal-mining, steel manufacture and ship-building can be developed to a point where they can stand on their own legs and enter the competitive markets of the world.

The weakness of the steel industry in Canada lies in its too great dependence on the United States for supplies of iron ore and coal. Only five per cent of iron ore reduced in Canadian furnaces is mined in Canada, although a large tonnage, at least 900,000 tons annually, comes from the Canadian owned mines at Wabana, Newfoundland. Canadian iron ores are plentiful, and well distributed, but they happen to be temporarily discounted in value by the more accessible, cheaper and more easily reducible iron ores on the United States' side of the Great Lakes. Some day, Canada's ores will prove a source of great wealth. In the matter of coal, Canada can, to a much greater extent than she has hitherto done, please herself whether she mines coal at home or goes to the United States and pays out good money for coal there. Canada has lots and lots of good coal, and is under no compelling necessity to spend some \$50,000,000 annually in the purchase of United States coal.

An interesting subject at this time is the desire of British Columbia to have a steel industry in that province. The permanence of the ship-building industry there almost requires a steel industry on the Pacific coast, and the probability is that before long a beginning will be made in the manufacture of steel, and possibly in the reduction of iron ores to pig-iron, in British Columbia. Wherever coal is found of suitable quality, and in sufficient quantity, an iron and steel industry is bound to follow the development of the coal fields, even should it necessitate the transportation of iron ore and fluxes for some distance, because the metal industries, from the mining of the metaliferous ores to the final fabrication of the finished metal, are entirely dependent on coal for motive power and heat—with some notable exceptions where large quantities of electricity generated by water-powers are available. Coal is the most important and basic raw material of the modern world. It is a first necessity of national defence and national independence, and no country can achieve industrial importance without coal. Therefore, that country which is most generously supplied with coal is most likely to lead in industry. In Canada, that most favored district is Alberta, which has within its borders more coal than all the remainder of Canada, and more coal than any one state in the American union.

#### Book Reviews

**MICROSCOPIC EXAMINATION OF THE ORE MINERALS.** W. Myron Davy and C. Marson Farnham. First Edition. Mc. Graw-Hill Book Co., New York. 154 pages with Indices. 6 ins. by 9¼ ins. Cloth Boards.

This work deals with the technique of polishing and examining the specimen, and with the photomicrography of polished sections. The main feature of the volume is a series of determinative tables, to which a thumb index is given. The index is arranged as to order of reagents used in identification. A number of supplementary tests are detailed. The examination of polished specimens of ores is in the work referred to as "mineragraphy" following the analogy of the better known term of metallography. The work is intended for advanced students and for professional reference in the laboratory. The printing, indexing, and general arrangement of the work leaves nothing to be desired.

# Miners' Nystagmus

(By SIR J. COURT, M.R.C.S.)

Miners' Nystagmus in the coal mines of Europe, its cause and cure, have been thoroughly investigated during the past thirty years. There is no doubt that the opinions, held by the majority of experts, that the deficient light of the safety lamp is the chief cause of the disease has led to great improvements in the illumination of collieries and in the construction of lamps. It may be said, therefore, that the greater the light the less the disease. It has been affirmed, with much truth, that miners suffering from myopia hypermetropia or astigmatism are more liable to develop the trouble than those men with normal vision. A high proportion of nystagmus cases have been found to have errors of refraction, a high proportion also of all adult working men have errors of refraction, and the same will be found in school children. Nevertheless, when these men work in naked light pits they seldom develop nystagmus. The condition of lighting in all mines should be made equal, or better than where naked lights are used. There is also a personal factor in some of the cases of nystagmus. It is remarkable that so many young men have the complaint. I have seen two brothers under 25 years of age suffering badly.

Many of the bad cases of nystagmus also suffer from photophobia and night blindness, and they cannot go out of darkness into bright light without shading their eyes and throwing back their heads.

Owing, however, to the great improvement in the lighting, especially by electricity, in all the collieries

of Great Britain, these bad cases are nothing like as common as they were ten years ago.

Exhaustion and fatigue have a bad effect upon some cases, and they suffer much more at the end of the day than their fellow miners. Others are very depressed in mind, and when insanity is inherited the nystagmus might possibly be an exciting cause of it. Nystagmus should therefore be looked upon as a neurosis, because of the headaches, giddiness and tremors which so often are present in bad cases. These miners ought to have special attention, and any means to help them to avoid eye strain should be adopted. Many of them complain of the unshaded light of the safety lamps, and also the white light of the electric lamp. Although they can get more coal and with much greater ease with the electric lamp, the white light is irritating when looked at.

Probably some kind of glass could be used in an improved lamp which would overcome the glare caused by the ultra violet rays of the white flame. Amber coloured glass has been used with advantage by oculists for eyes which are sensitive to bright light. Either this or Sir A. Crooke's smoked glass should be tried, either by the whole bulb of the lamp or a shade made to cut off a quarter of the light so as to relieve the eyes from the glare without diminishing the light directly in front where the miner is at work. Another advantage of an amber coloured glass is that it gives a better definition of the object looked at.—*Medical Times (Eng.)* Mch. 1920.

## Deep Boreholes

At a meeting of the Geophysics Committee of the British Association, held in London on February 6, a discussion took place upon the subject of deep boreholes. The debate was opened by the Hon. Sir Charles Parsons, who had previously put forward a suggestion that it might thus be possible to tap the heat of the earth's interior and utilize it as a source of energy at the surface. The project naturally strikes the imagination, and it does not at first sight appear to be beyond the realm of practical engineering, especially as something of the kind has already been accomplished at La Darello, in Italy, where volcanic heat, in the form of high-pressure steam, is already developing 10,000-horse-power, and other projects are on foot for turning to practical account the heat of Vesuvius.

We venture to call attention to this discussion for several reasons. In the first place, the possible, utilization of any natural sources of energy—more particularly in a country like Italy, where coal has always been an expansive luxury, and is now almost unobtainable—assumes a position of real economic importance. In the second place, our knowledge of the rate of increase of temperature in the earth's crust is still far from complete, and mining engineers cannot but take deep interest in any investigation which is likely to throw light upon it. In the third place, we are still lacking in precise information respecting the condition and behaviour of rocks at considerable depths below the surface. And finally, great im-

portance must necessarily be attached to the views of practical engineers as to the limits of depth it would be possible to reach with the resources now at our disposal.

Upon all of these points the discussion referred to above afforded useful and highly interesting information. Let us take, in the first place, the rate of increase of temperature. It is a striking fact that, so far as actual experience in other countries has gone, the average rate of increase of temperature with depth, as measured in English collieries, seems to be altogether abnormal. The geothermic gradient estimated by this criterion is generally assumed to be about 72 ft. per degree Fahr., but in Brazil, in the Morro Velho Mine, where a shaft has been carried down by successive steps to a depth of 6,426 feet the rate of increase of temperature is less than one-third of this amount. The same conclusion is reached in the Rand mines of South Africa, where a shaft at the Village Deep mine has reached 5,400 feet in vertical distance below the surface, and the geothermic gradient has been found to be about 250 ft. per deg. Fahr. The apparently exceptional and steep heat gradient found to exist in the British area at one suggests that some special local reason for it may exist, possibly of a chemical character, and there is no absolute certainty that the same rate of increase would be maintained in deeper workings. This, however, is pure conjecture, and can only be put to the test by actual experiment.

As to the practical limit of a deep borehole Mr. Hugh F. Marriott, whose experience in the deep mines of South Africa lends exceptional authority to his opinion, thinks that it would not be possible to carry a borehole down much deeper than the one recently sunk in West Virginia, which reached a depth of 7,579 feet, and can claim to be the deepest borehole yet made. Probably even this depth could not have been reached by any other method than cable drilling, which is a most unsatisfactory method from an exploratory standpoint. Core-drilling, as is known, suffers a great disadvantage owing to the difficulty of maintaining anything like a straight line. If the deviations are unchecked, the rod becomes deflected more and more, and might eventually reappear at the surface. If this tendency to deflection is systematically checked, on the other hand, the rod ultimately assumes a corkscrew shape, and the resulting friction absorbs all the energy that can be put into it from the surface. Thus, a core drill seems to be strictly limited in vertical range, and may be dismissed from consideration for any borehole greatly exceeding one mile in depth.

There remains the shaft method, in regard to which experience gained at Morro Velho and in the Rand is highly instructive. The two most fundamental factors in deep shaft sinking are the ventilation of the working and the stability of the rock. With regard to ventilation, it is necessary to keep the air at the bottom of the shaft at a temperature at which men can work continuously for some hours. An ordinary air current would appear to be unsuitable for this purpose in a very deep shaft, because as the depth increases the air becomes heated by adiabatic compression at a rate which is nearly equal to the temperature gradient in the earth's crust. Other methods of cooling are, of course, practicable; but they all involve an expense which would soon be prohibitive. As to the stability of the rock at great depths, the little that is known of this factor is by no means encouraging. When an engineer makes a hole in the earth he is constantly in danger of disturbing the balance of forces, which, in the case of rocks under great compressive stress, may become highly dangerous to the stability of the shaft walls. Mr. Marriott gave some graphic illustrations of this effect. In Mysore, where the rocks are highly contorted, and are strained almost to the breaking point, miners are killed or injured by the sudden explosion of the rock, and even in the Rand, where the strata are dipping uniformly, the deep workings are groaning and cracking most unpleasantly. If these things are happening at depths of one mile only, the effect at greater depths may be expected to be considerable, and Mr. Marriott expressed the opinion that a depth of three miles would be the maximum that could be expected to be reached in any shaft. The 10 or 12 miles contemplated by Sir Charles Parsons, therefore, appears to be quite beyond any possibility of achievement.

The moral of all this is obvious. The exploration of the earth's crust at such great depths being beyond the powers of engineering skill, we should be content for the present with less ambitious schemes. From the point of view of the mining engineer, as well as that of the geologist, it would be highly desirable to put down a number of boreholes of more modest dimensions, rather than to attempt what seems to be practically unattainable, and to undertake which, in any case, would involve a huge capital expenditure.

—"Colliery Guardian."

## U. S. BUREAU OF MINES ISSUES BULLETIN ON FLAME-PROOF MOTORS FOR COAL CUTTERS

A proved Explosion-Proof Coal Cutting Equipment is the title of Bulletin 78, just issued by the Bureau of Mines, Department of the Interior. L. C. Hsley and E. J. Gleim, the authors, say: "Electrical apparatus because of its flexibility and its adaptability to all classes of service has become essential to the mining industry. Hence the problem of providing electrical equipment that is safer for use in explosive mixtures of methane and air is of prime importance in coal mining. Investigators and experiment stations early recognized this fact and much work has been done in the investigation and the development of electrical apparatus for use in atmospheres containing fire damp. The term 'fire damp' as applied throughout this bulletin means an explosive mixture of methane and air.

"Direct current motors and alternating-current motors of the slipring type when running usually give off electric arcs or flashes that will ignite fire damp. Other motors that have no moving electric contacts may become dangerous through accident, deterioration, or neglect. Auxiliary apparatus such as fuses, switches, rheostats, and controllers may arc, flash, or become heated to such a degree that fire damp can be ignited. Such equipment is still more dangerous when worn or out of repair.

"In the United States the development of apparatus for use in gaseous mines has been associated largely with coal-mining equipment run by electricity. This is undoubtedly due to the use of such equipment at the face of the mine workings, where the chance of igniting fire damp is necessarily greatest. One American manufacturer built a coal-mining equipment of the totally inclosed type for use in fire damp atmospheres in 1903. Another built similar equipment with special protective devices in 1906 for export.

"During the years 1910 and 1911, the Bureau of Mines at its Pittsburgh experiment station conducted a preliminary investigation of the safety of such protection as was then in use or under consideration. Five motors were submitted for this investigation, each having somewhat different methods of protection.

"Although none of the motors tested met all the conditions for safety, the investigation was of value in laying the foundation for future tests and development. Based on the experience gained a schedule of tests was published by the bureau that stated the fees and requirements for the test of motors designed for use in gaseous mines and also stated that the bureau would give its seal of approval to such motors as met the requirements.

"The first part of the bulletin just issued deals with the general theory of protection from fire damp, gives the bureau's schedule, and shows its application to the testing of commercial apparatus. The second part covers a detailed description of the apparatus that has been tested and, approved under this schedule, together with a résumé of the tests on which the approvals were based."

Copies of this bulletin may be obtained free of charge by addressing the Director of the Bureau of Mines, Washington, D.C.

**WORLD PRODUCTION OF COAL IN 1919.**

(Prepared by G. F. TRYON, and published by the United States Geological Survey.)

The world's production of coal in 1919 seems to have dropped back to the level of 1910. Preliminary estimates, necessarily, rough, place the total output of all kinds of coal in 1919 at 1,170,000,000 metric tons, or 1,290,000,000 net tons. This is 162,000,000 metric tons less than the production in 1918, the last year of the World War, and about 171,000,000 tons less than that of 1913, the year before the war began.

This estimate is based by the Geological Survey upon reports to the Supreme Economic Council from countries which contribute about 85 per cent of the world's output. Obviously, returns from the other countries may materially alter this figure, if anything, they will probably reduce it still further.

The following table shows the estimated production of the world for each year from 1910 to 1919. Because of disturbances and interruptions in the compilations of Government statistics, particularly in Central and Eastern Europe, the figures since 1913 are not to be regarded as final. The metric tons of 2,205 pounds is used because it is the prevailing unit in non-English speaking countries. Americans will remember it most easily as being equivalent to the gross ton and the English ton.

**The World's Production of Coal, 1910-1919.**  
(Metric tons of 2,205 pounds.)

Year	Production in part estimated	Per cent produced by United States
1910 . . . . .	1,160,000,000	39.2
1911 . . . . .	1,189,000,000	37.9
1912 . . . . .	1,249,000,000	38.8
1913 . . . . .	1,341,000,000	38.5
1914 . . . . .	1,208,000,000	38.5
1915 . . . . .	1,190,000,000	40.5
1916 . . . . .	1,270,000,000	42.1
1917 . . . . .	1,336,000,000	44.2
1918 . . . . .	1,332,000,000	46.2
1919 . . . . .	1,170,000,000	42.1

Comparative production in five of the belligerent countries before and after the war is shown in the following table:—

**Production of Coal in Certain Countries, 1913 & 1919.**  
(In millions of metric tons.)

	1913	1919
United Kingdom . . . . .	292	237
France (present boundaries)a . . . . .	44	22
Belgium . . . . .	23	18
Germany (present boundaries)b . . . . .		
Bituminous . . . . .	173	109
Lignite . . . . .	87	94
United States . . . . .	517	494

It is pointed out by the Supreme Economic Council that from 1913 to 1919 the output of bituminous coal in the four European countries shown in the table has failed from 532 millions to 386 millions, the decrease being about 20 per cent in the United Kingdom and Belgium, and nearly 40 per cent in Germany. In the Saar Valley, whose output appears to have fallen from 12 million tons in 1913 to about 8 millions in 1919, the percentage of decrease was over 30. The reduc-

(a) Includes Alsace-Lorraine.  
(b) Excludes Alsace-Lorraine and the Saar.

tion of the mines in the Nord and Pas de Calais.

The output of lignite in Germany in 1919, though less than in 1918, was still greater than before the war, being 94 million tons, as compared with 87 millions in 1913.

In the break-up of Austria-Hungary the bulk of that country's coal and lignite, the production of which amounted before the war to about 55,000,000 tons, was inherited by the Republic of Czecho-Slovakia in the French output is mainly due to the destruction of the mines in the territory produced in 1913.

**CHANGE IN THE PRESIDENCY OF THE DOMINION STEEL CORPORATION**

Roy M. Wolvin has been elected president of the Dominion Steel Corporation, Ltd., Sydney, N. S., to succeed Mark Workman, who resigned the position in order to devote his attention to personal affairs. Mr. Workman, however, has continued as chairman of the board of directors. He will become a member of the London advisory committee of the corporation at the instance of the British interests, who have become associated with it. After a rest at Atlantic City, he will sail for England.

Mr. Wolvin who has risen rapidly to a position of prominence in the industrial world, was born at St. Clair, Mich., Jan. 21, 1880. After a high school education in that city, he commenced his business career as clerk with the Western Transit Co., Duluth in 1896. remaining there about one year. He then became manager of the Great Lakes & St. Lawrence Transportation Co., and the Standard Steamship Co. and occupied these positions from 1901 until 1910. He next became president of the Standard Steamship Co., Winnipeg, Man., the Duluth Shipping Co., Duluth, and the Central Shipping Co., Chicago, in 1910. Later he became president of the Montreal Transportation Co., Ltd., Montreal, Que.; president of the Canada West Coast Navigation Co., Vancouver; vice-president and general managing director of the Halifax Shipyards, Ltd., Halifax, N. S.; president of the Canadian Towing & Wrecking Co., Fort William, Ont.; vice-president, Collingwood Shipping Co., Ltd.; president, Reid Towing & Wrecking Co., Sarnia, Ont.; president of the Maritime Wrecking & Salvage Co., Halifax, and occupied other important and responsible positions. He was elected a director of the Dominion Steel Corporation in the middle of 1919.

**Saward's Annual, 1920.**

We are in receipt of the 1920 edition of Mr. F. W. Saward's well-known compilation of data on the coal trade of the United States and Canada. Prefaced by a readable review of the coal trade of 1919, the volume contains figures on output, prices, freight rates, transportation, exports and trade conditions generally that are most useful to those who have to deal with the sale or transportation of coal. We would suggest that the value of this compilation might be increased if the coal production of the United States were to be given for each year since the beginnings of the industry. The growth of the industry has been so extraordinary that it is necessary to go back over the annual outputs for at least 25 years in order to get a proper perspective.

# The Last Stand of the Reciprocating Steam Engine

By The EDITOR

Readers of a journal devoted to mining interests, particularly those connected with coal production, may, upon first impulse, view the spread of railroad electrification with hostility, or, at any rate, with but mild interest.

The "Canadian Mining Journal" would put forward the suggestion that the fuel problem in Canada is of such a specialized and such an urgent character that every possible means should be adopted to lessen our national handicap and to make Canada self-supplying in light, heat and power.

Canada has excellent waterpowers, but like the coal reserves, they are not evenly distributed. It may be stated (as a generalisation to aid our thinking) that in sedimentary-rock regions of Canada in which the coal reserves are found water-powers are not important, with the possible exception of Vancouver Island. For example, in Nova Scotia, while the waterpowers are not to be despised for local uses, no great outpower of hydro-electric power can be looked for. In the central plains, water-storage for irrigation and town-supply is important, but great waterpowers are absent. In the Archaen Shield, and in the Cordilleran region where coal is not found, waterpowers of great importance occur, and have already been partially utilized for the generation of electricity. It is stated that the undeveloped waterpower of the St. Lawrence River which could be harnessed by the construction of canals totals 4,200,000 h.p. By Combining the electrical power that could be raised from coal in Nova Scotia, with the hydro-electric power possibilities of Quebec and Ontario; and linking these up with the coalfields of the plains and the foothills of the Rockies and the waterpowers of the British Columbian Pacific slope, the possibility of transcontinental railways operated by electric power from Sydney to Vancouver is indicated, nor is the idea to be lightly dismissed in the light of what is being accomplished elsewhere.

The April issue of the "General Electric Review" is specially devoted to electric traction, and is a number that deserves the consideration of all who are interested in railways or the coal supply of railways. Under the striking title of "The Last Stand of the Reciprocating Steam Engine," Mr. A. H. Armstrong, contends that the steam locomotive is gradually disappearing from the railway field, as the reciprocating steam engine is disappearing from the industrial field and the propulsion of ships.

The table below given in Mr. Armstrong's paper subdivides the tonnage passed over the tracks of the United States railways in 1918.

The first four items, representing 85.56 per cent of the total ton-miles made during the year 1918 are common to both steam and electric operation.

By introducing the electric locomotive the last four items are reduced to extent of completely eliminating items 6 and 7, reducing item 5 by possibly 80 per cent and item 8 by one-half.

Of the total 14.44 per cent affected, it may be assumed that about 12 per cent of 146,000,000,000 ton-miles at present hauled by steam engines could be totally eliminated with electric locomotive haulage. This ton-mileage equals 20 per cent of items 1 and 2 representing the revenue-producing traffic on the United States railroads.

In other words, if the railways were electrified they could carry one-fifth more revenue-producing freight with no change in present operating expenses of track congestion.

The steam engine-tender would entirely disappear, while the haulage of coal on the railways would be largely curtailed by the use of hydro-electric power, and the establishment of steam power-houses at the coal mines.

Mr. Armstrong remarks that while water-power should be used to the fullest possible economical extent, the greater portion of the power must undoubtedly be supplied by coal, due to the unequal geographical distribution of water power available—so far as the United States is concerned.

It is exactly this feature which should commend the use of electric locomotives in Canada. The economical distribution radius of coal is much increased when it is used to generate electricity for long-distance transmission, and, as previously suggested in the "Journal" (see issue of Nov. 5th, 1919) the electrification of the Canadian National Railways in the Maritime Province could be carried out from Sydney to Moncton, N.B. in such a manner as to avoid the necessity of hauling either water or coal for locomotive power purposes throughout the whole of that distance.

Similarly, the establishment of central power-stations with long-distance transmission in the prairie coalfields should enable the radius of western coal usefulness to be enlarged both eastwards and westward.

## TOTAL TON-MILE MOVEMENT.

### All Railways in United States—Year 1918

	Per Cent	Ton Miles
1—Miscellaneous freight cars and contents . . . . .	42.3	515,000,000,000
2—Revenue coal cars and contents . . . . .	16.23	197,000,000,000
3—Locomotive revenue, driver weight only . . . . .	10.90	132,300,000,000
4—Passenger cars, all classes . . . . .	16.13	196,000,000,000
Total revenue, freight and passenger . . . . .	85.56	1,040,300,000,000
5—Railway coal . . . . .	5.00	60,600,000,000
6—Tenders, all classes . . . . .	6.50	78,800,000,000
7—Locomotive railway coal . . . . .	0.39	4,700,000,000
8—Locomotive, non-driving weight . . . . .	2.55	31,000,000,000
Total non-revenue . . . . .	14.44	175,100,000,000
GRAND TOTAL (All classes) . . . . .	100	1,215,400,000,000

The New 3,000-Volt Direct-Current Gearless Passenger Locomotive of the Chicago, Milwaukee & St. Paul Ry.

For mountainous districts the electric locomotive has exceptional advantages, particularly the feature of generation braking by means of which power is returned to the trolley circuit on a down-grade instead of being used up as is the case in the steam locomotive.

The coal operators of Canada are much interested in the cheap production of power from coal, because the greater the value the consumer of coal can get out of his purchase, the larger will be his future purchases. In other words, the cheapening of coal, or its complete utilization, will increase the uses to which it can be put. Just now, the high price of coal is a deterrent to its use, and consumers are scanning every possible substitute. Unfortunately, all indications point to still higher costs for coal production, making it still more necessary to examine every new development that promises more efficient utilization of the power-value of coal.

On the Chicago, Milwaukee & St. Paul Railway, 42 electric locomotives have replaced 112 steam engines, and are hauling a greater tonnage with reserve capacity for still more.

From the results obtained on this road, Mr. Armstrong estimates that had the railroads of the United States been electrified in 1918 approximately 122,500,000 tons of coal, or more than two-thirds the coal now burned in 63,000 locomotives could have been saved.

## Northern Ontario Letter

### THE SILVER MINES.

During the month of April the quotations for silver averaged approximately \$1.20 an ounce. At the beginning of the month, it was quoted at \$1.26½, and at the close of the month was quoted at \$1.14½. During the month the lowest point reached was \$1.12 an ounce. The April average, therefore, was well above the price for the whole of 1919 when an average of \$1.11 1/8 was established, and compares with 96.77 cents in 1918 and a low average of 49.69 cents in 1915.

Metal authorities, as well as the silver producers of Cobalt in making a careful observation of the situation with the object in view of ascertaining the influences which have recently caused more or less violent fluctuations, seem still to have arrived at no uniform opinion. Among the advices received from abroad, and which would tend to throw some light on the situation, is the declaration that Great Britain is discouraging the mania for silver in India, and that the Chinese are less aggressive as bidders, not for the reason that they do not want the metal but due to the balance of trade operating against them. Also, that another large amount was not long ago released from the United States Treasury.

While influences such as the above may stem the tide of rising quotations, and, in fact, may cause violent fluctuations with a lowering tendency, yet those vitally concerned with the producing mines appear to cling unalterably to their opinion that the law of supply and demand must inevitably ultimately hold sway and that higher prices seem to lie in the future. As to this, time will contain the verdict.

The large surplus accumulated by the Nipissing Mining Company has been the subject of considerable comment and also criticism, according to the Toronto and London newspapers. The view is expressed that the shareholders are entitled to large dividend returns

under the circumstances, and that the company is needlessly holding government war bonds. The matter has been received with deep concern in Northern Ontario where the policy of the Nipissing Mining Company is held up as an example of what all real mining companies should be. It is pointed out that during the past three years which is the period in which the increase in surplus occurred, the shareholders have been paid 30 per cent annually in dividends, and that the increase in the surplus has been placed largely in war bonds (chiefly Canadian). In the North, the policy of the company is admired; and, while the company could no doubt market its war bonds without any serious effect on the market, yet if all companies adopted a similar policy the result might become serious, and, therefore, leads to the belief that such would be quite wrong in principle. Another factor is that the Nipissing Mining Company is regarded as a leader in its fair dealings with its shareholders. Not only does the company issue an annual statement that would do credit to any company, but a financial statement is presented every three months, as well as a monthly report of production and developments exactly as reported by the manager to the president and directors.

At the 1,400-ft. level of the Beaver-Consolidated the four-inch vein opened up some time ago and which contains some high grade ore, is expected to be the forerunner of interesting developments on that part of the property. Also, in that the vein passes onto the adjoining Prince claim which the Beaver now has under lease on the basis of an even division of the net profits, the prospects of finding additional veins and ore on the Prince are favorable.

The McKinley-Darragh has again pressed its oil flotation equipment into service, after leaving the plant closed since January when cold weather interfered with pumping operations. Production will accordingly be increased to the extent of the silver recovery from the re-treatment of from 175 to 200 tons of sand and slimes daily.

In view of the intimation that the La Rose will curtail to some extent its exploration policy, particularly in fields other than Cobalt tends to indicate that with work centered largely upon the companies four Cobalt properties the total cost of operation will this year be reduced considerably. While the cost of labor and expense as that incurred by the company last year on material may continue high, yet the elimination of such prospect work will reduce the overhead, and should cause a corresponding increase in net profits.

Figuring ore reserves at over 23,000 tons and containing 22 ounces to the ton or more than 500,000 ounces of silver insight, and calculating costs at \$8 a ton with silver at \$1.25 an ounce. Mr. A. J. Young, president of the newly incorporated Bailey Silver Mines estimates a daily net profit of \$768.75 from the operation of the old Bailey-Cobalt Mine. In addition to this, the Bailey Silver Mines owns the Northern Customs Concentrator on which the net profit from treating customs ore amounts to about \$250 daily. This makes a total of \$1,018.75 as indicated daily net profits, as against an authorized capital of \$1,250,000, divided into 1,250,000 shares of the par value of \$1 each. Following is an interesting extract from the report, and which shows the added possibilities of the future of the mine:—

“The engineers’ report show that ore actually developed amounts to 23,126 tons, with an average assay

value of 22 ounces of silver per ton, containing 510,294 ounces of silver. The report does not include any ore which may be stoped to a greater width than six feet, nor any values for the higher grade veins, several of which may be seen in the mine. It also does not include the ore on the dump, which amounts to several thousand tons, and which has considerable commercial value; neither does it include any probable ore which may be found by the development of the unprospected areas where there are a number of known veins."

Information has just been received that the interests now in control of the old Keeley mine in South Lorrain have acquired an option on the adjoining Beaver Lake property and have made the second payment on the option. The plan of operation on the Keeley includes the continuation of the shaft from its present depth of 230 feet to the contact which is estimated to lie at a depth of between 350 to 400 feet. At or near the contact the main veins will be explored, the largest of which passes from the Keeley onto the Beaver Lake property. Work is now proceeding at a satisfactory rate at the Keeley.

Senator Sharp, of Ottawa, paid a recent visit to the Leroy Lake section of the Gowganda district for the purpose of looking over the Silver Bullion and Dodds properties which were recently merged. Senator Sharp declared himself as being favorably impressed with the properties.

After having toured the United States with the purpose of gathering ideas in connection with ore testing laboratories with a view to erecting one in British Columbia, Charles Kamsell of the Geological Survey in B. C. and William Timm, head of the Ore Dressing Laboratory at Ottawa, paid a visit to the Haileybury Mining School. It is understood the modern plant in operation in the Haileybury School left a favorable impression.

During the week ended April 30th, six Cobalt companies shipped an aggregate of nine cars containing close to three quarters of a million pounds of ore, the output being the highest record for any previous month during the current year. The Mining Corporation with three cars containing close to a quarter of a million pounds was the heaviest shipper.

Following is a summary:—

Shipper	Cars	Pounds
Mining Corp. . . . .	3	240,277
McKinley-Darragh . . . .	2	189,188
Coniagas . . . . .	1	88,000
O'Brien . . . . .	1	77,673
Hudson Bay . . . . .	1	61,522
Peterson Lake . . . . .	1	60,000
Totals . . . . .	9	716,660

During the corresponding period the Mining Corporation was the only bullion shipper, sending out 50 bars containing 50,783.50 ounces. The Nipissing, the leading producer, continues to store its output.

**THE GOLD MINES.**

Opinion is divided on the question of placing a tax on gold used in the arts and in return paying a bonus to the gold mines. The plan being advocated in the United States whereby the arts would be taxed \$10 extra for each ounce of gold used, would presumably constitute a fund from which the producing mines could be paid a bounty on each ounce of gold produced. Some of the operators believe the scheme

should be carried out, while others fear that it might only serve to create offices for another small army of men and with an overhead expense that might leave no very material amount available for bonus payment to the mines.

It is announced that the annual meeting of the shareholders of the Porcupine V.N.T. Mines will be held in Toronto on May 27th, at which time the usual routine of business will be done, as well as a discussion and consideration of suggestions which the shareholders have to make with regard to the affairs of the company. In view of the improved conditions in regard to the supply of labor, and that the Porcupine V.N.T. is equipped with a mill with a capacity of 100 tons daily, and with a large tonnage of ore immediately available, it is thought that some decision may be reached with regards to resuming work.

At the Dome Mines the indications are that full capacity may be shortly attained, and in which case the net profits may be expected to increase. There is considerable speculation as to the probable contents of the coming annual report covering the twelve months ended March 31st. It is thought that the report will be divided into two periods, that prior to the date of re-opening the mill and that covering the productive period. In this way it will be possible to arrive at a more accurate idea of the performance to be expected during the current year. More men are becoming available, and this is stated to be making it possible to prosecute with increasing vigor the work of exploring the Dome Extension property at the lower level. The question of exercising the opinion held on the property before October, next, will depend upon the result of this exploration work.

Results at the Hollinger, McIntyre and Porcupine Crown continue comparatively uniform, with a tendency toward improved production, and with a fairly satisfactory increase in the supply of labor.

The annual report of the Sovereign Porcupine Mines Company shows an expenditure of \$16 872.43 during the year 1919 on exploration and development work. During the period approximately 4000 feet of diamond drilling was done. In doing surface work on the southern-part of the property "an excellent vein, heavily mineralized, was uncovered". This vein was stripped for about 45 feet in length.

In the Kirkland Lake field the arrival of spring has been marked by further increase in activity. At a meeting of the shareholders of the Hunton-Kirkland, held in Haileybury on April 29th, it was decided to commence operations at once on the property, a satisfactory deal having been arranged with United States interests. Machinery for a mining plant is already being placed on order. Details will appear in next week's issue of the Journal.

Since resuming work very recently, the Wright-Hargreaves Company has added about fifty men to its pay-roll. The underground workings have been dewatered and machines are now in operation. The construction of the mill is also to be carried forward as fast as the supply of labor will permit, and the mine is expected to join the list of important gold producers before the end of this summer.

At the Kirkland Lake mine of the Beaver Company, it has been decided to continue the main shaft from its present depth of 700 feet to a depth of 900 feet, work toward this end having already commenced. It is also stated that an excellent shoot of high grade ore has been opened up in a stope from the 300-foot level.

The plan of development includes the driving of a log development drift at the 500 foot level to the west boundary of the property.

On the Lake Shore, production continues normal at approximately \$1,500 daily and with mill heads ranging from \$23 to \$25 a ton. The mill is treating a little over 50 tons of ore daily.

The main shaft on the Ontario-Kirkland has reached the 450-ft. level and the work of cutting a station will be carried out. It is proposed to cross-cut both north and south so as to intersect and drift along the veins which were developed at the 300-ft. level so as to determine the extent of the downward continuation of the ore shoots. Plans have been made with R. C. Coffey to design and supervise the construction of a mill, but actual work will be held in abeyance pending the result of work at the 450-ft. level.

Boston Creek and Skead township interests have combined toward providing a road to Skead by way of Boston Creek, instead of following the present road from Englehart. The distance from Englehart is about 24 miles, while from Boston Creek it ranges from eight to twelve miles. The appeal for government assistance having failed, the prospectors and claimholders have joined together and already have cleared and fairly satisfactory trail, and have built a foot bridge over the Blanche River. It is stated that if the government will build a bridge suitable for vehicle traffic, the prospectors and mining men will provide a right of way for wagon traffic from the railway to the center of activity. The present band of amateur road-builders have been self-named the "Boston Creek and Skead Township Overalls' Brigade." At any rate, they have exhibited a degree of enthusiasm that bids fair to have some effect on the government.

One the Miller Independence Mines at Boston Creek, although the crosscut at the 500-ft. level has not yet reached the point where the downward continuation of the main ore body is expected to be encountered, yet a narrow vein has been found in which gold tellurides occur. This is pointed to as an excellent indication that the crosscut may intersect the main vein at a mineralized horizon.

In the Sesekinika Lake district, in the township of Maisonville, the Golden Summit Mining Company has completed the purchase of the Jensen Farm, the price paid being \$10,000 in cash and small block of stock. Two veins occur on the property, both of which are very narrow at surface, but one of which widens out to about two feet in width at a depth of eighteen feet. The formation is andesite, with intrusions of porphyry. A limited amount of surface exploration is being carried on, and a special car with visitors from Detroit will arrive on the ground about May 13th.

A meeting of the shareholders of the Thompson-Krist Mining Company will be held in Toronto on May 10th for the purpose of considering and if approved ratifying the deal which is to merge the company's property with that of the Porcupine Crown. A new company is being incorporated, to be known as the North-crown Mining Company, with an authorized capital of \$3,000,000, divided into 3,000,000 shares of par value of \$1 each. The Porcupine Crown will pay into the treasury \$20,000 and receive in return 1,999,997 shares; while the Thompson-Krist will pay \$10,000 into the treasury and receive 999,997 shares.

Contracts were left on April 30th for the sinking of a shaft on the Fidelity property in Teek township from

150 to 300 feet, and for 2,000 feet of lateral work at the 300-ft. level. The work is already underway. This company is also planning to let a contract for a large amount of drilling on its properties in Skead township on which large sulphide dykes occur.

## British Columbia Letter

Victoria, V. C.

Stewart, B. C.: The Benson Brothers, of Victoria, B. C. who staked in the Salmon River District, Portland Canal, before the war from which they have just returned, have sold a two-third interest in their properties to a Vancouver syndicate of business men for a substantial amount. There are two groups of claims involved, one known as the white Mouse being situated on the Canadian side of the line and the other group, which has been given no special collective designation, consisting of fifteen claims located on the American side. The Bensons assert that while no considerable development has been done they uncovered a lead containing native silver and that assays gave first class returns.

George Clothier, government mining engineer, discussing conditions in northern British Columbia recently made it clear that, although there is much excitement over mining prospects in this section and notwithstanding that this sentiment appears to be justified to a large extent, there are as yet only three proven mines of note. These were the Dolly Varden, at Alice Arm, the Engineer, in the Atlin District, and the Premier of Salmon Arm. But these were great properties. He continued: "The Engineer, at Carcross, is a proven gold mine and will operate this year if the will of the late Capt. Alexander, who was the owner, is executed. Shipments from this mine would be made by water to the White Pass Railroad where ore would be taken by rail to Skagway and thence south to the smelters. This Mine will have the same effect in making Atlin an active town as the Premier and the Dolly Varden have on Stewart and Alice Arm. In the Stewart and Alice Arm Districts there are many properties under development and many of them show great promise. Nothing more however, can be said of these until they are proven. A mining country cannot be made in a single year and we will know more about the country a year from now. Vancouver and Victoria are full of companies, many of which are formed over properties on which no development work has been done. Some such companies no doubt will fall through because of lack of funds to carry out development work. In every mining country there are a flock of these. It is hard for good companies to get properties on account of the prices asked for by prospectors. Big companies are always willing to put their money in the ground but they do not like to have to pay and spend it on the chance of proving up a good thing."

Stewart and Hyder, situated at the head of Portland Canal and the Canadian and American portals to the Salmon River mining district, are very busy little towns according to advices from the north. Miners, prospectors, speculators and many others whose business it is not easy to define are being taken into the camps in boat-loads, every north-bound vessel from

either Vancouver or Seattle being crowded. Real-estate values in both communities are said to have soared, having practically doubled in the course of the last six months. It is reported that the Provincial Government intends placing some of the lots of the Stewart townsite, which reverted to the Crown, on the market. Mining machinery is being taken in over the trail to both the Premier and properties of the Angelican (Belgian) Mines, as well as to some prospects on which development is underway, and the whole trend of travel, at least on the part of those who are entering the country for earnest work this season, is up the Salmon or the Bear Rivers. In Hyder there is a building boom. The tide flat area is being improved, foundations being laid over it for buildings which are in course of construction or which are planned. A sidewalk 1,900 feet long is being laid to connect up these structures.

With reference to development work on the Spider Group, under bond to the Algonquin Development Co., of Belgium, and which is situated on the Salmon River District, it is interesting to note that camp supplies, as well as mining machinery including a compressor, have been freighted over the snow. To accomplish this horses were fitted with snow-shoes of a special design which are reported to have served admirably.

There is much talk over the prospects of the Marmot River Section of the Bear River zone, Portland Canal. Mr. George Clothier, government mining engineer, reported on a number of prospects in this locality last year and on the whole his observations were favorable. It is said that there are a number of properties with showing of ore high in silver. This season there is no doubt that much prospecting will take place here as well as throughout the Bear River Valley, while development is planned on a number of claims. C. B. Bush and associates and the Sterling Mining Company are among those interested in the development of properties in this zone.

The Silver Group, Salmon River, consisting of three claims and situated about 21 miles from Hyder, has been bonded by R. H. Stewart, mining engineer of Vancouver, B. C., and associates in the sum, it is unofficially reported, of \$77,500 and \$5,000 has been advanced as an earnest of the intention of the bondees to proceed with development this year.

**Alice Arm, B. C.:** The Dolly Varden Mine will continue at least for the present under the ownership of the Taylor Mining Co., subsidiary to the Taylor Engineering Co. This property and its affairs occupied the limelight to a considerable extent during the closing days of the Provincial Legislature. R. T. Elliott, solicitor for the original holders of the property, the Dolly Varden Mines Co., telegraphed Premier Oliver accusing him of all evil doing in this connection. The opening paragraph of Mr. Elliott's first telegram, for there were two, is a good specimen. "The influence brought to bear" he said "upon the Oliver Government in attempts to secure further legislation affecting property rights in Dolly Varden mines constitute direct lobbying for fraudulent purposes, being wilful attempts to substitute forces of secret illicit lobbying for open public administration." The premier read this to the House, defended the course that the Legislature had taken with reference to the

property and introduced a Bill confirming the Taylor Engineering Company in its title to the mine, the mine plant, the railway, etc., in short of all the holdings embraced in the property commonly termed the Dolloy Varden Mine. This passed the legislature without division and now is a part of the British Columbia Statutes. This legislation is expected to strengthen the position of the Taylor Engineering Company with the question of ownership comes before the Court, where it is being taken by Mr. Elliott on behalf of the original Dolly Varden Company.

Development on the La Rose Claims, Alice Arm, is reported to have opened up a strong lead of high grade ore. That some mine machinery is to be installed to facilitate work, that a 450 foot crosscut is to be driven and that some diamond drilling is proposed is the effect of an announcement from the company's headquarters, Vancouver, B. C.

A two-drill compressor and power plant is to be installed on the North Star Property states P. Oleson, who is in charge of development work. The machinery is being obtained from San Francisco.

**Anyox, B. C.:** One of the diamond drilling outfits which has been in use by the Granby Consolidated Mining & Smelting Co., on Eestall River properties is to be sent into the Salmon River section for work to be undertaken this summer.

O. B. Smith, connected with the Granby Consolidated Mining & Smelting Co., for the past twenty-one years, has resigned. At the time of his retirement, which was forced because of ill-health, he was assistant to the managing director and head of the exploration department of the Company. Mr. Smith graduated from the Massachusetts Institute of Technology in 1897. From 1899 to 1904 he was engineer for the Granby properties at Phoenix, B.C. and from 1904 to 1908 he was superintendent at the same place, following which date he was general superintendent of mines for the company in all the districts in which it operated.

#### Douglas Channel, northern B. C. Coast.

The Drum Lummon Mine is reported by C. L. Copp, Superintendent, to be showing up satisfactorily on development. Mr. Copp, who is about to take north some special parts for the Mill, which is to be ready for an early start this season, states that the tunnel is in high grade milling ore and that a large tonnage has been taken out during the winter and is ready for treatment.

#### Barkerville, B. C.

Pickeringite, a hydrous sulphate of magnesium and aluminum, which has not been observed previously in British Columbia, has been found in the Cariboo Country. Samples have been brought out by W. H. Brock and analysed by Dr. V. Dolmage, of the Geological Survey. The mineral, which is of a creamy color, with a silky lustre, was found in considerable quantities but it is not thought that the deposit goes far beneath the surface. The mineral has been observed in Chili, Argentine, Colorado, and Nova Scotia.

**Sheep Creek, B. C.**

Harold Lakes, Superintendent of the Nugget Gold Mines Ltd., reports that the old Motherlode Mill is ready to commence the season's work as soon as a shipment of cyanide, now on order, arrives. Recently efforts at the mine have been concentrated on the laying of track, the construction of chutes, and otherwise preparing for production. Mr. Lakes reports that the drift on the main vein at a depth of 625 feet has developed the ore for a total distance of nearly 200 feet. Drifts driven both to east and west still are in ore, the vein widening and narrowing with the advance but, it is said, the values are maintained. At the recent annual meeting of the Company an encouraging report was submitted by R. H. Stewart, consulting engineer. Officers were elected as follows: President, A. C. Burdick; secretary, G. S. Bothwell; directors, Captain W. H. Logan, E. H. Beasley, R. S. Lennie, K. C., and Professor J. M. Turnbull.

**Nelson, B. C.**

A full crew of men is employed on the Texas-Yankee Girl Mine, near Ymir B. C., getting it in shape for production. The power plant is being repaired and soon will be ready for operation and it is the intention of the new owners to proceed with a systematic plan of development.

**Riondell, B. C.**

Water conditions in most sections of the Kootenays having improved many of the Mills, which were closed down for some weeks, either have resumed operations or are preparing to do so. The Blue Bell Mine at Riondel is one of those planning to again become an active producer. As soon as a crew of men can be obtained the development work underway will be continued and the Mill will be re-opened.

**Ainsworth, B. C.**

The property of the Florence Silver Mining Company, Princess Creek, is being re-opened. The Mill again is active after a period of some weeks idleness caused by lack of water.

The Utica Mines Ltd. will operate its property, Paddy's Peak, after the 1st of June. It will be recalled that A. J. Poyntz and associates obtained a lease of a portion of the workings where they developed some high grade ore. Their interest lapses on the date named.

**Greenwood, B. C.**

The Waterloo Property, Lightning Peak, is reported to be showing up well on development, a good sized body of high grade silver bearing ore having been struck on the second level. On the Kootenay property a tunnel is being driven which now is in 36 feet.

**Slocan, B. C.**

A serious tie-up of mining operations in the Slocan District, B. C., is threatened, officials of the One Big Union, which is said to be at least well enough organizer among the metalliferous mine workers of the section to be able to cause trouble, having given the Mine Operators notice that on and after the 1st of May the miners must have a substantial increase of wages. The present scale is \$5.50 for miners and \$5 for muckers with 50 cents extra in each case of wet

mines. The demand, generally speaking, is for an extra \$1 a day and, it is asserted, the men also want the employers to supply them with blankets and white sheets.

As the Mine Operators are understood to have refused to consider acquiescence it is likely that the O. B. U. will be permitted to carry out the threat behind the ultimatum. The issue, however, still is in doubt as arrangements are being made for a meeting of the representatives of both sides to take place on the 30th of April.

If there is a strike quite a number of active silver-lead producers would be closed down. Among the properties of the Slocan Mining Division that have shipped 1,000 tons of ore or more this year, and whose operations would be interfered with, are the Bosun, Galena, Rambler-Cariboo, Silversmith, Standard, and six of the Clarence Cunningham mines, viz., Ivanhoe, Sovereign, Hewitt, Queen Bess, Van Roi, and Wonderful. From this Division, and from the Slocan City Division, there have been shipped this year upwards of 140,000 tons of good grade ore and there are employed below ground 417 men and above 206 men.

As is it likely that the Ainsworth Mining Division, which is adjacent and no doubt is included in the scope of the O. B. U. demands, it is interesting to note that the Florence and the Cork-Province Mines would be affected and that throughout that section, according to late returns, there are employed 127 men below ground and 95 men above.

**Trail, B. C.**

Receipts at the Trail Smelter of the Consolidated Mining and Smelting Co. for the week ending April 14th totalled 4,408 tons, of which 48 tons were concentrates. This brings the aggregate for the year up to 82,232 tons, of which 78,874 tons was ore and 3,358 tons concentrates. There are two new shippers, namely, the Last Chance, of Sandon, and the old St. Eugene, of Moyie.

On the 15th of April 1920 the Consolidated Mining and Smelting Co. of Canada, operating the Trail Smelting and Refining Plant as well as a number of large and small producing mines in British Columbia, took out a blanket insurance policy covering the lives of its employees and protecting their families or dependents against their permanent disability. Roughly the Company employs 2,000 men. The amount of insurance is based on length of service. One who has been employed for five years and six months and over has a policy in his favor of \$1,500 while one working for six months and less than one year has been insured for \$500. Those ranking between the maximum and the minimum have policies the amount of which are based on a graduated scale which, of course, mounts as length of service increases.

In announcing this innovation the Company, among other statements, makes the following: "On leaving the service of the company the insurance ceases"; "In the event of re-employment a man is classed as a new employee". In the case of permanent or total disability before the age of sixty years the amount of the insurance will be paid in one sum or over a period of years; "There is no cost to you and no medical examination is required; "It does not in any manner take the place of or interfere with the benefits provided by the Workmen's Compensation Act or any other insurance the employee may have; and "This

# A MARSH HOIST

## IS MADE THE RIGHT SIZE FOR YOUR MINE

and in either Steam Power or Electric Power

This shows one of our Electric Mine Hoists. We make many other types. Send for our catalogue of Mine Hoists, Cars, Cages, Buckets, etc., and see what we offer you. It will repay you.

From the little 10 Horse Power size for prospectors or small mines to the massive 50 Horse Power size, one of our 7 sizes should be just right for your mine.

We are specialists in the building of Hoisting Machinery of all sorts. For nearly a quarter of a century we have been designing and building Hoists, and have developed a Hoist that we are really proud of—proud because of the record of good work they have done, and are doing in mines, quarries, and other classes of work from one end of Canada to the other.

action is voluntary on the part of the Company and constitutes no contract with any employee and confers no legal rights on him."

### Greenwood, B. C.

The Silver Cloud and Skylark properties in the Greenwood Mining Division are being developed with promise of good results. On the former a mine foot lead is receiving attention the ore giving good results in gold and silver. The operators are considering the installation of a small concentrator. Some years ago the Skylark was a considerable producer and it is claimed that the old lead has been discovered.

### Comox, B. C.

The Providential Mining Co. is reported to be developing a copper property in the Buttles Lake District, Vancouver Island, having been working all winter and now being engaged in taking in a diamond drill and other machinery to continue development on a more comprehensive scale. It is said that about \$10,000 already has been invested.

### Victoria, B. C.

Among the mining companies to be incorporated in British Columbia recently are the Northwest Silver Mining and Development Co. Ltd., with a capitalization of \$1,000,000 with headquarters at Vancouver B. C. and the McLennan Silver Mines Ltd., with a capitalization of \$1,500,000, headquarters Vancouver B. C.

## Nova Scotia Notes

### The Mabou Areas

The Montreal "Star" seems to attach much importance to the Mabou areas, which a recent dispatch described "as the last large independent mining area in Cape Breton." This dispatch says the mine "has not been worked for several years since American interests were forced to let go their holdings through a Wall Street Panic." The Mabou Colliery was flooded by an inbreak from the sea in 1909, and it has usually been presumed that this was the reason for its abandonment. Residents in Inverness County will be best able to appreciate the accuracy of the "Star's" frequent news items regarding Mabou, and will also be able to form conclusions as to the disinterestedness of an announcement which intimates that Scotia and Dominion Steel are dickering for the Mabou area with a view to bettering their positions in prospect of the expected amalgamation of interests. The Mabou area is actually one of quite limited extent, and in its operation some difficult questions of extraction and transportation will have to be faced, and its acquisition would not materially strengthen either Dominion or Scotia, both of which companies possess areas much more adapted to their requirements.

**MACHINERY FOR SALE.**

One 50 H.P. Wood Burning Boiler, 14 feet long, 4 feet in diameter, with fifty, three inch flues.  
 One Canadian Ingersoll-Rand Compressor, size 12 inches by 18 inches, speed 140 revolutions per minute, air capacity, 320 cubic feet per minute.

# The Mining Society of Nova Scotia.

# Twenty- Eighth Annual Meeting

Glance Bay  
May 4 and 5  
1920

**A Well Attended, Worth-While Meeting, with Conservation as its Key Note.**

THE 28th Annual General Meeting of the Mining Society of Nova Scotia was, for the first time, held in Glance Bay, the centre of a mining district that has during its productive life added more wealth to Canada than any other mining district in the Dominion. In actual monetary value, according to current market prices, the Sydney coalfield has yielded a greater revenue, over a longer period of time, than any other mining operation in Canada, but the intrinsic value of the coal produced, regarded as a source of national energy, so far exceeds that of all other products of the mine as to make it proper and fitting that the Mining Society of Nova Scotia should meet in what its citizens are pleased to call "The Biggest Town," but unfortunately only known throughout the rest of Canada in inverse ratio to its real importance.

Not only has Glance Bay and its environs produced the major portion of the coal production of Canada, up to this date, but, until Alberta comes into its own as the greatest storehouse of Canadian coal, Glance Bay will continue to be the centre of the most important coal mining industry of our country. As the central point of access to the undersea coal areas, Glance Bay can never be lessened in importance until that day, far distant, and recessive in the ratio that human knowledge grows, when the extraction of the undersea coal will have grown too expensive to be profitable.

In the transactions of mining societies the name of Glance Bay will frequently recur in years that are to come, as the fascinating problem of profitably mining undersea coal seams develops new inventions, and as necessity compels novel methods of which the mining fraternity will be eager to learn. Some premonition of this enkindled the Glance Bay meeting, and the

dominant note in the papers and in the discussions was not that of things actually accomplished—although this note was not lacking—but dwelt upon things yet to come. There was a definite feeling that the coal mining practice of Nova Scotia was entering a new stage, that new difficulties would compel the adoption of new methods.

The keynote of the meeting was "Conservation," and, as will be seen from the papers that were read, in part reproduced in this issue, economies were suggested in regard to the supporting pillars in coal extraction, in connection with mine timber, waste heat and power economy, and in regard to labour turnover.

Thanks to the courtesy of the Dominion Coal Company, the new club-rooms of the company, recently provided for the staff, were put at the disposal of the Mining Society, thereby, in large part, making possible the unqualified success of the meeting.

About seventy members took part in the meeting, the interest of which was sustained from the opening. The President, Col. Thos. Cantley, who has had much experience of society meetings, remarked that he did not remember to have seen a larger attendance at the opening session.

The excellence of the attendance was matched by the quality of the papers, and the keenness of the discussions was a natural result of a gathering of men daily occupied and immersed in the problems dealt with by the papers. One eminent member of the profession deplored the sustained excellence of the papers as depriving him of all excuse for criticism.

Visitors from outside the immediate district of Glance Bay and the Sydneys included Mr. Hiram Donkin, the Deputy Commissioner of Mines, and Messrs. H. M. Wylde and H. C. Wright from Halifax, a re-

presentative deputation from Pictou County and Cumberland, and Mr. H. Y. Russel and the Editor from the Montreal Branch of the Institute.

The new President of the Mining Society is Mr. A. J. Tonge, the General Superintendent of the Dominion Coal Company at Glace Bay. Mr. Tonge was President of the Manchester Geological Society in 1910, succeeding Sir W. E. Garforth, and is a Councillor of the Canadian Mining Institute.\* He is a mining engineer of large experience and of acknowledged eminence in his profession. The retiring President, Col. Thos. Cantley, is sufficiently well known throughout Canada to make recapitulation of his offices unnecessary. As President of the Mining Society of Nova Scotia he succeeded Mr. D. H. McDougall, the immediate past-President of the Institute. This is a presidential record of which the Mining Society of Nova Scotia may be justly proud. The Canadian Mining Institute was much strengthened when the older society decided to join forces, and, we think, it may be fairly stated from observation of the recent meeting, that added prestige and virility has resulted to the Mining Society of Nova Scotia from the union.

As a member, and as the Editor of the Mining Society, the writer is diffident in praising in these columns the doing of the "mother lodge," but in fairness to this eastern representative of the Canadian Mining Institute, it is necessary to say that at no metropolitan gathering at headquarters has the general excellence of papers and discussion been surpassed, and that a larger representation from headquarters would not only have been welcomed, but would have received good value as compensation for the long journey.—F. W. G.

#### PROCEEDINGS OF THE MEETING.

Business was opened at 10 a.m. May 4th, in the Club Rooms of the Dominion Coal Company at Glace Bay. The President, Col. Thos. Cantley, was in the Chair. After an address of welcome by the Mayor of Glace Bay, Mr. E. McKay Forbes, the members present, numbering about fifty, proceeded with routine business. The Secretary-Treasurer reported a balance on hand of \$1,265.

Mr. Hiram Donkin, the Deputy Commissioner of Mines, expressed the regret of the Hon. E. H. Armstrong, Minister of Mines, that he could not attend the meeting owing to his duties at Halifax, the Houses of Assembly being in session.

The Report of the Council, among other matters, referred to a Resolution which had been forwarded to Ottawa deploring the numerous resignations from the Geological Survey. (See issue of 16th April, 1920, page 305, and March 5th, page 184.) The President briefly emphasised the gravity of the situation, and said he was unable to say whether remedial action was proposed by the Government or not.

\* See Journal, Nov. 26, 1919.

#### Change of Date of Meeting.

A resolution, of which notice of motion had been given, was unanimously adopted to change the date of the meeting to "a date chosen by the Council between the 1st of January and the 1st of July."

#### Change of Name of Society.

Notice of motion had been given to change the name of the Society to the "Nova Scotia Mining & Metallurgical Society." This proposal did not meet with unanimous favor, and after discussion, it was moved that the recommendation of the Council to change the name of the Society be adopted, and that a letter ballot should be prepared by the Council, and submitted to the vote of the members, and that upon this vote action should be taken by the next Annual General Meeting.

#### Presidential Address.

Col. Cantley gave the Presidential Address on "The Importance of Cheap Power to the Industrial Life of Nova Scotia. A vote of thanks was moved by Mr. C. M. Odell and seconded by Mr. Hiram Donkin, who said it was reassuring to those who had given thought to power problems to note that men who filled important positions on the Canadian National Railways Board, as did Col. Cantley, were abreast of the latest developments in sources of motive power.

In replying, Col. Cantley said there was no doubt but that the Diesel engine was the most economical prime mover of today, but the drawback was that not sufficient oil is being produced to supply current demand, and that in comparatively few years it was unlikely that oil would be available in anything like the quantity in which it is being produced today.

#### The Application of Hydraulic Stowing to Undersea Coal Workings with Special Reference to the Sydney Coal Fields.

Mr. Walter Herd, the Mining Engineer of the Dominion Coal Company, read a paper on the possible application of hydraulic stowing to the undersea conditions of the Sydney Field.\*

A vote of thanks to Mr. Herd was moved by F. W. Gray and seconded by Mr. T. J. Brown, both congratulating the author. Mr. Brown said that the paper had been written with especial reference to the application of hydraulic stowing to undersea areas, and had not laid much stress on its usefulness in the extraction of pillars on land, particularly under towns.

Mr. Alexander McEachern (Asst. Supt. Dominion Coal Company) said that Mr. Herd's paper was an intimation that new methods were becoming necessary to meet new conditions.

Mr. J. J. McDougall (Mining Engineer, Acadia Coal Co.) suggested the application of the system to the conditions of Pictou County.

Mr. Hiram Donkin said that the subject of hydraulic stowing was one to which he had not given the detailed thought that was necessary to enable comment, but he thought the deciding factor in its use would be that of cost, as there was no physical impossibility involved in its application. He suggested that the un-

\* See also issue of Jan. 23rd, 1920, page 56, "Primary Considerations in Hydraulic Stowing," by C. A. J. Hendry.

dersea mining problem would be largely one of transportation, and that perhaps not enough attention had been paid to the civil engineering side of mining. He humorously applied the story of a Chinaman upon first seeing a trolley-car, who, after some study, expressed himself by saying: "No pushee, no pullee, go like hellee allee samee!" He congratulated Colonel Cantley upon the successful solving of the transportation problem in the Wabana Slopes, where great speed had been obtained by spending thought on the special nature of the haulage required to meet the special conditions. In this connection, readers of the "Journal" are referred to the article on the Wabana Slopes, in our issue of March 26th last (see page 241), in which Mr. R. E. Chambers remarked that this type of haulage was significant "inasmuch as it points to a solution of the haulage problems arising from the moving of submarine deposits of coal at increasing distances as the working faces recede from the shore."

Mr. Tonge, in congratulating the author, said the paper would be one that all could look back upon when the day came, as he believed it would, when the practical problems of hydraulic stowing would be a matter of everyday routine in the Sydney field. He mentioned that he was looking into the practice of water flushing as practised in Belgium when the war broke out, and that conditions had since prevented further consideration of such matters. Mr. Tonge referred to the practice in the Seranton field, and to the excellent Bulletin on this which was published by the U.S. Bureau of Mines. Mr. Herd has prepared his paper with special reference to coal lying between the 200 and the 800 foot cover line. There are no other

means by which the coal can be all extracted in this area except by some such system as water flushing with solid materials. Speaking generally, about 50 per cent of the coal had been taken out, which means that if some such method of supporting the roof so as to enable the pillars to be extracted is not adopted, fifty per cent of the coal will be entirely lost. The application of the method to pillar areas under towns promised well. Mr. Tonge referred to the troubled conditions occasioned by the war which had prevented mining engineers from developing the scientific side of mining practice as they would have liked.

Mr. Neil Nicholson (Inspector of Mines) expressed his belief in a panel system of retreating longwall combined with hydraulic stowing.

In presenting the vote of thanks, the Chairman referred to the use of crushed slag in hydraulic stowing in the Ruhr District of Westfalia. He also suggested that the problem of getting workmen to face, more particularly in the iron-ore mines at Wabana, would in time become so great that consideration might be paid to providing temporary underground residences for workmen.

Mr. Herd replied at length to the questions raised in the discussion. With regard to the super-imposed undersea seams down to 800 ft. of cover he would advise stowing one seam solid, and then it would be a question for deliberation as to what percentage of the other seams should be stowed. It might not be necessary to stow the whole area; perhaps half-stowing of the goaf might suffice, which would represent the percentage of pillar support now left.

MR. ALFRED J. TONGE,  
President, Mining Society of Nova Scotia

In the matter of cost the additional cost of hydraulic stowing over and above the present practice was not so important—relatively—as it had been in the past.

In reply to a remark by the President that the Germans, in using hydraulic stowing, had developed an idea which they did not originate, a characteristic national trait, Mr. Herd said that the system of hydraulic flushing pursued at Scranton had been originally conceived by an English engineer, who could not get his own countrymen to consider his plans, and had been listened to in the United States, but that it was really in Germany that the system had been perfected.

Mr. Herd's paper will be published in a following issue of the "Journal."

As the whole of the afternoon had been taken up, other papers purposed to be read on the first day were deferred until the following morning.

MR. WALTER HERD,  
Dominion Coal Company, who read a Paper on  
"Hydraulic Stowing."

### THE SMOKER

During the evening a smoker took place, which was—well, it was a "Smoker," and fully up to the Penhale standard, with—oh yes, just a dash of Holland.

### SESSION OF WEDNESDAY, MAY 5th.

Mr. E. G. Mackay, Superintendent of the Open Hearth and Blast Furnace Departments of the Nova Scotia Steel and Coal Company, read a paper on "Generating Steam by Use of Open-Hearth Furnace Waste Gas." The paper was a description of a waste-heat boiler attached to one of the open-hearth furnaces at Sydney Mines, and, as was pointed out by the President, showed a saving of 91 cents per ton on steel manufacture by the interception of the heat of the waste gases. On the production of pig-iron in Cape Breton, such provision, if applied to the existing open-hearths, would amount to a possible saving of \$400,000 per annum.

Mr. H. C. Wright (Canadian General Electric Co.) pointed out that Cape Breton was much interested in saving of waste coal-heat, because the Island had no water powers, and coal was the only source of power. The Province of Nova Scotia was definitely committed to a policy of developing its hydro-electric powers.

Mr. J. S. Whyte (Acadia Coal Company) said many possibilities were yet untouched in the salvage of waste heat, which Mr. Mackay's paper barely opened up.

Mr. Tonge recommended the extended use of recording apparatus in steam plants. Mr. Mackay, replying to questions, said the boiler he described gave between 50 to 75 per cent efficiency, and he emphasised that it was merely an interceptor of waste heat, and did not use gas as fuel, the gases utilised being exhausted and non-combustible waste products of the open-hearth furnace.

### "Conservation, and Drawing Mine Timbers."

Mr. P. T. Prendergast, Manager of Dominion No. 2 Colliery, read a paper, published in this issue, with the foregoing title.

Mr. Herd, who was an officer in the Canadian Forestry Corps during the war, referred to the great destruction of growing timber in the woods, and the tremendous depletion of the forests by pulp mills. As to quality, pine was best, followed by spruce, and the much inferior balsam fir. Nothing was growing today in Cape Breton suitable for pit timber, but second-growth balsam fir. It had not the lasting qualities of spruce, and as Mr. Prendergast rightly pointed out, it should be treated for preservation. He referred to the necessity of barking timber used for mine support. Elaborate treatment, such as creosoting was not advisable for such poor timber. Boiling in a saturated solution of common salt with the admixture of a little alum was a simple and successful practice. He suggested sorting timber into separate piles, so that the timber best suited for certain underground purposes could be readily selected. Props are sometimes tapered so that they will not break readily in the middle, and used timbers can thus be made of further service by cutting into shorter lengths for thinner seams.

Mr. D. H. MacLean (Manager, Princess Colliery, N. S. S. & Coal Co.) said in the deeper mines the weight played havoc with the timber, and it lasted so short a while that treating would be wasted expenditure. Mr. MacLean's description of the effect of roof-weight in deep mining suggests that possibly utilisation of the roof-pressure to break down the coal by use of the longwall method would be preferable to endeavoring to hold up the roof at great depths of cover.

### Pit-Timber Supply of Eastern Canada has Life of Ten Years.

Mr. J. W. Revere (Purchasing Agent of the Dominion Coal Company), whose knowledge of the pit-timber situation in Nova Scotia is more complete than that of any other person, expressed himself as satisfied that the present growth of timber in Nova Scotia was not making up for what was being used, and that in ten years the pit timber supply of Eastern Canada would be exhausted. The pulp mills in Cape Breton were offering \$12.00 a cord for pulpwood.

Mr. J. J. McDougall commended the practice recommended by Mr. Prendergast of chucking the high side and thus shortening the length of the timber required, which was the practice in Pictou County. In regard to preserving timber, creosoting could not be used in the Pictou collieries because it had been found that the odor of the creosote underground was indistinguishable from the "fire-stink" which the miners relied upon to give warning of underground fires.

Mr. Neil Nicholson pointed out that the system of mining largely decided the amount of timber that was required, and he advocated retreating longwall wherever possible to obviate the use of timber for support.

Some discussion took place on barking timber. It was stated the use of the "barker" of the pulp-mill men would not suit for pit-timber as it also took off about twenty per cent of the wood. Mr. Herd mentioned that in South Wales men would not accept barked timber. They liked wet timber, timber that would "talk" when the weight came on, and give warning to the miner. Timber in South Wales was sold by weight, the wetter it was the better in the miner's opinion. He referred also to the effect of heavy roof pressure in South Welsh collieries, where in the course of two years, in one instance, the intake road, originally driven in the coal on the same level as the return, was raised to a level thirteen feet above the return.

Mr. Revere said a machine existed by which timbers were rotated in a cylinder with an admixture of water and gravel, which removed the bark satisfactorily.

The President, in presenting the vote of thanks to Mr. Prendergast, said that timber was becoming so scarce that the use of reinforced concrete in large quantities for underground support was likely in the near future.

In the unavoidable absence of Mr. W. H. Graham (Superintendent of Construction, Dominion Iron & Steel Co.) a paper on the Plate Mill of the Dominion Iron & Steel Company, bearing particularly on the construction work, and prepared for the Toronto Meeting of the C. M. Institute was taken as read.

### The "Turn-Over of Labor."

Mr. Angus W. MacDonald (Employment Agent, and Welfare Superintendent, Dominion Steel Corporation) read a paper on "Labor Turnover in Industrial Plants and what can be done to minimize it." Mr. George D. Macdougall (General Superintendent, N. S. S. & Coal Co.), in moving a vote of thanks, said that the available supply of labor did not promise improvement, and that time and thought devoted to conservation of labor would be well repaid. Mr. F. W. Gray seconded, remarking that labor—reduced to its lowest denominator—was a marketable commodity, but was

also the commodity of greatest value dealt in by corporate organizations. It was therefore worthy of at least as much study as the duties of the purchasing agent who dealt only in materials. Prof. Sexton warned against the regarding of the laborer as a commodity, and he deplored the system which had developed the motion-study and stop-watch man, and had speeded-up production without proper regard to the physical and mental needs of the worker. Mr. Tonge said the author had touched upon the question of safety, and that conservation of life was not to be regarded as the least of the subjects drawn to the attention of the meeting.

The President said he would place the cost of educating new men at a figure greater than Mr. MacDonald had mentioned. He would put it at \$150 per man. With regard to the effect on safety, accidents

MR. HIRAM DONKIN,  
Deputy Commissioner of Mines, who urged greater attention to the "Civil Engineering" side of Coal Mining

occurred at two distinct periods, namely, the first week of employment, when men were becoming accustomed to their surroundings, and later, when familiarity had bred contempt. In the middle period there was comparative immunity. The first stage of employment was, however, the one that yielded most accidents.

### Longwall Mining and Conservation.

Mr. J. H. Cunningham (recently Superintendent of Mines, N. S. S. & Coal Co.) read a paper on the theory and practice of longwall mining which was one of the clearest expositions of a difficult subject for description we remember to have heard. Mr. Cunningham's paper will be published in a following issue of the "Journal."

Mr. Herd congratulated the writer upon his interesting and able account of longwall mining. He referred to the mining of the Torbane Hill mineral, (sometimes known as "Torbanite") in Scotland, which was originally two feet thick and was extracted by the longwall method, and thinning out, had been followed down to a thickness of four inches, this being possible because of the valuable character of the mineral. There was really no limit to the thickness of the seam that could be worked longwall, as it is common practice to work thick coal by longwall faces in layers. He did not think there was any necessity to blast coal after it had fallen from a longwall face. It could be broken up with wedges, unless the area was too confined.

Mr. Angus MacKay (Acadia Coal Company) said longwall mining had been practised in Pictou County. The height of seam was 3 ft. 11 ins. It was difficult to break coal with wedges under conditions existing in this mine, because the height was too small to allow proper use of hammer and wedge, and the coal came down in pieces weighing three to four tons. Mr. Neil Nicholson said the smaller amount of travel involved in the examination of a longwall mine as compared with pillar and room was a consideration. The longwall face at the Jubilee Mine Sydney Mines, was a successful operation.

Mr. Tonge said that the longwall system had been in successful and extensive use at the Emery Mine of the Dominion Coal Company, but had been abandoned in favor of pillar and room because of the loss of longwall miners, chiefly Belgians, during the war. He thought longwall had not been successful because it had been tackled in a half-hearted fashion, or in a partial manner. Sufficient space had not been allowed for full play of the bending action of the roof, and too many pillars had been left. He had himself worked longwall faces a mile long and in all heights from 1 ft. 6 ins. to 7 feet thick, and had never thought of working coal any other way. Once longwall had been decided upon, it did not matter whether it was used under sea or under land. Mr. Tonge said he did not know when he had heard a clearer description of longwall practice than had been given by Mr. Cunningham.

One speaker mentioned what is probably the true explanation of the non-success of longwall mining namely, that the local miners do not favor it.

Mr. F. W. Gray mentioned that there was in the Joggins Field, at the collieries of the Maritime Coal & Iron & Railway Company, a unique longwall operation, inasmuch as a thin seam was being completely extracted from under the sea by the longwall method. In view of the number of thin seams which exist in the Sydney field, and proceed under the sea, none of which have as yet been touched, the Joggins Mines operation was of some significance. He suggested that if it were possible to obtain a description for the next meeting of the Society, this should be done.

### Fighting Mine Fires in Pictou Field.

A paper was read by Mr. Angus MacKay—in the absence of the author, Mr. F. E. Notebaert, Acting General Manager of the Acadia Coal Company—on "The Theory and Practice of Fighting Mine Fires from Practical Experience gained in Pictou County." Mr. Notebaert's valuable and historical paper is published in this issue of the "Journal."

Mr. F. W. Gray stated that he was glad to note Mr. Notebaert stated his belief in the existence of the McCulloch fault, and his opinion "that the Westville seams are only the regular continuation of the series of Stellarton seams, thus adding an enormous tonnage of coal to that already known to exist in the Stellarton district." He had himself come to the conclusion four or five years ago, after studying maps loaned by Mr. Notebaert, that the "existence and size of the McCulloch fault seems to have been presumed from surface indications and from a belief that the "Main" or Ford seam of the Albion area was identical with the "Main" or Acadia seam of the Westville area, worked at the Drummond and Acadia Collieries." No proof of the identity of the two seams had however been furnished.

HON. E. H. ARMSTRONG,  
Commissioner of P. W. and Mines, Nova Scotia.

The reading of Mr. Notebaert's paper concluded the morning session, and there was not time to hear Mr. H. Y. Russel's talk on the manufacture of explosives, or to deal with the papers on "Transportation of Coal" by Mr. M. A. McInnis, and that on "Canada's Coal Supply" by Mr. F. W. Gray, read at the Toronto Meeting of the Institute, and placed on the programme of the Glace Bay Meeting for discussion.

At noon-hour the Society was the guest of the Dominion Coal Company at luncheon.

In the afternoon, a meeting was held in the Savoy Theatre, to which the public were invited, at which there was displayed a series of moving pictures, lent by the U. S. Bureau of Mines, showing the manufacturer of coke and by-products, and modern colliery power

plants. Prof. F. H. Sexton spoke on "Vocational re-training of Workers in Industry" and illustrated his remarks with lantern slides. Prof. Sexton's enthusiasm and successful work in this connection are well known and much appreciated. Mr. W. S. Wilson, of the Economy Engineer's Department of the Dominion Steel Corporation, read a paper on "Conservation in Colliery Power Plants."

The newly elected officers of the Society were announced these being as follows:—President, Mr. A. J. Tonge; Vice-President, Mr. Geo. D. MacDougall; 2nd Vice-President, Mr. C. M. Odell; Secretary-Treasurer, Mr. E. C. Hanrahan.

The new President was suitably installed by the retiring President, and this closed the proceedings.

PROF. F. H. SEXTON, who spoke on "Vocational Re-Training of Workers in Industry."

MR. F. E. LUCAS, Economy Engineer, Dominion Steel Corporation, whose work on the Committee was largely responsible for the successful meeting.

## The Conservation and Drawing of Mine Timber

A paper read before the Mining Society of Nova Scotia, Glace Bay, April 5th 1920.

By P. T. PRENDERGAST.

When asked to read at this meeting a paper on the conservation and drawing of mine timber, it was with a full realization of the fact that this subject had already been discussed before you on different occasions, that I reluctantly consented.

This matter has heretofore been discussed from the theoretical point of view; and while, no doubt, much valuable knowledge is obtained from a discussion of this nature, it is proposed in a few remarks to deal with the subject from the view point of practical experience; by which is intended my own personal experience, as acquired during years of connection with mines and mining in Cape Breton.

Conservation of raw materials has so taken hold of the public mind, and is regarded of such vital importance by those of us who realize our responsibility

to those who are to come after us, that it behooves all to use every available means to prevent wastage of timber in and around the mines. In recent years the item of mine timber has entered so largely into the cost of coal production, that any measures which we can take towards the economical use of our available timber supply will prove a great investment in the years to come.

When the Dominion Coal Company was organized in the year 1893, the cost of the regulation 9 ft. prop was from 54 to 50 cents per dozen laid down at the pit mouth, and the specifications followed at that time required that they were all to be of black spruce and six inches in diameter at the small end. This was in the days when the mines were working under comparatively shallow covers. Today the only avail-

able supply of timber is of balsam fir, with a small proportion of spruce, and the cost has reached four and a half times as much.

Mining under greater depths with an interior wood to support the roof means that more timber will be required, and the manner of use of our present supply will have to be dealt with more energetically in the future. The drawing of mine timber and the use of preservatives are two ways of assisting towards this end.

We are each successive year going deeper and deeper into the earth in order to obtain the coal to keep our industrial plants in operation, and furnish our homes with warmth. This means that each successive year much greater weight of strata has to be contended with. It will be found where mining operations are carried on at any great depth, that even an increase

MR. GEO. D. MACDOUGALL,  
Vice-President of the Mining Society of Nova Scotia.

in the size of pillars will not prevent the breakage of timber.

Where great weight of strata has to be reckoned with and where lateral pressures are troublesome, we find that on our roadways the roof is forced down on the timber causing them to lag and finally break. To overcome this breakage is one way of assisting in the great cause of conservation, as all broken timber must be replaced by new ones, and the writer submits that a great deal of over-head timber destroyed in this way might be saved by shortening the span between the supports. It may not be good policy to

recommend the placing of props too close to the haulage roads, but the shortening of the span of overhead booms could be done in a great many cases with increased safety to employees, and at a saving in expensive timber, if certain methods are adopted, with the idea of conserving timber supply.

Take the case of landings and turnouts where long booms are required, and where, on account of the length of the span and the area to be supported, extra heavy timbers are required, it will be found that even these timber very often break, and it becomes necessary to replace them. Also, the thin end of the pillar here is continually breaking away, necessitating more timber and labor, adding greatly to the cost of production. This, you will all agree, is an unpardonable wastage, as it not only means an unnecessary use of new timber, but also very often results in a decreased output of coal, both of which could have been avoided had the work been properly done in the first instance.

The building of neat packs in the "V" of the road, on which would rest one end of the overhead timber, thus shortening the span, would result in a great saving of timber. This would not only be a safer method, which is in itself sufficient to justify its use, but would result in a great saving in cost, as much shorter and cheaper timber could be used. It would also serve the purpose of preserving the ends of the pillars which are continually splitting off. These packs could be built of broken and discarded timber of which every mine has a fairly good supply. The only cost would be that of labor.

Not only would such packs tend to conserve our timber supply, by lessening the amount of broken timber and protecting the weak end of pillars, but it would be a satisfaction to the mine official to have this work done properly along roadways and landings. To have long booms carrying a heavy load is by no means a nerve-soothing condition.

I might give here a few figures showing the cost and quantity of timber used today as compared with, say eight years ago, in some of the coal mines. In one mine there were 64,000 more pit props used in the year 1919 than were used in 1911, and the cost of props increased in that period 100 per cent. In 1911 there were four tons produced per prop, and in 1919 only 2.4 tons. This difference may be attributed partly to different conditions, but principally to the deeper workings, and the maintaining of longer roadways and airways. The replacing of broken props along roadways is a heavy drain on our timber supply.

In the deeper local mines, where the edges of pillars can not be depended upon as a safe support for booms, and where all booms must be supported by props or packs, such props are very often subjected to more stress by the heaving of the bottom than by the weight of the roof. Props are thus forced up until they cut through the overhead roof, thus weakening the roof support, and new timber must be put in. This heaving of the bottom is generally from one of two causes, (a) Where pillars are not left sufficiently large, (b) Where the strata below the coal is of a weak and broken nature. The first of these causes suggests its own remedy, while the second presents a problem which is somewhat more difficult to grapple with.

Since heaving of the bottom results in a great wastage of timber through breaking, one might suggest that the most easily applied remedy to overcome

this wastage would be to use a better quality of timber. With this statement no doubt you will all agree provided it did not materially increase the cost of coal per ton. However, looking at this question from the view point of conservation of valuable timber resources, and bearing in mind the fact that future mining developments must be carried on at a much greater depth than that of the present day, it might be the proper thing to conserve for future generations the more valuable woods, while the cheaper and faster growing woods might be drawn on in quantities to meet present requirements.

While still dealing with the question of conservation of mine timber, there is another phase of it which is worthy of attention. At present the wood that is to be used as timber in our mines is cut and handled in large quantities during the winter months, and while the hauling is good, it is hustled out of the woods and piled along the railway and highway. Some of this will not be used in the mines for a year and in many cases for a much longer time. During all this time it is laying in close piles and deteriorating from disease and decay, and when it is finally placed in the hands of the miner, its strength and life in many cases, is reduced at least fifty per cent. In timber that is closely piled, thus preventing a free circulation of air, and on which the bark is continually moist, we have the most favorable conditions for fungoid growth.

A great deal has been done and said by mining men with regard to curing timber before putting it into the mine, and much good has been accomplished in this way to lengthen the life of mine timber, but to apply remedies to wood that is already well advanced in decay is so much energy wasted. The proper time to apply the remedy, if wood curing is to be done with a sufficient degree of satisfaction, is when the timber is green from the woods, and before the parasites have had an opportunity to get in their work, and not after they have had many months start.

The drawing of mine timber from finished places is a question that has been given a great deal of thought by those interested in coal mining. It has been contended on many occasions that timber cannot be drawn profitably in our Cape Breton mines, as such work cannot be done by common labor. I agree with this statement in so far as it applies to inexperienced labor. Experienced men must be employed at such work, and labor of this kind must be paid a fairly high rate. The timber must then be carried to the roadways, from whence it can be again hauled to the working places.

In this country, where mine timber is principally of balsam fir, a large percentage after being drawn is not worth resetting. I have had this work done myself with a fair degree of profit by having men take only such timber as could be drawn without too much labor and make good timber for resetting.

I do not know to what extent these ideas will meet with your approval, but I believe that, having in mind only the cost of coal per ton without regard to the conservation of timber, the drawing of timber in this way will be found most profitable. In places where the bottom is fairly strong, and does not heave sufficiently to break the timber, and where the roof is not too heavy, it will be found that a great many timbers can be drawn which will be fit for resetting. Probably from 50 to 75 per cent, particularly where such timber is of spruce.

I have also used broken timber in the making of road ties in the mine, and find that these can be made at about the same cost as new ties, but it requires a man who has had some experience at this kind of work to make it come out even. It might be suggested that this work could be done better on the surface, if the wood was brought there; but the extra handling would increase the cost, and probably result in the lessening of the output, by interfering with the free handling of the coal.

Where booms have of necessity to be removed, because of their being broken, either through deterioration of the wood, or through some other cause, and where either end of such boom is of sufficient length to make a prop, they may well be used for that purpose; and even when the fibre becomes brittle through

MR. H. M. WYLDE, Halifax,  
A Charter Member of the Society.

deterioration, and the stick is of no further use as a boom, it can be used as a prop with fairly good results.

Rafted timber, or in other words, timber that has been soaked in water for some time until it sheds the bark, will stand underground conditions much better than wood sent into the mine with the bark on. I might also say that timber which is cut from areas that have been swept by forest fires, and are cut after they dry on the stump, have much better lasting qualities than wood cut in the sap. It follows then, that it might be better to have timber peeled when cut, and piled so as to give it a chance to dry out. This would of course add materially to the cost.

It might be argued that the additional cost would not be justified from the fact that the life of much of the timber used in the mine is of short duration owing to conditions already mentioned. However, it might be recommended that a certain percentage of the timber be prepared in this way, so that the mine official could use them in travelling ways and airways, and such other places as are to be maintained for a longer period.

In the timbering of mine roads, where it was necessary to maintain such roadways for a number of years, and where such timbering must of necessity be of a more or less permanent nature, imported timber of a quality superior to our native wood is sometimes used. This is generally yellow hard pine. This wood, if it is in good condition when put into the mine, and has not too much resin extracted from it, does not seem to be affected by underground conditions.

Steel girders are sometimes used where support of a permanent nature is required. The initial expenditure is fairly large, but allowing for the cost, and having due regard to the permanency desired, any reasonable expenditure is justifiable, as it will ultimately prove much cheaper than if ordinary timber had been used.

It has been proven conclusively that main roads can be supported as cheaply, particularly where double tracks are repaired by using steel rails that have been condemned for ordinary railway use, as with round spruce timber. This is for the reason that many more spruce booms would have to be set for a given

distance; and as for durability, the life of the steel boom, as compared with the spruce, might well be placed at 20 to 1, and the difference may be much greater than this. This refers to the ordinary 80 lb. steel rail.

Portions of haulage road boomed with these rails, say six feet apart, supported on cured spruce props, and having sufficient overhead lagging, would require, if spruce booms were used instead, three spruce booms to every rail so used, and would entail three times the labor in getting.

It is generally supposed that when steel is used instead of wood for timbering, that the first cost is much greater, but in the cases referred to it does not work out that way. For instance, we take a case where roof conditions will require a steel boom every three feet, then at least two spruce booms must be placed in the same space. The average cost of a steel boom 14 feet long is \$5.00. Supported on two special spruce timber at 30 cents each, the cost of putting up would be about \$2.40, making a total cost per boom of \$8.00. The cost of two spruce booms 14 feet long is \$2.00, with four props for supports \$1.20, and \$4.80 for setting, makes also a total of \$8.00. Where it becomes necessary to set steel booms a distance less than three feet apart owing to the weight of the roof, I would not take any chance with spruce even if set skin to skin, unless propped in the centre, and centre props on haulage ways are always a source of annoyance and delays.

## CANADIAN COAL MEN.

### Alexander S. McNeil.

Alexander S. McNeil, the Superintendent of Mines of the Nova Scotia Steel & Coal Company at Sydney Mines is another of the native sons of Scotch Highland descent that are the moving spirits in the coal mining activities of Cape Breton Island. Mr. McNeil was appointed Overman at Dominion No. 1 Colliery in 1899, and after holding various official positions was appointed manager of No. 8 Colliery in 1908. He filled successively the position of manager at No. 9 and No. 2 Collieries, and was in 1916 appointed District Superintendent, having charge of Collieries Nos. 2, 7 and 9, and later of Nos. 1, 5 and 10 in addition. In 1919, Mr. McNeil joined the staff of the Nova Scotia Steel Company as Superintendent of Mines.

Like so many other men in official positions in Nova Scotia, whom it has been our privilege to know, Mr. McNeil has risen from a junior position underground by dint and personal merit, and studious nights, to the superintendency of a group of collieries producing 600,000 tons annually. His long experience in connection with the submarine collieries of the Dominion Coal Company, namely, Nos. 1, 2 and 9, and 7, and his charge of the Princess Colliery at Sydney Mines, has given him a unique knowledge of undersea coal-mining at long distances from shore, and with heavy cover.—F.W.G.

ALEXANDER S. McNEIL,  
Supt. of Mines, Nova Scotia Steel and Coal Company,  
Sydney Mines.

# The Theory and Practice of Fighting Mine Fires from Practical Experience Gained in Pictou County

Paper Read Before the Mining Society of Nova Scotia April 5th 1920, Glace Bay.

By F. E. NOTEBAERT.\*

A large portion of the Pictou County Coal Field is composed of very thick seams. Amongst these are seams that have been known for years past, namely:

The Foord Seam—40 feet thick;

The Cage Pit Seam—18 feet thick;

The Third Seam—14 to 17 feet thick;

The McGregor—The thickness of which at certain places reaches over 22 feet.

These four seams are the old seams known as the seams of the Stellarton district, and have been worked, some of them for over a century.

To these seams a series of thirteen new seams underlying the four first ones mentioned, were added—when in the winter of 1915 a borehole drilled by the Acadia Coal Company, made this discovery.

As in the upper seams, the heavy thickness of these new seams seems to have prevailed, and we have to record:

One—21 foot seam;

One—28½ foot seam;

One—20'4" seam;

One—24'2" seam;

One—23'0" seam.

These seams were found intermingled with thinner seams, such as: 3 ft. 6 in.; 5 ft.; 6 ft. 2 in.; 4ft. 11 in.

## McCulloch Fault Considered Non-Existent.

Undoubtedly had the borehole been extended further down, other seams would have been discovered, and eventually the borehole extended still further down, would have entered the Westville coal measures. These very often have been considered as being the same seams as those of the Stellarton district, but thrown in a south-westerly direction by a fault of great amplitude known as the "McCulloch Fault," the existence of which has never been proved. Without certainty, although without much doubt, we are fairly safe to abandon the old conception of the so much talked of "McCulloch Fault" and to accept that the Westville seams are only the regular continuation of the series of Stellarton seams, thus adding an enormous tonnage of coal to that already known to exist in the Stellarton district.

Having so outlined what may be properly now called the main coal field of Pictou County, we will enumerate the main features of this field.

The angle of dip may be called steep in comparison with the great majority of the Cape Breton fields. At the southern end of the field, the seams outcrop with an angle of 21° to 23°, dipping northerly until they reach a basin line, then they rise up in a northerly direction at various inclinations, varying from the true level up to 90° and in certain disturbed sections of the northern portion of this field, the seams are completely reversed, the foot wall resting on top and the hanging wall lying underneath.

The angle of the dip, the thickness of the seam, the fact that the space left open by the working out of the seam is not flushed nor filled, implies almost

necessarily a method of working by "Bord and Pillars," retreating from the limit of the field towards the main slope, leaving only a crush behind the working faces.

## The Cause of "Gob" Fires in Pictou County.

The immediate consequence of such a system is the unavoidable abandonment of a more or less important tonnage of coal in the gob. This coal being subjected to the heavy pressure of the roof, is crushed, and provided that the oxygen of the air is allowed to get in contact long enough with this "loose coal" great heat is bound to be generated, which ultimately will provoke a "gob fire."

These gob fires are naturally frequent in the seams of the Stellarton district, or more correctly, would be quite frequent if special precautions were not taken. These precautions are of three different natures, namely:

1. Reduce the quantity of combustible matter left crushed in the gob, the presence of which is the original cause of the fire.
2. Reduce the prolonged contact of air (oxygen) and crushed coal in the gob.
3. Emergency measures, consisting of heavy stoppings which allow us to isolate and to seal off any sections or part of section whenever this section is threatened or affected by fire.

These emergency measures are naturally very expensive, but our experience has proven to us that they may be, after all, the cheapest and safest method to prevent gob fires, or to fight them.

## Hydraulic Filling Advocated as Gob Fire Preventative.

The amount of combustible matter left in the gob, when attempting to work out such thick seams, can only be reduced to an unimportant quantity by the adoption of the "flushing system," also called "hydraulic filling," but at this date of the coal industry in Nova Scotia, it is very questionable if in long slopes with an abnormally high cost of labour as compared with the selling price of the coal the time has yet come when "hydraulic gob-flushing" can be introduced in Nova Scotia mines with financial profit. Although, as we have just stated in the case of the Pictou County mines, the "flushing system" is and will be the only system by which all the coal being recovered, the gob fires may be completely suppressed. Let us also incidentally mention that with the hydraulic flushing, dust explosion will be a thing of the past.

## Gob Areas Should Be Air Tight as Possible.

To reduce the prolonged contact of air (oxygen) with the crushed coal left behind in the gob, the most efficient disposition is to advance the working faces as rapidly as possible, so as to bring the roof down; also to avoid any filtration of air through the gob. This can best be done by retreating towards the slope, also by ascensional ventilation, the air being allowed in at the bottom of the pillar section and being exhausted at the upper end of the section in a direction opposite to the gob.

To reduce a prolonged contact of the air with the gob, implies also that the gob resulting from the work-

\* Acting General Manager, Acadia Coal Company, Stellarton, Nova Scotia.

ing out of a pillar section be properly and completely sealed off, so as to avoid as much as possible filtration of air through the gob and oxidation of the crushed coal left therein.

These are roughly speaking, the general points that should always be kept in mind in the extraction of pillars in a thick seam dipping at a steep angle, without having recourse to the "flushing system," if an earnest attempt to avoid gob fire is made.

We have mentioned the nature of the seams and of their dispositions, and we believe it might be interesting to point out that although commonly qualified as "very apt to spontaneous combustion" the coal seams of Pictou County and especially of the Stellarton district are the least subject to spontaneous combustion; this being due to their very low percentage of sulphur, which in most cases does not exceed 1 per cent.

#### The Progress of a Gob Fire.

But even when all precautions are taken, gob fires are apt to take place. Usually the first indication of fire is only a very slight odor of distillation of coal. According to the nature of the seam, and to the general dispositions which are causing the fire, the odor will persist for hours or for days, and we know of cases where it has persisted for weeks without showing any increase of temperature, or any sign of smoke, which are the next indications of a gob fire.

At this stage when smoke appears, conditions are always very serious, because even if the seam does not liberate explosive gases, the distillation of coal with a restricted amount of air will generate carbon monoxide, which is highly explosive. It is at this stage that good judgment must be used and a quick decision arrived at.

When smoke has made its appearance, the tendency is usually to continue carrying out the dispositions which had been adopted in the earlier stages when the only indication of the gob fire was the odor of distillation.

In many cases this may have resulted in apparent success, but very often the fire has already been allowed to smoulder too long, heat has increased and flames have made their appearance. Conditions then may be termed as highly dangerous, and alarming, since all the elements required to provoke an explosion are present. If conditions have unfortunately been allowed to develop this far, there remain very few remedies to be depended upon, and any one of these remedies is entirely affected by a very great factor of "chance." The natural remedy against flames is water, applied by sprinkling or by flooding. The flooding of the section will usually take a great time, during which the fire will continue to progress, kept alive by the suction of the fan. Besides, flooding against fire can only be adopted as a very extreme measure. As a matter of fact, it is almost always worse than the complete and forced abandonment, except if the flooding may be restricted to a small area, because without controlling the fire quickly, you add to the damage and risk of the fire the destruction from the flood.

As regards the sprinkling, it will generally not be very efficient and will almost in every case amount to failure, since the water will only reach the outside manifestation of the gob fire (the flames) without reaching the real seat of the fire, which is away inside in the gob. We have known of flaming fire being successfully extinguished by sprinkling of water,

and the officials who were supervising the fight are today still wondering why it was that the water put the fire out. A closer study might have shown that the steam generated by the water on a very hot fire and carbon dioxide were the decisive factors. The fire will in most cases, continue to gain in violence and make its appearance at other places in the district, until conditions are so alarming that the mine has to be abandoned. This abandonment means the stopping of the fan. The natural ventilation, which will likely be reinforced by the heat of the fire zone, will carry a current of air through the mine and in the vicinity of the fire. The next available step is to seal off the mine at the main intake and main return, and to wait developments. The moment is naturally a very serious and anxious one, since the conditions and the elements are all present to cause a very serious and destructive explosion, which even on the surface may cause loss of life.

It is an order to avoid this alarming situation that we recommend never to wait to face these desperate conditions, and instead of being guided by "luck and chance" to control the conditions whenever the first smoke has made its appearance. Even then conditions are dangerous, but in our opinion, it is at this stage, that radical decision should be taken without waiting and without hesitation, and that the mine should be sealed off as tight as possible at the main intake and return. The purpose is total suppression of oxygen, not only in the fire district, but in the whole mine, and its replacement by a high percentage of other gases, explosive or not, the mixture of which will after a short time be in explosive, due to its lack of oxygen.

As an illustration, are given some analyses of mine gases taken at a slope mouth of one of our mines, after it had been closed for only a few days, as follows:—

	Per cent
Carbon dioxide . . . . .	7.2
Carbon monoxide . . . . .	0.0
Oxygen . . . . .	3.1
C. H. 4 . . . . .	31.4
Nitrogen . . . . .	58.4

and a few days later, the percentage of oxygen had fallen to .86 and .42.

The mine referred to here, is the Albion Mine of the Acadia Coal Company. This mine, ever since its opening away back in 1881, has been affected by numerous very serious fires, almost always due to one of the causes mentioned hereabove. In this particular case, (the fire which took place in 1917-1918) an old abandoned section in the Third Seam, had been entirely isolated by a line of very substantial concrete stoppings, which unfortunately, due to a special disposition of the ventilation circuit, were subjected to a heavy water gauge, that except for the stoppings themselves, would have allowed a short circuit of the ventilation through the old section.

Workings in an underlying seam, having disturbed the stoppings in the Third Seam, odor of distillation of coal, was first perceived at almost every stopping, showing conclusively that most of the section was affected by heat: This heat was generated by the oxidation of the coal, occasioned by the filtration of the air through some defective stoppings and also through the coal itself, as we show later on.

The first step taken was naturally a general reinforcement of every concrete stopping, followed by further reinforcements of weaker stoppings. The odor of distillation would disappear for a few days or even

weeks, to suddenly reappear at some other place; until finally after about eight weeks of special watch, a slight vapor of smoke made its appearance in one of the bottom stoppings which was being reinforced.

The section which was affected had an area of 1,410,000 sq. ft. in which a considerable body of crushed coal had been left. Following the policy herein advocated we decided without any hesitation, at the very moment smoke was seen, to suspend any further reinforcements of the stoppings isolating this section, and to surround this body of smouldering heat slowly but undoubtedly developing into a flaming fire, with an atmosphere entirely deprived of oxygen.

We have given above, the analysis of the mine atmosphere, and will only recall that after a very short time, the percentage of oxygen in the mine was less than 1 per cent. that the percentage of CH<sub>4</sub> was about 36 per cent and the percentage of carbon dioxide between 7 per cent and 8 per cent. Such a mixture made the extension or even the existence of any fire impossible.

But this mixture, efficient as it was to suspend the fire and prevent its expansion, could not kill the heat which had been generated by the first stage of the coal oxydation, in the time estimated. The extent and importance of this heat we did not know and could not have known, since at the first appearance of light smoke we had decided to seal off the mine for the reasons already explained.

We had considered that the fire zone was of small extent, in that after the previous reinforcement of the other stoppings, the warm points could be located only very near the stopping where we had noticed the first smoke. Therefore, basing our decision on similar experience in the past, we had decided that the mine being closed for over thirty-six days, the temperature of any heated point should have been equalized by the natural and much lower temperature of the strata and of the whole atmosphere of the mine. But apparently the area of the zone which had been affected by heat was far more important than we had estimated as will be seen from a brief relation of the stages of the method of re-entering a mine, abandoned on account of a gob fire and subsequently entirely filled up with mine gases that we recommend.

During the last six years, underground conditions in the Pictou County coal field have faced us five times with reopening of mines, abandoned either on account of fires getting beyond control, or because of explosions creating fires compelling the temporary abandonment of the mine.

#### Natural Ventilation Currents from Fire Areas.

In all our re-entering of mine workings, under similar conditions, we have never made use of the fan. The mine having several outlets all sealed up as tight as possible, with the exception of one, (the one intended to be used to re-enter the mine) a current of air or of gas is bound to be set up, notwithstanding the fact that there is only one opening. The slightest leakage in the stoppings of the return airways, if the intake is open, or of the intake if the return is open, will cause the heavy cold fresh air to drive out the light warm gas included in the mine.

Supposing that all the openings could be kept theoretically absolutely tight, with the exception of the one through which the re-entering of the mine is going to be made, a current will be set-up. The cold air will travel down on the pavement of the slope chasing the warmer gas which will escape by following the roof of the slope.

As a matter of fact, during the reopening of the mine which we are going to describe, we made an experiment. We reinforced all the surface stoppings, covering them with sand and clay, even covering certain portions of the surface with sand and clay, and then opened the main return-air slope, lying alongside the main air-shaft.

The first effect was a large quantity of gas coming out of the full section of the slope and after a very short while a regular current was noticed, going in at the foot wall of the slope and coming out at the roof.

After several hours of this experiment, the cold air gradually found its way down the mine, the whole section of the slope becoming an intake. In order to counteract this motion, a wooden stopping was built below the connection which existed between the slope and the air shaft in the main return slope. This had the effect of reducing the amount of fresh air going down, but did not stop the current.

In order to still further counteract this tendency, an opening of 16 square feet was made in the fan shaft, in the expectation that the air, instead of keeping down towards the mine, would return up the fan shaft. Of a total quantity of 8400 cubic feet of air the greatest part was going straight in the mine, and barefaced men could reach the stopping which we had built in the main return slope.

Finally, as a last effort to prevent the air from going down, the steam fan was started at 14 R.P.M. in order to draw the air up the fan shaft. Of a total quantity of 5148 cubic feet of air at the slope mouth, 4500 cubic feet was rushing in the mine at a point 25 feet below the crosscut between the main slope and the main air-shaft.

This experiment ought to show the effect of natural ventilation, especially on pitching seams. At first sight it should be evident that a state of equilibrium does not exist when placing in contact light warm gases, and cold heavy air. The quantities involved being very large, with considerable difference in temperature and density, heavy exchange setting up currents or natural ventilation are bound to take place and to persist for a very long time.

Therefore, in every reopening of mines, the question of natural ventilation will have to be taken very seriously into consideration, especially in cases where it is important that fresh air does not get away ahead at places where fire may exist, because under these circumstances fires may be apt to start again suddenly. In such cases, it will be most important to direct the natural current by short circuit or new circuit away from any point where the oxygen of the air could and would cause damage.

As an illustration, at the time of re-entering the Albion Mine on January 1918 the first inrush of air, entirely due to natural ventilation, was 50,000 cubic ft. of air per minute, both fans being standing, every opening being closed, with the exception of the main slope (through which the re-entering of the mine was made) and a few boards taken off the fan shaft.

In order to prevent this flow passing anywhere near the seat of the heated section, this amount of air must be deflected before it gets near the fire zone by short circuiting the main intake and the main return. In our case, this had been done when closing down the slope at the time of the temporary abandonment of the mine. The short circuit of the air current was established at a distance of 1,300 feet from the seat of the fire. Only a short distance below this point we

had a blanket of gas through which no living person could pass without the use of breathing apparatus.

The mine was then allowed during three or four hours to clear, the great bulk of the gas lying on the circuit which had been established at a point 1,300 feet above the fire zone. The ventilation being then considerably reduced, due to the cooling effect of the circuit, and also due to dilution of the gas in the return, the short circuit at this point was suppressed and established further down, closer to the fire zone at a distance of only 460 feet from the fire.

Our men following the air circuit reached the point where the light smoke had been seen at the time of the closing of the mine. At this point, a strong odor of distillation was detected and soon after was followed by a smell of coal smoke. This discovery was most disappointing because it did not leave us any doubt that the smouldering gob fire which had been surrounded by an atmosphere less than 1 per cent of oxygen during thirty-six days, had not been extinguished.

A few hours after, smoke again made its appearance, and for the same reasons as before, we decided to close down the mine and to let it fill again with gas.

The mine had been opened for only 18 hours and all the different phases of the re-entering had been carried out as scheduled. As stated, this attempt was somewhat disappointing, coming after four other successful reopenings carried on exactly under the same theory. In each of these cases, one month had been considered as being fully sufficient, not only to extinguish the fire, but also to cool down the surrounding coal and strata. In some cases less than one month had been the waiting period.

This apparent failure caused hesitation in the mind of many an official, and every supposition was considered; namely, the possibility of the section being connected with some workings of upper seams which were on fire, or connections through subsidence which might have taken place between this seam and the underlying seam and so on.

Finally, after new consideration and study of the situation, it was decided to proceed according to the same method as that adopted previously, but to keep a closer control of the natural ventilation. Since our first attempt had shown us that thirty-six days had not been sufficient to cool down the fire zone, the new attempt was made almost three months after the first one, and contrary to what had been done in this case, the new attempt was going to be made in different stages.

The first one included the establishment of a ventilation circuit to No. 4 level 1,900 feet, and from there upwards towards the surface in a separate ventilation slope, the idea being to keep the ventilation as far away as possible from the fire zone. Instead of starting with as heavy a quantity of air as during the first attempt, the air current given by the natural ventilation at the start was only 10,000 cubic feet of air per minute, which ultimately was increased to 21,000. The composition of the mine atmosphere at the time of this start was:

	Per cent
Carbon dioxide . . . . .	9.98
Carbon monoxide . . . . .	0.89
Oxygen . . . . .	1.00
Methane . . . . .	42.6
Nitrogen . . . . .	45.9

in other words, highly favorable.

The rest of the program of this first day included the

opening of a door on No. 5 level at 260 feet away from the seat of the fire. This door having been previously left closed by mistake, meant that any ventilation passing below No 4 level would pass on the fire zone. This part of our programme meant that in order to avoid sending the ventilation past No. 4 level, as this part of the mine had to be kept under gas, the door had to be opened first by a Draeger team. The distance down the slope from the air station to the door was 940 ft. Our men went down to the door but found that a fall which had taken place, prevented its opening. At this stage, a sample of gas taken on the slope at No. 5 level, 2,800 feet, was analysed, and showed 17 per cent of oxygen. The mine having been opened for almost 10 hours, dilution of the gas in the air current was taking place. It was decided to end there this first stage of the operations and to let the mine fill up again with gas for a few days. This was done, and after a very short while, a gas sample taken through the pipe at the slope mouth gave us:

	Per cent
Carbon dioxide . . . . .	10.9
Carbon monoxide . . . . .	0.42
Oxygen . . . . .	0.62
Methane . . . . .	30.00
Nitrogen . . . . .	59.00

A few days later we proceeded with the second part of the programme, which consisted in levelling off the fall which prevented the opening of the door at No. 5, also the closing by a temporary wood partition of a small ventilation head next to the fire stopping. 20,000 cubic feet of fresh air forced in the mine through natural ventilation was admitted in the slope, but only down to No. 4 level. From this point the work which we had planned to do was done by our Draegermen, in an atmosphere including only a small per cent of oxygen, and working at 940 feet from No. 4 level which was our air station. This was practically all that was done that day. At the end of the day, our Draegermen had levelled off the fall, opened the door referred to and closed up the ventilation head. They also took a sample of gas almost against the fire stopping; this sample was most reassuring since it included carbon dioxide, 5.5 per cent—oxygen 10 per cent, methane 24.5 per cent, after the mine had been opened up for almost almost twelve hours.

**A Proper Use of the Breathing Apparatus**

The value of this information alone would fully justify the use that can be made of a well-trained and well organized corps of Draegermen. This valuable information meant that all our previous work had been successful in keeping away from the fire zone an explosive mixture; also that it was possible to work with a restricted ventilation in the close vicinity of the fire stopping for about 12 hours, without allowing the diffusion of the air and of the methane to constitute an explosive mixture.

**Men Wearing Breathing Apparatus as "Scouts."**

Further valuable information brought back by our Draegermen was that nowhere close to the fire section could they feel any indication of heat. We had therefore every reason to believe that the period of three months of rest which we had given to the mine, during which the percentage of oxygen had been less than one per cent, had been sufficient to equalize the temperature of the smouldering fire to the surrounding temperature of the mine. In other words, not only had the combustion been suspended, but the surrounding temperature was low enough to avoid excessive avidity of hot combustible matter for oxygen.

At this stage, it would have been quite possible to complete our programme, which included the building of a temporary stopping outside the one where on two different occasions we had noticed smoke; but before proceeding to this last stage, the whole mine was once more allowed to fill up with gas.

**Mr. Notebaert's Method Justified.**

Finally the last day came. Through the same proceeding, the air was allowed in the mine, and this time allowed to pass No. 4 Level, travelling down towards No. 5. Barefaced men started, followed the air and built the temporary stopping mentioned above. The old stopping and all its surroundings were found to be perfectly cool, giving no indication of heat and no odor of distillation. The building of the temporary stopping was rapidly completed, and right after the permanent concrete stopping was started. We had been successful, and once more our mine officials felt that their confidence in this system of fighting fire was well justified.

In order to remedy the real cause of the fire, namely

filtration of air through the coal surrounding the stoppings sealing off the lower part of the section, a system of pipes connected to a natural supply keeps a head of a few feet of water all over the bottom part of the section. The overflow taking place through the coal itself is the best proof that the air cannot again enter to feed the gob with oxygen.

All this took place late in the year 1917 and early in 1918.

This time as before, we had found out that it was not only possible to suspend a gob fire by curtailing its oxygen supply, but also that it was possible, if time were liberally granted, to equalize the temperature of the smouldering fire with the rest of the temperature of the mine by means of a restricted natural ventilation.

Our faith in this logical, safe and efficient system of stopping an underground fire, passing rapidly beyond control, had once more been fully rapid, adding another mining experience to many other anxious ones of the Pictou County Coal Field.

COL. THOS. CANTLEY,  
Retiring President, Mining Society of Nova Scotia.

### COAL CONSERVATION CAMPAIGN. Engineers' and Firemen's Year Book.

We have received a copy of the "Engineers' and Firemen's Year Book", issued under the patronage and with the co-operation of the Fuel Administrations of Canada and the Provinces, the Railway Association of Canada, Mr. J. K. L. Ross and Mr. R. M. Wolvin, supported by the large railways of Canada and a number of leading banks and manufacturers.

The volume contains some striking reproductions of crayon sketches by Hal. Ross Perrigard, showing the part played by coal in our national life.

The text of the volume is an extract from the Final Report of the Fuel Controller of Canada. We congratulate those who conceived the idea of giving this Report such an attractive dress, and a wider opportunity for perusal by Canadians. Mr. Magrath's studied conclusions on the Canadian fuel problem deserve the widest publicity, much wider publicity than they have obtained. The Canadian public is extraordinarily apathetic about the fuel problem, and we are coming to the conclusion that the men who really know are afraid to face it. It is the skeleton in the Canadian closet, and too many people prefer to forget it. It is therefore encouraging to come across a volume that is deliberately designed to haul this skeleton into the daylight for public inspection.

The foreword to the volume, is as follows, and in quoting it, we would remark that it is an epitome of the view that the "Canadian Mining Journal" has preached regarding our domestic coal supply since it commenced publication in 1907.

"The most immediate, if not the greatest, experience of Canada from the war has been the absolute necessity for our country to produce more Coal and to conserve it more than we have done in the past.

"We are starving for coal today as we have done in the worst days of the war and whether the blame should rest upon industrial unrest here or in the United States, or upon any other cause, we are confronted with the fact that we have very little coal to burn and that a few days could see us reduced to the straits in which Germany and Austria find themselves today.

"Every body is agreed upon the necessity for an increased production of coal in Canada; this takes time however and two to four years will be required as a minimum before our coal production is increased to such a level as would relieve us from the coal shortage from which we are suffering today and would also enable us to secure that most desirable of results: the establishment of a foreign market for our surplus coal production. Meanwhile we must save coal and save it more than we have done during the last two years if we want to live, to prosper and to develop.

"We have preached and spread the doctrine of Coal Conservation in and out of season; our reception has been in directly inverse ratio to the weather: warm in winter, cold in summer. Who worries about coal in July and August?

"This is precisely the point we wish to emphasize; coal is just as vital in the hottest day of summer as in the bleakest day of winter. we must keep in mind that the year is short

and that the seasons revolve quickly. Uppermost before us at all times should remain the fact that we must work untiringly: 1.—TO SAVE MORE COAL. 2.—TO PRODUCE MORE COAL."

### A NATURAL QUESTION.

?

Racey, in Montreal "Star."

"Canada (disgusted and worried at the constantly increasing size of its coal bill). "Why in thunder should I be at his mercy and be forced to pay these millions annually when I have sixteen per cent of the world's supply right under my feet?"

Note:—Canada has greater coal reserves than any other nation, with the lone exception of the United States.—Ed.

### SAWARD'S ANNUAL—1920. A CORRECTION.

We regret that, through a printer's error in the "Journal" of last week, we were made to refer to Mr. Saward's publication as a "well-known 'complication' of data." The unfortunate wording might in some instances contain sufficient truth to prove embarrassing, but it can hardly affect the reputation of Mr. Saward's handbook, which is unexcelled in the fullness and accuracy of its information regarding all phases of the coal trade in North America.

Mr. F. A. Combe who was, until recently, Chief Engineer for Canada for Babcock and Wilcox Limited has opened an office at 603 Southam Building, Montreal to practice as a consulting combustion and steam engineer. Mr. Combe will specialize in power plant design and operation and the utilization of waste head and steam.

## Northern Ontario Letter

### The Silver Mines.

Quotations for silver during the first week in May continued to decline. Big silver producers in Cobalt which have been hoarding their output since the price began to fall below \$1.25 an ounce, now find their vaults fairly bulging with bullion and with quotations having dropped to \$1.05 an ounce at the time of writing. It is obvious that the recession in the price of the metal was quite unexpected, and was due to influence which may not be altogether visible even to the most astute metal authorities. While the decline has caused some disappointment, yet the current quotations are still higher than the fixed price which ruled during the closing years of the late war, when the mines were exceedingly prosperous.

An outstanding feature in connection with the silver situation is that while a decline of a further 25 per cent in price would cause curtailment of work in many of the silver mines throughout the world, it would still leave a big margin of profit for the leading producers in the Cobalt field. It is a noteworthy fact that the entire silver production of Cobalt is maintained at an average cost of under 60 cents an ounce. The Nipissing has the lowest cost, each ounce being produced at about 35 cents an ounce. Such mines as the Coniagas and Kerr Lake produce their silver at less than 45 cents an ounce.

The Beaver Consolidated Company having succeeded in leasing the adjoining Prince claim, is now making arrangements to also get control of the Badger property which corners the Beaver on the north west and lies adjacent to the Prince claim. Lateral work is being carried from the Beaver onto the Prince on a vein opened up on the Beaver at the 1,400-ft. level and which has been found to run over the boundary to the Prince. It is proposed work through the latter claim to the Badger.

It is stated that the Dominion Reduction Company has agreed to treat the old tailings pile of the Peterson Lake Company for one-third of the proceeds. The slimes are estimated at over 300,000 tons and while the exact average silver content is still undetermined, yet it is known to be such as to leave room for a substantial margin of net profit.

The appeal in the previous decision on the dispute between the O'Brien Mine and the La Rose is scheduled for an early date. It has to do with the determination of the exact location for the boundary between the Violet property of the La Rose and the O'Brien Mine of the M. J. O'Brien, Limited.

Official announcement is made this week that the Canadian Light Railways Construction Company has already engaged one engineer and a small force of men to scout out the most suitable location for a roadbed, and that actual work of construction is held in abeyance only pending the bill for the charter receiving the Lieutenant-Governor's assent. It is also announced that not only will work commence on the Gowganda line, but it is also planned to proceed with the line from Swastika to Kirkland Lake. Following is the official statement in part as submitted to the correspondent of the Journal:

"We intend to overcome every obstacle and to make a great success of our transportation scheme and hope to have all our lines constructed and in operation before the end of the year. Our bill has passed the committee and received its second reading in the

House. We now have an engineer and force of men on the job at Elk Lake and as soon as our Bill receives the Lieutenant-Governor's assent, we will go ahead with a large force not only on the Elk Lake-Gowganda line, but also in the Kirkland Lake district.

"As soon as we have reached Gowganda, it is our intention to continue right into Shiningtree and Fort Matachewan."

It is stated at Elk Lake that the Coniagas Company of Cobalt has secured a working option on the Gamble-Thompson properties in the Gowganda district, and that the terms governing the deal are moderate. The vendors are stated to have demonstrated their faith in their property by granting fairly easy terms, with an ultimate large price provided the property makes good.

According to official advice to the "Journal", the Aladdin-Cobalt and the Tough-Oakes Company's have completed all details in connection with consolidation, and that arrangements have been made to commence work on the Tough-Oakes about May 20th. It is also stated that following a meeting to be held this week, the Burnside will also be included in the merger. Concerning the outlook for the consolidated properties, the physical condition of the Tough-Oakes and the Burnside is dealt with under "Gold Mines."

Ex-Governor Smith of Vermont, holder of an option on the Kells Silver Property in the township of Corkhill in the Gowganda Mining Division has made application for an extension of time to make the large cash payments which shortly fell due. In the meantime, an order has been issued to close down this week. The attitude the vendors will take is problematical, but the belief of local men is that they may consider the application favorably. This opinion is based on the fact that it is quite difficult to interest capital in such outlying properties, a condition with which the vendors are fully familiar.

It is expected that a shipment of ore may be made early in June by the Bailey Silver Mines, the company in control of the old Bailey-Cobalt Mine. In the meantime, preparations are being made to commence making regular shipments of medium grade ore to the Bailey Mill, formerly known as the Northern Customs Concentrator.

According to a despatch from New York, the Nipissing Mining Company has brought in three or four small oil wells on its oil lease in Kansas, with indications of the venture being a profitable one. At the same time deeper drilling is being carried on in Texas on the 1000-acre lease held by the company there. This new speculative aspect attracts added interests to the Nipissing. As regards the mine itself, the first four months of the year have been marked by a production of around \$375,000 monthly, the highest record so far in its history.

### Ore and Bullion Shipments.

During the week ended May 7th, six Cobalt companies shipped an aggregate of eight cars containing approximately 576,364 pounds of ore. The Mining Corporation with three cars was the heaviest shipper, as shown in the following summary:—

Shippers	Cars	Pounds
Mining Corporation . . . . .	3	196,873
Northern Customs . . . . .	1	88,000
La Rose . . . . .	1	87,211
McKinley-Darragh . . . . .	1	84,280

Coniagas . . . . .	1	60,000
Dominion Reduction . . . . .	1	60,000
<hr/>		
Totals . . . . .	8	576,364

During the corresponding period, the Mining Corporation was the only bullion shipper, sending out 99 bars on May 4th, containing 99,987.25 fine ounces.

### The Gold Mines.

Net profits being realized by the leading gold producing mines of Northern Ontario continue satisfactory, with indications of continuance. Present conditions justify a fairly general belief that the Hollinger may decide not to increase its present rate of one per cent every eight weeks, that the McIntyre will continue to disburse 5 per cent at intervals of about every four weeks, and that the Dome and the Lake Shore will each probably pay  $2\frac{1}{2}$  per cent quarterly. A departure from these rates would be brought about only by a change in the labor situation. With more men available, it would be possible to increase net earnings but, as at present, with no assurance of more than about 75 per cent of the required number of men, the mines are strengthening their position as much as possible. Shareholders in close touch with the situation express confidence in the sound policy generally adopted which carries with it promise of greater longevity and increased dividends in due course.

Considerable importance attaches to the meeting of the shareholders of the Porcupine V. N. T. called for May 27th in Toronto. Obligations incurred by Sir Henry Pellatt in connection with stock underwritten some years ago by him are believed as likely to be dealt with. The meeting is also expected to reveal some idea of the cause of the friction between the English and the American directors. It is believed that all differences may be disposed of, and a decision may be reached to resume work.

Unofficial reports that the Schumacher would resume work at an early date have been current in Porcupine. Among other things, it is reported that provided work should be resumed this summer, the main shaft will be carried from its present depth of 700 ft. to the 1000-ft. level. The treasury of the company is in fair shape, there also being upwards of 100,000 treasury shares as yet unissued, and which the directors have authorized the sale of at 45 cents each. The location of the Schumacher and the nature of its gold ore deposits lends a high degree of importance to the property. It corners in between the Hollinger and the McIntyre, and is located on the contact of the porphyry and the greenstone formations under similar conditions.

To the visitor the Kirkland Lake district now present a busier appearance than ever before. To those in touch with all phases of the industry, the field promises to experience further rapid growth, and within a year or so to see as many miners engaged in work there as the total employed in Cobalt. By this, the importance of the area may be gauged.

At the 300-ft. level of the Kirkland Lake mine of the Beaver Company, some remarkably rich ore has recently been opened up. Stopping operations are being carried on at that depth. It is also learned that

in addition to the usual developments, the main shaft will be continued from the present depth of 700 ft. to a depth of 900 ft.

With reference to the Tough-Oakes and the Burnside properties, the merging of which is being completed this week, and the operation of which will commence May 20th, an official of the company stated to the "Journal" that ore actually in sight amounts to between 17,000 and 18,000 tons, and that the average gold content is from about \$12 to \$15 to the ton, or in all amounting to close to a quarter of a million dollars. The reason for the comparatively small amount of ore in sight is said to be on account of the development work having fallen far behind production during the few months prior to closing down. With work again under way at full blast, it is believed the reserve can be greatly increased in about six weeks by which time the mill will be set in operation.

A deal has been closed in connection with the Hutton-Kirkland, whereby M. Porteous and his associates have agreed to place funds in the treasury of the company so as to finance the installation of a mining plant and an extensive plan of development work. In return for this necessary money, treasury shares are to be issued. It is learned, however, that the control of the company will not be changed. Work has already commenced, and orders for machinery have been placed. It is proposed to contract for electric power from the Northern Ontario Light and Power Company and to at once build a transmission line to the property.

It is announced that the Fidelity Mining Company has let a big contract for work on its property in Teck township. The work of sinking the main shaft to the 300-ft. level has already commenced and the contract calls for an additional two thousand feet of lateral work at a depth of 300 feet.

According to official advice, the Bidgood Company, operating property at Mud Lake in the township of Lebel has raised adequate finances to assure the completion of preliminary work, which consists of 300 feet of sinking now under way, as well as over one-third of a mile of drifting and cross-cutting at the latter depth.

At the Argonaut Gold Mines at Beaverhouse Lake, about twelve miles east from Kirkland Lake, a shoot of ore 190 feet long has been passed through at the 200-ft. level. Official figures show the average gold content of the ore to be high. It is stated that 100 feet in length and seven feet wide contains average values of \$11 to the ton, while an additional 90 feet in length and five feet in width shows average gold values of \$17 to the ton. The information is entirely reliable, coming from John W. Morrison, who is charge of the operation. Mr. Morrison obtained a good reputation as the result of the work in opening up the Lake Shore Mine and bringing it to a producing basis.

It is unofficially reported that the Boston Creek Gold Mines may be re-opened within the next few weeks, and that the interest of John K. Pappas makes has been purchased. Among those interested in the property are Messrs. Bickell, Symmes, Richardson and Albright.

W. H. Seaman has been appointed manager of the Fort Matachewan Gold Mines, to succeed T. J. Flynn who has managed the work since the company was formed.

## British Columbia Letter

### Stewart, B.C.

That recent development on the L. L. and H. group of Mineral Claims, situated on Bitter Creek, Bear River Valley, has exposed an ore bearing body twenty-seven feet in width is the statement of C. N. Tubman, of Victoria, B.C., who, with E. M. Molander, of Everett, Wn., one of the original stakers of Mount Sicker, Vancouver Island properties, bonded this group last February from J. S. Hartley, one of the first stakers. The ore carries values in copper, silver, lead and gold. When Messrs. Tubman and Molander went to work on the 14th of last March they found two tunnels had been driven one for forty feet on the upper or galena ledge and the other for two hundred feet on the lower or arsenical ledge. The former crosscut the ledge and the latter had struck the vein and had been carried forward in ore for a distance of seventeen feet. Mr. Tubman and his partner continued the latter work and, the former states, have gone forward another ten feet in ore. They, therefore, now have exposed a body 27 feet in width which, assays have demonstrated, gives encouraging returns in the minerals named. The L. L. H. is about sixteen miles from Stewart and it is the intention to carry on development throughout the season now opening.

### Alice Arm

Miners employed by the Taylor Mining Co., at the Dolly Varden Mine left their work on the 22nd of April and, as far as could be learned on the date of writing (3rd May), still are on strike. Negotiations, however, then were reported to be underway which, it was hoped would result in the resumption of operations. As matters stand both the actual mining and the railroad, which furnishes transportation between tidewater and the mine, are tied up. The men's demands for a raise in wages from a minimum of \$5 a day to \$6, single cot bunks, scrubbing of camps, and free blankets and sheets. The Company's rate of board was to remain at \$1.25 a day. This ultimatum was presented to the management on Monday, it being specified that three days, or until the next Wednesday night, would be allowed for the announcement of a decision. The decision was that under no circumstances could what was asked for be allowed and that rather than submit the whole work would be permitted to cease. This is what happened and as stated no word has as yet been received indicating a settlement.

### Anyox, B.C.

The Granby Co. Two and Three, consisting of six ten mineral claims situated in the Hidden Creek District and adjacent to the property of the Granby Consolidated Mining & Smelting Co., are reported to have been bonded by P. Oleson. The owners are William Hanna, Charles Flood and associates. Mr. Oleson also has bonded the Ptarmigan, Rex, and Monty Groups in the same section. Development work is to start on the first mentioned claims next June, it being the intention to use three diamond drill outfits.

### Nelson, B.C.

Samples of mineral taken from the upper workings of the Utica Mine are being shown in Nelson District which because of their exceptional quality have attracted special attention. They are from a showing

between five and six feet wide and represent a rich stringer in the showing two feet wide, the latter being of grey copper with ruby and native silver, running it is estimated from \$100 to \$1,000 a ton. The average of the whole showing of five and a half feet of ore will be 500 to 600 ounces of silver per ton.

### Cranbrook, B.C.

A. J. Palmquist, manager of the Wild Horse Creek Mining Company, who has been spending the winter in Texas, has returned to British Columbia and is making preparations for the resumption of placer mining operations on Perry Creek. The company did a lot of work last season in the shape of repairs to flumes and other plant. Washing operations, therefore, should be started in the course of a month.

### Vancouver, B.C.

Dr. E. T. Hodge, for several years professor of mining in the University of British Columbia and in that time prominently active in outside mining circles, has resigned to accept a professorship in the Department of Mining, Geology, and Petroleum in the University of Oregon at Portland. Dr. Hodges states that, while he is leaving the university of this Province, he will not entirely cut off his association with the mining industry and the mining fraternity of Western Canada. As his new duties will not necessitate the spending of his entire time at Portland he has agreed to become the executive head of a group of engineers organized with the object of assisting in the development of the natural resources of the Pacific Northwest.

### Revelstoke, B.C.

Recent development on the Lanark Mine, an old and well-known British Columbia property situated near the City of Revelstoke, appears to confirm the faith and judgment of the present owners, Fred. C. Elliott and William Dornberg. At a depth of 1,000 feet on their vein they have opened up a body of ore containing a high grade streak from two to four feet in width, with about six feet of milling ore. The high grade averages 90 oz. silver and 65 per cent lead. The vein has been drifted on for 30 feet and holds its width and values. In addition it is asserted that a vein of high grade copper has been exposed on which little work has been done. During the winter considerable work has been done in blocking out ore and the Lanark now is practically ready to commence production. Since Messrs Elliott and Dornberg have acquired control they have installed a modern hydro-electric plant and a concentrator.

### Victoria, B.C.

A total reduction of 318,101 tons of ore and concentrate by the properties of the Consolidated Mining & Smelting Co. for the 15 months ending December 31st, 1919, is shown in the report of W. M. Archibald, manager of the British Columbia mines of that corporation.

J. Warren, the president reported in part as follows:—

"The ore reserves have been largely increased, the developments in the Sullivan Mine being most satisfactory.

"Owing to the strike the prosecution of the power Company's line to Copper Mountain was seriously interrupted. It should be completed early in the coming summer. As usual your Company was the large consumer of the power company's output.

"For many years your directors have been ambitious to make your company a large producer of copper. Originally the Rossland Mines promised to contribute considerable quantities of this metal, but latterly the copper content is almost negligible, the gold values being the important ones.

"With the acquisition of the controlling interest in the Coast Copper Company (Quatsino) and the Sunloch Mines (Jordan River) both properties being situated on Vancouver Island the ambition referred to seems about to be realized.

Outside of the remarkable advancements in the Sullivan Mine, the outstanding occurrence of the period was the demonstration of a satisfactory process of treating the lower grade ores of the Rossland Camp—a problem that it has taken over 20 years to solve. This followed months of operating a large sized experimental mill. As a result many years have been added to the life of the Rossland Mines.

Another important incident of the period was the improved practice brought about in the concentrating mill at the Flourspar property, in consequence of which a product of the highest grade can be turned out, and also the lower grades can be produced more uniformly and economically.

The copper refinery is being enlarged to a capacity of 50 tons per day. A rod mill of the same capacity is being installed.

These extensions are necessary to take care of the concentrates of the Canada Copper Corporation, shipments of which will begin in the coming summer. Three Dwight & Lloyd sintering machines are being provided to treat these concentrates prior to the main smelting operations.

S. G. Blaylock, general manager, in a more detailed report makes the following statement:

**Copper Plant:** The main source of supply for this plant is the company's Rossland property. Owing to the very high cost of operation and the small available tonnage of ore sufficiently high in grade to offset this cost, it was not considered advisable to mine a large tonnage at Rossland. Mining operations, therefore, were conducted on a very small scale and only one copper furnace, was operated at the smelter. While the tonnage was so small that both mining and smelting costs were high, the metallurgical recoveries were the best that have ever been obtained in the smelter, and tonnage considered the costs were very low.

**Lead Plant:** Most of the ore treated came from the Sullivan Mine and consisted of crude ore or zinc plant tailings, but there was an insufficient supply of ore, a condition that will be remedied when the new Sullivan concentrators have reached the point where they can provide the required lead tonnage. There has been much improvement in the class of customs ore received, shippers taking more care to eliminate the zinc from their lead concentrates. The metallurgical work of the lead plant has been much improved, this year's work, considering the analyses of the ore treated, being better metallurgically than that of any of the last 10 years.

**Zinc Plant:** Owing to the delayed completion of the magnetic concentrator through non-delivery of machinery, the cost of production in this plant did not decline as had been expected. The cost was increased too through the raw ore dropping in grade owing mainly to the shortage of labor at the mine. The magnetic concentrator is now completed, so that much lower costs and higher production should prevail.

**Copper Refinery:** Improved methods have been introduced and better practice prevails. The product is now admitted to be thoroughly high grade and most suitable to the trade. The present capacity (20 tons of refined copper per day) is being increased 50 tons of refined copper per day, to take care of the production of the Canada Copper Corporation under a contract with that company.

**Lead Refinery:** This plant has continued to turn out its uniformly high grade product, and has shown marked improvement in costs, which are now well below the costs of a Parkes' Process Plant operating on the same tonnage.

**Gold and Silver Refinery:** The gold and silver refinery has been practically rebuilt, and is now thoroughly up-to-date.

**Zinc Lead Ores:** A floatation mill of 200 tons daily capacity was run for several months on the low grade Rossland ore. This mill proved beyond a doubt that the Rossland ores can be concentrated at reasonable cost and with good recoveries. Plans are well underway for a concentrator to handle 1,500 tons of Rossland ore daily.

**Research Department:** This department is a very important factor in the development of new processes and improving old methods, and has done much good work during the period under review.

Mining costs have been affected by the low tonnage produced in the same manner as the reduction plants. While the developments in the Coast Copper and Sunloch properties have been very satisfactory, probably the most gratifying thing has been the actual opening up of the ore bodies on the lower tunnel level of the Sullivan Mine. The ore opened up here while slightly different in character, is richer and larger than anyone expected, and assures even greater tonnage in this tremendous ore deposit. The tonnage developed at this mine easily justifies the building of a concentrator of from 2,000 to 3,000 tons of ore per day. The erection of such a plant at the mine will make great savings in freight, besides which the operation on such a large scale will greatly lower the cost of production. Another advantage derived from a mill of this size will be that it will insure a sufficient supply of lead concentrates to make a very substantial lead production.

**Flourspar:** The opening of the Rock Candy Mine and the building of a concentrator at that mine has added a new industry to the list. The company are now able to supply practically any grade of flourspar required in the trades.

### THE COLLIERIES

The production of British Columbia collieries for the month of March follows:

#### CROWS NEST PASS

	Tons
Crow' Nest Pass Coal Co., Coal Creek . . . . .	27,090
Crow's Nest Pass Coal Co., Michel . . . . .	21,529
Corbin Coal & Coke Co., Corbin . . . . .	10,116
Total . . . . .	58,735

#### NICOLA-PRINCETON

Fleming Coal Co., Merritt . . . . .	3,344
Coalmont Collieries, Coalmont . . . . .	81
Princeton Coal Co., Princeton . . . . .	993
Total . . . . .	4,418

#### VANCOUVER ISLAND.

Canadian Western Fuel Co., Nanaimo . . . . .	55,769
Canadian Collieries (D) Ltd., Comox . . . . .	32,587
Canadian Collieries (D) Ltd., Extension . . . . .	19,277
Canadian Collieries (D) Ltd., South Wellington . . . . .	7,219
Pacific Coast Coal Mines Ltd., Wellington . . . . .	10,338
Nanoose Collieries, Nanoose Bay . . . . .	1,849
Granby Consolidated Mining & Smelting Co., Cassidy . . . . .	17,566
Total . . . . .	144,595

#### NORTHERN BRITISH COLUMBIA

Telkwa Collieries, near Prince Rupert . . . . .	200
---	-----

Coal deposits situated on the North Thompson River near Kamloops City are being developed. Drilling is to be undertaken and those interested state that the necessary capital is available to open up a mine and put it on a producing basis. This is to be done as soon as the preliminary work now underway is complete. Chu Chua Coal, as it is termed has been tested out for efficiency as against the product of the Province of Alberta and the terms given indicate that it is of first class quality. A good market is looked for in Kamloops and among the different metal mines of the district.

The Settlers' Rights Act of 1920, passed at the last session of the Provincial Legislature, is not likely to receive the sanction of the Lieut. Governor, who has re-

fused his signature to the measure. This, it is presumed, he has done on advice of the Dominion Government authorities. The result is that settlers within the E. and N. Railway Belt, Vancouver Island, will not be permitted further time in which to make application and receive provincial title to the coal under their lands on proving the validity of their claims. This is the third time that the federal administration has refused to assent to like legislation passed by the Legislative Assembly of British Columbia.

### GEOLOGICAL SURVEY PLANS EXTENSIVE FIELD WORK IN BRITISH COLUMBIA DURING SUMMER.

Despite the reduced condition of the personnel of the staff of the Canadian Geological Survey Branch, Dominion Department of Mines, there will be more parties in the field in British Columbia this summer than for years past. Charles Camsell, in charge of the Geological Station of this Province, who returned from Ottawa a few days ago, has made this announcement. While the proposed distribution of the work planned has not yet been formally approved, it is confidentially expected that parties will be sent out as indicated below:

Portland Canal District, with particular reference to the Salmon River section, of which so much has been heard of late.

Eutsuk Lake Country.

Taseko (Whitewater) region. Here discoveries have been made of Hematite and Limonite ore on which W. M. Brewer, provincial mining engineer, has reported favorably. If Mr. Brewer's findings are confirmed it is figured that the deposits will have an important bearing on the question of the establishment of an Iron and Steel Industry in British Columbia.

West Coast of Vancouver Island.

Coquitalla Valley, from Hope to the Summit.

Lardean and Windermere Districts. This examination, it is stated, has not been definitely decided upon but is under consideration.

Fraser River Delta Country.

In addition to these two parties are going into the field which do not come under the jurisdiction of the British Columbia Geological Station, one into the Peace River District from Hudson's Hope to Mount Selywn and the other into the Elk Region, the latter's object being the investigation of coal deposits.

Topographic parties are slated for the districts of Alice Arm, Eutsuk Lake, Cariboo and Barkerville, Teseko District, and Vancouver and Fraser Delta.

It is assumed that the attention this Province is to receive is the result of the keen interest taken in the work of exploration in the Canadian West by Mr. Camsell as well as the fact that Hon. Wm. Sloan, Minister of Mines, at the last session of the Provincial Legislature made a fervid plea for the maintenance of the high standard of service set by the Canadian Geological Survey.

### PORT ARTHUR NOTES.

J. J. O'Connor.

A party of men left May 6th for Silver Islet, in charge of R. C. Jamison of Duluth, Minn. and J. D. Lamont, of Virginia, Minn. with mining supplies and equipment, including a large smokestack, and material for the erection on the Islet of a bunkhouse for the men.

Such of the old buildings as are still available will be put in repair for use in the new operations. One

structure, built of logs in 1870, is still intact, with walls in good condition. Very little will have to be done to the shaft house to put it in condition for use.

The work of unwatering the mine, will begin soon as the necessary surface preparations can be completed.

The Silver Islet Syndicate have under option, and are now carrying on operations on the following old properties in the Port Arthur district; East End Silver Mountain (Shuniah Weachu), West End Silver Mountain, Badger, Porcupine, Porcupine Jr. and Rabbit Mountain mines. The option requires the expenditure of a fixed sum per month, on this group of mines. The expenditure so far, has met the option requirements, up to June 15th next.

The Prince Location Syndicate, composed of Montreal and Boston gentlemen, are about to undertake a careful exploration of the "Prince Location", comprising 6400 acres situated in the township of Blake, on the shore of Thunder Bay. This was the first mining location staked and patented on the Canadian shore of Lake Superior. A Crown patent was issued to the late Colonel Prince, for this location in 1846. It was located for copper, and was operated during a part of 1845, and the whole of 1846. Men and supplies were brought from Montreal by batteaux, up the Ottawa and French Rivers, the Sault River and Lake Superior. Three men left in charge of the property during the winter of 1846-47 were never afterwards heard of. In the spring of 1847, a body was found on what is now known as Deadman's Island, and was supposed to be the remains of one of the party. From this incident the Island was named.

### MANITOBA LETTER

Experiments are being made between Winnipeg and Selkirk with wireless telephony. These are being carried out under the supervision of Prof. R. C. Wallace, and with a view to installation of necessary equipments chiefly between Winnipeg and the Rice Lake District, and between Le Pas and the Northern Manitoba mine areas which at present have no method of quick intercourse, and, at this season of the year, are absolutely cut off from all means of rapid communication. Just now, and for a few weeks to come the lakes will be frozen and the trails fit for neither winter or summer travel.

Prof. Wallace is conducting these experiments with the object also of having any installations controlled and operated by the Government. In the abstract, this is all right—but from a matter of fact point of view, it has this objection, i.e., the Provincial Government does not own its natural resources, and therefore has little incentive to go in for much expenditure even though the enterprise would be largely commercial. So we cannot look for rapid action along this line, and it is understood that no assistance would be given to corporations to install privately controlled commercial plants.

The Rice Lake district has been added to the territory over which Prof. R. C. Wallace acts as Government Commissioner. This is good news as the Professor is not only conversant with his new territory, but entertains a kindly interest for it as a prospectively rich part of the new mining areas which have recently attracted so much attention in and to Manitoba as being other than a strictly agricultural Province.

Comparatively little news is available of activities at the various mines East of Lake Winnipeg. Travel in or out is at a standstill. Navigation on Lake Winnipeg itself will not be earlier than the first week in June, as the ice is extraordinarily thick this year—being from 5 to 6 ft. in most places. The late spring, with the steady northerly winds of the last month has resulted in keeping the ice very firm.

While the summer trip to Rice Lake will, this year and from now on, be comparatively easy, those contemplating the journey this summer will be well advised to arrange for canoes before reaching Hole River. It is almost impossible, at the present time, to secure the proper kind of canoe in Winnipeg, and all canoe manufacturers seem to be well sold out of freight canoes far in advance. In all probability the Gabrielle Mines, Ltd., will arrange this summer to have a small launch on the upper Hole River which will be available for a limited freighting service. With the new Government wagon road complete it will not be a difficult matter to take in two or three tons of supplies on one trip, as the matter of portaging will very soon be eliminated.

An effort is being made in Winnipeg to offset any further attempts at "brokers" mining booms and the wildecating of mining stocks. Just recently the management of the Winnipeg Stock Exchange decided to allow the members of the exchange to trade in several of the Rice Lake and Le Pas mining companies' stocks. These will be quoted in the unlisted section. To date development stock of the following Manitoba mining companies can be quoted:—Gabrielle, Northern Manitoba Mining & Development, Bruce Consolidated, Northern Copper and Nickel, Boulder, Pan Extension, Gold Pan (8 p.c. pref.), Marigold and Golden Vein. No activities as yet have been evident as far as exchange trading is concerned, as most of the companies still have development stock available from treasury sales, but it is expected that, in the near future mining stocks will be quite active as progress reports are forthcoming from the camps, and the Winnipeg Stock Exchange taking hold of the situation in time may prove a most desirable feature in mining speculations and investments.

**FIFTEEN RESIGNATIONS FROM GEOLOGICAL SURVEY.**

The staff of the Geological Survey Branch of the Canadian Mines Department faces the season of 1920 very much thinned, and no doubt to a large extent disorganized, because of the failure of the Dominion Government to provide in the year's estimates for increases necessary to bring the salaries of these technically qualified civil servants to an acceptable standard. Many did not wait to learn what the authorities intended to do during the Season now in progress but took advantage of offers from private companies for service in various parts of the world. Those who did hold their positions expecting consideration are reported to be far from satisfied and some have since given clear evidence of their feeling by submitting their resignations. A list of those who have left the Canadian Geological Survey recently follows:

Name and place of Geological Work	Approximate length of Service Years
S. J. Schofield, British Columbia . . . . .	15
L. Reinecke, B. C. and Quebec . . . . .	13

J. J. O'Neill, B. C. and Arctic . . . . .	12
H. C. Cooke, Quebec . . . . .	16
M. Y. Williams, Ontario . . . . .	14
B. Rose, B. C. and Arctic . . . . .	12
O. A. Hayes, Eastern Canada . . . . .	12
E. L. Bruce, Manitoba and B. C. . . . .	12
B. R. McKay, B. C. and Ontario . . . . .	12
W. Wright, Eastern Canada . . . . .	13
F. Alcock, Manitoba . . . . .	10
V. Dolmage, B. C. . . . .	8
J. Stewart . . . . .	10
W. E. Cockfield, Yukon . . . . .	8
M. F. Bancroft, B. C. . . . .	10

**GOVERNMENT ASSISTANCE REQUIRED FOR ONTARIO IRON-ORE MINING**

By J. J. O'CONNOR

To prevent the iron ore situation becoming as acute as the fuel problem is today, Canada should take immediate steps to provide against such a contingency. A leaf should be taken from the book of experience now being written on the richest iron ore range in the world, the Mesabi range in Minnesota. On this range, and on the contiguous ranges of Vermilion and Cuyuna, there are many millions of tons of the highest grades of iron ore, ready at hand, susceptible of being mined by the cheap steam shovel method, yet millions of dollars are being expended in the erection and equipment of beneficiating plants, for the treatment of their low grade ores.

The experienced operators of the Minnesota ranges are quite well aware, that with an annual consumption of sixty million tons, the high grade ores must necessarily be exhausted within a comparatively short time, and, therefore, are preparing for the time when their low grade ores must be drawn upon for the nation's supply.

The percentage of treated ore being shipped from the United States Lake Superior mines, is increasing annually. Washing plants, crushing plants, and concentrating plants are being installed at many of the mines, for the conservation of ores, that a few years ago were not considered merchantable.

The huge plant now being erected at Babbitt, (formerly Argo) Minnesota, by the Mesabi Iron Co., is the most outstanding example of what is being done in this direction. This company have expended \$750,000 in the operation of a testing plant at Duluth, and in the acquiring of iron lands on the eastern Mesabi. The operation of their pilot plant at Duluth, has amply demonstrated to them, the commercial feasibility of the undertaking, and has cleared away all doubts of the success of the enterprise. They are now erecting at Babbitt, a concentrating and sintering plant, the first unit of which, is to cost \$3,000,000. This plant, will have a capacity for handling from 3,000 to 4,000 tons per day. The operations of the Mesabi Iron Co., are under the immediate direction of Mr. Dwight E. Woodbridge, M.E., of Duluth, Minn., a gentleman of long experience in the mining, handling and treatment of iron ore, on the Minnesota ranges. This company is not rushing into this vast expenditure, without having proved their theory of beneficiating the low grade magnetites of the eastern Mesabi.

The knowledge gained by these experienced operators, in the treatment of low grade ores, should be an object lesson, as to what may be done with our own

# A MARSH HOIST

## IS MADE THE RIGHT SIZE FOR YOUR MINE

and in either Steam Power or Electric Power

This shows one of our Electric Mine Hoists. We make many other types. Send for our catalogue of Mine Hoists, Cars, Cages, Buckets, etc., and see what we offer you. It will repay you.

From the little 10 Horse Power size for prospectors or small mines to the massive 50 Horse Power size, one of our 7 sizes should be just right for your mine.

We are specialists in the building of Hoisting Machinery of all sorts. For nearly a quarter of a century we have been designing and building Hoists, and have developed a Hoist that we are really proud of—proud because of the record of good work they have done, and are doing in mines, quarries, and other classes of work from one end of Canada to the other.

ores. It shows that it only needs capital and enterprise to make of our iron deposits, real nation builders.

The chief disadvantage our own ores are under is the easy accessibility of United States Lake Superior ores, so long as these ores can be imported free of duty, and at low freight rates, just so long will our own ores be neglected. Added to this ease of import, is the fact that practically all Ontario ores must go through some form of treatment. If the cost of this latter handicap were overcome, it would be plain sailing for Canadian ores. Capital would be induced to invest in the development of our iron deposits, and make Canada independent of imported ore.

Already retaliatory legislation has been asked for at Washington, in the matter of news print. If the retaliation should take the form of an embargo on the export of United States iron ore, where would Canada be? This matter is so serious, that it invites the immediate attention of the Federal Cabinet, Members of Parliament, and all public bodies, to the end that the present situation may be remedied, and Canada made independent of foreign ore.

The remedy may be found in governmental aid to iron ore operators, to the extent of the cost of treatment necessary to place our low grade ores on a parity with United States ores. There can be no division of interests in this form of assistance, the benefits would be widespread and beneficent to the whole people. The iron industry is just as basic as agriculture, just as necessary in the building up of a great country, as the latter. No word of criticism has ever been heard, in or out of parliament, against the government aid given to agriculture. No class in the community would benefit more largely, through government aid to the iron ore industry, than the agriculturists, through increased markets, better prices, and cheapened implements.

The shipbuilding industry, so necessary to an exporting country, would be very largely benefitted, and enabled to compete successfully with foreign yards. Canada is, and must be, an exporting country, therefore, to reap the full benefits of our exports, we must have ships, whether privately or government owned. We are as much a maritime country as Great Britain, and relatively, just as much interested in shipping, anything that will encourage ship-building, to the extent that government aid to iron ore would do, should have the support of every Canadian, whether he be a resident of the prairies, the metallic fields of northern Ontario, or any of our commercial centres.

### THE CANADIAN EXCHANGE PROBLEM.

By GEORGE E. ROBERTS, Vice-President National City Bank.

(From an address before the Merchants' Club of Boston.)

The exchange problem is usually more or less obscure to any one who is not intimate with it, but the principles are very simple. I might illustrate them by the situation between this country and Canada. If the payments both ways were equal, the drafts drawn in each country on the other would meet in the clearing houses and offset and cancel each other. But this country sold to Canada last year nearly \$300,000,000 worth of products in excess of Canada's sales to us. Canada must pay this balance. There is a balance in favor of Canada in her trade with Great Britain, and ordinarily Canadian bankers would draw

on London and sell the drafts in New York to settle the account with the United States, but part of Canadian exports to England were for credit and did not provide a cash balance.

In normal times, when the balance is first one way and then the other, bankers might ship gold from their reserves to make the settlements, but the total gold reserves of Canada are less than \$200,000,000, and under present conditions they might be all drained away, taking the foundation from under the whole banking credit situation. And so the Canadian government has placed an embargo upon exports of gold.

Under these conditions, the demand in Canada for means of remittance to the United States is greater than the supply, and this results in competition which has sent credits in the United States to a premium. From this side of the situation, we say that Canadian exchange is at a discount; in Canada they say that exchange on the United States is at a premium.

In the fall of 1918 the premium on American drafts in Canadian cities was about 2 per cent. In the spring of 1919 it was about 3 per cent; by November, 6 per cent, and now it is about 15 per cent. That premium amounts to an open public offer for any one to come forward and provide funds in the United States. It is an inducement to those who have the means of creating credits here to do so. A resident of Canada who owns American securities, or any securities that have a market in this country, may sell them on this side of the line and realize a premium of 15 per cent above the selling price by selling his New York draft in the Canadian market, and the same is true of the Canadian producer of any kind of goods which are saleable in the United States. The exporters of pulp and paper from Canada to this country are making handsome additions to their profits by means of the premium on exchange.

It is not a situation created by bankers or that can be cured by bankers. It is due to the one-sided state of trade. It is not a reflection upon the credit of Canada or upon the money of Canada. I read the other day of an interview with a prominent public man in Canada, a parliamentary leader, who spoke rather bitterly about the discount on Canadian exchange. He said that he would not buy anything from a country which did not accept Canadian money at its face value. That was a rather ill-considered remark. We recognize and continue to accept the Canadian gold dollar as an own brother to our dollar, but the Canadian paper money was never intended to circulate in this country. We cannot use it here. We cannot pay wages with it. We cannot pay taxes with it, and that is one of the principal uses of money nowadays. We cannot pay debts with it. The banks cannot use it in their reserves or pay it out, and merchants cannot have it. We have to ask them to settle with something we can use, and it is the competition among themselves for means of payment which makes the premium upon exchange. Moreover, it would not be desirable to have paper money issued in Canada enter into free circulation here. It would not be sound from the Canadian standpoint, for it might lead to undue inflation of the currency.

The situation is not pleasing or advantageous to us, for it is a barrier to our trade. It makes American goods cost more in Canada. We hear daily from our customers who are having trouble in holding their Canadian trade. Some of them say they cannot hold it; some of them are dividing the cost of exchange with their Canadian customers; some of them have

# THE PRINCIPLE THAT APPEALED TO ENGINEERS

## Simplified Reduction

When engineers learned that ideal step or stage reduction could be effected in a single machine—and the Hardinge Conical mill proved this by past performance—they knew it would mean a decided increase in production and a marked decrease in operation costs.

**AND IT DID!** The Engels Copper Company submitted three distinct repeat orders after using their first Ball Mill for 1 year. There is no greater proof of satisfaction.

Maximum production, continuous operation, minimum repair costs, decreased labor and operating costs are present wherever Hardinge Mills are installed.

*Let our Engineering Department co-operate with you*

been taking their pay in Canadian funds; that is, checks on Canadian banks, and some have been converting their funds into Canadian investments, which is all right if they are able to spare the capital from their business. I had a talk a couple of months ago with the treasurer of an important corporation, who said that he had \$2,000,000 in Canadian banks. He said: "We did not want to bring it home last spring when the discount was 3 per cent, we did not want to bring it home when it was 6 per cent, and we do not want to bring it home when the discount is 10 per cent." I suspect it does not feel any better with the discount at 15 per cent. He wanted to borrow against his Canadian balances. He said: "I am getting my working capital tied up in Canada." And I said: "Yes, and now you want to get our working capital tied up in Canada." That is something which has been going on to an extent which we can only estimate, but undoubtedly our exporters, not only to Canada, but to Europe, have been taking pay in foreign funds which are not realizable at present, and borrowing of their bankers to replenish their working capital. That is one factor in the rise of bank loans in the last year.

There are always people at such a time coming forward with remedies and so all sorts of arrangements are proposed now. An international currency, an international clearing house, an international gold pool and a foreign exchange bank all have been suggested, but all these people overlook the fact that in the long run trade must be brought into balance, and these high exchanges are a powerful influence to bring it into balance. The influence is to reduce exports from the United States to Canada, and to increase exports from Canada to the United States, and that is the only real remedy for the situation.

**This Convenient Powdered Separated Milk**

**KLIM** is absolutely fresh pasteurized separated milk in its lightest and most easily transported form

A dry powder that will not freeze in Winter nor sour in Summer. KLIM is always fresh and ready for use. Just whip the powder into water and make as much separated milk as you need — anytime — anywhere. Fine for tea, coffee, and all cooking.

In 10 pound tins—6 to the case—order from your Supply House.

**KLIM**  
PURE SEPARATED MILK IN POWDER FORM FOR ALL USES WHERE SUGAR MILK IS REQUIRED

## Canada's Coal Supply

Commenting on the paper prepared by the Editor for the recent meeting of the Canadian Mining Institute in connection with the coal supply, the "Colliery Guardian" of London remarks: "A thriving country such as Canada cannot face the future with any serenity if it is unable to provide for a growing consumption of fuel. . . . Happily, relations between the peoples of Canada and the United States are very cordial, but the latter country has often in recent months found great difficulty in supplying the demands of its own population, and, at the same time, is stirred by the compunction that it has obligations to assist by large contributions of coal in the industrial rehabilitation of Europe. Under these circumstances, we can conceive that the feelings of the patriotic Canadian are not very dissimilar from those of our French Allies at the present time."

We are afraid that the bulk of the Canadian population has never bothered to think out the fuel problem of Canada, except insofar as attention is forcibly drawn to it by the constantly increasing price of fuel. Neither do we think it will entail any great strain on the coal resources of the United States to supply both this country and Europe with coal. The difficulty of coal supply in North America is at least seventy-five per cent a difficulty of transportation, complicated and exaggerated by seasonal demand. There is no shortage of coal in the ground, neither in Canada or in the United States. Our neighbors come first, and we come second in possession of the coal reserves of the world. These remarks apply to bituminous coal but they require much qualification. In the case of anthracite there is a decided shortage, as was clearly pointed out by the article on the anthracite supply available to Canada that appeared in our issue of 2nd April. There is every likelihood of decreased supply and increased price of anthracite to Canadian consumers. It will shortly be a luxury for the rich alone, and we should indeed be facing calamity were anthracite so indispensable as it is popularly supposed to be.

Under these circumstances, and in face of the greatest demand for Nova Scotia coal that has been known in the Maritime Provinces, Quebec and a portion of Ontario, it is surprising to know that no attempt is to be made during the present season to bring Nova Scotia coal into the St. Lawrence market. There are

certain passing reasons that justify this condition, the chief being that the Nova Scotian collieries are producing so little coal that they cannot do more than overtake the local manufacturing and domestic demand, and the bunker and export trade that is at the present time so brisk. The present attractiveness of the export market to coal operators on the Atlantic Coasts, or having access thereto, is not to be gainsaid, but it is upsetting to all pre-conceived ideas regarding the Canadian coal trade to read in the "Financial Times" a statement attributed to a gentleman who is associated with the promoters of British Empire Steel Corporation, as follows: "We—the Nova Scotia coal operators—have been for some time convinced that the markets in the central and western provinces are practically lost to Nova Scotia coal and steel. . . . . the years of the war have given almost complete control of the St. Lawrence market to dealers in American coal." This expresses a complete reversal of the policy of those who directed the affairs of the Dominion Coal Company until it became as important a transportation agency as it was a coal-mining enterprise, and until it possessed loading plants at the mines and discharging plants in the St. Lawrence River that exceeded in speed and efficiency, and in low cost of handling, any coal transportation system in the British Empire. To imply that because through Admiralty requisitioning of coal freighters during the war period and because of shortage of miners occasioned by enlistments and the stoppage of immigration, United States' coal controls the St. Lawrence market and that this market cannot be regained, is a counsel of despair which the circumstances do not warrant. There is an immediate and pressing home market at St. Lawrence ports for not less than three million tons per annum of Nova Scotia bituminous coal. Any reversal of policy which implies that Nova Scotia coal is henceforward going to look to Europe and South America for its markets, and that the provincial operators are prepared to consider the Montreal market as the exclusive possession of United States' coal operators, will have the most dangerous consequences.

The coal reserves of Great Britain are estimated at 189,533 million tons. Those of Nova Scotia are estimated at 9,718 million tons. The total reserves of Europe are 784,190 million tons or over eighty times greater than the reserves of Nova Scotia. If it were

possible to extract every pound of coal represented by the ten billion tons which is approximately Nova Scotia's reserve, it would serve the coal requirement of the British Isles about thirty years. Compare the map of Britain and that of Canada, and consider the extent of the coal reserve of Eastern Canada in relation to its extent and expected population with that of Great Britain, and it will be speedily apparent that, unless Canada wishes to become a satrapy of the United States, it must look to Nova Scotia to provide the coal that is an indispensable requisite of national independence. Nova Scotia, so far as its coal resources are now known, contains 0.7 per cent of the coal reserves of Canada, and it is the only supply that Canada can call her very own in a territory that contains eighty per cent of the population of our country.

The dependence of Europe on America for coal is at this time very impressive, but it is only a passing phase. Europe contains great stores of coal, iron, potash, sulphur, lime, salt and timber, the essential raw materials of modern industry, and, though its present political position is a precarious one, the trained technical workers and scientists of Europe still exceed in numbers and are not less intelligent than their contemporaries on this side of the Atlantic. It is only a matter of time until Europe will recover. Recovery may take years, but it will come, and those who should exchange the policy of developing a home market for Nova Scotian coal for an export market will find that they have exchanged substance for shadow.

If coal is a first necessity of nationhood, and after 1914-1920 there can be little question about it, then the coal of Nova Scotia, and in particular the coal of Cape Breton Island, is a national asset of far greater importance than all our gold and silver mines, because it is a guarantee of national independence, and it should be so used and regarded at all times.

#### MINING CORPORATION OF CANADA TO PAY GREATER ATTENTION TO CANADIAN DEPOSITS.

The annual report of the Mining Corporation of Canada strikes a cheering note when it states its general policy to be "to lessen its field activities at great distances from headquarters, and pay more attention to possibilities nearer home." It is not the desire, or purpose, of the "Journal" to criticise the extension of the activities of Canadian mining companies to distant and foreign fields, but the number of such far away activities, and their tendency to increase, causes doubt regarding the future of such districts as Cobalt and Porcupine, as it is very well known that the large mining companies whose original activities have centred in these fields have the very best knowledge of the prospects that are as yet undeveloped. When they therefore choose to re-invest in other fields it suggests that these prospects have been found uninviting.

The publicly announced policy of the Mining Corporation, in pleasant contrast, suggests the opposite, and to that extent is encouraging. It is a little too soon yet to regard Canada as holding out no further attractions to development companies.

#### HYDRAULIC STOWING.

In this issue will be found a paper read before the Glace Bay Meeting of the Mining Society of Nova Scotia by Mr. Walter Herd, the Mining Engineer of the Dominion Coal Company, dealing with the applicability of hydraulic stowing to the winning of the undersea coal areas off Cape Breton Island. Mr. Herd has confined his discussion to that portion of the undersea coal area lying between the 200 and 800-ft. cover line, the most accessible, and therefore the most important part of the submarine coalfield. Mr. Herd did not discuss the applicability of hydraulic stowing to the recovery of pillar coal under the land, nor the extension of the system to the undersea coal lying beyond the 800-foot cover line, but some very interesting possibilities suggest themselves in both connections.

It may be forecasted that beyond the 800-foot coverline we shall see extensive winning of the undersea coal by adoption of the longwall method of extraction, assisted possibly by such application of hydraulic stowing as may prove possible when that point is reached. The conveyance of solid stowing material by water in seams of small inclination will present difficulty, and may even lead to the establishment of underground crushing plants near the goaf areas requiring to be stowed. That, however, is a very long-range forecast, but we may look for experiments on a large scale in hydraulic flushing in inshore undersea workings that will lead to a development of a local technique suited to local conditions. Mr. Herd's paper probably will be looked back upon as marking a definite break with hitherto accepted methods of extraction in the Cape Breton coalfield. The greater adoption of longwall mining in this district, both in land and sea areas is a certainty. The reluctance of the local miners to engage in this form of coal extraction will be gradually overcome, as it becomes increasingly evident that thorough-going adoption of the longwall method offers about the only possibility of profitable mining of the undersea coal.

It is of interest to know that the iron-ore workings at the Wabana Mines are also being laid out with a view to the adoption of hydraulic flushing should it seem advisable at a later date.

Mr. Wilson is an unfortunate phrase-maker. That "panic-stricken Navy" is a term which will survive, and it will be surprising if it is not adopted by the British Navy as a nickname, much as the Army adopted the Kaiser's phrase, and became the "Contentibles."

**"WHOM THE KING DELIGHTS TO HONOR"**

The presentation of the Czowski Medal at a recent meeting of the Engineering Institute of Canada to Messrs. Phelps Johnson, G. H. Duggan, and George F. Porter, in recognition of their brochure on "The Design, Manufacture and Erection of the Superstructure of the Quebec Bridge" which merited the award as being the best contribution to engineering literature of the year 1919, raises some interesting considerations. The engineers who have been so rewarded by their fellows do not require the congratulations of others, but this periodical desires to commend those who made the award, and undertook, in so doing, to name the Quebec Bridge as "the greatest engineering feat of the century." The reason we venture upon these remarks is that we believe that men who achieve success in the arts of civilization should be privileged to receive the commendation of others than their fellows, and that the accomplishment of engineering work of the outstanding character of the Quebec Bridge should be signalized by honor from that source, which in our guileless and archaic fashion we believe to be the fountain of honor in the British Empire, namely the King. Either that, or Canada should provide some means by which honor can be conferred upon her eminent citizens, (other than those circumscribed—although highly prized honors—that proceed from incorporated societies with specialized scope) through which the desire of the people to honor some chosen person may be expressed.

The resolution adopted by the Canadian House of Parliament requesting the King to confer no further honors upon Canadians meant, in fact, that Canada no longer looked upon the King and his advisors as the source and fountain of public honor. That, presumably, is a course of action well within the rights of the Canadian Parliament, but the good taste, not to say anything about the wisdom of the Resolution, are open to the gravest doubt. The offensiveness of the Resolution lies, to our mind, in its essential snob-bishness. The ordinance was by no means a self-denying one, for, while the average parliament of a self-governing country usually contains these men who excel in shrewdness and oratory, it is also usually singularly lacking in those men whom it has been the custom to honor by public decree from the earliest times because they have contributed to the world's progress in literature, science and the arts of civilization, of which engineering is not least. The Resolution meant, therefore, in addition to its remarkable lack of good taste, that a group of persons unlikely to be made the subjects of honor for their achievements of real and intrinsic value undertook to prevent, for ever, the expression of the desire of the Canadian people to honor a worthy citizen by the conferment of a title.

We would also submit that the conception of the office of the Sovereign as representing any other thing

than the voice of the people is contrary to British ideas the world over, and there is no other way under our present institutions by which the desire of the people to signalise worth in an individual can be accomplished except through our ancient and national custom of titular honours.

There are in Canada many men who have achieved world wide recognition of their achievements in engineering, medicine, literature, and art, but, within the conception of our legislators, these men are not worthy of any distinction above their fellows.

A recent issue of the "Atlantic Monthly" contained the life-story of a Russian Jewess, who, despite excellent wages and kind treatment decided to leave Toronto, "because of its parochial atmosphere." The parish-pump outlook is not confined to Toronto, but it is unworthy to parade such a viewpoint under the guise of democratic ideals or republican simplicity.

There are men who should be publicly honored for scientific and engineering achievements, and the erection of the Quebec Bridge is such an achievement.

It has been truly said that a prophet is not without honor, "save in his own country and among his own people."

---

## Correspondence

The Editor,  
The Canadian Mining Journal.

Sir,

Regulations of the University of Toronto governing students in the Department of Mining Engineering contain the following:

"Candidates for the degree in the department of Mining Engineering will be required to present satisfactory evidence of having had at least six months' practical experience in work connected with mining, metallurgy or geology, for which they must have received regular wages.

"The time may be spent on geological survey, in ore dressing, smelter or lixiviation works, in an assay office in the vicinity of mining or metallurgical works, on any work in or about a mine other than as an office man or clerk, or in prospecting. Not more than three months on geological surveys will be accepted, and prospecting will only count one-half (i.e., four months' prospecting will be counted as two months) and must not be submitted for more than three of the six months."

These regulations which were introduced some ten years ago have met generally with commendation but occasionally I have heard adverse criticism. Within the last few weeks a number of students have gone to our mining districts and obtained work along these lines, and I suggest that the matter might be a good subject for discussion in your columns.

H. E. T. HAULTAIN.

# The Suggested Application of Hydraulic Stowing to Undersea Coal Workings, With Special Reference to the Sydney Coal Field

By WALTER HERD.\*

A Paper read before the Mining Society of Nova Scotia, Glace Bay, May 14th, 1920.

## Introduction.

Although the hydraulic stowing of mine workings has long since passed the experimental stage and is today adopted with success in many European coal mines and in South African and Australian gold mines, yet with the exception of a few American thick seam mines the English speaking countries generally have been very slow to adopt what has proved to be the best method of filling the space left by the extraction of a coal seam so as to cause a minimum of subsidence.

## History.

Hydraulic stowing was first attempted in Pennsylvania, but to Upper Silesia belongs the credit of first having demonstrated its practicability on an economic basis. Previous to its adoption in that coal field about 20 years ago, seams of 20 feet to 40 feet in thickness were being worked which caused great surface damage and there was a large loss of coal through the difficulty of taking out the pillars in these thick seams. At the same time spontaneous combustion was added to their troubles, often necessitating building off large areas of coal. Since the adoption of hydraulic stowing practically the whole of the coal is extracted with a minimum of surface damage and gob fires are almost unknown. Very much less timber is required and accidents considerably reduced.

## Sydney Coal Field Conditions.

Although these conditions do not exist in the Sydney Coal Field, there is the condition of large areas of coal lying under the sea at comparatively shallow depths where it would be imprudent to extract the whole of the seam. To be more definite, this applies to seams lying under the sea and having a cover of from 200 feet to 800 feet of solid measures. Already between these depths the greater portion of the best seams in the coal field have been formed into pillars, representing at least 50 per cent. of the seam left to support the roof. No doubt in the past when considerable areas of these seams remained to be worked on the land area, the loss in leaving in these pillars did not seem so apparent as it does today, when Conservation Commissioners are bringing home to most of us the necessity of husbanding our natural resources. This should apply particularly to coal, which is a wasting asset. The Sydney Coal Field undoubtedly contains a large tonnage but it has not the illimitable resources popularly supposed. The workings in the thicker and best seams extend a considerable distance seawards and the necessity of conserving coal suitable for metallurgical purposes is very apparent.

## Recovery of Undersea Coal.

By hydraulic stowing it ought to be possible to recover the many millions of tons of coal left in pillars having 200 ft. to 800 ft. of cover. The cost of recovering all these pillars now after the lapse of many years since they were found, would in some cases be prohibitive due to the roof in the rooms having fallen and the difficulty in collecting the stowage water, and

many will have to be left till coal has a greater value than it has today, but there are many pillars which could be economically recovered at the present time. However, the plea the writer wishes to put forward is not so much for the recovery of pillars which have been formed in the past as the need for guarding against a repetition of the same procedure in the future.

In the future working of seams underlying or overlying those already formed into pillars and which extend under the sea, the writer would suggest that the area in these seams down to 800 feet of cover below the sea bottom, be blocked off into panels of suitable size, which in the case of the thicker seams would be formed into pillars to be extracted as soon as the broken work in the panel is completed, the pillar coal pulled up hill to the top level and the space left stowed by hydraulic means, as shown in Fig. 1. In the case of thinner seams the panel would be worked out by retreating longwall, the space left being filled as in the case of the pillar extraction in the thicker seam.

## Stowing Material.

Generally it may be stated that the economic success of hydraulic stowing depends upon the existence of suitable stowing material near at hand; to a lesser extent the distance the material has to be transported underground and the head against which the return water has to be pumped must be considered. Of all the substances tried as a stowing material, sand has proved the best, both from the point of view of cost and for forming a densely packed stowed area with a minimum of shrinkage. Less water is required to flush sand than other subsidences tried and less material is held in suspension in the return water, reducing the cost of renewal to pump parts and pipeline. Experiments in recent years have shown that in some cases a ten per cent mixture of clay with sand produces a better filling material than sand alone. This experience not being general may possibly be explained by some of the clays tried being more or less of a cement nature which would bind together the particles of sand after the water had run off. Where sand is not procurable, pit-refuse heaps, boiler ashes and granulated blast-furnace slag have been used with success. The last named material is however very hard on pipes and if of too porous a nature to be used alone. In one large European installation special quarries have been opened to supply stowing material, the whole of the stone being crushed before being sent to the mines. As high as 4,000 tons of stone a day has been sent from these quarries to the various mines they supply.

## Supply of Stowing Material.

The Sydney coal field is fortunate in having within a reasonable distance of the mines an adequate supply of sand. This sand could be extracted by means of suction dredges which should work backwards and forwards across the various beaches and sand bars in the vicinity of the mines. The sand would be delivered from the dredges into railway cars for trans-

\* Mining Engineer, Dominion Coal Company, Glace Bay, Nova Scotia.

port to the mines, or where the sand has only to be taken a short distance an aerial ropeway would probably be the cheaper form of transportation. 150 tons per hour can be economically carried by this means.

Where sand is employed as the stowing material it should be possible to extract the entire seam up to the present legal limit of 180 ft. of solid cover between the seam and the bottom with practically no risk of the sea breaking in. It is not possible to entirely replace the original seam with stowing material as there will always be a certain amount of shrinkage consequent upon the stowage drying, but at least 90 per cent and possibly 95 per cent of the excavated space is filled. It is a generally conceded fact that the better an excavated area is stowed the further is the line of fracture thrown ahead, making in the case of 95 per cent stowing a line which forms an angle of about 60 deg. with the vertical in a seam dipping one in nine. Conversely an area which is not stowed at all will make an almost vertical break to the surface. In other words, the better the stowing the further is the extension of the "draw," with of course proportionately less subsidence. Consequently the risk of the sea entering through a break with a line very little removed from horizontal is much less than through an almost vertical break.

**Description of Plant.**

A short description of the procedure in hydraulic stowing may be of interest to those who have not seen it in use. The stowing material, whatever its composition may be, is conveyed from a storage bin by a spiral conveyor into a hopper in the shape of an inverted cone about 3 feet diameter at the top. The reason for using the spiral conveyor is that the quantity of material to be delivered can be accurately gauged to suit the water supply. The storage material is met at the bottom of the hopper with several jets of water and a little lower down the main jet enters

ensuring a thorough mixture of the material with water. This water flushes the material down a pipe to which the hopper is attached. This pipe may either be placed in a shaft or slope from the bottom of which it is continued into the workings, or it may be placed in a borehole sunk close to the sea shore and as near as possible to the workings it is desired to stow. A simple arrangement is fitted on the hopper which stops the supply of stowing material should the water supply fail otherwise the pipe would fill with dry material which would soon choke it up. Branches are put in from the pipe to the various areas to be stowed and blank flanges instead of valves are used to divert the stowage to the required area.

**Underground Layout.**

In figure 1 the writer has endeavoured to show a standard panel formed into pillars in the usual way. These pillars are half cut and the sketch shows the panel at its maximum production. The next panel inbye is being split into pillars, the lower one being ready for extraction to replace the almost extracted lower pillar in the outside panel. These panels are designed to give a maximum output of 200 tons per day in a six-foot seam and an average output of 150 tons per day. The tonnage of sand required per panel would, due to it having a greater specific gravity than coal, be a maximum of 300 tons and an average of 225 tons per day to replace the coal extracted in pillars, but as the pillars only represent about half of the coal originally in the panel area the quantity of sand required daily will be double the figure on the average. An 8-inch diameter pipe will flush 120 tons of sand per hour under the conditions existing in this coal field, so that this size of pipe would be sufficient to store the output from two panels in one shift.

It will be observed that the stowing pipe is taken in the main level and down the headway, branches being put in to each room. The pillars are extracted

by a series of upward slices about 15 feet wide and when a cut is through it is immediately stowed. When a cut runs between the stowing and an old crosscut the latter should be stowed before the cut is begun.

The depth of the panel viz., 700 feet between main levels, may seem excessive in comparison to the width of 500 feet but the reducing of narrow work to a minimum has been kept in view also the fact that after a cut is through and has been stowed it will be a couple of days before the next cut can be started, as the stowage will take about that time to dry out, and a few extra places must be maintained to take care of the men in these circumstances. It will be noticed that after the first lift, three levels must be driven for future lifts, viz., a water level, main haulage-level and pipe level. The latter level is necessary to take out the pillar to the rise of main level otherwise the stowing would have to be forced uphill. Under certain conditions of good roof this level might be driven room width. For ventilation and also as a waterway it is necessary to keep open the main headway after the pillars have been extracted. It could be stowed as the pillars are extracted to a minimum width of 5 feet and left that way.

Fig. 2 shows an enlarged view of a cut-through about to be stowed. The stowing material and water pour into excavated area at point "A," From there to point "B" two parallel rows of props are set about two inches apart with 3 ft. between each couple, one inch boards are placed between the two-inch space forming a wall from roof to pavement, and this wall is backed with bratticecloth. As the stowing material and water flow into the space, the solid material gradually settles and the water drains off through the bratticecloth and spaces in the boards, leaving after a day or two, a hard compact filling, through which roadways can be driven. After a few days the props, boards and brattice are withdrawn and are ready for further use. The water will run through the various crosscuts till it reaches the water level and finally the sump from which it is pumped back again to the surface. In the case of using sand very little trouble is experienced in clarifying the water. All that is necessary is to lend it into the bottom of a wooden tank letting it overflow into the sump. The tank can be cleaned out after flushing ceases. Where material of a clay nature is used for stowing a series of silt recovery boxes would be required.

It will be noticed that the stowing is not flushed tight up against the next cut. If this were done it would not be possible to drain off the water. At the same time the leaving of a space ensures good ventilation, an open end for the next cut and the coal does not become mixed with the stowing material.

All stowing should be done on the night shift and telephonic communication established between the men in charge of stowing below ground and the surface.

Before the commencement and after the completion of stowing operations, water only, should be run through the pipes for a few minutes to make sure there are no obstructions.

#### Water.

The quantity of water required varies with the stowing material used. In the case of sand volume for volume is sufficient, that is 6 to 7 gallons of water will flush a cubic foot of dry sand into the workings. Twice this quantity of water would be required if material of a clay nature was used. This quantity of water is based on the assumption that no stowing material has to be forced into the workings to the rise as the water required increases very rapidly when a head is put against the stowing material.

#### Pipes.

The choice of type of pipe through which to flush stowing material is a very important matter. In the early days of hydraulic stowing the cost of renewing pipes was serious, plain cast iron pipes being used which were given a periodic quarter turn to ensure even wear. Many wore completely out due to the scouring action of the stowing material before 100,000 tons was passed through them and this to some extent accounted for the scepticism with which hydraulic stowing was looked upon for a number of years. Attention was then given to various forms of liners such as earthenware, porcelain and wood all of which proved comparatively successful. The type of pipe which of late seemed to meet with the most general approval is the oval-shaped steel or cast-iron pipe fitted with a tapered steel or cast-iron liner as shown in section in Fig. 3. The diameter of the long axis is about 3 inches and the tapered liner when made of steel has a maximum thickness of one inch. These liners are made in 3 foot to 4 foot lengths and 500,000 to 1,000,000 tons of stowing can be passed through the pipe before the liner requires to be renewed. In order to prevent these liners slipping out in the event of replacing a broken pipe in a column set either in a shaft or incline, loose flanges are inserted between the fixed

flanges as shown in Fig. 4. These loose flanges have a space area equal to the internal diameter of pipe and liner combined. Special bolts keep this loose flange fixed to the flange of the pipe above so that when the lower pipe is removed the liners are held in place.

The greatest wear takes place in bends and a simple and effective method of counteracting this wear is to have a series of ribs a few inches apart in these bends at right to the flow as shown in Fig. 5. The material collects between these ribs and protects the metal from excessive wear.

**Cost.**

It is often argued against hydraulic stowing that it will put a prohibitive cost on the coal mined. In some cases this would be so. Below, the writer has attempted to give an approximate estimate based on present day prices of the cost to instal a plant in this district under average conditions, also the extra cost it would put on the ton of coal produced. The estimate is based on one installation supplying two panels similar to those shown in Fig. 1, each producing 150 tons of coal per day for 200 days in the year. The writer does not consider it economically possible to

continue hydraulic stowing during the winter months in the Sydney Coal Field. During this period the formation of panels could be pushed forward and in the thicker seams the pillars formed.

**Cost of Average Installation.**

2 Lined boreholes 600 ft. deep 8" and 6" diameter respectively . . . . .	\$ 7,000.00
2,000 ft. of lined piping (laid) at \$2.50 per foot . . . . .	17,000.00
Storage Bin, Hopper and water supply pipe . . . . .	10,000.00
Return water pipe . . . . .	3,000.00
Pump and Motors complete . . . . .	5,000.00
<b>Total cost of installation . . . . .</b>	<b>\$42,000.00</b>

This, taking interest and depreciation at 20 per cent per annum entails a yearly charge of \$8,400.

Approximately 1½ tons of sand will be required to replace every ton of coal taken from the panels, but at the time of stowing, in the thicker seams where the panel is first split into pillars, approximately 3 tons of sand is required. In arriving at the cost the total coal in the panel is taken.

**Estimated Cost of Stowing Two Panels Producing 300 Tons of Coal per Day.**

	Per ton of coal
450 Tons sand at 50c per ton = \$225. . . . .	= 75c
Interest and depreciation on Plant . . . . .	= 14c
Pumping . . . . .	= 2c
Labour . . . . .	= 7c
<b>Total . . . . .</b>	<b>98c</b>

In the case of pillars already formed the cost would be practically double this amount.

This estimated cost is no doubt higher than would actually be the case in comparison with the coal won from the lower levels of the mine where hydraulic stowing was unnecessary; as, being nearer to the outlet, haulage charges and upkeep of roadways would be less, ventilation would be much simpler and more timber could be recovered. Again the pillars left are in the thicker and more profitable seams and their extraction, using hydraulic stowing, might not be actually more costly than certain seams now being worked. Also it must be remembered that these pillars will constitute an extra tonnage to the mines as presently developed, making possible an increase in output which would further reduce overhead charges, for which credit must be given.

**Conclusion.**

In conclusion the writer would suggest that some form of hydraulic stowing be adopted in the remaining seams to be worked under the sea down to 800 feet of cover. If this is not done then the seam could be left intact until a cover exceeding 800 feet, is reached, with the exception of driving winning places through this area to reach the coal having a cover greater than 800 feet. Beyond this cover there ought to be no danger in extracting the whole of the seam without solid packing. A Crown Lease permits of the total extraction of a seam eleven foot thick after a cover of 810 ft. is reached. It may however be necessary to carry hydraulic stowing beyond the 800 ft. cover mark, in the case of working superimposed seams simultaneously; in fact hydraulic stowing would allow of this simultaneous extraction, an operation that without it should be highly condemned, being the ruin of many mines.

The writer does not mean to argue that to introduce hydraulic stowing into the Sydney Coalfield is a simple and easy matter. There are many difficulties, but it well deserves the careful consideration and co-operation of those interested in the ultimate recovery of all the coal.

Jutland was fought in May, 1916. The United States did not come into the war until a year later. During the interval it is curious that the Germans, who had the second most powerful navy in the world, did not take advantage of the indecision and timidity in the British naval command that Washington so clearly perceived at long distance, and from a disinterested viewpoint. The Germans had the benefit of a closer acquaintance with the Navy, and were in an excellent position to judge the fighting qualities and spirit of our ships. They came out eventually, in 1918, on a piece of string.

## BRITISH COLUMBIA ADOPTS MODIFICATION OF CANADIAN MINING INSTITUTE'S PLAN FOR SOLDIER PROSPECTORS.

An outline of proposals formulated jointly by the Provincial Departments of Mines and of Industries for the general encouragement of prospecting for minerals in British Columbia and in particular for the extension of aid to returned soldiers wishing to engage in that line of work is made public by Hon. Wm. Sloan, Minister of Mines.

Briefly it is intended that 25 parties shall be put in the field, each of which will consist of two men, one a practical prospector of experience and the other a returned soldier. The parties will be grub-staked and the total number for which provision is being made will be divided among the six mineral survey districts of the Province in proportion to the population of each of the said districts.

The details in connection with organization are being placed in the hands of the Resident Mining Engineers of the Provincial Mineral Districts and Hon. Mr. Sloan states that it is expected that the scheme will become operative, at least in respect of preliminary preparation for the season's work, in the course of a few days.

Following is the complete memorandum referred to:

The general idea of such assistance is not new; it was proposed by the Canadian Mining Institute over a year ago, and the scheme as then outlined in the May, 1919, Bulletin, page 521, was to send out parties under returned mining engineers, all of whom would be paid "a reasonable salary or wage," together with expenses.

Any moneys realized from sale of properties found would belong, 75 per cent to the Government, while remaining 25 per cent would be divided among the prospecting parties.

Dr. J. A. Dresser was deputed to elaborate this scheme and to lay it before the Dominion Government. The scheme as elaborated by Dr. Dresser was fully set out in the July, 1919, Bulletin, page 725. In brief, the organization consisted of a head office under a "Chief Engineer," with staff of accountant and clerks; Divisional Engineers; and with each party of four prospectors a Field Engineer. The estimated cost of from thirty to fifty parties was from \$135,000 to \$255,000 for the field season.

The ownership of the results of such prospecting was to be 50 per cent to the field party making the discovery and 50 per cent to be divided among the entire number of men employed.

The Government to be recouped from a royalty on output of such mines as might be discovered, but the Government having no direct ownership interest in these properties.

The memorandum indicates that this scheme was chiefly intended to provide employment for "mining engineers, miners, and other suitable returned soldiers in prospecting" rather than a direct stimulus to prospecting.

In the August, 1919, Bulletin, C.M.I., page 820, is a copy of letter from Dominion Minister of Mines, Mr. Martin Burrell, dated July 8th, 1919, in which he says: "The proposal has been definitely refused by the Department of Mines."

In October, 1919, General R. G. E. Leckie proposed a scheme which aimed, not so much at providing employment for mining engineers and miners, but rather to educate returned soldiers to become prospectors. In outline General Leckie's scheme was about as follows:—

(a) To establish in cities "Prospecting Schools or Schools of Mines," where returned men could receive instruction in prospecting, elementary mineralogy, and geology.

(b) After successfully passing the "prospecting course" these men would be formed into groups of, say, ten prospectors under charge of a more experienced leader, outfitted with all requisites, and sent to some district selected by the Government, where a central camp would be established, from which the prospectors would radiate under supervision and control of the leader.

(c) When a discovery of mineral was made, it would be examined by the leader, who would sample it and send samples and report to the Resident Engineer of the Dis-

trict, and if he considered the discovery of sufficient importance, he, the Resident Engineer, would examine it and report, and might direct the whole party to do some development-work on the property.

(d) The Resident Engineer's report would then be sent to the larger exploration companies, and thoroughly advertised as for sale by tender or public auction.

The Government was expected to supply the men during schooling, etc., with a "good living." The proceeds of any sales would be divided, first, 50 per cent, to the Government; then, after deducting all expenses, the remaining 50 per cent would be divided among the men.

While both these schemes mentioned met with the general sympathy of the British Columbia Minister of Mines, neither of them seemed to be sufficiently practicable or directly to the point to meet with his unqualified endorsement.

The present need is for more prospectors in the hills, and the kind of training prospectors need, required to more nearly approach practical working conditions. Prospectors in real life do not go out in parties of ten under the control of any person; they are a very independent lot of men; the independence of the life is its very charm to them; are used to act on their own judgment, and ready to stand the consequences for better or for worse. They go out separately or in pairs, seldom more than partners.

The point desired is to offer good substantial assistance to the prospector who really desires to prospect for the chance of what mineral he may find.

With these points in view, Hon. Wm. Sloan, British Columbia Minister of Mines, has tentatively suggested a scheme only roughly outlined in the following:—

The object aimed at in this proposed scheme is to encourage prospecting in districts selected on the advice of Resident Engineers of the Department of Mines and, secondly, to create new prospectors by giving them a season's instruction in the school of practical experience under exact working conditions and under the guidance of an experienced prospector.

In extension of the present proposed scheme it would be intended to institute during the following winter a series of lectures by the various Resident Engineers, bearing on the technical and the theoretic aspect of prospecting.

The indirect benefits to be gained therefrom by the Province are considered sufficient to justify the expenditure required.

It would be proposed this season to put out twenty-five parties, each party to consist of two returned men who have been overseas. The leader to be an experienced prospector who would be in charge, and the second man a man who desires to learn prospecting.

Those selected would have to have a doctor's certificate as to physical fitness for the work. They should be vouched for as to character and willingness to work by responsible parties, and, if possible, should be recommended by one of the returned soldiers' organizations.

These prospectors would be obliged to determine to spend a definitely stated time specified by the Department of Mines, actually in the field, and at the close of the season and so often as the Department of Mines may require would be obliged to make report by affidavit giving time, places, dates, and nature of the work on which they were engaged, together with such other information as may be required of them as to the nature of the country traversed and mineral formations, etc.

The Government would undertake to provide camp equipment consisting of tent, fly, ground-sheet, blankets, cooking utensils, and tools and incidentals, which at the end of contract would become the property of the prospectors, or in lieu of such equipment the government would contribute \$50 towards the purchase of same; the prospectors to supply their own personal equipment.

Further, the Government to make an allowance, uniform for all the Province, of \$1.50 for food and other expenses, etc., to each man for each day in the field, payable monthly or as might be arranged.

At the end of the season men who had served the full term of their contract undertaking properly attested to, would be allowed, to the experienced prospector the sum of \$125 and to the inexperienced man \$100. In exceptional cases the Resident Engineer might remit a portion of the contract time.

Further, transportation to the nearest point on transportation lines, including pack-train or boats, would be paid by the Government to men going in and coming out to starting-point. So as to bring amounts expended on transportation within reasonable limits, the Government reserves discretionary right with regard to men desiring to go to districts very distant from their starting point, in which case the Government might

offer to pay a portion only of such transportation costs.

The Government will provide each man with a free miner's certificate.

The services of Resident Engineers in the districts in which the prospectors are employed and of the assay laboratories and other branches of the Department of Mines, would be available for assistance and advice to these prospectors.

All recording fees, assessments work, etc., to be paid for by the stakers, exactly the same as an ordinary prospector, and as set out in the "Mineral Act."

The following is a tentative proposal as to disposal of any claims that might be staked:—

Any claims staked by such prospectors shall belong equally to the two partners, and be so recorded in the Record Office of the District.

There shall be recorded a first charge on behalf of the Government on such claim or claims equal in amount to sums advanced by the Government to such pair of prospectors with interest thereon at the rate of 6 per cent per annum, together with a bonus equal to the amount so advanced with interest at 6 per cent per annum, computed annually. It shall be payable to the Minister of Mines and shall be a first and paramount charge upon the claims as a debt due to the Crown in the right of the Province of British Columbia.

Every such Crown debt shall be recoverable in the manner following, and not otherwise:—

(1) By taking 10 per cent of the value of any ore or mineral or gold or silver or metal, precious or base, or coal or substance mined, won, or gotten from the premises charged;

(2) By charging and recovering a sufficient portion of the purchase price on any sale of the premises charged, provided that a sale of any premises charged may only be subject to satisfaction of the Crown debt; and

(3) By foreclosure of sale after ten years from the date of the recording of the charge.

It has been suggested that in selecting the personnel of the parties, comprising in all fifty men, these be assigned, as to their origin, to the various Mineral Survey Districts about in proportion to the population thereof.

The parties would not be restricted to the district of their origin, but could elect to go to any part of the Province, subject to the approval of the Minister of Mines.

The following rough approximation gives an idea as to how this would allot the assignment of the parties:—

Memo re Population from Health Department.

District No.	Population	Percentage	No. of Parties
1	9,069	2	1
2	23,078	5	2
3	25,442	6	2
4	25,064	6	2
5	39,060	9	3
6	318,484	72	15
	440,197	100	25

**DIAMOND DRILLING AT THETFORD MINES.**

Diamond drilling on a large scale is now in progress at Thetford Mines. The Asbestos Corporation of Canada has let a contract for 20,000 feet of drilling to the Sudbury Diamond Drilling Co., and Mr. Fitzgerald, the president of the drilling company, has six drills in operation. A churn drill is being used in the overburden and five diamond drills are cutting cores. The drilling should give the owners of the property a much better idea of the future possibilities. There is a good demand for asbestos and the ever widening market makes it more necessary to learn what the resources or raw materials are.—R. E. H.

The President of the United States did not apparently believe in "watchful waiting" for the British Navy.

**JAMES MCGREGOR SUCCEEDS GEORGE WILKINSON AS CHIEF INSPECTOR OF MINES IN BRITISH COLUMBIA.**

The resignation of George Wilkinson, Chief Inspector of Mines for British Columbia since early in 1917, and the appointment to the vacancy of James McGregor, senior member of the Mines Inspectors' Staff of the Province and a trusted official of many years service, are important changes recently announced by Hon. Wm. Sloan, Minister of Mines, in connection with his department.

Mr. Wilkinson, who has accepted the management of the Pacific Coast Coal Mines Ltd., succeeded Thos. Graham, now general superintendent of the Canadian Collieries (D) Ltd., as Chief Inspector. At the time of his appointment he was the manager of the Reserve Mine of the Canadian Western Fuel Company. His term of office has been marked by signal advances especially in respect of the improvement of underground working conditions. Mr. Sloan expresses regret at Mr. Wilkinson's decision, asserts that the civil service is losing a valuable member and the public a capable and loyal servant, and wishes him every success in the performance in the duties of an active mine operator.

The selection of Mr. McGregor to the important post thus vacated it is assured will meet with general approval and this applies particularly to the mining men of the Province who are familiar with his work during the twenty odd years he has been connected with the Department of Mines. Mr. McGregor is a native of British Columbia, his parents having come from Scotland when Vancouver Island was a Crown Colony. They were among the passengers by the sailing ship "Harpocner," which reached the Canadian West early in the year 1849, his father being one of a party of eight coal miners engaged by the Hudson's Bay Company to open up coal mines at Fort Rupert Vancouver Island, the first coal mining undertaking of which there is any record in western Canada.

Among the earliest recollections of the present Chief Inspector of Mines, therefore, are those of coal mines and coal miners. He grew up in the atmosphere and as a boy went to work in the Nanaimo mines, in this way obtaining a practical knowledge that has been invaluable to him in the official duties he was to perform later as an inspector in the service of the public. Ambitious to qualify himself technically for higher and more responsible position Mr. McGregor started when a lad to attend both day and night schools, obtaining by this means a foundation which later was supplemented by private tuition under the late C. C. McKenzie, formerly Superintendent of Education for the Province of British Columbia. While Overman at the South Field Collieries of the New Vancouver Coal Company in 1888 he qualified for a First Class Mine Manager's Certificate. His standing as a citizen in Nanaimo is indicated by his election in the year 1894 to represent that constituency in the Provincial Legislature. Later he was appointed to the position of Inspector of Metalliferous and Coal Mines for the Kootenays which position he still occupied at the time of receiving his present well earned preferment.

The policy of the British Navy during the war was one adopted deliberately, and its long, patient waiting must have galled Nelson's Navy to the limit of endurance, but in the Navy orders are orders. Scapa Flow was its supreme justification.

### BUREAU OF MINES REPORT ON WEST SHINING-TREE GOLD AREA.

The Ontario Bureau of Mines has just issued a report and geologically colored map of the West Shiningtree gold area, Sudbury Mining Division. It is the work of Mr. Percy E. Hopkins of the geological staff of the Bureau. Mr. Hopkins spent four weeks in the area last September and in spite of bad weather and the short time available for the work he succeeded in getting together much useful information.

The area mapped includes parts of four townships, Churchill, MacMurchy, Asquith and Fawcett. The properties mentioned in the report include the Wasapika, Herrick, West Tree, Saville-McVitte, Atlas, Churchill, Corona, Cochrane, Miller-Adair, Foisey, McIntyre-McDonald, Bennet, Wood, Gosselin, Buckingham, Holding, Kubick, Burke, Steep, McRae, Moore, Gibson, Moore-Macdonald, Clark, Thompson-Peterson, and McGuire.

Of these properties Mr. Hopkins says "a few have promise, but they are still in the prospect stage. Whether they will become mines or not will only be determined by further developing the veins underground and sampling the same. It is not the practice of the Bureau of Mines to undertake systematic sampling of gold or other deposits this being naturally a function of the technical or professional men employed by the property owners."

Mr. Hopkins states that the greatest development in the area has been done on the Wasapika property, but the poor transportation facilities and lack of capital have retarded development considerably. When he visited the mine in September cross-cutting at the 100 ft. level was in progress.

At the Herrick property Mr. Hopkins found that a shaft had been sunk 50 feet on the "Kingsley" vein and diamond drilling to test the vein at depth was in progress. At the West Tree a shaft was being sunk. At the Atlas a tunnel was being driven into a hillside, to test a vein exposed some 60 feet higher up.

Mr. Hopkins in his report outlines briefly the geology of the area mapped and gives descriptions of the several mineral deposits which he examined. He concludes from his examination that:—"The encouraging results obtained on a few properties will probably lead to mining being conducted on a larger scale. There seems no reason why the veins which have a satisfactory length and width should not extend to considerable depth. One would also expect to find the veins underground much the same as they are within a foot or two of the surface, since any oxidized or weathered surface has doubtless been removed by glaciation. All the rock formations are worthy of prospecting except the diabase."

Copies of the report and map can be obtained on application to the Department of Mines, Queens Park, Toronto.—R. E. H.

### SHININGTREE NOTES.

It is reported that "Tommy" Saville has sold his interest in the Saville-McVittie claims, Shiningtree, to Toronto parties for \$10,000. Some work has been done recently on these properties which are now known as the White Rock claims. "Tommy" is a well known and popular prospector and guide and it is said that he and his wife were the first to discover gold in the West Shiningtree Area, though claims were staked by others a few days before they arrived to prospect an area in which the Tenagami Indians had told "Tommy" that there were outcrops of quartz. He reached Was-

apika lake on his prospecting trip and found gold in a quartz outcrop at the edge of the lake on the property now known as the Atlas. It had been staked a few days previously by Mr. Jefferson. "Tommy" staked the adjoining claims and has held an interest in them for several years.

Mr. M. P. McDonald of Cobalt is at the Atlas property in the Shiningtree district. He will have charge of development work at this property and is at present engaged in making a preliminary examination of it.

The headframe is up and machinery is being installed at the Herrick mine. The early break-up made the transportation of plant difficult; but it did not prevent the accomplishment of the task. The company proposes to resume sinking of the shaft as soon as the plant is installed and can be operated. Last summer this company carried on exploration by diamond drilling.

The road to Shiningtree has naturally been a rough one since the frost came out of the ground. The first 13 miles from Westree station to Boreland's is now in fairly good shape but the next six miles is bad and the last six almost impassible. There are some men at work on the road and it is hoped that a considerable improvement will be effected this summer. To as great an extent as possible the operators use the winter roads for transportation of heavy loads; but there is always some work that must be done after the snow has gone and any improvement in the waggon road is therefore much appreciated.

Those who travel the Shiningtree road this summer will be pleased to find improved accommodation at Shiningtree Lake. The "Palisade" Hotel, built last fall, is reached by stage from Westree. Bob Adair runs the place and it is proving popular.—R. E. H.

### DR. SORBY OF SHEFFIELD, ENGLAND.

#### Pioneer of Microscopic Examination of Rocks and Metals.

At a symposium held in London, England, by the Faraday Society, the Royal Microscopical Society, the Optical Society, and the Photomicrographic Society on the design and uses of the microscope, fitting tribute was paid to the magnificent pioneer work of the late Dr. Sorby, of Sheffield. It was Sorby who first hit upon the notion of studying the structure of rocks by cutting thin slices and examining them under the microscope. In the face of ridicule he continued his experiments until he founded the science of microscopic petrography. When he turned his attention to the structure of meteorites, he found it impracticable to obtain thin sections and accordingly he developed the plan of etching a polished surface with acid and examining it microscopically under reflected light. Thus he gave birth to the microscopic study of iron, steel and other metals—a study which has been of incalculable benefit to industry. One remarkable fact about this British genius is that he did all his work in a private room in his house, with only the simplest materials. As Sir Robert Hadfield remarked at the symposium, "from the humblest of beginnings this method of research has grown into a giant."

The foregoing tribute to the late Dr. Sorby, of Sheffield is from the South African "Mining and Engineering Journal". Dr. Sorby's memory is perpetuated in the "sorbite" constituent of steel, and is also fresh in the recollections of those who remember him in his old age at Sheffield University. Dr. Sorby, among other things, was an authority on deep-sea organisms, and on Egyptology.—Ed.

## THE TREASURE VAULT OF ONTARIO.

By J. A. McRAE.

From the silver and gold mines which have been developed in the district of Temiskaming during the past sixteen years, a total of \$240,911,729 has been produced in new wealth. Nor does this appear to comprise more than the result of having developed what mining geologists declare to be only the southern fringe of the Canadian pre-Cambrian Shield, which spreads over the most northerly reaches of northern Ontario.

The silver production from this district up to the end of 1919, having amounted to 303,610,836 ounces valued at \$182,039,972, and the gold output which only commenced in 1911 having \$58,871,757 at the end of 1919, marks a commencement which compares favorably with the world's most important precious metal mining areas.

Beginning at North Bay and extending to the northward is the great Canadian pre-Cambrian Shield above referred to. It has its narrowest point at North Bay, and spreads like a giant fan to the north, north-east, and north-west, attaining a width of perhaps 2,000 miles at its widest point, where it reaches into the Arctic Circle. This great stretch of territory has been described by geologists as the vertebra of the earth. This is believed to have been a debutant of geological time, having probably been the point where earth first projected above the sea. The series of rock formations over the greater part of the area are essentially metal-bearing.

In that part of the territory already penetrated by the railway, silver and gold in lavish quantity has been found to be associated with the rocks peculiar to the region. With this fact in mind, and also mindful of how small is the area so far opened up, and how enormous is that territory which still awaits the pioneer, the careful observer cannot avoid the logical conclusion that as wherever the outer edge of this territory has been explored it has been found to contain rich stores of precious metal, so in the unexplored area there exists excellent possibilities of similarly rich stores of metal.

Silver was first discovered in Cobalt in 1903. The discovery was the direct result of the construction of the Temiskaming and Northern Ontario Railway. The veins at outcrop were exceedingly rich, but were extremely narrow—being measured in inches. Not a few experienced mining men predicted a short life for the mines that were subsequently developed. The production of 303,610,836 ounces of silver bears testimony to the inaccuracy of the early predictions. The dividend record of \$81,000,000 is material evidence that the deposits have been worked with a high degree of commercial success.

As to the present, the silver mines of the district are producing at the rate of about \$1,250,000 monthly. An average of about 30 mines are being operated. The important producers amount to about one-half that number. Working forces engaged total about 2,700 men, while an abundant supply of motive power is generated in hydro-electric plants located on the Montreal river, within a few miles of Cobalt. For the operation of machines, etc., compressed air is supplied by a 5,000 h.p. hydraulic air compressor plant located at Ragged Chutes about nine miles from Cobalt. The largest silver-producing mine in the district is that of the Nipissing Mining Company. This property produced 3,731,892 ounces of fine silver dur-

ing 1919, thus clearly demonstrating that age has not yet impoverished the mine. The mine is rated among the leading silver producers in the British Empire.

Silver deposits in Northern Ontario are not confined to the producing area of Cobalt. Contrary to the impression often gained by visitors to Cobalt, they cover a large area. The Casey-Cobalt mine situated fifteen miles north-east from Cobalt has been a heavy producer of silver, while the Wettlaufer mine, fifteen miles south from Cobalt, produced large quantities of silver ore. In the Gowganda district about seventy miles north-west of Cobalt, the Miller Lake-O'Brien mine is located and is producing about \$1,000,000 a year. The intervening territory offers abundant scope for further exploration.

The proven riches, and the enormous potentialities lend to the silver-bearing area an excellent opportunity for capital to be employed to good advantage. The high quotations for commercial bar silver offer added incentive to intensify effort in connection with the exploration for new deposits, and the unremitting operation of those already found. In addition to this, the mining laws of the province of Ontario are such as to command the admiration of all who come into intimate touch with them; while the government, fully cognizant of the added prestige arising from the possession of a basic industry of such importance, is constantly endeavoring to encourage the development of mines. To the individual or corporation actively engaged in the mining fields, the abundant reasons for confidence in the Government's mining policy is a very favorable factor. It is to this desire of the Government to at once offer encouragement as well as protection that the citizens of this country point with much pride. Actual achievements justify the expectation of even greater rewards from future prospecting and mining in the unexplored areas.

### The Gold Mines.

After thus reviewing the record of the silver mines of the district of Temiskaming, and finding that, barring a slight decline caused by the labor strike in 1919, the value of the metal produced compares favorably with the average of the past decade, it is interesting to turn to the gold-bearing areas where the industry, though young, is experiencing rapid growth despite the economic strain to which it has been in common with other industries subjected to during the past few years.

The gold mines of the Porcupine district, though having only commenced production in 1910, had up to the end of 1919 produced \$54,205,836 out of the total of \$58,871,757 produced by the entire province of Ontario during the ten years referred to.

Perhaps the most significant feature in connection with the gold mining industry of this district is the fact that during 1919, the province of Ontario produced a total of \$10,451,688 in gold, of which Porcupine accounted for \$9,941,804. Both for the province as well as for the Porcupine mines, the 1919 achievement was the best in their history.

The leading gold mine in Canada, in fact the leading gold mine in the western hemisphere, is the Hollinger Consolidated Mines, Limited, located in the Porcupine field. This mine during 1919 recovered a net value of \$6,722,266. It closed the year 1919 with an ore reserve estimated at \$39,928,430.

The vast area over which occur gold-bearing formations has caused a significant phrase to be coined among even the most conservative mining engineers,

which is: "Northern Ontario has been scratched only."

Gold mining, while having attained leading proportions in the Porcupine district, is being carried on successfully in other localities throughout Northern Ontario. For instance, at Kirkland Lake, some sixty miles south-east from Porcupine, there are four mines which are equipped with modern mills, each with a capacity of from 60 to 150 tons of ore daily. Mining has been carried to a depth of 700 feet, the average grade of the ore for the entire Kirkland Lake camp being \$11.99 a ton up to the present. This compares with an average of \$9.19 a ton to date at the mines of the Porcupine district.

In the order of their importance, the five leading gold producing mines of Ontario are the Hollinger Consolidated, Dome Mines, McIntyre-Porcupine and Porcupine Crown, all four being located in the Porcupine field; and the Lake Shore, the leading property in the Kirkland Lake field. These five mines are each earning substantial profits, in the case of the Hollinger amounting to close to \$2,500,000 a year net, after paying all costs and providing liberal allowance for depreciation.

Diamond drills are exploring far ahead of actual mining operation, showing no change in the geological conditions down to 2,000 feet below the surface. Confirmation of this is established by mining at a depth of 1,150 feet on the Dome and the Porcupine Crown, 1,250 feet on the Hollinger Consolidated; at the time of writing, and, 1,560 feet on the McIntyre-Porcupine. In each case commercial deposits of gold ore have been found to continue, while in the case of the McIntyre-Porcupine, the gold content of the ore has increased at depth.

It is certain that but for the scarcity of labor caused by the war, the gold mining industry of Northern Ontario would be even further advanced. This is made clear by repeated statements from the mines that many hundreds of mine workers are required.

Extensive building operations, comprehensive development schemes, and a general enlargement of the scope of work throughout the gold mining districts is held in abeyance pending the time when a full quota of men will be available.

As brief but conclusive evidence of the growth of the gold mining industry of Ontario, are given in the following figures, the importance of which is that despite the economic strain experienced during 1919 the gold output actually established the highest record in the history of Porcupine, as well as in Ontario:—

**Ontario's Gold Production.**

Year	Total Ontario Production	Porcupine
1910	\$ 68,498	\$ 35,539
1911	42,637	15,437
1912	2,114,086	1,730,628
1913	4,558,518	4,294,113
1914	5,529,767	5,190,794
1915	8,501,391	7,536,275
1916	10,339,259	9,397,536
1917	8,698,735	8,229,744
1918	8,567,178	7,833,966
1919	10,451,688	9,941,804
<b>Totals</b>	<b>\$58,871,757</b>	<b>\$54,205,836</b>

Following is a summary of gold produced in 1919 from the various parts of the British Empire from

which it is interesting to note that Canada was the only country to record an increase.

	1919		1918	
	Ozs.	Pds. Sterling	Ozs.	Pds. Sterling
South Africa	8,330,091	35,383,974	8,413,292	35,758,836
Australia	1,074,713	4,565,088	1,277,474	5,426,360
Canada	767,167	3,260,459	699,681	2,973,644
Rhodesia	585,700	2,499,498	624,000	2,652,250
India	461,171	1,959,976	485,236	2,062,253

Canada's favorable record for 1920 is attributable to the successes met with in Northern Ontario, particularly in the Porcupine district.

Regarding the outlook for 1920, it is believed that the Canadian output will increase at least twenty per cent over that of 1919.

**Our Northern Ontario Letter**

**THE SILVER MINES**

The second week of May was marked by a further decline in quotations for silver. Influences at work are difficult to discern, but the chief one appears to be the British Government. As to this, the commonly accepted view of the situation as gathered from careful local observers is that the British Government has induced the banking houses of the Chinese Empire to curtail their silver purchases to a minimum, and, also, has caused the complete curtailment of silver shipments to India. The two ordinarily heaviest purchasers thus practically eliminated has so lessened the demand as to make the current supply appear adequate to meet immediate requirements.

That leading metal authorities in the United States may be more or less mystified is indicated in the presence of perhaps a million dollars in silver bullion stored in the vaults of the Nipissing Mining Company of which E. P. Earle of New York is president. That New York authorities believed prices would rule high is obvious, and has given rise to the belief that while a matching of wits may not have been indulged in between British and United States Governments, yet such may have reasonably been the case between the metal brokerage houses of the two countries mentioned.

As to the future prospects in connection with the price of silver, the "bear" raid is believed now to have perhaps attained its objective, and prices may rule for some time at around the present level. This, of course, is mere presumption, based upon the belief that further pressure would cause low-grade silver mines in various parts of the world to close down, and by thus lessening production defeat the very aims of the British Government. For that reason, pressure is expected to be regulated, and not become too severe.

As regards the outlook in Cobalt, with silver quoted at around \$1 an ounce at the time of writing, the margin of net profit is still high. The mines as a whole are able to produce silver at an average of around 55 cents an ounce. This leaves around 45 cents net profit on each ounce of silver produced, and is almost equal to the gross value of the metal in 1915.

Statistics being prepared show the mines of the Cobalt district to have ended the year 1919 with a greater amount of ore in sight than that with which the year was commenced.

The annual report of the Mining Corporation of Canada for 1919, just issued, is favorable. Production during the year amounted 1,230,652 ounces of silver, as compared with 1,708,252 ounces during the preceding year. Net profit amounted to \$908,748 as compared with \$925,760 the previous year. During the period \$622,518 in dividends were paid, thus leaving a balance sufficient to increase the surplus from \$3,025,347 at the end of 1918 to \$3,311,577 at the end of 1919. The report deals at length with the activities of the company in other fields, and contains the important announcement that from this date forward less attention will be paid to properties in faraway countries, and that the home field of Canada will receive greater attention. All other things being equal, Canada will be given the preference, with the United States taking second place and with Central America coming third. A feature of the report is that while the year's production amounted to almost as much as the total estimated reserve at the beginning of the year, the period was ended with a greater new reserve than that with which the year began.

During the month of April the Kerr Lake mine produced some 61,000 ounces of silver, as compared with 99,400 ounces in March, the decline amounting to more than fifty per cent. It is intimated that this decline may be permanent for the reason that the higher grade ore shoots in the mine are being exhausted, and that from now on it may be found necessary to deal with lower grade material. The question of making arrangements to have its 75,000-ton dump treated is still under contemplation and appears likely to be considered favorably, although definite announcement is still withheld at the time of writing.

A favorable feature of the week is the receipt of official advice that the Nipissing mine during the first four months of the current year produced \$1,501,521. This being at the rate of more than \$4,500,000 a year, is the highest record for any previous period of similar length in the company's history. In his regular monthly report, Hugh Park, manager, states that during April the mine produced \$364,258. This compares with \$384,723 in March, \$329,401 in February and \$423,139 in January. The report shows that during April no bullion shipments were made, the output being stored in the company's vaults at the mine.

Cobalt mining men and prospectors are taking considerable interest in the Butt township area in the district of Nipissing where the promising discovery of radium-bearing ore was made last year. The Mining Corporation plans an early commencement of exploration work on its claims in that district, adjoining the original discovery group.

The assent of the Lieutenant-Governor is still being awaited in connection with the proposed construction of a light narrow gauge railway from Elk to Gow-

ganda. The indications are that the construction of the line will mark the commencement of added activity in that district.

Stuart M. Thorne has taken over the management of the Castle property of the Trethewey Company, and has engaged Wm. Gowans as assistant. Mr. Thorne was manager of the Trethewey prior to enlisting for service overseas in the late war. His re-appointment is in accordance with an understanding at the time of his enlistment.

The Oxford-Cobalt is making good headway with its exploration work on property in Gillies Limit. The shaft is now down 50 feet and is being driven to a depth of 200 feet at which point lateral work will be carried on. Later on it is proposed to continue the shaft to a depth of 300 feet.

Arrangements in connection with the operation of the Victory Silver Mines, formerly the Hylands property, are again being made after a temporary delay in connection with the details. It is now proposed to increase the authorized capital from 500,000 shares as at present to 2,000,000 shares.

### ORE AND BULLION SHIPMENTS

During the week ended May 14th four Cobalt companies shipped an aggregate of ten cars containing 715,131 pounds of ore. Nipissing was the heaviest shipper, sending out five cars, as shown in the following summary:—

Shipper	Cars	Pounds
Nipissing . . . . .	5	388,707
Mining Corp . . . . .	3	214,809
Coniages . . . . .	1	87,360
O'Brien . . . . .	1	64,255
Totals . . . . .	10	755,131

During the corresponding period, no bullion shipments were made, although it is learned in official circles that a limited amount will be released during this week.

### THE GOLD MINES.

On account of the distinction won by the gold producing mines of Northern Ontario during 1919 in making it possible for Canada to lay claim to being the only country in the world to increase its gold output during that year, added attention is being directed to this country by leading mining interests the world over.

Also, despite the most severe economic conditions, the mines of Porcupine and Kirkland Lake are actually producing now at a rate about twenty per cent greater than during 1919. Events following one upon another tends to make the likelihood of quite general expansion in the leading gold-mining areas of the province.

Shareholders of the Porcupine Crown Mining Company, and the Thompson-Krist Company have ratified the by-laws authorizing the transfer of the two properties to the newly incorporated Northerown Mines Company. The management will continue as at present at the Porcupine Crown.

Shareholders of the Porcupine V.N.T. await with interest the holding of the annual meeting of that company to be held May 27th. It is thought that some action may be taken with regard to obligations entered into some three or four years ago by Sir Henry Pellatt to underwrite a block of treasury shares. The agreement at that time specified a price ranging from

40 to 60 cents a share, as compared with current quotations of around 18 to 20 cents on the open market.

It is stated that the annual meeting of the Dome Mines Company will be held about June 18th, and that the annual statement for the fiscal year ended March 31st will soon be in the hands of the printers. While reticence is maintained as to the contents of the report, it is understood that a surplus of upwards of \$750,000 will be shown. The achievement is regarded as exceedingly favorable as when the company resumed operation of its mill a year ago, the surplus at that time amounted to only \$56,000 and during the intervening period the shareholders have been paid \$200,000 in dividends.

Discussion of the affairs of the Gold Reef Mining Company will take place this week with a view toward arranging a program of work for this year. It is intended to sink a shaft to a depth of perhaps 300 feet for the purpose of exploring a vein indicated as a result of diamond drilling the property last year.

In the Kirkland Lake field the large volume of money being subscribed by United States interests toward exploration and development of new prospective mines is steadily increasing. Buffalo, Dayton and Rochester appear to have become alive to the favorable prospects and are now heavily interested.

Arrangements are being completed to resume work at the Tough-Oakes at the end of this week, and by June 1st it is hoped to have operations again well under way. Through the merging of the Tough-Oakes, with the Aladdin-Cobalt and the Burnside, ample funds have been provided to take care of the aggressive development program outlined, and sufficient ore is assured upon which to resume milling operations about the middle of July.

The Ontario-Kirkland has established another working level at a depth of 450 feet and the lateral work required to prove up the downward continuation of the ore bodies found at the 300-ft. level is underway. Following the completion of this work, the question of installing a mill will be gone into.

The Lake Shore, Teck-Hughes and Kirkland Lake all continue to produce at a normal rate, with prospects of an early further increase in output. The supply of labor is still below normal, but conditions seem to be showing some improvement.

The work in connection with mill installation at the Wright-Hargreaves is under way at full swing and it is evident that this mine will join the producing list by the end of the summer.

Farther east in the township of Lebel some real progress is being made, and the prospects of new mines being developed appear bright. The Bidgood property is standing up well under aggressive work, while on a number of other properties good results are also obtaining.

The Boston McCrea Company, controlled by Buffalo and Dayton interests has purchased the Jerred group of claims on which a vein some three feet in width and containing tellurides of gold has been opened up for a distance of about 200 feet on surface. In a test-pit driven to a depth of 15 feet the vein is found to carry an average gold content of about \$25 to the ton. It is proposed to add to working forces immediately and to prosecute a vigorous exploration and development campaign.

Other properties in Lebel where good results are reported include the Wood-Kirkland and the Pinelle group.

From Skead township, returning prospectors report at least two new gold finds, and further increased activity. On their own initiative the enterprising claimholders of this area have cleared a road to the railway by way of Boston Creek, thus reducing the distance to rail by some 26 miles to between 8 and 12 miles. The road is now passible for teams and wagons with the exception of the crossing of the Blanche River. The Ontario government is being requested to bridge the stream.

At the 500-ft. level of the Miller Independence, while the cross-cut has not yet reached the point where the downward continuation of the main ore body is expected to be encountered, it is officially reported that in a small vein cut gold tellurides have been found. This is taken to indicate the likelihood of satisfactory mineralization at that depth.

Re port last week that the management of the Fort Matachewan Gold Mines had undergone a change were erroneous. Official advice to the "Journal" conveys the information that T. J. Flynn is still manager of the mine.

The report written by Percy Hopkins, geologist for the Ontario Bureau of Mines of the West Shiningtree Gold Area is receiving favorable comment in the mining centers. The frank declaration that mineral deposition has so far been found to be patchy, but that considerable inducement is offered for further work is received with fairly general satisfaction. It has appeared to place the standing of the district on a firmer footing than that formerly enjoyed, and the early future is expected to witness greater attention being paid to the exploration and development of the numerous promising prospects in that field.

---

#### PERSONAL.

Mr. Henry Schoch, Sales Engineer of the General Briquetting Company, has been elected Vice President of the Nukol Fuel Company, of Ontario, Canada—and will take up his work for that Company with headquarters in Toronto on May 17th.

The Nukol Fuel Company is actively manufacturing "Nukol," a high-class anthracite briquette for the Ontario Market. One plant is operating in Toronto; another is in course of construction at Port Stanley, and three more are prospected within the next two years.

---

Dr. Edwin T. Hodge has accepted the position of Professor of Economic Geology at the University of Oregon, and expects to leave Vancouver about October first.

During the past few years Dr. Hodge has been active in furthering the advancement of the mining industry in British Columbia. At the present time he is President of the British Columbia Chamber of Mines, on the executive of the Vancouver Branch of the Canadian Mining Institute, and is a member of the Mining Bureau of the Board of Trade. He was convener of the last C. M. I. convention, held in Vancouver. He was at the head of the contingent of B. C. Mining men who attended the recent International Mining convention held at Seattle, and took a very active part in the proceedings.

For the present Dr. Hodge has opened consulting offices in Vancouver, and will have branches in Seattle, and Portland for a group of engineers.

## British Columbia Letter

### THE METAL MINES.

#### Stewart, B. C.

The concentrator designed to treat the lower grade ores of the Premier Mine should be ready for operation before many weeks as the last of the machinery has been despatched over the trail. The mill will have a capacity of 100 tons daily and will be the first unit of a larger plant. Diamond drill development on the property is proceeding the contract being in the hands of Boyle Bros., of Spokane Wn.

It is stated that Boyle Bros., of Spokane Wn., have obtained a contract to perform 12,000 feet of diamond drilling this season on the Province Claim of the Big Missouri Group, Salmon River.

High grade ore, recently struck on the Forty Nine Group, Salmon River, is being developed, drifting being underway. Wesley W. Warren, consulting engineer, is directing operations and it is expected that it will be possible to commence shipping this year.

Lieut.-Col. T. A. Hiam, who is connected with the Pacific Coast Exploration Company which controls the Big Missouri Group, Salmon River, as well as other properties in which Sir Donald Mann is interested, is responsible for the statement that a limited service may be inaugurated this year on the Canadian Northwestern Railway. This road traversed the Bear River Valley from tidewater to its upper waters. The railroad was constructed years ago and has been lying idle since. If it is possible to put it in shape for rough and intermittent service it will be a boon to prospectors and mine operators.

#### Hedley, B. C.

A dispute between the employees and the management of the Hedley Gold Mining Co., regarding wages has been settled, the former receiving fifty cents a day increase. The minimum wage paid to any man in the mine now is \$5 a day. G. P. Jones, the manager, states that it is not certain that the property will be able to operate at a profit under these conditions but he was willing to give it a trial, hoping that the Government would pass a bill giving a bonus to gold mine operators of \$10 per oz. for gold used for manufacture.

#### Trail, B. C.

The supply the new concentrator to be installed at Trail B. C. the Consolidated Mining and Smelting Co. of Canada is constructing a pumping plant possessing some novel features. In order to be at the required distance from the water in the Columbia River at its lowest stage, and to avoid being flooded at high water, the plant is being housed in a waterproof solid concrete chamber approached by a waterproof sloping tunnel also of concrete. The tunnel portal is well above high water mark.

#### Kalso, B. C.

At the annual meeting of the Gibson Mining Co. Ltd., held recently, officers were elected as follows: President, F. E. Archer, Kalso; vice-president, S. C. Warr, Spokane; secretary-treasurer, E. H. Latham; directors, W. H. Phillip and D. P. Cosgriff. The property now is involved in litigation which, however, it is hoped will be straightened out before long, thus permitting operation on a satisfactory basis.

#### Sidney Inlet, B. C.

It is announced the the new 300-ton mill, recently installed by the Alaska-British Columbia Metals Company at Sidney Inlet, Vancouver Island, has commenced operations.

#### Nelson, B. C.

The Vincent Development Co. has relinquished its bond on the Eureka Mine, Eagle Creek, after doing considerable development. This work done consists of stoping on the 250-ft. level and driving a long cross-cut on the 450 foot level with the object of striking the vein at depth. The Company proposes making a thorough examination of the Granite-Poorman Property, which it also has under bond, as soon as the snow leaves, with the idea of formulating plans for its development.

#### Dawson, Y. T.

The ice has broken on the Yukon River. This occurred some weeks ago. Navigation on the entire river soon will be possible. A considerable influx of miners and prospectors will take place to the Mayo Silver Camp. Spring operations are already underway in the Klondyke. The thawing of the dredges is underway and before the end of May it is expected that much hydraulic work will be started.

#### Vancouver, B. C.

Counsel representing the Dolly Varden Company has made application to the Supreme Court of British Columbia for an extension of time in which to file its statement of claim in connection with action being brought against the Taylor Engineering Company, holders of the Dolly Varden Mine, Plant, Railway, and general mine and transportation equipment. The explanation of this course is that the first mentioned Company does not wish to act until the Dominion Government has had an opportunity to disallow the legislation passed at the last session of the Provincial Legislature re-affirming the title of the Taylor Engineering Company to the rich Alice Arm property.

Metalliferous mining in the Sloean District of British Columbia has been tied up by a strike of the miners, who are demanding an increase of one dollar a day in wages. One of the richest silver producing camps of the Canadian West thus has become inactive for an indefinite period.

### THE COAL MINES.

The coal miners' strike in the Crow's Nest Pass, which has more or less affected the mines of that district, particularly in the Alberta section, since the beginning of March, has been settled, according to a statement issued from the office of the Director of Coal Operations. There is a full crew working at Blairmore; at Bellevue the men are being taken on rapidly and much the same condition is reported from Hillcrest. The adoption of a new wage scale in line with United States' rates which would mean an additional increase to the miners' wages of about 11 cents a day, is to be discussed.

Lump coal for domestic use now is selling in Victoria, only eighty miles by rail from the Nanaimo collieries, at \$13.50 a ton. For nut coal the charge is 50c. less. A few days ago the retail merchants an-

nounced an increase of \$1 a ton which brought the sale figures to the point named. They state that no benefit whatever will accrue to them from the advance which will be absorbed by the following increased charges; (a) An advance of 65 cents per ton at the mine. (b) A towing-charge advance of 10 cents a ton. (Most of the coal used in Victoria is transported from the mines by water.) (c) An increase to the men employed in the handling of coal at the wharves and delivery of 25 cents per day. (d) An increase in gasoline and oil for deliveries.

**TECHNICAL EDUCATION IN RELATION TO COAL MINING**  
**British Columbia Night Schools and Correspondence Mining Classes**

Pursuant to the Public Schools Act passed in 1914 night classes were established at different coal mining centres of the Province for the benefit of those who wished an opportunity to continue studies left off when they went to work and to qualify technically for higher and more responsible positions in connection with coal mining operations.

While admittedly this was a move in the right direction, it was agreed by the Provincial Departments of Mines and of Education in 1919 that this did not go far enough, that the miners on leaving the mines after a day's work could not be expected to leave their homes to spend the remainder of the day's leisure hours in school, and that more good would be derived by the establishment of a system of education by correspondence. This would permit the student to do his work at home, to study in quiet without leaving the house, to answer the questions asked by mail and to prepare his replies for posting the next day.

This system, therefore, was introduced and its popularity and success have been gratifying. Of a total of 88 applications received for registration for instruction by correspondence, 44 are boys who are taking the preparatory mining course, 16 of whom are residents of Nanaimo and 28 of Cumberland, so that a large proportion of those who are taking advantage of this educational opportunity belong to the chief coal mining centres of Vancouver Island.

As to the Mining Classes it is interesting to note that they continue to serve the purpose for which they are intended. These classes are established at Nanaimo, Fernie, Coal Creek, Merritt, and Cumberland. The average attendance at each of these schools per course follows:—

Nanaimo .. . . .	7
Fernie .. . . .	8
Coal Creek .. . . .	8
Merritt .. . . .	11
Cumberland .. . . .	7

As to fees the Provincial Government has made them so low that they may be termed nominal, causing no hardship to those who are in earnest. For instance applicants for registration in the correspondence preparatory course are required to pay only \$5.00. This course, it may be explained is sub-divided or graded in sections running from "A" to "F," the former grade providing for elementary study and the various intermediary grades to "F" carrying the student to the point where he may sit for a Mine Manager's Certificate. It is interesting and gratifying to note in this connection that the operating companies of Nanaimo and Cumberland (Canadian Western Fuel Co. and Canadian Collieries (D) Ltd., have shown their

interest in the ambitious boys of their respective sections and in their employ by paying their admission fees.

Other courses, together with the fees set, are as follows:—

Preparatory course in arithmetic .. . . .	\$10.00
Course for Fireboss, Shiftboss, or Shotlighter's papers (3rd Class) .. . . .	15.00
Course for Overman's papers (2nd class)	25.00
Course for Mine Manager's papers (1st Class) .. . . .	35.00
Course in Mine Survey Work .. . . .	35.00

The laying out of these studies, setting the questions, correcting answers, etc., is in charge of James Hargeaves, who is attached to the Department of Education. He is a mining engineer, a holder of First-Class Mine Manager's Certificate, in short a highly qualified man technically as well as a practical miner with experience covering years in this Province as well as in Alberta.

In regard to the mining classes in the different centres, the teacher is selected by the Department of Education from residents of the districts in which the school is opened. He must have the necessary qualifications, of course, and the utmost care is exercised in his selection. His salary is paid as follows: Four-fifths by the Government and one-fifth by the School Board of the Municipality, this last named body also taking care of incidental expenditure.

**Correspondence**

**IRON ORE BOUNTIES IN ONTARIO**

Port Arthur, May 8th, 1920

To the Editor,

"Canadian Mining Journal."

Dear Sir:—In your issue of March 6th, 1920, there is an article taken from "Iron and Steel of Canada" on the Iron Bounty question which is being presented again to the Federal Government for consideration.

Special attention is drawn, and rightly to Mr. Mills' expression as to the advisability or necessity for developing our own iron ore deposits.

The Port Arthur Board of Trade has a mining Committee entirely of owners, prospectors, geologists and engineers who have, as far as lay in their power, given very careful consideration to the question of developing the iron ores of Northern Ontario. Up to the present time, however, the Minister of Mines has not met this Board, or as I can learn any member of it to discuss this matter at all. While it was quite true that in an issue of your journal of January 23rd, there was an article stating that a deputation of mining men from the City Council had been invited to meet the Minister of Mines, it was also quite true that this invitation never reached the Mining Committee of the Board of Trade and as far as I have been able to ascertain, there was not a single man in that City Council who has any special knowledge of mining, more particularly the more intricate subject of the development of our iron ranges.

In connection with the conserving of our iron ore reserves as stated by Mr. Mills, why not go further if we wish to take that line of thought and conserve all our coal, go on importing in huge quantities, our nickel deposits, also our pulp-wood areas, and only manufacturing what we need absolutely for our own use. As it takes forty years to grow spruce trees of

merchantable size, it can readily be seen our present areas might easily be largely or partially used up before new forests can be brought into service. We have iron-ore reserves in Northern Canada that will fill all demands for probably several thousand years. Many of these ranges are of course inaccessible at the present time, but can always be made available when urgently needed.

The Minister of Mines of Ontario is also much interested in the project of bringing iron ore from the Belcher Islands, Hudson Bay, down to the proposed Terminal of the T. & N. O. Railway, thence over that line to Lake Ports. As this ore is admittedly of low grade, freight charges alone would more than cover the total returns of the ore, leaving nothing for mining costs or any other branch of the work. This project was carefully considered a few years ago by very competent engineers who simply stated that it was economically impossible and the condition now exists that though iron ore prices have increased greatly in the last two years, freight charges and costs of production have also increased in proportion.

In the article taken from the "Iron and Steel," it is stated that those who are requesting a bounty desire it to be paid upon the quantity of pig iron or steel made in Canadian furnaces or mills from domestic ores. **There is absolutely no foundation for such a statement.** A large number of Boards of Trade made representations to the Government asking for a bonus on iron ore to be payable to the operator of the mine, for the principal reason that formerly when bounties were paid on pig iron produced, the operator of the mine received none of this assistance and he is the one who does all of the pioneer work, puts up with the fluctuations of iron ore prices, etc., while the smelter received a great amount of assistance from the bonus during the lean periods. This plan was proven to be a failure by the results of the former bonus which was given to pig iron produced, and the fact that the same bounty given recently in British Columbia to smelters has not had the desired effect, the development of the iron ore resources remaining as before.

The Algoma Steel Corporation is in the rather unique position of being mine operator, beneficiator and user of its own beneficiated ore. Last year they produced a beneficiated ore from the Magpie Mines which ran, natural analysis, Iron 49.41 per cent, Phos. .014 per cent, Silicia 8.68 per cent, Mang. 2.72 per cent, Lime 7.82 per cent, Sulphur .16 per cent, Loss by ignition none, Moisture 1.72 per cent. This makes a very desirable product, and while it is quite true that individual furnaces might not take a very great tonnage, the same reasons for not doing so would apply to many of the larger producers of straight mine-run ore in the United States. The marketing of beneficiated ore should not be any special worry as this is going on quite steadily from different States.

For its own furnaces and mills at Sault Ste. Marie the Algoma Corporation expects this year to use 40 per cent of its beneficiated ores and there will be ample demand in the American markets for any surplus. The granting of a bonus on pig iron would suit this isolated case admirably, but as the greater ore reserves are tributary to the head of the lakes, these would not receive any benefit.

The smelters and steel mills of Eastern Canada have received millions in subsidies, while the production of iron ores for domestic uses has dropped to 4 per cent of the raw material used. As this plan was a complete failure, why not give the bonus to the operator of the iron mine, and get this great import reduced.

The Western Provinces which were the strongest in opposition to the granting of the bonus on iron ores had no hesitation in recommending expenditure of public monies on the development of their coal resources, as is evidenced by the programme now arranged in the Western Provinces for the expenditure of \$400,000 in experimental work on the western coal ranges. This sum is divided as follows:—50 per cent paid by the Federal Government and 25 per cent payable by each of the two Western Provinces, Manitoba and Saskatchewan. The principal objection would seem to be the word bonus.

Other writers in different articles have stated that the Government should give a bounty sufficient to pay the beneficiation. Personally, I would not be in favor of such a plan as the cost of the beneficiation varies so much that there would be endless controversies. The mine owners do not want to be guaranteed a profit, but simply assistance to tide over the installation of large plants which could only be planned after extensive and costly experiments on the individual ranges. This would be absolutely necessary as the operation that would suit one selection of ore might be entirely unsuitable for another. To give a bonus on Canadian ores equivalent to cost of beneficiation, to place these ores on a parity with straight ore mines, would mean that as soon as the bonus stopped the mines would have to shut down.

Suggestions have been made and it has been broadly hinted that if a bonus is granted at all it will be for \$1.00 per ton and for a short term of say, from three to five years. This would suit Moose Mountain and the Magpie Mines, but would be absolutely worthless to any other part of Ontario.

It would take weeks, if not months, to complete negotiations in connection with the acquiring of a range; months for an expert survey of the same; still more months for diamond drilling to ascertain tonnage and get information as to plant needed at least a year to get this plant delivered and erected; another year to get on a reasonable shipping basis, but it would not take many minutes to figure out how much of the short-term bonus one would get. The benefit in figures would be represented by ciphers only.

A bonus of 50 cents per ton on iron ore for a term of fifteen years would have a far greater effect and a much more equitable distribution than a larger grant for a shorter term of years. This bonus should be payable only on production of certificate of sale to smelters or manufacturing agent.

Beneficiation must come and soon. So far as is known there are no large ore bodies of commercial grade in any of the provinces, but so little exploration has been done, and so many miles of favorable structure have been found on of the iron ranges that it is quite safe to assume that large bodies of good grade ore will be found, but it may take years to locate these, while it would take but a few months to bring our large deposits of easily accessible low grade material into active service.

The United States operators are turning their attention to this problem more and more every year and in a generation or two, when the larger deposits of marketable grade ores are worked out, they have only to turn to their own almost inexhaustible supplies of lean ores. They will probably never have to call on the Canadian ore reserves for any supply.

The solution of the problem of the iron and steel supply for west of the Great Lakes and provinces east of the Rocky Mountains would be comparatively easy by following out the same line as was followed in establishing shipyards and dry-docks where **most needed** in the Dominion. Given a similar subsidy for for a term of years on actual capital invested, we would see large steel works established where Iron, Coal, Power and Shipping meet, at the Head of the Great Lakes. Enough of a subsidy to give the iron mine operator 50 cents per ton for an equal number of years could easily be arranged and this development could go on at once, as would be absolutely necessary before the establishment of mills and furnaces. The Government would not pay out one dollar unless it was well earned, and the resultant revenue, not only to the Government, but also to the Canadian National Railways which serve 75 per cent of the Iron Ranges of the Canadian Lake Superior Districts, would in itself much more than balance the expenditure. Every agriculturist in the west utilizes from \$1,000 to \$5,000 worth of steel and iron implements. On every one of these there would be effected a saving of from eight to twenty per cent of cost in the freight charges alone by the establishment of such a system, and the tariff critics would be saved much labor and argument.

Yours very truly

J. E. MARKS

#### TORONTO NOTES ON MINING COMPANIES.

Among the new mining companies recently incorporated under the Ontario laws is the Miller Lake Silver Star Mines, Limited, with an authorized capital of \$2,000,000 and head office at Gowganda. The Camburn Silver Mines, Limited, have been granted authority to increase its capital stock from \$1,500,000 to \$3,000,000. The Bousquet Gold Mines, Limited, with head office at Haileybury, has been formed and granted a charter, with an authorized capital of \$2,000,000. The provisional directors are R. R. Tough, G. Tough, J. H. Tough, Pearl Devenny and Dollie Dwyer.

At a meeting held on May 10th the shareholders of the Thompson-Krist Mining Company approved of the action of the directors in the amalgamation of the company with the Porcupine Crown and the North Crown Mining Co. of the company's stock of \$1,900,000 there was represented \$1,800,000. It was also stated that a meeting in Montreal gave similar endorsement to the merger. Plans for the operation of both mines will be discussed at a meeting of the directors of the new company to be held in Toronto in a few days. The board will comprise six directors of the Porcupine Crown and three of the Thompson-Krist.

The Iroquois Mining Co. which was incorporated in 1911, with head office in New York, was wound up in Toronto this week on the application of R. T. Newman, a creditor for \$858. The capital stock of the company was \$1,000,000 and the liabilities are \$4,122.

#### OBITUARY

L. T. O'SHEA, Hon. Secretary of the Institute of Mining Engineers,

The "Canadian Mining Journal" regrets to learn from English advices to hand of the death of Captain Lucius Trant O'Shea, Professor of Applied Chemistry in the University of Sheffield and Honorary Secretary of the Institution of Mining Engineers.

Professor O'Shea was a pioneer worker in the chemistry of fuel, and the phenomena of mine gases. In the chemistry of the coke-oven he collaborated with Mr. G. Blake Walker at the Wharfedale Silkstone Colliery, where the first by-product coke-ovens in Britain were installed. To his work on the chemistry of mine gases, and his lectures to mining students on this subject is due a great deal of the improved knowledge of the behavior of mine gases now possessed by coal miners in the Midlands District of England.

Professor O'Shea was the son of Major Rodney O'Shea of the 20th Regiment, and his mother was a daughter of Admiral Lucius Curtis, and, he was to be expected from such parentage, he took a keen interest in military affairs. He served, as a Royal Engineers Volunteer, through the whole course of the South African War, and during the recent war was commander of the O. T. C. of Sheffield University.

The respect in which the late soldier-professor was held is shown by the attendance at his funeral, which included the faculty of Sheffield University, representatives of the Institution of Mining Engineers, Coke Oven Managers' Association, Sheffield Society of Engineers and Metallurgists, Midland Counties Institute of Engineers, Manchester Geological Society, Mining Institute of Scotland, Midland Institute of M. C. and M. Engineers, North Staffordshire Institute, many colliery companies, military organizations and other technical societies not mentioned.

One of the most valuable historical papers of recent years was "Notes on the History of the Safety Lamp," which Prof. F. W. Hardwick and the late Prof. O'Shea prepared in collaboration for the Institution of Mining Engineers in 1916. This is the completest monograph on the safety lamp as yet published.

The Editor was a student under Professor O'Shea and received many personal kindnesses from him, and desires to be included in the hundreds of mining men to whom Prof. O'Shea's forceful and yet kindly personality is still a source of inspiration and pleasant memory.

Those who month after month watched the assemblage of convoys, and their regular departure under naval guard from the harbours of Sydney and Halifax did not notice any signs of panic during the late war.

Coal and steel shipments from Sydney, Nova Scotia, were never once interrupted during the war. It was very very occasionally that watchers on Canadian shores saw a glimpse of the ships of the Navy, but they also never saw a German ship.

## Labor Turnover of Industrial Plants, and What Steps Can Be Taken To Minimize It.\*

By A. W. MACDONALD, Welfare Superintendent Dominion Steel Corporation.

It is only within the past few years that the question of this factor in the labor problem has received very much attention from executives.

When it is realized that labor cost is by far greater than material cost in producing, it behooves companies employing large numbers of men to devise ways and means of reducing the turnover of labor on their plants to the lowest figure possible.

It has to be admitted that the putting to work of new men is one of the most important causes of a high accident rate.

Comparatively few employers have realized that for every man on their pay-roll they are probably hiring at least one new man every year. This shows a labor turnover of 100 per cent and should be a sufficient argument to cause any employer to study the reason for his works labor turnover. Any manager or superintendent of an industrial plant or other works employing large numbers of men, who is still of the opinion that the methods that obtained ten years or more ago are good enough to-day, as far as the hiring and discharging of workmen is concerned, is making a mistake that is costing his company dearly.

It might be well to give some consideration to what it costs a company to make a new employee efficient, that is to bring him from the stage of a "green man" to that of being a productive workman.

Some of the sources of this cost are:

(a) The difference between a standard day's work and that which a new man does while getting used to the job.

(b) The extra supervision required by a green man.

(c) Interference with the work of other men.

(d) Accidents caused by green men.

Various executives have computed the total amount of the costs according to their own conditions, and the results range from \$25.00 to \$100.00 per man as the cost to a company of bringing a green man up to the stage of a productive workman.

It is evident therefore that the cost of replacing workmen is enormous and the necessity of taking drastic measures to prevent labor turnover is of first importance.

Of course to get rid of an employee is far easier than to help him "make good" and to let him go less troublesome than to find out in advance any condition of dissatisfaction and to attempt to remedy it.

One of the chief reasons why this matter has received so little attention from companies in the past is that they have no records to show what their labor turnover was, and therefore they did not know what it was costing them.

In the last analysis this hiring of men to replace men who have left the employ or, in other words labor turnover, is simply wasting labor, particularly at this time when men are scarce and most companies have already passed from the position of buying labor to selling employment, and it is clearly a matter of sound business for industrial organizations to hold out inducements for capable men to enter their em-

ploy, and to fully develop the capabilities of those they get.

The only reason why a company engages in business is to make profits, and any activity of the company that does not tend toward that end is poor business.

Large companies developed slowly from the primitive stage of industry in which each employer was his own foreman, and the tradition has been handed down that in order to preserve discipline the foreman must be able to hire and discharge his own men.

It has been pointed out in a foregoing paragraph that the labor cost of production is very much in excess of the material cost, probably in some instances two and one-half or three times as much, and we find that every company purchases its material through a well-organized purchasing department, while in the majority of cases its labor supply is picked up haphazard. More attention is certainly paid to the purchasing of material and the designing of equipment than to the selection of workmen.

This in no small measure contributes to unrest and dissatisfaction among workmen, and consequently is a dominant factor in labor turnover.

Work of all kinds can be analysed to determine the qualifications necessary for its performance, and in some places efforts are being made by executives along the line of selecting and training workmen, and the time is not far off when this will be a regular part of industrial activity. The majority of men are neither lazy nor unwilling to work. The trouble is that they are picked up without any effort at selection and placed at work for which they are unfitted.

The question of hiring and discharging workmen, on which alone rests the labor turnover of a plant, may be placed under two headings:

(1) Hiring and discharging by foremen.

(2) Hiring and discharging through a properly organized Employment Department.

In the first place hiring by the foremen frequently leads to practices that are detrimental to all concerned. It very often leads to the building up of racial and other cliques in a department that will cause trouble later. This is inevitable, as the only source of labor supply that is open to a foreman is through his relatives and friends and the friends of the men in his gang.

The only basis of judgment the foreman has in interviewing an applicant for work is the impression the man makes on him at the time. If the applicant is unknown to him personally he cannot tell anything at all about his ability, and he has not the time or means at his disposal to make the enquiry necessary to even approximately determine the fitness of the man for the work that has to be performed.

We can now consider the centralized hiring of employees through an employment department.

One of the objections to this method was that it interfered with the authority of the foremen and superintendents. As a matter of fact it does nothing of the sort. It does not mean that they cannot dispense with the services of any man who is not doing his work in an efficient way. Instead of the faulty workman being discharged from the plant to the

\* A paper read before the Mining Society of Nova Scotia at the Annual Meeting, Glace Bay, N.S., May 4th and 5th, 1920.

street, he is sent back to the employment office, where a further effort will be made to have him placed on a job where he will fit. It is evident that although a workman may not suit one job he may do all right on another one. If after a reasonable number of trials have been made, the man persists in being "no good" he should be discharged. In a modern organization no man should be allowed to leave the service without a searching enquiry into his reasons for doing so. These interviews with men who are leaving the employment frequently reveal objectionable conditions that in many cases can be easily remedied, and that are actually a disadvantage to the company as well as to the workman. The modern employment bureau is the only agency that is equipped to handle the problem of distinguishing between the man who is no good and the man who is wrongly placed.

Certain things are essential to successful centralized hiring of workmen. In the first place the employment manager should be personally familiar with the various works for which he has to secure workmen. He should have notice as far as possible in advance of the number and class of men required, so he can provide them when needed. He should have sufficient assistant so that his time will not be used up doing work that can be equally as well done by an ordinary clerk. He should have the standing and the authority in the organization that will enable him to perform his duties satisfactorily, so that the company for which he is working will get the best possible results.

#### Summary.

(1) The cost of labor turnover in industry is so large as to justify the adoption of any means to bring about its reduction.

(2) The most important and effective method is the establishment of an employment department properly administered.

(3) Hiring through an employment department does not impair the authority of the foreman or superintendent immediately in charge of the work.

(4) He hires his men from the employment department and discharges them back to it instead of to the street.

(5) The employment department is able to give the applicant for work special attention, and properly conducted it is able to devote special skill and knowledge to selling employment in the organization to the workman.

#### DIAMOND DRILLING AT KINGS ASBESTOS MINE.

The Sudbury Diamond Drilling Co. has taken a contract for drilling at Thetford Mines, Quebec, for the Asbestos Corporation of Canada. The contract calls for the drilling of 20,000 ft. and is an exceptionally large one. Mr. S. J. Fitzgerald, President of the Company, is on the ground and has started five diamond drills and one churn drill at the Kings property.

This drilling exploration should give the mining company much useful information concerning its property.

## VANADIUM--Its Occurrence and Utilization

(Abstracted from a paper on the Development of Ferro-Vanadian Metallurgy presented at the Boston Meeting of the American Electrochemical Society, April 10th, by B. D. Saklatwalla, General Supt. of the Vanadium Corporation.)

We will discuss briefly the technical evolution of the processes of reduction, and the general properties bearing on such processes, of an element which up to only a few years ago was characterized as a chemical curiosity, a so-called rare element. Following a recognition of its useful properties, this element, "vanadium," was suddenly converted from its laboratory obscurity into a commercial necessity of far-reaching importance. In this commercial evolution it resembles, to some extent, the element aluminum, which was similarly transformed from an element of chemical catalogs into a metal of everyday necessary technical domestic use. Vanadium, like aluminum, destined to be a great engineering factor, was known to exist, and its chemistry fairly well developed, years ahead of its actual entry into commerce.

This neglect of its useful properties was due to various substantial reasons. In the first place, its technical uses were limited until Prof. Arnold's researches conclusively proved its value in the manufacture of steel; hence there was very little incentive for its technical development. In the second place, though its presence was widely manifested, it was of rare occurrence in a commercially workable deposit. Vanadium had been classed among the rare elements, with very little justification. It was not the distribution of the element, but its occurrence in a concentrated form at one locality that was lacking until the discovery of the Peruvian deposits in the Andes, near Cerro de Pasco, by Don Antenor Rizo Patron, in 1905. In fact, vanadium is one of the most widely distributed elements on the face of the earth. It is diffused through all primitive granites and many sedimentary rocks and clays. Besides forming a number of special minerals, its presence has been proved, as accompanying other elements, in at least fifty different minerals. In large amounts it occurs in lead ores, and in very small quantities in iron and copper ores. It is found in the ashes of very many coals and various plants. Its distribution as to locality also is not restricted, none of the continents of our globe being free from it. To get an idea of the quantity of vanadium contained in our globe, Vogt comes to the conclusion from various quantitative determinations in minerals, that the entire crust of the earth would show an average content of between 0.0025 and 0.05 per cent vanadium. Further, the presence of vanadium is no restricted to our planet alone. Sir Norman Lockyer has shown its presence in the spectra of various heavenly bodies. Also a number of meteorites have been shown to contain vanadium.

The history of vanadium is more than a century old. It was discovered in 1801 by Manuel del Rio, in the lead ores of Zimpan in Mexico, but was considered by Collet Descotils, who analyzed these ores in Paris, to be identical with chromium. Thus del Rio's discovery was forgotten, until Sefstroem, in 1830, re-discovered the element in iron produced from certain Swedish ores. Then Woehler, taking up the analysis of the Mexican lead ores investigated by del Rio, conclusively proved that Sefstroem's new element was

# A MARSH HOIST IS MADE THE RIGHT SIZE FOR YOUR MINE

and in either Steam Power or Electric Power

This shows one of our Electric Mine Hoists. We make many other types. Send for our catalogue of Mine Hoists, Cars, Cages, Buckets, etc., and see what we offer you. It will repay you.

From the little 10 Horse Power size for prospectors or small mines to the massive 50 Horse Power size, one of our 7 sizes should be just right for your mine.

We are specialists in the building of Hoisting Machinery of all sorts. For nearly a quarter of a century we have been designing and building Hoists, and have developed a Hoist that we are really proud of—proud because of the record of good work they have done, and are doing in mines, quarries, and other classes of work from one end of Canada to the other.

the same as that found by del Rio., viz., vanadium. This controversy inspired Berzelius to investigate the chemistry of this new element in a most thorough manner. It will not be too much to say that the foundation on which the chemical knowledge of this element is erected is formed by the work undertaken by this old master in 1831. Comparatively little was added to it, until Sir Henry Roscoe, about 40 years later, through his researches from 1867-1870, furnished additional valuable data. The first suggestion of technical application of vanadium to metallurgy carries us back to the year 1863 when Lewis Thompson expressed the idea of vanadium having a similar effect to nickel on iron, since it was found in iron of remarkably ductility. A year later, Edward Riley suggested the extraction of vanadium from pig iron, which being analyzed by him, seemed to contain this element.

The treatment of vanadium-bearing materials and

minerals can be said to have started following Roscoe's work in 1867-1870, when vanadium found application in the dyeing and ceramic industries, but it was not until 1896 that its entry into metallurgy can be said to date. In that year the Firminy Steel Works in France experimented with the use of vanadium in armor plates. However, the superiority of vanadium steels cannot be said to have been established until the year 1900, especially by the comprehensive investigations of Prof. Arnold in Sheffield, England, which work was further completed by the publications of Sankey and Smith in 1904. Immediately after these publications, establishing the usefulness of vanadium in steel metallurgy, the most important known deposit of vanadium-bearing mineral was discovered in Peru in 1905, thus ensuring a permanent supply for the establishment of a vanadium industry and a commercial technology for the treatment of vanadium minerals.

# EDITORIAL

## Capitalization of British Empire Steel Corporation Coal and Ore Reserves

A series of three well-informed articles on the financial condition of the nine companies which it is proposed to consolidate as British Empire Steel Corporation appears in the Toronto "Globe," and is concluded with the following discriminating comment, viz.:

"On the question of total assets Col. Morden insists that there has been a conservative valuation of the iron-ore and coal in the ground belonging to the various companies, the value of which is now placed at \$203,000,000 of the total assets valuation of \$407,000,000. The fact remains that the total assets of the leading companies of the nine in the merger are placed at slightly less than \$200,000,000 in their last annual reports. It is manifest that Col. Morden has adopted a different basis of valuation from that of the unit companies in preparing their annual reports. It is to be presumed that the coal and iron ore has hitherto been regarded as a nominal asset, which may explain the difference. This does not, however, relieve the new company from the necessity of most efficient management in seeing to it that the valuation put upon the coal and iron as in the ground is not above what is warranted in consideration of the coal and iron as a marketable commodity—in other words, the plan of organization to this extent capitalizes the future and contemplates many years of successful operation in bringing the raw materials to the Corporation's plants, and making them into millions of tons of marketable articles."

The capitalization of minerals in the ground is a difficult matter, and probably the safest method is to regard them as a nominal asset. This is particularly so where the mineral deposits are so largely submarine, as in the case of the coal and iron-ore areas of the constituent companies of the new Corporation. The greatest asset of the new Corporation will be its complete control of the points of access to the submarine mineral deposits, and the advantages that will accompany unified direction of the technical operations of winning the minerals. Another substantial asset is the land area of unworked coal.

With the exception of the winning of the three upper seams in the Sydney Field the land area is virgin coal. The seams crop concentrically each outside of the next superimposed seam, and thus, as the lower seams are reached, each one contains a larger superficial area of ungoten coal. These lower seams have hitherto been disregarded because of the better quality and great accessibility of the upper seams. Nevertheless, it may be stated that the ungoten land coal will provide the most dependable and lasting asset of the future. Comparative thinness of seams, less desirable quality, and, to an inexcusable extent, lack of accurate knowledge of the lower seams, are hindrances to profitable extraction that will gradually disappear under the compulsion of necessity, improved methods of extraction, and modes of preparation that have long since been matters of ordinary practice in other countries.

In connection with the submarine area, both coal and iron-ore, only a nominal value should be placed on the estimated content of mineral, because, while the supposition of their extension at least to the limits of profitable extraction is founded on excellent grounds, in the absence of actual knowledge there can be no absolute certainty such as is required in actuarial calculations.

There are also some fixed and unavoidable first charges on coal and iron-ore won from the most accessible and certain situations, which are emphasised in making future calculations on ungoten submarine areas, namely charges for depletion of areas, for redemption of capital, and for the provision of new openings to take the place of abandoned winnings. It will be an essential to the permanency and success of the new Corporation (which we desire again to emphasize, believing that exaggeration of emphasis on this point is impossible, is founded on the extraction of coal at a profit) that these charges shall be a primary addition to the other costs of coal production.

We note that the nominal capital of the new Corporation is fixed at \$500,000,000, and that while the appraised value of the aggregate assets of the constituent companies is placed at \$407,000,000, it is only proposed to issue securities of a par value of \$207,000,000, or approximately the sum of the assets of the combining companies as shown by their respective

balance-sheets. From this we deduce that it not the intention of the promoters of the new Corporation to issue share capital to the full extent of the appraised assets. In view of all the factors of uncertainty that surround the profitable winning of coal and iron-ore from submarine areas—some of them very remote from land—it is probable that the technical advisers of British Empire Steel Corporation will counsel the inclusion of the ungotten coal and iron-ore tonnages in the balance-sheet of the Corporation at purely nominal figures. It is also to be expected that the cost-sheets of the mining companies will be complete cost-sheets, showing the ultimate cost of coal over the whole expected life of the deposit under consideration, and not partial, and therefore inaccurate, cost-sheets such as have too often in the past led to erroneous conclusions and consequent financial embarrassment.

#### PIT TIMBER VERSUS PULP WOOD

At the recent meeting of the Mining Society of Nova Scotia, Mr. J. W. Revere, the veteran Purchasing Agent of the Dominion Coal Company, made the significant statement that the present growth of timber in Nova Scotia is not making up for the current consumption, and that in ten years' time the pit-timber of Eastern Canada will be exhausted.

Taken in conjunction with Mr. Frank J. D. Barnjum's exposé of the forest situation of Eastern Canada (see issue of January 30th, 1920) and the ravages of the spruce-bud worm, Mr. Revere's pronouncement, coming as it does from an expert of unique experience in the pit-timber trade of Nova Scotia, should alarm the coal operators of that province.

The competition of the pulp-wood industry is now being felt in Nova Scotia, and in Cape Breton Island itself the mills are paying twelve dollars a cord for pulp-wood.

We suggest that the acquisition of an adequate pit-timber reserve is fully worth the immediate consideration of the coal interests of Nova Scotia. The associated companies who will form the British Empire Steel Corporation own, it is true, some valuable lumber limits, but these are not particularly suited for growing pit-props. There are, however, areas in Cape Breton Island, which if properly forested and looked after, and reserved for the growing of pit props, could assure the coal mines of a fairly well-sustained supply for the future. The timber on these areas is well-suited for pulp-wood manufacture, but it should not be a hard matter to decide which is the more essential requirement, pulp-wood, or the provision of coal.

Mr. Jack Hammell is in Toronto. He is confident that a large amount of development work will be carried on at the Flin Flon property. The New Yorkers who have taken the option on the property are making good headway.

#### BRITISH EMPIRE STEEL GRANTED CHARTER IN NOVA SCOTIA.

British Empire Steel Corporation applied for a Dominion charter, but the way was made hard for it by the legislators at Ottawa, who criticised the proposals at long range and without understanding them. Nova Scotia, because of her vital interest in the main constituent companies of the consolidation, made the way of provincial incorporation easy, knowing from close acquaintance with the coal and steel industries, and through a thorough understanding of the problems that counsel consolidation, how desirable it was. Nova Scotia has tried independent operation of the coal fields, and has seen it fail.

A province which depends on coal royalties to the extent of between \$750,000 and \$1,000,000 annually, is not likely to gauge incorrectly the benefits which will follow the new capital investment, the larger markets, and the merged energies and purposes of its major industries, nor are the people of Nova Scotia to be accused of any lack of native shrewdness. The incorporation fees and corporate taxes of the new Corporation, added to those of the existing companies are not to be despised, but what chiefly disposes the Nova Scotians to favor the consolidation is the knowledge that it will effect economies in operation and in marketing, will increase the production of coal, steel and ships, and in many other ways will bring much grist to Nova Scotia's mill.

#### PERSONALS.

Mr. J. C. Murray is in Toronto.

Dr. W. L. Goodwin will preside at the Convention of Canadian Chemists in Toronto this week. The meetings will be held at the University of Toronto May 27 and 28.

Mr. David Rorison has resigned as Manager of the Inverness Colliery, Cape Breton, and has been appointed Manager of the Ridge Coal Co., near Minto, New Brunswick. He assumes his new duties at the beginning of June.

Mr. Balmer Neilly, secretary of the recently formed Ontario Mining Association is now located in the Trust and Guarantee building, 55 Bay St. Toronto.

Mr. Geo. R. Rogers, president of the Wasapika Consolidated Mines Ltd. is in Toronto this week, after being at the property for several weeks. He reports that the shaft has now reached a depth of 204 ft. where a station has been cut and a cross-cut run into the ore-body.

Mr. Jas. McEvoy expects to leave for the West this week. He will examine coal properties in the Edmonton district.

Mr. C. H. Hitchcock, of Sudbury, was in Toronto this week. He reports that diamond drill exploration is being carried on in several districts.

Mr. T. R. Jones, who lived for several years at Cobalt and managed the Buffalo mine is visiting Cobalt this week. Mr. Jones has taken an active part in developing properties in many districts in Northern Ontario.

# Coast Erosion of the Coal Measures in the Sydney Coalfield, Cape Breton

By the Editor.

In a Bulletin on the coalfields of Eastern Canada, prepared by the writer for the Department of Mines, Ottawa in 1916, two photographs were re-produced showing the effect of the sea and the elements upon a sandstone spur that lies between the crops of the Hub and Harbor Seams, not far from the Harbor of Glace Bay. By the courtesy of Mr. B. A. L. Huutsman, of Sydney, an amateur photographer of much skill, the writer has been able to obtain a chronological series of later views of this spur that show the rapidity with which coast erosion proceeds on the exposed Coal Measures of the Sydney Field. The series is of sufficient interest to justify re-publication of the two original photographs with those that have been taken at later dates, the whole extending over a period of twenty years. For the original photograph of 1900, the writer is indebted to Mr. Stuart MacCawley of Glace Bay.

By the courtesy of Mr. C. M. Odell, the following view of the disintegrating and wasting Coal Measure sandstones and shales is reproduced from a photograph taken near Point Aconi in 1908 (on the North Sydney side of the coalfield) and originally published in a description of the operations of the Dominion Coal Company by the writer that appeared in serial form in the "Canadian Mining Journal" in 1908. In this view it will be seen that the overhanging marls have been undermined by wave action, much as a miner undermines the coal seams, and eventually the whole face of the cliff will slide into the sea.

Isolated Sandstone Spur at Indian Head, Sydney Coalfield, Cape Breton.

*Shore Line. Showing overhang  
N.W. Corner 16/63/56  
Jan. 2-08.*

The isolated sandstone spur, the completed work of erosion, shown in the following photograph, is to be seen near Indian Head, between New Waterford and Glace Bay.

Another view of a sandstone spur is given, which is in the Waterford District of the Sydney Field. The spur is undergoing the same process of destruction that is illustrated by the Glace Bay series. This photograph was taken by Mr. Odell.

It is certain that a large portion of the undersea coal seams—probably nearly all the workable portion—is overlain by waters of the sea that have steadily encroached upon the land by the unceasing wave erosion along the shore line of Cape Breton. The ancient shore line can be detected by soundings at varying distances from the existing coast-line, and the intervening ocean floor has undoubtedly been gained from the land in modern geological time. The late Richard Brown, from observations extending over thirty years, estimated the wastage of the coast at about five inches a year, but the photographs will demonstrate, it is probably much more rapid in exposed spots. The shales and sandstones, because of their parallel bedding, and their seaward inclination, easily slide into the sea when loosened by the winter frosts. In the Spring, under the combined action of the thaw, the scour of the drift-ice and the frequent storms, the cliffs waste very rapidly.

The probability that the workable portion of the undersea coal seam is, in greater measure, overlain by an area of modern encroachment of the sea, has a favorable bearing on the extraction of the coal in undersea workings, inasmuch as the sea bottom will present a slight inclination seawards, free from pockets and fissures. The wave action prevents any heavy deposit of sand, and the ocean floor, for a long dis-

tance out is probably a rock bottom. There is also every likelihood that the earth movements which caused the four parallel folds of the Sydney Field, separating the main basins, were much prior in time to the modern sea encroachment, and that no disturbances of the measures in the areas intervening between the folds has occurred in modern geological time.

**Some Examples of Coast Erosion of the Coal Measures of the Sydney Coalfield, Cape Breton Island.**

A Sandstone Spur of Strata Lying Between the Outcroppings of the Hub and Harbor Seams, Glace Bay. Photograph dated 1900. Wreck is that of "Napoleon" an iron ship.

## The Importance of Cheap Power to the Industrial Life of Nova Scotia

*Presidential Address by Colonel Thos. Cantley to The Mining Society of Nova Scotia, Glace Bay, May 4th, 1920.*

Gentlemen:—

Officers, and Members of the Nova Scotia Mining Society, I bid you hearty greeting. The Mining Society of Nova Scotia is entitled to congratulations for the success which has attended its yearly gatherings during past years, and this Annual Meeting now in session in the chief mining centre of our Province, will, I doubt not, prove as important and profitable as any in our history.

The Province also may be congratulated on possessing a Society composed of its leading miners and metallurgists, active men mainly of the class known as practical, men for the most part not only practical, and of seasoned experience, but also of commanding personality, proved ability, with that resourcefulness which practice in mining and metallurgy in a new country, and in some respects an isolated country, demands and creates. Of such is the Mining Society of Nova Scotia—a body for many years composed of men who have perhaps done as much to advance the material prosperity of our native province as any similar group of men, given equal opportunity, have accomplished elsewhere.

In any remarks I may now make it is not my intention to refer to present business conditions, the labor situation, or the present world unrest. All of us naturally must look forward with some misgivings to the future—the immediate outcome of which is uncertain, but as to its final issue I personally have no doubt. Without a League of Nations, or in spite of one, men of the British breed can and will hold their own in the ship, the mine, the field, or the

main. All these our fathers and our sons have worked, wrought, fought and sailed, and in all won the respect of our peers, and we have “aye been provided for and saw will we yet.”

The custom of our Society is that your President should address the Society on some topic of mutual interest, yet pertinent to the community at large. Certainly there is no lack of problems that might with advantage be considered—and equally no doubt there may be many opinions concerning the subject most worthy of attention at the present time.

The mineral resources of the Province and the processes in the mining and metallurgical industry have been dealt with in their many and varied aspects. transportation and labor problems today have the eyes of the world focussed upon them—while familiarity with the laws and operations of high finance and so-called “big business,” not to say mergers, is expected in all well informed citizens, and certainly assumed in industrial executives.

Possibly the most important remaining problem of wide spread concern to industry in Nova Scotia is the production of cheap power. And I have selected it as the subject of my address, treating it from an economic rather than from a strictly professional or technical angle, with a hope of perhaps better orientating our views on the situation in Nova Scotia at the present time. This position in one or more of its several forms, is of vital interest to most industries, which with cheap power may make considerable progress, but under the reverse conditions, will find it diffi-

cult to meet the competition of those more favorably supplied with this necessity.

The amount of power required and the relationship between cost of power and the cost of product vary a good deal, probably reaching a maximum in the electro-chemical industry—and the metallurgical processes used in the smelting, refining and manufacturing of metals.

In these cases power is one of the principal factors and reaches a requirement in the manufacture of certain chemicals of about 5,000 H.P. continuous load per 100 tons of raw material converted into finished product. Reference might be made in this connection to the recent discovery of salt near Malagash, the development of which makes the future establishment of important electro-chemical plants in the Maritime Provinces probable, provided cheap power is obtainable, as salt and coal are basic materials for such an industry, and a most important one it is.

In the electric steel furnace from 200 to 800 K.W. hours per ton treated is used, depending upon the materials charged and the degree of refinement required. Following these we have the more familiar application of power in iron and steel plants, mining and the transportation of materials where mechanical power originally was a secondary factor, but now has become of great importance as a means of increasing production and reducing costs, especially in countries where wages are high. And we find the power consumption amounts to 6 h.p. per ton of pig iron made in blast furnaces, 2 h.p. per ton produced in open-hearth steel furnaces, and 5 to 15 h.p. per ton of steel rolled in steel mills, depending in the latter case largely on the amount of work done in reduction, etc. In the further manufacture of steel into unusual shape, or where tonnage manufactured to any single section or pattern is small, this percentage may be appreciably increased.

In mining, where the power employed is steam and compressed air, the costs cover a wider range, and may reach from 10 per cent of the output for machine operated, heavy pitching, wet coal seams, to 5 per cent where the mining equipment is electrically operated. In metal mines, too, extreme examples may be cited—on the one hand in the case of rarer metals, given outputs of various magnitudes ranging from a comparatively few tons to several thousand per day, frequently located in inaccessible regions, and at points where a supply of fuel is obtainable only with great difficulty. The opposite type is represented by mines producing large tonnages under favorable conditions, such as our iron ore deposits where, on account of the nature of the materials to be mined, and the unusual thickness of the seam, lying at a moderate pitch, it is possible and necessary to use relatively large amounts of power for the operating of mechanical loading, trimming, and haulage equipment. Such a situation may demand 1 to 1½ h.p. per ton mined.

In the field of transportation, we have for land service on steam railways an average figure of 3 h.p. per ton moved, with a fuel consumption of about one-quarter pound of coal per gross ton-mile. At sea one-quarter h.p. per ton moved is required for bulk freight carriers, of moderate size, to one-sixth h.p. for the largest size, with coal consumption of 1¾ and 1½ lbs. per h.p. hour, and 0.045 and 0.032 pounds per ton-mile, respectively.

The principal prime movers in use at the present time are the reciprocating and turbine steam-engines, internal-combustion engine and the water-turbine.

Each has its field of service, and under certain conditions is most economical, which fact must be considered together with its reliability for the service required. By way of comparison, the thermal efficiencies of each type considered as heat engines, may be stated as for modern steam-turbine installations of moderate size, 10 to 15 per cent, and in the case of the largest modern units 15 to 21 per cent. Engines using blast-furnace gas 18 to 26 per cent, while with the full Diesel type of oil engine 33 per cent is obtained, even in small units.

The improvement in thermal efficiency of what is as yet the greatest of our prime movers—the steam engine—during the past 220 years, has been really great. Beginning with the year 1700 Savery's engine then required 40 lbs. of coal per h.p. hour. Newcomen's engine, introduced in 1711, required 55 lbs. Watt's engine of 1778 required only about one-quarter of these amounts, or nine pounds per h.p. hour. The Cornwall engine of 1844 again divided this quantity by three, or to be exact, 3.2 lbs.. Higher pressure and greater ratio of expansion some years later reduced this to two pounds, and in the first decade of this century to 1½ lbs. The turbo generator of 1903 demanded a consumption of about two pounds—fifteen years' study and the outcome of designing experience brought the coal consumption of the turbo-generator in large units down to one and one-tenth pounds, and it would be very unwise to predict that that figure represents finality in that direction.

In Nova Scotia our principal source of power is coal used directly, or indirectly in the form of waste heat from coal in gas fired furnaces, and burned under boilers to actuate steam engines. In the Sydneys, blast-furnace gas might be used to actuate steam engines, while water powers of moderate size are available in various parts of the Province. In some districts use might be made to advantage of oil-driven engines of the internal-combustion type, but it now seems probable that this will be limited to requirements taken care of by small units due to the rapidly increasing price of fuel oil. In view of the efficiency of this type of engine and the other advantages this method of producing power affords, the shortage of fuel oil is regrettable—and a situation already serious is being augmented by the increased use of oil to generate steam in the merchant marine.

As the amount of oil available is far from inexhaustible, and it is a natural resource not replaceable by any known means, we are faced at the present rate of increase in consumption with finding the world's oil reserves depleted before many years, and the problem of finding a substitute is important. Tar, tuluol, and other coal distillation products are now being used to replace natural fuel oils, but while this practice will undoubtedly increase, their source is also circumscribed, due to their being the by-products of coal. What is needed is a fuel capable of replacing them produced from vegetable products. Crude alcohol meets these requirements, and as it may be produced in quantity by systematic cultivation without depletion of natural resources, this problem is one deserving serious attention by governments and departments of conservation.

The situation may in the future be materially relieved by the development of our oil-shale resources, which show marked indications of considerable extent in some districts of this Province, and as they can be mined cheaply, speaking generally, it should be only a short time when these resources will be utilized.

The power of the tides now wasted in the Bay of Fundy, and its tributaries, has received considerable attention from time to time. In our opinion the scheme of this development by the use of two tidal basins is technically practicable, where the land features are such that basins of requisite capacity can be built at a reasonable cost. The initial expenditure would, of course, be great, but so would the power. With the increasing scarcity of fuel and demand for power this source of energy will surely be put to practical use in the future.

In addition to these there are rather indefinite possibilities in the use of peat, which will be of great local value in Newfoundland and elsewhere where there are extensive deposits, when we have learned how to utilize its heat value economically.

While the use of blast furnace and coke-oven gas in internal-combustion engines has been to a very considerable extent tried out, and is still used with success in some localities, such use of these fuels locally seems problematical, especially where the gas can be used to advantage for heating purposes, as the capital expenditure for a gas engine-driven plant of reasonable reliability is very high, and while it is true that the fuel used per unit is still lower than the most efficient steam-driven units, this difference is now very small, as compared with the figures of a few years ago, due to the relatively greater advance made in steam turbines designed for the higher range of steam pressures and superheat: and the higher efficiencies now obtained in the regular boiler room practice where 76 to 78 per cent is maintained without the use of economizers.

Having briefly outlined the probable sources of power, it will be of interest to take up the question of cost production. In consideration of this phase of the question, the cost of electric current generated by steam power plants will be first taken up, and as we all have, to some extent, a conception of the operating cost of most common units, we will not deal with them other than to point out the marked variation in the coal consumption, which is the principal item.

The average consumption of coal per K.W. hour with compound expansion engines of the best type, condensing, ranges from 2½ to 5½, perhaps 4 lbs. might be taken as a fair average, equivalent to, say, 7 per cent efficiency. In the case of non-condensing engines, simple and compound, such as used for pit-winding and rolling mills and similar class of factory engine, where power is distributed by shafting, ranging from 5¼ to 8 lbs., averaging 6¾ lbs., or an efficiency of, say, four per cent.

Miscellaneous small engines, steam pumps (the former located where power is required all over factory and engineering shops, deriving steam through a long system of pipes) probably take from 10 to 20 lbs. or more, and would not average less than 13 lbs., or, say, 2 per cent efficiency.

The efficiency of the units of the two last mentioned classes is so low that their use should be restricted where possible for more economical means, although there is a field for their usefulness within certain limits in plants using large quantities of low pressure steam for the purpose of heating.

Within the last five years large central steam-driven stations received close study as an important factor bearing on the conservation of coal, and the possibilities of obtaining relatively low cost electric power

from this source has been fully demonstrated in both the United States and England. The unusual size of these stations should be kept in mind, as generators of 20,000 to 45,000 K.W. are used, and units of over 60,000 K.W. are building, indeed, if not now actually operating, and size has a most important bearing on power costs.

With the use of somewhat smaller units the efficiency, while not as high, is closely approached—as is shown from the operating cost of a central station of this class—which has a switchboard cost for the year ending December, 1916, of 0.262 cents, and for a later period of three months of 1917, when coal was more expensive, of 0.360 cents.

In Table No. 1 the first column shows the various items entering into the switch board costs here referred to, and opposite it is a revised cost using native coal at \$5.00 per ton, also allowing for increase in labor and supplies and showing a cost of 0.528 cents per K.W. hour for local conditions:—

TABLE I.

For Three Months Ending March 31, 1917.

	Expense per K.W. hr. Original.	Expense per K.W. hr. Corrected for local conditions.
Superintendence . . . . .	.009	.009
Wages. . . . .	.050	.056
Coal . . . . .	.264	.418
Lubricants . . . . .	.001	.0015
Station Supplies. . . . .	.005	.006
Station Buildings . . . . .	.013	.016
Steam Equipment . . . . .	.016	.019
Electrical . . . . .	.002	.0024
Total . . . . .	.360c	.5279c

For year of 1917 corrected column based—

- Labor increased 12½ per cent.
- Fuel increased \$5.00 per ton.
- Lubricants, Supplies, etc., increased 25 per cent.
- Maximum demand (20 minutes), 45,000.
- Average load, 25,300.
- Total K.W. hours, 54,654,900.
- Coal per K.W.—pounds, 1.56 lb.
- Total cost coal, \$144,735.71.
- B.T.U. per K.W.H., 20,300.

Twelve (12) Months Ending December 31, 1916. . .

	Expense per K.W. hr. Original.	Expense per K.W. hr. Corrected. for local conditions.
Superintendence . . . . .	.013	.013
Wages. . . . .	.042	.047
Coal . . . . .	.174	.391
Lubricants . . . . .	.001	.0015
Station Supplies. . . . .	.006	.007
Station Buildings . . . . .	.007	.0087
Steam Equipment . . . . .	.016	.019
Electrical . . . . .	.003	.0037
Total. . . . .	.262c	.4909c

For year of 1916 corrected column based—

Labor increased 12½ per cent.  
 Fuel increased \$5.00 per ton.  
 Lubricants, Supplies, etc., increased 25 per cent.  
 Maximum demand (30 minutes) 36,000.  
 Average load, 18,500.  
 Total K.W. hours, 162,117,600.  
 Coal per K.W., pounds, 1.45 lb.  
 Total cost coal, \$262,135.47.  
 B.T.U. per K.W.H., 19,800.

These figures do not include interest or depreciation.

It might be well at this point to refer to the differences in cost of power due to variation in local conditions. It will be apparent that high peak loads require reserve generating capacity in proportion to their magnitude, and this condition may apply to boiler capacity also, and when for this reason the ratio of the average station load to short period peaks is low, and we have a low load factor, this results in increased capital expenditure and operating costs. This has an important bearing, as this factor varies considerably under different conditions and a considerable diversity in industries is desirable when locating such a power unit.

The magnitude of the plant, the costs of which we have given ranging as they do to 200 million K.W. hours per year, is considerably in excess of the requirements of our industrial centres at the present time. The consumption of electric current in the Sydney district is, say, about 100 million K.W. hours, while in Pictou County forty million K.W. per year will possibly take care of present requirements. These smaller outputs materially affect the cost of production, and in order to show the extent of this effect the following estimate is submitted to demonstrate what practice might be expected under present day conditions, using local fuels.

Plants of three different capacities are given producing 46, 72, and 126 million K.W. hours a year, and at a switchboard cost of 1.07, 0.903 and 0.877 cents per K.W. hour, respectively.

TABLE 2.  
*Station Power Costs.*

Output . . . . .	43627	38289	30716
Net K.W.H. per yr. (mill)	46.08	75.26	126.0

Another source of power might be made available by the development of our water powers. There are within the Province a number sufficiently large which if developed, would provide several moderate-sized if not large units of electrical energy. While some of our larger rivers and a number of smaller streams have not been investigated in detail, the Nova Scotia Power Commission are of the opinion that 300,000 h.p. may be ultimately developed, and if the present programme as we now understand it is carried out, we may have soon installed transmission systems supplying the greater part of the Province, with the exception of the extreme Eastern section.

A considerable section of the public sometimes referred to as the "man on the Street," has a general idea that water power, in view of its being a natural product, provided by Nature and annually replaced, must therefore provide energy at the lowest possible cost. Unfortunately, however, the cost of such industrial power depends upon a considerable number of factors, and none of the energy possible of development at any of our Nova Scotian streams can be made available to the various manufacturing establishments and our towns and villages, except as the result of very considerable expenditures in the way of extensive dams, storage barrages, the installation of expensive hydro-electrical machinery, and a considerable mileage of transmission lines, and while operating expenses in one direction are low, the interest charges are bound to be high and these must be met.

So far as the cost of water power is concerned, we find that the tentative estimates made by the Commission suggest a total cost, including fixed charges and operation of 0.7 cents per K.W. hour for the St. Margaret's Bay development. This plant is now under construction and is expected to supply the Halifax district with a possible thirty million units per year.

Another possible development, and in this case of very considerable importance to Pictou County, is that of Sheet Harbor on East River, St. Mary's. From this development we are advised the estimated total cost of current delivered at a point in the vicinity of New Glasgow would be three-quarters of a cent for a total consumption of thirty million, or 1.10 cents for twenty million K.W. hour per annum. Indeed, it is stated that the output can be increased to 45 million K.W.H. at a cost of one-half cent per unit, when such a hydro system is completed, and tied together in a manner which will permit an exchange of current from one development to another. It is to be understood that these prices are based on delivery in the quantities mentioned at transmission line voltage, to a distributing station, and would approximately apply to a very large consumer, but would have to be increased to cover local distribution in order to serve the smaller industries located in a town using current at lower pressure.

The proposed system will link up many of the towns and pass through agricultural districts of the central part of the Province supplying current at a rate which would materially aid in the development of the country, and increase production along many lines.

A great deal has been written on the subject of internal combustion engines of the Diesel type, burning crude oil, especially for marine work, and certainly oil has many advantages over other kinds of fuel, either when used direct in the cylinder of an engine or by combustion under steam boilers. Unfortunately, we are to a large extent prohibited from its use in recent years on account of its high cost.

In the isolated locations where freighting of coal is a serious expense or storage a determining factor, or in cases where boiler feed-water supply is lacking, there is still a field for its use, and we have under these conditions, a very satisfactory and highly efficient plant in engines of the full Diesel and semi-Diesel type, particularly if they are operating under constant load or very light overloads.

As an indication of the operating cost to be expected in a small plant, we give the following figures from a station with semi-Diesel engines having an output of about 130 thousand K.W. hours per month, where the fuel oil consumption is in the vicinity of .0936 gallons per K.W. hour, or which based on the present cost of oil sixteen cents per gallon in tank car lots, the fuel cost is 1.50 cents per K.W. hour. An engine of the full Diesel type would give lower cost figures to some extent—the difference of the two types being represented by consumption of 0.40 lbs. per B.H.P. hour for the Diesel against 0.50 lbs. for the semi-Diesel type. Greater allowance in both types would have to be made for repairs and maintenance than in the case of steam plants.

The figures given in our estimates of cost are for power delivered at switchboard, which will be increased by distribution cost necessary to deliver the current to the ultimate consumer. Owing to the loss in transmission, cost of equipment and maintenance, this charge will depend on the distance, quantity of current to be transferred, and type of service, and the costs vary considerably. It is usual, however, to have losses of from ten to twenty per cent on power consumed in quantity—while two to five cents per unit is added in the case of current delivered within city distribution system for lighting service.

In estimating the possible saving it will be apparent that two principal classes of power consumers must be considered. First the large independent manufacturer whose requirements are sufficient to warrant operating an independent power plant. The other, the general consumer, dependent on a public course of supply, whose present cost of power probably varies from three to seven cents per K.W.H. It will be apparent that under any unification scheme that the saving to the latter class will be very great.

Some idea of the overall saving that may be effected will be given by the results obtained by the Northeast Coast Electric Power Scheme which supplied power to the largest industrial area in England. It is stated that the average price paid this company for current totalling one-third of a million horse-power a year delivered at the customer's terminals, is less than one cent while the coal consumption is 2.06 lbs. per K.W.H. It has been estimated that this latter figure has replaced former coal consumption of 9 1-5 pounds when various industrial establishments now connected with the power scheme generated their own power individually.

As power plays so important a part in manufacturing, it is a factor next only to those of fuel, mar-

ket and transport costs in deciding the location of a factory. At the present time while we have the coal power is relatively dearer in Nova Scotia, and it is only to be had by installing the necessary power plant to meet each individual requirement. This is a decided handicap to the manufacturer starting a new business, and at best gives very expensive power. It surely is apparent that if manufacturing in Nova Scotia is to develop in a satisfactory degree some effort must be made to improve the situation.

From the figures already given it is evident that large production of power is essential to low costs, whether steam or hydro-electric, and the fact that large central steam plants are now being worked and others developed in the United States and Great Britain confirms this view. Here, as in most cases of human endeavor, unity is strength, and need for all working together is self-evident.

It is important in this connection that all power users should, where possible, employ electric equipment of the same frequency. Unfortunately, this is not the case today, as in two instances in this Province we have practically adjoining districts using current which is not interchangeable without the use of frequency converters, and in this connection it is worth mentioning that the Nova Scotia Power Commission proposes using 60-cycle generating equipment in their various developments. While differences in voltage is not so serious, it should also be given consideration, and limited to as few standards as is economically possible. Standardization would also simplify the local supply of electrical equipment and make neighbors a more dependable friend in the day of spare part troubles.

Some of the larger companies in the Province have a surplus of waste heat or electric generating capacity or both, and could supply power to manufacturers in their locality at a comparatively low cost. Power sold in this way would tend by increasing total production to reduce the cost per unit, and such a policy would have the effect of stimulating the growth of associated subsidiary and smaller trade in the community, and in time build up an important market near at hand.

The situation in this Province from a manufacturing point of view is in some important, if not vital, respects far from favorable. We are situated far distant from the chief consuming centres of the Dominion, and while the cost of transport per ton-mile in the past has not been high, the distances involved have been so great as to make the transport cost a very large factor, particularly in the case of coal and heavy manufactured products, such as iron and steel. During the past few years the cost of railway operation has very largely increased, and is still advancing, and there is little reason to hope for much improvement in this connection.

If Nova Scotia is to advance along manufacturing lines and so provide employment giving a satisfactory return both to labor and capital employed, it is absolutely essential that power be supplied not only to our large but also to our smaller manufacturers, at rates at least as favorable as those enjoyed by like industries in the other Provinces of the Dominion.

A really economic national policy must be based on the necessity of using our coal for such forms of work as cannot be performed with other sources of energy. While our coal reserves are large they are not inex-

haustible, and after that section of our deposits which are immediately available is worked out, the cost of production will increase as our mines and workings become deeper and more extended. The question of man-power necessary to work over the greater and more extended areas of production, when the deposits near the surface are exhausted, is another factor which cannot be overlooked. In view of these considerations we must so far as possible obtain our supply of energy by increased development of hydro-electric generation of power, reserving our fuel supplies for the reduction of our iron and other ores, and the purifying treatment and manufacture of metals, which cannot be accomplished save by the agency of heat, whether this be supplied by solid or gaseous fuel.

To this end all should work together to improve the situation, and to enlist public interest in this subject of vital importance—which we gladly note is now commanding the attention of the Government of this Province, with, we trust, the likelihood of helpful results.

**PAYMENT OF BRITISH EXTERNAL DEBTS ADVOCATED IN GOLD COIN.**

Mr. Francis A. Govett, Chairman of the Ivanhoe Gold Corporation, in his speech to the shareholders at the Annual Meeting in London, May 3rd., expressed some unusual opinions regarding the status of gold. Among other remarks he stated "the notes issued (British notes) are only really backed by gold so long as gold is not seriously demanded, but in times of panic or serious danger, either the Bank Act is suspended, or the convertibility at once suspended. That is to say the gold backing for the paper is entirely Christian Science, you can get gold for your paper only so long as you do not want it."

Mr. Govett's conclusions were as follows:—

"Gold has rendered good services; it has provided a most convenient common measure for the internal exchange of all commodities, and for international exchange, there being a fixed amount of fine gold in the unit coin of any country. This being so convenient, it is absurd that complications involved by the use of silver as a collateral basis of exchange should be tolerated, or that any country should remain on a silver basis; still more absurd that any of these countries should be a country, within the British Empire, like India, Ceylon and East Africa. (Hear, hear.) We cannot compel China to come in, but there should be a uniform currency for the Empire, with its base the British sovereign. It does not matter what may be the denominations of the subsidiary token coins so long as they are really tokens and not, like the rupee, a coin of value above 2s. and possibly a token when silver falls below. Internally the use of gold itself as pocket coinage is most extravagant, for six years past we have done well without it, and I have shown that in practice it is never used in times of need for one of the purposes for which it nominally is available, the backing of the note issue in circulation. To me it seems, then, better to recognize the actual facts, that the note issue are not backed by gold at all, but rest on national credit; to confine the use of gold to the sole function of the adjustment of international indebtedness and actually to use it when it is wanted; that is to say, instead of hoarding the useless gold in the bank vaults, it should be used in paying our external debts at 4.86, instead of our buying bills, as we have done, as low as 3.20 at a heavy loss, which means that we were paying 40 per cent to 50 per cent more for what we buy and increasing our indebtedness by that amount. Take the whole of the gold and hurl it at them; one of two things will happen—either the exchange will immediately rise in their unwillingness to take gold, or they will take it, and we shall have saved some further debts, and then we shall be no worse off than at the present moment, and at least we then shall know where we stand, for we shall be back on the real basis of our national credit, when perhaps at last we may begin to grasp the facts and to economise a little, while the internal credit of the Bradbury will still be unimpaired."

**NOVA SCOTIA NOTES.**

**Colliery Doctors and the Workmen's Compensation Board.**

The colliery doctors in Cape Breton refuse to make out the accident returns which the Workmen's Compensation Board require to establish the claims of the injured workmen, alleging that to do so entails a great amount of clerical labor for which they receive no compensation. The Board states it is not empowered to pay the doctors for doing this work, and that it cannot make payments of compensation without the certificate of a physician. As the colliery doctors are paid by the workmen, who contribute a monthly sum, in the neighborhood of a dollar per month, to the doctor of their choice, through the medium of the colliery payrolls, the workmen naturally consider the certificate of injury to be of a service included in the monthly deduction for doctor's services. The Compensation Act contains the following provision, namely; "It shall be the duty of every physician in attendance upon any injured workman to give all reasonable and necessary information, advice and assistance to enable such work or his dependants to make application for compensation, and to furnish such proofs as may be required by the Board." It is very much to be doubted whether such a statutory provision is enforceable, because nothing is said regarding the payment of the doctor for the services asked, and it is generally understood that no services can be commanded under a statute of this nature for which remuneration is not made in some form or other. The Board is probably correct in demanding medical certificate of injury, but this it requires only for its own satisfaction. Someone, however, should pay the doctor. It is a generally accepted principle of Workmen's Compensation Act as recently enacted and amended that the workmen himself shall be put to no charges for medical aid, and there is no good reason why the workmen should be asked to bear the cost of whatever charges the doctors may consider cover the work entailed by making out the compensation returns. It is probable the doctors are making much of little, and that on the other hand the Compensation Board is asking something for nothing. It is also possible that the returns which the doctors are asked to fill out are unnecessarily detailed, and that if the doctors were asked to certify returns already made out and requiring only a signature for completion, the dispute could be compromised without the necessity for paying a fee to the doctors. The vagueness of the provision above quoted from the Act, and the duty required from the doctor without specification of his remuneration was certain sooner or later to raise a question. "Such proofs as may be required by the Board" is a phrase capable of indefinite extension according to the interpretation placed upon it by the Board.

**METAL QUOTATIONS.**

Fair value for ingot metals at Montreal, 27 May 1920.

	Cents per lb.

Antimony . . . . .	12

## OUR NORTHERN ONTARIO LETTER

### The Silver Mines.

At the time of writing, silver quotations appear to have become fairly steady at a fraction below \$1 an ounce. This is believed to be due to the United States having entered the market to replenish its somewhat depleted treasury supply of the metal. Opinion now is that as the United States, according to the Pittman Silver Bill, is to replace more than a quarter of a billion ounces previously sold which must be repurchased at not more than \$1 an ounce, the price may be expected to show no further serious decline. Outside buyers, therefore, would be obliged to bid over \$1 to get the market. This is pointed to as indicating at least \$1 silver, plus the rate of exchange on New York funds at present around ten per cent, leaving the mining companies of this country still in a favorable position.

Work at the Temiskaming mine is one of the most favorable factors in recent months in the Cobalt district. Less than two years ago the ore reserves were pretty well depleted and the mill was closed down, while today, as a result of an aggressive and wisely directed exploration campaign the mill is treating ore at the rate of 135 tons daily, the highest record of the Temiskaming. A considerable quantity of the ore is high grade. A further indication of the expectation of the management and directorate that the mine has a big future ahead of it is that at the present time the company is installing silver refining equipment of its own in the present mill. These facts, taken together with the knowledge that the present surplus is over \$900,000 and may be approaching \$1,000,000, offer reasonable indications of steady dividends from this date forward.

At the Beaver Consolidated, the low cost of treating the ore is enabling the company to maintain its earnings, while the recent leasing of the Prince property, and the probability of also acquiring the Badger offers fair promise of operations being still further enlarged.

Combined, the Beaver and the Temiskaming mines lend an importance to that part of the Cobalt field, which, with the other smaller operations now getting under way, is fully maintaining its place as one of the most productive parts of this rich silver field.

Normal conditions, or at least conditions to which the mines have become fairly familiar, prevail in Cobalt, with the one exception of a labor supply slightly below requirements. That this shortage will continue for the summer seems probable. An indication of this is shown in the presence this week of a representative of the international Nickel Company who is in Cobalt to engage all the drill-runners he can at a wage somewhat higher than that being paid locally. Whether or not the mining companies of Cobalt will be content to work at a slightly reduced capacity by maintaining the present wage and bonus schedule or will also enter into competition with outside industries is not yet clear. Just now opinion appears to be more or less divided on this phase of the situation.

The Cobalt Radium Syndicate, made up of a number of Cobalt men, has engaged men to explore the surface of property held in the township of Butt in the near vicinity of the radium-bearing ore discovered in that district last year. The Syndicate holds six mining claims in that area.

In connection with the proposed light railway from Elk Lake to Gowganda, the Bill has passed its third

reading, and it is learned that the Northern Light Railways is making a bond issue of \$300,000 in denominations of \$1,000 bearing interest at 7 per cent with a bonus of one share of common stock per \$1,000 bond. The company is capitalized at \$500,000 made up of 5,000 shares of the par value of \$100 each. In addition to the mines already in operation, more than a dozen other property owners have signified their intention to commence work just as soon as rail transportation is provided. The promoters of the enterprise are confident of success. Indications are that other work in the district, particularly lumbering will provide additional freight revenue. The Bill to establish The Mining Court of Ontario bids fair to pass, and may become law in September. The proposal has met with quite general favorable comment throughout the mining districts.

Sir Clifford Sifton, together with Geo. Glendenning has just concluded a visit to the Bonsall property in the Gowganda district. It is understood arrangements will be made to operate the property if rail transportation is actually provided this year.

The Coniagas Company is proceeding with the preliminary working connection with exploring their recently optioned property in the Gowganda field. A road is being cut, and camps erected preparatory to taking on miners.

### Ore and Bullion Shipments.

During the week ended May 21st, five Cobalt companies shipped an aggregate of ten cars containing approximately 776,648 pounds of ore. The Nipissing alone sent out four cars containing 356,424 pounds.

Following is a summary:—

Shipper	Cars	Pounds
Nipissing . . . . .	4	356,424
Mining Corporation . . . . .	3	199,409
La Rose . . . . .	1	83,416
Beaver . . . . .	1	72,799
Right of Way . . . . .	1	65,800
<b>Totals . . . . .</b>	<b>10</b>	<b>776,648</b>

During the corresponding period the Nipissing made one shipment of bullion, sending out 74 bars containing 100,416.48 fine ounces. This is the first shipment of bullion to be made since March from the Nipissing.

Arthur A. Cole, Mining Engineer, has issued the following statement of ore shipments over the T. & N. O. Ry., for the month ending April 30th, 1920:—

### Silver Ore.

	Tons of 2,000 lbs.
<b>Cobalt Proper.</b>	
1. Coniagas . . . . .	118.00
2. Dominion Reduction . . . . .	32.50
3. Hindson Bay . . . . .	30.76
4. La Rose . . . . .	105.17
5. Mining Corporation . . . . .	423.52
6. McKinley-Darragh . . . . .	94.59
7. Northern Customs . . . . .	65.20
8. O'Brien . . . . .	104.17
9. Peterson Lake . . . . .	30.00
10. Temiskaming . . . . .	78.33
	<hr/>
	1,082.24

The above shipments were made to the following Companies:—

**Canada.**

Deloro Smelting & Refining Co., Marmora	
Deloro . . . . .	759.95
Coniagas Reduction Company, Thorold . .	183.09

**United States.**

American Smelting & Refining Co., Pueblo	139.20
--	--------

**Note.**

April 6th. Highest price of Silver during month . . . . .	127,000
April 30th. Lowest price of Silver during month . . . . .	111,500
Average price of Silver during month . . . . .	119,779

**The Gold Mines.**

The expected relief in the way of labor supply has not materialized in the Porcupine gold area, and the mines are all still operating under this handicap. In spite of this, however, the earlier prediction of the Ontario Bureau of Mines that the output for 1920 would set a new high record promises to be fulfilled. According to figures now being prepared, the production from January 1st to May 31st will about equal that from January 1st to June 30th during the previous year.

Ore being treated at the Hollinger Consolidated has been reduced to around 1,700 tons daily, as compared with an average of 1,950 tons during 1919, and compared to 2,200 tons monthly earlier during the current year. The performance, therefore, at the Hollinger promises to about equal that of the preceding year, and tends to show that the increase in output from the Camp as a whole will be due to the operations of the Dome and Porcupine Crown, and, also, to an increase at the McIntyre-Porcupine.

The question of increasing dividends on the Hollinger was shelved at the annual meeting of the company. Shortage of labor is stated officially to be the only reason why the dividend could not be increased to one per cent every four weeks, or 13 per cent annually. At the same time, some of the shareholders have expressed the opinion that the company could continue its present policy of paying one per cent every eight weeks, with one extra at the end of each year or a total of seven per cent per annum, and in addition to this pay an extra of one per cent in July of each year and thus increase to a return of 8 per cent interest instead of 7 per cent as at present. As to this, the fact that no action was taken at last week's meeting would indicate no change until perhaps the end of the current year.

Following are the directors of the North Crown Porcupine Mines, Ltd., the newly incorporated \$3,000,000 company which takes over the combined Porcupine-Crown and Thompson-Krist properties;—Sir John Carson, president of managing-director; J. R. L. Starr, K.C.; Wm. I. Gear; J. B. Bertram; Percy Galt, K.C.; James G. Ross, C.M.G.; James Cooper; A. G. Gardner; and Ziba Gallagher. Messrs. Starr, Bertram and Galt represent the Thompson-Krist in the new merger, while the remaining six are original members of the former board of the Porcupine Crown Company. The North Crown begins its career as a going concern, with \$30,000 in its treasury and mill in operation treating ore at a substantial current rate of profit.

The Clifton-Porcupine, as a means of overcoming labor shortage has decided to engage diamond drills for exploration work. Following up its policy of keeping its shareholders fully informed as to progress and results achieved, the Company has issued a quarterly statement, dated May 19, as follows:—

Since our last report, dated February 19th, was mailed, considerable progress has been made in the development of your property.

On the 200-foot level a crosscut has been driven East for 160 feet. Nos. 7, 5, 6 and the Boulder Veins have been encountered in this crosscut. The first three have increased in width, while the Boulder vein has shown a tendency to split up on the first level. The same high values encountered on surface and on the first level, persist at this greater depth, considerable free gold being in evidence in the vein material.

70 feet of drifting has been done on No. 7 vein, both North and South of the shaft, with good results. A crosscut has been run west for 90 feet, but at the date of writing, the objective—No. 8 vein—has not been reached. 125 feet of drifting has been done on No. 6 vein North, with the object of proving the values in this vein and of reaching the contact area which lies North of our present workings. In this contact area, we are advised by our Consulting Engineers, lies our best possibilities of an increase in size of our ore bodies. It is significant that at every producing mine in the camp, the largest ore bodies lie in reasonably close proximity to the contact between the keewatin and porphyry rocks.

The labor situation is a hard problem to solve. Employees of the mines, lured by equal or higher wages in less hazardous occupations, have been leaving the mining districts in considerable numbers. The gold mines, with a fixed price for their finished product, have advanced wages to the highest possible point, in spite of which they have found it impossible to compete with other employers for the necessary labor to operate at the highest efficiency.

All of the mines have been affected by this situation. The larger mines have found it necessary to curtail operations to some extent, while the smaller mines have been affected in even greater degree. We have found it almost impossible to replace the skilled workmen who are leaving.

For these reasons, your Directors deem the present an opportune time to carry on an extensive diamond-drilling campaign recommended by our Consulting Engineers. Contracts for several thousand feet of this work will be immediately let on tenders in hand, and the work will start as soon as the drills can be moved to the property.

The results of this drilling will provide us with information as to the size and depth of the ore bodies that will make it possible to carry on the further development of the property in the most efficient and economical manner.

Announcement is made that property owners in the Boston Creek district are making arrangements to engage the services of Alfred R. Whitman, mining geologist, to make a study of the geological structure as revealed by mining to date. The work is to be done with the full cooperation of the property owners interested, and will include a very careful examination of the Miller-Independence mine, now working at a depth of 500 feet, and the Mondeau, where work is being carried on at the 250-ft. level.

Tenders are being called for the sale of the assets of the Kirkland-Porphyry Gold Mines, including several unpatented mining claims in the township of Teck in Kirkland Lake, and also a lease on the Orr Gold Mines. It is learned from usually well-informed quarters that there is likelihood of early resumption of work on the Orr property. It is intimated that the differences which arose between Hamilton B. Wills and the Wettlaufers of Buffalo are being so adjusted as to make it possible to resume work on the promising property. The Orr lies adjacent to the Kirkland lake as well as the Teck-Hughes mine, and has a substantial tonnage of good grade ore already blocked out.

On the Fidelity property in the township of Teck, the main shaft has reached a depth of 192 feet, and is being driven at the rate of about 80 feet a month, indicating that the 300-ft. level will be reached by the early part of July.

The shaft is being driven on an incline, following the vein. It is stated the main vein continues quite uniform in width, and that a small vein measuring about four inches in width has come in along the foot-wall side of the shaft.

The first or 100-ft. level has been reached at the Bidgood property in the Lebel township part of the Kirkland Lake gold area. The vein is stated to have dipped north out of the shaft at a depth of about 65 feet, and a crosscut consisting of a round or two of shots is being driven to intersect the vein at the 100-ft. level. Sinking is proceeding at about 100 feet a month at the Bidgood, inclusive of timbering. In addition to cutting a station at the 200-ft. level it is thought the shaft will reach the 300-ft. level by the last week in July.

At the Kennedy-Boston, the newly installed mining plant is now in operation and the deepening of the former 100-ft. shaft has commenced. The shaft is down 120 feet, and it is officially announced that the vein which dipped north out of the shaft at a depth of about 60 feet has come back into the shaft at a depth of 112 feet where it measures about three feet in width and is highly mineralized, with visible gold.

Mining claims Nos. 4655 and 4656, situated in the township of Skead, between the Manlev property and the Wisconsin-Skead Gold Mines have been purchased by a syndicate from Niagara Falls.

The deal is stated to have been arranged by A. C. Thorburn, and arrangements have been made to commence work at once. It is proposed to spend about \$2,000 in determining the most suitable place for the commencement of underground operations.

### BOOK REVIEWS

**PROSPECTOR'S FIELD-BOOK AND GUIDE.** By H. S. Osborn. Revised and enlarged by Mr. W. Von Bernewitz. Ninth Edition.  $4\frac{5}{8}$  by  $7\frac{1}{8}$  ins. 400 pages. Flexible Fabrikoid backs, designed for pocket use. Price \$3.00. Henry Carey Baird & Company, 2 West 45th St., New York.

This volume is a completely reset and revised edition of the issue of 1910. The information regarding ore occurrences outside of the United States is fuller and more correct than is often the case in New York publications and Canadian references, particularly in the new chapter on alloy minerals, are reasonably accurate. The chapter on petroleum, asphalt and oil-shales contains much information in condensed space.

The introduction to the work gives preparatory instruction in elementary geology, the use of the blow-pipe ore analysis and surveying, and the work emphasizes that "the search for ore deposits is becoming a specialized profession, and those that keep this fact in mind are the ones most likely to benefit by it."

From a United States viewpoint, the list of minerals and metals prepared by C. K. Leith of the U. S. Geological Survey is interesting, as showing to what extent the United States is self-sustaining in minerals supply. Minerals which our neighbours must import include nickel, mica, graphite, asbestos, and cobalt, all found in Quebec or Ontario.

The book appears to be well worth the price asked. It is well bound and adapted for pocket use. The condensed accounts of ore occurrences throughout the world constitute one of the most valuable features of this book.

The revisor has had practical mining experience in New Zealand, Australia, Dutch East Indies and America, and, judging from the Canadian references, his facts are reliable.

### BRITISH COLUMBIA LETTER.

#### Hazelton, B. C.

J. D. Galloway, resident mining engineer, has returned to take charge of the season's government operations in his district. He states that much road and trail work is planned to assist in the opening up of mining properties on Hudson Bay Mountain, on Driftwood Creek, and in other sections of the wide area covered by the Northwestern Mineral Survey District of the Province. Mr. Galloway intends making an early inspection of placer mining in progress in the Cariboo and hopes later on to be able to arrange to make a trip of inspection into the Peace River Country. The examination of a group of mica claims near Tete Jaune Cache is proposed at an early date, the owners having in mind the opening up of the deposits on a large scale, it having been shown that the mica yield is of as fine a quality as can be secured on the North American Continent.

#### Stewart, B. C.

The Provincial Government, as a result of recommendations made by George Clothier, President Engineer for the District, proposes the expenditure of a substantial sum this year in further opening up the Salmon River mineral area, as well as the zone north of the Portland Canal Mining Division. The wagon road, built last year to the Premier Mine will be continued and trails will be constructed to assist both operators and prospectors. In order to make easier the recording of mineral claims staked in this country the whole of the region where are found the head-waters of the Naas, Unuk, and Iskut Rivers has been included in the Portland Canal Mining Division so that hereafter prospectors will travel along the line of the Salmon River, making use of the trails mentioned, to Stewart to make official record of their claims and assessment work. The change simply means that an imaginary line has been drawn by the Department of Mines from Mount Brown to a point where the 56th parallel intersects the eastern boundary of the Omineca and Naas Mining Divisions which throws all that part of the Naas Division lying to the north of this line into the Portland Canal Mining Division. The section to the south of this line will be administered as before from Anyox, where there is a mining recorder. Previously it was thought to be easier to reach Anyox from the head-waters of the Unuk, Naas and Iskut Rivers than to get to Stewart owing to the intervening coast mountains. Recent exploration in connection with the opening up of the Salmon River zone, however, has proved that a comparatively good pass exists and that, with the development of the past two years and that underway, prospectors will be better able to get to Stewart than to Anyox.

#### Kamloops, B. C.

The report that diamond drilling operations on the Aspen Grove Group of Mineral Claims had been suspended indefinitely has been denied by J. H. Bate, one of those interested in the property. He asserts that powerful machinery is being installed and that a programme of exploration and development has been prepared that is likely to take two or three years to complete.

#### Cranbrook, B. C.

A copper deposit has been located on the Skookumchuch River, about thirty miles from Cranbrook, which

is said to have exceptional merit. Development work to a depth of about 40 feet is announced to have shown up a considerable body of high grade ore. The property has been bonded by Dan McIntosh, a well-known mining man, for \$15,000.

#### **Kaslo, B. C.**

At the annual meeting of the Utica Mines Ltd., it was decided to decline an offer received for a controlling interest in the property.

#### **Barkerville, B. C.**

L. A. Bonner, manager of the Lightning Creek Hydraulic Company, Cariboo, who returned recently from a business trip to England, states that the season in northern British Columbia in respect of placer mining is extraordinarily backward. A few weeks ago he snowshoed into his property over four feet of snow and expects that later on trouble will be experienced through freshets. Mr. Bonner looks for a greater output of placer gold from the Cariboo this season notwithstanding the handicap which the operating companies face owing to the scarcity of labor.

#### **Vancouver, B. C.**

A mining property known as the Opporgol, situated on Howe Sound, a short distance from Vancouver City is attracting considerable attention as recent development, financed by a syndicate of business men of Vancouver, is reported to have brought ore to light carrying gold, silver, and copper values. The first work done at elevation of 1500 feet and in the initial forty one feet of cross-cut four veins were cut ranging from 2 1-2 feet wide. Between the veins is a replacement of the same character and values as in the veins. The ores in the cross-cut are reported to have averaged \$8.51 a ton. Both copper and lead occur in sulphides. At sea-level another adit was run opening up the ore vein. The company plans to instal a couple of drills, an air-compressor, and an hydro-electric plant, power for which can be secured from any one of several waterways in the vicinity. The property is most advantageously situated for operation as it can be worked from a portal practically at sea-level.

#### **New Denver, B. C.**

The strike of metalliferous miners of the Slocan Silver Mining Camp of this Province has been settled, the operators at a meeting held recently having decided to grant the men an advance in wages amounted to practically 75 cents a day. The mines ascribing to this agreement include the Roseberry-Surprise, the Noble Five, the Cunningham properties, the McAllister, the Carnation, the Lincoln, the Rambler-Cariboo and the Standard. There has been little work done on any of the properties mentioned since the 1st of May. It is understood that the Silversmith Mine at Sandon compromised with its men before the general readjustment was arrived at, allowing its men 50 cents a day increase in wages and blankets.

#### **Victoria, B. C.**

It is announced that the issue between the Taylor Engineering Company and the original Dolly Varden Mines Co. which threatened to develop into long sustained litigation through the courts of Canada has been settled. Under the terms of the agreement the Taylor Company, who are in possession of the Dolly Varden Mine and all the plant in connection therewith,

undertakes to pay a debt of approximately \$613,000 without delay. This charge was an incumbrance against the property in favor of the first owners, and those who accorded them financial assistance, but it was not specified that the amount should be paid over on any particular date. The settlement, therefore, means that the obligation will be discharged at once and that the Taylor Engineering Company will be allowed to retain possession and to operate the mine without further molestation, the agitation in progress for some weeks at Ottawa for the disallowance of legislation passed at the last session of the Provincial Legislature being discontinued.

### **B. C. GOVERNMENT CONSIDERING ESTABLISHMENT OF IRON AND STEEL WORKS BY THE PROVINCE.**

The Hon. Wm. Sloan, Minister of Mines for British Columbia, in an address on the second reading of the Bill to extend the operative period of the Iron Ore Bounties Act until 1925, said with reference to the much debated possibility of an iron and steel industry in the Province:

"That the Government has received many applications from various quarters for substantial support in the launching of this industry. All these applications have been given careful consideration, but in every instance it has been found that the individuals or corporations concerned, required that the Government enter into financial responsibilities of a very serious nature, in many instances to the full financial requirements of the enterprise. This, it will be appreciated, would involve a binding obligation not lightly to be undertaken under the conditions with which the Province has been faced during the past few years. For this reason consideration has been given the question of whether it would not be the best policy of the Government itself to lead the way to the establishment of an industry for the manufacture from our iron ores of commercial iron and steel rather than finance private enterprise to do so.

#### **Province will take the initiative..**

"It is proposed therefore," continued the Minister, "that should no more favorable terms be submitted by private enterprise to assemble full and complete data, having special reference to the recent important discoveries of hematite ore in the Whitewater district, all with a view of considering the undertaking by the Government of the establishment of an iron and steel industry at an early date in the Province of British Columbia, thereby paving the way to the obtaining for our Province what is recognized as the basis of all industrial enterprise."

#### **Government is Determined to Grant Every Encouragement to Iron Industry.**

"The bill before the House," he continued, "is merely one of a series of measures each of which, directly or indirectly, has the same object. Others that may be instanced are the Mineral Survey and Development Act and the Iron Ore Supply Act of 1919. The former furnishes the machinery through which more detailed and accurate information regarding our mineral resources—and our iron ore bearing areas are in an important part of these resources—may be obtained. In passing I may say that it has served and is serving this purpose."

# A MARSH HOIST

## IS MADE THE RIGHT SIZE FOR YOUR MINE

and in either Steam Power or Electric Power

This shows one of our Electric Mine Hoists. We make many other types. Send for our catalogue of Mine Hoists, Cars, Cages, Buckets, etc., and see what we offer you. It will repay you.

From the little 10 Horse Power size for prospectors or small mines to the massive 50 Horse Power size, one of our 7 sizes should be just right for your mine.

We are specialists in the building of Hoisting Machinery of all sorts. For nearly a quarter of a century we have been designing and building Hoists, and have developed a Hoist that we are really proud of—proud because of the record of good work they have done, and are doing in mines, quarries, and other classes of work from one end of Canada to the other.

## MARSH ENGINEERING WORKS, Limited

TORONTO, CANADA

By those who had been and were concerned in the establishment of an iron and steel industry Mr. Sloan wished it to be understood that the Government was behind them to the full extent of its power having regard to the serious financial obligations of the country and to its responsibility as the representatives of the taxpayers and electors of the country. The Government was sincere in its determination to help those whose enterprise and confidence in the future of the Province had induced them to take up the task of launching the industry which, everybody was agreed, would mean the opening of a new, a broader and a more prosperous era in the commercial and industrial development of British Columbia.

#### The Whitewater Discovery.

"Possibly the most noteworthy of recent events bearing on this subject," recalled Mr. Sloan, "is the discovery of large deposits or what are described as limonite and hematite ores in the Whitewater River section of the Lillooet Mining Division. When information was received regarding the existence of these bodies of iron ore Wm. M. Brewer, one of our mining engineers, was instructed to proceed to the district to make an examination and submit a report thereon. This he did last summer. While Mr. Brewer was unable to make a full and complete inspection he was able to see and to satisfy himself of enough to demonstrate that the field merits the very closest examination in the public interest. Mr. Brewer places himself on record as estimating the 'actual ore' at 7,200,000 tons, the 'probable ore' at 15,000,000 tons, and the 'possible ore' at 50,000,000 tons. Assays of the ore show it to be of high commercial value.

#### Steps Taken.

"Recognizing the importance of such a deposit," said the Minister, "the Department of Mines immediately took steps to interest the Geological Survey of Canada. Through Charles Camsell, its western representative, the services were obtained of S. J. Schofield, who proceeded to the district to make a further report. His party, however, was too late to make any extensive investigation. In the meantime, through the instrumentality of the Department, a reconnaissance of possible route of transportation from the Whitewater District to the coast has started, having been partially completed last season. It will be continued this year.

#### Further Work Promised.

"This work," Mr. Sloan went on, "both in regard to the geology of the section, the extent and quality of the iron ore available, and as to the feasibility of arranging transportation facilities, will be proceeded with this year as soon as conditions permit. The assurance of the Geological Survey has been received that although hampered by a shortage of properly qualified geologists, every effort will be made to assign a party for exploration in this section during the Summer months.

"It is scarcely necessary," he said, "for me to emphasize the importance of such a deposit of accessible Hematite and Limonite ore to British Columbia. If all is as represented it means that the establishment of blast furnaces in this Province, is as practical as it has been found in any other industrial centre of the American continent. In short it simplifies the problem of the treatment of the Magnetite Ores of the Coast

and brings the establishment on a firm and lasting basis of an iron and steel industry within easy reach of those with capital looking for a sound investment that will assist at the same time in the opening up and the development of the country.

#### Progress Has Resulted From Government's Action.

"Broadly speaking," the Minister concluded, "we are, unquestionably, some distance further ahead towards the solution of the problem of the development of the iron ore resources of the Province. The Government has not lost sight of the importance of the question and is using every means possible to bring about the result so fervently desired. With our policy of obtaining more information regarding the deposits at our disposal, of bonuses, of assisting those undertaking experiments in treatment, and lastly of obtaining from the Legislature the power to prevent the tying up of such holdings for speculative purposes, we may expect action soon."

#### BOOK REVIEW.

TECHNICAL WRITING. By T. A. Rickard, Editor of "Mining and Scientific Press." First edition. John Wiley & Sons, New York and Chapman & Hall, London. 178 pages with index. Buckram and Boards. \$1.50 net.

Those who have read Mr. Rickard's previous work, "A Guide to Technical Writing," will need no introduction to his abilities to point out the frequent faults of technical writing, a subject which, as the editor of a technical publication, must be constantly before him. "This little book" states Mr. Rickard in his preface, "has grown from a set of five lectures delivered before the engineering classes of the University of California in 1916. It is a ticklish task to write on writing, because the effort provokes self-consciousness. All I hope to accomplish by means of these printed lectures is to cause members of my former profession to 'sit up and take notice.'" We believe Mr. Rickard can claim to be master of two professions.

As a writer, Mr. Rickard is well qualified to advise on style, having himself developed one of the most lucid and readable styles in contemporary technical literature. A mode of expression such as that employed by Mr. Rickard is not, however one that can be easily come by, and it will be admitted by those who have any experience of writing that what is apparently the happy and spontaneous expression of the moment is in reality the outcome of much reading, much experience, much labor, and a thorough knowledge of the subject written about. Those who have had occasion to look over the papers of students and immature writers will have noticed that half assimilated and incomplete knowledge leads to a turgidity that no amount of use of technical terms will help to clear, and, conversely, the speeches of eminent scientists, who thoroughly comprehend their subject, are remarkable for their simplicity of wording and the clearness with which the ideas they discuss are presented to the reader.

One of Mr. Rickard's happiest essays dealt with the romance of mining, and was doubtless much appreciated by the International Mining Convention before which it was delivered recently at Seattle, but this essay could not have been undertaken without wide knowledge, and revealed an acquaintance with litera-

ture, old and new, sacred and profane, that is attained by few technical writers. While, therefore, the attainment of Mr. Rickard's own felicity of expression is only possible to those, who in addition to the ability to think clearly and the possession of accurate technical knowledge, are deeply read and possess more than an ordinary education in English, there is a widespread necessity existing among engineering students to improve their use of English as an instrument to convey technical knowledge to others.

Mr. Rickard's slogan is "Remember the reader," which he correctly terms the fundamental rule of writing. "Somebody must put hard work into every technical article that is written for publication, if not the author, then the editor; if both the author and the editor shirk their duty, the reader will have a headache."

A quotation from Quintillian by Hill is used by Mr. Rickard, to emphasise the necessity for clearness, that is very apt. "It is not enough to use language that must be understood."

"Superlatives and other Diluents," is a chapter touching a common fault of writers. "Diluent" is a delicious sarcasm. The word "very" it is stated can be deleted nine times out of ten. The qualification of the unqualifiable word "unique" is properly condemned. "Considerable" is described as "a woolly word, usually out of place in a technical statement." Such loose and indefinite terms as "more or less," "some," "greater or less extent," "more or less completely" are shown to be a source of weakness. "The secret of a vigorous style is the rejection of the superfluous word" is Mr. Rickard's conclusion. At the same time he shows that clearness is desirable even if it requires seeming tautology.

A helpful chapter is that on hyphens and compound words, the trend of which is to be seen from the following examples :

"A 'single stamp-mill' is a lonesome mill.

"A 'single-stamp mill' is a mill consisting of batteries of one stamp each.

"A 'single-stamp-mill' is a mill containing only one stamp.

"A 'crude ore-bin' is an ore-bin of crude construction.

"A 'crude-ore bin' is a bin made to contain crude ore.

"A 'crude ore bin' is an example of crude writing." In the chapter of "slovenliness" Mr. Rickard criticises, not too hotly, the befouling of the English language with vulgarisms and colloquialisms that are understood only locally or regionally. "Chucking muck in the gob" may be a phrase understood in Yorkshire coal-mines, but it is not preferable to "packing the waste," a term that does permit of ambiguity.

"Jargon" is dealt with entertainingly but in a root and branch fashion. It is described as dealing in periphrases rather than going straight to the point, it loves the abstract rather than the concrete, it dabbles in words of sound rather than meaning." Sir Arthur Quiller-Couch is quoted as writing; "In literature as in life he makes himself felt who not only calls a spade a spade, but has the pluck to double spades and re-double."

We think Mr. Rickard's truest statement is that slovenly writing is the result of slovenly thinking, "for slovenly habits of expression corrode the very substance of thought." A notable quotation is given from Whewell, who in the "Philosophy of the Inductive Sciences" writes: "Language is often called an instrument of thought, but it is also the nutriment of thought; or rather it is the atmosphere in which thought lives; a medium essential to the activity of speculative powers, although invisible and imperceptible in its operation; and an element modifying, by its qualities and changes, the growth and complexion of the faculties which it feeds."

Mr. Rickard's little book is commended to all who desire that their writing shall clearly express the thoughts they desire to communicate. While not all can hope to attain to the ideal of language expressed by Mr. Rickard in the concluding sentence of his book, is here quoted as a fine example both of style and idealism. "Language is a factor in the evolution of the race and an instrument that work for ethical progress—it is a gift to be cherished as the ladder by which man has climbed from his bestial origin and by which he may ascend to a loftier destiny, in which, ceasing to stammer in accents that are but the halting expression of swift thought, he shall unfold his mind in the fulness of speech, and, neither withholding what he wants to say nor saying what he wants to withhold, shall be linked to his fellows by a perfect communion of ideas."

## Coal—A First Essential of National Independence

The Report of the United States Committee on Canadian pulpwood embargoes contains the following statement:—

"The testimony also conclusively shows that we must have pulpwood from the Crown Lands and three provinces in the Dominion, otherwise our papermills will be eventually compelled to close down or move into the Dominion of Canada. Canada must have coal, sulphur, kaolin and dyes from the United States, or suffer a similar misfortune."

The ending of this phrase is ambiguous. Whether it is intended to imply that it would be a misfortune to United States mills to move into Canada, or that it would be a misfortune to Canadians to have to move into the United States we are unable to gather from the wording, but there is no ambiguity about the statement "Canada must have coal, sulphur, kaolin and dyes from the United States." Nevertheless it is an incorrect statement. Canada does not have to obtain either coal, sulphur, kaolin or dyes from the United States. All, or any of these materials we can supply from our own resources, if we care to.

Ontario can produce the sulphur, Quebec can supply the kaolin, and either Nova Scotia or Alberta can supply the coal and the dyes, if it is considered necessary.

There is one thing, however, that Canada can not do. She cannot maintain her national independence unless she will proceed to make the Dominion self-supporting in coal supply.

We do not make the statement that Canada can obtain coal from her own mines as cheaply as it can be brought from the United States, but we venture to reaffirm the opinion expressed before the Annual Meeting of the Canadian Mining Institute in relation to our coal supply, namely, that "Canada cannot be run as a successful economic whole if we ignore the obligations of nationality and insist on buying goods in the cheapest market merely because they are cheap. That way lies loss of independence and national disintegration."

These definite opinions are admittedly dogmatic. The circumstances do not, in our opinion, admit of any modification, if it is admitted that the possession of a sufficient supply of bituminous coal is a necessity of national independence and defence. On this point the

rulings of the Supreme Council are specific. Pick out any part of Europe affected by the war where coal occurs, and there the fighting will be found to have been most prolonged and bitter. Select any territory regarding which the framers of the Peace Treaty found greatest difficulty in satisfying the disputants, and usually it will be found to be a coal district. The places that are recorded with greatest pride on the war banners of the Canadian Expeditionary Force might also be a record of the coal-mine villages of France and Belgium. There is no activity of peace or war in our modern life that is not based on some phase of the utilization of bituminous coal.

If therefore, Canada, through lack of taking thought, or following a policy of ease, continues to allow her own coal deposits to remain undeveloped, and voluntarily places our country in a position of economic dependence for the essential and indispensable raw material of our times, there is no escape from the conclusion that little by little Canada will become economically subservient to the United States. We express no opinion on the desirability of such an evolution. That is politics, and not the business of a technical journal, but it cannot be otherwise than proper to point out how inevitable are the consequences of continued lack of national interest in Canada's coal supply.

In the Canadian Mining Institute "Bulletin" during May 1917, the Editor contributed the following opinions, which are quoted as reflecting to some extent the more pleasant spirit of those crucial days; as a reminder that the foregoing opinions are not expressed with any desire to be captious or lacking in appreciation of the comradeship that has existed between this country and its neighbor; and also as bearing on the national importance of coal.

"The Allied Nations are grateful to the United States first, because the adherence of this great Republic is an open vindication of the righteousness of the common cause, and secondly, because the United States is an Ally possessing unlimited potentialities."

"The idealistic and spiritual strength of her people, her great wealth, her large population and military possibilities, are gratefully acknowledged and duly weighed, but what is the greatest asset of the United States as the Ally of the free nation of Europe?

"Is it not undoubtedly that the United States possesses within its borders the largest, most accessible, and the most valuable bituminous coal deposits in the world? That is the basic fact underlying all the wealth and industrial activity of the United States."

"The part that the United States will play in the war will be measured and limited by the production of bituminous coal."

So also will Canada's progress towards a place of honor in the councils of the Empire and among the sovereign nations of the World be measured and limited by her production of bituminous coal.

### INVESTIGATION OF INTERNATIONAL NICKEL COMPANY'S OPERATIONS.

A Toronto newspaper, commenting on Premier Drury's promise to investigate the questions affecting provincial taxation of the profits of the International Nickel Company, writes editorially:—

"Perhaps Mr. Curry will not succeed in having his view adopted that all the International Nickel Company's lands should be confiscated if it is shown that nickel reached Germany during the war with the Company's knowledge."

So far as the operations of the International Nickel Company are concerned, these were investigated by a Royal Commission that had an unassailable personnel, and were reported upon in one of the completest and most satisfying documents ever issued by the authority of a legislature. In this Report no less than twenty-three pages are devoted to consideration of the taxation of mines and the mining industry as practised in all parts of the British Empire and in the other countries of the world, and as bearing upon the question of taxation of the nickel industry in Ontario. Whatever form the promised investigation may now take, it may be stated that the basic and pertinent facts are all to be found in the Report of the Royal Ontario Nickel Commission of 1917.

As to the implications that nickel reached Germany during the war with the knowledge of the International Nickel Company, this is as unworthy as, in the best-informed circles, it will be considered unfounded. Probably the problem that gave most worry, not only to the International Nickel Company, but to the British Government and the State Department of the United States, was to prevent nickel finding its way to Germany. Up to April 1917 the United States was a declared neutral, but there was a very large portion of the population in the United States that during the interval between the Summer of 1914 and the declaration of war upon Germany — a space of thirty-two months — was whole-heartedly in favor of Germany's cause. The cordial reception given by the people of

Newport to the "Deutschland" is an instance of the forces that had to be overcome by those who desired to keep munitions of war from reaching Germany, nor was there anything illegal in supplying such munitions to a German vessel. If, in spite of all precautions, Canadian nickel reached Germany during the war, the persons who managed the International Nickel Company were not in a worse or more blameable position than the secret service men of the Allies who labored night and day to close the door to Germany.

If the Government of Ontario contemplates wading through the portfolios of Dr. Albert, the memoirs of Count Bernstoff, the "ditty-box" of Capt. von Papen, and tracing the spoor of German intrigue through the mucky labyrinth of the period immediately preceding and following August 1914, the imposing bulk of the 1917 Report will have to be far exceeded. It is a long trail, very sinuous, and will be found to lead nowhere.

### SIR AUCKLAND GEDDES ON OIL PROPAGANDA.

Sir Auckland Geddes shows wisdom and courage in giving an unqualified denial to the statements which have recently been given prominence in both British and United States' newspapers that the British Government, in conjunction with the Dominion Governments, is seeking and deliberately planning a world monopoly of oil.

We have previously expressed the opinion that the sedulous dissemination of false statements of this kind is the work of the propagandists of rival oil interests, and Sir Auckland Geddes' categorical statement corroborates that opinion. In the time of her gravest national emergency, when oil and coal supplies were a matter of life or death for the Empire and its soldiers, British interests controlled, according to our Ambassador's statement, but five percent of the world output. At the same time, he reminded his United States' hearers, "you have 82 percent of the present world supply of oil under your control."

In the paper prepared by C. K. Leith of the United States Geological Survey to show his country's relative economic world position with regard to mineral supplies, petroleum is listed along with copper as one of the two minerals "of which the exportable surplus dominates the world situation". This statement, from such a source, should be authoritative.

Sir Auckland Geddes' characterization of oil wells in the British Isles as "a geological curiosity, not a commercial proposition" may not please some people, but it correctly describes the oil occurrences in the British Isles to date.

English newspapers are much to blame. The cables that are sent to Canada and to the United States purporting to come from well-informed British sources are all too often wrong in fact and foolishly provoc-

ative in purpose. When the proposals for the British Empire Steel Corporation were first given publicity in London, the titbit of the journalist who cabled the news was that English experts had examined the Sydney Steel Works, and had decided they were fit only for the scrap pile. Here was an instance of important news of very general interest turned into provocative nonsense. The instance is typical of many. We cannot conceive, for example, that Sir E. Mackay made the statements attributed to him by a London "Sunday World" cable claiming control of the world's oil resources by British interests in words that no patriotic citizen of the United States could fail to take umbrage at.

Those who send news cables from Great Britain to Canadian newspapers should remember the many bonds of mutual interests that tie this self-governing Dominion to our friends in the United States. Canada's whole-hearted adherence to every British ideal, and her ability, while strictly guarding her national status, to live and work amicably with her great neighbor, need no demonstration after the years 1914 to 1920. We need no spur, or preachment, from jejune imitators in Great Britain of Wm. R. Hearst, nor do we desire that the business game which our citizens and their compeers in the United States have played with energy, yet in all friendship, for a century of peace, across an unguarded frontier that has not its like in history, shall be embittered and endangered by the paid propagandists of selfish interests.

The world is not at peace. In many respects the chances of a world catastrophe are greater today than they were before Germany attacked the pillars of civilization in 1914. From motives of simple self-protection against the forces that threaten to dissolve society, the United States and Britain should hold together. Our Ambassador's categorical exposure of the lies that are being disseminated by the press of the British Isles and the United States is a wise and necessary step, and one that in Canada will be properly appreciated.

---

"Meantime a new field of perhaps promise looms on the slopes of James Bay, where Professor Williams of the Dominion Geological Survey has been making an examination. His Report, stripped of its "geological ornamentation," is practically to the effect "that there is plenty of evidence of seepage, and the future may yet find much of commercial value."

So states a well-known Toronto newspaper. The term "geological ornamentation" is ill-chosen. Dr. Williams' condensed report on the James Bay region was, as a matter of fact, rather remarkable for its clearness and avoidance of unnecessary use of geological terms. (See page 82, issue 30th, Jan. 1920.)

### THE LATE G. G. S. LINDSEY..

The "Journal" desires to voice a general feeling of regret among the mining profession of Canada at the loss by death at a comparatively early age of Mr. G. G. S. Lindsey. Mr. Lindsey was an illuminating example of the distinctive advantage of combining legal ability and a practical acquaintance with mining. During his term as President of the Canadian Mining Institute, Mr. Lindsey was very largely responsible for the affiliation of the Mining Society of Nova Scotia which followed his visit, accompanied by a most representative delegation of members of the Institute, to Sydney, Nova Scotia, in the Spring of 1914. This was a courtesy not forgotten by the members of the Institute in Nova Scotia, where Mr. Lindsey, by his alert and engaging personality, left a pleasant and enduring memory.

By Mr. Lindsey's death, the mining profession in Canada, and in particular the Canadian Mining Institute, loses a member whose lifework has added distinction to its annals, and permanence to its foundations. Mr. Lindsey's attendance at the March meeting of the Institute in Toronto was doubtless made at the expense of much physical effort, but it was an instance of his devotion to the affairs of the Institute, as is only too plainly evidenced by his death at this time.

---

### GOOD PROGRESS BEING MADE AT FLIN FLON

Mr. Jack Hammell has returned to Toronto after spending some time at The Pas and Flin Flon making preparations for the development of the great sulphide orebody at Flin Flon Lake. Acting for the men who have taken option on the property, Mr. Hammell has assembled at the mine the necessary machinery and supplies for the work to be done this summer. The plant at the Mandy mine and that at Beaver Lake have been purchased and taken to the Flin Flon mine. The dismantling was successfully accomplished before the winter roads broke up. Owing to the difficulty of moving machinery and supplies in this district during the summer months, an effort was made to fully utilize the winter roads while they lasted. This meant haste, but Mr. Hammell believes that the engineers who take charge of the development work will find the necessary materials on the job.

It is planned to sink two shafts. The Mandy plant will be used for one and the Beaver Lake plant for the other. The contractors have an excellent reputation as shaft sinkers and it may be expected that no time will be lost in opening up the orebody. It is understood that work at one shaft will proceed to depth without interruption, while at the other lateral work will be started at several levels as soon as the necessary depths are reached. It is said that about \$85,000 has already been spent in making preparations for the work. Col. W. B. Thompson and associates, of New York, and the Mining Corporation of Canada, of Toronto are said to be the holders of the option.

# The High Grade Silver Ores of the Stewart District, British Columbia

By VICTOR DOLMAGE.

The rich silver deposits of the Stewart District, British Columbia, are now engaging more attention than any other silver deposits in the world. The camp is still in its infancy, no development work having reached a depth greater than 250 feet, and, as in the case of all high grade deposits, the operators and investors are facing the vital problem of whether the orebodies are of the secondarily surface enriched type, and consequently of relatively shallow depth, or whether they are high grade primary ore-shoots with good chances of persistence to relatively great depths.

At the Western Annual Meeting of the Canadian Mining Institute held in Vancouver in November, 1919, Mr. E. E. Campbell<sup>1</sup> read a paper on the mineral deposits of this district in which he stated somewhat arbitrarily, that the high grade orebodies were "rich surface ores," which I take to mean ores enriched by downward moving surface waters and commonly referred to as secondary ores. Although he spent considerable time in pointing out the great importance of the discovery of this class of ore in the northern districts of the Province, he entirely neglected to give any evidence that would prove that these ores have a secondary origin. He mentioned the fact that the deposits carried minerals of "unquestionable secondary origin" but failed to give any examples of this small uncertain and rapidly dwindling class of minerals. He named the following as the minerals occurring in the rich orebodies; pyrite, native silver, argentite, rubysilver, sphalerite, galena, and chalcopyrite, but we fail to find in this list any of the "unquestionably secondary" class, rather they are conspicuously absent. Ruby silver is the only one of those mentioned which approaches this class, and of it W. H. Emmons<sup>2</sup> goes only so far as to say that it is *nearly* always secondary. The other minerals of this list undoubtedly occur as primary minerals.

In the discussion which followed the reading of this paper, the present writer took exception to the arbitrary manner in which this vital problem had been handled, and pointed out the lack of any evidence to prove the statements made. A few months later, when a splendid collection of ore from this locality was submitted to me at the British Columbia Branch of the Canadian Geological Survey for examination, I naturally took advantage of the opportunity of searching for evidence having a bearing on this point, and made a careful microscopic study of the ore, the results of which follow.

The specimens were collected and brought in by Mr. Charles Bunting, one of the original locators of the rich deposits of this district, and the author of the first authentic history of the Salmon River Camp.

<sup>1</sup> E. E. Campbell, Mineral Occurrences in the Stewart District, Monthly Bulletin of The Canadian Mining Institute, March 1920.

<sup>2</sup> W. H. Emmons, The Enrichment of Ore Deposits, Publications of the United States Geological Survey, Bulletin 625, page 261.

Three classes of ore were represented in this collection, namely: (1) stephanite-native silver ore, which is the richest silver ore of the district, carrying as high as 3,000 oz. of silver to the ton; (2) a type which is known in the district as "Black sulphide ore," which carries from 500 to 1,000 oz. to the ton, and (3) lower grade silicious ore.

The *Stephanite ore*, though exceedingly rich, is not abundantly distributed, but confined to a few small veins less than a foot in width. In appearance it is quite spectacular, consisting of masses of stephanite and tetrahedrite cut by a close net-work of native silver veinlets and sprinkled through with a few small grains of pyrite. Gangue minerals are absent excepting for small inconspicuous grains of milky quartz. Plate 1, 2, 3 and 4 illustrate this class of ore.

The microscope revealed the following minerals and structures in them which indicate that they were deposited in the order named:—

1. Pyrite
2. Quartz
3. Zincblende
4. Tetrahedrite
5. Chalcopyrite
6. Galena
7. Argentite
8. Stephanite?
9. Polybasite?
10. Native silver
11. Native gold.

The Pyrite occurs as sparsely scattered grains ranging in size from a few millimeters to a centimetre, which are invariably rounded, embayed and veined by replacements of quartz, zincblende, chalcopyrite, tetrahedrite, galena, native silver and gold. One of these pyrite grains is shown in Plate 5.

Zincblende, though abundant in the black sulphide ore is comparatively rare in the ore of this class, and only visible under the microscope. It is sprinkled through with minute grains of chalcopyrite and is replaced by tetrahedrite and stephanite.

Tetrahedrite is an abundant mineral in this ore, as is shown by Plate 1. It is replaced by stephanite and native silver.

Stephanite is the predominating mineral in this ore and constitutes at least 50 per cent of the total volume of the specimens examined. It replaces the pyrite zincblende and tetrahedrite, and is itself replaced by native silver.

Polybasite is a rare mineral in these deposits and is found closely associated with stephanite and native silver.

Native silver is abundantly present in this ore, occurring as small blebs in the pyrite grains as shown in Plate 5, and as veins in the stephanite and tetrahedrite, as shown in Plates 1, 2, 3, and 4. These veinlets in some places have sharply defined contacts such as those in Plates 2, and 3, and in other places they gradually merge into rich disseminations, such as is shown in Plate 4.

Though assays show that this ore carries considerable gold, very little could be detected, even under

PLATE I

Stephanite (St.) and tetrahedrite (T) replaced by veinlets of native silver (S) from Stephanite-Native silver ore. Mag. 300 diameters.

PLATE II

Stephanite (St) replaced by native silver (S). Mag. 300 diameters.

PLATE III

Stephanite (St.) cut by silver veinlet (S) and etched by the action of light. Mag. 300 diameters.

the highest magnification. It was, however, observed as minute particles, both in the pyrite grains and in the gangue minerals free from other metallic minerals. Plate 6 shows a grain of pyrite including a small bleb of gold.

The second class of ore, known in the district as black sulphide ore, is the usual type of ore encountered in the workings. In hand specimens it is seen to consist of a dark-gray fine-grained mixture of gangue minerals, zincblende, galena tetrahedrite, and pyrite. It is slightly porous, and the vugs are usually found to be lined with crystals of galena and drusy quartz.

Under the microscope it was seen to contain the following minerals which were deposited roughly in the order in which they are named:

1. Gangue (chiefly quartz)
2. Pyrite
3. Quartz
4. Zincblende
5. Chalcopyrite
6. Tetrahedrite
7. Galena
8. Argentite
9. Native silver
10. Gold.

PLATE IV

Stephanite (St.) replaced by veinlets and disseminations of silver (S). Mag. 300 diameters.

The similarity of this list to that of the stephanite ore is striking, the only difference being in the absence of polybasite and stephanite. The great difference in appearance is due to the much larger proportion of zincblende, galena, pyrite and gangue and a smaller proportion of native silver. Plate 7 illustrates this class of ore.

The pyrite of this ore is precisely the same as the pyrite of the stephanite ore, being replaced in a similar manner by the same minerals, as is shown by Plate 8.

The zincblende is the most abundant mineral of the sulphide ore and, as usual, is impregnated with minute specks of chalcopyrite. It is also replaced by tetrahedrite, galena and native silver.

The chalcopyrite, which was confined to the zincblende in the stephanite ore, is in this ore freely distributed through the gangue and other minerals, but only as very small particles.

Tetrahedrite and galena are both abundant in this ore, and though no silver minerals could be detected in them other than an occasional grain of silver, there can be little doubt that they are both argentiferous.

The native silver of this ore, though not as abundant as that in the stephanite ore, is nevertheless quite

PLATE V

Pyrite (P) grain replaced by silver (S) galena (G) zincblende (Z) and quartz (Q). Mag. 330 diameters.

plentiful. In this ore it never occurs in veinlets, such as those of the stephanite ore, but is always found in the form of small rounded grains in the galena, zincblende, tetrahedrite and pyrite, usually showing a preference for pyrite and tetrahedrite. This mode of occurrence is well shown in Plate 9 and seems to strongly indicate that it was deposited in the same general period as the other sulphides and is therefore a primary mineral in this ore.

Argentite is a rare mineral in this ore and is associated with the other sulphides in a manner indicating that it also is a primary constituent.

PLATE VI

Pyrite (P) replaced by gold. Mag. 500 diameters.

The third class of ore is a strongly silicious type, consisting of white granular quartz with small scattered particles of pyrite, tetrahedrite, polybasite, stephanite(?), galena, argentite, ruby silver and native silver. It is low grade in comparison with the other ores, but is very abundant in the district. All of the minerals are replaced to a marked degree by native silver, but the other minerals were not associated with one another, being distributed through the quartz as isolated grains, and their paragenesis therefore not indicated.

Of the minerals which have been identified in this deposit, the only ones that might be used as criteria for secondary enrichment are stephanite, pyrargyrite, and native silver. Stephanite has been proven to occur as a secondary mineral in a great many enriched deposits, and is generally regarded as a mineral characteristic of the enriched zone, but a possibly primary origin is admitted by many of the closest students of this subject. Its presence therefore may be regarded as a strong indication of secondary action, but not

PLATE VII

Black Sulphide ore, P = pyrite, T = tetrahedrite, G = galena. Mag. 75 diameters.

as conclusive proof. Pyrargyrite is a much more common constituent of secondarily enriched ores than stephanite, but it, too, according to Emmons<sup>3</sup>, has been found in mines at depths greater than those reached by surface solutions.

Native silver was at one time thought to be invariably of secondary origin in sulphide ores, but it is not now regarded as such. In a recent paper on the "Veins of Cobalt, Ontario," W. L. Whitehead<sup>4</sup> has given excellent proof of the primary nature of the native silver of these deposits. In the ore under discussion the native silver occupying rounded pockets in the pyrite, tetrahedrite, and galena (such as is shown in Plates 5, 8, and 9) is almost certainly of primary origin, while that forming veinlets in the stephanite as shown in Plates 1, 2, 3, and 4 may be of secondary origin.

The impossibility of definitely determining the origin of this ore without an examination of the conditions obtaining in the field and without a study of the

<sup>3</sup> W. H. Emmons, Principles of Economic Geology, page 445.

<sup>4</sup> W. L. Whitehead, The Veins of Cobalt, Ontario, Economic Geology, March 1920.

enclosing rocks and gangue is evident. Nevertheless, the above observations furnish evidence capable of supporting the following conclusions.

(1) The black sulphide ore is at the same time a very plentiful ore of the district, one of the highest grade ores of the district, and one composed of essentially primary minerals. This establishes the important and interesting fact that much of the high grade ore of the Stewart District is of primary origin, and has therefore a much better chance of persisting to relatively great depths than if it were of secondary origin, a fact of considerable significance in a camp so highly promising on the surface and as yet so slightly developed.

(2) The stephanite-native-silver ore may have been enriched by the replacement of primary minerals by stephanite and native silver, and the silicious ore by the addition of ruby silver, stephanite and native silver, but in neither case is it definitely proven.

(3) The small amount of stephanite ore to be found in the district, the comparative low grade character of the silicious ore, and the great preponderance of primary minerals over secondary minerals in all the ore excepting the stephanite ore, indicate that the processes of secondary enrich-

PLATE VIII

Pyrite grain (P) from black sulphide ore replaced by silver (S) tetrahedrite (T) and galena (G). Mag. 250 diameters

ment may have played only a very subordinate role, if any, in the formation of these rich silver deposits.

**Silver Minerals Etched by Light.**

An interesting phenomenon observed in connection with the microscopic examination of these specimens, and one which served as an aid in determining the minerals, is the etching of the stephanite and native silver by the action of light. This peculiar property of silver minerals was first described by W. L. Whitehead<sup>5</sup>, who made observations on all the common silver minerals and recorded his results in tabular form, so that they could be used for purposes of identification. The Stephanite of the Stewart District was found to be very susceptible to light, and on an ex-

posure of from 10 to 30 seconds it would become covered with minute specks similar to those shown in Plate 3. Areas in the vicinity of silver veinlets and along scratches were found to be the most sensitive. Plate 10 shows some of these spots of unusually large size developed in two sets of parallel rows intersecting one another at a small angle, which are thought to be related to scratches produced during the process of polishing.

It is a well known fact in polishing that when a scratch is made on the surface of any material there

PLATE X

Stephanite etched along polishing scratches. Mag. 600 diameters.

is developed in the material below the visible scratch a zone which though not apparently affected, is nevertheless considerably modified so that it behaves differently under etching reagents. These modified zones vary in size and degree of modification with the size of the scratch which has produced them, and it is for this reason that the spots etched on the surface of a polished mineral are sometimes found to be arranged in lines such as those shown in plate 11.

These spots were of such a large size that an attempt was made to determine their character by the usual methods employed in mineralography. They were found to react with nitric acid and *aqua regia* in a manner similar to that of native silver, and their color also resembled native silver. It is therefore probable that they are to some extent at least composed of this metal and that the effect of the light on the mineral is to dissociate it into its elements. This is, however, only a suggestion and far from being proven.

The silver occupying the veinlets in stephanite was also in many instances found to be altered to a brownish red color by the action of light, a peculiar feature I think not previously mentioned in the literature. The coloration was found to be confined to the smaller veinlets, to the margins of the larger veinlets and was most strongly marked in the fine disseminations of silver in the stephanite, such as are shown in Plate 4. The phenomenon is thought to be the result of impurities in the silver, though this appears to be homogeneous under the highest powers of magnification. These facts show that the minerals stephanite and polybasite are very unstable, and it is therefore not surprising to find them so extensively replaced by native silver.

*Note.*—Since the above article was written, the attention of the author has been drawn to Professional Paper 104 of the U.S. Geological Survey on "The Genesis of The Ores of Tonopah, Nevada," by Edson S. Bastin and Francis B. Laney, in which these authors find the minerals stephanite, polybasite, pyrrhonyrite, argentite, electrum, etc., occurring as primary minerals as well as secondary minerals in the ores of that camp.

### THIRD ANNUAL MEETING OF THE CANADIAN INSTITUTE OF CHEMISTRY, TORONTO, MAY 27th and 28th, 1920.

The third Annual Meeting of Canadian chemists was held in Toronto on May 27th and 28th, and was well attended by members from all parts of Canada, and by visitors from the United States.

Among the papers read was one by Messrs. Roast and Pascoe, given before the Montreal Branch of the Society of Chemical Industry in February last, on the "Inner Life and Habits of Metals." This paper was fully illustrated by a series of microphotographic slides, prepared by the authors. Mr. Roast is the Secretary-Treasurer of the Canadian Institute of Chemistry, and an ardent worker in the interests of the profession.

A much appreciated feature of the meeting, which was held in Chemistry and Mining Building of the University of Toronto, was the public display of chemical apparatus and instruments.

Dr. Charles H. Herty, Editor of the "Journal of Industrial and Engineering Chemistry," and a past-president of the American Chemical Society, addressed the meeting on "Chemistry under a Constitutional Government," and pointed out convincingly how great

a part the chemist played in the industrial life and in the military defence of a democratic state.

Prof. Matthew A. Parker, of the University of Manitoba, was appointed a delegate to the inter-Allied Chemical Congress in Rome during July. This is the second meeting of the Congress, which was organized last year in Brussels to pool chemical progress and research in the interest of the countries that were allies during the war.

The Toronto Meeting was the first annual meeting of the newly formed Canadian Institute of Chemistry, a full description of which, with a list of the original officers was published in our issue of 23rd April (see page 341).

The members of the Institute now number 140 qualified chemists.

Prof. Neish, of Queen's University, Kingston, who returned to Canada last August after nineteen years absence in New York, gave to the meeting his impressions of Canada upon returning home. Speaking at the dinner with which the proceedings were concluded, Prof. Neish said Canadians were ultra-conservative, and did not take advantage of their opportunities as they should do.

### PROSPECTING IN BEATTY TOWNSHIP.

Some years ago many discoveries of gold were made in Beatty township, east of Matheson. Development was started on several properties in the vicinity of Painkiller lake. The great fire of 1916 destroyed the plant and buildings over a wide area and prospecting was discontinued for some time.

There is now again some activity in this district. At the Hill mine about 20 men are working and drifting is in progress at the 200 and 250 ft. levels. At the Cartwright Goldfields property camp buildings have been recently erected on the northern claims and surface prospecting is being systematically carried on. This company lost mining and milling plants in the fire of 1916.

It is said that development work is to be resumed this week at the Hattie property.

Fig. 6 (see page 460). 400 K.W. Alternator, built by Dominion Bridge Co.

# The Turbo-Blower Installation at the Blast Furnaces of the British-America Nickel Corporation, Sudbury, Ont.

The following sketch Fig. 1 shows the arrangement of an interesting turbo-installation built in its entirety by the Dominion Bridge Company at Lachine, Que. to deliver air for the blast of the furnaces in which the nickel ore mined by the British-America Nickel Company at Sudbury is reduced to a matte for further treatment at the Refinery at Deschênes, Ottawa.

The extent to which the Dominion Bridge Company has engaged in the manufacture of steam-driven turbine machinery is not widely known, and it will probably be a surprise to many Canadian readers to know that this very compact and workmanlike unit was built, including the alternator, in the Bridge shops at Lachine. This department of the Bridge Company's activities is entirely distinct, and is in addition to the manufacture of water-driven turbines and paper-making machinery in which the Dominion Engineering Works engaged at the Rockfield shops.

In the British-America Nickel Company's blower unit, the five machines in continuous alignment consist of two groups.

At the left, a high-pressure steam turbine drives a 500 k.w., 60-cycle, 3-phase generator in tandem with

a 30,000 cu. ft. blower, delivering air at about 36 ozs. per sq. inch.

The two remaining machines consist of a steam turbine connected to another blower of the same capacity as the first-named.

Under normal operating conditions, the blast is supplied by the last-named blower, but in the event of trouble on the outside transmission line, the other turbine and generator and the blower connected to them are put into operation, and the other blower is shut down.

By taking out the coupling bolts between the turbine and generator, the generator can be run as a synchronous motor at 3,600 r.p.m. to drive the blower next to it.

Each turbine is equipped with its own surface condenser, and condensate-removal pump. The steam-jet air-evactors, however, are grouped in a battery, and withdraw air from a trunk airline with branches to each condenser. This arrangement has been found to be very convenient in practice, as it makes the evactors interchangeable, and enables some to be shut down at light loads. The evactors also discharge into a common line; the outlet from which is submerged

Fig. 1.

Fig. 2. Blower Installation under construction.

Fig. 3. Impeller for 30,000 c. ft. Blower.

Fig. 5. Rotor of 2,100 h.p. Condensing Steam Turbine.

in a tank through which the condensate is pumped, the water being thereby raised in temperature, and the heat units remaining in the evacuator steam conserved.

The air pressure delivered by these blowers is determined with certain limits by adjustment of the pressure regulators connected with the governor valve of each turbine. When once set, the turbo-blower will continue to give air at the desired pressure without further attention.

Fig 2 shows the blower installation in course of erection in the shops. In order from the foreground may be seen the following component parts of the unit, namely, the blowers, alternator and steam turbine. Fig. 3 shows the impeller for the 30,000 cu. ft. blower. The design of this impeller, the blades of which are securely slotted into the shaft, ensures complete freedom from vibration and an absence of end-thrust. The turbine machinery is all made under the Rateau-Smoot patents.

Fig. 4 is a photograph of a low-pressure wheel for

Fig. 4. Low-pressure Wheel of 2,100 h.p. Steam-turbine on static Balancing-wheel.

a 2,100 h.p. steam turbine, (built for the British-America Nickel Corporation) on the static balancing-table.

The rotor of a condensing steam-turbine, 2,100 h.p. is shown in Fig. 5. This is also for the British-America Nickel Corporation.

In Fig. 6 is shown a 400 k.w. alternator, designed to be driven by a non-condensing steam-turbine, that was built by the Dominion Bridge Co. for the Imperial Tobacco Company of Canada. It is direct-connected with the exciter.

The supercession of reciprocating-motion engines by the rotary engine for the furnishing of compressed-air as a motive-power, and for the furnishing of air-blast, is almost complete in all new construction, and it is not only interesting, but a matter for congratulation that Canadian machine-shops are in a position to supply machinery so modern in type, and so well adapted for the purpose, as the turbo-blower installation hereinbefore described.

**G. G. S. LINDSEY**

Mr. G. G. S. Lindsey died at his home in Toronto on Thursday, May 27. He was well known among mining men, not only in Canada, but also in other parts of the world, and it is with great regret that they will learn of his decease. He was also prominent as one of Toronto's leading lawyers and had a wide acquaintance among members of that profession. By many others he was known as one of the shining lights of the Liberal party for he was a strong supporter of that party until the conscription issue came up and he left the old party to campaign for the Union Government and conscription. In his younger days Mr. Lindsey was known to many as an enthusiastic sportsman and as a cricketer especially.

As a student at the University he found time not only for studies and athletics, but also for journalism and he founded the publication "Varsity," which has from that time been the organ of the Varsity students.

THE LATE G. G. S. LINDSEY.

Mr. Lindsey had long been interested in mining affairs. Though by profession a lawyer he had experience as mine operator, and was for some years general manager of the Crow's Nest Pass Coal Co., one of the largest coal mining enterprises of Western Canada. His experience as a lawyer and miner made him practically well informed on mining law and he was a recognized authority. He always did his part to further any effort made to improve laws and regulations governing mining in various parts of Canada.

Mr. Lindsey was one of the best known and best liked members of the Canadian Mining Institute. He took an active part in Institute affairs and served on the Council for several years. He also gave his services to the Institute in legal matters at all times. In 1915 he was President of the Mining Institute. In

1915 his business took him to China where he carried on negotiations with the Chinese Government for English mine operators. He found there a difficult situation owing to the fact that the Chinese Republic had no mining code. He was delayed much longer than he expected owing to the fact that he was recognized by the Chinese Government as a man who might draft a suitable mining code. He undertook the work and when he returned to Canada he had framed the mining code of the Chinese Republic.

Mr. Lindsey took an active part in the campaign for conscription, and in other war work during recent years. Latterly he had been physically unfit for great activity and he had been unable to take his usual active part in mining affairs during the past two or three years.

Mr. Lindsey's life was an active one and he crowded into it more work and more experiences than come to most men. He leaves behind him a host of old friends.

R. E. H.

**NOVA SCOTIA NOTES.****Dominion Coal Company.**

An official announcement is made that Mr. E. P. Merrill is appointed General Manager of the Dominion Coal Company and the Dominion Iron and Steel Company and subsidiaries, and will reside in Sydney.

The new shaft, situated between Collieries Nos. 1 and 2, has reached the Phalen Seam. The sinking has been done under contract by the Foundation Company, whose work is now completed. The completion of this shaft will save much underground travel, and will assist in the ventilation and pumping of the Phalen workings in this district.

The unwatering of the Morien Colliery is approaching completion, and construction men are at work on a re-arrangement of the surface plant.

The Surface plant of the Hub Colliery has been dismantled, much of the equipment having been utilized at No. 17 Colliery (New Waterford.) Other portions of the Hub Plant, including the boilers, will be removed to Morien Colliery.

Much underground work has been done at No. 17 Colliery. The proportion of undersea coal now drawn upon by the Cape Breton Collieries of the Dominion Coal Company is striking. Counting the newly operated mines No. 24 (Emery Seam), No. 17 (Victoria Seam) and the Morien Colliery, the Company now has eleven submarine collieries and six land collieries in the Sydney Field.

A number of scattered stoppages of work arising from local dissatisfaction with rates and mining conditions have recently taken place in the Dominion Collieries. The men appear disinclined to allow their union officials to act for them, and, upon very slight occasion, cease work. Difficulties of this kind have taken place over the rates of landing tenders, over the question of new pit-boxes at the Springfield Collieries, and in other instances.

Discomfort and danger has been experienced at various mining centres in the Maritime Provinces through forest fires. At New Waterford, in Cape Breton, and in the vicinity of the collieries at Springhill, Joggins, Maccan and River Hebert, in Cumberland Co., much damage has been done.

An impression appear to have been general, and certainly a despatch appeared in the newspapers purporting to come from Ottawa, that the Industrial Disputes Act was being amended to allow of collective

adjustment by a Conciliation Board of wage questions affecting more than one company and its employees. It was rather difficult to understand how such an arrangement was possible, in view of the spirit and intent of the Industrial Disputes Act, but, under the impression that such an arrangement was possible, the Executive of the U. M. W. in Nova Scotia requested of the Minister of Labour that collective adjustment of their common demand upon the Nova Scotia coal operators for a 27 per cent increase at May 1st should be attempted by a Conciliation Board having wide powers. The Minister of Labour has replied stating that such a proceeding is not possible under existing legislation.

The U. M. W. officials state they will press the new demand, and it is stated, by a Cape Breton newspaper, that the Secretary has advised the miners to reduce their output by one-half if the new wage demands are not conceded.

The Wage Scale Committee of the U. M. W. is in session at Halifax, and it is probable that the new demand will result in another series of Conciliation Boards.

In view of the recommendation to reduce output it may be noted that coal production in Nova Scotia is even yet thirty per cent below pre-war outputs, and the statement was recently made by the General Superintendent of the Dominion Coal Company, that "We cannot mine enough coal to handle the St. Lawrence trade." In June 1914 the output of the Dominion collieries in the Sydney Field was 452,000 tons. It is unlikely to exceed 300,000 tons in June 1920.

### PROPERLY DOMICILED

There is considerable press comment over the fact that the British Empire Steel Corporation has been incorporated under the Nova Scotia Joint Stock Companies Act, and that its head office is to be at Sydney. There should be nothing surprising in the circumstance that the big Corporation is to be domiciled here. "Where a man's treasure is, there his heart is also."—Sydney "Post."

### MANITOBA LETTER.

By C. A. MILLICAN.

A Mining Syndicate has recently been formed to acquire the Falcon Mineral Claims at Turtle Lake in the Rice Lake District.

The interested parties are chiefly Winnipeg, Dauphin, and Gilbert Plains men. Mr. R. R. Pattenson, of Winnipeg is the Trustee.

These claims to the north and north-east of Turtle Lake were first staked by William Walton.

Two engineers, it is stated, have favorably reported on these properties, and a further report is to be obtained from a Professor of the University. If his report is equally favorable, a company will be formed to carry out active mining operations.

Work will commence on the Gabrielle Mine early in June. A party is being made up to proceed to the property via Riverton and Hole River—taking advantage of the water route, which will bring the men and supplies to within two miles of the mine. As soon as the shafts and drifts are de-watered, an inspection will be made by Mr. J. B. Tyrrell, of Toronto, who will advise the lines for future operations.

Active work on the Gold Pan Extension commenced on the first of May, employing two shifts. The Com-

pany is engaged in sinking and at last reports the shaft was down 80 feet. The vein measures about 4½ feet in width, with quartz over 3 feet showing high mineralization carrying sulphides and galena and some free gold. The work is being done on the vein, which has a slight dip to the north, but stands almost perpendicular. It is the intention of the Company to continue sinking, without doing much lateral work, to the 200 foot level. Good progress is being made and the directors are well satisfied with the showings so far.

Work on the government road from the Lower Bellevue Landing on Hole River is making slow progress. Word from the camp states that there are several log jams in the river between this point and Hole River Lake—which will have to be removed before this route can be used freely.

For the time being work on the Gold Pan Mine has practically been suspended. The drift is in 285 feet from the shaft following the vein, but the showings are not of a very encouraging nature, and there is not likely to be any more work done until a close inspection of the property has been made.

This will likely be done by Mr. Tyrell, when he is in the Rice River Lake region in June.

It is the intention of the Directors to have a very thorough examination made into the situation, and much will depend on the result of the pending inspection and report.

Word from the Commonwealth mine, received within the last week, is very encouraging. Test pits have been made on the main vein, which is 7 feet wide, and carries a well distributed showing of free gold across the entire width. Mr. Porter, the managing director has gone in to the mine, and expects to return with some nice samples of free gold ore. From present appearances this should develop into a really good proposition. In addition to sinking the test pits, considerable attention is being paid to stripping.

There is a prospect of much movement in the Rice Lake area this season.

Engineers are going in for the purpose of making examinations for interested parties and some further prospecting is being undertaken.

The fine weather of the last ten days has caused a more interested feeling in mining matters, and some very promising samples of ore are coming out. The writer looks for a healthy movement during the present year, and for some really good prospects to be brought to public notice.

Activity at Herb Lake is concentrated upon the Bingo, where a gang of miners are sinking a shaft to the 200-ft. level, and then to drift for 200 ft. Ten additional miners were sent up on yesterday's "Muskeg," ("Muskeg, Ltd." is the name given to the train that runs over the Hudson's Bay Line out of Le Pas.) and the machinery will be taken in at the end of the month, when the lake is expected to be free of ice. There is ample equipment on the ground to carry on with in the meanwhile.

The results of the sinking will be watched with interest. The strong gold showing on the surface in a promising series of veins has caused the owners to regard the property as a sure producer—(Pas Herald.)

### COMMISSIONER WALLACE RECOMMENDS SINKING TEST SHAFT FOR OIL IN DAUPHIN DISTRICT

In a report of the possibilities of the presence of oil in the Lake Dauphin district, made public today at the Parliament Buildings, R. C. Wallace, commissioner of Northern Manitoba, and former professor in geology in Manitoba university, recommended to the government that a drilling outfit be sent to that district, capable of sinking a shaft 1,000 feet in order to settle the question once and for all and make speculating impossible. Prof. Wallace's report covers several typewritten pages in which he goes into the arguments for and against the presence of oil in the district very thoroughly.

In concluding his report he states:

"The limestones of our province are not considered to be favorable for the collecting and retaining of oil pools. Sufficient work has been done in the southern part of the province to establish the fact that discoveries of oil are unlikely. In the north part of the province, from Dauphin northward, however, little work has been done. It must not be forgotten that it is now generally agreed that the last possibility for oil in the Canadian west is in the limestones of a similar age in the Mackenzie basin."

"Two points must be definitely established and it is impossible at the present stage to establish anything further: (a) That the oil is a natural oil and had not in anyway been faked. From enquiries made rather carefully in Dauphin and from the result of analysis made by Milton-Hersey company—my opinion is that the well has not been salted.

(b) The oil must be found to issue vertically through the four feet of limestone which was opened up at the bottom of the claim and not laterally from the surface of the limestone. If the oil is coming in from the bottom of the four feet of limestone the probabilities are small that it is connected in any way with the shale deposits of the Riding Mountains, part of which is oil bearing."

Prof. Wallace in his accompanying letter recommends that the government clear up the two points definitely before commencing operations. He recommends that the Hugh McNair, of the Public Utilities Commission who was named by the legislature as the other expert to co-operate with Prof. Wallace in making a report on the oil deposits, be asked to do this work. So far the government has not received any report from Mr. McNair.

Prof. Wallace, together with Hugh McNair, engineer of the Public Utilities commission, was appointed by the legislature to make a thorough survey of the Dauphin district with regard to oil.

This action was taken as a result of the many conflicting reports given publicity concerning large oil deposits there. In digging a well, it is reported, oil was found and this is the well which is referred to by Prof. Wallace. It went to a depth of four feet in the limestone. The legislature ordered that if the report of the commissioner and his assistant was favorable, the department of public works should purchase a drilling apparatus capable of sinking a shaft 1,000 feet in order to permanently establish the presence or absence of oil.

Prof. Wallace in concluding his report continues: "If conclusive evidence is obtained on both these points I am of the opinion that the government should entertain the expense of putting down a test hole at the

well itself. While no one who knows the situation well can feel enthusiastic at the present moment in regard to the possibilities of oil reservoirs in this district, yet the importance of oil is so very great that its possibilities even if merely possibilities should not be overlooked. There is another reason which is in itself important. Direct action by the government will go far to prevent unlimited speculation which is at any time possible where evidences of oil are reported.—"Free Press," Winnipeg.

### R. C. WALLACE TO CONTINUE AS COMMISSIONER OF NORTHERN MANITOBA UNTIL SEPTEMBER, 1921.

It was officially announced by a member of the provincial cabinet today that Commissioner R. C. Wallace, of Northern Manitoba will continue to hold the post despite former announcement as to resignation. The government has completed arrangements to retain his services until Sept. 1, 1921.

Commissioner Wallace was loaned to the provincial government by the University of Manitoba, where he filled the post of professor in geology. As commissioner of northern Manitoba he is the administrator of law in a vast unopened tract of country. As a professor of geology his knowledge has been of inestimable value in connection with the mining industry which is opening up the northland.

Mr. ANGUS W. MACDONALD,  
Welfare Supt. and Employment Agent, Dominion Steel Corporation, Sydney, N.S.

## OUR NORTHERN ONTARIO LETTER.

### THE SILVER MINES.

Announcement is made in Cobalt that despite the decline in quotations for silver, the mining companies will continue to pay their employees the bonus of \$1.25 a day, just as though the price of silver had remained at over \$1.20 an ounce. This brings the schedule to a level with that of the International Nickel Company and is likely to stop the exodus of miners which has been going on for the past few weeks. The agreement made last Autumn with the men was that the wage should be from \$3.50 to \$4.00 a day, plus a bonus of 25 cents a day when silver averaged 80 cents an ounce or over, plus an extra 25 cents a day for each ten point advance in silver above 80 cents an ounce. On this basis, the bonus amounted to \$1.25 a day when silver averaged over \$1.20 an ounce as during March and April. At the same time, the May rate would be only 75 cents a day bonus on account of silver having declined to below \$1.10 an ounce. Not only has it been announced officially to the "Journal" that the full \$1.25 bonus will be paid for May, but this rate is definitely promised for at least six months.

During the closing week of May, therefore, with the labor question stabilized by the timely action of the companies, and the price of silver strengthened, a prosperous period seems likely. It is to be noted, also, that selling silver in New York and receiving payment in New York funds, receipts are increased by some 12 or 13 per cent. by the premium on New York funds, making the price \$1.15 an ounce for silver produced in Canada.

The McKinley-Darragh has declared a regular quarterly dividend of 3 per cent., payable July 1st. The disbursement will amount to \$67,428, and make a total of \$5,821,591 paid to date by this company. This is equal to 262 per cent. on the company's issued capital. It is expected the financial statement which will accompany the dividend cheques will show a surplus of around \$450,000 to \$475,000 as compared with \$474,864 as of the previous quarter.

On May 24th the Beaver Consolidated disbursed a 3 per cent. dividend, the first in some three years. It is believed probable that disbursements will now be made at reasonably short intervals, owing to the company having been relieved of the financial burden of paying the way of the Kirkland Lake Mine which the Beaver controls. In the past three years the Beaver paid out over \$750,000 in developing and equipping the Kirkland property, which only within recent months has paid its own way.

The Coniagas Company has a force of men engaged in erecting camps and clearing a road to the Gamble-Thompson property in the Gowganda district. The claims are held under a working option agreement, with a certain amount of work to be done monthly.

It is noted that bonds which the Northern Light Railway are to issue will bear interest from June 1st., which is pointed to as an indication that it is proposed to carry out the construction work immediately. The work of surveying the route from Elk Lake to Gowganda is being continued, and it is stated that a very suitable grade will be established.

Harry Stewart, manager of the Crown Reserve Mine has been appointed a director of the Canadian-Kirkland Gold Mines. This property is held under option to the Crown Reserve Company, and the new appoint-

ment was made to fill the vacancy caused by the resignation of R. W. Brigstock. The annual meeting of the Canadian-Kirkland is to be held within the next few weeks, notice of which will be sent out in due course.

As regards the question of arrangements to treat the large dumps on the Kerr Lake mine, nothing of an official nature has so far been announced, although it is believed that suitable terms will eventually be agreed upon. The dumps are estimated to contain something like 75,000 tons of material of low silver-content, but believed as likely to be workable at a fair margin of profit.

The Coniagas Company has made arrangements to treat approximately 40,000 tons of tailings by cyanidation in the Buffalo mill of the Mining Corporation. The lease covers only the cyanide equipment of the Buffalo mill and does not include the flotation.

### Ore and Bullion Shipments.

During the week ended May 28th, three Cobalt companies shipped an aggregate of eight cars containing approximately 646,251 pounds of ore. The Nipissing alone sent out five cars. Following is a summary:—

Shipper	Cars	Pounds
Nipissing . . . . .	5	434,390
Mining Corporation . . . . .	2	129,659
McKinley-Darragh . . . . .	1	82,204
Totals . . . . .	8	646,251

During the week, the Nipissing and the Mining Corporation were both heavy bullion shippers, and sent out a total of 299 bars containing 351,570.03 fine ounces.

Following is a summary:—

Shipper	Bars	Ounces
Nipissing . . . . .	149	201,156.53
Mining Corporation . . . . .	150	150,413.50
Totals . . . . .	299	351,570.03

### THE GOLD MINES.

Higher wages at the gold mines is perhaps the chief announcement during the week in connection with the industry. While this announcement comes only from the Hollinger Consolidated, yet with the requirements of this one mine being almost as great as all the other gold mines of the Province combined, it indicates that other companies must also meet a similar schedule. Loaders are offered \$4.72 and machine runners \$5.28 for 8 hours work. The new scale compares with \$4.75 and \$5.25 at Cobalt and is also about equal to that being paid by the International Nickel Company at Sudbury.

It is believed that with gold mining likely to prove one of the steadiest industries in the country during the period of reconstruction, and probably destined to flourish most when other industries are confronted with depression, they may now be a tendency for men to find their way in greater numbers to the gold-mining camps of the North. The present appears to be an opportune time to establish themselves in the gold-mining centres, and to thus be freed from the uncertainty of conditions in other centres where a break in present wages appears likely due to effort being directed toward the manufacture of luxuries instead of the provision of necessities, such as we consider gold to be.

Advance information to the correspondent of the "Canadian Mining Journal" would suggest the belief that the coming annual report of the Dome Mines Company will be exceedingly favorable. It is known that the company commenced its fiscal year on April 1st., 1919, with a surplus of only \$56,000 and that about two months later this had been reduced to almost nothing. However, at that time the mill was put into service, and it is learned that the annual report will show a net profit of around \$650,000 during the last ten months of the year ended March 31st., 1920. In addition to this large net profit, the company is stated to have written off close to \$250,000 for deferred development, plus about \$200,000 for depreciation. The fact, therefore, is, that despite the adverse economic conditions, and being forced to operate at only two-thirds capacity, the Dome realized net profits amounting to about twenty per cent on its issued capital in the ten months during which the mill operated. Mill heads are stated to have averaged over \$6.50 a ton, while the total costs, inclusive of the large amount written off for depreciation and deferred development amounted to only between \$3.50 and \$3.60 to the ton. The achievement is believed to be one of the best recorded in the history of mining in Canada.

At the annual meeting of the Porcupine V.N.T. held May 27th, it was decided not to resume work until such time as workmen are plentiful. It was stated, however, that all is in readiness to commence work just as soon as the labor supply becomes satisfactory. This is taken as an indication that harmonious conditions have been established among the directors and that the course to be adopted will be governed by conditions other than lack of inside cohesion.

The Hollinger Consolidated has declared a dividend of one per cent payable June 16th to shareholders of record June 14th. The disbursement will amount to \$246,000.

Announcement is made by the Ontario-Kirkland Gold Mines that lateral work at the 450-ft. level has opened up the downward continuation of ore bodies developed at the 300-ft. level. It is stated that ore will average about \$16 to the ton at the point where encountered. Further work is proceeding, and it is planned to reach a decision during the next month as to the size of the mill required so as to proceed with the work of installation at as early a date as possible.

A delay has occurred in connection with the reopening of the Tough-Oakes, and work may not actually resume for another week or so, according to official advice. It is felt that the process of resuming work will be gradual on account of the difficulty to secure men.

The Crown Reserve Mining Company, holders of an option on the Candian-Kirkland has commenced to de-water the shaft on the latter property. This is considered as particularly significant owing to the fact that underground work was discontinued some weeks ago, and that effort has since that time been concentrated on diamond drilling. It is believed that drilling results has encouraged further underground work.

It is reported at Boston Creek that the Ontario Government has decided to build a bridge over the Blanche River to accommodate the prospectors and mining companies engaged in exploration and development work in the Skead township gold area. This will encourage traffic to Skead by way of Boston Creek

and will reduce the distance from the railway by fifty per cent.

Dan Smith has been granted a contract to sink two 50-ft. shafts on the property of the Better 'Ole Syndicate, near Bourke's Siding. The syndicate is composed chiefly of returned men, some of whom are disabled. It is their aim to put forward an earnest effort to develop a mine, for which purpose the syndicate was formed. The work is already well under way.

The suggestion in Washington that Canada could be compelled to export pulp wood to the United States by threatening to cut off her coal and sulphur supply has aroused considerable interest in Northern Ontario. The question of a solution of the coal problem is believed to lie with Eastern as well as Western Canada, but sulphur is a matter of much local interest in this district where large iron-sulphide dykes await development. These dykes occur in Porcupine, Swastika, Skead and other parts of the district of Temiskaming, and in many cases the percentage of sulphur is said to exceed forty per cent. The importance of the chemical is realized when it is pointed out that it takes from 250 to 300 pounds of sulphur to make a ton of sulphite, and paper consists of about 20 per cent. sulphite. Light thrown upon the subject may reasonably lead to lively interest in the large sulphide deposits awaiting development.

#### BRITISH COLUMBIA LETTER.

##### The Metal Mines. Vancouver, B.C.

By the staking of mineral claims within the municipality of Point Grey and demanding that he be given title under the Mineral Act, James Adair, a prospector, has presented the Provincial Government with a problem that promises to be difficult of solution. Mr. Adair asserts that he has a good showing of ore in a section the residential property of which has given property considerable value. The terms of the Act, it is said, have been fully complied with but Mr. Adair's application for the completion of the record has not yet been approved. He declares that it is his intention to press the matter so that it is possible that the courts may have an interesting point to settle.

Oscar Lachmnd, consulting mining engineer of Spokane, Wn., and formerly general manager of the Canada Copper Company, announces his intention to leaving for the Orient next month on professional business.

##### Stewart, B.C.

There seems to be some foundation for the report that the line of Railway up Bear River in the Portland Canal district, is to be repaired and operated this summer. The Algonian Development Co., Ltd., is reported to have made an arrangement with the Canadian Northeastern Railway Company under the terms of which the long deserted line will be put in shape and used for the transportation of supplies and equipment during the season. The work involved reconstruction of the Bitter Creek and Bear River bridges, clearing a right of way etc. Tenders are being called for.

The Northern Light property is actively under development diamond drilling is to be undertaken as soon as weather conditions render it feasible. Five thousand feet in this work is contemplated.

There has been much activity in the transport of supplies to the Spider property, Salmon River. Hauling was done on Yukon sleighs. A temporary camp

has been established and a compressor-house is under construction. A three-drill compressor and engine is being installed, it is expected, will commence in a few weeks.

**Alice Arm, B.C.**

It is altogether probable that at the time of writing (May 25th) work will have been resumed on the Dolly Varden Mine and Railroad. Some weeks ago the miners and employees on the railroad went on strike, their demands being of such a character that the management felt they were beyond reason. A statement was made that the walk-out was engineered by the O. B. U. Since then, successful efforts have been made to obtain members of the International Union at lower coasts points, for employment on the plant and at the mine. These men have gone north and no doubt now are at work.

**Trail, B.C.**

Receipts of ore and concentrates at the Trail smelter have passed the hundred thousand ton mark. During the week ending May 14th, 5,345 tons of ore and concentrates were received. This brings the total for the year up to 104,086 tons.

Three returned soldiers, who took the special Soldiers' Civil Re-Establishment Assayers' Course in connection with the B. C. University, passed the B. C. Board's examination recently at Victoria. They are M. J. Bajus, Vancouver; S. E. Okell, New Westminster; and C. S. Gardner, Victoria.

**The Collieries.**

While definite figures cannot be given as to the coal production of British Columbia for the month of April because of the lack of returns from the Crow's Nest Pass Field it would appear, from statistics available, that the output of the collieries has fallen off slightly. Companies which show a decline in comparison with March are the Fleming Coal Co., of the Nicola-Princeton District; the Canadian Western Fuel Co., the Canadian Collieries (D) Ltd., at Extension and South Wellington, and the Pacific Coast Coal Mines. Those which have increased production are the Princeton Coal and Coke Co., of the Nicola-Princeton District; the Canadian Collieries (D) Ltd., at Comox; Wellington-Nanoose Collieries, and the Granby Consolidated Mining and Smelting Co. at Cassidy, Vancouver Island. The growth of the latter's output is one of the features of the trade. For some months it has been steadily mounting, an indication of the adoption of a policy of the development to the fullest extent of the Island fields recently opened up by the Company.

The returns in detail follow:—

**NICOLA-PRINCETON FIELD.**

	Tons
Fleming Coal Company . . . . .	2,352
Princeton Coal and Coke Co. . . . .	1,267
<hr/>	
Total . . . . .	3,619
<hr/>	

**VANCOUVER ISLAND FIELD.**

	Tons
Canadian Western Fuel Co., Limited . . . . .	54,019
Canadian Collieries (D) Ltd., Comox . . . . .	35,139
Canadian Collieries (D) Ltd., Extension . . . . .	15,853
Canadian Collieries (D) Ltd., S. Wellington. . . . .	7,076
Pacific Coast Coal Mines . . . . .	9,332
Wellington-Nanoose Collieries . . . . .	2,015
Granby Consolidated Mng. & Smelting Co., Cassidy . . . . .	18,421
<hr/>	
Total . . . . .	141,855
<hr/>	

**Pacific Coast Coal Mines, Ltd., to Enlarge Production**

On assuming the position of General Superintendent of the Pacific Coast Coal Mines, Ltd., George Wilkinson, late Chief Inspector of Mines for British Columbia, announces that his Company has adopted a plan for the development of its Vancouver Island coal properties that will mean the expenditure immediately of some \$500,000. Already the Company has invested over \$2,000,000 in the opening up of its Morden Mine which is fed by 1,600 acres of coal bearing land, there being three seams known as the Douglas, Newcastle and Wellington. The plant is thoroughly modern, the pit head and screening plant being constructed of steel and reinforced concrete. It is about five miles from the mine to the shipping point at Boat Harbor, transportation being furnished by a standard gauge railway. At Boat Harbor bunkers have been erected with a capacity of 5,000 tons and washing plants also have been installed. The loading is done by a conveyor of a capacity of 750 tons an hour. The Morden Mine now is producing about 400 tons of coal a day and it is expected that the daily output will reach 1,000 tons by the end of the year. It is estimated that the area held by the Company at this point will yield a quarter of a million tons a year for ninety years. The first work in connection with the Morden property will be the construction of officials and workmen's houses, sixteen acres of land having been purchased on which will be constructed excellent living quarters. The Suquash holdings of the Pacific Coast Coal Mines, Limited, are situated on the east coast of the Island, on Broughton Straits opposite Alert Bay and at the entrance to Queen Charlotte Sound, about 200 miles north of Nanaimo. The coal field there is one of the largest undeveloped proved areas on the Pacific Coast and the company owns some 10,000 acres of it. Three workable seams have been located at a moderate depth. The mine workings on the second seam now are developed to a point where from 300 to 400 tons daily can be produced when a second opening is made and permanent shipping facilities are provided. Mr. Wilkinson is of the opinion that Suquash is to become one of the largest coal centres of the Pacific Coast from the standpoint of production and estimates that employment ultimately will be given 2,000 men. If the coal seams run evenly and consistently over the whole area, as appears to be indicated by drilling and other development, the company will have sufficient coal here to yield half a million tons a year for two hundred and sixty-four years. The Suquash Mine was closed down with the beginning of the war but Mr. Wilkinson states that it is the intention to resume operations there without delay. Some 200 men will be employed without delay. As development proceeds modern plant will be installed, and it is believed that, as the coal is comparatively

hard and well adapted to domestic use, it will not be long before the product wins popularity among the consumers of the northwest.

The coal product of the Nicola-Princeton Field of British Columbia has been attracting some attention of late and, if reports from responsible quarters are to be credited, there is to be considerable new development in that section. The Harvard Coal Co., of Princeton, recently sold some of its product in Spokane, Wn. and it is said to have given satisfaction and to have been marketed at a price that proves it can be shipped across the line and successfully compete with the output of Washington State Mines. The property of the Coalmont Collieries, Ltd. also is to be extensively developed, a bond issue of \$600,000 having been floated among Vancouver City and Calgary citizens to supply the needed finances. A tramway is to be constructed for a distance of two and a half miles between the Kettle Valley Ry. to the mine shaft, and quarters will be provided for officials and men at the mine. This work will be prosecuted with vigor during the summer to the end that transportation facilities may be available to permit a much larger production than the present to be placed on the market at Vancouver and elsewhere next winter.

A determined counter-offensive is being waged by the United Mine Workers of America against the O. B. U. in the Crow's Nest Pass coal field. The Miner's Hall at Fernie has been seized by the U. M. W. of A., so that that organization again is in possession of its old headquarters. Locals are being re-organized at Fernie, Michel, Natal and other centres with, it is stated, considerable success.

In order to better co-ordinate the coal mining industry in the Province of Alberta from the viewpoint of the operators an amalgamation has been effected which will bring under the jurisdiction of the Western Coal Operators' Association six sub-district organizations, including the Red Deer Valley Coal Operators' Association. While each sub-district will deal with questions inside its own association, all matters of policy will be referred to the Western Coal Operators' Association. The officials of the new organization are: President, O. S. Whiteside; first vice-president, Jesse Gouge; second vice-president, John Shanks; secretary-treasurer, W. R. McNeill.

In an effort to meet the situation caused by the attitude of American coal operators, and in response to an appeal from the Manufacturers' Association of Toronto, Ont., the Boards of Trade of Western Canada at a recent conference passed the following resolution:

"That every effort possible be made to increase the area of use of Western Canada's Coal, and that this conference favours the investigation of freight rates on coal from Western Canada to the manufacturing centres of western Canada to the manufacturing centres of Ontario, with a view to making Canada independent of any other country in its fuel supply.

"And that the Canadian Pacific and the Canadian National Railways be asked to give special rates for the summer haulage of coal from Western Canada.

"And further that the coal operators be requested if they have not already done so, to make special summer prices for the sale of this fuel."

## BRITISH COLUMBIA HAS DEFINITE POLICY TO ENCOURAGE IRON AND STEEL INDUSTRY. Ore Areas to be Examined and Reservations Effected (By Our Victoria Correspondent)

F. J. Crossland, mining engineer of Vancouver, B.C., has been appointed to make a thorough inspection of the hematite and limonite deposits of the Whitewater River section of the Clinton Mining Division. Hon Wm. Sloan, Minister of Mines, has commissioned him to ascertain, as far as possible in one season's work, the tonnage of this mineral available.

In an address before the last session of the Legislative Assembly Mr. Sloan spoke of a report received from Wm. M. Brewer, Government Mining Engineer, on these deposits which estimated that they afford a possible 50,000,000 ton reserve of limonite of good quality, eminently suitable for fluxing with the magnetic ores of the coast in the production of pig iron by blast furnace, and so situated as to be easily recovered. The Minister then stated that it was his intention to have the district well explored and Mr. Crossland's engagement is in line with that undertaking.

This Provincial Government work is to be supplemented by the Geological Survey Branch, Ottawa, which will have two parties in the field. One, under J. D. McKenzie will make a geological survey of the Taseko (Whitewater) Lake area and the other, under C. H. Freeman, will conduct a topographical survey.

Notice has been given, also, that a reserve, as authorized by a recent amendment to the Mineral Act, has been placed on the drainage area of the Taseko (Whitewater) Lake, Chilko Lake, Tauniah, Chilquoit and the Chilko River and Big Creek, Clinton Mining Division. This reserve takes effect on the 1st of June. Claims already recorded will not be interfered with but all open iron showings within the limits defined will be held by the Crown until it is determined how far they may be needed for the encouragement of the industry.

## BRITISH COLUMBIA COPPER OUTPUT PROMISES IMPORTANT INCREASE

(By Our Victoria Correspondent)

The announcement that the Consolidated Mining and Smelting Company, proposes becoming one of the large copper producers of the Province of British Columbia has occasioned much interest and speculation. The Company it is found, has been laying the foundations to this end for some time. It has two large copper deposits in Vancouver Island under development, one being the Old Sport, situated on Elk Lake near the southeast arm of Quatsino Sound, and the other the Sunloch, at Jordan River not far from Victoria. Through surface work, diamond drilling, etc., some 1,500,000 tons of copper ore approximating 1.8 per cent, have been proved on the former property and it is authentically reported that reconnaissance surveys have been made of a number of railroad routes to tidewater. The Company recently acquired control of the Sunloch where it is estimated that 2,500,000 tons of proven ore, averaging between 1 and 2 per cent copper per ton, have been blocked out. The big Interior group also has been bonded. It is situated at the head of the Great Central Lake at an altitude of 6,200 feet. This season's work will consist of the securing of all possible information regarding its possibilities, the topography and geology of the area being investigated with a view, it is understood, of es-

establishing the practicability of attacking the deposit from about the 1,500 foot level. If this can be done the problem of making the mine will be much simplified. As to transportation, the E. & N. Railway is to be extended from the town of Alberni to the south end of the Great Central Lake so that it will be a matter of running the ore down the mountain side to the water, loading it in scows for transport over water for 22 miles and dumping it in railway freight cars for removal to the point selected for treatment.

While on the subject of Vancouver Island mineral development it may be said that the Tidewater Copper Company at Sydney Inlet is proceeding with the opening up of its deposits with satisfactory results. There are at least 500,000 tons of 1½ to 2 per cent of copper ore proven in reserve with good prospects of larger quantities being shown as work continues.

Neither the Cranby Consolidated Mining and Smelting Co., Hidden Creek, nor the Britannia Mining Company are working up to capacity at present. In the old workings of the Britannia, Howe Sound, it is roughly estimated that there are 9,000,000 tons of ore in reserve and on the Victoria Claim, newly under development, it is figured that there are a possible 5,000,000 tons.

British Columbia, there is no doubt, is ready to take a more prominent place than heretofore as a copper producer as soon as labor and other costs decline or the price of the metal advances.

#### **FORT RUPERT, VANCOUVER ISLAND. WAS FOUNDED AS A COAL DEPOT.**

Few people are aware that Russians loaned to the Company their brig "Constantine" and crew to build a fort and established the mines at Fort Rupert. As a better idea of this operation may be had from the opening entry in the Fort Rupert Journal, dated Friday, May 11, 1849, as follows:

At 8 a.m. the H.H.B. Company's steam vessel, having the Russian American Company's brig "Constantine" in tow entered Beaver Harbor, Mr. Chief Factor Work, having with him Mr. Chief Trader MacNeil and clerks Blenkinsop, Beadmore and Simpson also a party of 28 men, being on board the two vessels to establish a fort for the trading of coal and furs. Shortly after anchoring, the above-named gentleman and a few men landed to search for a site which was found towards evening on the southeast side of the harbour rather a rugged spot but conveniently situated for a good supply of water, this article being of paramount importance. The Indians appear friendly and well pleased at our coming to establish amongst them, and have so far done all in their power to assist us, and there is every reason to believe that we shall be free from molestation; one thing, however, is certain, that they are second to none in the art of stealing. We commence to-morrow morning in earnest clearing a place for the Fort with rather a motley set for such an undertaking."

The fort was finished and the Russians sent back. Coal was not at first mined, but brought from the Indians who picked it up from a small exposed seam only 18 inches wide. In a short time there had been delivered according to the amount paid one thousand tons, but when sold and loaded on ships it was found that only about seven hundred tons were on hand. The Indians were living up to their reputation by stealing what they had already sold, then reselling it.

In order to mine in an economical and up-to-date manner necessary machinery was ordered from England, but before its arrival the Company were convinced that Fort Rupert as a coal field was a failure. Quatsino Inlet was examined with the idea of making that a great coaling port for the immense fleet of ships that these far-seeing men knew would soon swarm to the Pacific Ocean.

Before anything further was done, coal was found at Colville town, but now known as Nanaimo.

Robert Dunsmuir was soon an outstanding figure at these mines. So much were his capabilities relied on that a separate agreement was entered into with him in which he received a higher rate of remuneration than the others.

At the commencement of the operations there was an ample market but later, when the output became greater, it was a problem what to do with the stock on hand, and in spite of the numerous British warships requiring coal during the Crimea war the supply on hand reached nine thousand tons. The greatest market, San Francisco, could only pay \$8 per ton, and the freight rate was \$10 per ton so that the outlook did not appear bright.

The London management were not satisfied and sent out a new man, Mr. A. G. Dallas, to take over the full management of their affairs.

A new broom sweeps clean, and this new broom lived strictly up to that reputation. All the old hands were let out, and a Mr. C. S. Nicol, in 1860 was given full charge. He, it was, who was instrumental in forming a company to take over the whole interests of the Hudson's Bay Company, at Nanaimo, which subsequently found its way into the hands of Mr. Robert Dunsmuir. The immense fortune accumulated by him, together with the high place he reached in the affairs of the country generally, are worthy of special note in British Columbia history.—From the "Victoria Times."

#### **WASIPIKA CUTS OREBODY AT 200 FT.**

Development work at the Wasapika Gold Mine has recently been confined to sinking to the 200 ft. level. This level has now been reached and the orebody broken into by crosscutting. The first round in the quartz exposed good ore. Crosscutting is now being continued.

When sinking the shaft, the orebody was encountered at the 160 ft. level and for forty-four feet below that depth a large part of the drilling was in quartz. The vein dips to the west at about 65° and as the shaft is a vertical one it cuts diagonally through the vein.

Systematic sampling of the quartz in the shaft and crosscut is not yet completed. Preliminary sampling, however, gives assurance that the values are holding well with depth.

The numerous channel samples taken at the Wasapika indicate that the values are almost entirely in the quartz. The adjacent schist nearly always shows some gold when assayed; but the values in it are low. There is unfortunately a large tonnage of quartz in the orebody and the schist can advantageously be discarded.

Ore from the 200 ft. level is similar to that at the 100 ft. level; but somewhat higher in pyrites content. It has the same minute black stains as noted in the ore from the 100 ft. crosscut and which may possibly be a silver mineral. It has been noted that high gold

# A MARSH HOIST

## IS MADE THE RIGHT SIZE FOR YOUR MINE

and in either Steam Power or Electric Power

This shows one of our Electric Mine Hoists. We make many other types. Send for our catalogue of Mine Hoists, Cars, Cages, Buckets, etc., and see what we offer you. It will repay you.

From the little 10 Horse Power size for prospectors or small mines to the massive 50 Horse Power size, one of our 7 sizes should be just right for your mine.

We are specialists in the building of Hoisting Machinery of all sorts. For nearly a quarter of a century we have been designing and building Hoists, and have developed a Hoist that we are really proud of—proud because of the record of good work they have done, and are doing in mines, quarries, and other classes of work from one end of Canada to the other.

values are frequently present in quartz showing these small black areas.

It was noted in the quartz from the 100 ft. cross-cut that the silver values are quite important at the Wasapika. The many surface samples were assayed only for gold and the silver values there are not known. Samples from the 100 and 200 ft. levels that have been assayed for silver as well as gold show important quantities of the former. One sample from the first round in the quartz at the 200 ft. level showed three and a half ounces of silver per ton as well as \$20.18 gold per ton. This would mean about \$3.50 in silver. Another sample from the quartz near the bottom of the shaft showed one half ounce of silver per ton as well as \$7 in gold per ton.

At the 100 ft. level a sample cut across the 40 inch rich shoot at the footwall assayed \$26.84 gold per ton and showed also four ounces silver per ton. Several samples showing about \$12 gold per ton for a width of 5 ft. in the 100 ft. crosscut all show silver present in important quantity. There seems good reason to believe that silver can be counted upon as an important asset in addition to the gold.—R.E.H.

It is reported that Cobalt bloom has been discovered four miles east of the Mandy Mine on Schist Lake, Northern Manitoba. Commissioner Wallace states that a sample submitted to him contained smalite.

## Oxy-Acetylene Welding and Cutting

### *Prest-O-Lite*

## The Rivets Have Been Burned Out

Consider the ease with which Oxy-acetylene accomplishes the most trying operation that comes to any ship-yard—repair work on framing and plating.

Compare this modern method of cutting out rivets, of covering frames, of sundering plating to the absolute method of the cold chisel, drill and hack-saw. It's like comparing the craft of Columbus to the enormous ships of today.

In the ship yards, in fact wherever welding and cutting is done

## The Training of Mining Engineers

In our issue of May 21st, Professor Haultain of Toronto University, asked for criticism of the regulations applying to students in the Department of Mining Engineering in that University. Candidates for the degree are required to present satisfactory evidence of having had at least six months' practical experience in work connected with mining, metallurgy or geology, for which they must have received regular wages. It is not often that those who sit in the chairs of learning at our universities ask criticism from the layman. Perhaps it is a stray eddy of the wind from Russia?

The question raised by Prof. Haultain has almost as many possibilities for discussion as the tariff, and it is one that very largely occupied the proceedings of mining societies in Britain during the past year. In Britain the difficulty was not so much to give theoretically trained men acquaintance with the actual practice of mining, but to give some theoretical knowledge to men fully acquainted with the practice of mining. Here it may be remarked that the college-trained mining engineer is somewhat of a rarity in Britain, more particularly in coal mining. The practice has been to article young men to reputable mining engineers for a term of years, during which period the aspirant is given an opportunity to learn every branch of coal mines direction, including the commercial side of the business and such by-ways as the work of the warehouse, the time-office and the traffic office. Concurrently with his daily work at the mine, the student is required to study and to take his certificates of competency for the various grades of official mine positions. Briefly, the training of the mining engineer at British collieries is theory super-imposed upon practice, and, while university training is by no means under-rated, it is given a secondary place in the training of the mining engineer, or at

least, in that most responsible man, the certificated colliery manager. In Canada, this course of training sometimes places the old-country mining engineer at a disadvantage, as he is not the possessor of a university degree, nor, in British mining circles is he expected to be.

We believe that the regulation of the University ask the very minimum of practical knowledge from the aspirant for a mining degree, but we do not quite understand why it should be necessary to stipulate that during the required probationary period of practical work the student should have received "regular wages." In some instances this would pre-suppose a philanthropic spirit on the part of the employer. It is the work, and not the remuneration, that is of practical value to the student. If he needs the money the student himself will see to it that he receives "regular wages." There have been budding financiers among students before now.

Also we suggest that instead of ruling out mine-office work as a qualification, students should be encouraged, in addition to the practical work, to spend some time in the commercial side of mining. Many mining engineers sadly need education in the economic side of their profession. It is not less essential that the fully educated mining engineer should be able to intelligently analyse a cost-sheet or interpret a financial statement than that he shall be able to read a blueprint. In his actual lifework it will probably advantage the mining engineer more to be able to calculate the ultimate cost of the material he is mining than to know how to make an ultimate analysis of its chemical composition, or to be able to specify its exact stratigraphical occurrence.

We suggest that our readers should follow Prof. Haultain's suggestion and discuss this many-sided question in the columns of the "Journal."

## Dominion Coal Company Offers Scholarships to Employees

It is announced from Glace Bay that the Dominion Coal Company will offer annually two scholarships at McGill University to employees. In this connection the Dominion Coal Company follows the example of the International Nickel Company and the Granby Consolidated Mining & Smelting Company. We hope that the adoption of the granting of schol-

arships by such a representative group of Canadian mining companies will lead to an even more widespread and general acceptance of the principle.

In the issue of the "Journal" for 24th December last there was noted in this column a plan adopted by fourteen of the largest mining companies in Australia by which bursaries at the Universities of Mel-

bourne and Adelaide were provided for students in mining and metallurgy. Provided the students selected respond to their opportunity, the associated companies undertake to provide him with a suitable position with an initial salary of not less than £250 per annum.

The employees, and the children of the employees of the mining companies in Canada, have been placed at a disadvantage in educational opportunities by the remoteness of the mining centres from seats of learning, which to some extent explains the tendency for the more ambitious men to move to metropolitan centres. The paucity of suitable applicants for official positions, and the lack of understudies to officials in responsible charge of important departments is a matter that concerns the mining companies very intimately and is reflected in their balance-sheets. While the provision of bursaries for selected students is a proper and commendable thing, which the "Journal" would be the last to appear to disparage, we do not think it will solve the real problem of mining education, which is to extend the scope and the influence of the universities to the sons of the miner, the minor official, and the clerical employees of the mining companies. For this reason we cannot agree with the present campaigns for the augmentation of the endowments of denominational universities in Nova Scotia, so far as the training of technical workers is concerned. If the people of the Maritime Provinces could agree among themselves upon one centre of technical training, would concentrate their energies upon equipping such a centre as it should be equipped, then something might be done to bring the staff and equipment of such a centre into close and permanent touch with the technical workers of the Province. The denominational colleges could then proceed to develop as schools of ethical culture, freed from the hopeless endeavour to maintain engineering laboratories and faculties entirely beyond their means, and the Maritime Provinces might under such circumstances redeem itself from the shame and consequences of such inadequate provision for the technical training of its workers as has hitherto distinguished it. The Nova Scotia Government has done much by its mining schools, but its revenues are inadequate to allow of the extension of the mining schools to suit present-day standards and requirements. Technical education is costing enough in Nova Scotia, but the money and energy spent is being dissipated to little purpose, and, from the point of the mining companies is money and energy lost, as it does not reach the homes of their workmen. For example, there is as yet no means by which a promising student of the provincial mining school can take a short course at any of the places where engineering science is taught in Nova Scotia, and in the whole Island of Cape Breton, which has 100,000 inhabitants and produces eighty per cent

of the coal output of Nova Scotia, there is no technical school, nor any institution of learning containing scientific equipment superior to that of the average town high-school. The circles of university instruction and the life of the mining population of Nova Scotia do not anywhere intersect, which fact we believe to be a drawback, and a condition calling urgently for a remedy.

---

#### *THE FINE ARTS VERSUS STYRACOSAURUS ALBERTENSIS.*

In order to make room for specimens of the fine arts in the Victoria Museum at Ottawa the members of the Geological Survey have been asked to clear out the fossils in the Hall of Vertebrate Paleontology, at the Museum, which contains, among other unique fossil remains, the complete skeleton of the great horned dinosaur from the Cretaceous of Alberta, of which the Geological Survey is justly proud. The suggestion is made to the Paleontological Branch that if the dinosaur is allowed to remain where it is, as is very desirable in order to avoid damage in removing it, it should be boxed up. As the Ottawa "Journal" remarks, "the value of a boxed-up dinosaur for museum purposes is apparent."

We would not care to comment upon the incident, except it is just another of those little indications of non-appreciation of the work of the Geological Survey that we have noted in these columns from time to time. The work of the Survey is not understood, therefore it is despised. Possibly some itinerant scientist will come across the "boxed-up" dinosaur and express himself as Samuel Butler did about the pantless Discobolus in Montreal. If the right of the Paleontological Branch to continue its exhibits in the Victoria Museum is to be taken away, then it were a pity to have disturbed the dinosaur from its age-long rest in Alberta, and in justice, the bust of Logan and the boulder on which it is placed should be removed from the entrance to the Museum. Perhaps, if Ottawa does not want the dinosaur, the Province of Alberta, or the United States, might welcome it. That is where most of the geologists have gone anyway. If the Styracosaurus could use his frontal horn and his bony mane there might be another kind of clearance in the Museum.

---

#### *"ALL LEAVE IS STOPPED."*

Rudyard Kipling was some time ago described in the "Atlantic Monthly" as a seer of "remarkable rightness," and we believe him to be happier in his interpretation of the British mind than in his analysis of the Canadian mind, if recent cabled reports of a late work are true—which they probably are not.

Some recent remarks of Mr. Kipling in the "Times" upon the national evolution of the Englishman (the word is Kipling's) have such general application, and

ring so true, that we believe they should be widely quoted. "What will he do in the future?" asks Mr. Kipling, and answers: "We are too close to the dust of the main battle to see clearly. We know that England is crippled by the loss or wastage of a whole generation. Her position from the civil point of view is that of our armies in the worst days of the war—that is to say, *all leave is stopped for every man who can stand up to his job*, no matter how sick or stale he may be, and there is undreamed of promotion for untried men, who, merely because they are not dead, will have to face heavier responsibility, longer hours, and criticism that will certainly not grow milder as the years pass."

Mr. Kipling's tonic sentences are equally applicable to all the British peoples, and it is a singular tribute to his acknowledged position as a seer and poet of the Empire, that, even when he descants upon the characteristics of the Englishman, and thereby deliberately limits his pen, we feel a secret umbrage at the limitation. Not since Mr. Kipling penned, "Stand up and meet your fate" has he written anything so true as this call to hard work and the acceptance of responsibility.

#### OIL PROPAGANDA.

In this issue are published editorials from the "Mining Journal" and "Petroleum Times," of London, which express fairly the attitude of British mining men towards the restrictive policy of the various governments of the Empire in connection with oil concessions. The "Mining Journal" expresses its belief that propaganda—by the oil interests presumably—is being directed at the present time towards inducing a modification of present restrictive policies, and states that if the big oil interests reached an agreement "it is impossible to suppose that the policy would not be modified." Which is to say that if the oil interests remain dissatisfied the widespread propaganda we have previously deprecated in these columns will continue in an aggravated form. This is indeed a pleasant prospect for international amity.

An example of this particular irritant is the editorial of the "Engineering & Mining Journal," of May 29th on the "Petroleum Drama," which, while it may be unexceptional reading for citizens of the United States, is not acceptable to Canadian readers.

The Canadian point of view, if we are able to interpret it, is that we do not desire to see the friendship between this country and the United States endangered by a propaganda that is based on untruths and issues from the offices of commercial rivals. At the same time, we would suggest to the editors of United States periodicals catering to Canadian circulation, remembrance of the fact that Canada is an important factor in the British Empire.

#### AMERICA AND GREAT BRITAIN'S OIL POLICY.

The report which has during the present week been transmitted by President Wilson to the American Senate in response to an enquiry by the Senate as to what restrictions were placed upon American enterprise in developing the oil resources of the world, has not unnaturally caused considerable stir in international oil circles. We might even go further and say that by reason of several of the statements which are contained therein, and which have been prepared by the Secretary of State, the report is viewed in a seriousness which only reveals itself when it is closely studied. For the first time, in regard to Great Britain's oil policy, we see the writing on the wall, and even as Belshazzar at his feast in scriptural times saw the solemn warning which those mystic letters foretold, so let us hope Great Britain will exercise due care in the moulding of its Imperial oil policy lest, as Mr. Francis E. Powell put it last week, it should antagonise too greatly irritate too much those sources which have served her so well in the past.

This is not the time to deal in detail with the very important negotiations which have been in progress (despite Mr. Bonar Law's denial) for a long time past between the Government and our friends, the Shell-Royal Dutch group by which this Empire will be in the position of having inalienable supplies of oil for its future needs. Such a consummation will have far-reaching results, and if it achieves the ends in view, then there is ample justification for its adoption. But there are two methods by which this can be secured, and we venture to suggest that in regard to the Mesopotamia oil regions which are admittedly vast in extent, the absolute exclusion of all American interest is not a policy of wisdom. Our great organizations in the oil industry to-day have risen to their present proud positions not solely by reason of grasping opportunity when it presented itself, but rather by managerial control and far-sightedness in appreciating the force of and meeting strong competition. Thus, then the presence of American interests in the new oilfields of Mesopotamia cannot be a source of weakness to our own Imperial oil policy, but will be a factor of strength and one which will have a most beneficial effect upon our relations with the United States.

That the United States takes somewhat of a distorted view of Great Britain's world hold on oil, is not to be wondered at seeing the misleading statements that have freely been circulated through the press of late by certain writers, who, in order to clothe their own speculative oil propositions with some degree of importance, have glibly written of the not distant time when the United States would have to come cap in hand to this country for its oil supplies.

Such statements are not opinions based upon optimism, for there is nothing in Great Britain's oil policy as at present moulded to even suggest this; they are made obviously, as we say, to bring importance to an enterprise which, registered not in this country but in Canada, is out to make at least a show for the millions which are already sunk in it.

While there are feelings that Great Britain is out to capture all the great oilfields of the world, the serious fact prominently stands out that to-day there is produced in regions under the British flag only about one-fiftieth of the crude oil production of the world. If only this fact is fully appreciated, it will be seen what a very long way we have to go before there can be any suggestion of our even controlling sufficient supplies of oil to meet our own demands.

And even with the development of the great fields in Mesopotamia it must take several years before any appreciable amount of oil is available for our home needs; therefore, it behooves us as a Nation to so mould our Imperial oil policy that it shall not create discord among those interests upon which we so greatly depend to-day—"Petroleum Times."

### OIL ECONOMICS AND POLITICS.

We have insisted for a long time past on the immense seriousness of some of the issues which underlie the fuel industry. Hitherto these have been viewed mainly in relation to coal and its derivatives, but there is also a wide range of anxieties connected with the other branch—petroleum. In certain directions these problems meet and overlap, apart altogether from the question of competition and substitution of one source of power for the other. On this occasion it is some of the questions connected with the oil industry which claim attention. It is obvious from the activity of the cables that the forces of oil are mobilizing. What exactly that means very few persons can entirely perceive, though the consumer has a shrewd idea that in the long run it is he who will pay the cost of the campaign. Experience of, and participation in, the oil industry has come to this country comparatively late, and we have not, therefore, the experience in traditions which exist in regard to it, such as have long existed in the United States, and to a lesser extent perhaps in the Caucasus. A centralized oil control has so long been recognized in America that, rightly or wrongly, the Oil Trust in popular imagination represents the most brilliant achievement in trustification and the practice of the arts of monopoly and its satellite, business politics or "lobbying." It is possible that the reputation of the Standard in these respects has achieved an eminence which does less than justice to other industrial organizations, but it undoubtedly exists, and imparts an atmosphere into the domain of oil which is an important factor in considering the world's situation and the position of the other competitors or participants in international business. Some appreciation of the atmosphere which exists in the oil world, combined with a recognition of the intense concentration subsisting, is a necessary preliminary to any serious study of the subject, and it largely explains why even those who have a close acquaintance with the matter find it most difficult at the present time to align the protagonists and penetrate their designs. A moment's reflection will convince any of our readers that, as all commercial struggles are designed for the benefit of the participating interests, where these are individually powerful, at any moment competition may give way to agreement, and the foes of yesterday may be allies—nay, even the master combination—of to-morrow.

At the present time there appear to be three leading groups in the oil world: the Standard, the Shell-Dutch, and the Anglo-Persian. The relations between these cannot be known. Obviously they must touch at many points, and as co-operation, where possible, is a general desideratum, they must have understandings on many subsidiary points, such for instance, as common interests affecting transport and marketing. Beyond this we know that the Anglo-Persian Oil is bound by marketing contracts with the Shell which do not ex-

pire until 1922, while it is a matter of common report that a price agreement between the Standard and the Shell also exists, coupled possibly with the usual agreements as to spheres of interest. Such understandings do not necessarily preclude extreme antagonisms on the main fronts, but they always offer the prospect of compromise and agreement on big issues, based on the recognition of the fact that combination is economic and competition is wasteful. In the magnitude of resources these three groups vary greatly, the Anglo-Persian Oil being only able to claim any place in the sun through the fact that the British Government is the chief proprietor, and on the assumption that the Cabinet consider it to our interest to maintain an independent producer in consonance with the principles enunciated by Mr. Winston Churchill at various times, and on the view that independent State enterprise of this kind is the matter of settled policy to which the resources of the British Empire should be directed. Such an assumption is, however, by no means unquestionable. During the war we had the remarkable arrangements come to by the Petroleum Committee designed to give a monopoly of oil production in this country to the Pearson interests which have since been absorbed into the Shell, and all kinds of rumours have been circulated in the Press and Parliament recently of "patriotic" offers by the Shell group to place their great organization at the disposal or combination which has had experience of bureau- or combination which has had experience of bureaucracy during the war can be conceived to desire to thrust themselves under departmental control with any conviction that the industry or business which they have created is going to benefit thereby, and we may be pretty certain that if such propositions have been made the active control would be in the hands of the Shell and not of the Admiralty, or whatever department is selected for the responsibility. As we read the situation, therefore, any such negotiations would be along the lines of an extension of the policy already adopted in regard to the monopolization of any possible oilfields in this country.

Thus far we have glanced at the problem from the internal point of view of organization within the industry itself, but the aspects of the problems which are offering themselves at the moment are perhaps rather national than international, and though very possibly the national movements are merely a move in the game of the big operators, it would be presumptuous to regard them as nothing more than that. During the last two or three weeks we have witnessed the beginning of a political agitation in America, which is almost certainly the precursor of further action, and which was clearly foreshadowed in a leading article in the Journal of February 7, commenting upon an official demand from the head of the United States Geological Survey for action by the United States Government. Recent issues of the Journal have recorded various alarmist statements by leading oil authorities of the United States as to the exhaustion of crude stocks, and these have been emphasized by advances in prices, despite the protests of Federal Commissions and State authorities, to say nothing of the general public. The facts as regards the increasing seriousness of the growing excess of consumption over production in the United States admit of no doubt. Following the statistics of the world's production in 1918, given in our issue of February 14, when the United States' output was approximately 356,000,000 barrels.

it is stated that the production last year was 376,000,000 barrels, but the consumption was 413,000,000 barrels. The result is that whereas the crude stocks in California four years ago were over 60,000,000 barrels, at the beginning of March last they were rather less than 29,000,000 barrels, and at the present rate of consumption the stocks should be completely cleared out in another year. Moreover, the consumption is growing monthly. In 1918 the average rate of consumption of Californian crude was 279,576 barrels, in the second half of 1919 it was 292,278 barrels, in January last 301,100 barrels, and in February 304,120 barrels. The Standard Oil Co. are now installing new processes, which will provide for the cracking of about 30 per cent of their current fuel oil production, so that while the immense demand for petrol may to some extent be met, fuel for ordinary power plants will be to that extent diminished. Such being the state of affairs in the United States one of two things—or possibly both—will happen. Exports will be partly embargoed or the price will be sharply raised.

It is just at this point that the more strictly national aspect of the business asserts itself. Mr. Otis Smith, in the paper which we printed on February 7 last, emphasized the fact that the United States must either restrict her domestic supply to home requirements or must secure large sources of supply abroad. He pointed out that the British Government had adopted a restrictive policy in regard to foreign undertakings in territories under the British flag, and suggested that the American Government should make up its mind whether it would insist on the open door or the export embargo. In speaking thus Mr. Otis Smith was voicing protests and opinions which have been current in American oil and business circles for a considerable time past, and the British Government certainly cannot be surprised at their making their appearance. Free trade and equal opportunities for foreign capital has been a cardinal principle of British commercial policy for nearly a century past. With the growing interference, however, of various departments in commercial matters—especially in mining—a distinct change of attitude has presented itself to foreign observers. The Indian service, which is peculiarly subject to reactionary influences, was perhaps the first to exhibit this policy in restrictions upon the alienation of mining land to foreigners. The idea, however, was speedily extended to oil, where the Trinidad leases formed a precedent upon which American attention quickly fastened. Since then these tendencies have had a farther advertisement through Mr. Hughes' policy in Australia, while that peculiarly futile piece of legislation, the Non-Ferrous Metals Industry Act, impressed American opinion connected with the mineral industry most vividly. We are not concerned here to argue the preponderating advantages of a general policy of free trade or of protection. Undoubtedly, however, protection begets countervailing measures, and ultimately impairs international relations, and this effect must be weighed up among the disadvantages of a change in our traditional commercial policy, in view particularly of our dependence on foreign nations for so much of our raw products. No doubt much of the rising tide of protests in America, which appears to be directed against this country to the exclusion of others like France, which has developed a promising petroleum supply in North Africa (which is closed down for eventualities), is unreasonable. We may naturally point out that

America was offered the mandate for the Turkish Dominions, and refused, it, although, as American papers then pointed out, they were denying themselves the development of mineral interests in those regions. We are on even stronger ground, perhaps, in refusing to permit indiscriminate exploitation of national territory in a country so unstable as Persia at the present time, but these considerations will not avail to prevent America considering her own interests first, and the possibility of steps to restrict free imports of some essential commodities, especially lubricants, must be considered. At the same time, as the Petrol Profiteering Committee pointed out recently, it is not to the interests of the big American concerns to restrict their business here. They have large sums of money locked up in distributing media—trucks, reservoirs and tanks—and restrictions on supply would in the long run tend to diminish their preponderant influence in the control of our markets. It is, therefore, intelligible that propaganda should be directed at the present time towards inducing the Home and Dominion Governments to modify their restrictive policy as regards participation in the exploitation of the oil resources of the Empire, and it is impossible to suppose that the policy would not be modified if the big oil interests reached an agreement.—The "Mining Journal," London.

#### OBITUARY.

##### Hon. James Dunsmuir.

With the death of James Dunsmuir there passes a dominant figure in British Columbia development, and a man whose life, together with that of his father Robert Dunsmuir, covers the story of the growth of mining, finance and railway building in British Columbia from their beginnings. James Dunsmuir and his father were representatives of that band of forceful Scots whose names are linked with the Hudson's Bay Company, the Canadian Pacific Railway and the Bank of Montreal.

James Dunsmuir was born in Fort Vancouver, in 1851, two years later than the first attempt of the Hudson's Bay Company to open coal mines on Vancouver Island. Robert Dunsmuir was soon an outstanding figure in the young coal trade of the Island, and became eventually the largest owner of coal-lands there. Young Dunsmuir entered his father's business at the age of 17 years, eventually succeeding him as president and chief stockholder of the Union and Wellington collieries and of the Esquimalt and Nanaimo Railway, which properties he later sold to MacKenzie and Mann and the Canadian Pacific Railway.

From 1900 to 1902, Mr. Dunsmuir was Premier of British Columbia, and was Lieutenant-Governor from 1906 to 1909. Like other men of the dominant Scotch-Canadian type to which he belonged, Mr. Dunsmuir was a generous, but discriminating donor to hospitals and educational institutions.

#### BRITISH COLUMBIA MINE INSPECTOR KILLED.

William Lancaster, Inspector of Mines for the Kootenay District of British Columbia was killed on May 29th by an automobile accident. He had been Inspector of Mines for three years, being previously Assistant Manager of the Coal Creek Mine of the Crow's Nest Pass Coal Co.

# "Longwall" Mining and Coal Conservation

J. H. CUNNINGHAM.\*

A prominent mining man has remarked that when a coal miner is once inoculated with "Longwall" he is forever after immune against future attacks of 'Room and Pillar.' While this statement is perhaps slightly overdrawn, since its author was evidently a "Longwall" enthusiast, yet the fact remains that a "Longwall" miner when selecting a method of working will generally view the situation first from the "Longwall" standpoint and then resort to some other method only after finding that conditions are totally unsuited to his particular system. This point of view may not be as prejudiced as it at first appears. For a person who has actually found a superior way of doing a thing, is undoubtedly the best judge of whether his new method is better than the old; and for this reason a miner who has once experienced the numerous advantages of "Longwall" when worked under suitable conditions, is very loath to change to any other system, unless the conditions make the use of "Longwall" prohibitive. The remarks which follow are not intended however to introduce a controversy between "Longwall" and "Room and Pillar," for both systems have their own advantages under certain conditions, but they are designed merely to point out the considerations which should govern the use of the former and to emphasize the connection existing between the use of "Longwall" and the conservation of the coal resources of the country.

The application of "Longwall" mining is of course governed by certain natural conditions existing in the coal seam itself, and in the overlying strata. Any seam of a hard or medium hard nature, varying in thickness from 30 inches to 6 feet, with a good roof and floor lying from 300 to 3000 feet below the surface, is capable of being worked "Longwall" provided it is not badly faulted; and the success of the operation depends entirely upon how these conditions are made use of. Some operators prefer to add that the seam should also have a low inclination, but there are so many examples of "Longwall" worked successfully in seams of high inclination that this does not appear to be essential.

A good roof for "Longwall" is the same as for any other method of mining, but in addition it should be of a material that shoots well and is suitable for building rock walls. The floor also should be fairly hard so that it will not "creep" readily when the pressure comes on it. Above the working roof the most suitable measures consist of alternate strata of sandstone and shale. If they are all sandstone it makes a good enough roof, but after a break once occurs the fissures extend too far and there is too much opportunity for them to gather water. With shale piles intervening fissures are kept from spreading, and with any subsidence of the measures the shale strata open out and help to cushion the weight so that the effects of the subsidence are not felt at any great distance above the coal seam.

The preliminary development in connection with the seam need not be discussed here since the shaft sink-

ing, opening out of pit bottom and arrangement of shaft pillar will be attended to in the same way, irrespective of whether it is to be worked "Longwall" or by some other method. "Longwall" proper therefore may be started as soon as the main roads have reached the boundary of the shaft pillar, and there should be sufficient information available at that time to indicate how the work should be opened out. While the shaft was being sunk the thickness and nature of the overlying strata have been ascertained, and while driving the various roads from the pit bottom to the boundary of the shaft pillar there has been an opportunity to find out the nature and thickness of the seam and the direction of the cleat. If the seam is hard, the direction of the face which is to be laid out should run nearly parallel with the cleat and if it is medium hard, the face may proceed "half on". In some instances, it has been found feasible even to work "Longwall" in a fairly soft seam by keeping the face going "end on". Another feature which helps determine the direction of the face, is the direction of the joints in the roof strata. These of course, should not run parallel with the face.

In continuing main roads after the shaft pillar is passed, two methods are followed. One is to protect these roads by pillars of a suitable size for the purpose of maintaining a tight air-course and insuring height for the roadways. The other is to begin extracting all the coal as soon as the shaft pillar is left behind and carry the main roads forward through the waste and depend upon the excellence of the road-side packs to insure having a proper air-course. The latter method certainly entails more brushing for height than the former, but it is contended that the advantage of having all pillars removed from the area of the "Longwall" operations will in time more than offset the temporary disadvantage of higher cost for brushing. And it is also true that the first cost of the pure "Longwall" roadway may not be any greater than the cost of driving in the solid, in spite of the brushing entailed, since where the complete extraction method is followed, the main road is also a part of the working face and carries the same mining rate as the regular face does. In this way the high yardage rate for level and headway driving is done away with.

One of the most frequent mistakes made in "Longwall" come from not giving proper attention to the contact zone existing between the solid coal and the "Longwall" waste. And here is probably the best place to consider this phase of the question, because the whole system of "Longwall" has often been condemned as unsuitable, simply because proper precautions were not taken in starting off the work. As soon as "waste" is opened beyond solid coal, there is bound to be a subsidence of the roof. How much there will be depends upon how tightly the waste is stowed in the area included within the contact zone. If the method of complete extraction of pillars on main roads is followed, special care is necessary in building the pack walls next to the shaft pillar and the waste should be stowed as near solid as possible. This will reduce the breakage of the roof measures to a minimum and will also prevent air leakage which would otherwise occur at this point. In continuing the perman-

\*A paper read before the Mining Society of Nova Scotia, May 1920, Glace Bay Meeting.

ent roads a greater thickness of packwall should be used than on the secondary roads for the double purpose of making it tight from an air course and also for maintaining its height for both haulage way and air course for some time to come. What the thickness of the roadside packs should be will depend largely upon the depth of the seam from the surface, and the roadways as first laid off should be a little wider than required for a finished roadway, since the roof weight is bound to push the walls out a few inches into the road. When a double-track road is necessary, it is sometimes well to consider if two narrow roads had better not be built than a single wide one, and allow the outgoing traffic to travel on one road, and the incoming traffic on the other. The upkeep of two single roads will in many cases be less than on one wide double road.

In the case of a "Longwall" road running alongside of a pillar, the coal rib should never be used for one side of the road. Immediately against the pillar there should be a well-built packwall from 10 to 20 feet thick, so that the road will be formed with packwalls on each side of it. This will cushion the weight on the road and throw the loose end of the broken roof in the waste, rather than directly over the roadway.

In turning off secondary roads care should be taken to strengthen the turns. This may be done by using a timber packwall in the case building, stone is not of the best and in case there is any doubt about the roof. If these roads are also to be used for haulage purposes, the same precautions should be taken with them as with main roads, only to a lesser degree.

In breaking off the "gateways" or short roads leading directly to the face, the distance between centres will depend largely upon the thickness of the seam and on the amount of building available and also upon the method of dealing with the coal at the face. A glance at the origin of this system will throw light upon the practice to be followed.

"Longwall" originated in the north of England, and was devised as a measure of necessity. Many of the thick seams in that part of the country had been worked out and it became necessary to operate the thinner seams in order to hold up the production. No particular difficulty was met with in operating these thin seams by the "Room and Pillar" method, although it was found in order to do so a considerable increase in both the mining and day-paid labor was necessary and during a portion of the day rock had to be hoisted instead of coal, all of which made it very difficult for the thin seams to compete with the thicker seams still operating. The "Longwall" system was therefore devised to increase the daily production of the miners and also to provide stowage for the rock instead of sending to the surface, and it was found in addition that the stored rock could be used to support the roof and to assist in making the coal face work properly.

Gateways therefore came to be broken off at such distances so that the waste would absorb all the rock brushed down in providing the necessary height for the gateways. In seams varying from 4 to 6 feet in thickness it has sometimes been found advantageous to lay a temporary track for the mine cars along the face and lead out the coal directly and thus reduce shovelling to a minimum. In order to do this a good roof is necessary so that the roof supports can be kept back some distance from the face. If this system can

be followed, gateways can be placed further apart and a considerable saving made in brushing. In a thinner seam the same result is sometimes attained by the use of face conveyors travelling between two consecutive gateways.

But the system most commonly used is to load the mine cars as they stand at the face in the gateway. In applying this system it is evident that the gateway must be kept sufficiently close so that excessive shovelling will be eliminated. Where the direction of the face is on the "level" it is customary to divide the face equally on both sides of the gateway for loading the coal. Or if the direction of face is inclined it is divided so that the long shovel is on the rise side of the gateway and the short level on the low side.

With these preliminary considerations disposed of, we now come to the actual working of the "Longwall" face. The method of mining employed may be either by hand or by machine, but owing to the comparative scarcity of skilled "Longwall" hand-miners in this country, it is probable that any development of the "Longwall" method will be by the use of continuous cutting-machines. The "post" or other types of reciprocating machines are useful for some of the auxiliary work, but they are not suitable for steady cutting along the face. The selection of the motive power used for the machines depends upon whether the seam is gassy or not. If it is gassy, compressed air should be used, but if not, electric power is more efficient and satisfactory. The type of cutter used on the machine depends upon the hardness of the material to be cut. If the coal is very hard the disc type will be found strongest. In some workings this type is even used for mining iron-stone. If the coal is medium hard, the chain type will probably give the best satisfaction. In a soft seam or one in which the coal is apt to settle, and jam the cutter, the best type is the bar machine. This latter type has also been found very satisfactory in seams where the floor is uneven since the bar is more flexible than the other cutters and will ride more easily over the irregularities in the pavement.

The length of cutter-bar used, or in other words the depth of the undercut, depends upon the hardness of the coal. This may vary from 4 to 6 feet and should be graduated so as to prevent the coal from falling and clogging the machine before the cut is properly made. When used properly, the depth of undercut can be made of great assistance in working the coal so that very little explosive need be used. In many instances the coal will fall in large blocks without the use of any explosive, although in such cases light shots have to be put in the coal after it is down to break it up so that it can be loaded out.

In undercutting a hard seam, especially where the roof is also hard, very little spragging of the coal after the machine will be necessary, whereas in a medium or soft seam sprags or breakers should be set fairly close to the cutter as it moves along the face. The purpose of this is twofold; first it prevents the coal from settling on the machine and secondly it assists in breaking the coal so that it does not come down in blocks too large to be handled.

The ease with which coal comes down after it is "mined" depends also upon the nature of the roof. A hard roof does not "give" immediately after the coal is undercut and the face therefore needs to stand a while before it is worked, so that it will get the benefit of the roof pressure. On the other hand, a flexible

roof will begin to bend and exert pressure almost as soon as the undercutting is completed.

For these reasons, under a hard roof the face should not be advanced as rapidly as under a soft roof, otherwise a part of the advantage gained from roof pressure will be lost. The main idea is to advance the face rapidly enough to keep the roof stratum bending and still prevent it from breaking. "Breaks" will occur from time to time but they should be controlled so that they will ease themselves in the waste rather than over the working places. When excessive weighting shows in the roof on the gateways, it is sometimes beneficial to stiffen up the roadside packs and leave a waste space between the packs without any support. This has a tendency to throw the "break" in the waste and thus relieve the weight on the road. For this reason standing timber should never be left in the waste, since it prevents regular subsidence and throws additional weight on the roadways and face instead of allowing it to come where it will not do any damage. It might be noted here that the distance between the packs and the face has a great influence on how the coal will work. If the roof bends easily and breaks the coal down freely after it is undercut, the packs should be kept close up to the face, whereas if the roof is stiff and is slow in exerting pressure on the face, the packs should be kept farther back so as to give the roof a better chance to work.

It will be seen from the forgoing remarks that a considerable amount of skill is necessary in handling a "Longwall" face properly, and each face must be made a subject of study in itself. It is probable that this reason accounts largely for the backwardness in undertaking "Longwall" operations.

Having sketched the main points to be considered in "Longwall" mining, let us briefly point out its application to coal conservation. In the first place it provides for complete extraction of the seam as compared with a system of partial extraction under the "Room and Pillar" method. Under the last-named system as a rule more coal is left standing in pillars than is taken out in the first working, and it is only in rare instances that these pillars are completely recovered. Even if they are ultimately recovered, here has been a continued loss in them year after year, due to a certain amount of crushing and spalling of the coal. Also when they are finally worked there is a larger percentage of slack produced than there was in the first working. With "Longwall" there has been no chance at all for deterioration since the face is kept fresh continually.

"Longwall" will produce a larger percentage of round coal than any other system, since there is always a loose end to work on, thus permitting a smaller quantity of explosive to be used, and being able to make use of the roof weight the quantity of explosive required is still further reduced. A reduction of explosive means a lower mining rate and also a conservation of materials used in explosives.

With a continuous face producing coal, rather than a number of separate faces separated by pillars, it is possible to have a greater concentration of work. This feature reduces the cost of supervision as well as the haulage costs. For example, a "Longwall" headway with gateways broken off on the level need only be half the length of a room and pillar headway producing the same tonnage, provided that in the last-named case half the coal is left in pillars. This will

permit the use of less rope, fewer rails, smaller haulage engines and less rolling stock.

Ventilation of the mine is also much simplified, and can be carried on more efficiently and with a smaller quantity of air. The nature of the face permits it to be swept continuously with a stream of fresh air reaching all parts of the face equally instead of having it travel up one side of a room and then back the other side and then passing through a crosscut and traveling up one side of the next room before it reaches the face again. In other systems, for seams of the same thickness, there is a greater frictional loss in ventilation than in "Longwall" and in the case of deep seams, the additional heat generated from the crushing of pillars occasions an increased temperature which must be met by increasing the volume of air. All of these losses lead us back to the economic use of power. A saving in power means a reduction in steam consumption, which also means a saving in the quantity of coal used. Additional power saving also is possible in the operation of the mining machines, especially where the heavier types are used. These machines require power to load and unload them and power to transport them to the next place, whereas in "Longwall" practically all the power they consume is for productive work. The removal of machines from one place to another entails other losses as well. If half the time in the shift is used in moving and setting up the machine, both men and machines are engaged in unproductive work during half their time.

Besides saving coal and explosives and haulage material, and all other materials incident to power production, "Longwall" leads to a considerable saving of timber. With a good roof practically no timber at all is required overhead in the gateways, especially if the roof can be arched, and the only timber necessary on the sides is at the turns of the road and perhaps on occasional timber pack in case it is necessary to stiffen up the rock wall. At the face a certain amount of timber is necessary to protect it while working, but as fast as the pack walls are built up this timber should be withdrawn. It can generally be used several times over and when no longer fit for face timber, it will do for building packs. With the rapid depletion of our forests, the mine-timber problem will become increasingly difficult each year. Up to the present there has not been a great demand in Nova Scotia for the smaller sizes of timber, such as are commonly used for mine timber, but with the advent of pulp mills at both ends of the Province, consuming hundreds of cord of this size of timber every day, the situation will be different and the cost of mine timber will in a short time go much higher than it is today. Therefore, the necessity for adopting a mining system wherever possible which requires a smaller quantity of timber is apparent.

In a locality where there is a large and cheap supply of timber available, it is sometimes possible to work "Longwall" under rather unusual conditions. The writer has in mind an operation in Western Canada where the thickness of the seam varied from two to ten feet and which would ordinarily not be considered suitable for "Longwall", because, in addition to the variation in thickness, the roof was not particularly good and the seam in many places contained several thick layers of soft dirt, which was not suitable for packs, but because of a plentiful supply of timber, the packs were built entirely of timber set skin to skin alongside the roadside and the dirt from the

seam was stowed behind the timber packs.

Another set of conditions permitting the use of "Longwall", but a little out of the ordinary, may be noted. In a seam where the roof is only fair but where the floor contains good building material, it is feasible to leave the roof unbroken and support it on timber resting on top of the pack walls and then brush the pavement in order to secure the necessary height and to provide sufficient material for building the walls.

There are also a number of other special conditions apart from the standard conditions required which will permit the working of the seam by "Longwall," but space does not permit of them being referred to at this time. It may be noted however, that there are two main varieties of "Longwall" which differ only in general principles, but not in detail. These are "Longwall Advancing" and "Longwall Retreating." We have been considering the former since it is in most common use. In "Longwall Retreating" the main roads are driven through the solid to the boundary as quickly as possible, and the face is opened out first at the boundary instead of near the shaft bottom. This system will probably pay even better than the other in the long run, but it requires a much longer time, to get up a large output than by the other method. To compensate for this loss however, the cost of production will be less, because the roadways are easier to maintain and the wastes as they are formed are forever being left behind. In "Longwall Advancing" when the workings open up clear of the shaft pillar, a large output can be produced in a comparatively short time. Sometimes a balance is struck between the two systems, and one side of the pit is opened up for "advancing" and the other for "retreating." Or a further variation is sometimes introduced by laying off the pit in large panels, each of which is surrounded by its own pillars, and then each panel is worked out individually by "Longwall." A very successful example of this system is found in Lancashire. The seam is from 6 to 7 feet in height and contains a rock band one foot in thickness in the centre of the seam. A section of the mine was laid off in panels, and the main roads and gateways were "driven in" the full height of the seam. The bottom half of the seam between the gateways was worked "Longwall" and the bottom bench of coal and the rock band were taken out in the first working, and the top bench of coal left for the roof. After the boundary of the panel has been reached, the top bench of coal was bought back by "Longwall Retreating." In the second part of the work, one of the principal advantages was the ease with which the coal could be loaded out. When retreating the tops of the mine cars as they stood in the gateways were on a level with the floor from which the coal was loaded.

In the excellent paper which was presented by Mr. Herd yesterday, the subject of Hydraulic Stowing was discussed. This expedient is feasible of course for either "Room and pillar" or "Longwall" mining but even without it, "Longwall" can be practiced in under-sea workings with very little danger, provided there is sufficient cover and the roof measures are suitable. What is probably the most successful "Longwall" operation in the Dominion today is carried on as a sub-sea operation. I refer to the workings in the Newcastle seam in No. 1 shaft at Nanaimo. "Longwall" was started in the bottom seam of this colliery in the year 1904, and to date the "Longwall" production has totalled about 3,000,000 tons. This is in addition to the

output from the Douglas seam which lies above it and is much thicker. Practically all of the "Longwall" operations have been submarine with a covering varying in thickness from 400 to 600 feet. The subsidence noted to date is only from a foot to 18 inches and the seam has an average thickness of three feet six inches.

Within the limits of a paper it is impossible to give an adequate idea of either the advantages or the problems of "Longwall" operation, and for anyone who is particularly interested in the subject, the only way to become satisfied is to visit an actual operation. So far as the writer is aware, the best demonstration of a seam that contains all the elements of successful "Longwall" operation in this district is found at Sydney mines, in the bottom seam or Jubilee Colliery. Practically all the ideal conditions noted in this paper are there present, and although the development is not yet very extensive, the preliminary work already done has been carried on in a very thorough and careful manner, and it will probably before long take its place as one of the principal "Longwall" operations in the country.

When this is accomplished, the introduction of "Longwall" operations in other seams of similar nature in the Cape Breton field will soon follow, and a development take place in some of the submarine areas which will result in the saving of thousands of tons of coal a year, that would otherwise be left standing in pillars and probably lost, not only to this, but to all future generations.

#### THE MCGILL SUMMER SCHOOL OF MINES AT TRAIL, B.C.

The mining class of McGill University, which arrived here last week-end in their private car were not idlers while here, but on the contrary were a most industrious class.

All during their stay they took advantage of the opportunity of seeing how practical mining was done in the big gold-copper producers of the Consolidated Mining and Smelting Company of Canada, Limited and the Le Roi No. 2, "Josie" mine.

Officials of these companies took great interest in giving the young fellows who will devote their future lifework to the development of the mining industry, in showing them every in-and-out of the game.

The students remained here until Monday when they went to Trail where they have been studying the smelting industry which is conducted on a large scale at the Sister City.

Last Saturday evening they were guests of the members of the Rossland club at a smoker arranged in their honor and a most enjoyable time was had.

Today the party will disband at Trail, some returning East, while others will take positions with the Consolidated Company of Kimberley and at Trail, several going to the McGillivray Creek Coal and Coke Co., at Coleman, Alberta, where they will remain during the summer vacation.

Sunday the Rossland Tennis Club was host to the visitors, and some good tennis was enjoyed. Monday evening, the young men were guests of the Great War Veterans, many of them being returned men, at the Victoria Day dance given by the veterans.

Friday evening at Trail a dance was given in their honor by the school staff, which was largely attended, a number being present from this city.

Quite a number of informal dinner parties were also

tendered Prof. Bell and members of his class while they were here.

Altogether the young men found their visit most instructive and enjoyable and are loud in their praise of the hospitality extended them while here and at Trail.—“Rossland Miner.”

#### THE MEASUREMENT OF GEOLOGICAL TIME.

The new sixpenny English monthly “Discovery,” founded by a Committee of distinguished scientists, and edited by Dr. A. S. Russell as a medium for the dissemination of new scientific knowledge in non-technical and understandable form, contains in the April issue an interesting article on the measurement of geological time by Dr. Arthur Holmes, Lecturer in Geology at the Imperial College of Science and Technology, South Kensington.

Dr. Holmes states that earlier attempts to deduce the duration of geological time from the temperature gradient of the earth's crust, on the presumption that it represented a simple cooling from a molten state, were made in ignorance of the existence of radio-activity, and of the fact that the earth contains within itself supplies of potential energy, which, liberated as heat, counterbalance the external loss by radiation. The discovery of radio-activity not only revealed with dramatic suddenness the unjustified restrictions which had been placed upon geologists, states Mr. Holmes, but it led directly to the elaboration of the most elegant and refined method of measuring geological intervals of time that has yet been devised. Each fresh uranium-bearing mineral is now regarded as a natural chronometer registering time by the atoms of helium and lead that are produced unceasingly within it year after year. Lead is taken as representing the stable end-product of the uranium family, and, when series of minerals of different geological ages are compared, it is found that the ratio of lead to uranium increases with the geological age. The interesting suggestion is made that the lead-ratio may be used to determine the geological age of rocks the stratigraphical position of which is not accurately determined. The oldest mineral hitherto analysed appears to be a zircon from the lower Pre-Cambrian of Canada. This gives an age of 1,580 million years, but as it is based on a single analysis, it can only be considered to give an approximate estimate of the time that has elapsed. Mention is made of a zircon from Mozambique, the lead-ratio of which is calculated indicates an age of 1,430 million years. This zircon is assigned to Middle or Lower Pre-Cambrian age solely on the ground of the lead-ratio shown by analysis.

The article states that correlation of the Pre-Cambrian formations in different parts of the world has long been one of the most difficult problems with which the geologist has been faced. The methods of lead-ratios, however, “has already done good service in leading the way towards a world-wide solution.”

The concluding paragraph of the article may be quoted in full, as follows:

“In conclusion it may be pointed out that the age of the earth is likely to be greater than, say, 1,600 million years; for the oldest known igneous rocks are themselves intrusive into sedimentary formations which in turn must have been derived from still older rocks. The latter may possibly have been the original crust of the earth, but of this no certain trade has ever been detected. Now, is in Hutton's day, geologists can still find ‘no vestige of a beginning.’ Astronomical considerations have shown

“however, in recent years that the new demands on geological time are not too high. The movement of the solar system across the void of space from its supposed birthplace in the Milky Way is a journey for which something approaching 3,000 million years is a dynamical necessity. Supporting this figure is an estimate by Dr. Harold Jeffreys of the age of the solar system. From a consideration of the present orbital elements of Mercury and their evolution, he finds that the requisite order of time is roughly 3,000 million years. Thus the earth recedes into an inconceivable remoteness far beyond the bounds of geological investigation, and there we must forsake her, and invite the astronomer, whose laboratory is the universe, to carry the story back still further.”  
—F.W.G.

#### PROSPECTING FOR RADIUM ORES IN BUTT TOWNSHIP

Mr. W. J. Lennox, of Toronto, who is interested in claims in Butt township where radium ore was found last year reports that a few men are at work on different claims. At the original discovery, Mr. Wm. Elliott did some work during the winter. Mr. Albert Trafford of Sundridge is working steadily on his claims which lie a short distance west of the Elliott. Mr. James Elliott did some work on his claim in the winter. Mr. Charles Bullock of Chicago, has three men at work. Ryan and Mann are working their claims. Mr. Lahay of Kearney, has opened a deposit on his claim near the village. Others are doing some assessment work. The Mining Corporation which was reported to have taken over the property north of the Elliott is not yet doing any exploration.

The discovery of radium ore in Butt township aroused considerable interest last fall, for such ore is very valuable. It occurs in the form of pitchblende, a black, lustrous heavy mineral, in pegmatite dykes. Mr. Lennox says that during the past few months numerous samples from several claims have been tested and found to be radio active.

R. E. H.

#### GRANBY CONSOLIDATED.

##### Reorganizing Its Western Management.

Boston—A reorganization of its western operating management has been started by the Granby Consolidated Mining, Smelting and Power Co. F. M. Sylvester has been succeeded in general charge by H. S. Monroe, who had been in the Nevada copper fields prior to his new appointment. Mr. Sylvester has been a vice-president with the title of managing director. This position has been abolished and Mr. Monroe will be known as the general manager. It is understood that Mr. Sylvester will resign as vice-president.

E. P. Mathewson has been appointed consulting engineer. He has seen service with the American Smelting & Refining Co. and the Anaconda Copper Mining Co. During his regime the Anaconda Co. did extensive work in readjusting and enlarging its smelting capacity.

An inspection of Granby was first made by Mr. Mathewson last February. He made recommendations following that trip which will now be carried out.

Within the past dozen years Granby has made two complete changes in its mine management. Several years ago J. P. Graves, one of the pioneers in the company, who was also a large stockholder, was relieved as general manager and later resigned as director.

### THE WASAPIKA GOLD MINE,

By R. E. HORE

The accompanying diagram illustrates the method of development of the Wasapika ore deposit.

There was exposed on surface a strong gold bearing quartz vein striking north across one of the company's claims, and extending on to others north and south. The exposure is on the face of a rock outcrop which dips into low wet ground. The footwall portion of the deposit is well exposed for several hundred feet, but the hanging wall portion is hidden under the wet ground.

After careful channel sampling of several hundred feet of the surface exposures, the manager, Mr. G. R. Rogers, decided to sink a vertical shaft to test the deposit at depth. This shaft was started on high ground west of the depression.

At 100 ft a cross cut was run east from the shaft and through the deposit. It was here found that there is a large hanging wall quartz portion in addition to the footwall quartz portion which is exposed on sur-

face. A sericitic, carbonate bearing gray schist forms part of the deposit.

Sampling in the 100 ft. crosscut showed that the footwall quartz portion, with some schist, carries about \$12. gold per ton for a width of 5 feet. The schist in the deposit generally shows only \$1 or \$2 in gold. Quartz stringers in the schist carry good values, but the schist itself is of no value. Samples from the hanging wall quartz gave varying results, running from \$3 to \$11. It may prove an important additional source of ore; but comparatively little is yet known about it as there is no opportunity for sampling it at surface. The footwall quartz here showed high values in silver as well as in gold and it is worth mentioning that there appears to be more silver than gold in the Wasapika ore. Assayed samples carrying an ounce of gold per ton carry about three ounces of silver per ton.

After the completion of the 100 ft crosscut, shaft sinking was resumed and the ore deposit was recently encountered in the shaft at about 160 ft. and crossed diagonally. About one half of the material hoisted from this depth down to 204 ft. was quartz. Preliminary sampling indicates good values in both hanging wall and footwall quartz, but again little in the schist.

At 204 ft. a crosscut has been run west through the deposit. Preliminary sampling indicates good values here also. It is interesting to note that the presence of silver in larger amount than the gold has again been determined. A sample of quartz from the first round at the 204 ft. level carrying a little under one ounce of gold per ton carries three and a half ounces silver per ton.

The company proposes to proceed with development by drifting along the footwall quartz portion of the deposit. This will give further desired information and make the openings needed for mining the ore and will at the same time give easy access to the hanging wall quartz, which can be tested by short crosscuts.

The Wasapika Consolidated Mines, Ltd., is a recently organized company which took over, a few months ago, the property of Wasapika Gold Mines, Ltd. and also three adjoining claims lying along the strike of the deposit. The new company has continued the work begun by the old company. Mr. Geo. R. Rogers, a mining engineer with long experience in gold mining, is president and general manager.

### IMPERIAL OIL COMPANY'S PROGRAM.

The Imperial Oil Company has planned a programme of oil exploration in Western Canada of considerable dimensions, and larger than was projected at the beginning of the season. There are now nine drilling rigs in different parts of Saskatchewan and Alberta, ranging from the vicinity of the 49th parallel of latitude to close to the Arctic Circle. It is understood that no very definite results have been attained as yet, but early information on the subject is looked for soon. The party that wintered on the Mackenzie River is being relieved by others who were expected to leave Peace River crossing during the latter part of May. Besides the well that is being sunk in the far North, there is a drilling rig near the Great Slave Lake: three drilling parties are operating in southwestern Alberta, near the foothills, one of which is not far from the international boundary: one well is being drilled in Southwestern Saskatchewan, near Consul: another is located in Eastern Alberta, near Czar, and there are two others in central America.

## THE SILVER MINES.

Cobalt mining interests evince considerable concern over a new Bill which has just been presented to the United States Senate by Senator Henderson, which has for its purpose the establishment of a government fund for the assistance of the silver-producing mines of the United States, the plan being to loan money to the producers so as to enable them to hold their bullion for sale at such times as the demand is strong.

It is quite common knowledge that a large proportion of the world's silver comes from low-grade mines, and that the bear raid on the price serves only to cause curtailment of this source of supply. As a consequence, only such high-grade silver mines as those in Cobalt are able to operate profitably. The situation is one which promises to still further reduce the visible supply of the metal until there is required another upward movement in price to encourage the low-grade mines to operate. Either this, or the cost of material and labor going into silver production will have to decline. In any event, the conditions necessary to cause the low-grade silver mines to operate steadily are bound to bring added prosperity to the mines of Cobalt, where even now the margin of net profit being realized is large.

Announcement is made to your correspondent that the Bailey Silver Mines will join the shipping list within one month, and this will mark the commencement of regular shipments. It is officially stated that the amount of silver ore in sight is such as to assure steady and comparatively large production for some months. Also, that with a number of veins awaiting development, together with considerable undeveloped territory, the indications are that a big future lies ahead of the mine.

The Mining Corporation of Canada has declared a dividend of 12½ cents a share, payable June 15th, and amounting to \$207,455. This makes a total of \$6,943,220 paid by the Mining Corporation and component companies. The company is also reported to be negotiating for control of the West Dome Mine at Porcupine, which lies adjacent to the Dome Mines on the West. It is also unofficially reported that a bid is being made for an option on the Ritchie Veteran claim which adjoins the West Dome on the South.

The lease on the cyanide equipment in the Buffalo mill secured by the Coniagas Company is to be made use of as quickly as possible. It is proposed to re-treat some 40,000 tons of Coniagas tailings by cyanidation. The lease does not include the flotation equipment in the mill on the Buffalo mine.

Officials of the Peterson Lake declare that a shipment of high grade ore is now being assembled, it being estimated that close to \$50,000 can be taken out, which amount should finance operations for the balance of the year. It is also stated that the arrangements to have the old tailings pile re-treated by oil flotation by the Dominion Reduction Company having been completed, this work should commence by about the end of July. At the annual meeting of the company held last week, the following board of directors was elected:—W. A. Lamport, president, Toronto; J. E. Carter, Vice-president, Guelph; E. Bareiman, Guelph; W. H. G. Browne, Toronto; A. G. Cumming, Toronto; D. E. Kennedy, Teeswater; C. A. McLean, Toronto; A. H. B. Moore, Niagara Falls, N. Y.; C. M. Nickel,

Toronto. P. M. Goff was re-appointed secretary-treasurer.

Good headway continues on the Oxford-Cobalt. The shaft has now reached a depth of about 100 feet, and will be continued to a depth of 150 feet at which point lateral work will be carried out. It is also proposed to continue the shaft to the underlying diabase-keewatin contact, and to cut stations at regular intervals of each 75 feet.

The Crown Reserve Mining Company is stated to have acquired an option on the Hylands-Offor group of claims, situated in the township of Whitney, and lying adjacent to the Porcupine-Keora. It is the plan of the company to explore the claims by diamond drill.

The Lafayette Silver Mines, Limited, has been incorporated for the purpose of taking over mining claims G.G.-4101 and 4102, situated in the Gowganda silver area. The company is composed of business men of Buffalo who propose to carry on an aggressive program of development work, and who announce that they have engaged the services of Newton Bigbee to manage the work, and that camp building is to commence this month. The head office of the company is at 130 Franklin Street, Buffalo, N. Y.

The first carload of steel for the construction of the light narrow-gauge railway from Elk Lake to Gowganda has arrived on the ground, and the indications are that work is to be carried on aggressively.

Announcement is made that work has been resumed on the White Reserve property in the Maple Mountain section of the Elk Lake district. For the time being only a small force of men will be worked, pending a more plentiful supply.

### Ore and Bullion Shipments.

During the week ended June 4th, three Cobalt companies shipped an aggregate of nine cars containing close to three quarters of a million pounds of ore, the Nipissing being the heaviest shipper as shown in the following summary:—

Shipper	Cars	Pounds
Nipissing .. . . .	5	442,880
Mining Corporation .. .	3	240,215
Hudson Bay .. . . .	1	60,034
Totals .. . . .	9	743,129

No bullion shipments were reported during the corresponding period.

### THE GOLD MINES.

A feature in connection with the labor situation in the gold mining districts of Northern Ontario is the increase in the number of applications for naturalization by former citizens of countries in middle and Eastern Europe, now seeking Canadian citizenship. In recent months, the exodus of foreigners to the countries above mentioned attained quite large proportions, and actually left the mines very short of men. This trek to the east appears to have about run its course, the favorable feature being that many of those who were discontented or restless have gone, and a steadier element remains. General opinion appears to be that even those who departed will before many months be clamoring to get back to Canada to resume the prosperity they enjoyed in this country. Not only that, but each one will probably persuade others to seek admittance into the Dominion.

It is noted in Porcupine and Kirkland Lake, as well as in Cobalt that the percentage of British and

American born citizens is on the increase, and that immigrants from the British Isles are already finding their way to the mine in encouraging numbers. This is particularly true of Cobalt.

Mining men and prospectors have expressed considerable disappointment over the fact that the draft bill to establish "The Mining Court of Ontario" has been shelved until the next session of the Ontario Legislature. The Bill had for its object the creation of a Mining Court, with a duly appointed Judge instead of a Commissioner as at present. It would give such a Judge the power to try all mining disputes whether having to do with either patented or unpatented mine claims, instead of dealing only with unpatented claims as at present. It is stated that the Minister of Mines, Hon. H. Mills, will pay a visit to the mining districts at an early date and will endeavor to secure the consensus of mining men and prospectors as well as of members of the legal profession, so as to be enabled to deal intelligently with the bill at the next session.

During the month of April, according to the regular monthly report by manager R. C. Coffey, the Lake Shore mine produced \$35,388. During the period 1,860 tons of ore were treated, the average gold recovery being a little over \$19 to the ton, and an average of 62 tons of ore being treated daily. This is the highest tonnage record so far in any one month in the company's history. The Lake Shore has declared a dividend of 2 p. c., payable June 18th. The disbursement will amount to \$40,000. A feature of this announcement is the fact that former dividends amounted to 2½ p. c. The company pays interim dividends, and the reduction as above shown is of no special significance unless it should indicate a decision to go on a regular dividend paying basis of 2 p. c. quarterly.

A small force of men is at work on the Granby-Kirkland property in the township of Lebel and surface exploration is showing up a number of promising veins.

On the K. Ayonb group of six claims, situated in Bernhardt township, adjacent to the north boundary of Teck township, free gold has been found in encouraging quantities in a vein several feet in width and traced for about three hundred feet.

The Ontario Government is proceeding with the construction of a bridge over the Blanch River, following the completion of the wagon road from Boston Creek to Skead. It is believed the large proportion of traffic to Skead will not go by way of Boston Creek instead of from Englehart as was formerly the case.

The Ontario Bureau of Mines continues to be aggressive in connection with field work. A report has just been issued by Cyril Knight, assistant provincial geologist, covering the Ben Nevis Gold Area, lying between Larder Lake and Lake Abitibi, which holds out encouraging prospects.

A report on the geology of the Fort Matachewan Gold Area has been issued by the Geological Survey, Ottawa, the work having been prepared by Dr. H. C. Cooke.

At the Bidgood property, at Kirkland Lake, the

main shaft has reached a depth of 160 feet and is being driven at the rate of over three feet per day. It is expected to have it completed and timbered to the 300-ft. level before the end of July.

At the 100-ft. level about 28 feet of cross-cutting was required to tap the vein which showed a width of from 12 to 15 feet and with considerable visible gold.

Diamond drilling is being discontinued on the Fort Matachewan Gold Mines, pending the completion of arrangements for electric power from a plant to be installed on the Montreal River.

A load of supplies, containing among other things about one ton of dynamite which was being transported to the Thesauris property by Jim Nelson, was caught in a bush fire and was destroyed by fire and explosion. The loss will be over \$5,000.

### THE NIPISSING MINING COMPANY.

By J. A. McRAE

A review of the position of the Nipissing Mine may be of interest at this time. Its reduction plant represents the most advanced stage of existing practice, and annually produces not much less than one-third of the total silver production of the entire province of Ontario. Also, it is rated as being one of the leading, if not the actual leader among the silver producing mines in the British Empire.

Since its discovery in 1904, the Nipissing has produced approximately 58,000,000 ounces of silver up to the opening week of June, 1920. The value of the production amounts to over \$39,150,000.

To illustrate how stable is the physical condition of the mine, it is interesting to note that production first reached \$2,000,000 a year in 1909, and for the eight years ended with 1916 averaged a little over \$2,500,000 each year. In 1917 the production increased to \$3,338,682.41, and, in 1918 actually amounted to \$4,040,446.10. In 1919, despite the labor strike which caused a loss of over two months, the gross production amounted to \$3,752,083.60, or at a rate actually the best in the company's history.

As regards the present physical condition of the mine, the official reports issued each month show an output of \$1,501,521 for the first four months of 1920, or at the rate of \$4,504,563 annually.

The company owns 840 acres right in the heart of the Cobalt camp, and, although no doubt the most highly mineralized areas have been drawn upon, yet so large is the area and so great the possibilities as to assure a further long life to the mine. The increasing value of the production from year to year seems to constitute genuine evidence in this respect.

With an authorized capital of 1,200,000 shares, the company actually has upwards of 12,000 shareholders, showing that the average holding of each shareholder is around 100 shares, and offering reasonable indication that the net profits realized are being widely distributed. The company has disbursed a total of \$21,240,000 in dividends, an amount equal to \$17.70 a share, or equal to 354 per cent on the company issued capital, which has a par value of \$5 a share. In addition to this was a net surplus of \$4,372,952.33 at the beginning of 1920.

The jewellers protest that the fifty per cent luxury tax will kill their business. Is not that the intention of the tax?

## NOVA SCOTIA NOTES.

## Coal Production.

May was a short month, there being five Sundays and two idle days, making a month of only 24 working days. The 1st of May was declared a protest "strike" by the U.M.W. against the action of the courts in the trials of the Winnipeg strikers. This particular action caused much local condemnation, but it did not have much real effect on production, as the first of May was a Saturday—a short day—a fact that doubtless entered into the calculations of the U.M.W. leaders, who have shown themselves to be adepts at obtaining effective publicity very cheaply, being well assisted in this regard by the local newspapers and their metropolitan correspondents.

The Wage Schedule Committee of the U.M.W. has been in session in Halifax considering ways and means of enforcing their newest demand for a 25 per cent increase in wages. The U.M.W. leaders are steadily reaching their goal, which is the acceptance by the Nova Scotia operators of a wage scale convention, representative of the miners and the operators in the Nova Scotia district as a whole, modelled on the practice of the bituminous coal districts in unionized fields in the United States. To this end the U.M.W. are suggesting the appointment of a Royal Commission, charged with settlement of the wage question as a whole, which it is stated the leaders consider preferable to Conciliation Boards sitting consecutively upon the cases of the several companies and their employees. The suggestion that has been made, and duly reported to and commented upon in the newspapers, that the coal-cutters should reduce their production by half in case the coal operators prove disinclined to concede the request for a further increase in wages, is of course merely a *ballon d'essai*, being a rather belated example of the "Ca canny" policy so well-known and so thoroughly discredited by experienced trade unionists.

The output of the Cape Breton Mines of the Dominion Coal Company during May totalled 256,874 tons, which compares with 261,338 tons in April, and with 244,718 tons in May, 1919.

The production of the individual collieries was as follows:

Colliery	Tonnage.
1	25,780
2	46,271
4	27,002
5	8,162
6	18,281
9	22,318
10	9,904
11	13,853
12	14,272
14	15,254
15	10,970
16	11,688
17	2,370
21	11,785
22	14,528
24	2,885
	————— 256,874

The feature of these figures is the increasing production from No. 11 Colliery and No. 24, both Emery Seam collieries, the excellent output from No. 22, and

the increase shown by No. 17 Colliery. The production of June, 1919, was very small, being only 224,000 tons, and the outputs for the current month should exceed this figure by 50,000 tons. In this event, the production for the half-year will approximate 1,608,000 tons, against 1,538,000 tons in the first six months of 1919.

## NEW ENGLAND'S COAL PLIGHT.

New England at the beginning of summer faces a coal outlook so disturbing that Gov. Coolidge urges appointment of a fuel administrator in Massachusetts. Apparently Mr. Storrow returns from abroad just in time to resume his war time post of that nature. He comes back with gloomy opinions on the coal prospect.

This situation is in nowise the result of underproduction, it being possible for the bituminous mine operators to expand their production from the 550,000,000 to 600,000,000 tons yearly they now output to a billion tons, if necessary. This, however, pre-supposes adequate transportation facilities, so that the coal can be loaded as fast as it is mined, for none of the bituminous companies has storage facilities at the mine.

The primary stricture, therefore, which is cutting off the coal supply, and thus forcing up the price, is the tie-up of the roads which serve the bituminous regions. In addition, the railroads which serve New England have brought in practically no bituminous coal for months. They have, to be sure, handled considerable bituminous, but practically all of it has been for their own use.

Coal dealers declare that they have had hundreds of cars shipped to them, which have been confiscated by the railroads for their own use, almost without exception. It takes more than six months, in some cases, to determine who has seized a car of coal. Sometimes a road will commandeer coal for the account of another, necessitating long delays to find the final recipient. It is oftentimes a matter of months to find who will pay and what the price will be. As a consequence, local coal dealers declare that their books are in an absolute tangle.

Being thus deprived of its possible coal supplies by rail from Pennsylvania district, there was brought in the supplies from Hampton Roads by water freight. Hampton Roads, it is pointed out, was originally nothing but a shipping point for New England coal by water. There was practically no coal sent abroad from there, although something like 4,000,000 or 5,000,000 tons was sent in one of the war years. With the suspension of English and Continental mine production in quantity, however, foreign buyers have invaded the American market, willing to pay any price for the coal to keep their factories going.

The result of this bidding is that it is now impossible to buy bituminous at Hampton Roads for \$13.00 or \$13.50. It is going overseas at the rate of 1,200,000 to 1,500,000 tons a month, and coal men say we are heading for \$20 or \$25 a ton bituminous coal unless the export is restricted.

In addition to that, congestion at Hampton Roads is so bad and the railroad tie-up so severe that coal coming from there carries a demurrage charge of \$3 and sometimes \$6 and \$8 a ton; due to the time the vessel has to wait for its load; this is in addition to a water freight rate of \$2.75 per ton (it was in the neighborhood of 55 cents a ton a few years ago) and a tax of 3 per cent on the demurrage.—"Boston News Bureau."

**BRITISH COLUMBIA LETTER.****Alice Arm, B. C.**

A syndicate has been formed to explore and, if investigation proves satisfactory, to develop the Royal Group of Mineral Claims adjoining the Dolly Varden Mine. This property consists of seven claims held under a \$100,000 bond. It is conveniently situated as to transportation, a short aerial tramway being all that would be necessary to connect it with the Dolly Varden Railway.

A settlement of the strike of employees of the Dolly Varden Mine has been effected. It is stated that practically all the demands of the men were granted. Mines will be paid at the rate of \$6.25 a day; muckers, \$5.75; and trackmen \$5.75. The union scale will apply to cooks, mechanics, etc.

**Queen Charlotte Islands.**

George Clothier, government mining engineer, has returned after an examination of some prospects of the Queen Charlotte Islands. He went over a free milling gold property situated near Skidegate on the west coast of Moresby Island and states that it possesses some fair quartz but that further development is necessary. The Ikeda Mine near Jedway is to be opened up this season and it is reported that a concentrator is to be installed. Quantities of high grade copper ore have been shipped at various times and there now is a good deal of comparatively low grade ore on the dump which, if facilities were available at the mine for treatment, might be handled at a profit. Surface work is being done on the Southeastern Mine in the same section and another property near Jedway is being inspected and reported upon by representatives of the American Smelting and Refining Co.

**Nelson, B. C.**

The McAllister Mine at Three Forks is under active development with promising prospects. R. A. Grimes, manager, states that the Slocan strike did not close down the work he has underway. This mine may be expected to join the shippers of the silver zone of British Columbia at an early date. Some first-class ore has been uncovered and those interested are so well satisfied with the outlook as to be considering the installation of further plant.

It is proposed by the British Columbia Prospectors' Association that delegates to the International Mining Convention to be held at Nelson shall be taken on a tour of the mining sections of East Kootenay. The suggestion is that the trip be divided into two or three sections, one travelling up the St. Mary's valley to the Sullivan Mine, the Stemwinder, North Star and a number of other properties and another setting off for the Windermere district.

**Princeton, B. C.**

Preparations for the commencement of operations at Copper Mountain by the Canada Copper Corporation are well advanced. Trains already are running between Princeton and Allenby on the Copper Mountain Branch of the Kettle Valley Ry. The concentrator has been completed and but waits the power which is being brought over a high power line from Bonnington Falls by the East Kootenay Power and Light Co. A large brick power station has been constructed. H. R. Van Wagenen, the Company's general manager, has returned from Denver Colo., and it is expected that

the mine and mill will start work either next September or October.

**Rossland, B. C.**

The Velvet Mine, situated near Rossland, is being re-opened by H. E. Innes, of Sandon, B. C. Some months ago it was taken over by the Granby Consolidated Mining and Smelting Co., and the mine was unwatered and worked for a short time. The Company, however, then ceased operations. It is well equipped and, if Mr. Innes is successful in making it a producer, it should become a valuable addition to the shippers of the camp.

**Vancouver, B. C.**

The Eureka Mine, near Hope B. C., is to be put under development by Messrs. Foley, Welch and Stewart. The property is situated in Silver Creek and machinery and supplies are being shipped now in order that work may commence as soon as weather permits.

Before the expiry of official business hours on the 31st of May of each year all miners' licences granted under the Mineral Act of the Province of British Columbia must be renewed. To hold mineral claims, or to operate in mineral in any form, all individuals, groups of individuals, or joint-stock companies must be possessed of such a licence. It is at the basis of the mining laws of the Province Section 12 of the Mineral Act reading "Subject to the provision herein-after stated no person or joint-stock company shall be recognized as having any right or interest in or to any mining property unless he or it shall have a free miner's certificate unexpired." For this reason it is of first importance that the renewal is obtained within the time limit which explains the rush facing the mining recorders throughout the Province every year during the month of May. This year has been no exception to the rule and, although the official figures are not yet available, it is probable that the number of licences issued will equal the best twelve months on record.

**Princess Royal Island.**

Announcement has been made of the purchase by the Tonopah Belmont Development Co. of the Princess Royal Property, situated near the company's mines. Plans have been completed for the carrying out of comprehensive development during the summer.

**MR. W. R. WILSON APPOINTED PRESIDENT OF CROW'S NEST PASS COAL CO.**

Succeeding the late Elias Rogers, Mr. W. R. Wilson has been appointed President of the Crow's Nest Pass Coal Company. Mr. Wilson has been General Manager of the Company for a number of years, and has been 2nd vice-President and a director of the Company for about a year.

Mr. Wilson's family record covers the period of coal-mining activity in Canada. His father sunk the shafts of the General Mining Association at Sydney Mines in 1867, and his son is in charge of one of the newest and certainly the finest colliery in Canada, that of the Granby Consolidated Company at Cassidy's, Vancouver Island. Mr. Wilson's own ability in his profession is evidenced by his new appointment. He is much valued member and a Councillor of the Canadian Mining Institute.

Mr. Wilson's headquarters will be at Fernie.

**MANITOBA LETTER.**

By C. A. Millican, Winnipeg.

The first crew to go into the Rice Lake District since the break-up on Lake Winnipeg left on the 1st. of June for the Gabrielle property. The crew which includes five geological students from the University of Manitoba will commence active exploration work on this property at once. The Gabrielle will not install any heavy machinery until next winter, but a great amount of surface stripping will be done as well as the existing drifts on both shafts being extended. The management of this property have decided to confine all their energies this summer to exploration work on a large scale, and it is expected that Mr. J. B. Tyrrell will make a very comprehensive report on all surface and underground showings about the end of June.

For the information of those who may be visiting the Rice Lake gold fields this summer, we might mention that the summer route now being established is via the Hole River, and from Winnipeg the easiest way to reach this territory is as follows:—

Winnipeg to Riverton, C.P.R. Ry. (practically all supplies can be procured at the latter point).

Riverton to Lower Rapids on Hole River, Tug or Launch. (5 hour journey). Guides may be arranged for at the Hole River settlement, but canoes are scarce.

Hole River settlement to Mining District, by canoe. (1 to 2 days trip). Very good hotel accomodation is now available at Riverton, and by leaving Winnipeg in the afternoon an early start can be made from Riverton the following morning, reaching the canoe route on the Hole River by early afternoon. By July or August the new road being built by the Provincial Government should be quite passable for wagons as for as Clearwater and Caribou Lakes. As pointed out before canoes should, if possible, be arranged for before leaving Winnipeg.

For general information we are publishing herewith a list of Mining Companies with headquarters at Winnipeg. These Companies are, or will be, carrying on active operations this year.

Gabrielle Mines Ltd., 207 Scott Block, Winnipeg.

Gold King Mines Ltd., 846 Somerset Blk., Winnipeg.

Marigold Mining Co., Ltd., 618 Mc. Intyre Blk., Winnipeg.

Bellevue Mining Co., Ltd., 806 Union Bank Bldg., Winnipeg.

Commonwealth Gold Mines Ltd., 236 Curry Bldg., Winnipeg.

Pan Extension Gold Mine Co., Ltd., 220 Curry Bldg., Winnipeg.

Gold Pan Mines Ltd., 200 Trust and Loan Bldg., Winnipeg.

Golden Vein Mines Ltd., 315 Paris Bldg., Winnipeg.

Brooklyn Mines Ltd., 509 Paris Bldg., Winnipeg.

Boulder Gold Mines Ltd., 1203 McArthur Bldg., Winnipeg.

Bruce Consolidated Gold Mines Ltd., 101 Tribune Bldg., Winnipeg.

Northern Copper and Nickel Mines Ltd., 704 Merchants Bank Bldg., Winnipeg.

Laura Mines Ltd., 502 Mc. Intyre Blk., Winnipeg.

Pas Consolidated Mines Ltd., 220 Curry Bldg., Winnipeg.

Reahill Gold Mines Co., Ltd., 220 Curry Bldg., Winnipeg.

Angus McDonald Mines Ltd., 200 Trust and Loan Bldg., Winnipeg.

Adanae Collieries Ltd., 315 Paris Bldg., Winnipeg.

Western Dominion Collieries Ltd., 807 Paris Bldg., Winnipeg.

It is expected that several new Companies will be incorporated this summer, especially in connection with operations in the Rice Lake District. It is expected that an information bureau will shortly be established by the Overseas Development Corporation, Ltd., Scott Blk., Winnipeg.

It now looks as though considerable interest will be taken in the Lac. du Bonnet district where several experienced prospectors are now busy exploring the copper deposits. Excellent showings have been uncovered along the Winnipeg River but just to what extent copper values exist is still an unknown quantity. On two of the properties diamond drilling will be continued this summer.

Further tests are being made in connection with the recent oil discoveries in the Dauphin District. Whether oil exists in commercial quantities has not yet been ascertained, although samples analyzed have shown the traces to be of good quality.

In view of the coming Provincial elections, it is interesting to note that the Norris Government have given an unqualified promise to assist in opening up Manitoba's hinterland and assist in every possible way in furthering the development of her unknown resources as well as those now being prospected and explored. In this connection it is to be keenly regretted that Eastern interests have continued to baulk any real effort to rush the Hudson Bay Ry. to an early completion. Apart from giving Western Canada a near-by ocean port the completion of this line will hasten to a remarkable degree in the opening up of several thousand square miles of country which, from present indications, may yet produce enormous values in minerals, pulp and water power.

#### **SAFETY NET UNDER CONCRETE DISTRIBUTING CHUTE REDUCES FALLING STONE ACCIDENTS**

To catch large stones jumping out of chutes used for distributing concrete and so avert injury to men below, a safety net has been used successfully on a large construction job under way at one of the plants of E. I. du Pont de Nemours & Co. At four-foot intervals a ¾-inch angle iron is fastened across the chute, extending outward a foot on each side. Through holes at the ends of each angle iron a wire is run parallel with the chute and one foot distant on each side. A chicken wire screen, ¾-inch mesh, is fastened to these wires and thus suspended below the chute. This interesting information is contributed by Mr. F. L. Hurlbutt of the Du Pont Company.

Not a single fatal accident occurred among the industries of Worcester, Mass., during 1919 as compared with an average of five fatalities yearly during the preceding three years. In commenting on this, the press of Massachusetts says: "One of the most potent influences in bringing about this new condition is the National Safety Council, a thriving branch of which in Worcester has been actively engaged in furthering the good work."

# A MARSH HOIST

## IS MADE THE RIGHT SIZE FOR YOUR MINE

and in either Steam Power or Electric Power

This shows one of our Electric Mine Hoists. We make many other types. Send for our catalogue of Mine Hoists, Cars, Cages, Buckets, etc., and see what we offer you. It will repay you.

From the little 10 Horse Power size for prospectors or small mines to the massive 50 Horse Power size, one of our 7 sizes should be just right for your mine.

We are specialists in the building of Hoisting Machinery of all sorts. For nearly a quarter of a century we have been designing and building Hoists, and have developed a Hoist that we are really proud of—proud because of the record of good work they have done, and are doing in mines, quarries, and other classes of work from one end of Canada to the other.

TORONTO, CANADA

### TORONTO NOTES

Mr. A. D. McMillan, C. P. R. Toronto, has returned from a ten days visit to the Hughes-McElroy and Mondan mines. On the latter property cross-cutting at the 250 foot level, and drifting operations are in progress with promising results. Mr. McMillan states that he observed signs of increasing activity in the Gowganda area.

Shareholders of the Black Lake Asbestos Corporation met in Toronto on May 26th when there was considerable manoeuvring on the part of the buyers of Black Lake securities, for position. When the meeting adjourned practically nothing had been done towards deciding the control of the company. The President, R. F. Massie, declared for the present directors:

“Our position is that we are practically trustees for the shareholders and bondholders and we want to do the best we can for them. If either Mr. Jacobs or the Corporation makes a proposition, we will consider which is the more favorable.” President Ross of the Corporation defended the legal proceedings to upset the previous offer of purchase by saying that it was the right of the shareholders to receive due notice of such an offer, which had not been given in that case until the meeting came together. He said that the Corporation’s experience in the asbestos mining industry should enable it to operate the Black Lake property to advantage. During the meeting Mr. R. S. Cassels announced the resignation of himself and Mr. A. L. Malone from the directorate. Mr. John D. Kay was appointed to fill one of the vacancies.

**GEOLOGICAL SURVEY PARTIES ENGAGED ON MAPPING PORT ARTHUR SHEET.**

(By J. J. O'CONNOR.)

Dr. T. L. Tanton, of the Geological Survey, Ottawa, is out with a party of five men, engaged in mapping the Port Arthur sheet, which ties on to the Shebandowan sheet. Dr. Tanton expects to be in the Field during the months of June, July, August, September and October.

Percy E. Hopkins, M.E., of the Ontario Bureau of Mines, has gone to the Big Duck area, north of Schreiber, with a party of four, for the purpose of making an examination of the gold claims located in the Autumn of 1919, about six miles north of Schreiber. He will map in detail the whole area, including the Big Duck Lake field. Mr. Hopkins expects to be engaged there from June to August.

Prof. A. L. Parsons, of the University of Toronto, has gone to the Kaministiquia iron belt, with a party, for the purpose of his investigations, for the Ontario Bureau of Mines.

Strong representations were made to the Hon. Harry Mills, Minister of Mines, by a Port Arthur deputation in December last, urging him to cause these surveys to be carried out this summer. The Hon. Mr. Mills, was found to be in hearty accord with the suggestions made, and is now implementing them. He is at present in the district, and is evincing the keenest interest in the work of placing this necessary information in the hands of prospectors and investors.

The work of unwatering the Silver Islet Mine, began this morning. At six o'clock, the water had been lowered to a depth of fifty feet.

**RESEARCH FELLOWSHIPS OFFERED BY THE SCHOOL OF MINES, UNIVERSITY OF IDAHO.**

In co-operation with the United States Bureau of Mines and the Idaho Bureau of Mines and Geology, the University of Idaho offers in the School of Mines a number of fellowships. These fellowships are open college graduates who have had good training in mining, metallurgy, or chemistry, and who are qualified to undertake research work. The income of each fellowship is \$900 a year for the twelve months beginning July 1st., 1919.

Fellows will register as students in the University of Idaho and become candidates for the degree of Master of Science in Mining or Metallurgy (unless this or an equivalent degree has been earned.) Their class work will be directed by the heads of the departments of construction, but the greater portion of their time will be spent in research work under the direction of the Bureau of Mines staff resident at the University. The purpose of this work is to undertake the solution of definite problems confronting the mining and metallurgical industries of the state of Idaho. For 1920-21 the following subjects are being considered:

- (1) Flotation—with especial reference to differential separation of various minerals.
- (2) Treatment of the complex gold-silver ores of the state.
- (3) Ore Dressing problems.
- (4) Mining problems.

Applications, with copy of college record, statement of professional experience, and names and address of three references will be received up to June 15, 1920. The applications should be addressed to Francis A. Thomson, Dean, School of Mines, Moscow, Idaho.

**PERSONALS**

Mr. A. R. Whitman of New York, who was for some years at Porcupine and Cobalt is in Toronto this week on his way to Alaska. Mr. Whitman was at one time geologist for the McIntyre Company and later for several Cobalt silver mining companies.

Mr. W. E. Simpson, manager of the Miller-Independence mine at Boston Creek is in Toronto.

Several applications for the position of secretary of the Canadian Mining Institute are said to have been made. Two or three come from Ottawa and some from the west are expected.

Mr. C. G. Daimpre has organized a company to carry on prospecting work in Northern Ontario.

Mr. F. L. Sutherland has returned to Toronto after visiting the Herrick mine.

B. Neilly, Secretary of the Ontario Mining Association, is now permanently located in his new office, 55 Trusts and Guarantee Building, Bay St., Toronto.

H. J. McCann is appointed Assistant General Manager of the Dominion Coal Company. Mr. McCann has been in the Coal Company's service approaching twenty years, having successively been Chief Clerk of Company, Assistant Sales Agent and Superintendent of Retail Stores. In 1910 he was transferred to the Sydney offices of the Dominion Steel Corporation and appointed Purchasing Agent of the Steel Company, Recently he was appointed Assistant to the President, which position he held until his present promotion. Mr. McCann's long service with the Coal Company has included experience in every branch of executive direction.

Peter Christianson is transferred from the management of the Jubilee Colliery of the Nova Scotia Steel and Coal Company to the Engineering Department of the Company, and is succeeded at the Jubilee by John Murphy, whose official experience was chiefly gained in the collieries of the Dominion Company.

**NEW GEOLOGICAL SURVEY MAPS.**

The following new maps are issued by the Geological Survey.

Map 185A Sandon, Slocan and Ainsworth Mining Divisions, Kootenay District, British Columbia. A topographical map on scale of 4,000 ft. to the inch. Includes district between Slocan Lake and Kootenay Lake, and towns of New Denver, Silverton, Sandon and Kaslo. Publication No. 1641.

New Glasgow, Pictou County, Nova Scotia. A topographical map on a scale of 2,000 ft. to an inch. Shows valley of the East River, and towns of Westville, Stellarton, New Glasgow and Thorburn. Publication No. 1707.

Matachewan District, in Temiskaming area of Northern Ontario. To accompany Memoir by H. C. Cooke. Scale of one mile to the inch. Publication No. 1793. Coloured geologically.

**METAL QUOTATIONS.**

Fair prices for Ingot Metals, Montreal, 10th June, 1920.

### BENEFICIATION OF LOW-GRADE ORES ON THE MINNESOTA RANGES SUGGESTS SIMILAR UTILISATION OF ONTARIO ORES.

(By J. J. O'CONNOR.)

The prophetic vision of iron-ore operators of the Minnesota ranges, in meeting and mastering the problems of beneficiating the immense quantities of low-grade ores, will enable these ranges to hold out a supply of iron ore, far into the future, after the present known high-grade ores are exhausted.

All over the central portion of the Mesabi, are almost unlimited quantities of low-grade ore, a few points in iron below what the furnaces today can handle at a profit.

The washable ores are in great quantity, and are already being washed up to commercial grades by millions of tons per year.

The eastern end of the Mesabi has great low grade deposits of magnetic ore, for the handling of which, a process has been worked out, at a cost of half a million dollars actually expended.

The Vermillion range has large deposits of banded jasper, streaks of ore, separated by bands of jasper and silica.

Minnesota's high-grade ores have enabled her to gain a commanding position in the iron-producing world. Her iron-ore operators are far sighted enough to prepare for the successful holding of the lead she now enjoys, as the greatest iron producer in the world, by lending their money and talent in devising ways for the beneficiating of her low-grade ores.

When Judge Gary of the United States Steel Corporation was in Duluth, Minn. in January 1918, he said: "Within this state are billions of tons of iron ore not now considered of any market value whatever, which some day will be valuable and which may be used practically and profitably for conversion into iron and steel. And it will be hundreds of years before this ore is exhausted."

The conditions obtaining on the Minnesota ranges, are almost exactly duplicated on the northern Ontario ranges. Judge Gary's terms may be easily applied, and with equal truthfulness, to the Ontario ranges, where the quantity, grade and variety of ores are repeated on range after range to an almost unlimited extent, all susceptible of some form of treatment to bring them to merchantable grades.

No one process or scheme can be devised to beneficiate all kinds coming under the head of lean ores. Each variety requires separate treatment, at varying costs.

The work done by the Hayden-Stone interests (Mesabi Iron Company) upon ore already magnetic by nature, makes the problem of handling non-magnetic ores very much easier. A non-magnetic ore can be converted into a magnetic ore by giving it a magnetic roast. That is to say, if a small percentage of coal or coke, or even peat, be mixed with a non-magnetic iron ore, and the mixture then heated in a suitable furnace, to a suitable temperature, under suitable conditions, the ore become magnetic.

The muskeg and peat beds of northern Ontario, together with the enormous hydro development possible in the territory, would solve the fuel and power problem of any such undertaking on Ontario ranges. The preparation and production of peat for this purpose, has as great possibilities in it, as has any scheme for briquetting it, and selling it in competition with coal.

The day is not far distant when Canada must look to its own sources for a supply, of at least a very large

percentage, of its iron ore requirements, if not for the whole tonnage charged to Ontario furnaces. Everything points to an increasing demand for iron ore throughout the continent. This demand will be lasting, and so increase the consumption of United States Lake Superior ores, that, in justice to themselves, they will be obliged to curtail the export of their high-grade ores.

It would, therefore, seem to be a fitting time for the Government to give the necessary encouragement to capital to invest in the development of our enormous deposits of iron ore and be ready for the day that they must be used, and may be our only dependence.

Everything that is being done on the Minnesota ranges in the way of beneficiating lean ores, can be repeated here in Ontario. All it needs is Government encouragement, to induce capital to invest in this greatest of all industrial enterprises. There never has been a time in the history of Canada, when the conversion of this great natural resource into an active element of progress, as the present. There never has been a time when so much interest has been shown by her public men, or such keen sympathy felt for a step of this kind. All agree, that anything that will bring about the rational development of our natural resources, must be in the general interest of Canada, and of the whole people.

It must not be forgotten, that the only chance the Government would be taking, would be the cost of the legislation. If the passing of this legislation did not bring about the industrial development of our iron ores, it would not be called upon for any outlay by way of aid. With the development it would be certain to cause, the advantage to Canada would be Canada would be immeasurable.

### TWO CAN PLAY IT.

The report of the Foreign Relations Committee of the United States Senate in favor of a resolution authorizing the appointment of a commission to deal with the Canadian Government regarding newsprint and pulp imports from Canada contains suggestions of retaliatory measures if the Dominion does not abandon her policy of imposing embargoes upon the export of articles of this character in order to protect her domestic consumers. It hints at similar embargoes by Washington upon the export to Canada of coal, sulphur and dyes.

The Foreign Relations Committee appears to have overlooked a few possibilities in its contemplation of retaliatory measures. For example, Canada need only put an embargo on nickel, of which she controls four-fifths of the world's supply, to cripple the steel industry of the United States. We are heavy exporters of other important materials urgently required for industrial purposes south of the international boundary line, an embargo upon which would be very embarrassing.

On the other hand, an embargo on American coal exports would have a serious effect upon central Canada until Canadian coal producers could meet the new demand. Retaliation would be bad business for both sides, so bad, in fact, that we are fairly certain it will not be started. In other words, the Senate Committee is bluffing—a rather stale and futile proceeding to adopt towards a neighbor as familiar with that game as Canada is, particularly one who is as capable of "calling" that kind of bluff as she is.—"Victoria Times."

# THE PRINCIPLE THAT APPEALED TO ENGINEERS

## Simplified Reduction

When engineers learned that ideal step or stage reduction could be effected in a single machine—and the Hardinge Conical mill proved this by past performance—they knew it would mean a decided increase in production and a marked decrease in operation costs.

**AND IT DID!** The Engels Copper Company submitted three distinct repeat orders after using their first Ball Mill for 1 year. There is no greater proof of satisfaction.

Maximum production, continuous operation, minimum repair costs, decreased labor and operating costs are present wherever Hardinge Mills are installed.

*Let our Engineering Department  
co-operate with you*

**A BIG SHOT.**

Boston—A recent mining operation by the New Cornelia Copper Co. in Arizona serves to show the extent to which modern mining companies of the porphyry type must go to keep costs at a minimum.

The company late last year completed the layout of powder chambers and connecting tunnels in its hill No. 3, the length of underground excavations being 661 feet. It set for explosion 80,000 pounds of Trojan nitro-starch powder and used an electric current of 110 volts to ignite it. Cost of the blast for labor and supplies was \$15,305, which with the cost of drifting and excavating made a total of \$17,720.

Approximately 300,000 tons of ore were displaced by the blast, the cost averaging about six cents per ton.

John D. Ryan was one of the audience who viewed this mammoth eruption.—“Boston News Bureau.”

**CHEMIST**, with experience in usual Copper Smelter analyses. Must be accurate and rapid on routine work. Graduate Preferred.

The International Nickel Co. of Canada, Limited, Toronto, J. W. Rawlins, Metallurgist.

## Two Empire Drills for Sale

### At VANCOUVER, B.C.

*In charge of the GEOLOGICAL SURVEY, DEPARTMENT OF MINES, Pacific Bldg., VANCOUVER, B.C.*

### TWO Complete 6 in. EMPIRE DRILLS

which have never been used

These Drills were Purchased for the Munitions Resources Commission to be used in prospecting for certain minerals just before the close of the War. The total value of the complete equipment, which includes clean up and assay outfits and all accessories, is upwards of \$9,000.

#### EMPIRE DRILLS ARE USED FOR

prospecting gold, tin and other placer deposits,  
prospecting coal, iron and copper deposits,  
prospecting kaolin, phosphates, etc.,  
boring in conglomerate or gravel or material of similar nature,  
drilling of oil and water wells,  
testing of foundations, etc.

The drills were purchased from the New York Engineering Company, 2 Rector Street, New York City, and among their circulars there are testimonial letters from Mr. F. S. Clarke, British Columbia Drill and Dredging Company, Vancouver, and Mr. G. H. Knowlton, Vancouver.

Full Particulars and Prices on application to the Geological Survey, Department of Mines, at address given above, or to the Secretary, War Purchasing Commission, Ottawa, Ont.

## EDITORIAL

### Final Report of the Munitions Resources Commission

The Final Report of the Munitions Resources Commission is an interesting record of much hard work compressed into a short time, and performed, as is evident from the restrained wording of the record, in spite of much official apathy and with little indication of the scope of the work that it was proper for the Commission to undertake. The Mines Branch and the Geological Survey appear to have given every assistance and encouragement to the investigations of the Commission, and in particular the laboratories of the Mines Branch at Ottawa appear to have been most useful. The publication of this Final Report is to be commended, as it will not only serve to record the emergency measures of war time as a guide to the future similar emergencies that are to be anticipated, and the labours of the Commission itself, but will preserve for reference most of what is known in Canada regarding its 'war minerals,' those strategic raw materials that are earnestly desired in war time and completely forgotten in peace days.

The Commission had as Chairman Col. Thos. Cantley, and as Secretary, Mr. G. C. Mackenzie. Messrs. Robert Hobson and the Hon. W. C. Edwards were the other two members of the original Commission, to which was later added Col. Carnegie and Mr. Geo.

W. Watts. It would have been difficult to select a more representative personnel, or one more nicely combining knowledge of business and operating technical conditions with scientific attainments

The instructions given to the Commission were as wide as they were necessarily vague, but they were in effect to cruise Canada for such minerals as aluminium, chromium, fluorite, manganese, molybdenum, platinum and tungsten. How thoroughly the work was done, and what tremendous distances and physical difficulties were overcome by the investigators is revealed in the Report, which shows that the battles of the Empire were fought at home as well as abroad. Nor were the searchings of valley and mountain for scattered and elusive deposits unaccompanied by casualties.

To those who read between the lines, the Final Report of the Munition Resources Commission is a document that, despite its official wording and character, ranks in its record of labour, adventure and patriotic purpose, with despatches from the actual fighting fronts, and it is in fact the despatch of those who stayed at home and "minded the stuff" while others met and overcame the Philistine.

### Geological Survey Undertakes Study of Paleobotany of the Sydney Coalfield

It is announced in the Sydney, Cape Breton, newspapers that Mr. W. A. Bell, Assistant Paleobotanist of the Geological Survey, with two assistants will make a special study of the coal horizons in Nova Scotia during the summer, with particular reference to the evidence afforded by the plant remains as to the co-relation of the separated coal basins. The Survey is to be congratulated upon the decision to take up this long-neglected and very necessary enquiry. The recent discovery of salt at Malagash, Nova Scotia, and its possible association with potash-bearing minerals; the growing importance of oil-shales, and the necessity to elucidate the geological history of the Carboniferous of Nova Scotia so as to assist in the

search for hidden coalfields, are some of the reasons that make it urgently advisable that the geological maps of Nova Scotia, in particular those of Carboniferous areas, should be brought up to date. The recently issued topographical map of the Stellarton district is a welcome sheet, and it is hoped that it may be followed by a revised geological map. It is also suggested that maps are required of the topography and structural geology of the Sydney Coalfield, and that some attempt should be made to indicate the structural character of the submarine strata in this field, for which, when the paleobotanical evidence is collated, there is ample information available. The inspection of the data upon the several sheets of the

Sydney coalfield will in itself provide a sufficient reason to ask for a revision of the existing geological ordnance maps. They are compiled from the field sheets of 1874-76, with additions and corrections to 1898. Of the collieries operated by the Dominion Coal Company in 1898 there are today only remaining three. These three are entirely exhausted—except for pillars—in the land area, and will shortly be superseded by new shafts sunk close to the shore so as to command as much submarine coal as possible. All the other operating collieries are new since 1898, to the extent of sixteen mines. When the old Reserve mine closes down, which will be before long, and when Dominion and Caledonia Collieries are superseded by new shafts at the shore, there will not remain in operation a single colliery that was working in 1898. In other words, the entire development of the existing collieries of the Dominion Coal Company has taken place since the last revision of the geological maps, and nothing of the knowledge gained by this development is shown on the existing sheets.

#### THE PRICE OF BITUMINOUS COAL.

Some interesting figures regarding the price of bituminous coal were divulged by the General Manager of the Montreal Light, Heat & Power Co. during the hearing of that company's application to increase the price of gas to the consumer, which we desire to comment upon without criticism of the policy of the company to which, we believe, no exception can be taken.

In 1914 this Montreal company was buying gas coal in the United States at figures as low as \$1.05 at the mine, with a freight to the lake front of 83 cents and a water transportation rate to Montreal of about the same, a total of \$2.71. Today, coal is costing \$9.00 at the mine, plus freight charges of \$3.86 per ton, a total of \$12.86, and it is mentioned that the coal is inferior in quality to the obtainable in 1914.

These figures are a sufficient argument for the protective duty on coal in 1914, and they are at the same time a partial explanation of the high cost of bituminous coal today. Coal was never mined and sold at a profit in the United States at \$1.05 per ton on cars at the pit mouth. It was only possible for coal mine operators to believe they were making a profit at such a figure by borrowing from posterity, and, unfortunately, this generation happens to be that posterity. The chief contemporary reasons for the high cost of coal are fairly well known, and need not be here enumerated, but one reason that is not so well known is that we are paying today for coal that was given away in previous decades. Some indication of the competition that had to be met by Canadian coal-mine operators is given by the figures above quoted, as in domestic mines \$1.05 would not have covered the labour charges incurred in mining and placing coal on railway cars.

It was this unfair and unwise competition by United States coal, utilised to the fullest extent by the large Canadian consumers, that has prevented our domestic coal industry from expanding its outputs and strengthening its financial position. The competition was unfair because it consisted in the sale of a product in Canada at less than its cost in the United States. The unwisdom of the procedure is just beginning to dawn upon the United States. That country finds itself obliged to pay today for yesterday's dissipation. The analogy between coal supply and pulpwood supply is fairly exact in the United States, except that in the case of coal the ultimate resources are immense. It is the immediately available coal that has been rendered costly, for the reason that coal operators have not realized that coal is a wasting asset, and that mining costs are only accurate if they are calculated on the whole life of a coal mine.

We believe it may be accurately affirmed that if the large Canadian consumers had been willing, say between 1907 and 1914, to pay a reasonable price for bituminous coal to domestic coal operators, the production of coal in Canada during the war, and at the present time, would have been larger; the cost of production would have been cheaper; transportation costs throughout Canada would have been smaller; and the Canadian consumer would today be assured of an ample supply of domestic coal at much cheaper rates than it is purchasable for at this date in North America.

It is poor national policy to starve and throttle a domestic industry in the days of peace and plenty, and then to expect in the day of emergency and want to find this industry lusty and productive.

It was recently stated in the Commons that in Canada we had the coal, but had not the brains to utilize it. Perhaps it would be more accurate to state that no concentrated application of national thought has ever been given to the fuel problem in Canada. If this should ever happen, there can be little doubt but that the problem could be satisfactorily solved.

#### WORKING MINING CLAIMS WITH AXES AND SAWS.

The disclosures made during the investigation being carried on in reference to the disposal of timber on Crown Lands in Western Ontario should serve to emphasize the need for more frequent investigation of applications for mining claims. It cannot be expected that a mining recorder should know a great deal about each of the many hundreds of properties that are taken up by prospectors. When a claim holder presents a statement that a certain amount of development work has been done, as required under the Mining Act, that statement cannot be carefully investigated before filing is permitted. The recorder's business is to file the sworn statement, not to investigate it.

In the development of our mineral sources the forest plays an important part. Fuel and mine timber necessary for preliminary work are commonly found on Northern Ontario mineral lands. The removal of the timber suitable for other purposes is desirable, and should be encouraged; but it should not be possible for anyone to cut timber on mining claims for other than mining development purposes without permission from the Lands and Forest Department and without proper compensation to the province.

The disclosures indicate that it is now possible to secure large tracts of forest in Ontario by taking up mining claims and filing statements that development work has been done on them. It is obviously the duty of the Provincial Government to see whether the statements filed are in accordance with the facts. But whether the statements filed prove to be honest statements or not, there will remain an obligation to see that there is a change in the regulations concerning the removal of timber from mining claims. One of the ways in which the Government has been willing to help the prospector has been that of allowing him to obtain fuel and mine timber on easy terms. The misuse of this privilege by others is likely to result in a further burden on the prospector if care is not taken in changing the regulations.

#### GOLD PRODUCTION IN ONTARIO.

A Toronto newspaper in its financial columns states: "There are many indications of a rapidly growing interest in the gold fields of Ontario. With the near exhaustion of deposits in all other parts of the world, northern Ontario must soon come into its own." "The near exhaustion of deposits in all other parts of the world" is a statement having all the inaccuracy of sweeping generalizations, and is a fair example of the "journalese" of the mining sections of our newspapers. The gold fields of Ontario will stand and fall on their own merits, of which the price of mining stocks is the last and least indication, but the figures of production are sufficiently impressive not to require bolstering by ridiculous inaccuracies.

The quarterly report of the Ontario Bureau of Mines states that owing to Ontario's contribution, Canada was the only country able to report an increased output of gold for 1919, and that production for 1920 so far shows an increase of nearly 46 per cent over the first three months of 1919. This is a record of which the Province may well be proud, and it is the best possible testimony to the producing capacity of Ontario's gold mines when such a record is possible under conditions of high cost of production and shortage of workers. It is the quantity and availability of gold in Ontario that is causing it to take so important a rank among producers. This is the fact that should be stressed. The falling off in gold production elsewhere—with the exception of certain

fields—is not caused by exhaustion of mineral but by the increased cost of mining and the fixed price of the product.

The concentrated character of Ontario's gold production is to be seen from the Bureau of Mines Report, which gives credit to the Porcupine District for ninety-one per cent of the gold output. The remainder came from Kirkland Lake, with the exception of the contribution of the Argonaut Mine, amounting to \$11,000 for the quarter.

#### CONSOLIDATION OF STEEL AND COAL COMPANIES A MEASURE OF NECESSITY.

During the Budget debate, the Hon. Mr. T. A. Crerar is reported to have quoted Col. Grant Morden as stating that British Steel Corporation, if and when completed, would be able to compete with the world. "Why not then," asks Mr. Crerar, "remove the duty on coal and steel?"

We do not believe that Col. Morden ever expressed himself to this effect, and if he did, he made an inaccurate statement. What we believe Col. Morden desired to convey was that only by a consolidation of the coal and steel interests of Nova Scotia could these hope to enter the markets of the world. On a fair and square basis of competition, without regard to the desirability of possessing operating collieries and active steel works in Canada, the coal mines of Eastern Canada, and those industries which are based upon coal, namely, the manufacture of coke, the recovery of the chemical products of coal distillation, the smelting of iron, the manufacture of steel and finished steel products, and the fabrication of steel ships, none of these can hope to compete successfully against the coal industry and its offshoots in the United States; or against the coal industry of Great Britain, Belgium, Germany, Russia, and China and its offshoots, under normal peace conditions.

The acceptance of Col. Grant Morden's proposals to consolidate their interests by the directors and shareholders of the coal and steel companies in Nova Scotia will not be evidence of a desire to water the stock, but it will be evidence of a realization that these various companies cannot anticipate successful survival under independent management. As we stated in the last issue of this monthly, "the formation of British Empire Steel Corporation is above everything a measure of necessity and self-defence. Its first duty will be to consolidate its position, to conserve its resources, and these tasks, rather than dreams of aggression, will occupy all the energies of those who are chosen to manage the Corporation for many years to come."

Mr. Crerar proceeded to express his inability to support a fiscal policy that develops mergers such as British Empire Steel, "which is practically cornering all the coal and iron ore in sight in the Maritime Provinces." It would not, by the way, be a great task

to corner all the iron-ores in the Maritime Provinces. The commercial occurrences are negligible, so far as known. They are probably not all known, however. "I would suggest to the Minister of Finance," continued Mr. Crerar, "that one of the most effective ways in which he can combat this growing tendency to combine various companies into huge combinations is by using the weapon of the tariff." Apparently Mr. Crerar considers combination to be wrong, in itself. In this regard Mr. Crerar is not consistent. Combination for the grain-grower was brought about by precisely the same economic laws that have suggested the steel merger, and we see little intrinsic difference between the high fixed price of wheat and the protection given to coal and steel by the tariff. The coming together of the coal and steel companies in Nova Scotia has been occasioned by a much more potent weapon than the tariff. Independent and competitive operation of the coal trade in Nova Scotia has been tried for sixty years, and has proved to be a conclusive and dismal failure.

The cost of mining coal in Nova Scotia is relatively high, and the physical difficulties adding to the cost of mining are increasing and must continue to increase. The supply of labor is relatively scarce, and a review of the past record of the dispersal of emigrants to Canada would indicate that it is likely to continue so. Moreover, Nova Scotia has only 400,000 inhabitants, and whether it can be remedied or not, it is a fact that the newly arrived immigrant only rarely goes to Nova Scotia, and, after residence in Nova Scotia, shows a desire to go westwards. These are some of the permanent drawbacks to mining coal on a large scale at relatively cheap cost in Nova Scotia, and explain why it is considered necessary to get together for mutual self-help and protection.

The main feature of Col. Morden's proposals as they appeal to the coal and steel companies, is the undertaking to raise \$25,000,000 of new capital from outside sources. This is not a large sum in consideration of the requirements. Much more than \$25,000,000 of new capital expenditure is required to place the coal and steel production of Nova Scotia on a basis that will make it a respectable factor in the world's markets. Some sense of proportion is required in viewing these matters. The statement has been made that five billion tons of coal are at the disposal of the proposed constituent companies of a mooted merger. Such a statement does not accurately represent the facts unless it takes into account the position of the coal reserves. It would be much more accurate to state that large capital expenditures, necessitating the obtaining of outside assistance, are necessary to place the coal holdings of the companies at their own disposal.

As to the effect of the protective duty on coal, what does it amount to? There is no duty on anthracite, and a very small duty on bituminous slack coal. The duty on bituminous coal is 53 cents, and by judicious

shipments of slack and screened coal and their subsequent admixture, it can be lessened to an average of 33½ cents. Can it be contended that an impost of this amount inflicts any great hardship on Canadian consumers, or that its complete removal would lower the cost of United States coal to the consumer here? The protective value of the duty has almost disappeared in the rising cost of coal production and transportation. The duty might be taken off United States coal tomorrow, and the Canadian consumer would never know it from study of his coal bill. The chief loser would be the Canadian Treasury, and the most apparent result would be the necessity for new taxes to make up the deficit occasioned by loss of this revenue. And there are a few other reasons, which the Finance Minister could doubtless mention, why it is not desirable to encourage greater importations from the United States at this time. A thirteen per cent discount on the Canadian dollar is one of them.

The coal duty today does not represent any appreciable or adequate measure of protective tariff. It is really an excise duty for the raising of inland revenue.

The value of the coal deposits of Nova Scotia consists in large measure in their being the one Canadian source of coal east of Saskatchewan. They constitute 0.7 per cent of our national coal reserves, but they are the only source of coal supply that Canada owns within a territory that contains 80 per cent of her population. It is their position and strategic value that is remarkable, not their extent. They can only be made fully available as a source of coal supply in Canada by the expenditure of very large sums of money, and any consolidation of interests that carries with it the promise of such expenditure will benefit the country as a whole. If Mr. Crerar were Minister of Finance in Canada we can conceive that he would welcome a business consolidation that promised increase of employment, increase of internal revenue, increase of provincial coal royalties, decreased public taxation, and a decrease in imports accompanied by an increase in exports. All this, and much more, will proceed from the consolidated operations of British Steel Corporation if its organization should be consummated, and if its promoters will recognize from the first the relatively high cost of mining coal in Nova Scotia.

#### WORKMEN'S COMPENSATION IN NOVA SCOTIA

In this issue is published a digest of the Report of the Workmen's Compensation Board of Nova Scotia for 1919. Of especial interest is the gratifying reduction in the number of fatal accidents, and the lowering of the assessment rates in the coal-mining and iron and steel trades. In commenting in these columns on the 1918 Report we suggested that it should be possible eventually to fix the coal-mining assessment at 2.5 per cent of the payroll. The rate was fixed for 1919 at 3 per cent, but the year's opera-

tions show a surplus in this class of \$127,640. The rates for the iron and steel trades is placed at 1.5 per cent, and in this instance the surplus of approximately \$30,000 indicates that it is probably a permanent rate. We do not believe that the hazard in coal-mining is twice that in the iron and steel trades, and with the respectable disaster reserve now accumulated, a further reduction in the rate of coal-mining assessment may be anticipated. Coal mining is not so distinctly a hazardous occupation, as it is an occupation in which a large number of simultaneous deaths may occur for well-known reasons.

**WORKMEN'S COMPENSATION IN NOVA SCOTIA DURING 1919.**

The Report of the Workmen's Compensation Board for 1919 in Nova Scotia records a gratifying decrease in the number of fatal accidents. The figures were abnormally high in 1917 and 1918 because of the incidence of two disastrous coal-mine explosions and a lumber camp fire in those years, but after allowing for these occurrences, the record is still very encouraging, as will be seen from the comparison following:

	1917.	1918.	1919.
Fatal Accidents .....	146	185	47
Deduct Disasters .....	65	105	..
	<u>81</u>	<u>80</u>	<u>47</u>

"A further analysis," states the Report, "discloses that the greatest improvement must be credited to the coal mining industry, in which not only were disasters avoided but the ordinary fatal accidents were reduced to exactly half what they were in 1918, as shown by the following statement:—

	1917.	1918.	1919.
Total Fatal Accidents .....	97	126	19
Deduct Disasters. . . . .	65	88	--
	<u>32</u>	<u>38</u>	<u>19</u>

The total number of compensable accidents has varied very little, being 4,888 in 1919, comparing with 4,836 in 1917 and 4,931 in 1918.

Assessment rates were lowered from those of 1918 as follows:

	Assesment Rates 1918.	1919.
Coal Mining .....	4.	3.0
Steel and Iron Mfg. ....	1.9	1.5
Building . . . . .	2.0	1.5
Stevedoring . . . . .	4.0	3.0
Steam Railways . . . . .	4.5	2.0
Lumbering, etc. . . . .	3.0	2.5

The lowering of rates is stated to have been justified, and to have resulted in substantial surpluses during 1919, except in the case of lumbering and saw-mill industries, which shows a deficit. The divisions of mining, iron and steel manufacture, and railways showed quite large surpluses.

The ratio of administration expenses to the total assessment has shown a steady increase, being 5.76 in

1919, compared with 3.66 in 1918 and 2.58 in 1917, the first year of operation. This understandable, as the work of the Compensation Board will be for a certain period a cumulative condition.

The investments of the Board at the end of 1919 totalled \$2,233,026, compared with \$1,579,031 at the end of 1918. The whole is invested in Nova Scotia provincial bonds and Dominion Government bonds, the last-named to the extent of \$1,990,000.

The Report mentions the formation of an Accident Prevention Association, previously noted in these columns.

The accounts of the Board has been audited by the Provincial Auditor.

A significant statement is that out of 4,504 cases of temporary disability during 1918 there developed sepsis in 104 cases. In 1917, by a coincidence the number of similar cases was also 4,504, but only 74 cases of sepsis developed.

The Report contains a number of interesting statistical tables, which, if continued under the same arrangement for a number of years, will permit of valuable deductions.

**CORRESPONDENCE**

**"Fine Arts vs. Styracosaurus Albertensis."**

Quebec, June 13th, 1920.

The Editor,  
 "Canadian Mining Journal,"  
 Ste. Anne de Bellevue, Que.

Dear Sir,

I read with dismay your editorial in the Journal number of June 11th, entitled **Fine Arts vs. Styracosaurus Albertensis**, and I hope that you will not let the matter rest there.

It is a disgrace on the part of the Government authorities, that they should entertain, or even think of, such a thing as boxing up the collection of Vertebrate Paleontology, to put it in the "oubliettes" of the Victoria Museum, for the sake of making room to display oil paintings and water colours by Canadian artists.

This paleontological collection was put together by the labour of love and the love of labour, representing the life-work, of many Canadian scientists. Its educational and scientific value to the nation (excepting perhaps the philistine element, which unfortunately seems to be largely represented in the powers that be) is beyond all doubt, whereas the worth of the intended substitute, as an agency and means to develop and improve Canadian taste and culture is doubtful. We have good Canadian artists, but judging from the display of pictures at present exhibited in the Victoria Museum, there are also many poor ones, and the latter are liberally represented in the Art Gallery of the Museum.

Our neighbours to the south realize the value of fossil collections such as the one the fate of which now hangs in the balance. The Smithsonian Institution, the Carnegie Museum, the American Museum of Natural History, the United States Geological Survey, have collectively, spent hundred of thousands of dollars in digging out vertebrate fossil remains from our own Cretaceous and Jurassic beds in Alberta and Saskatchewan, and they have deemed the money well spent, as they have obtained many unique specimens, which would have remained in Canada, if adequate facilities had been extended in time to our own Geological Survey.

My plea may sound feeble, but I sincerely hope that personalities, more authorized to speak than I am, will take up the matter and raise such a voice of protest and deprecation that the skeletons of the denizens of our country in past geological ages will remain on view in the Victoria Museum. Otherwise, may the shades of Cuvier, Cope, Marsh, Logan, Dawson, Whiteaves, and Lambe haunt the sleepless nights of those responsible for their removal.

Yours very truly,

THEO. C. DENIS.

### INSTITUTE NOTABILITIES.

#### Mr. Charles Camsell.

Mr. Camsell's career is one of such variety and interesting adventure that it is impossible to even summarize it within the limits usually assigned to this purpose by the Bulletin. A volume would be better devoted to the purpose. Son of Julian Stewart Camsell, Captain in the British Army and Chief Factor of the Hudson's Bay Company, Charles Camsell was born at Fort Liard, N.W.T., in 1876. At an early age he was sent to school at Winnipeg, journeying across the plains from Edmonton by ox team.

At Winnipeg he received his primary education at St. John's College, and then in due course graduated in science at the University of Manitoba, also the alma mater of Professor J. C. Gwillim, who slightly preceded him. In college days Camsell was captain of the University football teams, both association and rugby, and seems to have been recognized as an all-round athlete.

On leaving college in 1894, he returned to the Mackenzie River country intending to spend a winter at his home. But by the trend of circumstances he actually spent the next six years in the region north of latitude 60 deg., ranging between the Coppermine river and the Pacific coast. He describes his occupation during this period as "hunter, trapper, fur trader and dog-driver." It was naturally one of incident and adventure. Amongst other experiences in this return to the 'simple-life,' he set out on snow-shoes, in 1897 to go to the Klondike, then in its early 'hey-day,' by way of the Liard and Pelly rivers. This seems to have been one of the few cases in which Camsell ever failed to reach his objective. Game and supplies failing on the head waters of the Pelly, he fell on evil days and barely subsisted for three months on rabbits, squirrels, fish-hawk and wolf. Reaching the Cassier country in the fall of 1898, 'dead broke,' he, for a time, worked as boatman and cook on a freight scow plying on the Dease river. It is interesting to note that of the three other members of the crew, two were graduates of Cambridge University and the third, of Trinity College, Dublin. The captain was an Indian, and the mate, as became his intermediate position, was a halfbreed.

Disregarding the social symmetry of these surroundings, with the coming on of winter Mr. Camsell engaged as mail carrier on the Stikine river between Wrangell and Telegraph Creek, driving a dog team throughout the winter of 1898-99. In the summer of 1899 he again crossed the mountains to the Mackenzie river, this time by canoe, and met experiences in traversing the Grand Cannon of the Liard from which few others would have emerged to tell the tale.

After spending the following winter in trapping furs at Fort Wrigley, he joined a Geological Survey

party under Dr. J. M. Bell in the spring. This party explored Great Bear lake and later in the season made a dash to the Coppermine river. On the return journey to Great Bear lake they barely escaped starvation and exhaustion and later being frozen in at Fort Chipewyan covered the remaining 600 miles to Edmonton on snow-shoes.

Turning from the 'wild and woolly,' Mr. Camsell then proceeded to Kingston, Ontario, and spent the remainder of the winter at Queen's University, studying geology and mineralogy under Dr. W. G. Miller and Professor Wm. Nicol. The summer of 1901 he spent exploring for the Algoma Central Railway in the Moose River basin and on James bay. On the way out from this trip, he sampled parts of the present Hollinger mine, but obtaining an assay of only \$5.20 per ton, no ground was staked.

After spending the summer of 1902 in exploring the wood buffalo country between Peace river and Great Slave lake, for the Geological Survey, Mr. Camsell devoted the following winter to post-graduate study in geology at Harvard University under the instruction of Professors Wolff, Davis and others. Obtaining appointment as geologist to the Canadian Northern Railway Company he was engaged in explorations in northwestern Ontario and eastern Manitoba, until June 1904, when he was appointed to the

Mr. CAMSELL, who is appointed Deputy Minister of Mines at Ottawa.

permanent staff of the Geological Survey on which he has since accomplished much valuable and well-known work. In 1904 he traversed parts of Patricia and in 1905 from Dawson Y.T., explored the Stewart and Peel rivers and reached the mouth of the Mackenzie.

From 1906 to 1913 he was occupied largely with problems of economic geology in southwestern British Columbia. His reports on Hedley, Tulameen and other mining districts made during this time are well-known standards. During 1908, he also pursued post-graduate study at the Massachusetts Institute of Technology, under Professor Daly, Lindgren and their associates.

In 1914, Mr. Camsell was placed in charge of the exploratory work of the Geological Survey and besides directing several parties in the field also made an exploration of the country between Athabaska and Great Slave Lakes, which amongst other results made known the Taltson river for the first time.

When it was decided to establish an office of the Geological Survey in British Columbia, Mr. Camsell was selected to open and take charge of the division of the Survey with headquarters at Vancouver, where he has since resided.

Mr. Camsell is a Fellow of the Geological Society of America, of the Royal Geographical Society and of the Royal Society of Canada, and is also a charter member of the Harvard Travellers Club. He joined the Canadian Mining Institute in 1906, became Secretary of the British Columbia Division in 1919 and a Councillor for British Columbia in 1920.—From C.M.I. "Bulletin."

### C. CAMSELL APPOINTED DEPUTY MINISTER OF MINES

It is announced from Ottawa that Charles Camsell has been appointed Deputy Minister of Mines, succeeding Mr. R. G. McConnell, who is superannuated at his own request. Mr. Camsell has for some time been in charge of the British Columbia office of the Geological Survey, where his capabilities for direction of affairs have been recognized and appreciated.

### THE PRODUCTION OF NICKEL OXIDE

The recently issued report of the Ontario Bureau of Mines shows the Province to be now a large producer of nickel oxide. This metal has been made here in small quantities for some years; but only recently has the amount been notable. The report shows that during the first three months of the present year there was produced 1,788,183 lbs. nickel oxide valued at \$413,944. This doubtless came largely from the Port Colborne refinery of the International Nickel Company of Canada. This company sends a large quantity of the oxide to England. Other producers include the refineries at Deloro and Thorold where nickel oxide are recovered in treating silver ores from the Cobalt district. It was not until refining of nickel-copper mattes was started at Port Colborne that the production of nickel and nickel oxide in Ontario assumed its present proportions.—R.E.H.

### RESIGNATION OF MR. R. F. M. SYLVESTER.

(From the Victoria "Colonist.")

All those who know how Mr. R. F. M. Sylvester has been instrumental in developing the mining industry of British Columbia will regret to learn that he has resigned as managing director of the Granby Consolidated Mining and Smelting Company. That organization owes a great deal to his progressive business capacity and the vision which he brought to bear on its operations in this Province. He was aggressive and keenly alive to the possibilities of the acquisition and the development of new prospects. Vancouver Island owes to him the opening of the coal mining area at Cassidy's Landing, where there is now in existence the most model coal mining town in the world and where the industry gives employment to between 400 and 500 men. Taking his administration of the affairs of the company in this Province from every standpoint, he was responsible for an era of progress which is seen today both on this Island and at Anyox, and we believe he was determined to bring about such further development as would have redounded to the advantage of both the company and British Columbia. The Granby Consolidated loses an asset by Mr. Sylvester's resignation. It is of interest to learn that he intends to make his home in Vancouver. No doubt before long he will be heard from as instrumental in mining ventures on a large scale.

Mr. R. F. M. SYLVESTER, who has resigned as Managing Director of the Granby Consolidated Mining and Smelting Company.

The Dominion Government proposes continuing the office of Director of Coal Operations in the Province of Alberta. A Bill authorizing this was before the Canadian Senate recently and Senator Robertson, Minister of Labour, answering a question, stated that the Department of Justice had ruled that the legislation was constitutional.

## IV. The Graphite Industry

By CHAS. SPEARMAN\*

Foreign crucible graphite vs. domestic (Canadian and American): A Comparison.

Of all the foreign graphite placed on the market that from Ceylon is probably the most important and commands the most attention on account of its reputation based upon chemical purity and physical properties. The next foreign producer of importance is probably Madagascar, which, as far as quantity is concerned, is probably equal in output to, if not greater than that of Ceylon, but the quality is said to be inferior.

Of course it is to be expected that the grades of graphite from the various producing deposits of Ceylon and Madagascar vary in quality for the different commercial standards. Uniformity in this respect could hardly be expected, but, generally speaking, although there may be just as good graphite in Madagascar as in Ceylon yet the average of the output from Ceylon appears to be of a better grade for the market requirements than that of Madagascar. In this regard there are, chemically speaking, many grades of each commercial standard on the market from both countries classed according to size of product, etc., such as the lump, chip and dust of Ceylon, which vary considerably in carbon content for products of like physical classification; and the quotation varies as the carbon content, for instance, Ceylon lump may vary in price from 5 cents to 16 cents per pound at the present time according to its graphite-carbon content, and to some extent its physical properties.

Ceylon graphite found its way into the markets of the world at an early date. The nature of the deposits\* offered unparalleled opportunities to place a relatively high-grade stock on the market at a low cost as compared with the disseminated deposits of Canada and the United States.

Generally speaking, Ceylon graphite is gathered from the deposits and sorted, averages between 80—85 per cent carbon. It is for this reason put on the market for crucible trade. Domestic deposits range from 2½ per cent. to 10 per cent. carbon only. It was very difficult to recover graphite from the grade of domestic deposit and at the same time show a margin of profit in the operation. Thus foreign stock became established in most countries and was regarded as unequalled for practically all commercial purposes. Then again the output from Ceylon and other foreign producers was so large that capital hesitated to venture into the development of the relatively low-grade disseminated domestic deposits on account of the higher costs and the primitive state of the milling art, which was purely experimental and too often led to grievous financial losses; more especially where the deposits contained such impurities as mica, fibrous silicates, etc. All this experimental work and consequent losses served in a great measure to promote the interests of

the foreign producers at the expense of the interests that attempted to foster the domestic industry.\*

Ceylon graphite had the advantage of being sufficiently pure, commercially speaking, to market with but little sorting after being extracted from the deposits and not only this but in every instance where the domestic graphite was of equal or even greater carbon content the physical properties of the flake were such that it was vastly inferior, due to the method of milling. This feature permitted foreign graphite to meet all domestic opposition and further discouraged the local industry.

The local industry meeting with but little encouragement thus far, due primarily to the lack of efficient processes for the recovery of the graphite, and to the decided natural and local facilities of the foreign producers, contributed but a small tonnage to the world's requirements. Spasmodically the industry would make attempt to recover by taking advantage of some unusually favorable local condition and thus contribute a small tonnage for the time being, then because of excessive costs and foreign competition would cease operation, and add another chapter to the history of failures.

With improved milling methods gradually introduced within the past few years which make it possible to produce flake graphite from domestic disseminated graphite ores, comparable to, and even better, physically and chemically than the so-called high-grade foreign massive stocks, the establishment of the domestic graphite industry on a permanent basis may be expected in a comparatively short time.

The demand has now a tendency to call for a relatively high-grade graphite of better than 90 per cent. graphite-carbon content. The foreign deposits capable of marketing such a product, without first milling and refining, are indeed but few in number and wholly inadequate to supply the consumption. Foreign stock 90 per cent. graphite carbon is quoted at about 16 cents per pound today, which, if added to the expense of milling and refining, would bring the price per pound somewhere around 19 and 25 cents. This would be a disadvantage to the foreign producer and would probably eliminate foreign stock to a great extent from active competition with domestic flake, which could be sold at a much lower figure and still maintain a good margin of profit.

Much has been said regarding the relative merits of Ceylon graphite as compared with domestic flake for use in the crucibles industry. By way of comparing the properties of each it would be well to mention a few points in a general way. For example, suppose at one end of a series a graphite crucible be carved

\*W. Lindgren—Mineral Deposits, page 703.

\*C. Spearman, Can. Mining Journal, Jan, 16th, 1920 —P. 32.

from a mass of pure graphite of the crystalline variety such as is used in the industry and at the other end of the series a crucible made from a very finely divided crystalline graphite. The crucible made from the pure massive graphite at the one end of the series would fail from lack of tensile strength in a direction normal to the cleavage planes, and under relatively low pressure the crucible would have a tendency to part along the cleavage planes. To overcome this weakness the graphite must be reduced to a certain mesh and the individual particles so placed in the crucible mixture so as to eliminate as far as possible the general parallelism of the cleavage planes of the mass taken as a whole. At the other end of the series where a finely powdered graphite was employed, a high percentage of clay would be required to coat or cover the particles, and thus the crucible approaches excessive impurity, lacks conductivity, is apt to brittle, and may possess drying cracks, etc. There is a degree of disintegration somewhere between the one massive piece at the one end of the series and the finely divided powder at the other end of the series, where the crucible stock will possess the maximum efficiency for its special use. Therefore, to sum up, an ideal crucible should:

(1) contain as much graphite carbon as possible without impairing its strength. It is then essential to start with a fairly high grade graphite,—the higher the grade the more suitable for the purpose,—and all impurities such as the usual non-metallic gangues, and in fact everything except graphite, constitutes an inert member to the whole. These impurities may be termed inert as they are useless in this particular art, and besides call for additional clay to coat their surfaces and thus further reduce the carbon content of the crucible. There are again other impurities which cause certain chemical reactions that are to be avoided.

(2) The flake must be of certain dimensions as to area and thickness. The size of the particles taken collectively must vary uniformly within certain limits. The area must be such that the least possible clay be used to coat the surfaces and at the same time preserve efficiency, and in this the area created must cease before the point is reached where the thickness of the flake is such that its tensile strength is endangered in a direction parallel to the cleavage planes. In practice the above points referring to dimensions are embraced in a general way by the average specifications of the consumer which are as follows:

“All particles should pass through a standard 16-mesh screen, about 50 per cent. rest on a 50-mesh standard screen, not more than 2-4 p.c. pass through an 80-mesh standard screen and all rest on a standard 90-mesh screen, and to regulate the thickness of the flake it is specified that 100 gms. loose stock shall occupy less than 110 cu.cm.”

(3) The promiscuous arrangement of the graphite in the crucible mixture is also a matter of importance. This destroys parallelism of arrangement and promotes tensile strength. It is therefore necessary to have a uniform arithmetical progression of sizes between any two limits such as the 16 and 90-mesh sizes.

With the foregoing dealing principally with physical specifications, a few comparisons between Ceylon and domestic graphite may now be made.

Some consumers believe Ceylon graphite to be the “acme of purity.” This was true up to a recent date. Statistics will show that the average graphite im-

ported for crucible manufacture ranges from 83-87 per cent. graphitic carbon while it is now possible to place domestic flake on the market ranging from 92 to 98 per cent. pure, depending upon the demand.

Some claim that the peculiar fibrous structure of Ceylon graphite acts as a stronger binding agent, and requires less clay in a crucible batch or mixture than the flake variety.\* If Ceylon lump be crushed to the required size for crucible use the fibrous structure is more or less destroyed, and where it did exist the lateral axis of the fibre is so diminished as compared with its longitudinal axis that the strength of the fibre as a whole is greatly reduced. For the most part, rough angular particles predominate, which probably possesses a little more density, which in turn is more or less offset by lack of tensile strength due to the tendency to part at the cleavage planes when the density exceeds a certain degree. Then again as far as a regular balanced binding-area is concerned, the more or less disc-shaped flakes afford an interlocking medium vastly superior to the so-called fibrous stock, which range in shapes from the thin needle shaped “fibre” to the roughly shaped parallelepiped, the smaller axis of which just passes through a standard 16-mesh opening; and, when the right thickness of flake is maintained, less clay is used than with the angular variety. These shapes do not combine in a crucible mixture to give the same general efficiency as to the flake-shaped particles, and any attempt to alter the general shape of these particles so as to have them compare favorably with the flake variety, would cause abnormal losses by the creation of fines due to the more or less brittle nature of the fibrous variety as compared with the relatively tenacious domestic flake.

It has also been claimed that when flake graphite is mixed with the requisite clay for crucible making and subjected to the necessary pressure for moulding purposes, this pressure causes the flakes to orient themselves with the planes containing the longer axis normal to the direction of pressure. This argument is rather far-fetched and is not borne out in practice. In the first instance, if properly mixed so as to avoid general parallel arrangement of the flake and the more or less plastic mass then subjected to the necessary pressure, this pressure will be distributed equally in all directions upon the enclosed mass and therefore there will be no tendency to parallel arrangement of the flake. Even though all other conditions were such as to permit this law of parallel arrangement to take place, the time period, which is the important factor, is so insignificant that readjustment of the flake could be scarcely measured and from the practical standpoint could be treated as though it did not occur at all.

A point in favor of Ceylon graphite is the greater density of a unit volume of the loose crucible stock, 100 gms. occupying approximately 90 cu. cm. while the damaged thin domestic flake\* resulting from the older experimental process tested from 130 to 150 cu.cm. for an equal mass. Domestic flake made by recent processes has tested lower than 100 cu.cm. and probably makes a better-balanced crucible than Ceylon graphite

\*H. S. Spence—Can. Graphite Industry. Can. Bureau of Mines, Summary Report 1918.

\*F. G. Downs, E. and M. J. No. 6, Vol. 105, Feb. 9, 1918, P. 282.

by combining tensile strength with high carbon content.

As to chemical purity, the domestic flake can now be placed on the market with a much higher carbon content than that of any of the foreign product now offered. This reduces any of the deleterious gangues, if present, to a quantity so small as to come well under all chemical specifications of the consumer.

As far as the combustion test is concerned the domestic flake is equal and in many cases superior to that of the foreign stock.

From the above it is difficult to see where the foreign graphite taken as a whole can compare with the domestic flake such as can be placed on the market today. Many of the buyers still claim that it would not be advantageous for them to buy domestic flake due to its impurity. This is done, in many cases, to obtain a better quotation, and is effective, generally speaking. If this domestic product is really inferior why do the consumers consider it at all?

For a time during the war it was made compulsory to use domestic flake mixed with Ceylon for crucible purposes. The mixture was approximately 75 per cent. Ceylon material supplied the higher carbon content to have made a very good mixture because the domestic flake furnished extra binding material to compensate for the weakness in the Ceylon graphite, while the Ceylon material supplies the higher carbon content to compensate for the relatively low carbon of the domestic flake then used.

Great strides have been made in the art of concentrating disseminated graphite ores in the past few years, stimulated no doubt by the demand caused by the war. These improvements have practically placed foreign graphite where in a short time the competition will be so keen as to practically eliminate it, if disseminated deposits can produce and maintain the tonnage to meet consumption requirements. The outlook for the future tonnage appears to be promising as the domestic disseminated deposits have been scarcely developed as yet, and there is the possibility of finding new deposits to replace those that become depleted.

Th old prejudices against domestic flake are gradually disappearing and when the formulae for crucible mixtures are so arranged as to admit of its use a great obstacle to the industry will be removed.

Much could be done to assist the domestic industry if consumers and producers insisted upon a strict physical and chemical standardization of the stocks to meet the requirements, establish a high standard and have the price based accordingly.

Note:

This is the fourth article on the Graphite Industry contributed to the "Journal" by Mr. Spearman. For previous articles see issues Feb. 12th, page 87, Aug. 6th, 1919, page 586, Jan. 16th, 1920, page 32. See also account of Dominion Crucible Company in last-named issue.

#### INCREASE IN SELLING PRICE OF COAL AT CALGARY

Calgary prices for coal have been raised from \$9.75 to \$10.50 per ton for lump coal, and to \$8.75 for steam sizes. This increase is necessitated by the advance in miner's wages. The miners have not yet signified their acceptance of the proffered increase, but if ratified it is retroactive to 1st April.

#### "THE CANADIAN INSTITUTE OF MINING AND METALLURGY."

The "Bulletin" announces change of name, and appointment of Mr. Lamb as Secretary Emeritus

With this month the Institute opens a new chapter in its history. The legal formalities which were necessary in order to give effect to the decision to change the name having now been all complied with, the Canadian Mining Institute became, on April 11, the Canadian Institute of Mining and Metallurgy. As the letter ballot proved, the change was desired by the majority of the members, and there is no doubt that those who, for sentimental or other reasons, were in favor of adhering to the original name will soon become reconciled to the change. It is probable that the majority of those who would have preferred to perpetuate the old style are charter members, or at least members of very long standing, who have watched the Institute grow from very humble beginnings, and who have helped to steer it through troubled waters on many occasions. The Institute has attained its present strong position largely as the result of their labors, and is only natural that they should be jealous of its traditions; but it is safe to say they will be no less loyal to the Canadian Institute of Mining and Metallurgy than they were to the Canadian Mining Institute. As showing the present-day tendency of mining men to give proper recognition to metallurgists, however, it

Mr. H. MORTIMER LAMB, who retires after 15 years' service as Secretary of the Canadian Mining Institute, and is appointed Secretary Emeritus.

is of interest to note that the Mining Society of Nova Scotia, with traditions extending back even further than our own institute, and with a record of which any society might well be proud, is now considering the advisability of changing its name to "The Nova Scotia Mining and Metallurgical Society."

This month also marks another break in the continuity of the Institute's history, the Council having accepted, with great regret, the resignation of Mr. H. Mortimer-Lamb as Secretary. Mr. Lamb has ably filled this position for a period of fifteen years, and has thus been very closely associated with the work of the Institute throughout the most critical stages of its growth. Fortunately, the Council has been able to retain in some degree his services and the benefit of his experience, and as Secretary Emeritus Mr. Lamb will continue for the time being at least, to devote attention to the affairs of the Institute, particularly as the editor of the Annual Transactions.

**FIRST QUARTER FOR ONTARIO MINES SHOWS INCREASE.**

The Ontario Department of Lands, Forests and Mines has just issued a report showing an increase in the value of the output for the first quarter of the year in metalliferous mines, smelters and refining works of Ontario, of nearly one million dollars over the corresponding period of 1919.

Owing to Ontario's contribution, Canada was the only country able to report an increased output of gold of 1919. Production for the first quarter shows an increase of nearly 46 per cent over the first three months of 1919. Of the total output of \$2,953,036, Porcupine contributed \$2,694,665. Kirkland Lake \$247,339, and the balance \$11,032 came from the Augonaut mine in Gauthier township and from refining of nickel-copper matte. The output from Porcupine came from the following mines: Hollinger Consolidated, McIntyre, Dome, Dome Lake, Porcupine Crown, and Davidson Consolidated. At Kirkland Lake the producers in order were Lake Shore, Teck-Hughes and Kirkland Lake. Production is still hampered by insufficient labor, and although the wage scale has been increased to equal that at Sudbury and Cobalt, the effect has not been appreciable. In addition, gold mines produced 24,913 ounces of silver valued at \$31,373. The total tonnage of ore milled was 360,327 tons. As regards mill equipment the producers report 5,485 tons daily milling capacity which includes 210 stamps capable of treating 3,880 tons. Ball and tube mills installed have a capacity of 1,605 tons daily.

**Silver.**

The quantity of silver marketed during the period shows a falling off, despite the high price of the metal, which averaged \$1.30 per fine ounce. When the price began to recede, some of the larger producers held a considerable proportion of their output in the hope that the market would recover. The course, however, continued downward, the present level being about \$1 per ounce. The average price was \$1.01 for the corresponding period in 1919. Of the total of 2,280,665 ounces, Cobalt and Gowganda contributed 2,244,709 ounces while 11,763 ounces were recovered from nickel copper refining and 24,193 from gold ores. In addition certain silver producers were paid \$7,111 for 54,518 pounds of cobalt contained in the ores and concentrates sold.

**Refineries:**—At Deloro, Thorold and Welland the three operating silver-cobalt refineries treated 219 tons of ore, 655 of concentrates and 626 of residues for a total recovery of 829,142 ounces of silver in addition to arsenic, cobalt and nickel in various forms. Only 5,535 lbs. of nickel oxide were marketed in this form, the major part of the output, as noted in the table, coming from the Port Colborne nickel-copper refinery. Metals Chemical, Ltd., at Welland has sold its plant to Ontario Smelters & Refiners, Ltd., which will carry on the business in future, using a different process. The new company also owns the plant at Chippawa formerly operated by the Standard Smelting and Refining Company.

**Summary of Metalliferous Production—First Quarter of 1920.**

	Quantity		Value \$	
	1919	1920	1919	1920
	Ounces	Ounces		
Gold . . . . .	98,188	142,840	2,026,536	2,953,036
Silver . . . . .	3,105,002	2,280,665	3,152,700	2,954,695
Platinum metals . . . . .		100		7,172
	Lbs.	Lbs.		
Copper, blister . . . . .	1,724,631	1,508,014	270,493	242,630
	Tons	Tons		
Copper in matte exported (*) . . . . .	2,674	1,976	588,280	553,280
Nickel in matte exported (*) . . . . .	5,610	4,571	2,692,800	2,285,500
Iron ore exported, short . . . . .	4,840	44	41,118	322
Iron, pig (†) . . . . .	14,170	13,428	399,963	344,241
	Lbs.	Lbs.		
Cobalt, metallic . . . . .	13,594	46,479	20,889	108,430
Cobalt oxide . . . . .	127,954	213,024	186,036	340,232
Nickel oxide . . . . .	5,070	1,788,183	1,421	413,944
Nickel, metallic . . . . .	1,830,569	2,159,316	756,062	753,169
Other Nickel Compounds . . . . .	33,716	159,183	5,804	15,308
Other Cobalt Compounds . . . . .	14,189	1,417	9,827	1,417
Lead, pig . . . . .	567,716	509,075	34,684	48,278
Total . . . . .			10,186,613	11,021,654

\* Copper in matte was valued at 11 cents and nickel at 24 cents per pound in 1919. For 1920 the values have been placed at 14 and 25 cents per pound respectively. The total matte produced contained 7,038 tons of nickel and 3,631 tons of copper.

† Total output of pig iron was 152,022 tons worth \$3,897,211. Figures in the table represent proportional product from Ontario ore.

**SAVING THE PRECIOUS METALS**

It is now announced by the Ontario Bureau of Mines that gold, silver, platinum, palladium, rhodium, ruthenium, osium and iridium were recovered at the Port Colborne nickel refinery, where Sudbury mattes are refined. The amounts recovered were probably small and are not given separately. The announcement is an interesting one, as it is regarded as highly desirable that the production of these metals in Canada should have been undertaken long ago. The metals of the platinum group are very valuable and the sources of supply are few. The Sudbury nickel-copper ores have long been known to carry small quantities of these precious metals and their recovery is regarded as one of the advantages of the process adopted by the British America Nickel Corporation for refining ores from Sudbury properties.—R. E.H.

# Conveying Systems

JOHN S. WATTS, New Glasgow.

Of late years, there has been developed, and placed on the market, such a large variety of conveying apparatus, of so many different types, that it is now possible to purchase a type of conveyor to suit almost any conceivable conveying problem, with almost as much simplicity as the purchase of such standard products as a lathe or planer.

The manufacture and design of conveying equipment has reached the stage where these machines are made practically as standard lines, with the excellence of design which naturally follows from continuous experience in their manufacture and operation.

This is a distinct step forward from the older practice, when every conveyor was considered as a special problem to be solved only by the operating companies' engineers, who would naturally have less experience than that of the engineering staff of a company regularly manufacturing conveyors.

The operating companies' engineers, however, still have, and must continue to have, the final responsibility of deciding which of the numerous types of conveyors will best fill their requirements.

To decide this question intelligently, requires a knowledge of the characteristics of all the various types of apparatus, a knowledge which is not possessed by the average engineer, and it is in the hope that it will be of some assistance to engineers in deciding on the right kind of conveyor, that this article has been written.

The conveying problems may be divided into two broad classes, namely, those in which the receiving point, and delivery point are not in any fixed position, and those cases in which the receiving and delivery points are fixed.

In describing the various designs of conveyors that are used, under the conditions specified, it will be understood that no reference is made to what may be considered as standard equipment that is universally known and used, such as overhead travelling cranes, man or horse-propelled trucks, wheel barrows and the like. Not that these do not require study, and are sometimes the right solution to a conveying problem, but that the intended function of this article is to give a comprehensive list of the available, but less well known and more modern conveyors, with the limitations of each type.

Taking up the first-named class of conveying problem, the requirements may be stated in general terms, as being the moving of material from any point anywhere within a certain area to any other point, which may be anywhere within the same or another given area.

If the material to be moved, consists of a large number of comparatively light parts, which can be conveniently placed in boxes or trays, after being operated upon, and are to be moved to another point in the same shop, over a reasonably smooth floor, the transporting elevating trucks, which can be pushed under the loaded box, and the load then raised by the truck a few inches clear of the floor, are the best type. These transveyors or elevating trucks are now sufficiently well known to need no further description.

When the parts to be moved are single heavy pieces, but the other conditions are as outlined in the last paragraph, the best solution is to use a portable crane, similar to that shown in Figure 1. This, of course, assuming that an overhead travelling crane is not available, or already has more work than it can handle.

If the floor of the shop is not smooth enough to allow the transveyor or portable crane to be hauled over it with a reasonable effort, or if the floor space is too confined, or if the material has to be conveyed some distance, as into another shop, the overhead trolley will best fill the conditions. An example of this type is shown in Figure 2.

While the receiving and delivery positions, are, with this last apparatus, confined to points under the line of the overhead beams, by fitting switches and junc-

Fig. 1.

tions, in a manner similar to those used on a railway track, this system can be made to serve a large area at a reasonably low expense.

Outside of the older methods of handling material, such as trucks or cars, hauled by men or horses, electric or gasoline tractors, the above mentioned systems of conveying, represent the choice of apparatus we have, and knowing the conditions, there need be no trouble in deciding upon the right one.

The second class, where the delivery and receiving points are fixed, introduce a much greater range and variety of conditions, of material to be handled, and of equipment that may be used.

This class can be further sub-divided, in accordance with the general direction in which the material is to be conveyed, namely:

1. Vertically upward.
2. On an incline upward.
3. Horizontally.
4. On an incline downward.
5. A combination of any or all of the above directions.

Taking these sub-divisions in their numerical order, we have:—

**1—Conveying Vertically Upward.**

The available methods are:

The lift or elevator, operated by air, hydraulic, steam or electric power. These are used, when the material is in large heavy pieces, or varies in bulk and shape. The power to be used will be necessarily decided by what power is available.

The chain elevator fitted with buckets, arms or other attachments, suitable for the material. For light material, a belt is sometimes substituted for the chain, the buckets being fastened to the belt.

The choice of equipment for cases under this sub-division is practically decided by the class of material to be handled, and the problem should present little difficulty to the engineer.

Fig. 2.

The next subdivision presents a more varied combination of conditions, and is:

**2—Conveying on an Incline Upwards.**

This may be subdivided further into—

2a—Conveying up an incline of 20° or more, from the horizontal;

2b—Conveying up an incline of less than 20° from the horizontal.

**2a—Inclines of 20° or More.**

We are compelled to use either a bucket or chain elevator, similar to those described under sub-section 1. If the grade is not too steep, the chains may be fitted with flights or scraper plates, which drag the material along a trough of steel or wood but these can only be used for comparatively fine and light material.

If the material be very light, such as sawdust, tan bark, etc. and the distance not too great a very simple type of conveyor can be used made of a wire rope with circular discs of cast iron, clamped on it at intervals, and working in a semi-circular trough.

For very long distances, a cableway must be used with a carriage travelling on the cable, and hauled up by a hoisting engine at one end.

For slopes of 20° or over those conveyors having a flat conveying surface, such as steel plate or belt conveyors, cannot be used, because the material would slide backward.

The type of conveyor to be used must be decided to suit the material to be handled. Heavy material in lumps will be best conveyed by the bucket elevator. For barrels or packages use a chain elevator fitted with the proper attachments for carrying that shape of package that is to be elevated. Light material in small pieces can be elevated by the chain with scraper flights in a trough. Heavy materials to be transported a long distance, require a cable conveyor.

**2b—Inclines of Less than 20°.**

Under these conditions, we have the choice of all of the types described under section 2a, and in addition we have the following:

For moderately light material, we can use the rubber belt conveyor, but the material must be such that it can be delivered onto the belt without cutting or abrading it, and the weight must be low enough, not to sag the belt too much between the roller supports. Hard material must be delivered onto the belt at about the same speed, and in the same direction, as that in which the belt is travelling.

For heavy or hot material which would damage a rubber belt, we must use a steel plate or pan conveyor.

**3—Horizontal Conveyors.**

For horizontal conveying, we can use any of the types outlined in the previous sections, the choice depending on the class of material to be handled, and the quantity to be conveyed in a given time.

Where a large output of heavy material is to be conveyed a distance of not over about five hundred feet the bucket type of conveyor is the best. The buckets can be made of large capacity, holding a ton or more if necessary, and deliveries of one thousand tons per hour are being handled by this type with excellent results in low cost. This type can be run outdoors exposed to severe climatic conditions without detriment.

For smaller outputs of any kind of material that is not sticky and for any reasonable distance, the vibrating conveyor is most suitable, being simple and rugged in construction. This type consists, in general, of a steel trough mounted on wooden legs set at a slight angle. The trough is given a vibrating, or to and fro, motion by a crank shaft. The general idea can be seen from Figure 3.

Some makers use rollers to carry the trough and cause the material to travel along the trough, by giving the trough a quick forward and slow return movement, by means of a link motion actuated by the crank shaft.

This type of conveyor is not as well known on this continent as it deserve to be, but is much used in Europe, and for rough hard work is a machine that will

give little or no trouble. It will elevate material up a slight grade about 2 per cent being the maximum, but depending upon the difference between the coefficient of friction of the material, at rest and in motion.

This difference between the friction at rest, and in motion, is the basis upon which the machine depends to perform its function. The trough itself only vibrates backward and forward a few inches, while the material travels along the trough at a practically uniform speed.

When the material requires to be examined, and rock or other debris picked out, the bucket conveyor is eliminated from consideration, and a vibrating or a flat plate conveyor of either steel or rubber must be used.

For fine material of a gritty nature, to be conveyed a short distance, a screw conveyor such as that shown in Figure 4, makes an easily arranged system.

Fig. 4.

#### 4.—Conveying Downwards

When the material is to be transported on a downward inclination, we have the choice of all of the types already described, and also some others, descriptions of which follow.

Where the downward grade is at an angle of not less than about 35 degrees from the horizontal, depending upon the coefficient of friction of the material, all that is needed is a chute to guide the material. The force of gravity will cause the material to slide down the chute to its destination. The chute can be made straight, curved or spiral, or any shape required to join the delivery point to the receiving point, so long as the grade is not less than that needed to cause the material to slide.

If it is impossible to get an inclination of 35 degrees, the material will not slide, but one of the types of gravity conveyors can be used. These are made with sides, like a chute, but the bottom is made of rollers, which can be made of any shape or size to suit the material to be handled. The material must be nearly uniform in cross section, and must be long enough to span over at least three rollers.

When the inclination is not less than ten degrees from the horizontal, and the material such that it cannot be handled by a roller gravity conveyor, a shaking chute will deliver the material.

This is simply an ordinary chute, suspended by eyebolts, and given a shaking movement, backward and forward in the same direction as the flow of the material, of some four or five inches, by eccentrics driven by a revolving shaft running at fifty to ninety revolutions per minute, depending upon the inclination of the chute, and the friction of the material on the chute bottom.

If the material will float in water, or is fine enough to be carried in suspension by a current of water, the hydraulic flume may be a simple solution. This is merely a stream of water carried in a wooden trough, and where ample water is available provides a cheap method for the disposal of ashes.

#### A Unique System of Ash Disposal.

A very economical method of ash disposal is in vogue at the Wabana Iron Mine at Bell Island, Newfoundland. This island is situated in Conception Bay, and the bay is frozen over every winter.

The power house is situated on a wharf at the water's edge, and the wharf is equipped with a coal handling tower, which has a crane on it, handling a grab bucket, by means of which the coal is unloaded from steamers in the summer season.

In the Winter, the ashes are allowed to accumulate on the wharf until the ice commences to break up and drift out to sea. When this occurs there is a continuous procession of large ice cakes passing the wharf for some days, and as each cake passes the wharf, the grab bucket picks up a load of ashes and deposits it on an ice cake, which the ice carries out to deep water before it melts.

In any of the above types, the loading point can be placed anywhere on the line of the conveyor. The delivery point on the large bucket conveyor, is of necessity at the end of the conveyor.

The smaller bucket conveyors can be arranged to deliver at any point, in a horizontal part of the conveyor, by having a moveable tripper, which will upset the bucket at any desired point.

The rubber belt conveyors can also deliver at any point in their length, by the use of a moveable tripper, which is, however, a rather expensive and complicated piece of mechanism.

The flat plate steel conveyors, can only deliver at the end of the conveyor.

The chain conveyors, and vibrating conveyors, can deliver at any point in their line, by having gates fitted in the bottom of the trough at the desired delivery points.

The vibrating conveyor has the further advantage that by using perforated plates in the trough, it can deliver various sized products at various points.

#### 5—Conveying in both vertical and horizontal directions or any combination of indications.

This division requires further subdivision, as follows:—

5a—Where the centre line of the conveyor is always in the same plane.

5—Where the direction of the flow may be changed sideways, as well as changing in inclination.

##### 5a.

This constitutes the cases where the material has to be conveyed at varied inclinations, but in plain view the centre line of the conveyor will be a straight line.

With limitations depending upon the inclination, all of the conveyors described in the previous sections can be used, if the conditions specified in the other sections are not violated.

The steel plate type of conveyor would require a separate conveyor for each change of direction. That is, we could arrange a conveyor running up one incline, and delivering its material to another conveyor running on a different incline. The other types can change their direction without difficulty in one plane.

## 5b.

As in section 5a, all the types will fulfil this condition more or less easily, but require as a general thing, a complete conveyor for each change of direction that is not in the plane passing through the centre line of the conveyor.

However, there are a few types which can accomplish the conveying of materials in a tortuous direction, more simply if the conditions are favorable.

For heavy material, over long distances, the cableway is the most flexible apparatus.

For light material, such as shavings, sawdust, etc., a blower, will blow this material through piping in the most contorted construction, given pressure and capacity sufficient but is limited somewhat as to distance.

For conveying small parcels, in any direction, a lead pipe is used, of about 3 inches diameter, with a circular carrier made to fit it, and having a felt disc to make it airtight. This carrier is forced through the pipe by air pressure of about ten pounds, or sometimes a vacuum is used of the same amount. The carrier will convey anything that can be placed in it, and will travel around a radius of as small as twelve feet.

#### RECENT PUBLICATIONS OF THE GEOLOGICAL SURVEY.

The Survey has recently distributed an unusually numerous and useful series of maps and bulletins. In addition to the Stellarton, Nova Scotia, sheet and the Sandon sheet, previously noted, the following have been received by the "Journal":

**Blairmore, Alberta:**—A contoured topographical map, geologically colored of the district around Blairmore, including the colliery towns of Bellevue, Hillcrest, Blairmore, Coleman, Carbondale and Lille, and showing the mines of the following companies, namely, McGillivray Creek Coal and Coke Co., International Coal and Coke Co., West Canadian Collieries, Franco-Canadian Collieries, Hillcrest Collieries, Maple Leaf Coal Co., Leitch Collieries, and Burmis Coal Co. Seventeen sections are shown of the geological structure across the three parallel mountain ridges which are the features of this district. The map is a very interesting one. Geological work was done by W. W. Leach in 1911-12 and B. Rose in 1915. Topography by W. H. Boyd and B. R. MacKay. Scale is one mile to the inch. Publication No. 1584.

**Buckingham, Hull and Labelle Counties, Quebec:**—A map coloured geologically showing the vicinity of Buckingham, Que. An explanatory note states that the various rock types in this district are so intimately intermingled that uninterrupted areas of the same rock, even a few hundred square feet in extent, are uncommon. The colour scheme of the map is most involved, and it is a most creditable production. Geological work was done by M. E. Wilson in 1913-1915, and the geographical details are compiled by J. O. Fortin from various official sources. Publication No. 1691. Scale one mile to the inch.

**Geology of Matachewan District, Northern Ontario:**—By H. C. Cooke, Publication No 178, Memoir No. 115. Accompanied by geological map. Scale one mile to the inch. Although this Report is devoted to the geology of the Matachewan District, following the traditional and laudable custom of the Canadian Geological Survey, it is prefaced by historical information, and by a description of the fauna and flora and the general phisiological character of the district. Some

of the most far-sighted and discriminating remarks in Canadian literature are to be found in the records of the Survey, and it is pleasing to observe that the admirable tradition of the founders of the Survey is maintained.

The geological description is too extensive and detailed to admit of condensed review, but Mr. Cooke's summarized conclusions as to the origin of the ore-bodies are as follows:—

"The internal structure of the ore-bodies, consisting of a pegmatite vein at the centre, a middle zone of mineralized and altered rock, on each side, and an outer zone of altered rock without mineralization, which grades into unaltered country rock with irregular and embayed contacts, is clear evidence that the deposits in schist have been formed by the alteration and mineralization of the country rock by solutions coming up along the central vein. The partial calcitization of the feldspar of the pegmatite indicates a change in the character of the solutions during the formation of the ore-bodies.

The serial composition of the various veins of pegmatite, varying from veins of pure quartz up through pegmatites of increasing feldspar content, to dykes of pure porphyry, indicates an igneous origin for all.

The satellitic arrangement of the veins, in that with few exceptions they are grouped within an area bounded by a line drawn about 1,000 feet from the edge of the porphyry mass, with the major number within 500 feet, points conclusively to their genetic connection with the porphyry intrusive.

Veins or dykes approaching the porphyry in composition deposited little or no gold, but did in places deposit pyrite. They had no strong alterative action on the wall rocks. Pegmatites deposited auriferous pyrite, and had a powerful alterative action on the wall rocks. Quartz veins had little action on the wall rocks, and deposited little or no pyrite. Other things being equal a rough proportion exists between the size of the vein and the size of the altered zone around it.

It is concluded, therefore, that the schist ores of Matachewan district were deposited by juvenile solutions originating as the last products of the differentiation of masses of intrusive granite porphyry. The solutions were at first rich in silica, soda, and alumina, which crystallized out first to form the material of pegmatite veins. The separation of these constituents left the solutions relatively enriched in lime, carbon dioxide, iron, sulphur, potash, and gold, and their reactions with the wall rocks caused the formation of replacement deposits whose principal minerals are calcite and auriferous pyrite.

There is little direct evidence to connect the gold of the Davidson property with the porphyry, except the fact that the veins are confined within the intrusive mass. However, the proof that the neighbouring stock, which is petrographically identical with the Davidson porphyry, carried gold, renders the conclusion inevitable that the gold of the Davidson property was also a magmatic constituent. The differentiation has here continued uninterruptedly to the stage in which the mineral constituents of the magmatic solutions are silica and gold, and these are deposited as quartz with native gold."

The Report notes the occurrence of asbestos at Rahn Lake in the western part of Bannockburn Township. Specimens were submitted to Mr. Harvie of the Survey, who pronounced them of first quality, but not so good as the best Black Lake asbestos. The Report

states that should development prove a sufficient supply at Rahn Lake to make mining profitable, only improved facilities of transportation will be necessary to make this field economically valuable.

Small deposits of fluorspar, barite and hematite are referred to, which were not seen by Mr. Cooke, who copies the references made to these occurrences in the report by A. G. Burrows.

**Geology and Ore Deposits of Ainsworth Mining Camp, British Columbia.** By S. J. Schofield. No. 1773. Memoir 117. Accompanied by twelve coloured maps in pocket, which include topographical and geological maps of Ainsworth District, diagram of mineral claims in districts, and a number of diagrams showing the geology of selected mining operations.

The deposits of economic importance in this camp are entirely silver-lead ores. Previous to 1914 the zinc which was associated with the silver and lead in the primary deposits was worthless or detrimental to the ores, but owing to the increase in the value of zinc

and the erection of a smelter at Trail for its recovery, its presence now adds to the value of the deposits at Ainsworth.

Prospects for the continuance of mining in the Ainsworth district are considered to be good. The success of the Highland in proving that the ore bodies extend at least to 700 ft. below the outcrop in the case of veins of the true fissure type, and the occurrence of the replacement deposits in limestone 350 ft. vertically below the outcrop in the Florence mine, augur well for deeper mining, especially as, so far as can be determined, the tenor of the ore does not appreciably decrease at depth. A study of the various mines has been shown that the ore-bodies so far discovered have three well-defined modes of occurrence and in the future economic development of these deposits it is recommended that this fact should be kept in mind, and should govern the methods of exploration of the veins. The Report deals fully with these differing modes of occurrence.

Mr. W. R. WILSON, recently appointed President of the Crow's Nest Pass Coal Co., Fernie.

**REPORT OF DOMINION STEEL CORPORATION FOR 1919.**

The Report of the Dominion Steel Corporation shows production during the fiscal years 1918 and 1919 as follows:

	1918. Tons.	1919. Tons.
Pig iron . . . . .	307,863	184,229
Steel ingots . . . . .	341,603	219,943
Blooms and billets . . . . .	47,890	26,165
Standard rails . . . . .	164,972	28,976
Light rails . . . . .	.....	3,319
Wire rods . . . . .	26,746	44,436
Bars . . . . .	1,459	1,245
Wire (includes used in making rails) . . . . .	6,043	15,542
Nails . . . . .	5,508	12,386
Plates . . . . .	.....	3,252
Coal . . . . .	3,622,644	3,502,069

The Report states with reference to production:

"Although every possible effort was made by your directors and the officers of the Dominion Coal Company to maintain the output of the collieries, it was somewhat less than that of last year. The total production from all collieries for the past five years was as follows:

Year ending 31st March, 1920, 3,502,069 tons; March 1919 3,622,644 tons; March 1918, 3,781,615 tons; March 1917, 4,279,772 tons; March 1916, 5,261,198 tons.

"On account of trade conditions operation of the steel company's works was greatly restricted during the months of August, September, October and November, and in consequence the year's output of steel was correspondingly reduced. During the last quarter of the fiscal year operations were gradually increased and are now upon a more satisfactory basis.

"It will be noted that a new item has been added to the list of materials produced and that steel plates are now being made in quantity."

The net addition to value of properties during the year amounted to \$4,329,043, principally represented by the erection of the plate mill, additional electric power equipment at Sydney plant and at the Wabana mines, and improvements to the collieries and power systems of the collieries in Cape Breton and at Springhill.

The profit and loss account for the fiscal years ending March 31st compare as follows:

	1919	1918.	1917.
Op. income. . . . .	\$5,532,529	\$8,768,054	\$11,030,112
Depreciation, etc..	1,266,856	1,304,323	1,384,242
Balance . . . . .	\$4,265,673	\$7,463,731	\$9,645,870
Interest . . . . .	1,004,060	1,013,263	1,064,209
Net income . . . . .	\$3,261,613	\$6,450,468	\$8,581,661
Pref. dividends . .	420,000	420,000	420,000
Do. other Co.'s . . .	560,000	560,000	560,000
Net profits . . . . .	\$2,281,613	\$5,470,468	\$7,601,661
Com. dividends . .	2,029,629	1,765,373	1,444,397
Surplus . . . . .	\$ 251,984	\$3,705,095	\$6,157,264
Prev. surplus . . .	7,959,252	13,754,157	7,596,893

T'l surplus . . . . .	\$8,211,230	\$17,459,252	\$13,754,151
Reserves . . . . .	.....	9,500,000	.....
P. & L. balance..	\$8,211,236	\$7,959,252	\$13,754,157

The common stock shows an increase from \$32,097,700 in 1918 to \$37,100,000 in 1919, and the balance available for common stock dividends amounted to 7.1 per cent on the old capitalization, and 6.15 per cent on the increased common stock liability, the six per cent dividend being earned by a narrow margin.

Reference is made to the sale of 50,000 shares of common stock to British interests, as follows:—"During the year an offer was made by a syndicate of British capitalists to purchase on favorable terms 50,000 ordinary shares of the capital stock of the corporation which had been allotted to the Dominion Iron and Steel Company, Limited, which the directors of that company considered advisable to accept. The proceeds of this sale will furnish a part of the funds required to cover expenditures on its property undertaken and in prospect. The instalments payable under the agreement providing for this new capital have been received; the balance is included in accounts receivable under the heading of current and working assets. The discount on these shares has been written off general reserve, reducing the balance in this account to \$10,000,000."

In connection with the mooted entrance of Dominion Steel Corporation into a holding company incorporated in Nova Scotia as "British Empire Steel Corporation," the President, Mr. Roy M. Wolvin, states: "Your directors are carefully considering the proposals, and if they are approved, will submit them for your consideration at a special meeting to be called for the purpose."

The Balance Sheet for 1918 and 1919 compares as follows:

	1919.	1918.
<i>Assets:</i>		
Properties . . . . .	\$79,861,902	\$75,509,711
Trustees account . . . . .	145,752	142,432
<i>Current:</i>		
Inventories . . . . .	9,490,369	9,314,602
Accounts receivable . . . . .	6,737,807	5,039,479
Cash . . . . .	1,674,668	3,603,542
Prepayments . . . . .	.....	585,812
Interest, etc. . . . .	.....	1,715,034
Sale of common stock . . . . .	1,732,530	.....
Employes' Balances . . . . .	196,155	.....
Investments . . . . .	2,222,037	.....
Total current . . . . .	\$22,053,566	\$20,258,469
Total assets . . . . .	\$102,645,205	\$95,910,612
<i>Liabilities:</i>		
Funded Debt . . . . .	\$20,450,683	\$20,830,097
Reserves . . . . .	2,074,449	2,656,742
Pref. Stock . . . . .	7,000,000	7,000,000
Do. other companies . . . . .	8,000,000	8,000,000
Common stock . . . . .	37,100,000	32,097,700
Special reserves . . . . .	.....	11,500,000
Common stock . . . . .	37,100,000	32,097,700
Deferred payments . . . . .	208,000	234,000
Surplus . . . . .	8,211,237	7,959,252
*Gen. Reserve . . . . .	10,000,000	.....

<i>Current:</i>		
Accounts payable . . . . .	3,881,634	4,827,930
Accruals . . . . .	230,378	235,925
Bank loans, etc. . . . .	4,844,860	.....
Dividends payable . . . . .	643,966	568,966
	<hr/>	<hr/>
Total current . . . . .	\$9,600,837	\$5,632,821
	<hr/>	<hr/>
Total liabilities . . . . .	\$102,645,205	\$95,910,612

\* After deducting difference between par and proceeds of 50,000 shares of corporation common stock.

## ALBERTA MINERS OBTAIN LARGE WAGE INCREASE

An agreement has been arrived at between the coal operators of Alberta and the representatives of the United Mine Workers of America, whereby a 27 per cent increase will be given to all day men over October scale, to be retroactive to April 1. This increase includes a preliminary 14 per cent increase given last January. The contract men will get 24 cents a ton increase on the war bonus of 92 cents. This is seven per cent more than has been awarded in the United States central competitive field.

The agreement is to be submitted to a vote of the miners.

## Our Northern Ontario Letter

### THE SILVER MINES.

Great interest has centered during the past week about the trend of quotations for silver, the recent decline in price having apparently been quite contrary to the generally accepted opinion. In view of the calculations of many careful observers having proved to be quite unsound as shown during the past week, there is now a tendency to become reticent over the situation and to abide strictly by the verdict of events and time. Seemingly, however, when quotations during the second week in June declined to 81 cents an ounce and then fluctuated upward above 90 cents, the recession in price may have gone its full course, and steadier quotations may now rule.

Taking into account the amount of cobalt metallics and cobalt oxide produced by the silver mines of Cobalt during the first quarter of 1920, the silver mines of Ontario produced \$3,404,774 for the period as compared with \$3,369,452 during the corresponding period of 1919, thus showing an increase of \$35,322. The quarterly statement just issued by the Ontario Bureau of Mines shows a decline of \$198,005 in silver production for the quarter as compared with a year ago, and in that way leaves the impression that the value of the output from the silver mines decline that amount. An analysis of the report, however, brings out the fact of the increase.

It is learned in reliable quarters that the Ontario Bureau will conduct a resurvey of the geology of the Cobalt silver area, and that Cyril W. Knight, Assistant Provincial Geologist, will commence the important work at an early date. The decision appears to be the direct result of representation made by the Temiskaming Mine Managers' Association to Premier Drury, and to the Minister of Mines, Hon. Harry Mills, on the occasion of their visit to Cobalt last fall. This resurvey has long since been regarded as advisable, owing to the large amount of underground work done since the previous report was made, now making it possible to study the geology with greater accuracy and to present a report that will prove of value to the mines.

In order to combat the lower quotations for silver provided they should continue downward, the mines of Cobalt will reduce the amount of low grade ore being treated, and in that way by increasing the number of ounces in the ore handled will produce an equal value per ton as though silver had remained high. This will mean of course, a reduction in tonnage and lessened production at the lower-grade mines. Contrary to the pessimistic views expressed in certain newspapers,

the moderate producers will not be placed in peril, while the chief producers are still able to produce at a cost not far under fifty per cent of the gross yield. The standing of the camp is exceptionally strong, even in the light of present low prices for the metal.

Announcement is made that the Mining Corporation of Canada has become interested in the exploration and development of the Flin-Flon property in Northern Manitoba. At the annual meeting of the Mining Corporation, the following directors were elected:— 1st Vice-President; W. R. P. Parker, 2nd Vice-President; G. M. Clark, J. W. Watson, Thomas Plunkett and D'Arcy Weatherbe, directors.

Arrangements are being made to operate the old Colonial Mine, situated in the mineralized silver area of Cobalt, but which has been idle for some years. The Colonial adjoins the O'Brien Mine as well as the Violet property of the La Rose Consolidated. The rock formation consists of keewatin overlying diabase and with numerous veins opened up. Underground work formerly carried on resulted in considerable medium-grade ore being placed in sight. Some high-grade shoots more or less limited in extent were also encountered. A peculiar fact in connection with the property is that repeated bids have been made for it, but have all been refused, and that despite the property lying in idleness it has been regarded as a potential mine and one that may reasonably develop into a steady and important shipper. Tenders are being called for several hundred feet of underground work.

For the first five months of this year, the Nipissing mine has produced \$1,837,118, according to regular statements. The report for May, just issued by Hugh Park, manager, to the president and directors shows an output of \$335,597 for the 30-day period.

In summarizing the work during May, Mr. Park states:—

"During the month of May the company mined ore of an estimated value of \$335,597, allowing 99¼ cents per ounce of silver. Shipments of bullion and residue from Nipissing and custom ores are estimated to have a net value of \$405,746.

"Favorable developments were met with at the first and second levels of 63 shaft. Several new veins are being developed and results to date have been satisfactory. In all cases the veins are small but of good assay. The mill rock is of good grade. The distance between levels is 95 feet.

"Stopping operations and general development work at all shafts continue to be favorable during the month.

The usual amount of development is proceeding."

"Burrowite," a new explosive, is being tried out at some of the Cobalt mines, and is stated to have stood up well under careful tests. It is stated that provided sufficient encouragement is offered, arrangements will be made to manufacture Burrowite in the Cobalt district. Not only is the new explosive said to be non-freezing, but to produce less gas than some of the brands now in use.

Encouraging results are reported from the Bonsall property in the Gowganda district where a small mining plant is in operation and where work is being carried on between a depth of 100 and 150 feet. The Bonsall is controlled by Senator M. J. O'Brien, Sir Clifford Sifton and Mr. Glendenning.

Announcement is made to the "Journal" that work has just been resumed on the White Reserve mine in the Maple Mountain section of the Eelk Lake district. It is stated that work will be concentrated on the new rich vein opened up at surface last Autumn, just prior to being compelled to close through labor shortage.

In various parts of the Elk Lake and Gowganda districts, numerous bush fires are reported and at the time of writing rain is badly needed to prevent an enormous loss of timber, as well as restriction of prospecting activity in some parts of these districts.

**Ore and Bullion Shipments**

During the week ended June 11th, four Cobalt companies shipped an aggregate of seven cars containing half a million pounds of ore. The Nipissing with four cars was the heaviest shipper as shown in the following summary:—

Shippers	Cars	Pds.
Nipissing . . . . .	4	348,612
La Rose . . . . .	1	65,992
Mining Corporation . . . . .	1	65,070
Dominion Reduction . . . . .	1	60,000
<b>Totals . . . . .</b>	<b>7</b>	<b>539,581</b>

Bullion shipments during the week consisted of one quite large consignment from the Mining Corporation, 99 bars containing 100,333 fine ounces being sent out on June 10th.

**THE GOLD MINES.**

Gold mining in Ontario promises to attain a point actually in excess of silver mining by the end of the current year. The production of gold for the first quarter of 1920 showed an increase of 46 per cent over the corresponding period of 1919, and at a rate of close to a million dollars a month. This exceeds any previous record in the history of mining in the province and seems to offer conclusive proof of the strong physical condition of the mines.

Producing gold mines report a total capacity of 5,485 tons daily. Running at full capacity and recovering an average of \$9 a ton; the output would amount to more than \$18,000,000 annually. The present rate amounts to about two-thirds capacity, the only barrier to maximum output being the acute shortage of labor. The situation is one of great promise.

On June 16th the Hollinger will disburse a dividend of one per cent. the amount to be distributed being \$246,000. This is the third dividend of like amount to be paid this year.

At a depth of 140 feet on the Porcupine-Keora a vein measuring some ten feet in width has been encountered and, although average assays have not yet been announced, it is understood the vein matter shows

quite heavy mineralization. The development is regarded as the future of that part of the Porcupine districts hinges to an important degree on the measure of success achieved at the Keora. Former exploration work with diamond drills indicated the presence of ore at depth, and the present development program has for its object the confirmation of the earlier results.

The Davidson Consolidated is called for tenders to sink a central shaft to a depth of 1,000 feet, which is taken as an indication that the finances required have been subscribed. It is understood the result if work at depth has been more satisfactory than in the levels lying closer to surface.

The annual report of the Dome Mines is favorable. Although the mill did not resume operations until last May, after the shutdown of the previous year, and, therefore, earnings are really only for ten and two months, the recovery amounted to \$1,773,374, maintenance expenses of \$930,762, leaving net operating earnings of \$842,612, to which is added revenues from other sources, chiefly discount and exchange, amounting in all to \$109,372, making a total net profit of \$951,984. Deductions amounting to \$600,170 were made chiefly for depletion of mining claims and properties, \$325,190, and plant depreciation and replacement, etc., \$234,373, leaving a net surplus for the year of \$351,814. The mines improved financial position is seen in the fact that current assets exceed current liabilities by \$1,253,025 compared with \$488,895 a year ago. Total assets have increased to \$5,909,318, compared with \$5,002,625.

President J. S. Basche, whose comments are of the briefest character, says, "The company had a satisfactory year, in spite of starting it under the handicap of non-productive operation during the first forty days, and having to start the plant on a small tonnage, and increase gradually. As indicated in the report of the operating management, the mine and plant are in first-class condition to enable operations to be continued at a satisfactory profit, but the success of future operations must, to a great extent, depend upon the amount and efficiency of labor obtainable.

In the Kirkland Lake district, wages are being offered to the scale at Porcupine, Sudbury and Cobalt; the object being to induce men to remain at their jobs as well as to encourage others to enter the camp.

During the first quarter of 1920 the mines of Kirkland Lake produced close on a quarter of a million dollars. These mills were in operation, the Lake Shore, Teck-Hughes and Kirkland Lake. A similar performance is expected for the second quarter, while an increase for the third and fourth quarters may be expected. The reason for this is the fact that it is planned to operate the Tough Oakes mill during the third quarter, while, for the fourth quarter, the new mill of the Wright-Hargreaves is expected to be completed and in operation.

From the West Shiningtree district, conservative mining reports, notably by George R. Rogers of the Wasapika tend to expose various blatant reports which formerly circulated. Mr. Rogers presents an excellent report in which he expresses the belief that he can mine the Wasapika, adopting selective mining methods, at a profit, but makes it clear that the recent reports of sensational finds are misleading. The announcement is receiving favorable comment in mining circles in other parts of Northern Ontario.

### WASAPIKA GOLD MINE.

The following statement concerning developments at Wasapika mine has been given out by the president of Wasapika Consolidated Mines, Limited.

"The results obtained in the development of the Wasapika ore deposit by the new company which took over the property a few months ago, has given rise to some stories of sensational nature. It has been reported that ore carrying \$200 in gold per ton has been encountered at the second level. The company wishes to advise its shareholders and the public that the results obtained, do not indicate the presence of any considerable body of ore of such high grade.

"The preliminary sampling underground, as at the surface, indicates that the ore deposit carries enough gold to permit profitable mining, but the venture is still in the early speculative stage, which does not permit positive statements concerning its success.

"In order that the significance of the results obtained recently may be understood, it should be stated here that the underground work has indicated that the Wasapika ore deposit is a much bigger one than it appears to be on the surface. There only the footwall portion is exposed. The work at the 100 ft. level showed an additional hanging wall portion which at surface is hidden under a low wet depression. The footwall quartz at the 100 ft. level showed in the cross-cut ore carrying about \$12 gold per ton. The hanging wall quartz samples showed \$3 to \$11. The intervening schist carries only \$1 or \$2 gold per ton.

"The systematic surface sampling of the footwall quartz had indicated the presence of an orebody carrying \$8 or \$9 per ton. The work at the 100 ft. cross-cut gave the hoped for results with regard to the footwall quartz and also disclosed more quartz that may prove an important source of ore. In may prove profitable to mine the whole deposit, including quartz and schist, for a width of 20 ft.; but the present indications are that the low values in the schist will make selective mining preferable.

"The deposit has recently been cut twice at depths between 160 and 204 ft., and ore of similar character exposed. Here again the deposit shows much quartz in addition to the main footwall portion. The preliminary sampling indicates that the values are holding well with depth.

"The management proposes first to open up the footwall portion of the deposit and to begin mining and milling this ore before attempting to explore thoroughly the hanging wall portion. The alternative method of mining the whole deposit at once would give lower costs per ton, but there would be much dilution by the inclusion of lowgrade schist. When development is further advanced and milling tests are possible, the possibilities of this method can also be investigated."  
—R.E.H.

### MINING CORPORATION'S AFFAIRS

According to the annual report submitted at the annual meeting of the Mining Corporation of Canada held in Toronto on Saturday, June 5th, the profits on the years operations were \$908,000 for what was really only ten months, owing to the strike, compared with \$925,000 in the previous year. The Mining Corporation is an outgrowth of the old Townsite Mine, to which was subsequently added the Cobalt Lake, City of Cobalt, Cobalt Station Ground, Little Nipissing and Buffalo. It was announced that the Corporation is as-

sociated with W. B. Thompson & Co., of New York, on the option of the Flin Flon Mine in northwestern Manitoba. This great copper property is now being explored by the sinking of shafts and doing a number of drifts on the vein, with a view to confirming the diamond drill results which indicated twenty to thirty million tons of copper ore in sight. The option runs until next March, but the development work may justify decisive action before that time. It is estimated that a total capital outlay in connection with the project of \$8,000,000 to \$10,000,000 would be necessary to bring it to a completed stage. The Mining Corporation since its formation has paid dividends amounting to \$5,083,862, exclusive of the current dividend of almost \$250,000 soon to be paid. The former Board of Directors and officer were elected as follows: Sir Henry M. Pellatt, C.V.O., President; J. P. Watson, First Vice-President; W. R. P. Parker, Second Vice-President; G. M. Clark, J. G. Watson, Thomas Plunkett, and D'Arcy Weatherbe.

### THE SILVER MARKET

By R. E. HORE

The continued weakness of the market for silver is disturbing shareholders of silver mining companies. The metal still commands a high price as compared with that of a few years ago, but the higher cost of production and scarcity of high grade ore necessitates a fairly high price for silver. For some weeks, however, the price has been steadily downward and the recent sharp break has directed much attention to the changed position of the silver producers.

There are doubtless good reasons for the weakness of the silver market; but since the chief consumers are in far away countries, and are dealt with through metal brokers, there are few persons here who can give a very satisfactory statement concerning the recent drop or the probable future trend of prices. Metal brokers in London and New York could doubtless make some interesting comments on the situation, for they are in closer touch with the consumers than are many silver producers. Some of our silver producers are nevertheless in close touch with the markets and give to the selling of their product such attention that shareholders may have confidence that good judgement, based on experience in other periods of changing prices, will be exercised in selling Canadian silver.

Aside from the fact that high prices for silver mean large profits for the shareholders and permit high wages for the miners, there is under such conditions an opportunity to market ore that in periods of low prices would be useless. Since most of our silver is exported, higher prices for silver mean greater gain for this country generally and it is in the general interest that there should be no return to the pre war prices.

It may be true that Cobalt has seen its best days and is now showing by its declining production that a large part of the higher grade ore has been mined, nevertheless, if high prices can be obtained for silver, Cobalt will be a producing district for many years. It is well to realize that mining is a liquidating process and that long years of operation are not desirable from the operator's standpoint; but limitations as to mining and milling facilities will make even the mining of the relatively small ore deposits at Cobalt a matter of several years yet.

## British Columbia Letter

### THE METAL MINES.

#### Stewart, B. C.

The Patricia, Magee, and Montana groups of Mineral Claims, situated on the Marmot River, are to be actively developed during the summer. On the Patricia a 4-foot lead of good ore has been opened, samples from which have given returns from \$15 to \$35 in gold and as high as \$62 in silver.

General R. G. Edwards Leckie, who was prominently identified with the Canadian Expeditionary force, having been on foreign service throughout the war, has resumed practice in British Columbia as a mining engineer. In 1910 General Leckie became interested in the Hercules group of mineral claims, Salmon River district. Some development was done and the Crown grant was obtained to the property. No progress was made in opening the claims during the war. General Leckie, however, has now taken up the task of developing, proving, and if warranted putting the property on a producing basis.

J. D. Craig, an engineer in the employ of the Dominion Government, has left for Portland Canal to take charge of the Canadian party, whose duty it will be to co-operate with United States surveyors in the establishment of a clearer definition of the Canadian Alaskan boundary. Stone cairns on the mountains, bronze monuments and a 20-ft. lane through the forest will mark the boundary by the time the party have finished their season's work. Commenting on his task Mr. Craig said: "The wisdom of marking the boundary some sixteen years ago—a marking which has since become more or less obliterated—is now apparent. As it happens about 90 per cent. of the silver recently discovered has been on the Canadian side. If the survey had been delayed it might have made the settlement of the line more difficult to agree upon." A neutral strip of 60 feet on either side of the boundary is to be preserved, as is the custom on the whole 5,000 miles of Alaskan and U. S. boundary, except where titles to the strip had previously passed out of the Government. Mr. Craig does not think this will mean that the strip will be withheld from mineral development, but that in the case of location of mineral special leases will have to be obtained from Ottawa or Washington.

The Prospectors Association of Stewart, recognizing the value of publicity, have arranged for the assemblage and display of an exhibit of the minerals of the district. It is to be quite comprehensive including specimens from all the well known properties of the Portland Canal region, and should be both interesting through the town.

#### Alice Arm, B. C.

The snow is rapidly disappearing in this district and the mining industry is becoming quite active. The Dolly Varden mine again is in full operation and ore shipments are being received at tide water. The La Rose property is to be developed further and a force of men has been put to work. The Moose prospect also is to be opened up and the McLennan Silver Mines Ltd., already have started work on the Royal Group adjoining the Dolly Varden. In the course of the last few weeks a great many miners and prospectors have

arrived and as the snow recedes prospectors and miners will make their way up both the Kitsault and the Illiance Rivers.

#### Kamloops, B. C.

It begins to look as though the Stump Lake Mine of the Donohoe Mines Corporation is to be made productive within a short time. Machinery has been ordered for a modern concentrating plant, the foundations of which are now being constructed. The plant it is hoped will be ready for operation in three or four months at the outside. It will have a capacity of 50 tons a day. The ore of the Donohoe mine is principally silver bearing but carries besides gold, lead and copper, the metal content varying from \$20 to \$600. The property recently was inspected by William J. Shedwick, Jr. of the Kennecott Copper Corporation and Lewis A. Levensaler and Francis N. Myers, all of whom are mining engineers.

#### Nelson, B. C.

The Nelson Mining and Development Company, which is interested in a number of properties, in the Lardeau and Sandon districts, is preparing for considerable development work. The Whitewater and Comstock groups on Cascade Creek, Lardeau, are to be opened up and, to facilitate this, the construction of a nine-mile wagon road is planned. On the Comstock leases there is a good mill site and the erection of a mill is being considered. Some good silver lead showings have been uncovered on the Zincton property near Sandon and, in addition to high grade ore, a considerable quantity of good milling ore has been exposed. Clarence A. Marsh, Secretary of the Company, headquarters Nelson, B. C. also is interested in the Gold Cure mine, situated on the South Fork of Kaslo, and it is his intention to start development here immediately. Ore carrying high silver and lead values already is in evidence and, if the results of further work are satisfactory, the idea is to install a concentration and flotation plant having a capacity of 50 tons a day.

Development work carried on at the Mountain Chief Copper mine, Renata, Arrow Lakes, has demonstrated that the ore body has a depth of 68 feet below the original shaft. There is practically no change in the character of the ore, bornite and Chalcopyrite. It is the intention to explore further along whichever section of the vein appears most attractive.

#### Trail, B. C.

Receipts at the Trail Smelter of the Consolidated Mining and Smelter Company of Canada for the week ending May 31st were 6,832 tons, of which 67 were concentrates. One of the noteworthy independent shippers was the Bluebell of Riondell, which contributed 180 tons, this indicating that this mine, for a time inactive because of lack of water required for the operation of the mine plant, has resumed operation. Other shippers apart from the Company's properties were Electric Point, Boundary, Washington, 196 tons; Florence, Princess Creek, 67 tons; Josie, Rossland, 170 tons; North Star, Kimberley 181 tons; No. 1 Mine, Ains, worth 127 tons; and the Tom O' Shanter, Riondell 56 tons. The Sullivan Mine, Kimberley, evidently is getting back into its normal gait, having shipped 5,367 tons of zinc ore and 296 tons of lead ore during the week. The total amount of ore to be received at the Smelter up to the present this year is 110,928 tons.

**Ymir, B. C.**

The Texas-Yankee-Girl mine at Ymir, recently taken over by the Mining Corporation of Canada, is being systematically explored and developed in accordance with plans laid down by A. W. Newbury, one of the Company's engineers. A force of about forty men is engaged and it is expected it will take six months of this work to obtain the information necessary to determine the Company's future plans.

While dealing with this phase of the operations of the Mining Corporation of Canada in British Columbia, it is interesting to note that that concern has previously tried out a number of Provincial mining properties. One of the first of these was the Lode Gold proposition of Prosperine Mountain near Barkerville, upon which a considerable sum of money was spent without obtaining results considered sufficiently satisfactory to warrant the installation of the necessary plant for the handling and treatment of the quartz. In the Bridge River section options were taken on several small gold mines but as far as can be gathered these too after the investment of some money and development were allowed to drop.

**Vancouver, B. C.**

The retirement of F. M. Sylvester, for years managing director in British Columbia of the Granby Mining and Smelting Co., and the appointment as his successor with the title of General Manager of H. S. Munroe, of New York, has caused somewhat of a stir in provincial mining circles and has given rise to speculation as to whether the changes presage material revision of the Company's operation policy in western Canada. About all that is known regarding Mr. Munroe's intentions is that he proposes making his headquarters at Anyox, which means that the Company's business in this Province will be curtailed there rather than at Vancouver as in the past. Regret is expressed by the press and in many quarters that Mr. Sylvester should be severing his business relations with the Company, it being pointed out that he has been at the helm during a period marked by much notable achievement and expansion. It was under his direction that the Company took up, developed, and installed an exceptionally modern colliery on coal lands of Vancouver Island. He also saw the installation at Anyox of the first by-product cooking ovens of the Canadian West. In this connection it is said that the Island coal has not proved the success in coking that was expected, the ash content being, in the case of some shipments at least, rather embarrassing. In confirmation of this it is known that coal now is being received at the Anyox plant from eastern British Columbia properties and, as far as experiments with it have been able thus far to determine, promises to give satisfaction.

**Victoria, B. C.**

According to well authenticated reports Alder Island, one of the smaller members of the Queen Charlotte Group, consists of one large deposit of metallic arsenic. The two or three claims staked over the entire island and samples taken indiscriminately gives returns running from 18 per cent. to 24 per cent. arsenic while the locator states that it is possible to obtain specimens of almost pure mineral. This is interesting be-

cause it appears to be the first such deposit of which there is record in British Columbia although for years arsenic has been produced as a by-product from the arsenic-pyrite ores of the Hedley Gold Mining Company.

**Grand Forks.**

It is announced that the diamond drilling to be undertaken by the Provincial Government in the Frankline Mining Camp will be initiated on the Gloucester group of mineral claims. Drilling equipment has been installed and the work will commence in a few days. These operations are to be carried on under the supervision of T. B. Freeland, Government mining engineer. It is likely that other properties in this locality will receive similar attention.

At a recent meeting of the Mining Bureau of the Vancouver Board of Trade a number of important resolutions were passed. One recommends that the administration of coal and petroleum lands should be transferred from the Lands to the Department of Mines. Another deprecated the action of the Provincial Legislature in placing a reserve on coal lands in the Province. A third proposes the discouragement of the export of certain classes of mineral in order that their refinement within British Columbia might be brought about.

**Cowichan, B. C.**

The development of the Manganese Deposits of Hill 60, Vancouver Island, is proceeding apace. As work progresses it becomes apparent that a large tonnage is available. Operations have started almost at the summit of the hill and exploration indicates that the ore body extends down for a considerable distance. The aerial tramway, which has been in course of construction for some weeks, is now practically ready for service.

**THE COLLIERIES.**

Almost coincident with the announcement of the retirement of F. M. Sylvester as Managing Director in British Columbia of the Granby Mining & Smelting Co., and the appointment as General Manager of H. S. Munroe, of New York, comes word from Prince Rupert that shipments of coking coal are being received by the company at Anyox from eastern British Columbia. This coal is being tried in the company's by-product ovens, and it is said to be giving satisfaction. It is reported that some of the coal shipped from the Cassidy Collieries, Vancouver Island, has not been the success expected for coking purposes, and that it is proposed trying some from other fields.

An analysis of the latest figures available relative to the coal production of British Columbia shows that, while the output of the mines of the Crow's Nest Pass Field is increasing, that of Vancouver Island Collieries is declining slightly, although not sufficiently for serious comment. This is taken to prove that, notwithstanding general predictions that the shortage of fuel oil would increase the demand for coal, there has been no such result evident up to the present. However, the collieries of Vancouver Island anticipate that the present difficulty in securing adequate supplies of oil will affect their bunker trade. The reports of freight, and passenger vessels being re-converted into coal burners, and of many of those under construc-

# A MARSH HOIST

## IS MADE THE RIGHT SIZE FOR YOUR MINE

and in either Steam Power or Electric Power

This shows one of our Electric Mine Hoists. We make many other types. Send for our catalogue of Mine Hoists, Cars, Cages, Buckets, etc., and see what we offer you. It will repay you.

From the little 10 Horse Power size for prospectors or small mines to the massive 50 Horse Power size, one of our 7 sizes should be just right for your mine.

We are specialists in the building of Hoisting Machinery of all sorts. For nearly a quarter of a century we have been designing and building Hoists, and have developed a Hoist that we are really proud of—proud because of the record of good work they have done, and are doing in mines, quarries, and other classes of work from one end of Canada to the other.

Gardenvale, P.Q.

tion being designed for the use of the latter fuel, are known to be authentic and it is felt that there will be, consequently, an increase in business shortly. Meanwhile the domestic demands have fallen off somewhat and production, as far as the coast mines are concerned, is about stationary. Production in the Crow's Nest Field, on the other hand, is climbing, a good market being found in supplying the Great Northern Ry. Co., by which concern it is used in pulverized form in the operation of the railroad. The greater proportion of the Corbin coal is shipped to Spokane, Wash., a comparative small quantity being taken by the C.P.R. A recent development, the results of which may be of importance, is the shipping of four cars of coal to Winnipeg, Manitoba, by the Crow's Nest Pass Coal Co. This is explained as an emergency shipment arranged for to meet the shortage caused by the lack of coal usually obtained from the United States. It is an indication, however, that Eastern British Columbia and the Province of Alberta may be called on to meet the requirements of the Canadian Middle West to a greater extent in the future than in the past. Coke production in the Crow's Nest still is far below what it once was, the ovens at Fernie being idle and only some of those of Michel in use, the product of which is absorbed by the Canadian Consolidated Mining & Smelting Co., for the Trail Smelter. The coal output for the month of April in the Crow's Nest and Nicola Fields follows:

*Crow's Nest Pass.*

	Tons.
Crow's Nest Pass Coal Co., Coal Creek .....	37,931
Do., Michel .....	21,529
Corbin Coal & Coke Co., Corbin .....	17,713
Total .....	77,173

*Nicola-Princeton.*

Middlesboro Collieries .....	6,220
Fleming Coal Co. ....	2,352
Princeton Coal & Coke Co. ....	1,267
Total .....	9,839

The production of Vancouver Island Collieries for the month of May follows:

*Vancouver Island.*

	Tons.
Canadian Western Fuel Co. ....	52,193
Canadian Collieries (D) Ltd., Comox .....	29,169
Do., South Wellington .....	6,889
Do., Extension .....	14,175
Pacific Coast Coal Co. ....	7,793
Nanoose-Wellington Coal Co. ....	2,251
Granby Mining & Smelting Co., Cassidy .....	15,107
Total .....	127,577

It is possible that the explanation of the action of the Crow's Nest Pass Coal Co.'s shipment to Winnipeg lies in the recent issuance in eastern Canada of a warning circular for the guidance of manufacturers which pointed out that the coal year, starting April 1st, started out with practically no coal reserves, a condition without parallel in the history of the con-

tinents, and advising those users within the area of distribution of the coal fields of the maritime provinces and of Alberta and British Columbia to obtain their supplies locally, thus avoiding the overloading of transportation.

The head office of the Crow's Nest Pass Coal Co., as well as that of two subsidiary companies, the Crow's Nest Pass Electric Light & Power Co., Ltd., and the Morrissey Fernie and Michel Ry., has been transferred from Toronto to Fernie, B.C. W. R. Wilson, General Manager of the company, has been elected to the presidency vice the late Elias Rogers, and A. Klauer, chief accountant for a long term, has been made treasurer.

At the annual meeting of the Rocky Mountain Branch of the Canadian Mining Institute, which was held at Fernie on May 27th, an instructive paper was read by Robert Strachan, Inspector of Mines, on the coalfields of the Crow's Nest Pass. He told of operations from the year 1873 to the present, dwelt on the abnormalities of the formation, and explained some of the methods most useful in overcoming the difficulties and the dangers of extracting coal. W. P. Williams, president of this Branch of the Institute, presided, and Dr. McDonald, Inspector of Mines, Calgary, acted as secretary. There was an address of welcome by Mayor Henderson, of Fernie, B.C., and a speech was delivered by A. I. Fisher, member of the Legislative Assembly, who expressed the opinion that because of the precautionary measures introduced by the Department of Mines, the experiences of the past, always involving interruption of work and loss of production and sometimes causing loss of life, had not been repeated of late. However, the government officials welcomed suggestions, particularly from a practical man, and he recommended that Mr. Strachan's paper be submitted to the Department of Mines. W. R. Wilson, General Manager of the Crow's Nest Pass Coal Co., entertained the delegates at luncheon. Subsequently the mines were inspected.

The Canadian Western Fuel Co.'s (Nanaimo) First Aid and Mine Rescue Assn., held their third annual competition recently for the company's shield. This is confined to novice or first year men and the high grade of the work performed was gratifying both to judges and the discriminating spectators. The winning team for 1920 was as follows: David Simpson (Captain) and Chas. Nicholls, William Thorpe, Robt. Humphries, and Jack Carnelly.

Announcement was made in Vancouver, B.C., of another increase in the retail price of coal. This advance took effect on the 1st of June. It amounts to 50c a ton, which means that lump coal now is selling for \$14 a ton. The Vancouver Coal Dealers' Association assert that the cause of the rise is the increased cost of doing business.

**WANTED.**

**CHEMIST**, with experience in usual Copper Smelter analyses. Must be accurate and rapid on routine work. Graduate Preferred.

## EDITORIAL

### Coal Production in N. S.—Its Bearing on Canada's Fuel Problem

THE coal production of Nova Scotia has recently come into much prominence, and during the month of June a number of significant happenings have been recorded in the newspapers that have brought this long suffering industry to public attention.

A debate took place in the Commons on the general question of national coal supply, which elicited the information that the Government were keeping in close touch with conditions, but left the impression that our parliamentary leaders still look upon the United States as the sheet anchor of coal supply and possess small faith in our domestic resources. In the Senate, the Hon. Smeaton White brought the coal situation before the Government, and brought out the further intimation that the Government would shortly introduce legislation to control the disposal of coal mined in Canada, and that a sub-Committee of the Cabinet, consisting of the Minister of Railways and the Minister of Labor had been appointed to enquire into the whole question of Canada's coal supply "for the coming season." The inability of our national leaders to grasp the great importance of the fuel situation is evidenced by the limitation of the enquiry the Government propose. It provides a firsthand illustration of the hand-to-mouth manner in which our national fuel supply has been dealt with, and the partial view that has been taken upon every successive recrudescence of a question that will persist to the end of time, and will affect the national aims and evolution of Canada as no other question does or will do.

We have studied the coal question in Canada for many years, and the conclusion has been forced upon us that **Canada can not persist as a separate political entity in North America unless Canada becomes self-sustaining as to bituminous coal supply.** If any person can point out a way of escape from this conclusion we shall be extremely glad to hear of it. The conclusion is an uncomfortable one, but it is one that should be faced, and **must be faced** if Canada is to pursue in future years that orderly procession of national growth to which every patriotic citizen looks forward.

THE crisis in fuel supply has not come unheralded. Year after year in the columns of the "Canadian

Mining Journal" its approach has been forecasted. We trust that our readers will forgive the full quotation that is elsewhere given in this issue of a review of the coal production of Nova Scotia during 1918, reiterating similar statements made in 1917 and 1916. A recapitulation of the conditions attendant upon coal production in Nova Scotia at this time would necessitate identical statements, merely emphasised by their greater seriousness and wider application.

The present inadequacy of coal production in Nova Scotia arises from conditions that were categorically listed in 1916, the year when the output capacity of the collieries in Nova Scotia reached the recorded maximum of tonnage. Almost four years have passed since 1916, and in every succeeding winter a so-called "crisis" in fuel supply has taken place, with temporary excitement and temporary remedies having temporary results. The "crisis" of the coming winter may be greater or less according as Nature is kind, and in proportion to the number and extent of railway labor troubles, but Canada's trouble consists in a chronic fuel insufficiency, arising from neglect to develop the coal seams of Nova Scotia as a source of domestic supply.

THE fuel problem has been studied by various bodies and excellent reports have been made thereon, but there has been no concentration of aim or continuity of purpose in our national fuel policy. Perhaps this is because the problem has not been conceived as a national one, in which private enterprise and occasional departmental enquiry can play only a limited part. The Commission of Conservation has done good work in giving publicity to various phases of the question. The meaning of the term "conservation" has been defined by the Commission as applying to the efficient utilization of natural resources, which is a very happy definition in regard to coal supply. The work of the Commission is definitely limited by its lack of executive powers, and it can do nothing more than point out what should be done. The enquiry of the Manufacturers' Association will doubtless bear good fruit, but it can not be implemented by

the vigorous action that the problem demands. The work of the Advisory Council is of the utmost value, but the fullest utilization of carbonized lignites and peat can never amount to more than a palliation of the chronic inadequacy of domestic bituminous coal production in Canada east of Alberta. The functions of the Mines Department consist in assisting the mining industry of Canada in obtaining and recording scientific and statistical observations, but as the Department works upon a limited appropriation, and does not possess executive powers, it cannot direct the actual development of minerals. The functions of temporary government appointees such as the Fuel Controller and the Director of Coal Operations in the West arise out of temporary emergencies connected with war times and with the evolution of organized labor policies during a time of disturbed social conditions, and such government oversight will presumably disappear when the originating causes pass away.

**W**E would suggest, for the consideration of the Government, the creation of a permanent body charged with oversight of the fuel supply of Canada. This body should either be vested with executive powers, or its recommendations should be made the basis of legislation by the usual processes. The suggestion which is here made of what would practically amount to a Ministry of Fuel Supply is admittedly novel, and possibly has no peace-time precedent, but it is submitted in support of the suggestion that Canada's fuel problem has no precedent.

We do not believe that there is any question in Canada that approaches in gravity, or in its bearing on national life, the problem of a fuel supply within our frontiers. Put in another phrasing, the development of our coal resources is necessary to Canada's continuance as a nation, either within the British Empire or without that confederation of nations. We do not state that a development of the coal beds of Canada is essential to the wealth, the personal safety, or the culture of the population of that territorial entity known as Canada, because it is quite possible that all these things may be equally secured by those who may reside in that territory in the future should one political government only remain in North America. Our descendants cannot resist absorption into the United States at some future time if we rely on the United States for coal supply in preference to mining coal at home. No modern nation can persist that does not possess its own bituminous coal supply, except, as in the case of some small European nations, by the consent and the opposed national policies of surrounding nations—in other words, on sufferance. The non-development of our coal resources is precisely equivalent to our non-possession of such resources, and will have precisely the same consequences.

The functions of a Fuel Ministry would be, in certain respects, identical with the functions of a Committee of National Defence,

**I**N the recent parliamentary debate the Government was able to produce figures showing that it had been able to maintain importations of United States coal at as high a rate as in the corresponding period of last year, but no mention was made of any policy leading to an increase in Canadian coal production, and it is this implied resignation to a position of dependence in coal supply that is so discouraging to those who know that Canada can become self-supporting, if she wills to be so.

The road to fuel independence is not a royal one in Canada. Increase in coal production is only possible by large expenditures in development and by a large increase in the numbers of the coal-mining population. These things take time and thought, and what is planned today cannot bear fruit for years, and may be for decades. As an instance of popular misconception, a statement recently went the round of the newspapers that the Dominion Coal Company had "ordered" the immediate increase of its output to 20,000 tons daily. As bearing on this, it may be recollected that at a recent meeting of the Dominion Steel Corporation the President referred to the retarded development of the collieries and mentioned the shrinkage in output capacity occasioned by the lack of development expenditures during the war period. Deferred mine development can never be overtaken. Similarly, it is never possible to obtain emergency supplies from coal deposits unless the mines are at all times maintained in a position to put out coal. If Canada can only produce 13,000,000 tons of bituminous coal annually from her mines, there is no comfort in the thought that we own the second largest coal reserves in the world. All we can call our own; all the coal that is of any use to this country is 13,000,000 tons annually. We could use 30,000,000 tons annually. The United States is actually producing 700,000,000 tons annually.

**W**E admit that at the present time it is cheaper and easier to buy coal from the United States than it is to mine it and transport it to market in Canada. Canada's fuel difficulty is a consequence of her separate national existence in North America. If Canada desires to continue as an independent political entity in North America she must accept the fuel problem and overcome it. It is not possible to have one's cake and eat it too.

#### LIGHT RAILWAY FOR GOWGANDA.

The company which has undertaken to build a light railway into the Gowganda silver mining district is now selling bonds to finance the enterprise and it is expected that the railway will soon be built.

The great nickel-copper industry of the Sudbury district has grown from the discovery of ore during construction of the Canadian Pacific Railway and the silver mining industry of Cobalt dates from the

discovery of silver during the construction of the Temiskaming and Northern Ontario railway. In both cases railway transportation was available as soon as there was ore to ship.

There are great advantages in being located close to the railroad and those who endeavor to make mines in any other location find the burden of road construction a hard one. Too often the lack of vigor in attacking the transportation problem results in failure to develop promising mineral deposits in Ontario. A property lying a few miles away from a railroad is often considered as inaccessible. The building of light railroads and waggon roads to serve such mining districts would result in greatly increased development of the mineral resources.

It is to be hoped therefore that the men who are enterprising enough to build a light railroad to Gowganda will be well rewarded for their effort and that the success of their venture will lead to more ambitious plans for the opening up of Ontario's hinterland. Then we will have more intensive prospecting in areas that are at present ignored because of distance from the few railways that cross the country. The Government railways will be benefited by the business that will come from new mining districts reached by waggon roads and light railways. It is in the general interest that such feeders to the trunk lines be constructed.

## Conditions Attending the Mining of Coal in Nova Scotia

By The EDITOR

"The situation of the coal industry in Nova Scotia at the close of 1918 is similar to that at the end of 1917, but very much worse, and a description of the state of affairs today would necessitate practically a repetition of the statements made in the New Year Edition of The Morning Chronicle a year ago.

'The reduction of the production of coal in the years 1914, 1915 and 1916, and the inevitably still greater reduction in 1917, is a matter of very serious moment from any angle at which it may be viewed.'

Last year this statement was quoted, with the further remark that 'the complete certainty of a still further reduction in 1918 only adds greater emphasis to this statement.'

Unfortunately the writer's forecast of 1918 production—and he has been accused of pessimism—was too optimistic. A production for 1918 was forecast about 5,400,000 tons, but the actual figures for this year will not exceed 5,175,000 tons.

It is also unfortunately only too certain that the production of the year 1919 cannot materially exceed that of 1918, but the trade outlook is too uncertain to warrant any definite forecast of production.

In commenting on the production shown by the 1917 figures, the presence of an even more serious feature, namely, "the probability of a continuance of the diminished rate of coal production for a number of years to come, and this from causes not dependent on the length, or the outcome of the war" was forecasted.

Some of the causes for this opinion may be mentioned. Certain of these causes were operating before the war, as was pointed out in 1916; others are the result of the war during its continuance, and others again are now coming into operation as the combined result of pre-war tendencies and causes originating in the war and its aftermath.

Causes operating before the war were the coming exhaustion of many of the collieries then in operation, a number of which have in the meantime been abandoned; and the steadily increasing physical difficulties attending the extraction of coal because of the practical exhaustion of the land areas and the larger percentage of coal that must be mined from submarine areas to maintain the rate of output.

Another pre-war cause was the low selling price obtainable for coal, assisted by an incomplete apprehension among the operators of the ultimate and true cost of producing coal over a long period of years. The long continuance of low selling prices had before the war reduced the coal companies to a state of financial embarrassment that but for the stimulus of the war would have in the meantime forced them into liquidation, that is, such of them as were not already in that condition.

### Comparison of Output

The production of the larger companies compare with the year before the war as follows:

	1913	1917	1918	1919	1920 Estimated
Dominion Coal Company . . . . .	5,120,573	3,916,548	3,639,312	3,481,079	3,600,000
Nova Scotia Steel Company . . . . .	813,877	577,171	502,018	550,965	575,000
Acadia Coal Company . . . . .	539,121	398,507	277,526	407,326	500,000
Intercolonial Coal Company . . . . .	189,550	179,700	176,814	185,417	180,000
Inverness Coal and Ry Co. . . . .	293,847	202,719	204,495	139,200	545,000
Maritime Coal and Ry. Co. . . . .	155,051	200,000	180,000	396,013	
Other operators . . . . .	151,466	192,355	233,095		396,013
<b>Total . . . . .</b>	<b>7,263,485</b>	<b>5,667,000</b>	<b>5,213,260</b>	<b>5,160,000</b>	<b>5,400,000</b>
Percentage of production from Cape Breton Island . . . . .	81½ p.c.	78 p.c.	77½ p.c.	75½ p.c.	73 p.c.
Reduction from the basis of 1913 . . . . .		23 p.c.	28 p.c.	29 p.c.	25 p.c.

During the war period the production has declined in a manner that can be understood from the following tabular comparison of outputs:

Output of Nova Scotia Collieries. (Long tons).
1913—7,263,485
1914—6,500,031
1916—6,171,424
1917—5,667,000
1918—5,213,260
1919—5,160,000
1920—5,400,000 (Est.)

It is well understood that the reduction in outputs during the war period is due to enlistments in the army, and no useful purpose is to be served by discussing this phase of the matter. The producing capacity of the collieries might be restored so far as workmen employed is concerned, by returning to the collieries the men who left in the same proportions in which they were taken, but this is hardly possible, because there is a permanent loss of miners due to losses during the war, and to the fact that only a proportion of the men who went away will return to work at the collieries.

#### Composition of working Forces.

The working forces at the collieries today contain a larger proportion—a much larger proportion—of auxiliary or non-producing workmen than is necessary. The composition of the working forces at the collieries is in fact so inefficient and uneconomical that it cannot continue.

The truth is that there are more men employed in transporting and handling the coal to-day than were employed when the maximum outputs of 1913 were being obtained but the number of actual producers has been reduced by half. As the writer stated last year it is not implied that a smaller number of auxiliary workers could handle the outputs now being produced, but it is certain that the same number of men could handle twice as much coal as they are now doing.

#### Capacities of Collieries Reduced

The lack of capital during the first two years of the war, accompanied during the last two years by a shortage of workmen and inability to obtain deliveries of machinery and structural material, has resulted in reducing the capacity of the collieries for output, so that, no matter how large the number of men that could be obtained for work in the collieries, the production cannot be increased materially until the production of the advance work underground is made possible by several years work.

The combination of reduced outputs, increased rates of wages and material costs, inefficient working organizations and increased transportation costs and increased physical difficulties of extraction have brought the costs of production to an unremunerative point, and to a point that makes competition with American coal impossible. At the present time, and for some years, no Nova Scotian coal to speak of has gone to the Montreal market, but before the war two million tons per annum were sent there, and presumably this market must once more be looked to by coal operators in this Province.

#### Increased Cost of Production.

While there is a certain abnormality in the local coal situation which will gradually disappear as world affairs swing into the old accustomed channels, yet there are certain features which will affect the coal trade here either permanently, or over a long period to

come. A permanently increased cost of production has been brought about by the increased physical difficulties of mining, by altered standards of labor return for money expended in wages, by increased costs of material, on which similar influences have been exerted to those that have gone to increase the price of coal production; by increased taxation imposts, and by recently enacted laws such as the Workmen's Compensation Act and the weekly pay. No comment is here indicated on the advisability of these laws. They may be very advisable, and the trend of political thought should prepare us for even more radical legislation along these lines, but it is sufficient for the present argument that they have directly increased the cost of coal production.

Added to and accompanying this factor of increased costs of production, is the lessened capacity of the mines for output, a condition that must persist until peace has restored the years that the war has eaten.

There is also the permanent loss of mining population occasioned by the heavy enlistments of miners. This is without doubt a permanent factor, and one which will have to be reckoned with, as the drain of enlistment was concentrated on a selected class from a selected employment. The importation of workmen from Europe will be necessary to supply the labor shortage when the present slack and hesitancy in business has passed away and the essential soundness of Canada's future is revealed once more, but foreign importations cannot make up for the loss of the native Nova Scotian miner, who is a disappearing asset of this Province.

The summation of the foregoing factors do not permit optimism regarding the future of the coal industry in Nova Scotia."

(Re-published, with the addition of the figures of production since recorded, from the Halifax "Morning Chronicle" of January 1st., 1919.)

The deterrents to production above enumerated are not altered in kind, but they are more definite and permanent than when the foregoing was written. There is at this time at the collieries a shortage of production labor, and a surplus of non-productive labor, labor that insofar as it is surplus is also useless. The output capacity of the collieries is reduced, and its restoration will take years to effect. Permanent reduction in the resident mining population has taken place. This loss can only be made good by immigration. Increased cost of production and decreased hours of labor are also permanent factors, likely to increase in severity.

The conditions are of a nature that will not ameliorate under a waiting policy, but require drastic remedies. Some of the measures that would offset the small production and increased cost of coal—to a large extent cause and effect—are a reduction of the non-productive labor employed, large recruitment of productive labor, the adoption of double or treble shifts, and the immediate expenditure of money and labor on the development of new mine openings.

No single factor of development can have such an increasing effect on production as the unified management of the Sydney coalfield properties which will be possible if and when the consolidation of the companies takes place that is proposed under the charter of British Empire Steel Corporation. Upon the consummation of this event it will be possible to immediately enlarge the area of working faces tributary to collieries that are now circumscribed by lease lines

preventing further advance of the working places. The output of a number of collieries could under such conditions be much enlarged without important expenditure, and without necessitating the employment of additional non-productive labor. The coal which can be produced by working faces now idle can be handled by the men now necessary to deal with a very much smaller output of coal.

The proposed consolidation could not be undertaken at a more opportune moment in regard to the future development and the planning of new collieries. If this opportunity to plan out the future winnings of the Sydney Coalfield is taken it will enable a thing to be done that has always been eminently desirable but never previously possible, namely, the conception of the Sydney field as one continuous deposit, and the laying of plans for its development to serve one individual interest. The possibilities for simplification of the engineering problems, for economies in haulage, ventilation, pumping and generation and transmission of motive power; for the proper rotational working of the superimposed coal seams; for the adoption of improved technical methods, for comprehensive vision and resulting efficiency, are as immense as they are fascinating. Always provided that the direction is competent, the opportunity is unique, and if it is taken, the results will justify the dreams of those who have visualised the Sydney Coalfield as one that can only give its maximum yield under single management.

#### THE RE-OPENING OF SILVER ISLET MINE

J. J. O'Connor

The Silver Islet Syndicate are meeting with gratifying results in their explorations underground, in this famous old mine. The unwatering operation is proceeding at an easy pace, the level being kept just below the samplers, who are now sampling the upper levels and slopes. One hundred samples were dispatched to Haileybury on the 14th inst for analysis.

The airlift discharges one thousand gallons of water per minute. It is in striking contrast to the old Cornish pump, formerly in use, and still in position, that only had a capacity of about fifty gallons per minute, but yet, had no difficulty in keeping the mine dry. The power required for the air-lift, is scarcely one quarter of that used in operating the old pump.

Superintendent Greener announced today, that they had encountered a body of high-grade ore, 25 ft. in length, and from 18 to 27 inches in thickness, varying in values from 1,000 to 2,000 ounces per ton, about half-way down to the first level (approximately 35 feet below the surface) in the roof.

The Syndicate is to be congratulated on having its faith confirmed, at such an early date in its operations, and it is hoped that its enterprise will meet with the reward it deserves. It again suggests the old question: Will Silver Islet come back? Will it again take its old place as one of the leading silver producers in this Province? It is sincerely hoped that it may, and that its whistle, which blew a few days ago, for the first time in 36 years, may long continue to echo along the frowning shore line.

The Hon. Harry Mills, Minister of Mines, had the honor of starting the engine, when the present operations were begun. Captain James Cross, a veteran of over 50 years at this mine, hoisted the flag that was flown on the beginning of mining operations, by the Silver Islet Consolidated Mining Company, in 1870. The ore discovered is "macfarlanite" and is peculiar to Silver Islet.

#### BOOK REVIEW.

MANUAL FOR THE OIL AND GAS INDUSTRY, by Ralph Arnold, J. L. Darnell and others. John Wiley and Sons, New York.

This book has been compiled for the purpose of assisting the taxpayer of the oil and gas industry in preparing his Federal tax returns. It is consequently of comparatively little interest to Canadians, but those in the oil and gas industry will find in it much useful information for there is dealt within the book matters that vitally affect all companies here as well as in the United States. Part II of the volume deals with depreciation. Part III consists of descriptions of methods of estimating underground oil resources. The data given are based on a systematic study of thousands of production records by the Bureau of Mines.

#### NEW MAP OF THE RICE LAKE MINING DISTRICT MANITOBA.

The "Journal is in receipt of two sample maps of the Rice Lake District of Manitoba, one printed on thin paper and the other printed on stout paper, issued by the Topographical Surveys Branch of the Department of the Interior. We are advised by Mr. E. Deville, the Surveyor-General that this map shows all the surveys in the district and will be sold by the Branch at a nominal price. The map is on a scale of one mile to the inch, showing the Manigotan River and its lakes, Rice Lake and the Wanipigow Lake and river. The recorded claims are plotted and the map contains a schedule showing all the surveyed claims, giving location and lot number. An inset to the map shows the relation of the Rice Lake District to the province of Manitoba. The publication of this map will fill a public demand, and the Topographical Surveys Branch is to be congratulated on its opportune appearance.

#### TORONTO NOTES.

The directors of Ontario Kirkland Mines were in Toronto on Saturday last on their way back to Philadelphia, after having attended the annual meeting at the camp last week. It was decided to commence at once the erection of a mill and ground will be broken for a mill of one hundred-ton capacity.

A circular has been issued by the Teck-Hughes Mine in which it is intimated that some scheme may be arranged to reorganize the company and by increasing the authorized capital to effectually cope with the financial situation which has arisen, and which made it impossible to meet the payment of bonds which fall due to October. The mine is understood to be now on a profitable producing basis and that by the financial adjustments now in progress the affairs of the company may be worked into a sounder basis.

Mr. G. F. Hendricks, representing the firm of J. S. Rose of New York city, dealers in Industrial Diamonds for Mining Drills and diamond pointed tools, has opened a Canadian office in Toronto in the Page Building. The firm is sales agents for L. M. Van Moppes and Sons and J. K. Gullard, Ltd., of London, Eng., two of the largest dealers in this line in the world. Mr. Hendricks is well known to the Canadian mining industry, being a mining engineer who has spent considerable time among the mines of Northern Ontario.

# An Occurrence of Tin near the Ontario-Manitoba Boundary

(J. S. DeLURY).

In an article<sup>1</sup> which appeared recently, attention was called to the occurrence of tin in some bodies of sulphide minerals found in the vicinity of West Hawk and Star Lakes near the boundary line between Ontario and Manitoba. Since the writing of that article some additional information has been obtained in regard to these deposits and attention is being called to them again not on account of their commercial possibilities, for the tin is apparently not sufficiently abundant for profitable extraction, but on account of the interesting manner of occurrence and the mineral associations.

The reported occurrences of tin in Canada are few and none of them are of commercial importance. Reports of sulphide tin are exceptional, though it is believed that this form of tin is more common than is generally supposed. The difficulty of detecting small quantities of tin in combination with sulphur suggests that most commercial assays would fail to indicate its presence.

## Geology.

The geology of the area in which the stanniferous sulphides occur has been briefly discussed by the writer in some articles<sup>2</sup> written on the occurrence of which is bounded by the intrusive granite on either

iety and were derived from basic lavas. Metamorphosed conglomerates and other sediments are also found in the belt. The granite body appears to have been the source of most of the ore-minerals and, at different times during the later stages of cooling, there passed out from it mineral deposits of several forms and materials. There are some deposits in the locality which may not have been derived from the granite. In the list of occurrences which are now to be described, only those which appear to be directly attributable to the granite will be mentioned.

## Pegmatite Dikes.

These are found in the schists, generally within a few hundred feet of the contact with granite. Molybdenite is the prominent economic mineral found occurring in the dikes; it is usually in crystals of good size. Masses of crystals have been found weighing twenty pounds or more and some work done since the showings were examined is said to have exposed many masses even larger than these. A careful search for minerals of tin and tungsten was made in the excavations in the pegmatite dikes; but no trace of any of these was found.

## Aplite Dikes.

These are other off-shoots from the granite magma.

Neil Martin and Cabin on West Hawk Lake

Cabin on West Hawk Lake where Tin was reduced in Stove.  
Neil Martin on the right.

molybdenum and tungsten in the same locality and sketch maps were made showing the outcrops of rocks and geographical features, so that here only brief mention will be made of the relations existing between those rock units of the area which are of importance in connection with the ore-minerals. The formations are similar to those described by Lawson as appearing in the Lake of the Woods District and are all of pre-Cambrian age.

A biotite granite, mostly coarse-grained and reddish in appearance, is the youngest rock. It has intruded all the other types of the area. The ore-minerals are found largely in a belt of schistose rocks

They are not large and the molybdenite in them is in small crystals and grains and is very irregularly distributed.

## Pegmatitic Quartz-Veins.

Two of these veins have been found. They belong to a transition type between normal pegmatites and quartz-veins. The economic minerals found in these deposits are gold, bismuth, bismuthinite, molybdenite, arsenopyrite and small amounts of chalcopyrite. This association of minerals is identical with that reported of the contents of the Mikado Mine, which lies in the western part of the Lake of the Woods district and only about ten miles southeast of these deposits. There is consequently a strong probability that the Mikado vein and perhaps many of the other quartz veins found on the Lake of the Woods are directly attributable to the intrusion of the same

<sup>1</sup> Transactions, C. M. J. 1919. P. 326.

<sup>2</sup> Can. Min. Journal. Vol. 38. P.460. Can. Min. Journal. Vol. 39 P. 186.  
side. The schists are largely of the hornblende var-

granite that produced the mineralization in the boundary area and which is believed to extend into the Lake of the Woods.

**Molybdenite-bearing Quartz-Veins.** In some porphyries derived from the granite magma and in adjoining masses of schist are some wide bands occupied by quartz and fractured country rock filled with quartz stringers and carrying fine-grained molybdenite and small amounts of pyrite and chalcopyrite. Channel samples of this material, taken across considerable widths give assays showing a molybdenite content up to one per cent, and values in gold, silver and copper totalling about two dollars to the ton. Very little work has been done on this type of deposit, though considering the possible extent of them and the possibility of finding other and richer bodies of the same nature, it would seem well worth while to investigate the deposits already found and to conduct a search for more.

**Scheelite-bearing Deposits.** These seem to have been given off from the granite at a later stage than the deposits which have been already mentioned. Scheelite occurs in altered bands and patches in the hornblende schist in company with epidote, vesuvianite, feldspar and other high-temperature minerals. Small amounts of molybdenite, pyrrhotite, chalcopyrite, sphene and ilmenite are also associated as well as calcite and quartz.

**Sulphide-bearing zone in Schist.** These zones are numerous and large. They are found chiefly in the vicinity of West Hawk and Star Lakes. The abundant sulphide is pyrrhotite. Pyrite is fairly general in occurrence and in places is abundant. Other minerals found irregularly distributed and in varying though usually small quantity are arsenopyrite, zinc blende, galena, chalcopyrite, scheelite and its high-temperature associates, quartz, calcite and siderite. Low nickel assays have been reported from some of the pyrrhotite. The most interesting feature of these sulphide deposits is the presence of small quantities of tin.

**The Occurrence of Tin.** Mr. Neil Martin, a prospector who has been in this part of the country since the boom days of the Lake of the Woods district, has for years been roasting samples from these sulphide deposits in his stove and has been obtaining beads of metal from them. Samples of these metals were sent by Mr. Martin to different assayers and tin was reported from some of them. Unfortunately the people whom Mr. Martin informed of this were skeptical and hinted at tin cans, etc., as being the source of the metal. Though samples from the same places as those which furnished the tin were sent to many assayers, no tin was reported. Of the metal samples originally handed to the writer, the first ones examined contained lead or a mixture of lead and zinc, but one was examined which consisted mainly of tin.

An examination of the deposits was then made to ascertain if possible in what mineral the tin is carried. This was difficult, since most of the sulphides are intimately mixed. Many tests were made and of all of them, the original method adopted by Mr. Martin was the most successful. In only one case was a definite mineral found which gave a satisfactory test for tin. This was a sample of what appeared to be chalcopyrite; a good blowpipe test was obtained from this, indicating that the mineral is a member of the isomorphous group between chalcopyrite and stannite. Unfortunately not enough material was left for a complete analysis, but it is hoped that more will be obtained.

Samples from the sulphides lodes were sent to be

assayed. Most of the returns showed less than one per cent of tin; a typical set of samples showed 0.18, 0.18, 0.00 and 0.30 per cent of the metal.

Mr. Martin deserves great credit for his persistence and ability in demonstrating the existence of tin and the public who doubted his findings owe him an apology and a deal of praise.

Though a careful search has been made in many of the more promising places, no cassiterite has yet been found in the area.

**The Origin of the Sulphide Lodes.** The writer has not completed his examination of the sulphide bodies so that the following ideas concerning them must not be regarded as final conclusions, though the evidence is strong that they are correct.

The fact that the molybdenite came from the granite is obvious. The association of this mineral with scheelite, bisnuth minerals and gold connects the deposits carrying these metals also with the granite. The occurrence of scheelite in the sulphide lodes points to the granite as the source of the sulphides. Finally the presence of tin, so generally associated with granites and so commonly found with tungsten and molybdenum, shows beyond much doubt that many of the constituents of the sulphide lodes came from the granite. That the sulphide lodes are subsequent to the granite in their formation is indicated by the fact that a pegmatite dike, apparently an off-shoot from the granite, is seen at one place to be impregnated and partly replaced by sulphides connected with one of the principal deposits.

**Origin of Lake of the Woods Gold and Bearing on the Economic Geology of the Vicinity.** It has been pointed out that the associations of minerals indicate a similarity in origin between the gold-bearing veins of the Lake of the Woods and the mineral deposits of the district near the Boundary, which have been connected with the intrusion of a particular granite. It would be expected that this same granite would be found in the Lake of the Woods. Lawson's description of the granites of that area leads to the belief that this inference is correct.

There is reason for hope that deposits of tin and of tungsten will be found in the Lake of the Woods area. The wide distribution of molybdenite there adds considerably to the hope. It is more doubtful that commercial deposits will be found. Many of the larger deposits near the boundary appear to be too low-grade and the richer ones are generally too small to be considered. It is to be hoped that some of the bodies already found will prove to have the right combination of size and richness to be workable and that further prospecting in the Lake of the Woods area will bring some more of these interesting deposits to light. The general attitude of apathy and condemnation assumed towards the Lake of the Woods country are not altogether warranted.

It should be added that in view of the association of silver with tin in some valuable sulphide deposits in Bolivia and Tasmania, several samples from the sulphide lodes were assayed by the writer. No silver was found in any of them.

Mr. Stuart A. Marvin, of the firm of Fleming and Marvin, 1102 C.P.R. Building, Toronto, has formed a partnership with Mr. H. Herbert Scarlett, formerly with Bryant, Isard and Co. The new firm will operate under the old firm name and will conduct a general stock brokerage business, dealing in securities in all markets.

## Nova Scotia Notes

### Changes in the Official Staff of the Dominion Coal Co. Resignation of Messrs. Tonge and Herd.

Recent changes in the staff of the Dominion Coal Company have involved the resignation of Mr. A. J. Tonge, the General Superintendent of Mines and Mr. Walter Herd, the Mining Engineer of the Company.

Mr. Tonge was appointed Mining Engineer of the Dominion Coal Company in 1912. When Mr. D. H. McDongall was appointed General Manager of the Dominion Steel Corporation and removed his office to Sydney, in 1917, Mr. Tonge was appointed General Superintendent in charge at the collieries. At the Annual Meeting of the Mining Society of Nova Scotia in May, he was elected to the office of President of the Society. He is also a Councillor of the Canadian Mining Institute. Previously to coming to Canada, Mr. Tonge was General Manager of the Hulton Collieries in Lancashire, England, where he succeeded his father as certificated colliery manager, and was in charge of operations for 29 years. He is a past-President of the Manchester Geological Society. During Mr. Tonge's service with the Dominion Coal Company he has had to deal with several difficult mine fires and explosions, at the Springhill Mines and at No. 12 Colliery in the Lingan district, and he was consulted with regard to the extinction of the mine fire at the Allan Shafts, Stellarton, and the re-opening of this mine. A large number of additions and improvements have been made under Mr. Tonge's directions to the motive-

power and mechanical equipment of the Dominion collieries, but latterly, owing to the time occupied by executive duties and the adjustment of labor questions, Mr. Tonge was unable to devote much time to the technical questions of mine operations.

Mr. Walter Herd had been with the Dominion Coal Company about two years when war broke out, and, on the nomination of the Canadian Mining Institute was given a commission in one of the Tunneling Units. He later transferred to the Canadian Forestry Corps and served throughout the war, during which time he had oversight of large forestry operations, involving heavy money expenditures. Later he was placed in charge of the inspection of timbering of dug-outs and underground excavations with a view to the economy of supporting timber. During this work he saw much of the heavy fighting of the war. Mr. Herd retired as Lt.-Colonel and has the O. B. E.

Since returning from overseas, Mr. Herd has filled the position of Mining Engineer. Previous to the war he had experience in charge of Springhill Mines, where he was the resident Superintendent. He was also for a time in charge of the iron-ore operations of the Dominion Steel Company at Wabana. His previous experience includes management of collieries in Scotland and South Wales.

A paper was read before the Mining Society of Nova Scotia recently by Mr. Herd suggesting the application of hydraulic stowing to the recovery of the pillars in the first lift of the underseas collieries. (See "Journal" of May 14th and 21st, pp. 384 and 412).

It is understood that Mr. Tonge will return to England, and that Mr. Herd will become a directing officer and a partner in a lumbering company that has its headquarters in Halifax, N.S.

No announcements have been made of any appointments in succession to Messrs. Tonge and Herd in connection with the technical direction of the collieries.

The Dominion Coal Company has been singularly fortunate in attracting the services of mining engineers of wide experience and good reputation, but it has been singularly unfortunate in retaining their services. Within the past fifteen years the Dominion Coal Company has had four successive incumbents of the position of general superintendent of mines, or technical director. Each of these men upon leaving the Company's service obtained positions of greater responsibility and enlarged emolument. The conditions which brought about the severance of these engineers from the connection with the Company have been various, but they have had one constant feature, namely, that they were related to questions of executive policy, and were not in any case referable to the technical abilities or the engineering direction of the development of the collieries.

The unfortunate result of the numerous changes has been to deprive the mining operations of the Company of continuity in the technical direction of its mining operations, and of the fruition of the observations of competent engineers when these had ripened through the necessary length of experience. Each new incumbent in office has had to begin his education in local mining matters where his predecessor began, and the Company has lost all the benefits of accumulated observation and all the advantages which come from continuity of policy and definite aims. The lack of continuity in management has adversely affected the ambitions and life studies of the subordinate officers

MR. WALTER HERD

of this large Company. The number of officials of long service in the Dominion Coal Company is surprisingly large considering the frequency of changes in management and control, but the repeated changes of technical policy that are inseparable from changes in managerial personnel, tend to discourage the intellectual processes of subordinate officials and finally to reduce them to a state of innocuous acquiescence in any and all directions from a superior source.

If changes in control and management of industrial companies are inseparable from modern tendencies—and they seem to be so—it would perhaps be well to adopt the policy that is followed in government departments, where, when political changes occur, the minister changes, but the deputy-minister, who is the technical director and the repository of observed facts and accumulated experience, remains.

The plans for the colliery development of today should have been laid many years ago, and the programme of development for twenty years to come should be prepared today. The technical direction of a large coalfield is best achieved by the scientific mind, the possessor of which is not necessarily the best executive; and to achieve the best results in any scientific field it is requisite that a competent mind should be concentrated over a long period of years, undisturbed by passing events. Only in this way is the ripened vision and the thorough understanding requisite to technical success acquired, and, when the time comes, passed along to others.

A mining company can possess no more valuable asset than an engineer who has grown up with the mining field, has steeped his mind in knowledge of its characteristics, and has had leisure to follow technical problems to their logical conclusion. The evolution of such an officer requires first, the selection of the proper man, and, secondly, his retirement from all ephemeral executive duties, and, thirdly, the concentration of years of thought and investigation on the problems of the field selected for a life's work.

#### Revival of Former System of District Superintendence.

The division of the colliery into superintendence districts was begun under Mr. G. H. Duggan's management and was continued until a few years ago when through death and resignations the district superintendents were reduced to two in number, namely Messrs. A. McEachern and A. Macdonald who were appointed assistants to the General Superintendent of Mines.

Pursuant to a circular issued by M. H. J. McCann, the Assistant General Manager of the Coal Company the collieries are again divided into districts, but three districts of four, as previously are designated.

No. 1 District, of which A. McEachern is appointed Superintendent, contains the collieries in the central Glace Bay district, namely, Nos. 1, 2 and 9, 5, 10, 11 and 24. In this district is included most of the land area of the Hub, Harbor, Phalen and Emery seams, and the as yet unworked land area of the lower seams. A new shaft is approaching completion between No. 1 and 8 collieries, and the operations in the three upper seams are all submarine. The area of the Phalen seam in No. 5 (Reserve) Colliery is approaching exhaustion and No. 10 and 11 collieries represent the workings on the underlying Emery seam in the Reserve area. No. 24 colliery is the latest opening on the Emery seam, and at some future period another Emery seam colliery will be opened to work the seam where it under-

lies the exhausted land workings of No. 1 and 2 collieries.

Mr. A. Macdonald is appointed Superintendent of collieries Nos. 4, 6, 21, 22 and 25. No. 4 is Caledonia Colliery, and it is anticipated that a new shaft will be sunk to work the submarine area of Phalen seam coal now being drawn to No. 4 Shaft. No. 6 is a Phalen-seam colliery, entirely submarine with a large tributary area still to be drawn from. Nos. 21 and 22 are mining a tongue-shaped land area of coal in the Morien Basin which proceeds seawards at the village of Morien, where the old Morien Colliery, (successively known as the Gowrie and Blockhouse and North Atlantic Collieries) is being re-opened and designated No. 25 Colliery.

The Collieries in the Lingan-Victoria Basin, (now known as the Waterford District) are Nos. 12, 14, 15, 16 and 17, and are placed under the superintendence of Mr. J. C. Nicholson. In this district several additional groups of collieries are projected upon the Lingan and Victoria seams, and at some future date the underlying seams, of which there are several, will be worked. An overlying seam, the Barrasois, is being tapped from the Victoria seam by cross-measure drifts proceeding from the existing collieries. The Barrasois, Victoria and Lingan seams in the Waterford district are recognised as the equivalents of the Hub, Harbor and Phalen seams in the Glace Bay district, but the correlation of these with the Morien seams is still a matter of conjecture, as is also the correlation of the Waterford Seams with those across the entrance to Sydney Harbor that have been extensively worked at Sydney Mines. Much interest attaches to the progress of the sinking of the deeps in No. 17 Colliery, Victoria Seam, as these are now approaching the line of the disturbance that runs under Sydney Harbor.

MR. ALEX. MCEACHERN

Following the re-arrangement and revival of the district superintendence organization, other promotions have been given effect to. P. T. Prendergast formerly manager of Nos. 2 and 9 collieries is appointed Assistant District Superintendent in No. 1 District. D. J. McCuish is appointed manager of No. 2 Colliery, and W. S. McDonald becomes Assistant Manager. Mr. J. J. McNeil is appointed Manager of No. 9 Colliery, resigning his position as Deputy Inspector of Mine under the Provincial Government. Previously to taking a position on the inspectorate Mr. McNiell was Manager of the same colliery.

Vincent McFadden, who has for many years been the Electrical Engineer of the Dominion Company, and has since Mr. J. S. Whyte resigned the position of Mechanical Engineer to go with the Acadia Coal Company, also acted as Mechanical Engineer, has resigned and is succeeded by Maurice Murphy, Mechanical Superintendent of the Dominion Steel Company. Mr. Murphy has been with the Steel Company since it was commenced and has gradually risen in successive official positions connected with mechanical equipment.

**Re-organization of Dominion Coal Police Department.**

The police and watchmen employees of the Dominion Steel Corporation, which includes the Dominion Coal Company, are again placed under the direction of Capt. D. A. Noble. This appointment re-establishes a former arrangement. During the war period Capt. Noble was Registra and director of Aliens under the direction of the Ottawa authorities, and the absence of any unpleasantness in connection with large number of registered aliens in the Sydney District was in large mea-

sure due to Capt. Noble's careful handling of a delicate combination of circumstances.

**The Output Position of the Dominion Coal Company.**

The disastrous effect of war upon production of the Dominion Coal Company in the Sydney field is shown by the following comparison of the daily average output of the collieries in the Summer of 1914 as compared with the daily average of production in May 1920. It will be seen that the daily average has been reduced from almost 20,000 tons to about 10,700 tons. The periodic daily maximum, which comes midway between paydays, is at the present time around 12,000 tons, comparing with 21,000 tons in 1914.

Mine Number	Seam	Daily Average Beginning 1914 Tons	Daily Average May 1920 Tons
1	Phalen	2,000	1,070
2	"	3,200	1,930
3	"	400	Exhausted
4	"	1,600	1,120
5	"	700	340
6	"	800	760
7	Hub	800	Closed
8	Harbor	250	Exhausted
9	"	1,600	930
10	Emery	800	410
11	"	400	580
12	Victoria	1,600	600
14	"	1,600	640
15	Lingan	1,000	460
16	"	1,300	490
17	Victoria	200	100
21	Birch Grove	700	500
22	"	600	600
24	Emery	....	120
25	Morien	....	....
		<hr/>	<hr/>
		19,550	10,650

It will be seen from the foregoing that the development of No. 17, which was well advanced in 1914, was entirely arrested by the war.

During the war period three collieries were closed and conditions did not permit of replacement by new workings. No. 24 Colliery is still in the initial stages of production, and No. 25 Colliery (Morien Colliery) is being unwatered preparatory to commencing mining operations.

**METAL QUOTATIONS.**

Fair prices for ingot metals at Montreal, 23rd June 1920.

	Per lb.—Per cent
Electro copper	24
Castings copper	23½
Zinc	10½
Lead	10
Tin	57
Antimony	11½
Aluminum	37

**PERSONAL.**

Prof. J. S. Delury acting head of the Department of Geology, University of Manitoba, will spend several weeks in the Rice Lake gold area this summer for the Manitoba Government.

MR. ALEX. MACDONALD

# Sir John Cadman Defends British Oil Policy

## An Attitude of Impartiality and Fairness.

Reading an important paper on "The Oil Resources of the British Empire" before the Indian and Colonial sections of the Royal Society of Arts recently, Professor Sir John Cadman, who has for a considerable time been acting as official advisor to the Government as principal permanent official of the Petroleum Executive, said there had been of late in regard to the British Empire and its oil policy some idea that we were attempting to dominate the supplies of this planet. The British Empire consisted of one-fifth of the surveyed land of the globe, and it was only natural that we should in some measure look after our citizens. On the one hand, there were groups of capitalists attempting, and rightly so, to secure concessions in new territories; on the other hand, the results of the great war has brought about a world shortage of oil. That commodity has been used to an extent never before known. As inevitably happened, when there was a shortage, the price had gone up, and there were some people who imagined that this could be corrected by price-limiting machinery. Such regulation, however, would result in focussing the shortage more acutely on those nations which adopted it.

### Mesopotamia's Oil.

An outcry had arisen in the United States that Great Britain was attempting to "collar" the world's supply of oil and the people who were trying to secure territories at the moment were centering their activities on Mesopotamia. Now, it had been known for many years that oil existed in Mesopotamia. Indeed, it had been open to every comer, of no matter what nation, to prospect the oil territories of Mesopotamia, and to secure rights of exploitation. But at last Mesopotamia had come under the mandate of a stable Government, and it was wonderful how active people became in attempting to secure opportunities of working a territory when stable Government was going to keep law and order for these people to operate within such area. It was also wonderful that certain interests in America should wake up very readily to the possibilities of oil in those territories and rush into an attack upon those organizations which had tried to look after the supplies under the British flag.

As to the proportions in which oil supplies existed in various countries of the world today, Sir John Cadman said that the continent of North America produced over 85 per cent. of the world's output of crude oil. Of this the United States produced in her own territory nearly 70 per cent. If the quantity produced by the United States in Mexico was added, the total United States control in North America was at least 80 per cent. of the world's supply. The British Empire, however, produced only 2½ per cent. of the world's oil supply, or, if Persia might be said to be under British influence, about 4½ per cent. of the whole.

### Future Supplies.

For the invaluable assistance we had received from the United States in the way of oil supplies in war and peace we could not fail to feel profoundly grateful. But the greatest producer of oil to-day was absorbing more and more of her own supply, and it be-

hoved us to look around and see in the most friendly way where we were going to be served when the United States found it difficult to supply us, and we, too, were calling for more and more of this vital product.

Sir John proceeded to combat the statement that Great Britain was developing an oil policy which definitely excluded the foreigner from participating in and helping to develop any of the Empire's 2½ per cent. production to-day. In regard to Persia, the suggestion that Americans were under special disability in that country was absolutely incorrect. As the Anglo-Persian Oil Company held the concession, other British and foreign interests were naturally excluded, but there was no truth in the statement that the Anglo-Persian Oil Company's rights had been in any way strengthened by the Anglo-Persian agreement of 1918. The concession was acquired in 1910 through the individual enterprise of Mr. W. K. d'Arcy, and it was equally open to Americans or any other nations to secure it.

### Result of British Enterprise.

Any oil concessions which British subjects held abroad had been acquired purely by individual enterprise, and they enjoyed no special advantage in the way of Government backing, nor did they wait to secure Government encouragement and support. On this difficult question he could only say that Great Britain was too sensible of what she owed to those who had kept her so well supplied in the past to adopt any attitude other than that of strict impartiality and fairness.

Mr. E. G. Pretyman, M.P., who presided, said that personally he rather thought that, so far as the American oil magnates having any complaint against Great Britain, the boot was on the other foot, and the attitude of our Government and always been rather to leave our nationals, entirely unsupported, to their own resources, whereas other Governments had done their best to look after the interests of those who were trying to use their financial resources for the development of supplies outside of their own borders. His view was that, where private enterprise was acting entirely on its own, unsupported by the Government behind them, we ought not to interfere to give our own nations particular advantage over others, but where other nationals were being supported by their own Government then our nationals should receive similar support from our own Government.

### NEW COLLIERY PROPOSED IN THE MORIEN BASIN, SYDNEY COALFIELD.

It is understood that Mr. Vincent Mc Fadden, formerly Electrical and Mechanical Engineer of the Dominion Coal Company, in conjunction with Mr. Cavvichi of Halifax, N.S. contemplates the opening of a colliery at False Bay Beach, on what are known as the General Montgomery Moore areas. The area covered by the Moore leases is entirely a land area and is underlain by the Tracy Seam, the lowest of the Sydney Coalfield series, and partially underlain by one or more of the seams above. The areas are situated on the fringe of the Morien Basin. The coal seams proceed to sea under slight cover, the abutting submarine leases being held by the Dominion Coal Company as the assigns of the Cumberland Coal and Railway Company.

**PRESENT POSITION OF THE GOLD MINING INDUSTRY OF NORTHERN ONTARIO.**

By J. A. McRae, Cobalt, Ontario.

The gold mining industry of Northern Ontario is growing at a rate far in excess of expectations, as shown in the official figures from the mines. The increase of 46 per cent. in production for the first quarter of this year as compared with that of the corresponding period last year so strengthened the position of the industry as to assure it of actually exceeding the sister industry, silver mining, for the first time since the discovery of silver in Cobalt.

While gold production promises to approximate around a million dollars a month for this year, it is interesting to note that producing gold mines report milling capacity of 5,485 tons daily. These figures taken together with the average grade of the ore treated, shows that present equipment is being utilized at only two-thirds capacity and that when operated at full blast should produce close to \$18,000,000.

**Ore is High Grade.**

In arriving at the importance of such property, it may be well to keep in mind the fact that the average amount of gold recovered from each ton of ore treated was \$9.19 for the past year, a figure which promises to be well maintained. The ore at the Lake Shore over \$20 to the ton, at the Porcupine Crown runs about \$11 to the ton, the McIntyre a little over \$10 to the ton, the Hollinger \$9.09 a ton and the Dome \$6.50 to the ton. The other mines have ore approximating the above average.

The excellent physical condition of the mines as well as the comparatively favorable conditions under which they are developed enables them to operate at a favorable margin of net profits at a time when many gold mines in other parts of the world have been compelled to close down. This may reasonably be taken as an indication that with the return to conditions under which mines in other parts of the world may resume production, the mines of the Porcupine district will become doubly prosperous.

**Output Steadily Increasing.**

As evidence of the steady growth of the industry, the following figures may be presented, representing the production record during a period when some of the leading mines were operated at reduced capacity on account of a shortage of workmen as well as adverse economic conditions:—

Year	Ounces	Value
1910 . . . . .	3,089 . . . . .	\$ 63,849
1911 . . . . .	2,062 . . . . .	42,625
1912 . . . . .	86,523 . . . . .	1,788,596
1913 . . . . .	219,801 . . . . .	4,543,690
1914 . . . . .	268,264 . . . . .	5,545,509
1915 . . . . .	406,577 . . . . .	8,404,693
1916 . . . . .	497,836 . . . . .	10,339,259
1917 . . . . .	420,894 . . . . .	8,698,881
1918 . . . . .	450,000 . . . . .	9,100,000
1919 . . . . .	505,963 . . . . .	10,451,688

While the above figures cover the output for the whole of the province of Ontario, more than 90 per cent., or close to \$10,000,000 was Porcupine's share of the 1919 total.

As regards the present, current production from the mines of Porcupine has shown a considerable increase during the opening months of 1920, and the aggregate output is now close to \$1,000,000 monthly.

**The Future Outlook.**

Concerning the future, with such a record as that above referred to established at a time when conditions were quite abnormally unfavorable, and at a time when all the mines operated at reduced capacity, the various operating companies may be permitted to anticipate a greatly increased record from this rate forward, all of which tends to offer every inducement for mining interests in other countries to turn their attention to Canada and especially Northern Ontario.

**Big Virgin Field.**

While the Porcupine field is the centre of Ontario's gold mining industry, and, in addition to its present proven mines with ore blocked out and in sight amounting to more than three score million dollars ahead of production, has a large outlying area which offers big scope for further exploration and much promise of additional mines being developed; it would be entirely misleading to conclude without making reference to the other parts of the district where commercial deposits of gold-bearing ore have been found. Chief among these might be mentioned the Kirkland Lake gold area, situated some 60 or 70 miles south-east from Porcupine, where current production for three mines now amounts to over \$100,000 monthly, with a fourth mill ready to resume work in September and the construction of a fifth to be completed in the early Autumn. From these five mines it is calculated that a production at the rate of \$2,500,000 a year will be established during the coming year.

**The Newer Districts.**

Other centres where considerable development work is being done with promise of success include: Boston Creek, Larder Lake, West Shiningtree, Fort Matachewan, Munro Township and Bourke's Siding.

Summarized, with the likelihood of the Porcupine mines producing at the rate of at least \$12,500,000 by the end of this year, by which time the Kirkland Lake mines will be producing at the rate of approximately \$2,500,000 a year, considerable added encouragement may reasonably be offered to those who would enter these as well as the newer areas in search of new mines.

**DOMES MINES ANNUAL MEETING.**

The annual meeting of Domes Mines Company, Limited, was held in Toronto on Friday, when it was announced by J. S. Bache, the President, that the regular \$1 dividend would be continued, and that any further payments would be on the account of repayment of capital. Speaking of the question of future dividends, the President said that it was recognized that the \$1,000,000 which the company has today in cash and bonds, was all the working capital required and that repayment of capital in lieu of increased dividends was being considered. In regard to the operations of the past year it was stated that the progress made was remarkable when considered that only 250 men had been available instead of the 700 required. Answering the report given currency at the meeting that the gold mines of the Porcupine district might shut down, C. D. Kaeding, the general manager, said that unless labor quit, or their demands became higher than at present, there would be no shut-down of the Domes Mines. The regular dividend of \$100,000 was declared by the directors previous to the annual meeting. A vote of confidence in the directors and H. P. De Pencier was passed and the former board of directors was re-elected.

## Our Northern Ontario Letter

### THE SILVER MINES.

Announcement from New York that the Pittman Bill has become operative, tends to strengthen silver quotations in all parts of the world. The bill provides that more than a quarter of a billion ounces are to be purchased at \$1 an ounce or under. It also provides that such price is to be paid only for silver produced in the United States. Accordingly, quotations for the metal jumped from a low of 80 cents to 99½ cents an ounce during the third week of June, the quotation being in New York and for silver produced in advance to that point, yet a very marked increase occurred, and the indications appear to be that a minimum price approximating 99½ cents an ounce may rule for the next year or so, not only in the U. S., but in all parts of the world.

With a premium of around 15 per cent. on New York funds, the Canadian producers are receiving more in Canadian currency than the United States producers are receiving in the currency of that country.

Silver production is still stated to be far below consumption. In the period between April 1st and June 2nd, Great Britain exported more than \$27,000,000 in silver to the Far East, while imports into Great Britain amounted to less than \$11,000,000. During the corresponding period the silver stored in the national bank of Germany decreased to \$182,200, or practically nil as of June 3rd, as compared with more than \$3,000,000 as of May 20th. All these figures go to show that Europe is shooting a final bolt in the attempt to make permanent the break in silver prices. But, in the opinion of silver producers of the Cobalt district, this artificial scheme is bound to fail and the law of supply and demand is certain to prove immutable. It is for this reason that the recent price of 80 cents caused no very great alarm to the Cobalt miners.

A feature of this week in connection with the silver mining industry of Ontario is the increasing interest in the South Lorrain silver area. At the Keeley mine, now being operated by the Associated Gold Mines of Western Australia, a medium tonnage of ore is said to have been opened up in the lower workings in that section of the property adjacent to the boundary of the Beaver Lake ground. This holding is also under option to the Associated Company. Good values are stated to have been encountered on the Beaver Lake side of the boundary. In the meantime the installation of milling equipment is proceeding.

Work of surveying the Haileybury Frontier property in South Lorrain has been carried out preparatory to resuming exploration work. It is stated that about \$50,000 will be spent in further opening up this promising property which has lain idle for a number of years. It is situated close to the Keeley as well as the Wettlaufer Mines.

The address of the Associated Gold Mines of Western Australia, as well as that of the Haileybury Frontier Mines, is Haileybury, Ont.

Information from Gowganda continues to be encouraging. In addition to the leading operations, such as the Miller Lake-O'Brien and the Castle property of the Tretheway-Cobalt, quite a number of smaller operations are under way. Work in all directions in this district promises to take on added impetus provided the construction of the proposed light narrow-gauge railway is proceeded with this summer. In this con-

nection, a bond issue of \$300,000, 7 per cent, first mortgage ten-years, is being made by the Northern Light Railways Company. It is intimated that a part of the money may be subscribed by British interests already interested in mining in this part of Northern Ontario. The railway is to be 36-inch gauge, equipped with freight cars capable of handling 25 tons each, and passenger coaches with seating capacity for about 25 persons each.

A good deal of interest is now being shown in the possibility of finding crude oil in the northern part of the district of Temiskaming. The presence of oil shales at Long Rapids on the Abitibi River, an analysis of which was made by M. Y. Williams as well as J. Keele of the Geological Survey Branch, Ottawa, shows an encouraging crude oil content. The samples were taken from the exposed surface, and leads to the belief that if explored at a lower horizon the shales may be found to contain commercial deposits of oil.

Cobalt mining companies have been approached by would-be oil explorers, and considerable field work is expected to be undertaken within a reasonably short time, in the prospecting oil field. It is believed probable that one or more oil drilling outfits may be transported down river this summer so as to carry on exploration work during the coming winter. The distance from the railway is only a little over 100 miles.

### THE GOLD MINES.

During the 5½ four-weekly periods from January 1st, to June 2nd, the Hollinger Consolidated Gold Mines had a total income of \$2,879,706. This was at the rate of approximately \$575,941 every month or at the rate of \$6,911,292 a year. It compares with an income of \$2,822,858 in the corresponding period of 1919. Not only does the report show a slight increase in income, but it also shows a decline in expenditure from \$1,507,060 in the first five months of 1919 to \$1,448,020 in the corresponding period of 1920. The average number of men employed amounted to 1,098 as compared with 1,259.

A special general meeting of the Porcupine V.N.T. Gold Mines has been called for July 14th for the purpose of considering and if approved, ratifying a plan to borrow \$50,000 from the Associated Gold Mines of Western Australia against which a first mortgage would be given. This is believed to have been decided upon as a means of putting the mine and mill in shape for operation, following which the current production would provide for the necessary expenditure.

Intimation of encouraging development at the 10th level of the Dome Mines at the point where drifting has been extended onto the Dome Extension gave rise to renewed activity in the shares of the last named company. The Dome Mines holds an option on the Dome Extension which provides for the exchange of 30 shares of Dome Extension for one share of Dome Mines provided the latter company elects to exercise the option on or before October of this year.

The Dome Lake mine has been closed down indefinitely, and the underground workings are stated to be being allowed to flood. Economic conditions as well as labor shortage have militated against the profitable operation of the low-grade ore which has been found to occur only in patches. It is thought that at some future date, under more favorable conditions, the property can be re-opened, with possibilities of more satisfactory results.

It is stated at Kirkland Lake that although the Teck-Hughes Mine is now on a profitable producing basis, yet the earnings are not sufficiently large to retire the bond issue which comes due in October. As a consequence of this, a plan of reorganization is contemplated with increased capitalization to finance the retirement of the bonds. A meeting will be held some time in July to consider this matter.

At the Kirkland Lake mine of the Beaver Consolidated, production is stated to be at the rate of around \$1,200 daily. This is the largest output achieved by this property. In the meantime, the main shaft is being extended from the 700 to the 900-ft. level, at which point a station should be cut early in July.

The King Kirkland Gold Mines, with head office at Kirkland Lake, Ont., and promoted by interests in Buffalo, has completed its organization of a \$2,500,000 company, made up of 2,500,000 shares of the par value of \$1 each. Of this, 1,250,000 shares are in the treasury to finance development work. Visible gold is in evidence on surface. The company owns seven mining claims situated in the central part of the township of Lebel.

At the Miller Independence Mines of Boston Creek, good headway is being made in cross-cut work at the 500-ft. level. A number of highly mineralized veins have been cut, and the work is approaching the zone in which it is expected to encounter the downward continuation of the rich ore body which was developed to a depth of 200 feet in an incline shaft. Considerable interest attaches to this important work, the result of which should be known before the end of July.

Work has been stopped on the property of the Matachewan Gold Mines, the reason given being that it has been decided to await the development of electric energy on the Montreal River. Diamond drill work carried on is said to have been quite favorable and such as to encourage aggressive operations just as soon as cheaper power is made available.

From present indications, five mines in the Kirkland Lake district will be producing gold before the end of the current year. An output at the rate of close to two and a half billion dollars annually is predicted.

At present the Lake Shore, Kirkland Lake and Teck-Hughes are treating an aggregate of close to 300 tons of ore daily, and producing at the rate of about \$115,000 a month. With the Tough-Oakes mill to be pressed into service again in the late summer and with the mill of the Wright Hargreaves to be completed this fall, the daily tonnage should reach 600 tons and the monthly output should exceed \$200,000.

Following is a preliminary estimate of what may be achieved as of the closing months of the current year:—

Company	Daily Capacity in Tons	Monthly production
Lake Shore Mines .. . . .	60 .....	\$45,000
Wright-Hargreaves .. . . .	180 .....	45,000
Tough-Oakes .. . . .	120 .....	40,000
Kirkland Lake .. . . .	130 .....	38,000
Teck-Hughes .. . . .	120 .....	35,000
Totals .. . . .	610 .....	\$203,000

The properties next in line are the Ontario-Kirkland and the Orr Gold Mines, the former of which has been developed to a depth of 450 feet and on which arrangements are even now being made to install a mill. The Orr Gold Mines has considerable gold in sight, but

has been held in idleness, being involved with the Kirkland-Porphry Company which has gone into voluntary liquidation because of trouble between the owning interests.

Other properties in the Kirkland Lake district which hold out big promise for the near future are the Bidgood Mines, Canadian-Kirkland, La Bell-Kirkland, etc.

This summarizes the properties in the Kirkland Lake gold area which are already on a producing basis or in an advanced stage of development. There are also a number of promising prospects about which the future will probably bring interesting news, with considerable likelihood of additional mines being developed from among them.

The Robb-Clemens claim, situated in Fort Matachewan, restaked recently due to failure of its owners to record the necessary assessment work, has been reveyested in the names of the original holders, it having been found that the failure to record the work rested with Messrs. Norrington and Smith who had the claim under option, and who had performed a large amount of work, which they had forgotten to record.

At the Peerless Gold Mines, formerly the Mondeau property of Boston Creek, some good values are being encountered at a depth of 250 feet. Assays range from a few dollars to as high as \$148 to the ton, the latter being across about four feet in width. While the average for the vein as so far opened up is far below the figure above given, yet a fair tonnage of good grade ore is stated to have been placed in sight.

#### Ore Shipments.

During the week ended June 17th, seven Cobalt companies shipped an aggregate of thirteen cars containing more than one million pounds of ore. The output was the heaviest for a good many weeks. The Nipissing alone shipped five cars containing approximately 447,241 pounds.

Following is a summary:—

Shipper	Cars	Pounds
Nipissing .. . . .	5 .....	447,241
Coniagas .. . . .	2 .....	173,797
Mining Corporation .. . . .	2 .....	130,301
La Rose .. . . .	1 .....	81,207
McKinley-Darragh .. . . .	1 .....	80,410
O'Brien .. . . .	1 .....	64,000
Dominion Reduction .. . . .	1 .....	64,000

Totals .. . . . 13 .....

1,040,956

During the corresponding period, no bullion was sent out, the reason for this being that the price of the metal slumped sharply about the middle of the week. Now, however, with quotations strengthened, shipments may soon be released.

Accompanying the current dividend cheque, an interim report on Hollinger Consolidated Gold Mines, has been sent out. The report covers the five and half four-weekly periods from January 1 to June 2 of this year. For the period covered by the report the total income was \$2,879,706 compared with \$2,822,858 in the same time last year. Total expenditure, including maintenance, showed slight reduction of \$1,448,020, compared with \$1,507,060. Net profits, therefore, were \$1,431,685 against \$1,315,798, or an increase of \$115,000. Expenditure for plant was \$83,363 compared with \$75,079 and the dividends were unchanged at \$738,000. The average tonnage per day showed a favorable production, reaching a total of 4056 against 3907.

**BRITISH COLUMBIA LETTER.****The Metal Mines.****Alice Arm, B.C.**

Lieut.-Col. S. R. Heakes, O.B.E., who prior to the war was the Manager for the Kerr Lake Mines, northern Ontario, is visiting the Alice Arm District. He is making an inspection of various mining properties of the section and will continue into the Portland Canal area before returning. His purpose is to obtain first-hand information regarding the mineral possibilities of different northern British Columbia camps on behalf of English clients. Col. Heakes asserts that English capital will be available to assist in the mineral development of this country as soon as the exchange situation rights itself.

The Toric Group of Mineral Claims, situated on the east side of the Kitsault River, are reported to have been bonded by John C. Pederson, one of the pioneers of the Alice Arm Camp. He obtained control from the original stakers and proposes commencing development this summer. It is understood that, in addition to further general exploration, diamond drilling is to be started.

**Hearthley Boy.**

The Drum Lummon Mine is keeping its mill, erected at tidewater, busy handling ore of good grade and it is reported that a considerable quantity of high grade ore is being sacked ready for shipment.

**Cranbrook, B.C.**

Mining men of Cranbrook are more than usually interested in the placer operations on Wild Horse and Perry Creeks. The Gamble Mining Co., whose holdings are on the former waterway, is said to have obtained good results already while on Perry Creek, where a local syndicate is preparing for work, the prospects are said to be quite as satisfactory.

**Greenwood, B.C.**

Dunnean McIntosh, one of the lessees of the Bell Mine, Greenwood District, reports that the mine work is continuing as actively as the shortage of labor will permit. However the men available are working in ore averaging 175 ounces of silver, 8 per cent lead and about the same of zinc. About 1100 feet of driving and crosscutting has been done and several good leads are exposed, three of which are being worked.

**Trail, B.C.**

Two new shippers have joined the list of contributors to the Canadian Consolidated Mining and Smelting Company's smelter at Trail according to returns for the first week in June. They are the Mountain Chief, the Renata copper property which shipped 423 tons last year, and the Monarch, of Field, which shipped 190 tons in 1919. Ten properties shipped exclusive of the Company's proportion. Receipts for the week were 5353 tons, making the total for the year 124,979 tons.

The Consolidated Mining and Smelting Company has engaged Wm. Forrest of High River, Alberta, to take charge of the Company's several farms situated in the vicinity of the smelter at Trail. Mr. Forrest takes up his duties immediately. It is understood that at present most of the land will be seeded in alfalfa but eventually it is proposed that the farms will

be well stocked and made to yield dairy as well as general farm products. This, it is presumed, is the Company's answer to complaints made in the past by independent farmers in the neighborhood of Trail that the smelter fumes made profitable farming out of the question.

The copper plant of the Consolidated Mining and Smelting Company is expected to resume operations about July 1st. Only one furnace is likely to be blown in at first, other units being added as the smelter feed increases. The converter, whose utility is the conversion of copper matte into blister, also will be started as well as the first division of the copper refinery. When the concentrating mill of the Canadian Copper Co., Copper Mountain, with its daily capacity of 2,000 tons of ore, begins contributing its concentrates the copper section of the Trail Smelter will be kept active as, in addition, it will have to take care of the product of both the Consolidated and of custom ores. The refinery, as enlarged, will be capable of producing daily some 100 tons of refined copper.

Work on the new copper rod mill, estimated to cost \$250,000, is making satisfactory progress.

The magnetic test mill, operated for sometime on Sullivan Mine Ores in competition with the Sullivan flotation mill, has been closed down and is being dismantled. While this method of treatment was not altogether unsatisfactory it is not deemed as successful economically as the Company's improved flotation process in application to the particular ores in question.

**Vancouver, B.C.**

Charles E. Camsell, for several years in charge of the British Columbia Station of the Canadian Geological Survey, has been appointed Deputy Minister of Mines for Canada, succeeding R. G. McConnell, who has resigned.

Mr. McConnell, who is 63 years of age and a native of Quebec, has been associated with geological research work in Canada for many years. In 1879 he worked as assistant to the late Dr. G. M. Dawson in Western Canada. He has explored much in the north, having traversed the whole or large portions of the Stikine, Liard, Mackenzie, Porcupine, Lewis and Yukon rivers. He is the author of numerous reports and monographs, his "Geology of the Rossland Camp" being regarded as a text book.

In Mr. Camsell the Canadian Ministry has found a worthy successor to Mr. McConnell and his appointment is particularly popular from Western Canadian mining men by whom he is well-known and without exception highly respected. He is a product of the West, having been born at Fort Liard, where his father was Factor for the Hudson's Bay Company. After graduating from the University of Manitoba Mr. Camsell wandered over the wilds of the north country for six years. His adventures and experiences during that period are the subject of an interesting sketch in one of the recent issues of the Canadian Mining Institute Bulletin (see page 496, issue June 18th, 1920.) Subsequently he took post-graduate courses in geology at Queen's and Harvard Universities. There followed a few years of private professional work after which he became attached to the Canadian Geological Survey.

The operations of S. J. Marsh, of the Cariboo Gold, Platinum Extracting Co., headquarters at Quesnel, B.

C., are being watched with interest by the miners of the Cariboo, as well as by those interested in placer ground throughout the Province. Mr. Marsh announces that he is in the market for black sand such as is found along the Fraser, Tulameen, Thompson and other rivers of British Columbia. This contains values of varying importance in gold and platinum and it is Mr. Marsh's claim that he has invented, and demonstrated in a practical way, a device for the economic extraction of these precious metals from the sand. The Plant necessary to set in motion this electrochemical process, as it is termed is reported to have been assembled at Quesnel. Sixty days are set as the time needed to prepare for operation. Mr. Marsh in its request for black sand of the character indicated, undertakes to pay or to guarantee 90 per cent of the assay value of the same. In order to assure the continuous operation of the Quesnel Plant he is installing on the Quesnel River, some twenty-eight miles above the town a drag-seine dredge equipped with a concentrating device designed to separate the black sand from the gravel.

### Victoria, B.C.

Henry S. Fleming, of New York, chairman of the Board of Directors of the Canadian Collieries (D) Ltd. has stated here that he proposes investigating the local conditions with a view to the establishment of an iron and steel industry. He proposes calling into consultation Hon. Wm. Sloan, Minister of Mines, and the mining engineers of the Provincial Bureau of Mines. That there is an adequate supply of magnetite, that there is no lack of fuel, and, in short, that everything needed for production is to be found in quantity in the Province is admitted by Mr. Fleming and the question to which he wishes to devote special attention is that of market. In this connection he said: "The whole thing narrows down to whether 325 tons of steel can be disposed of each day in this territory or produced at a cost that will permit of export. Our product will have to be manufactured into such products as billets, nails, wire fencing, etc. It is likely with the present high freight rates we will be able to hold our market here for such products. But my present problem is to find out just how much of these products this territory requires and can absorb."

Mr. Fleming also said that before a steel plant is built there will have to be assurances from the Provincial Government that there will be no eight-hour day restrictions or Sunday laws enforced.

The situation respecting the attitude of the men employed in the coal mines of the Province of Alberta was canvassed in the House of Parliament, Canada, recently when a mill proposing the continuance of the office of Director of Coal Operations, and the confirmation of certain orders of the said officer, was under consideration.

Answering strictures of Messrs. W. L. Mackenzie King and W. S. Fielding, leaders of the Opposition, who declared that by passing the measure the House would be declaring for the principle of the closed shop as far as the mine in question were concerned. Hon. Arthur Meighen, Minister of Interior, dwelt on the situation existing when the orders were issued. The closed shop, he declared, was better than the frozen home. Coal had to be mined. Further the Bill did not perpetuate the orders but merely gave authority to the Director of Coal Operations, who would vary the orders if found necessary.

It should be explained that the orders in question have to do with the employment of adherents of the One Big Union and of the extreme principles for which that organization is said to stand.

Speaking as a member of the mining district under discussion W. A. Buchanan, of Lethbridge, Alberta, said that the effect of the activity of the Director of Coal Operations had been the promotion of harmony between the employed and employer. Since the appointment an adequate supply of coal had been available, the mines having been operated regularly. He did not think, however, that the director should be permitted dictate as to what Union's members should be permitted to work in the independent mines of the Province of Alberta and he asked whether his orders had this wide application.

Mr. Buchanan was assured that the Director of Coal Operators had never assumed such authority.

On the whole the Bill appears to have met with approval and there seems to be no doubt that it will be endorsed.

The aerial tram of the Lone Star Mine, Greenwood, B.C. District, is being dismantled for installation of the Coalmont Collieries. It is six miles in length and in good condition. It is to be used in the transport of coal from the pitmouth on the north fork of Granite Creek down the hill to the railway.

James Gray, superintendent of the Harvard Coal Co., operating at East Princeton, B.C., reports that the colliery plant has been augmented by a modern screening system and that screened coal is to be shipped to Vancouver City where a good market is assured. Work is in progress on two seams of coal, one six feet and the other nine feet in width.

Vancouver business men have acquired the coal lands formerly controlled by the South Nicola Coal Co., near Nicola, B.C., and proposed to proceed with its development.

George Wilkinson, General Superintendent of the Pacific Coast Coal Mines, Ltd., states that Samuel D. Wark has been appointed to re-open the Company's mine at Suquash, Vancouver Island. This mine has been inactive since 1914. Mr. Wark will unwater it, restore ventilation, and put it in shape for production.

The coal production for the month of May, as far as the figures are available at the time of writing, is as follows:—

#### VANCOUVER ISLAND.

Canadian Western Fuel Co., Nanaimo . . . . .	52,193
Canadian Collieries (D) Ltd., Comox . . . . .	29,167

# MINE HOISTS—STEAM or ELECTRIC

We Build Your Hoist to Suit Your Mine. Whether it be Large or Small  
**LET US FIGURE ON YOUR HOIST**

Note the Strong, Massive Construction of this Hoist.

The Gears and Other Parts exposed to much wear are made of best quality Cast Steel, and the Gear Teeth are all Machine Cut, ensuring smooth easy running.

The best quality material is used throughout, with sufficient metal to give strength where strength is needed.

We supply any diameter Drum up to 48 inches.

The Depth Dial is adjusted to suit the depth of the shaft where it will be used.

The Hoist in the illustration has Reversing Gear and Friction Drive. We also build it with Drums Keyed Fast to Shaft so it cannot revolve in either direction except under power.

50 H. P. Steam Hoist, with 40" Dia. Drum.

NOTE—The above Hoist is built also for Electric Power.

## THE MINING AND RAILWAY ACTIVITIES OF THE LATE JAMES DUNSMUIR

(Abstracted from the Victoria "Colonist")

Although the Hon. James Dunsmuir carried on the undertakings connected with the family name since the death of his father in 1889, it was the late Robert Dunsmuir who inaugurated the great coal mining industry and amassed the nucleus of the big fortune which has descended to the present generation.

"What Lord Strathcona did for Canada on a large scale, the late Mr. Robert Dunsmuir accomplished for British Columbia," said one of his biographers some years ago. He was a Scotsman, and, possessed of the best traits of his countrymen, he applied these to the creation of large industries on a Vancouver Island. Coal mining and lumbering engaged his activities from the first, and he was the first man to take practical steps toward the opening up of this part of the Province when he built the line of railway connecting Victoria with the mines at Nanaimo. This involved no trifling expenditure, and the fact that he was prepared to make the financial venture indicated vast faith in the resources of this section of Canada.

The sailing vessel on which Mr. Robert Dunsmuir sailed from Scotland stranded at the mouth of the Columbia River while heading up the coast. The crew had heard of the discovery of gold in California, and deserted in a body. There was no alternative but for the passengers to go ashore. This was at Fort Vancouver, Washington, and while waiting for transportation to Victoria, Mrs. Dunsmuir, on July 8, 1851, presented her husband with a son. This was to be the Hon. James Dunsmuir, who inherited some of the best characteristics of his parents, being practical, hard-headed, thrifty, and endowed with a good fund of common sense. In later years he possessed the advantage of receiving direct instructions from the founder of the family fortunes, who was but twenty-six years of age when he emigrated from the Old Land, but who made his personality and aggressive business sense felt as soon as he landed on Vancouver Island. Mr. Robert Dunsmuir acted for many years as a mining expert at Nanaimo, in connection with the Vancouver Coal Company, which succeeded the Hudson's Bay Company. The famous Wellington mines were discovered by him in 1869, and from these developed the collieries which became known as the Wellington Colliery Company.

### Started at Nanaimo

James Dunsmuir spent his early boyhood at Nanaimo. He was the first white baby that the Indians in that part of the Island had seen, and their curiosity and interest in the child on one occasion led to his disappearance. A search resulted in the discovery of the little boy in the possession of one of the local tribes.

He was educated first at Nanaimo, where his parents lived during the time that the father was engaged in the coal mining operations there, and later he went to Hamilton College, a military institute at Blackburg, Virginia, where he met the lady who afterwards became his wife. When he returned to Vancouver Island he at once joined his father in the management of the coal mining business, which was already assuming huge proportions. Here he gained experience which in later years proved of the greatest practical value, working down in the mines with the men who were digging coal. As time went on the

management of the business passed more and more into his hands, and eventually he became excellently fitted to take his place as directing head of the great interests which involved coal mines, logging camps, steamships, etc.

Both his parents were endowed with forceful character. All the children in some degree inherited this, and in none of them was independence of judgment, initiative, willingness to work, desire to grasp the detail of business, more keenly apparent than in James Dunsmuir. He became intimately conversant with every department of the properties which came under his control, and even before his father's death his executive ability was very generally recognized throughout the Island, and, in fact, wherever the Dunsmuir interests reached.

### The E. and N. Railway.

The construction of the E. & N. Railway was undertaken in 1882. The road was opened in 1886 from Victoria to Nanaimo, a subsidy of \$750,000 cash being secured from the Dominion Government, and a land grant of two million acres being made by the Provincial Government. The entire interests were acquired by the Hon. James Dunsmuir in 1902.

The Hon. James Dunsmuir, on the death of his father and brother, became the greatest landed and colliery proprietor in Western Canada, and one of its richest men. As a coalmining operator he was in his element; as a railway manager and landowner he did not feel at home, and this fact accounts for his business policy differing from the usual standards in such matters. Being a single-minded man and simple in his ambitions, having no desire to go beyond that which he understood, he devoted himself to the firm's collieries. The presidency of the railway was simply an inherited obligation, and he had no taste for it. The development of the Comox coal mines, the coke industry in connection therewith, the opening up and development of the Extension mines, the establishment of coal bunkers at Ladysmith, and the freight ferry from that point to Vancouver were all of his initiation, and carried out under his direct supervision.

As incidental to the Extension mine he laid out the townsite of Ladysmith, now a substantial town dependent largely, of course, upon the size of the payrolls at Extension and the smelter. It was at first contemplated to build the coal bunkers at Chemainus, to which point the ferry would have run, but there was some difficulty in adjusting the price to be paid for land for the site of the bunkers, and Mr. Dunsmuir went to Oyster Harbor instead, a decision characteristic of the man. The Alexander Colliery was closed down in a similar way—the result of a strike—and Mr. Dunsmuir never afterwards opened it.

Shortly after Mr. Dunsmuir's resignation of the office of Premier of British Columbia, he decided to dispose of the E. & N. Railway. He had received various offers in that connection, but he was a firm believer in the C.P.R., not only in respect of its ability to make a deal in a satisfactory manner, but also he realized the benefits to be derived from that corporation entering the field on the Island of Vancouver. The first proposal was to sell the roadbed of the railway, and to retain the land grant and all its accessory rights, but it became apparent that the effect of separating the railway and the land grant was to subject the latter to taxation. Eventually the railway was purchased by the Canadian Pacific Railway,

minus the coal rights, fire-clay, etc., Mr. Dunsmuir devoting himself exclusively to his other interests.

Early in 1910 he gave an option on his collieries and coal rights in the E. & N. Railway belt, and all business in connection therewith, for \$11,000,000, which was acquired by Messrs. Mackenzie & Mann, railway promoters, and thus separated himself practically from all former business with which the Dunsmuir name had been prominently associated for such a long period of years.

### MINERALS SEPARATION COMPANY.

#### Mr. H. L. Sulman Replies to Criticism.

The owners of the Minerals Separation process of oil flotation has experienced much difficulty in obtaining royalties from those who use the process. Many users of flotation consider that the Minerals Separation companies have attempted to collect royalties to which they are not entitled. There have been many processes used that the Minerals Separation company claims are infringements. The difference of opinion has been ventilated time and again in the courts. The endeavor to obtain royalties has naturally resulted in much fighting and the Mineral Separation companies have shown a tendency to fight hard and long for their rights. Some users of the process have had so much at stake that they also have gone to great expense to prove that the company is not entitled to such royalties.

Aside from the disputes over the validity of the patents, there has also been much criticism of the form of agreement required by the Minerals Separation companies from those who are willing to use the process on the company's terms. The Minerals Separation companies are for these and other reasons not receiving bouquets from the American technical press.

During the war the Minerals Separation North America Corporation received further undesirable notoriety, from the fact that its predecessor in America had as agents the German controlled firm of Beer, Sondheimer and Co. The association with this firm was not likely to increase the popularity of Minerals Separation companies.

However it would seem that the unpopularity of the company is to some extent due to parties interested in avoiding the claims for royalties. At times it seems that the criticisms are ill founded and much overdrawn.

It is therefore interesting to read what Mr. H. L. Sulman has to say in the May issue of the Mining Magazine with reference to some of the recent criticism.

Mr. Sulman deals at some length with the remarks published in American technical journals in reference to his contributions on the Minerals Separation process and his connection with the Minerals Separation companies. He states that he is not a large shareholder in the companies, but that he has been and now is consulting metallurgist and that those in control have nothing to fear from their detractors. Mr. Sulman evidently believes that much of the criticism is not impartial. He says "a small section of the American technical press apparently has motives for attacking the Corporation, seemingly with the object of creating a volume of hostile opinion designed to have what effect it may upon the interests of the corporation in matters still awaiting final decision in the United States Courts."

—R.E.H.

### CHANGES IN CANADIAN FAIRBANKS-MORSE ORGANISATION.

Mr. C. J. Brittain, formerly Managing-Director of the Winnipeg, Calgary and Saskatoon Branches of The Canadian Fairbanks-Morse Co., Limited, has been appointed Vice-President and General Sales Manager of that organization, with headquarters in Montreal. Mr. Brittain succeeds Mr. C. Graham Drinkwater, who has been Vice-President in charge of sales for many years, and who has resigned to join the banking firm of Aldred & Company, Limited.

Mr. Brittain brings to his new post a wide experience of many years and a splendid record of achievement. He was one of the first salesmen engaged by The Canadian Fairbanks-Morse Co., Limited in the early days of the company and he has made good in every position to which he has been appointed. He has the entire confidence and hearty support of all those who know him, both in the organization and as customers.

MR. C. J. BRITTAIN

Mr. Kenneth Forbes, who has been Manager of the St. John, N.B. Branch, goes to Winnipeg to assume charge of that Branch, together with that of the Regina Branch, which is under construction at the present.

Mr. Forbes is succeeded at St. John, N.B., by Mr. W. J. Hill. Other changes in the management of the Sales Department—all of which represent well-earned promotion and increased opportunity to assume greater responsibilities—are the appointments of Mr. Malcolm Cordell to be Montreal Manager, and Mr. George L. Nies and Mr. Archibald Turnbull, who will become Managers of the Calgary and Saskatoon Branches respectively, taking up a portion of the duties which formerly came under the direction of Mr. Brittain.

The funeral of the late J. F. Whitson, of the Northern Development branch of the Department of Forests and Mines, who died very suddenly of heart failure in Sudbury last Saturday, took place in Toronto on June 14th. The late Mr. Whitson was connected with the Ontario Government for thirty years, and was well-known throughout Northern Ontario. Previous to his appointment as Commissioner of Northern Development in 1902, he was Assistant Director of Surveys.

Mr. J. G. Ross of the Milton Hersey Company, Ltd., Montreal, is examining properties in the Western States.

# THE PRINCIPLE THAT APPEALED TO ENGINEERS

## Simplified Reduction

When engineers learned that ideal step or stage reduction could be effected in a single machine—and the Hardinge Conical mill proved this by past performance—they knew it would mean a decided increase in production and a marked decrease in operation costs.

**AND IT DID!** The Engels Copper Company submitted three distinct repeat orders after using their first Ball Mill for 1 year. There is no greater proof of satisfaction.

Maximum production, continuous operation, minimum repair costs, decreased labor and operating costs are present wherever Hardinge Mills are installed.

## POWER ROCK DRILLS SHOWN AT WORK ON SOUTH AMERICAN BANKNOTES.

(By F. A. McLEAN).

A representative of the Ingersoll-Rand Company who returned from a business trip to the West Coast of South America a few months ago brought back with him two interesting souvenirs in the form of Peruvian bank notes bearing on their reverse sides reproductions of rock drills of the type manufactured by this Company, as may be noted from the accompanying illustration, which is somewhat smaller than the original.

The banknotes were engraved for Peruvian bank customers by the American Banknote Company of New York, whose name appears in English near the bottom of the bills. The value of the Peruvian Libra in our money is nominally \$4.86 2-3, the same as the English pound, although the present quotation in New York is about \$4.30. As it is unlawful in most civilized countries to photograph or make any work of reproductions of currency, permission had to be obtained from the Peruvian Government before photographic copies of the notes could be made.

Mining is the most important source of national wealth in Peru, and the use of a rock-drill upon the country's bank notes as a symbol of the mining industry is interesting as showing how widespread is the standardization of this type of modern mining equipment.

## EDITORIAL

### The Reasoned Optimism of Canadian Geologists

Two significant statements have recently appeared in print made by geologists who have a thorough knowledge of Canadian rock formations. Writing in "Canada," Dr. Miller concludes an article dealing with the occurrence of silver in Ontario by remarking: "When Ontario's resources become better known there is little doubt that further prospecting will lead to discoveries quite as wonderful as those of Cobalt." There is no person better qualified to form a judgment on this question than Dr. W. G. Miller.

Alfred R. Whitman, writing to Mr. C. G. Daimpre of Toronto, states "it is no longer debatable, but is an established fact, that the whole Canadian field consists of formation geologically favorable to the concurrence of rich mineral deposits." "It has long rankled in my mind"—writes Mr. Whitman—"that a people enterprising and industrious in so many ways as the Anglo-Saxons of today should so obstinately ignore and neglect an area so rich and immense, and so near to a dense and wealthy population as the Canadian North."

Chase S. Osborn, in the "Iron Hunter" wrote: "North of us lies the vastest unexplored territory in the world. I refer to the Dominion of Canada. It is rich, and where it is untouched by man it is clean. There is not a drop of unwholesome water nor any poisonous insects or reptiles between Lake Superior and the aurora borealis. . . . To young men of courage and resource the limitless North offers the cleanest fight in the World, and if you win, the fruits of victory are plenteous and satisfying."

Charles Camsell, the recently appointed Deputy Minister of Mines, some time ago revised Dr. George Dawson's estimate of the unexplored territory of Canada and concluded that one-quarter of the Dominion remains untouched by the prospector. He quoted Dawson as remarking in 1908 that the existence of so vast a stretch of unknown territory might be considered a reproach upon Canadians "as indicating a lack of justifiable curiosity towards what our country contains."

Mr. Camsell remarked: "That reproach still remains on us, and will continue so long as such a large proportion of our country remains unknown."

A glance through a year's issues of the "Canadian Mining Journal" will show how new is the knowledge of some Canadian mineral deposits, and how tantalisingly scant and inexact is the information that exists in regard to them. Descriptions have appeared in our columns of most promising finds of the precious metals in the pre-Cambrian rocks of the Upper Harricana River in Quebec, in similar formations in Northern Manitoba, and attention has been drawn to the richness of precious metal ores in Northern British Columbia. The discovery of salt at Malagash, Nova Scotia, and its association with potash-bearing minerals, more detailed information on oil possibilities, the occurrence of radium-bearing ores in Northern Ontario, and, in our last issue, Mr. de Lury's account of the detection of traces of tin in another part of Ontario, are at least suggestive, and indicate that a complete conception of the genesis and occurrence of mineral ores in Canada is only in the making. So far, our knowledge of these matters consists of disjointed and unconnected memoranda, and the patient labors of a few generations of workers, all too few for the territory to be covered—a territory only three parts known even at this date—adumbrate the appearance of a coherent whole, and the availability of a sufficient accumulation of recorded data to enable a new generation of geologists to build a completed structure that shall be worthy of the herculean labors of their pioneer predecessors and instructors.

The consensus of authorities quoted combined with the periodical recording of new mineral discoveries justify a continued optimism in Canada's future as a mineral producer. Indeed we may look for further important discoveries as more and more the accumulated store of geological records are drawn upon and as the search for minerals is increasingly guided by deductions based thereon.

### THE UNIONIZATION OF TECHNICAL MEN.

The letter from the Secretary of the British Columbia Technical Association, contained in this issue, will be interpreted according to the mentality, the economic training and the corporate affiliations of the reader, but its significant feature is that unionization of technical men is an accomplished fact in one province of Canada. The reference in the concluding paragraph to a "Canadian Technical Association" is probably prophetic in the issue of being an intelligent anticipation of coming events.

The meat of the letter is the clear-cut statement: "The primary object of this Association is the protection and advancement of the material welfare of its members." It fell to Dr. Turnbull's lot at the Vancouver Meeting of the Canadian Mining Institute to acquaint that gathering with the aims of the newly formed Association, and in doing so he emphasized service as the primary object. He stated that the Association did not want to adopt the trade union method of forcing concessions if they could be obtained in any other way. Between service to others and self-interest Dr. Turnbull suggested a midway path could be found, and concluded by advising those technical men who did not agree with the aims of the Association to "come in, and make it suit you." It is just as well to avoid ambiguity, and as we suggested in this column some months ago, while the British Columbia Association began by making "service" the keynote of its policies, it is useless to disguise the fact that the genesis of this association, and similar associations in other countries, is the necessity laid upon the technical men either to organize for self-protection, or suffer piecemeal disintegration of all their hopes and ambitions in life.

The increase of the material welfare by any body of men is an understandable aim, much preferable to any claim for consideration based upon public interest. Notwithstanding all the Christian virtues supposed to reside in self-abnegation, it is generally regarded as eminently proper that men should look after their own. It is a viewpoint that all can understand, and the British Columbia Technical Association has done the proper thing to declare its real objects so unmistakably.

At the same time there is much danger in undue emphasis of the statement that the technical workers constitute a "third class," the remainder of the public being composed of Labor and Capital. There is also very much to be said against the attempt to legislate the prescription of the status and practice of technical employment in such wholesale blanket enactments as the draft of the Professional Engineers Act which the British Columbia Technical Association originated and backed in its progress through the Legislature of that Province. Class consciousness is a thing that is very much overdone in these days, and it is a thing foreign to the mentality of the technical

worker, who is above all men an individualist and a solitary seeker of untrodden paths. A coercion of the individual, a standardization of thought leading to stagnation and lessened initiative, is an unavoidable accompaniment of class legislation and a too pronounced class consciousness. History abounds with examples of national culture that have declined and died because of the rigid division of the people into guilds, castes, priesthoods and classes. We believe the safeguard against such dangers lies in the emancipation of class legislation and a too pronounced class consciousness, and would therefore endorse the recommendation already referred to that technical men should join their own organizations and assist in guiding along proper lines a movement that is already important, and bids fair to become much more influential and widespread.

Science has no bounds. The influence exerted upon mankind by scientific workers will not be in proportion to their mutual organization, but will arise in the future as it has done in the past from the unknown and often obscure investigator who plays very little part in the active life of men and is often careless of material welfare. The impossibility of defining the indefinable will always militate against the formation of technical workers into a bourgeois class, and our intellectual classes will persist as a vivifying, and sometimes disturbing element in our national life.

A further responsibility devolves upon those who advocate the unionization of technical workers, namely, that by a process which can be seen in daily operation in Canada, policies may originate which will eliminate from the organization those who enter the ranks of the employer and those daring and ambitious souls who will run their lifecourse untrammelled and scorn direction from any course. Thus such an organization may tend to become mediocre in its composition, and it will devolve upon the leaders to prevent a lowering of professional attainments and the creation of a class that will be midway between the trades unionist and scientific workers of acknowledged eminence, and content to stay there.

### .. ONTARIO GOVERNMENT ASSISTING IN .. MARKETING ORE.

Development of the mineral resources of Ontario is making good progress in spite of unfavorable conditions. Better progress might, however, be made if those who develop properties could more readily obtain some return from the preliminary work. At present the producer of small lots of ore finds the cost of marketing very high. Consequently production of metals in Ontario is confined to a comparatively small number of properties, most of which have costly equipment.

From time to time there has been some discussion of the advisability of establishing Government stamp-mills

for the treating of gold ores. It has been pointed out that in Australia a very large number of men are able to market gold from their properties without building expensive mills themselves. One mill serves for many small producers and the miner is then somewhat in the position of the farmer who can sell his grain to the miller. Mine owners of this class in Ontario are not as numerous as they should be. There are many properties lying idle because they are commonly considered as individual properties that would have to bear the burden of costly plant, rather than as sources of ore for a customs plant.

At Cobalt there has been some degree of co-operation between mine owners in treating ores. The customs concentrator has proven of great help in increasing production. Sources of ore have changed, but the concentrator has been kept continuously in operation and many improvements made in treatment methods. The ore sampling works established by Campbell and Deyell and recently taken over by the Ontario Government has also served a useful purpose and seems destined to play a vital part in the development of a new phase in the mining industry in Ontario.

Since the Government took over the plant it has been put in better shape to meet the requirements of mine operators. A very considerable portion of the product of Cobalt is now sampled at this plant and the assaying done here is becoming more and more the basis of transactions between sellers and buyers.

A feature of the work now done at this Government owned and operated sampling plant that could be developed with advantage to small producers is that of assisting in the sale of ore sampled. The producer of small amounts of silver ore can now ship to the Government plant and have his ore sampled there and sold. As yet comparatively few producers have taken advantage of this means of disposing of ore; but a beginning has been made and many will be glad to learn of the Government's endeavor to assist in marketing ore.

#### CANADA'S FUEL PROBLEM.

The Interstate Commerce Commission of the United States has directed that after June 24th priority in car supply and preference in traffic movement is to be accorded to bituminous coal for trans-shipment to coastwise points. The intention of this order is to help the bituminous coal situation in the New England States and the vicinity of New York. Its effect will be to place a restriction, which may or may not amount to a complete embargo according to domestic needs, on the export of bituminous coal from United States Atlantic ports.

As under existing conditions of dependence on the United States for coal supply, Canada is, in this regard, merely an extension of the United States, it is necessary that whatever regulatory action is taken by

the Government of the United States in regard to coal distribution, must be adopted in Canada also. The Canadian Government has therefore conferred the necessary powers upon the Board of Railway Commissioners, a proceeding that seemed to offer the best way out of an immediate difficulty. Probably the country, as did Parliament, will approve of course taken and will agree that the Board of Railway Commissioners is the body best fitted to handle a situation that is so very largely a difficulty of transportation.

Nevertheless, the action of the Government is nothing more than a temporary measure to meet an immediately pressing situation, and it promises no security against the annual occurrence of a condition that is caused by a chronic fuel inadequacy occasioned by the non-development of our domestic coal resources.

Deserved recognition of the good treatment Canada has received from the United States was accorded by speakers on both sides of the House when the Resolution above referred to was under discussion, and several speakers hoped for a continuance of friendly relations between the two countries. This is something that all the sane people on either side of the line take for granted, but what has the question of coal supply to do with the international relations? Canada's fuel problem is her own, and can only be solved by Canadians. What we take to be the outstanding fact connected with the supply of bituminous coal in Canada is that the Canadian production has steadily declined year by year, whereas the production of the United States has rapidly mounted by annual increments of astonishing proportions.

The effect of increased exports of coal upon domestic supply in the United States has, we believe, been exaggerated. The fuel difficulty in the United States is a reflex of the neglect of railways and railway equipment in years past. The term "car shortage" includes many other deficiencies besides a numerical shortage of rolling stock. The output capacity of the coal mines in the United States has never been really tested because the bottleneck of transportation has always prevented them from achieving the maximum of production. In Canada the tonnage of coal that has been shipped to Europe is absurdly small when compared with the actual deficiency in production, and in Nova Scotia the whole of the tale is told when it is pointed out that the output capacity of the collieries is at this time 5½ million tons annually, and that in 1914 it was 7½ million tons. Similar comparisons could be made with regard to the coal production of British Columbia and Alberta.

If Canada would produce more coal there would be enough for our own domestic uses and a much greater margin for export than has ever been seen yet.

We would repeat the suggestion made in these columns last week, namely, that a permanent body should be formed to study the means by which coal production

can be increased in Canada. The basis for this unusual suggestion is a belief that unless Canada becomes self-supporting in bituminous coal supply she must, for obvious reasons, lose her national identity.

### WILL MAKE NEW GEOLOGICAL SURVEY OF COBALT.

Mr. Cyril W. Knight, Assistant Provincial Geologist, is now at Cobalt making a study of the geology of the camp for the Ontario Bureau of Mines. Mr. Knight was Dr. W. G. Miller's assistant when the first examination of the discoveries at Cobalt was made by the Bureau. He helped to make the preliminary map in 1905 and the larger scale detailed map prepared by the Bureau in 1906-07. He has since made some underground studies, and is now beginning a systematic examination of the area.

The development of the several mines at Cobalt has given much information that is not easily obtainable by outsiders. The several companies have learned much about the nature of the deposits since they began to work them and the information has been pooled to some extent. There is however much work to be done that is in the general interest and the Bureau is looked to for geological work that individual companies are unwilling to undertake. It is not unlikely that systematic study will result in the obtaining of data that will help in the search for more ore.

### CORRESPONDENCE

The Editor, Canadian Mining Journal.

Dear Sir,—Acting upon instructions from the Executive Committee of the Provincial Council of the British Columbia Technical Association, I append herewith a brief statement of the history and accomplishments of our organization, with the hope that it may be of some service in inaugurating similar organizations in other provinces of Canada.

The action of the Toronto Branch of the Engineering Institute of Canada in drawing up resolutions which were forwarded to their headquarters, asking that an organization upon similar lines to those of the B.C.T.A. should be formed, is a further reason for our venturing to write to you upon this subject at the present time.

No doubt you are aware of similar movements in Europe, such as the Federation of Professional Workers in Great Britain and also in the United States, such as the American Association of Engineers.

"Labor," by means of "Unions," is forcing up "Wages" for the "Laborer." "Capitalists and Employers" by similar combinations are raising commodity prices. Neither of these two great classes are interested directly in promoting the welfare of the technical worker. Unless some effective force is organized the product depending upon technical effort will continue to be appropriated mainly by the two organized classes. A nation-wide combination of professional workers is the only effective method of as-

serting that there is a third class whose rights must be properly considered. That the existence of this third class is rapidly receiving prominent recognition is indicated by the discussions that took place in the House of Commons at Ottawa on May 7th last, on the establishment of a National Research Institute in Canada. For example, Mr. Alfred Thompson, Member for Yukon, made the following statement (See House of Commons Debates, May 7th, 1920, p. 2229):

"Canada is rich in mineral resources—immensely rich—but in order to transmute these resources into commodities which the world needs, one thing particularly is required, and that is applied science. Industry you must have—you must have the intelligent artisan; you must have people in the country who have faith enough in its future to put their capital into manufacturing enterprises; but without science that labor and those manufacturing enterprises would not go very far."

The demand for applied scientists and researchers is greater than the supply. What price should be paid for our absolutely essential and primary commodity? Who is to dictate the price? These are questions that we alone can settle.

Many professional and technical organizations exist in Canada. The primary object of these existing organizations is essentially the advancement of knowledge. In February, 1919 a number of technical workers in British Columbia co-operated to form the British Columbia Technical Association. The primary object of this Association is the protection and advancement of the material welfare of its members. At the same time this protection operates to the benefit and service of the public by refusing recognition of the pseudo-technologist.

Our infant organization slightly over a year old has in our numerically small province, already about 500 members, with local branches at Vancouver, Victoria, and Cumberland. The membership consists of Civil, Mechanical, Electrical, Chemical and Mining Engineers, Chemists, Geologists, Architects, Naval Architects, University Professors and allied professional workers.

I enclose for your perusal copy of our Constitution, By-laws, list of members, together with our First Annual Report, and would particularly call your attention to the following results of our work:—

- (a) List of members to date.
- (b) The Professional Engineers' Act of B.C. This Act was based on the Engineering Institute of Canada Model Bill, and was fathered by the Engineers' Joint Legislation Committee. The delegates from the B. C. Technical Association, backed by the organization throughout the province, were very active in working for the passage of the Act.
- (c) The Architects' Act of B.C. Our Association was able to give valuable assistance to the Architects Committee in charge of the Bill (a number of whom were members of the B.C. Technical Association).
- (d) The Schedule of Minimum Salaries for Civil Engineers.

In addition, special committees have under consideration the preparation of scales of Minimum Fees for Civil Engineers, and also scales of Minimum Fees and Schedules of Minimum Salaries for Mechanical, Electrical, Mining and Chemical Engineers.

Notwithstanding the results already achieved, the Council and Members of our Association feel that our work is circumscribed and that only by the formation of similar organizations in the other provinces and the subsequent federation into a "Canadian Technical Association" can we all obtain the just recognition and dividends that our scientific knowledge and work demand. This will unquestionably react to the advancement of Canada and of our Empire by encouraging more of our youth to choose a scientific career.

We shall be pleased to have you consider our suggestion favorably and to make any enquiries of us that may be of assistance to you and ultimately to our mutual benefit.

Yours faithfully,

R. SNODGRASS,  
Secretary-Treasurer.

### MINING AND PREPARING DOMESTIC GRAPHITE FOR CRUCIBLE USE.

The United States Bureau of Mines has recently issued Bulletin 112, "Mining and Preparing Domestic Graphite for Crucible Use," by G. D. Dub and F. G. Moses. The work covered by this bulletin was undertaken in connection with the war minerals investigations of the bureau.

Before 1915 nearly all the graphite used in crucible manufacture in the United States was imported, chiefly from Ceylon, Madagascar and Korea. Little domestic graphite was used, that mined being chiefly employed for the manufacture of paint, lubricants, foundry facings and other purposes. Not only was most of the graphite imported, but also all the clay used in crucible manufacture, this clay coming from Klingenburg, Bavaria.

As a result of clay imports from Bavaria being entirely cut off by the war, crucible makers had to turn to domestic sources of clay. The clay problem was soon well in hand, it being found that domestic clays could be obtained that compared favorably with foreign clays.

The use of domestic flake graphite in crucibles, however, in proportions of more than 25 per cent. mixed with imported graphite was not attended with much success.

However, the domestic graphite mining and milling industry expanded rapidly under the pressure of war conditions, being aided by a request of the War Trade Board on August 10, 1918, that crucibles manufactured during the balance of 1918, should contain 20 per cent. domestic flake and 25 per cent. thereafter. At the end of the war there were 39 graphite plants in Alabama, 3 in New York, 5 in Pennsylvania, and 3 in Texas.

The graphite investigations of the Bureau of Mines covered three phases: (1) Field examination of the graphite deposits in the States mentioned, and a study of the methods used in mining and preparing graphite for market; (2) Experimental work on the concentrating and refining of crucible graphite to improve the quality of the product and lessen waste; (3) Experimental work in crucible manufacture to determine the properties of domestic flake and the maximum proportions that might be used without impairing the qualities of the crucibles.

The present importance of these investigations lies in the fact that the domestic industry, if it is to survive the competition of imported graphite, which can

be mined and prepared more cheaply than domestic flake, must rely on improved and more efficient methods of producing and preparing graphite. Also, for full extension of the market to domestic producers, crucibles made entirely of domestic flake or nearly all domestic flake, in combination with domestic clays, should be developed.

The bulletin mentioned above outlines the results obtained in the first two phases of the investigation.

The bulletin is in two parts; the first part describes the methods of mining and milling used, suggests a standard method of sampling finished graphite, and describes a rapid and convenient method of analysis developed at the Pittsburgh station of the bureau, which had been assigned the analytical work and microscopic work. The second part describes experiments on the concentration and milling of graphite, made at the Salt Lake City station of the bureau.

The experimental work on crucible graphite, which was assigned to the Columbus station, will be described in a separate bulletin to be published later.

Copies of Bulletin 112, "Mining and Preparing Domestic Graphite for Crucible Use," may be obtained free of charge by addressing the Director of the Bureau of Mines, Washington, D.C.

### ANNUAL REPORT OF THE NEW BRUNSWICK OIL COMPANIES.

#### Maritime Oilfields.

The report of Maritime Oilfields from October 1st to December 31st, 1919, states that there is a profit of £6,629, in which is included dividends still to be declared of 10 1-3 per cent., less tax, on the Six per Cent. Cumulative Preference Shares and 5 per cent., less tax, on the Ordinary Shares of New Brunswick Gas and Oilfields, Limited. There is a credit balance, including £400 brought forward, of £7,000, out of which, subject to payment of dividends of New Brunswick Gas and Oilfields, Ltd., the directors recommend a dividend of 9 per cent., less tax, on the Ordinary Shares, absorbing £6,237 and leaving to be carried forward £793.

#### DRILLING IN WEST DOVER OILFIELD, ONT.

Mr. F. H. Stover of the F. H. Stover Drilling Company, recently announced in Toronto that the 12-inch drive pipe is set in the Vacuum Gas & Coal Company's well in the West Dover field, and that the well is down 300 feet, and the 10-inch casing will be set at once, when drilling will proceed as quickly as possible.

The Vacuum Gas & Oil Co.'s West Dover well is situated 600 feet from Petrol Oil & Gas Co.'s No. 1 well, northwest toward the Union Natural Gas Co.'s wells.

Mr. Stover has contracts for five deep wells in the West Dover field.

The Steel Company of Canada has closed down its Hamilton Plant, and two thousand men are thrown out of employment, through coal shortage. The coal used in steel plants is bituminous, and not anthracite. Canada has no anthracite, and must depend on the United States for a supply of that not indispensable, although desirable fuel. Next to the United States, Canada has more bituminous coal than any other nation in the World, and it is bituminous coal that is obtainable in such inadequate quantities in Canada at this time.

# The Coal Mining Tradition of the British Empire

Presidential Address by Sir John Cadman, Before the  
Institution of Mining Engineers.

The British Empire is a world fraternity and the most influential League of Nations history has yet recorded. It was founded by the constant flowing-out from the British Isles of adventurous spirits who, with their descendants, have kept in touch with the land of their origin. The material link has been maritime trade, based upon the mining of coal in Britain, the exportation of manufactured articles with the aid of British coal, and the export of manufactures and of coal in steel ships made in British yards, bringing back cargoes of the produce of those countries where British emigrants have settled.

Wherever British settlers founded states they have emulated, and in some cases, through the opulence of their resources, have outstripped the British Isles in the production of coal and iron; and, in every case, their wealth and importance stands today in proportion to the production of coal and iron within their borders.

In Sir John Cadman's speech there is more than a hint that if decline should mark the future of the British Isles, it will occur because of lessened coal production, and the President of the Institution of Mining Engineers—the parent society of all British mining societies—is living up to the traditions of the race and the Institution when he dares to assess the probable effects upon the Empire of the failure of the British Isles in coal production.

We meet to-day under conditions that are very different from those which were with us last year. Happily the war is over, and although its ravages are still with us, and the irreparable losses we have sustained are ever in our minds, we rejoice that, with our gallant Allies, we have won a victory which will add another page of honour to the history of our Great Empire, and which we hope and pray may have established the peace of the world for many years to come.

In reflecting upon a subject for my Address, I experienced a difficulty, for there is a problem which has been so prominent of late to which I feel that I must refer, a problem which, however, has become so controversial and has raised such divergent views, that I am bound to confess I feel some hesitation in referring to it.

Realizing to the full the risks I am running, and by no means without a feeling of diffidence, I am going to ask you to allow me to direct your attention to that industrial problem which is exercising so much public attention to-day. And in doing so I shall endeavor to indicate the "big side" of the problem with which not only the coal-mining industry of Great Britain, but the whole Empire is brought face to face.

I am, therefore, going to preface my remarks by directing attention to the coal resources of the world, with a view to indicating the magnitude of the subject, and if possible also to draw attention to the poor prospect there is for our industrial future unless we broaden our views and realize our true position in relation to the world's coal resources.

It is so easy for us to become lost in a mist of internal differences, and to forget all that is terrible

The figures quoted by Sir John Cadman, which were compiled in Toronto by the 12th International Geological Congress in 1913, show that in estimated physical content Canada has sixty times more coal than remains in the British Isles. Such a statement is not, however, sufficiently revealing unless it takes into account the geographical position of the coal deposits and their physical characteristics, but it points distinctly to Canada as the successor of the British Isles in those essential industrial activities that have founded the Empire and knit it together. The burden of Empire is being shifted to Canada. In the light of Sir John Cadman's presentment is it too much to say that Canada's neglect to develop her own coal resources, her thoughtless policy of ease and dependence upon the United States for coal, our present defenceless and humiliating position, have far wider bearings than the present comfort of eight millions of persons in Canada? In a time of world-wide necessity, Canada is found wanting in an essential of national independence, and when world-tides are setting in new directions and it is most desirable that our young country should take these tides at their flood, we are reduced to impotence because our statesmen are unacquainted with the coal-mining tradition of the Empire which, to those who will read it, recites that naval, military and commercial competence all proceed from and are based upon coal.—Ed.

war has taught us. Never was there a time when the necessity for combination of effort should be more obvious to us, and never was there a time, moreover, when energy and enterprise were more necessary to the welfare and prosperity of Britain.

Let us consider then the estimated coal resources of the world, first of all in relation to their geographical situation, and then with regard to their proximity to industrial centres and their national grouping.

The figures shown on the map exhibited are taken from the *Coal Resources of the World*, compiled and published by the Twelfth International Geological Congress (Canada) in 1913; they include all seams from 1 foot in thickness and over, and down to a depth of 4,000 feet. The estimated reserves of the world, expressed in million tons, are as follows:—

	Million tons.
America . . . . .	5,105,528
Asia . . . . .	1,279,586
Europe. . . . .	784,190
Oceania . . . . .	170,410
Africa . . . . .	57,839
Total . . . . .	7,397,553

These quantities may be subdivided, in accordance with the various nationalities, as follows:—

	Million tons.
United States. . . . .	3,838,657
British Empire:	
Canada . . . . .	1,234,269
Great Britain . . . . .	189,533

Australia . . . . .	165,572
India . . . . .	79,001
British Africa . . . . .	56,849
New Zealand . . . . .	3,386
Newfoundland . . . . .	500
British North Borneo . . . . .	75
	-----
	1,729,185
China . . . . .	995,587
Germany . . . . .	423,356
Japan . . . . .	7,970
Rest of the world . . . . .	402,798
	-----
Total . . . . .	7,397,553

*Tonnage of Vessels of 100 Tons and Upwards.*

Country.	1886.	1906.	1916.	1919.
British	11,165,092	17,611,096	20,901,999	18,607,875
U. S.	2,083,002	4,241,589	6,148,861	13,091,773
Worlds				
total	21,507,856	37,554,017	48,683,136	50,919,273

It would seem that about the year 1923 the United States will have a tonnage equal to that of Great Britain.

Before I elaborate upon the foregoing figures, I should like to say a few words regarding the conditions of production and consumption of coal as an article of wealth.

It will be observed that our resources are distinctly limited, and it may be assumed, with our limited knowledge of the nature of any new source of power, that, compared with any other nation, dearth of coal to this country must mean national ruin.

Enough has been said elsewhere as to the gigantic increase in the population of this country during the past centuries, of the increases in our exports, in all commodities, and of the increase in those areas comprising the British Empire.

But when we consider what have been the factors at work which have made this British Empire, we are forced to no other conclusion than that it is due to the growth of our coal-driven industries and the liberation of human energy.

I do not propose to touch upon this latter phase other than to say that no matter to what extent the enlightened policy of liberty which crept into Europe at this date, has played a part in our general prosperity, it would have been impossible to attain the position we enjoy to-day if it had not been for the power we possessed in our coal resources.

Now, what are the particular aspects of the question that are exercising the minds of thinking people in Great Britain to-day? There is great industrial unrest, a persistent clamoring for better conditions and better wages on the one hand, and for profits and freedom from Government control on the other. So violent did this controversy become that the Coal Industry Commission Act was introduced, and for the purpose of considering the question from every standpoint a Commission of Enquiry was appointed on which sat some of the most violent and vociferous members of each school of thought.

For a time, at any rate, it has afforded some relief to the tension under which the extremists were labouring. Many important points have been considered, but in the deliberations that took place the large aspect of the problem remained in obscurity, and the published proceedings of the enquiry can hardly be said to have added dignity to the parent coal industry of the world.

No sane person will deny that modern civilization requires better living conditions for all; no experienced observer, moreover, will fail to deplore the paucity of capital development into which a great many of the collieries of the country have dropped; nor will he allow his scientific mind to be satisfied with the extravagant waste of fuel that takes place in almost every industrial and social organization in which coal is used.

At this juncture, when the facts are staring us in the face, and when the nation's industrial existence is in peril, it is lamentable to see such an exhibition of feeling.

Although these figures are only approximate estimates, the basis on which they have been compiled is the same, and for comparative purposes they are of great interest and value.

It will at once become evident that if the potential value of coal resources is a measure of a country's industrial wealth, the United States of America, China, and Germany, with their stupendous reserves, will last longer in the industrial race than the United Kingdom, but that the British Empire taken as a whole, with her resources scattered about the world, is nevertheless in a position of considerable strength.

Let us examine now the rate at which these reserves have been depleted. It is significant how the order of annual output by nations is arranging itself gradually in accordance with the relative potential magnitude of each country's total resources.

These figures are very striking, for they indicate that for a short period prior to the war the output in the United States of America had increased at an annual rate of 6 per cent, Germany 4 per cent, China 3 per cent, and Great Britain 2 per cent. And it is clear, moreover, that unless some new source of power be discovered, the dominant industrial position will continue to move westward.

It should be observed that Great Britain has occupied a unique position in the past, in that her coal-fields are distributed within easy reach of the seaboard, and that as the coal merchant of the world she could place her surplus coal into ships with a facility not possessed by any other nation. With the growth of railways however, this natural advantage is by no means as great as it was. As some indication of the change in this respect, and indeed as an indication of the coal-using capacity of various nations in their industrial development, the railway mileage of some of these countries may be cited; and for this purpose the following figures are of interest:—

Country .	Date opened.	Miles of Railways.		
		1840.	1906.	1916.
United Kingdom . . .	1825	1,857	23,063	23,701
Germany . . . . .	1835	341	34,563	37,894
France . . . . .	1828	....	24,755	32,030
Canada . . . . .	1836	16	22,452	38,604
Japan . . . . .	1874	....	4,783	5,856
China . . . . .	1883	....	....	6,109
United States . . . .	1827	2,818	222,340	259,705

It is, moreover, instructive to examine the shipping tonnage, as recorded in Lloyd's Register, which again may be taken as a measure of a country's industrial capacity:—

What does this state of affairs reveal? It reveals a lack of organization in the industry as a whole, as well as a total ignorance of the rocks towards which we are slowly drifting.

A diminishing output is slowly having a serious effect upon us, and is indicated in the following figures:—

<i>Total Coal Produced Per Annum Per Person Employed</i>				
Year.	United Kingdom.	Canada.	Australia.	United States.
1886	312	341	333	400
1900	298	457	426	494
1906	275	439	462	596
1912	244	472	542	660
1916	263	471	547	731

The cause of this diminished production will be found in the increased difficulty of working the coal—not in an absolute sense, for there are probably no mechanical difficulties within very wide limits which ingenuity cannot surmount—but in relation to the ease of working other coalfields to which our own have been, and in some cases still are, superior, but which are gradually gaining on us as our mines become deeper and their more accessible.

There has been much speculation as to the real cause of this diminished rate of output, and it has been said that a policy of restriction of output has been introduced and encouraged by the workers. I have never seen any tangible evidence of such a policy, and I do not believe it to exist; nor do I believe for a moment that the great body of workers in this industry, with their great traditions behind them, are capable of any such policy.

As I have indicated, the deeper the coal has to be drawn, the farther it has to be carried to the shaft and the less must become the output per man unless there be at the same time a progressive and organized introduction of mechanical appliances and better conditions that will enable the human factor to be utilized with greater efficiency.

It seems to me that we must produce cheap coal. By "cheap," I mean relatively cheap, as compared with the ruling prices of the world; and there must be a large surplus for export: for when our coal becomes scarce and dear, as it is temporarily to-day, the world will not adapt itself to our convenience, but will buy elsewhere.

As we know to our cost at the present time, rising prices for coal mean rising prices for every article consumed by the miners as well as by the people; furthermore it is obvious that with the high price of coal, pressure must be exerted continuously to secure the highest wages for the workers. And as ill-paid and discontented workmen generally mean inefficient labour, one is bound to recognize that the real remedy for the production of cheap coal does not lie in curtailing the wages of the workers.

The remedy lies in every section of the industry realizing that the only way in which this country's industrial position may be maintained is by increased efficiency on the part of every human unit in it, by more efficient use of plant and materials, by greater care in the way coal is made use of in the various manufacturing industries and in domestic life, and by the export of greater and greater quantities of coal.

If England does not wake up to the recognition of

these fundamental essentials, she will assuredly be relegated to a position amongst the nations of the world very different from that which she occupies to-day.

So long as Great Britain continues to share in the great commerce of the world, so long will her coal-consumption and her output increase.

It is absolutely necessary that every advantage in the way of greater economies of motive power should be converted into capital to be devoted to the further development of the industry; and this applies not only to our collieries, but to every other industry as well.

It is unnecessary for me in an Address of this character to labour the fact that so little of the heat value contained in coal is utilized. It is well known that from 25 to 50 per cent of the total quantity of coal at present consumed can be saved and still the same amount of heat or power be generated. And in the discoveries still to be made in the better utilization of fuel, it is imperative that we should not wait for other nations to give us the lead. We must stimulate the Watts and the Murdochs among us, and must be lavish almost to the degree of the spendthrift in our investment in research, whether it be from the national or from the private purse. The coal-mining industry of the country has still much to do in this direction, and it is regrettable that the enlightened policy entered upon by the Doncaster coal-owners, under the able guidance of Dr. J. S. Haldane, and more recently by the Lancashire and Cheshire coal-owners, under the presidency of Mr. R. A. Burrows, has not been followed in other coal-mining centres.

It is in this direction that the solution will be found, rather in wrangling over such hypothetical discussions as to the merits or demerits of nationalization.

I do not wish to imply that considerable progress has not been made in the direction of economy in fuel: there are many industries in which great strides have been made. One has only to look at the progress in blast-furnace practice and in the development of the steam-engine. The excellent paper contributed by Messrs. Hill and Cork\* indicates what has been done in this district.

It is not unnatural that nationalization should be suggested at this period of our existence, and we must not dismiss the suggestion and dogmatize as to any hidden motive which has stimulated those who advocate it, for I believe that they are sincere in their belief that it is a simple remedy and an easy way of meeting the tide of circumstance and the difficult national conditions with which we are faced.

I say it is not unnatural that such a proposal should be seriously advanced to-day. We have become so accustomed to Government control in the everyday affairs of life during the war, we are so inured to the establishment of new State departments and to new controllers, that the invasion of what were formerly regarded as the rights of the individual no longer shocks or alarms us. The various functions which it is suggested that the State should undertake in industrial and domestic spheres have assumed truly staggering proportions.

If, however, we reflect on what such State control will involve, we shall realize that it would convert the State into a trading concern and, sooner or later, would involve us in international complications which

\* Trans. Inst. M.E., 1918-1919, vol. lvii., page 177.

could only increase the risk of war. We should, in fact, be emulating the example of Germany, whose method we have learned to despise.

In business it is absolutely necessary to act promptly, to have a free hand, and take risks, and we know that with the most efficient Government department and the very best-intentioned of civil servants such conditions are impossible.

A department of State, constructed under our present Government machinery, must err on the side of safety. With the possibility of public disclosures resulting from mistakes, no business could exist which had to compete in the markets of the world.

Another and most important factor presents itself to the student of this problem. The State, occupying as it does a detached and impartial position, must bring its power into play in the settlement of industrial differences, and, in order to perform this function impartially and honourably, it cannot itself be the controlling authority.

I am almost tempted to think that it would be better for the prosperity of this country if the coal-owners and miners were to combine and form a gigantic trust, so as to stimulate the output and an ever-increasing export of coal, and thus ensure to Great Britain the retention of her place as a seller of coal to the world.

If by maintaining a high price of coal in this country the population could be impelled to find ways and means of using more effectively the heat values contained in the coal, it is conceivable that even this drastic policy might ultimately be to the national advantage.

If the great traditions of the coal-mining industry—an industry of which the country should be justly proud, an industry in which all that is noble and good in the human characteristics of the race has been so conspicuous for centuries—is to count for nought, in Heaven's name let us prepare for our gradual decline under the cloak of nationalization.

In my remarks to you last year I pointed out the vital need there was for all of us to pull together in harmony and work in the closest possible co-operation if we were to secure that victory which we were determined should be ours.

These words I might repeat to you to-day, now that the victory is ours and peace is with us again. There is as great a need as ever at present for that spirit of co-operation and comradeship in the whole of our organization.

The solution of the problem appears to me to lie in a better understanding and a fuller co-operation between all those engaged in the mining industry. We must do our utmost to get rid of misunderstanding, and eliminate the causes of labour antagonism and dissatisfaction. There must be personal as well as collective interest in the prosperity of the industry, and a real and sincere spirit of co-operation among everyone concerned. We must also be thoroughly awake to the need for greater efficiency in our methods and a more complete utilization of the heat values contained in our coal. There must, moreover, be a full realization of the fact, which none of you, I am sure, will question, that this problem is one which stretches far beyond our own shores, and in which is involved the future prosperity—nay, the very destiny—of our country; a realization, too, that our own existence is merged into that of a Greater Britain and

that through the combined coal resources of the Empire we may still hold a leading place in the intellectual and industrial development of the world and bring peace and happiness to millions of its peoples.

### THE WORLD OUTPUT OF OIL IN 1919

"Petroleum Times," of London gives the world output of petroleum in 1918 and 1919 as follows:

	1919 (In barrels)	1918 (In barrels)
United States . . . . .	377,719,000	355,927,716
Mexico . . . . .	87,359,436	63,828,327
Russia . . . . .	34,284,000	40,456,182
Dutch East Indies . . . . .	15,780,000	13,284,936
Roumania . . . . .	6,352,929	8,730,235
India . . . . .	8,453,800	8,000,000
Persia . . . . .	8,320,000	7,200,000
Galicia . . . . .	6,255,300	5,591,620
Peru . . . . .	2,560,000	2,536,102
Japan and Formosa . . . . .	2,120,500	2,449,069
Trinidad . . . . .	2,780,000	2,082,068
Egypt . . . . .	2,548,000	2,079,750
Scotland . . . . .	2,048,000	2,032,000
Argentina . . . . .	1,504,300	1,321,315
Germany . . . . .	925,420	711,260
Canada . . . . .	220,000	304,741
Venezuela . . . . .	245,300	190,080
Italy . . . . .	38,254	35,953
Other countries (appr.)	25,000	20,000
Totals . . . . .	559,539,239	516,801,354

With reference to Canada's contribution the following curious editorial comment is made: "..... "It must come as somewhat of a regrettable fact that Canada's production is on the down grade. Here, recent events leave favorable impressions, but we think that until the Dominion's shale reserves are commercially tapped, the Dominion can do little to supply the enormous demand which exists within its own borders." Unless there is a very widespread misapprehension among Canadian geologists it is a little too early to conclude that Canada's oil reserve is all contained in the oil-shale deposits of Nova Scotia and New Brunswick. It is also evident that London opinion attaches greater value to these oil-shales than has been accorded to them by Canadian investors.

### NEW BRUNSWICK GAS AND OIL FIELDS

The report of the New Brunswick Gas and Oilfields for the period from August 1st, 1919, to December 31st, 1919 states that the gross revenue amounts to £40,773, and the net profit, after debiting against revenue all well sinking and deepening costs, except the cost of well 52 situated outside the area of the Stony Creek Field, is £18,670, to which add balance brought forward, £25,921, making together £44,591, out of which the directors have carried to general depreciation fund £15,235, bringing it up to £21,235. A dividend of £10. 6s. 8d. per cent. on the Preference Shares will complete payment on the cumulative preferential dividend to December 31st, 1919, including arrears, and the directors accordingly recommend the payment of same, less tax, together with a dividend of 5 per cent. (less tax) on the Ordinary Shares, leaving to be carried forward £17,810.

# The Mineral Resources of Alberta

First Annual Report to the Mines Branch of  
Alberta, 1920.

The Province of Alberta has issued a first annual report on mineral resources made by Dr. John A. Allan, Professor of Geology in the University of Alberta. As stated in the letter of transmittal, the Report, being the first of its kind published by the Provincial Government, is largely a compilation of the information published to date by the Geological Survey and the Mines Branch at Ottawa. About four weeks was spent by Dr. Allan during the summer of 1919 in making a general field survey of some of the mineral deposits, chiefly those containing iron and salt, the observations then made being included in the Report. The eighteen different minerals of economic importance known to exist in Alberta are listed, and the individual occurrences are referred to in detail.

The minerals are: Bitumen, building stone, clay, coal, copper, gold, gypsum, iron, lead, mineral springs, natural gas, nickel, petroleum, phosphate, potash, salt, tale, and zinc.

In order of economic importance these occurrences may be listed as coal, natural gas, clays and bitumen, the remaining minerals being present only in small quantity, or of potential value only, in default of more exact information. The most interesting possibilities are the occurrence of petroleum and the possible association of potash bearing minerals with partially known occurrence of gypsum and salt. The impression is to be gathered from reading the Report that as yet very little is known about the far northern portion of Alberta.

The Report is a fair and discriminating statement of the mineral resources of a province that has hitherto been chiefly interested in agriculture, and has only recently acquired the urban population that requires the development of minerals, or that concentration of capital that renders mineral development possible.

Very little space is given in the report to the coal deposits of Alberta but it is not necessary to be loquacious when it is possible to preface the chapter on coal with the statement that: "Alberta contains 17 per cent of the coal reserves of the world, and about 87 per cent of the coal reserves in Canada."

Whether Alberta's other minerals will prove to be large in quantity and valuable in themselves, the present state of knowledge of these deposits, as disclosed by the Report, will not permit of judgment at this time but their economic value will be relatively greater because of the proximity of so large a supply of bituminous coal. Speaking superficially, and basing the statement on what is admittedly only a superficial survey of the mineral deposits of Alberta, we believe that this province will some day be the seat of great chemical industries, having as their foundation the availability of coal in great quantity. The occurrences of salt are particularly interesting in this connection, and money spent on proving the occurrence of mineable salt, or sources of brine, will be well expended. A Calyx drill, to test the presence of salt, is being put down by the Provincial Government in the vicinity of Fort McMurray and definite information is expected to be obtained early in 1920.

The chapter on iron-bearing rocks disposes of some

fairy tales, and indicates that as yet no commercially workable deposits of iron-ore have been found. On the Sheep River, south-west of Okotoks, the presence of billions of tons of iron-ore has been reported in newspapers, but the Report states "not a single ton of rock exposed in this section would be classed as iron ore." Dr. Allan, quite rightly, remarks: "I wish to emphasize this point, that steps should be taken at once to prevent the circulation of such an erroneous report, which is most detrimental to the industrial welfare of the country when the facts are known."

Alberta should be very careful in the matter of iron ore. This material is of all raw materials dependant as to relative value upon location and the proximity of coal. A very lean ore within economically transportable distance of coal deposits is relatively of greater importance than rich ore situated at points remote from coal supply. The iron-bearing rocks of Alberta, so far as now known, are, according to report, disappointingly small in quantity and meagre in content of iron, and it may be that iron ore will have to be imported into Alberta, because one thing is very certain, namely, that wherever there is found a large deposit of bituminous coal of coking quality, there will be brought the ores necessary for metallurgical industries, of which iron smelting and steel manufacture is chief.

The mineral deposits of Alberta have a possible value out of all relation to their present commercial exploitation, and it would seem that there are some local problems that require to be solved before proper use can be made of the minerals of the Province. For example, the clays present difficulties in the drying stage of brick-making, and, as stated in the Report, "further investigation and experimentation on the physical properties of the raw material are urgently required before the manufacturer can be induced to operate on these resources." Similar problems are associated with the utilization of the bituminous sands on Alberta.

The Province is to be congratulated on the publication of this Report, marking, as it does, a stage in the development of Alberta, and that forward step on the historical road of human culture always signalized by the addition of mineral and metallurgical pursuits to agriculture.

Many of the problems of Canada, particularly the apparent conflict between the agricultural interests of the West and the manufacturing interests of the East, will disappear as Alberta comes into her own as the industrial centre of Canada, an evolution of the future that is predestined. As the flower is contained in the bud, so is an industrial dominance in Canada assured to Alberta through the possession of the greatest fuel concentration in North America. Coal she has beyond any doubt, and oil she may have, although that is not yet a demonstrated fact, and, sooner or later, Alberta will become dominant in industry, in population, in finance, in political influence and material power, as is the destiny of any country rich in coal beds and populated by a civilized and virile people, particularly if it is surrounded by a territory unprovided with coal resources.

**SILVER IN ONTARIO.**

By Dr. W. G. MILLER in "Canada."

The first great precious metal area discovered in North America east of the Rocky Mountains was that of Cobalt, Ontario. Prior to 1903, when this area was found, both gold and silver mines had been worked east of the mountains, but none of the fields were of first importance, and the belief had grown up that the precious metals in quantity were only to be found in the United States and Canada in the mountainous regions of the West.

The discovery of Cobalt has attracted attention to the many little-prospected regions that occupy a large part of Canada in the east and north. Silver veins were discovered at Cobalt in 1903, during the building of the Ontario Government railway—the Temiskaming and Northern Ontario. Owing to the fact that there was little real prospecting in the area at that time the discovery attracted little attention, and although Government officials, through publication, made the discovery known to the world, the public took little interest in it for a year and a half. The belief was strong that Ontario was not destined to become a great precious metal producer. Gradually, however, the value of the area came to be recognised, and by the second half of 1906 Cobalt was the centre of a great mining boom. The companies floated had an aggregate capitalisation of nearly £100,000,000. Of course, many of them were what are known as "wild cats," but a number of them have paid large dividends. Some, indeed, have paid in dividends two or three times their capitalization.

**Four Metals.**

The veins of cobalt are narrow and contain values in four metals, which, in order of their economic importance, are silver, cobalt, nickel, and arsenic. Since 1907, when mining began, the area, with two or three small outlying ones in the district, has produced about 300,000,000 ounces of silver. The value of the other metals produced there, especially that of cobalt, has also been large.

As regards the metal cobalt and its compounds, the mines of this area now absolutely control the world's markets. It is a curious fact that Ontario should have a monopoly not only of this metal, but practically all of the sister metals, nickel and arsenic. Both are necessities in modern metallurgy, especially in alloy steels.

A striking fact about the production of the Cobalt area is that about one-half of the receipts from the sale of ore have been paid out in dividends to the stockholders in the mines.

The Cobalt deposits, as a whole, require little capital to work them. One of the first men to begin work expended a total of \$2,500 on labor, buildings, mining tools, etc., and produced ore that sold for \$250,000.

The greatest production in the area was in 1911, when over 31,500,000 ounces of silver were produced. Although the production has declined since then, the value of the output during the last two years, owing to the rise in the price of the metal, has almost equalled that of last year of maximum output.

The silver deposits are not confined to the marvelously rich area in the vicinity of the town of Cobalt is shown by the fact that important discoveries have been made at 12 or 15 miles to the north-west, at Gowganda. In the last-mentioned area a very rich

mine is being worked. It is believed that discoveries of silver ore will continue to be made in this part of Ontario for years. When the veins are not exposed at the surface, prospecting is difficult. It is necessary to trench through the soil to the compact rock beneath. Most of the veins have been found by this method. Other veins have been found only by underground workings, as they do not come to the surface of the rock.

Cobalt lies within a few miles of Lake Temiskaming, which has a length of about 60 miles and is an extension of the Ottawa River, here forming the boundary between the two Provinces of Ontario and Quebec. This river was a great route for travel by the earliest explorers and Jesuit missionaries in this part of Canada. On the shore of one of the bays on the north side of the lake is a rather striking outcrop of lead ore. This outcrop was doubtless seen by the earliest explorers as they paddled their canoes northwards, following the shores of the bays for protection from wind and wave. On a French map, published in 1744, and based on a still earlier one, the bay is marked "Bay of the Mine," or "Anee a la Mine." That the Cobalt mines, only a few miles away, were not discovered till the building of the railway, nearly 160 years later, is a striking confirmation of the belief held by many of the best-informed Canadian mining men that great discoveries will be made in the unprospected regions of the Dominion.

**An Interesting Speculation.**

Had the Cobalt area been discovered during the French period, prior to 1756, the whole political complexion of North America would likely have been changed. The richness of the deposits and their general character would have enabled them to have been worked at a huge profit even in those days. The Ottawa River afforded a fine transportation route, and labor and most supplies were cheaper at that time than they have been during recent years, while the price of silver was high. The discovery of the Cobalt area at the beginning of the eighteenth century would naturally have led to the French coming to Canada in much larger numbers, and the likelihood is that they would not have lost the country in 1756. On the other hand, the New England colonists, with large additions to their numbers from the Homeland, might have swarmed into what is now the Province of Ontario and wrested it from the French at an earlier date. Then, if events had occurred as they did in 1776, when the United States detached herself from Great Britain, Ontario and the surrounding region would probably have become part of the Republic. In either case, owing to the large incursions of French or of English colonists at that early date, it is safe to say that the great riches of Cobalt would have had a lasting influence on the destiny of what has come to be called the Dominion of Canada.

When Ontario's resources become better known there is little doubt that further prospecting will lead to discoveries quite as wonderful as those of Cobalt.

Mr. Harrington, the Fuel Controller of Ontario, recommends as a solution to our national fuel problem that Canadians should dig for coal in Canada. Reams have been written, and many pages will still be written on this question, but when all is said and written, Mr. Harrington's terse advice will be found to point out the only way.

## Our Northern Ontario Letter

### THE SILVER MINES.

The first half of 1920 closes another favorable period for the silver mines of Cobalt. During the six months, the production of silver, according to preliminary estimates, amounted to around \$5,500,000. Added to this is a considerable amount of cobalt-oxide and cobalt metallies which brings the value of the whole up to not far under \$6,000,000 for the half year.

During the past week, some 140 members of the National Editorial Association of the United States were the guests of some of the leading mines of Cobalt. They were shown the standard methods of mining and metallurgy, following the silver as found in its native state through the process of treatment until actually run out in bars.

The Nipissing Mining Company has declared a dividend of 5 per cent., payable July 20th and amounting to \$300,000. This means a total of \$1,200,000 paid so far during the current year, making an aggregate of \$21,540,000 since the company first went on a dividend-paying basis in 1906. It is also announced that the cash in bank, Canadian and United States war bonds, ore in transit, etc., amounts to upwards of five million dollars, the highest point so far in the company's history and thus indicating earnings considerably in advance of the present large rate of dividend disbursements. A feature in connection with the standing of the Nipissing is that the 1,200,000 shares issued, are in the hands of more than 13,000 shareholders. This goes to show how widely are being distributed the earnings of the company.

Following last week's announcement in the "Journal" that a re-survey of the geology of the Cobalt silver area would be made this summer by the Ontario Bureau of Mines, it is now interesting to note that Cyril W. Knight, Assistant Provincial Geologist is already on the ground and has commenced this very important work. The task is perhaps one of the largest ever undertaken in this district, in connection with geological survey work and may occupy about six months. When completed, however, it will consist of an assembly of up-to-date data of great value to the owners of property in the district.

It is announced that the capitalization of the Victory Silver Mines, owners of the old Hylands property, has been increased from \$500,000 to \$2,000,000, being divided into 2,000,000 shares of the par value of \$1 each. It had formerly been planned to consolidate the Victory property with the Adanac, but this plan did not materialize, and the Victory Company is now planning to proceed with a comprehensive development program. The geology is favorable, and there appear to be excellent chances of commercial deposits of silver.

The Ruby Silver property, situated near North Cobalt, in the township of Bucke, has commenced work in a small way, having been idle since 1907. The shaft of 56 feet has been de-watered, and arrangements are being made to carry out a limited amount of underground work. A large calcite vein is in evidence, in which medium grade silver values occur, while a narrow pay-streak is found along one side of the vein.

Work has been suspended on the Bartlett property in the Gowganda district, it having been decided to await better transportation facilities. The property has been worked quite steadily during the past several years.

The possibility of work resuming on the Aguinico property in Bueke township is reported. It is thought possible to mine the large deposits of cobalt at a profit, and any work to be done would have this object in view. One of the strongest cobalt veins in the district occurs on the Aguinico.

Criticism of the Ontario Government has been volunteered by mining men interested in the Gowganda district. It arises from the fact that the crushing equipment with which the construction of a macadam road was commenced to the camp last year is now being removed. The equipment was assembled at considerable expense, and work had just gotten well under way when winter arrived. While no official announcement has been forthcoming from the Government, it is presumed that the removal of the equipment is due to a charter having been granted to the Northern Light from Elk Lake to Gowganda. As to this, the mining men point out, that unless the Government has received a guarantee that such a railway will actually be built, the decision to leave the mines of the district at the mercy of the fortunes that are to attend the efforts of the promoters of the light railway project to finance the enterprise is not good business.

An effort is being made to introduce "Thompsonite," a comparatively new blasting powder, into more general use in Cobalt than formerly. Its manufacturers claim the explosive has a greater breaking power and gives off less gas and smoke than other blasting powders in common use.

The Appellate Division of the Supreme Court of Ontario delivered judgment June 25th in the case involving the correct location of the boundary between the Violet property of the La Rose and the O'Brien Mine. The judgment declares the O'Brien is entitled to possession of everything west of a straight line from the No. 4 post of the Colonial property "To Shaw to Earle". An injunction is accordingly given against the La Rose trespassing past that point, with damages. No costs are imposed against either party.

The judgment is a reversal of the decision of the lower Court.

### Ore and Bullion Statement.

During the week ended June 25th, four Cobalt companies shipped an aggregate of nine cars containing approximately 720,723 pounds of ore. The Nipissing with five cars containing 444,304 was the heaviest shipper, as shown in the following summary:—

Shipper	Cars	Pounds
Nipissing .. . . .	5 .....	444,304
Mining Corporation .. . . .	2 .....	125,350
McKinley-Darragh .. . . .	1 .....	84,150
Temiskaming .. . . .	1 .....	66,919

Totals .. . . . 9 .....

720,723

During the corresponding period the Mining Corporation shipped 50 bars of bullion weighing 50,509 ounces. It is noted that one large shipment made on June 10th was omitted from previous reports. It was made up of 99 bars containing 100,333 fine ounces. The only other bullion shipped during the week just ended was the Dominion Reduction with seven bars containing 734 ounces.

### THE GOLD MINES.

Not a few of the gold miners of Northern Ontario believe they see a solution of the problem of the present shortage of labor. They point to the steady stream of immigrants pouring into Canadian ports of en-

try. Already the operating companies report a change for the better, and, emigration, while still more or less slow, is expected to gain momentum as the year advances.

For the first half of 1920, the preliminary estimates indicate a gold output of over \$6,000,000 from the mines of Northern Ontario, the production amounting to more than the value of the silver produced during the corresponding period. It is believed this rate will be still further exceeded during the last half of the year.

On July 20th the Dome Mines will disburse a dividend of \$100,000, amounting to 2½ per cent. It is understood to be the intention of the directorate to continue dividends at the rate of 10 per cent. annually, in addition to which a capital reduction may be made at such time as the treasury permits. It is pointed out that a comparatively small treasury of \$2,000,000 would make it possible to pay shareholders \$5 per share, and would thus reduce the par value of the issued shares from \$10 to \$5 each, upon which a dividend of \$100,000 quarterly would then amount to 20 p.c. annually. Following the recently held annual meeting, the directors of the Dome paid a visit to the mine, and were highly pleased with the general outlook.

Some opposition is developing in connection with the proposal made by the directors of the Porcupine V. N.T. to borrow \$50,000 from the Associated Gold mines of Western Australia for the purpose of financing the re-opening of the Porcupine V.N.T. The opposition is based upon the fact that the directors propose to grant a first mortgage against the mine, whereas it is felt that a better course would be to sell a part of the large block of treasury shares remaining in the treasury.

Operations have been indefinitely suspended at the property of the Dome Lake Mining and Milling Company. The small low-grade ore shoots have been found to be too erratic to treat profitably under the present economic conditions. It is believed, of course, that another attempt will be made to operate the property following a re-adjustment of conditions.

In May, according to an official statement just issued by R. C. Coffey, manager of the Lake Shore Mine, that property produced \$41,187.62, having treated a total of 1,636 tons of ore and recovered an average of \$25.18 from each ton treated. A feature of the monthly statement, is this brief announcement: "Preparations are being made to sink the shaft another 400 feet." In view of the ore treated during the past two years having averages between \$24 and \$25 to the ton, the decision to continue the shaft from its present depth of 400 feet to a depth of 800 feet is regarded as exceedingly important. Should the bonanza ore a found at the 400-ft. level be found to continue with similar volume and richness at the 800-ft. level the future of the Lake Shore would take on such proportions as to cause the company to greatly increase its milling facilities. The result of work at the 600-ft. and the 800-ft. levels will determine the extent of mill additions, according to a statement made to the "Journal" some months ago by Harry Oakes, president of the company. Now, with preparations actually under way to carry out this work the prospects of greater production from the Lake Shore appear to be extremely favorable.

At the Kirkland Lake Gold Mines, which is controlled by the Beaver Consolidated of Cobalt, the output of \$1,200 daily as reported not long ago in the "Jour-

nal," has now been exceeded, a record of around \$1,400 daily having been established for at least a part of the month of June. It is believed that the mine is now well on its way to earn substantial net profits, and that its large mill with a capacity of 150 tons is about to weigh heavily in its favor.

Shareholders of the Baldwin Gold Mines are reported to ratify an option of the property owned by the company at Kenogami Lake in which the holders of the option would be obliged to carry out a specified amount of work each month, in return for which they would be given treasury shares at the rate of 40 cents each and be permitted in that way to acquire a 51 per cent. interest in the company. The Baldwin property lies about six miles south-west from Kirkland Lake.

Having run out of money, the Bourks Gold Mines, situated at Bourk's Siding has closed down indefinitely. Considerable work was done on the property during the past couple of years, and substantial tonnage of ore was opened up in comparatively narrow ore shoots. The promoters of the enterprise appear to be confident of being able to handle the ore profitably provided the requisite capital were available. No official announcement has been made relative to what methods may be adopted to re-finance the enterprise.

An enthusiastic meeting of about 200 shareholders of the Crawford-Skead Gold Mines was held recently in Chatham. It is announced that subscriptions for shares are increasing and that an aggressive campaign of exploration and development work is now under way.

The work of surveying a route for the proposed light narrow-gauge railway from Swastika to Kirkland Lake has commenced. It is planned to build the line directly through the proven mining area of Kirkland Lake, thence to pass through the township of Lebel where very favorable results are announced at a number of new properties; after which it would pass through the township of Gauthier to the Argonaut Gold Mine, and, finally to Larder Lake. It is the intention of the builders to continue the line from Larder Lake through the township of Skead and back through the Boston Creek district to the T. and N. O. Railway.

#### TORONTO NOTES

A prospectus just issued by the King Kirkland Gold Mines, Limited, draws attention to the fact that the company has completed its organization with an authorized capital of \$2,500,000 and \$1,250,000 in the treasury. Seven mining claims in the Kirkland Lake District have been acquired, which consists of 309 acres in the township of Lebel, with a lake near the centre of the property for milling and mining purposes, and these will be thoroughly developed. It is stated that visible gold is in evidence in a vein which has been exposed for about 150 feet on surface and assay values are stated to be high.

Hamilton B. Wills, stock and bond broker, Toronto, on July 1st turn over the entire business to a company to be known as Hamilton B. Wills & Co., Limited, which will own the entire assets of the organization and assume all its liabilities. Mr. Wills will continue to be the guiding spirit of the new company and will remain as President and General Manager. The company has branches in Toronto, Detroit, New York, Rochester, Buffalo, Syracuse, Cobalt and Porcupine.

## British Columbia Letter

### The Metal Mines

#### Stewart, B.C.

A prospect has been located on Fish Creek about six miles from the town of Hyder in the Portland Canal District, over which Henry Benson, a resident of Victoria, B.C. and his sons are considerably excited. They are of the opinion that their property will turn on development to be fully as rich as the now well-known Premier Mine, situated somewhat further north on the Salmon River. Not enough work has been done, however, to indicate whether there is any justification for this optimism. Still there is a good lead and samples taken at the outcropping give returns of \$120 a ton in gold, silver and lead. No trace of zinc is shown. The Bensons have organized a company of business men in the cities of Victoria and Vancouver and propose carrying on development during the summer.

The definite announcement from official sources that the Provincial Government plans the building of a road from the Premier Mine, to which point there already is a fairly good avenue of transportation from tidewater, as far as what is known as the Joker Flats has been received by mining men of the district with satisfaction. It is indicated that this work will meet the needs of a number of the most important mining undertakings in the Portland Canal District. Among these are the "Big Missouri" Group, on which work has been in progress for over a year and which is being continued extensively this summer, it being the intention to do home 12,000 feet of diamond drilling; "Mineral Hill," on which nearly two years work has been done; the "Hercules," which is to be developed this summer in preparation for which supplies already have been forwarded; the "Silver Tip" and "Silver Crest" being opened up by Vancouver interests; and the holdings of the Algonian Development Company. Regarding the operations of the latter Company, which is said to be backed by Belgian capital, it controls a subsidiary concern known as the Northern Light Consolidated Group, a group of claims situated adjacent to the Premier Mine and diamond drilling thereon is contemplated this summer. The same Company has the Spider Group under option. This property, on which considerable development is planned, is situated on the west side of Long Lake and is equipped with an air compressor and other plant.

The Monitor Group of Mineral Claims, Salmon River, is reported to have been bonded by Vancouver interests. This is a well-known property having been located for years. Development consisting of surface stripping and some tunnel work has been done.

#### Alice Arm

The rolling stock of the Alice Arm Railway, running between tidewater and the Alice Arm Mine, Kitsault River, is being augmented materially. Part of a shipment of twenty cars is on the ground and three new locomotives are on order. It is thought that with heavier metal and new equipment not only will it be possible to make regular shipments of ore, but maintain the service for the greater part of the year: Preliminary work relative to the proposed extension of the railway to the Wolf Property, about three miles north of the Dolly Varden, has commenced. Surveyors are

busy and it is reported that the contract has been awarded.

#### Omineca, B.C.

Several of the properties situated on Legate Creek, Skeena section of the Omineca District, are reported to have been bonded and it is stated that there will be much development this year as soon as the snow goes. When that occurs there will be a number of prospectors in the field. The B.C. Exploration Company is one concern showing considerable interest in the mineral possibilities of the region. In the 1918 report of the Minister of Mines, J. D. Galloway, Government Mining Engineer, in describing the M & K. property, Legate Creek, observed that some 130 tons of ore had been shipped in the early months of 1917. This consisted, he explained, of float lying on the surface wash and but little work had been done to ascertain where this ore originated. The float ore occurred in pieces weighing up to several hundred pounds and. Mr. Galloway asserted "it does not seem likely that it has been moved any great distance from the vein in which it was formed. During the summer considerable work by the owners in prospecting stringers and showings of ore close to where the float had been taken out. Short tunnels have been run and cuts made and ore exposed, but it does not seem probable that the rich float ore came from any of these showings. "Again he explains that this ore consisted of an intimate fine-grade mixture of bornite and galena which was nearly solid mineral. Very little of this type of ore had been found in the ore showings occurring in solid formation. This more or less mysterious find of over two years ago, together with the evident merit of the properties of the creek in question, accounts for the promised activity of this summer both on the part of prospectors and operators.

#### Sheep Creek, B.C.

A new concentrating mill having a capacity of 50 tons of ore a day, has been completed at the Emerald Mine by the Iron Mountain Limited, operators of the property. This mine has been one of the steady producers of this section of the Province. During 1917 the mine run averaged about: lead, 27 per cent; zinc, 5 to 6 per cent; silver 1½ ounces. As originally designed the mill was to have a capacity of 30 tons, but the addition of an extra set of rolls for the crushing and some alterations in the process, principally in the direction of limiting the percentage of the product sent through the ball mill, makes it possible to run through 50 tons, while the crushing capacity is set at 100 tons.

#### The Nugget Mines Ltd.

Sheep Creek has its property on a steady producing basis, the Mother Lode Mill as remodelled and extended being in operation. It is giving entire satisfaction. The ore is being taken care of as quickly as it can be brought to the surface.

#### Nelson, B.C.

The annual meeting of the Californian Mining Company was held recently at Nelson when it was reported that good progress was being made in the development work underway on the California Mine as well on the installation of new machinery in connection with the Athabasca Mill, which is being put in shape for the treatment of the ore. Officers were selected as follows: President J. R. Casin, Spokane, Wn.; vice-

president, J. B. Schieger, of La Crosse, Wis.; secretary-treasurer, W. R. Orndorff, Spokane, Wn.; auditor, John Fraser, Nelson, B.C.; Mine Superintendent, W. H. Turner, Nelson, B.C.

#### Trail, B.C.

The site of the concentrating mill to be constructed by the Consolidated Mining & Smelting Co. for the treatment of the ores of the Rosslund Mines has been definitely selected. It is a point between the towns of Rosslund and Trail. Being on the hillside and within reach of an adequate and a sure water supply it is in every respect admirably adapted to the purpose in mind. A spur line of railway is to be constructed by the C.P.R. from Warfield to the new mill site, following a line surveyed by one of the staff of the Consolidated Company. This road will be down grade from Warfield, so that there will be no heavy hauling in bringing the ores from Rosslund. The arrangement of the Mill will be such that the ore will be unloaded at the highest point into ore-bins and will travel thence downwards through the crushers to the kilns, ball-mills, grinders and classifiers, separators, thickeners, filters, flotation and table concentrators until finally ready for delivery as concentrates to the smelter. This gravity system, of course, will reduce cost of handling to a minimum. The new wagon road from the smelter to the mill site already is under construction.

#### Vancouver, B.C.

The mining camp of Phoenix will soon be no more. It is gradually being dismantled. The Granby Consolidated Mining & Smelting Co., has a crew of thirty or forty men removing its plant and shipping it to Grand Forks and elsewhere, twenty or thirty cars having been forwarded already. This work will not be finished before August when the C.P.R. will remove its steel. Its depot now is being taken away. The Great Northern has been busy in dismantling its railway line for the past month, several buildings in the town also are being taken elsewhere.

H. S. Munroe, newly appointed General Manager of the Granby Consolidated Mining and Smelting Co. in British Columbia, before leaving to take up his work at Anyox made an interesting public statement as follows:

"I have just made an inspection of the Cassidy coal holdings on Vancouver Island. Cassidy is a miniature Gary and we expect to continue and expand our coal holdings at that point. The Granby Company has achieved in the mining world under its former management and our policy will continue to be one of progress. We hope to increase copper production at Anyox and to mine more coal at Cassidy.

"As to the general copper situation it is the belief among copper men that the industry today is in the best strategic position since the Armistice was signed and that by January, 1921, copper will have advanced to a price a little below that obtained during the war. Optimism reigns among copper interests. The domestic consumption is the heaviest now that it has been for two years and surplus stocks are less than at any time for that period. Exports to Europe are increasing right along and Japan is a heavier buyer.

"An example for the increased demand for copper is the work of centralization of telephone exchanges in Paris for all Europe. This alone will entail an outlay of \$165,000,000. The electrical equipment for this undertaking will make a heavy demand on copper.

"As the Granby operations at Anyox it may be stated that the difficulties at the Coke Plant, incident to new operations of this character, are readily being overcome and in the course of a few weeks a satisfactory solution will be found which will make Granby entirely independent, as far as its coke supply is concerned. Operations at the by-product plant are going right along and inquiries from Great Britain and the Orient have been obtained for all by-products

that Granby can furnish. However the home market is attractive just now and we are disposing of benzol, naphtha, coal tar and other by-products of coal to advantage.

"The policy of Granby will be to prosecute vigorously exploration for ores in Northern British Columbia which may be tributary to the Anyox smelter and it also will be the policy of the Company to extend smelter operations as tonnage available warrants. We hope to acquire new properties or buy ores from other companies. Granby always is in the market for cuperiferous and silicious ores."

#### THE COLLIERIES.

The results of examinations conducted by the Board of Examiners acting under the Coal Mines Regulation Act of British Columbia during the last week in May at Fernie, Merritt, Nanaimo and Cumberland have been announced. Certificates of Competency are to be granted as follows:

First Class: Arthur Newbury, Nanaimo.

Second Class: William Beveridge, Cumberland; Michel Donald McLean, Michel; Benjamin Ball, Michel; Louis Francescini, Cumberland; John Gilham, Nanaimo; William Park, Nanaimo.

Third Class: Edward Hardy, Fernie; Robert Taylor, Natal; Robert Clarkson, Natal; Henry Ferryman, Michel; Robert McFegan, Michel; Joseph Travis, Bankhead, Alta.; Joseph Lavin, Nanaimo; Robert Drybrough, Merritt; William Ross, Merritt.

Mine Surveyors: George W. Waddington, Merritt; Robert Strachan, Cumberland.

First class certificates qualify the holders to take a position as Manager of an active Colliery in the Province; second class certificates to act as Overman in the coal mines of the Province; and third class to take places in the mines as Shiftboss, Fireboss, or Shotlighter.

The retail price of coal in Calgary, Alberta, has been raised from \$8.75 a ton to \$10.50 for lump and \$8.75 for steam. This action has been taken, it is stated, to meet the wage advances granted the miners recently. No definite word, however, had been received at the time of writing and that the agreement between the Operators and the Men had been ratified, although it is understood to have met with overwhelming approval when put to a vote at Fernie.

It is possible that the City of Vancouver will go into the coal distributing business. The cost of fuel has been the subject of much critical comment of late among the citizens and Mayor Gale has made the statement that, from data gathered, it would appear that the City might purchase and deliver coal from \$4 to \$5 a ton cheaper than it now costs the consumer. The investigation on the part of the municipal authorities is continuing.

#### PARTY TO INVESTIGATE PEACE RIVER OIL FIELD.

Arrangements are being made by the provincial government for further investigation, this summer, of the petroleum possibilities of the Peace River section.

The minister of lands has engaged Dr. John A. Dresser, consulting geologist, of Montreal, to head a party which will include Prof. McLean, University of Toronto, and Edmund Speaker, of the department of geology, Johns Hopkins university, Baltimore, Md.

## THE YUKON PLACER MINING ACT AMENDMENT

An interesting piece of legislation, and one fraught with noteworthy possibilities as to mining in the Yukon Territory, Canada was recently before the Parliament of Canada, Ottawa. It is termed the Yukon Placer Mining Act Amendment.

On its second reading in the Canadian Parliament its design was explained by Hon. Arthur Meighen, Minister of the Interior, as follows:—

"Its design is to supply additional incentive to placer mining in the Yukon Territory. When the Yukon was opened up, and for many years thereafter, placer mining was vigorously prosecuted because the rewards under the then conditions were ample. They now are not so great as they were at that time, and it is sought by this Bill to amplify them in the following manner:

"To adopt the practice of issuing leases—that is to say lease of territory along creeks where placer mining is carried on of considerable extent—; practically a reservation of that territory for the applicant in order that he may prospect it and if he finds that it is in his interest to stake claims, to do so. The territory proposed to be granted in respect of land already worked over—that is land already taken up, cancelled or abandoned—is five miles in length on any creek, and the time allowed is one year. The prospector is bound to expend at least one thousand dollars in that year on prospecting operations, and if he does so he is entitled to a renewal, if he desires, for another year, and under similar circumstances for a third. He pays \$25 per mile or fraction of a mile rental for that prospecting lease. Then in respect of the class of claim already worked over, he is at liberty to stake within those three years any area he wishes, or rather as many claims as he desires. Each claim is about 23 miles in maximum.

"Now as regards new areas—that is to say creeks not already applied for, forfeited or abandoned, or not worked over—he is entitled not to five miles but to one mile. He is entitled to renewals in the usual way—or rather in the way I have just defined as respects the other class—but he cannot stake the whole thing. He can only obtain a discovery stake—that is to say three times the ordinary stake—the discovery stake being one that has always been given. Where a man is in the position of the discoverer of the area he gets three times the ordinary stake. So in this class of creeks already worked over, that is all he can obtain. He pays the same rental as I stated before for the other class, viz., \$25 per mile or fraction of a mile.

Mr. Alfred Thompson, the member for the Yukon, elaborated the above explanation, in the following terms:—

"It is now over twenty years since gold was first discovered in the Klondyke. A very large area of gold bearing gravels has been worked, many creeks have been prospected, and many worked, and others prospected but not worked and subsequently abandoned, which claims have reverted to the Crown. Now we have quite a large area of ground in that containing gold bearing gravels of this character; ground that is not sufficiently rich in gold contents to be worked by the ordinary placer mining methods or by the individual claims."

"But by placing these gravels in larger groups it is hoped that it may be possible to have them prospected by what is known as the core drill method, involving the use of machine drills, as opposed to the ordinary shaft sinking method. These amendments were suggested by a non-partisan organization known as the Yukon Development League and it is hoped that their adoption will prove an impetus to the further prospecting of this low grade gravel on abandoned creeks. So far as virgin ground is concerned the leases cover only one mile for a term of one year, and within that mile the prospector can secure at the end of the term only one discovery claim of the same size as he would be able to obtain if he were to make a discovery on any other ground upon which claims did not already exist."

Answering the question as to whether better results were to be expected by allowing five miles to be

included in a claim instead of the smaller area allowed heretofore Mr. Thompson said:—

"This low grade ground can only be prospected by the use of expensive power drills, and the gold contents of any one claim were not such as to warrant their continued operation, otherwise, the claims would not have been abandoned. The idea is to give the prospector a larger claim so that he will be able to secure the necessary capital to embark on this somewhat expensive prospecting."

J. M. Sinclair, of Guysborough, N.S., observed that a prospector in his Province required nothing more than a loaf of bread, a powder horn and a pick, the best mines of Nova Scotia having been discovered by men so equipped. He did not concur with an Act having the effect of shutting out the gold prospector. He wanted to know why it was necessary to confine the application (for leases) to "men of wealth or means."

To this Hon. Mr. Meighen replied:—

"It does not confine the application of men of wealth, it simply provides that before a man can get a lease he must show he is able to do something on the ground. It would be bad policy to grant to any applicant a lease, thereby tying the territory up, if he has no means at all of utilizing that territory. When the Yukon was new and the mining was carried on under the old method, the prospector did not require any capital, because the gold was there and could be mined by that method. But these worked-over claims can be mined only by the use of these powder drills. It is not we who compel the presence of capital; it is nature; consequently, to avoid tying up claims by those who cannot work them we simply say: Show us that you are able to work them, or show us that you have associated with you men who can work them, and that is sufficient."

## NOVA SCOTIA NOTES.

### Mine Illumination.

The miners in No. 2 Colliery of the Dominion Coal Company have demanded the replacement of the existing oil-flame safety-lamps by electric lamps of the cap and belt-battery type. There have been a number of instances in Canada where new collieries have been equipped with electric lamps, but few, if any, instances of replacement of existing equipment by them. While there is a growing inclination among colliery managers to recognize the undoubted advantages of the electric lamp, there is not by any means complete unanimity among mining engineers on this question. The doubt which exists in some minds centres chiefly about the problem of gas detection, for which the electric lamp is useless. There is no doubt that this difficulty can be overcome by appointing officials charged with gas detection and provided with oil-flame lamps in addition to an electric light, but, in a large and gaseous mine, the question of entire replacement of oil lamps by electric lamps requires careful consideration and much pre-arrangement. It is therefore difficult to understand the action of the No. 2 workmen in demanding—with the alternative of a strike—the provision of electric lamps within a given time. These lamps are not made in Canada, and the manufacturers in the United States are so full of orders that they do not particularly desire additional business. The cost is excessively high at this time, and the exchange premium adds greatly to that cost, and, what is more important in view of the action taken by the No. 2 miners, delivery is an uncertain thing. No matter how firmly convinced of the advantages of new equipment all parties may be, it is not possible for those who have the direction of collieries to allow themselves to be stampeded into the adoption of untried equipment before they are satisfied as to its wis-

# MINE HOISTS — STEAM or ELECTRIC

We Build Your Hoist to Suit Your Mine. Whether it be Large or Small  
**LET US FIGURE ON YOUR HOIST**

Note the Strong, Massive Construction of this Hoist.

The Gears and Other Parts exposed to much wear are made of best quality Cast Steel, and the Gear Teeth are all Machine Cut, ensuring smooth easy running.

The best quality material is used throughout, with sufficient metal to give strength where strength is needed.

We supply any diameter Drum up to 48 inches.

The Depth Dial is adjusted to suit the depth of the shaft where it will be used.

The Hoist in the illustration has Reversing Gear and Friction Drive. We also build it with Drums Keyed Fast to Shaft so it cannot revolve in either direction except under power.

50 H. P. Steam Hoist, with 40" Dia. Drum.

NOTE—The above Hoist is built also for Electric Power.

dom, nor is it likely to give the purchasing agent much opportunity for economy unless time is given for the trial of competing types of lamps, for comparison of bids, and for inspection of promises of delivery. The Dominion Coal Company estimate the cost of replacement of the existing equipment by electric equipment at \$100,000, and this is a moderate estimate, probably an under-estimate. It would be a pity to spoil the initiation of an advance in underground illumination, which has long been foreseen, by hasty and ill-considered purchases and by insufficient consideration of the large number of arrangements that such a change will require in the interest of safety.

The Rev. John Forrest, for almost thirty years President of Dalhousie University, Halifax, died on June 23rd. Dr. Forrest was well known throughout mining circles in Nova Scotia because of his membership on several Boards of Conciliation having to do with labor disputes. Dr. Forrest's keen intellect was well employed in this work, and he was very successful in adjusting differing points of view. Although 78 years of age, Dr. Forrest's death was unexpected.

The McKinnon Conciliation Board, which was appointed to adjust the differences between the United Mine Workers of Nova Scotia and the Dominion Coal Company, at the beginning of 1920, and was not called upon to sit formally because the two parties got together independently, recently recommended that a Royal Commission be appointed to consider the further request of the Mine Workers for a wage increase effective May first, empowered to deal with the matter as it affected every colliery in Nova Scotia. Such a procedure was, of course, only possible provided all the operators would agree to it, and this has not been the case. The Deputy Minister of Labor has explained the attitude of the Department in the following telegram to the Secretary of the Mine Workers:—"Re differences between coal companies and employees in Nova Scotia. Minister has given careful consideration to question of appointment of royal commission on lines laid down by resolution of McKinnon Board. Such commissions are appointed under the Enquiries Act which makes no provision for procedure on lines suggested. Government alone determines commission membership. It might not however have been impracticable to receive suggestions from parties concerned had companies been associated together as workmen by means of trades union. The minister's efforts to secure joint action by companies has not been successful and if commission is established members must be appointed in usual manner. Minister has understood that renewal of direct negotiations afford some prospect of settlement of grievances without Commission of Enquiry and requests that the latest information on this point be sent him."

The suggestion contained in this telegram that the coal operators should be associated together as the workmen are in a trades union is a singular one considering its source, and the attitude of governments in North America hitherto on the question of joint action of employers. The aim of the United Mine Workers, in which the Minister of Labor apparently concurs, is the establishment of a District Wage Board, upon which operators and union representatives will sit to adjust the whole of the questions affecting the

coal mines of Nova Scotia. It is not so very long ago since the coal operators of Nova Scotia were prosecuted at the instance of the present Secretary of the United Mine Workers on an unproven charge of conspiring together to maintain the selling price of coal. It is very difficult for non-judicial minds to see the difference between consultations on questions of wages and questions affecting the selling price of coal, as these two matters are indistinguishable from each other—in their effect at least.

#### NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES NEW YORK, SEPT. 20-25th, 1920.

The 1920 annual, which is the Sixth National Exposition of Chemical Industries returns to the Grand Central Palace in New York where it will be given during the week September 20th to 25th inclusive.

The Exposition this year will be more pretentious than ever; in fact, it will be the largest distinctly industrial Exposition ever held, and will surpass its own predecessors by one-third.

There are now engaged for the coming Exposition 358 exhibitors which is more than in the last Exposition in Chicago. The growth of this Exposition is remarkable and in a way indicates the growth and development of the chemical industries in America. In 1915 the first Exposition was composed of 83 exhibitors, the second increased to 188, the third to 288, the fourth to 334, and the fifth in which the available space was much restricted and exhibitors were held to a minimum to admit 351 exhibitors, the present number of 358 the managers tell us cannot be much increased in number because of the limited amount of space remaining. Another floor has been added giving four floors of the Grand Central Palace each of which covers a whole square city block so that exhibitors could secure increased space and not suffer the cramping felt in the last Exposition.

This year the Exposition will have three special sections, one, the Electric Furnace Section, another the Fuel Economy Section, and the third a Materials Handling Section, the two latter are new sections; the first will as its name implies be one of electric furnace exhibits; the Fuel Economy Section will consist of exhibits of machinery and apparatus, furnaces, producers, stokers and all devices for the economic utilization or more efficient combustion of fuel. The possible exhaustion of our fuel reserves in the not far distant future and the present high cost of fuel makes this section one of much interest to all industrial plants. The Materials Handling Section will be a series of exhibits of machinery and equipment for the handling of material such as: conveying, transporting, elevating, included in this will be weighing, measuring and power transmission equipment. So important have these mechanical features become for all industrial plants due to the shortage and high-wage for man-power than an unusual interest is expected in this new Section.

? The program for the Exposition will have sessions on subjects the phases of which will be developed in the exhibits of these latter two sections. There will be sessions on chemical engineering for which an elaborate program is planned. Motion pictures which will have a keen interest for technical men will form part of the program, and there will be popular public addresses as well.

Apply to **JOHN SEABROOK,**  
Preneveau, Ont., Canada.

Will Pep make her pay?

**Young Engineer Seeks Position.**

Technical graduate with five years of very best widely-varied experience, mining, milling, smelting and industrial metallurgy.

Can think clearly and reason soundly on any technical problem.

Open for engagement after July 15.

References from present and past employers.

Address Box 16, Canadian Mining Journal, Gardenvale, P.Q.

A special general meeting of the Vipond-North Thompson Mine has been called for July 14th for the purpose of authorizing the execution of a first mortgage upon the company's property to the Associated Gold Mines of Western Australia, for a sum not to exceed \$50,000.

The last issue of the Ontario Gazette contains the announcement of the incorporation of the Victory Silver Mines, Limited, with head office at St. Catharines. The incorporators are C. E. Ireland and Victor Nash, real estate agents, W. T. Tait, electrical engineer; David H. Tait and E. H. Moyer, all of St. Catharines. The authorized capital is \$2,000,000 and the company is empowered to carry on the general business of mining all its branches.

## EDITORIAL

### The Secretary-Emeritus of the Canadian Institute of Mining and Metallurgy

The June issue of the "Bulletin" announces the retirement of Mr. Lamb from the active secretarial duties of the Institute, and his appointment by the Council as Secretary Emeritus.

The title is one well earned, and there is no doubt that the necessity for Mr. Lamb's relinquishment of the secretaryship was occasioned by his long and difficult labors in that capacity. The members of technical society are usually vaguely informed in regard to the duties and importance of the work of the secretary, but it will be generally admitted that a society declines or increases in strength and public influence in proportion to the ability of its secretary to be all things to all men. The qualifications required of a secretary, should he attempt to fill all the requirements of the membership of a society, must indeed be as varied and as opposed as the individual characteristics of that membership. He is required to be a good executive, a person of tactful and polite personality, somewhat of a "literary gent," a good "mixer," an eloquent speaker, a financier, a possessor of varied technical qualifications, one who has had the leisure and desire to acquire the social graces and yet feels at home in a mining camp. We are strongly inclined to believe that there "ain't o sick person," but believe further that Mr. Lamb possesses as many of these essential qualifications as it is possible to combine in one who still functions on the terrestrial plane, and is limited by mortal inability to be in two places at one time.

If the success of a technical society is to be taken as an indication of the ability of its secretarial direc-

tion, Mr. Lamb is entitled to credit for unusual ability. It is to be regretted that the ex-Secretary was unable to make a formal leave-taking at the Annual Meeting of the Institute in March. What was in effect Mr. Lamb's valedictory was given to the Annual Western Meeting in Vancouver last November, and naturally very few of the eastern members of the Institute heard Mr. Lamb record his modest and moving account of the evolution of the Institute from small and unimportant beginnings to its present eminence. The kindly thought which prompted the President of the Institute to suggest to the members assembled at the Annual Dinner in Toronto that a telegram of remembrance should be sent to Mr. Lamb in British Columbia was excellently conceived, but we doubt whether it is sufficient recognition of the ex-Secretary's services, or one that fully expresses the sense of the historical value of Mr. Lamb's incumbency that is felt by many of the members of the Institute.

We endeavored some months ago to express a feeling that the Institute had emerged from adolescence as the result of "many years of hard work, much experimentation, much vision and tactful organization, some tribulation, but a far greater sum of good fellowship and a desire to help the other fellow." No person in the Institute can lay just claim to a greater share in its upholding than Mr. Lamb, nor has contributed more of these components of its success.

The work of Mr. Lamb's successor will be lightened by the perfection to which the organization of the Institute and its branches have been brought, but Mr. Lamb has set a pace that will require hard work and unremitting labor to excel.

### Labor Shortage at Canadian Mines

Reports from all centres of mining activity in Canada coincide in mention of a shortage of workman. Shortages are reported from the coal mines of British Columbia and Nova Scotia and from the mines of Northern Ontario, and in addition to the actual shortage of workmen statements have been appearing in the newspapers that the miners are not working efficiently. It is not fair to the miner that such statements

should be allowed to go on without correction of some evident genuine misunderstanding of actual conditions on the part of the public, which leads to laying unmerited blame upon the miner. The shortage of production at Canadian mines, and at Canadian coal mines in particular, is due first of all to the actual numerical shortage of workmen. At the Nova Scotia collieries, to take a specific case, the shortage of workers is

not less than five thousand men. In the Mines Report the 1919 the number of men "cutting coal", that is, actively producing coal, is given as having averaged during the mines year 2,874 men. This is some 500 men less than the number of men of this class employed in the Cape Breton collieries of the Dominion Coal Company alone before the war. Examination will show that the daily production of the contract workers is equal to, and during the war period, was in excess of the daily production of the same class of workers before the war. It is the excess of non-producers, brought about by the unremedied shortage among the producers, that causes the apparent inefficiency in production when the total production is divided by the total force of workmen employed. This condition of affairs will be found generally true in every mining operation in Canada. The unbalanced and inefficient state of the working organizations at the mines is the cause of the reduction in "Tons per man employed per day." Were only one man employed in the actual production of mineral, it would still be necessary, if that lone producer's output is to be marketed, to maintain the whole auxiliary and non-productive organization of the mine. Such a supposition is palpably absurd, but the actual reduction of the productive workers, unaccompanied by the reduction of non-productive workers, has in many instances proceeded almost to the point of practical absurdity, and certainly it has proceeded to the point of financial impossibility.

The productive side of mining employment has always attracted the best class of men, and has paid the highest wages, and, generally, has included the largest proportion of native-born or British-born workers. The sons of these men are not staying at the mines, and it might perhaps be enlightening if employers of labor were seriously to ask why they are not. From observation of a good many mining towns we believe that wages are a secondary consideration, and that it is social and cultural considerations that keep the men at their original vocations. If superior living conditions are to be found elsewhere then men will move to those conditions. As was recently stated most industrial companies "have already passed from the "position of buying labor to selling employment", and it would appear that employment at mines is the most difficult kind to sell. The farmers are asking themselves why farm work does not attract men, and the improvement in farm housing shows that they have found a partial answer to a question that is not less imperatively obtruding itself upon mine executives.

Recently much was made of the abstention of coal miners from work to attend a circus. It was not stated, however, that no circus had visited that mining district for forty-two years previously, or that there is not a free library, workmen's club or public park in the whole radius of the mining community.

### VISITS OF UNITED STATES TECHNICAL SOCIETIES TO CANADA.

The present Summer is notable for the number of technical and professional society meetings that are being held in Canada. The societies from the United States that have visited Canada recently include such varied industrial and professional activities as cotton manufacture, paper manufacture, the boot and shoe trade and editorial work, and from Great Britain there is coming to tour Canada probably the most influential group of newspaper men that have yet visited this country. No more important group of technical workers have, however, visited Canada recently than the American Institute of Chemical Engineers, now looking over the more important chemical industries in Ontario and Quebec. The reception given to the Chemical Engineers, so far as a representative of the "Journal" was able to observe it in Ottawa and in Belleville, was unusually cordial, and showed a discriminating sense of the value of the chemist in our day. In Ottawa, the local branch of the Canadian Institute of Chemistry were able to enlist the sympathetic assistance of the Government, and the attendance of Sir George E. Foster at the luncheon, and his speech there, undertaken under the pressure of business attending prorogation of the House, was appreciated as indicating the importance attached by the Canadian Government to the work of the industrial chemist.

In Belleville the visit of the Chemical Engineers coincided with Dominion Day, which was made the occasion for mutual international courtesies at the dinner given by the City of Belleville and the County of Hastings and their visitors. The thorough-going fashion in which the chemists were shown the chemical industries and mineral resources of this rich section of Ontario was we believe good business, both from the point of international amity and the future development of the mineral resources of Hastings County by chemical processes. As the Secretary of the Chemical Engineers well pointed out, the specialized work of this branch of chemistry is necessarily confined to a small number of men, because of the large capital investment necessitated to equip a chemical industry and to perfect its processes. The chemical engineer, therefore, is limited in his usefulness unless he is backed up by public opinion and large capital outlay. The members of the Canadian Institute of Chemistry, which body, together with the Engineering Institute of Canada, have joined to arrange and make pleasant and useful the itinerary of the Chemical Engineers in Canada, are well justified in the importance they have attached to this visit, and are to be congratulated on the manner in which they have succeeded in impressing the general public with this importance. That a good deal of quiet spade work was required to bring about so desirable a result is evident by the meagre

space devoted by the Canadian newspapers to this visit. Among the members of the American Institute of Chemical Engineers that have attended the Canadian visit were men who have contributed much to our civilization, whose names would be recognized in many and varied branches of scientific endeavor as being eminent in chemical work and literature. It is therefore well to know that—despite the small publicity given to the visit—this gathering of scientists was accorded such well-chosen and sincere hospitality in Canada by government and civic officials. Doubtless at Shawinigan the Institute would meet with similar courtesy, for of all places in Canada, Shawinigan understands the usefulness and the profitable uses of chemical engineering.

#### DIVERSIFIED INDUSTRIES ARE ESSENTIAL

The development of Northern Ontario depends largely on mining and lumbering operations. These are the pioneer industries that quickly and in a large way open up new areas for settlement. They help and are in turn greatly helped by the railroads. Following them comes agriculture, for the mining and lumbering communities afford a nearby market for farm products.

It is not sufficient however that the ore should be mined and milled and the lumber cut and shipped away. The continued growth of these new settlements depends upon the establishment of allied industries.

When silver was first mined at Cobalt the ore mined was all shipped away to southern smelters for treatment. As the industry developed a greater and greater amount of the treatment was done at Cobalt and for some years large quantities of silver bullion have been produced at the mines. This subsidiary industry, the treatment of the ores produced, is now perhaps the biggest industry at Cobalt.

At Iroquois Falls there is a splendid example of an industry subsidiary to lumbering. There is now a thriving community where ten years ago was an almost unbroken forest. If the trees had been cut and shipped away there would be no settlement of note at Iroquois Falls today. But a big pulp and paper mill was built here and a very large production of paper is being made and the plant is now being enlarged. A growing town with many of the attractions of southern towns, and some that many of these lack, has resulted from the establishment of the paper making industry at Iroquois Falls. The town in turn furnishes a market for the farmers who have taken up land in this vicinity.

The manager of one of the large copper mining companies in the United States, where mines have been in operation for scores of years, recently pointed out that mining companies would profit largely by the establishment of other industries in mining communities. Many a miner who likes his work leaves mining

districts because his children do not find there employment satisfactory to them. Many miners' sons want to make automobiles and many daughters want to work in offices or manufacturing plants. The miner leaves the work for which he is best fitted in order to afford opportunities to his growing children to take up their chosen occupations.

Mining companies have done much to make mining districts attractive. They appreciate that men must have facilities for amusing themselves and educating their children. Good schools and playgrounds and the encouragement of all forms of healthy amusement are recognized as desirable. The desirability of encouraging other industries to locate in mining districts seems however not to have received the recognition that it should. For many industries the location is not attractive but there are favorable features for certain industries in most mining districts.

#### MINERAL STATISTICS.

It is understood there is a likelihood that the statistical work of the Mineral Resources Department of the Mines Branch at Ottawa may be transferred to another government department. The re-organization of the work of the Mines Branch that is likely—if for no other reason than the depletion of the staff by resignations—is a matter that is in competent hands, and comment is only proper from those in close touch with the work. We would venture, however, to endeavor to present the viewpoint of those persons outside of the government service who have occasion to study mineral statistics, and who appreciate the years of work, the endless correspondence and the desire to be of service to the mining community of Canada, that have combined to bring the statistics of the Mineral Resources Department to their existing admirable condition, under the direction of Mr. John Mc. Leish.

The object of all statistics is to afford a basis for comparison, and their adaptation to this end is in proportion to the length of time covered by the records and the unchanging nature of the forms of tabulation. Statistics are only useful as they enable comparisons to be made. A change of the form of tabulation destroys its value. It is therefore to be hoped that any transference of the statistical work of the Mineral Resources Division will not lead to radical alteration in the forms of tabulation, or in their scope.

What has given particular value to the Mines Branch's Statistics of mineral production is that the information tabulated year by year has not been confined to actual mineral output, but has followed the mineral product quarried or mined to its sale as a commercial article. It is not desirable, or usefully feasible, that any attempt should be made to separate the processes of mineral production from those of mineral utilization, otherwise incomplete and less useful statistics will result.

As an example, the Deloro Smelting Company purchase high-grade Cobalt ores and recover from them—at a plant quite distant from the mining point—arsenic, silver, cobalt, nickel and other products. Accurate mineral statistics require that in one report, or volume, there shall be recorded both the figures of ore production and the figures of ore recovery.

Compilation of mineral statistics is, we believe, a proper and very necessary part of the work of the Mines Branch. The work can be best accomplished, and will give most intelligible results, if done under the superintendence of persons trained in the technicalities of mining work. If, however, through a desire to centralize statistical work, or to effect economies, it should be decided to relieve the Mineral Resources Branch of statistical duties, we would enter an earnest plea for preservation of the continuity and the comparison value of the familiar tabulations of the Mines Branch, upon which the mining men of Canada have so long placed reliance.

#### THE EFFECT OF SHORTER WORKING HOURS ON PRODUCTION.

The effect of shorter working hours on production is the subject of a special study by the United States National Industrial Conference Board (Research Report No. 27: Hours of Work Problem in Five Major Industries.) The investigators reach the conclusion that allowing for variations in managerial efficiency a shorter working day increases the efficiency of workers who are called upon to use intelligence at their occupation; but, in factories where the product results automatically from mechanical processes production is reduced in the same ratio as the working day. From this point of view no uniform schedule of hours, equally adapted to all industries, is recommended; shorter hours are conceded to skilled workers to enable them to concentrate their minds with greater efficiency while at work, but efficiency requires no such consideration for "automatic" workers. For example, in the boot and shoe industry, which calls for the exercise of skill, it was found that maximum production could be obtained on a schedule substantially less than 54 hours per week. In the metal-working group it was found that a 50-hour week could be introduced in some trades with no loss to production, but that no such rule could be applied throughout the entire group. Similarly, output in the silk industry was maintained after a substantial reduction of hours. On the other hand, the cotton textile industry of the northern states showed that reductions of the working week to 56 hours involves a proportional reduction of output; while in the woollen manufacturing industry reduction to a 54-hour week resulted in a similar loss, but less marked decline. No definite relation could be traced in any of the five industries under review between changes in wages and rate of production, but the investigators found some evidence of improved efficiency as the result of payment of a bonus, and in the piece-rate as compared with the day-rate system of wage payment. The information secured by the inquiry was not found sufficient to base upon it general conclusions as to the effect of shorter hours on the health of the workers. As to

the frequency of accidents the reports state that only 13 per cent. of the employers questioned had observed any noticeable decline, while 85 per cent. had found none and the remainder had even reported a slight increase, which they attributed to the hiring of new men to make up for reduced production due to shorter hours. In fixing the hours of work, however, the investigators point out that there are many other factors besides output and health to take into account and that their present inquiry does not cover the wider social field.

An inquiry lately made by the United States Health Service resulted in the finding that the output of industry was more steadily maintained under the 8-hour than under the 10-hour shift, the pace of work tending in the latter to be set by the less efficient workers, while under the 8-hour day the output varies more nearly according to the industrial capacity of the worker. In regard to the frequency of accidents, a direct relation was traced between fatigue and risk, as a large number of the accidents occur in the last hours of the 10-hour or 12-hour day. If for any reason production was speeded up in the last hours, when the workers were fatigued, the rise in the number of accidents was so rapid as to leave no doubt that the increased rate could only be explained by the decline of working capacity in the employees.

#### BENTONITE.

Ore variety of clay which is common in Alberta is known as Bentonite or Soap-clay. It varies in color according to the impurities which it contains, from a dirty white to a creamy yellow. It is exceedingly smooth and fine textured, and when soaked in water forms a soft soapy jellylike mass. It the early days it was used by the employees of the Hudson's Bay Company and by the Indians as a substitute for soap. The main characteristic of the clay is that it absorbs an excessive amount of moisture; this clay will absorb about three times its weight in water.

Bentonite with varying degrees of purity is common in the Edmonton and Belly river formations. As some of the surface clays have resulted from the breaking down of these older rocks, it is not uncommon to find streaks of Bentonite in these clays. When such clays occur on the surface they are better known by the name of gunbo.

Bentonite was previously regarded as unfit for clay products, but experiments carried on by Keele on some of the Alberta bentonitic clays, show that most of them can be made workable by some process of pre-heating, if the commercial conditions in the locality in question allow the use of such a process.

A new use for bentonite has been recently found in the textile industry for the sizing of yarn. If a bed of bentonite of sufficient thickness and purity can be found, the same may be of commercial value if situated conveniently to transportation. Only pure material can be made use of. The quality of the clay can be tested by anyone dropping a lump in a cup of water, if the clay changes to a jellylike mass it is bentonite, and if there is no sediment or dirt in the bottom of the container, the quality is good. A workable bed of bentonite should be at least two feet in thickness.

The foregoing account taken from the first Annual Report of Mineral Resources in Alberta is suggestive in view of the recently reported discovery in England of the adaptability of colloidal clay to soap manufacture

# Centrifugal Pumps and their Use

Some Notes on Their Design, Application and Installation.

By F. A. McLean, Canadian Ingersoll-Rand Co., Ltd.

Many people erroneously regard the centrifugal pump as a very modern invention, while as a matter of fact it is considerably older than the steam engine. The history of its invention is rather obscure but the credit for it is usually given to Demesne Papin, who lived in Hesse, Germany about 200 years ago. Like many other inventions, little interest appears to have been taken in it and it was allowed to be more or less dormant until Andrews and Bessemer made some improvements on the original designs in the early part of the nineteenth century.

Its first appearance in America was about the year 1819 or 1820 and it was improved by Gwynne and J. P. Appold, in 1848-1851. Appold's improvements were so far reaching that the most modern form retains many of the features which distinguished his design. Appold's pump, which was not affected by solids in the water, was capable of pumping continuously a volume of water equal to more than 1400 times its own weight and was found to be fairly efficient.

Fig. 1—Single-Suction, Belt-Driven, Open-Impeller Type Pump

Centrifugal pumps were for many years considered only suitable for handling water in comparatively large quantities at very low heads and due to poor design and consequent low efficiency, were considered too wasteful to allow their wide adoption. The development of the direct acting steam pump to a higher state of perfection put the centrifugal pump in the background where it remained for a number of years. The ability of the centrifugal pump to operate at high speeds brought it into the lime-light again, due to the rapid advance which had been made in the development of the steam turbine and the electric motor, and the consequent need for a pump which could be directly connected to these types of prime mover, thereby gaining full advantage of the reliability, low maintenance cost and compactness of this method of drive.

It is now possible to secure centrifugal pumps which will give most satisfactory and economical service on nearly all classes of low and high-head installations for which a few years ago only reciprocating pumps would have been regarded as suitable

The simple rugged construction of the modern centrifugal pump, its long life and entire absence of trouble from water hammer and shock, naturally appeal to users of pumping machinery. In their simple construction and lack of valves, pistons, rods and other reciprocating parts, they present a radical contrast to the ordinary steam or power-driven reciprocating pump. Due to the fewer wearing parts, they usually last longer, are not so much affected by semi-solids or solids in the liquid pumped, require far less attendance and generally operate with considerably less power.

## Types of Centrifugal Pumps.

Present day centrifugal pumps are made in two general classes, known according to the type of impeller used as either open or enclosed impeller machines. The open impeller has a number of spokes or arms which radiate from a central hub like the rotor in an ordinary rotary blower. The sides of the vanes or arms are usually machined to enable them to be run close to the sidewalls of the casing. The closer the blades run to the casing the less is the loss from slippage of the water or other liquid being pumped.

When well designed and properly built, open impeller pumps will give quite satisfactory results in delivering a large quantity of water at a small head but the large amount of slippage, skin friction and surging or internal disturbance which become worse as the head is increased limit the efficiency of this type of pump. As inherent losses in these pumps are variable quantities, it is impossible for the designer to accurately predetermine the ultimate performance of the pump. Open impeller pumps are particularly adapted to handling gritty or dirty water and semi-solids, and for this reason have been widely adopted in pulp and paper mills and for pumping tailings, slimes, etc. in concentrating plants. The open impeller pump illustrated is made in sizes to handle from 200 to 8000 gallons per minute at heads up to 70 feet.

The enclosed type of impeller consists of a number of vanes or arms radiating from a central hub and enclosed by discs on each side to form walls. In operation, the liquid which is being pumped is admitted at the centre or eye of the impeller and passes around the shaft and through the impeller in channels formed by the walls and vanes. In single-suction pumps the water enters on one side of the impeller only, while

Fig. 2—Belt-Driven, Double-Suction Volute Pump

in the double-suction type it enters on both sides. Double-suction impellers, which are subject to an equal pressure on both sides are therefore self balancing against thrust along the centre line of the shaft when operating at ordinary heads. Single-suction pumps do not have this self-balancing feature and consequently require thrust bearings.

With the enclosed-impeller type of pump the liquid being raised passes through passages, or channels of fixed form with a limited amount of leakage and considerably less disturbance than is the case with open impellers. The designer can thus quite accurately determine and control the performance of the pump over a broad range of requirements such as are met with in different classes of service. For this reason the enclosed-impeller pump will suitably meet all medium and high-head pumping requirements where efficiency is essential.

### Single and Multi-Stage Centrifugal Pumps.

Single-stage pumps contain usually one impeller and are built for almost any capacity and will operate efficiently on moderately high heads, the larger sizes naturally being more efficient than the smaller. Single-stage pumps are somewhat limited by the pressure existing between the suction and discharge chambers of the pump; the higher the head the greater the dif-

Fig. 3—Double-Suction Volute Pump, with Casing Open Ready for Inspection

ference in pressure and the larger the loss from internal slippage and leakage and the more rapid the destruction of the internal parts. These factors reduce the head or pressure allowable per impeller or stage.

To overcome this drawback and permit the use of centrifugal pumps on higher heads and higher pressures the multi-stage types were produced. These consist of two or more impellers mounted on one shaft and running in a casing with passages arranged in such a way that the liquid is led through the impellers in succession, each one adding its share to the total pressure required. By this arrangement pressures of several hundred pounds may be obtained from a single unit, the exact limit depending on the strength

of the materials from which the pump is constructed and their resistance to the wearing or abrasive action of the liquid at high velocity. In pumps of the multi-stage type the liquid is discharged from all but the last impeller at a very high velocity and must be turned through a half circle or 180 degrees in order to enter the succeeding one, and this necessitates the use of baffle plates or vanes to reduce the speed of the liquid and convert it into pressure as soon as it leaves the impeller, so that it will pass to its successor with a minimum amount of disturbance and shock on the walls of the casing. These vanes or baffles are called diffusers.

In all multi-stage pumps some means of maintaining the correct alignment of the passages of the rotating impellers with those in the casing, and equalizing any end thrust that may take place is necessary. This is often accomplished by means of a hydraulic device in which the end thrust is absorbed by a body of water acting against a diaphragm or piston on the pump shaft. This device is only applicable when the pump is used with clean water and is very simple in construction, automatically and quickly adjusting itself to the variations in the load with practically no friction or loss of power. Sometimes it is necessary to pump liquids which contain grit or solids which would wear out the hydraulic balancer very quickly and in such cases a marine or Kingsbury type of thrust bearing is used.

### General Design.

To be successful a centrifugal pump should be well constructed mechanically. Its performance should comply with all of the requirements of the particular class of service under which it is to be used, and should show the highest possible efficiency when in use on that service. It should be of simple and substantial construction in all its parts and the rotating elements should be accurately balanced in order to reduce vibration. The bearings should be of ample size and accurately fitted, and provision should be made for their proper lubrication, in order to preserve the alignment and small running clearance between the rotating element and its casing which serve to prevent leakage between the high and lower pressure portions of the pump. As with other classes of machinery, centrifugal pumps are no better than their bearings, from the standpoint of continuous operation, and the better proportioned these parts are the longer the life and the lower the maintenance cost.

All materials entering into the construction of the pump should be carefully selected in view of the duty to be performed, and care should be used in the various manufacturing and machining processes. The general design of the machine should be such as to allow ready accessibility to all parts without difficulty.

Fig. 4—Motor-Driven Double-Suction Volute Pumps in Series

### Principle of Operation.

The principle on which the operation of the centrifugal pump is based is quite simple and easily understood. The liquid to be pumped is speeded up or accelerated by passing it through the revolving impeller; energy received from the vanes resulting in an increase both in pressure and velocity, the velocity being subsequently converted into pressure in the stationary discharge passages. It is however, a very complicated problem to design and construct pump to deliver a definite quantity of water against a given head at a certain fixed speed, with the highest efficiency. An experienced designer can, however, predict within a very small percentage of error on either side, both the capacity and brake horse-power required at the normal operating point as well as over a wide range of variation from such conditions as free discharge against little or no head to a closed discharge with no liquid flowing. The solution of problems of this nature, of course, requires a thorough theoretical knowledge of centrifugal pump design and the examination of a vast amount of data obtained experimentally from pumps intended for similar service conditions. For this reason, the volume of output and reliability of the pump manufacturer, other things being considered, may be regarded as pretty good indications as to whether the pump will fulfil the requirements to the degree claimed by its maker or not.

To produce an efficient and satisfactory pump requires not only a correctly designed impeller, but the casing itself must be so made that changes in the velocity of the liquid will take place gradually with-

Two-Stage Motor-Driven Turbine Pump

out undue shock and disturbance. To put into practice all of the little details which are carefully worked out by the designer requires careful and accurate shop work of a high order, with rigid supervision and inspection throughout the various steps of manufacture. As an assurance against defects in material and workmanship, it is also essential that finished machines should be subjected to a thorough test under conditions like those which will be met in the field, or even more stringent if possible. When this method is thoroughly carried out any mistakes or discrepancies are detected and properly corrected before the pump leaves the shop, and where this testing is not properly carried out, it is impossible for the manufacturer honestly to guarantee the performance of the pump when it is finally put in service. To get the very best results each installation should be treated as a problem by itself as in this way it is possible to obtain far higher efficiencies than if the equipment is chosen haphazardly on a shelf hardware basis, on the recommendation of a small dealer or jobber.

(To be concluded in next issue.)

### THE "SINGING FLAME" LAMP FOR DETECTION OF METHANE.

Discussing the Fleissner Singing-flame Lamp at the June meeting of the Institute of Mining Engineers, Mr. William Manrice observed that it is known that the detection of very small quantities of methane by means of the safety-lamp requires the greatest attention, and a certain degree of practice, and that errors of observation are easily possible. In the lamp under consideration advantage is taken first of the means of methane detection by the phenomenon of the **explosive limit**—that is to say, by observation of the "cap" or "halo," and, secondly, by sound. It is to be noted that the observations are by no means final, and that only the first rough models of testing-apparatus are yet available. The experiments already carried out have, nevertheless, sufficed to establish the usefulness of the principle. The device has its origin in the phenomenon of the "chemical harmonica" or the "singing flame." The "chemical harmonica" effect, otherwise known as the "gas harmonica," results when a vertical tube, open at both ends, within which a flame is burning, produces a powerful resonance of the tube. The phenomenon was noticed as early as 1777 by B. Higgins, who, however, only published his observations in 1797, so that others (Deluc, 1787; Hermbstaedt, 1793; Tromdorf, 1794) preceded him in publication. At first the experiment was always made with hydrogen, which was allowed to escape through a tube with a narrow jet. The gas was lighted and another glass tube placed over it in such a manner that the flame was in the lower third of its length. Later, it was discovered that any other combustible gas could be used, and with acetylene-gas especially Dr. Fleissner had been able to produce exceptionally powerful tones.

### MINERALS OF HASTINGS COUNTY, ONTARIO.

On the occasion of the visit of the American Institute of Chemical Engineers to Belleville, Mr. J. W. Evans, who is the Vice-Chairman of the Hastings Branch of the Canadian Institute of Mining and Metallurgy, and who it will be remembered gave a paper at the last annual meeting of the Institute descriptive of the mineral occurrences of Hastings Co., had on view a number of mineral specimens. The most striking was a large piece of iron pyrite from Queensboro, said to be representative of a vein running five feet wide. A specimen of green fluor spar from the Bailey Mine, and a smaller piece of transparent white spar were shown. Samples of the talc from the Henderson Mine at Madoc were exhibited showing the material in various stages of density. Gold ore from the Belmont Mine, and specimens of molybdenum and galena were also shown. A fine sample of iron ore together with tool-steel made direct from this ore in the electric furnace was the occasion of much interested comment. This ore is stated to contain 53 percent of iron, 7.5 percent of titanium and .41 percent of vanadium.

Mr. Evans is an enthusiastic believer in the mining and metallurgical possibilities of Hastings Co., and is doing good work in bringing them to public attention.

Gold-bearing quartz is reported to have been found on the Boisdale Hills near Sydney, Nova Scotia.

# The Canadian Visit of the American Institute of Chemical Engineers

By the courtesy of the Secretary of the Institute a representative of the "Canadian Mining Journal" was enabled to accompany the visit of the Chemical Engineers to Ottawa and Belleville, and the following notes upon this portion of a notable gathering are necessarily confined to the events of two days and do not deal with the itinerary of the Institute, which covers a fortnight's travel in Eastern Canada. After spending two days in Montreal, where papers were read during a two days meeting and courtesies were extended by the Montreal branches of the Canadian Institute of Chemistry and the Engineering Institute of Canada, the visitors arrived in Ottawa at noon on June 30th, and were entertained at luncheon in the Chateau Laurier by the Ottawa members of the C. I. C. The Chairman of the local branch, Mr. Edgar Stansfield presided over the luncheon, and, in addition to the visitors there were present representing the Canadian Government and the City of Ottawa, Sir George Foster and the Mayor and President of the Board of Trade. Among those at the speakers' table were noted the Chairman of the Hon. Advisory Council and the Deputy Minister of Mines.

## Carbonized Lignite Briquettes.

The speeches turned largely on the contents of a small cardboard box placed by the plate of each visitor, which on examination proved to be a small briquette of carbonized lignite presented with the compliments of the Lignite Utilization Board. The President of the Chemical Society remarked that the researches of the L. U. B. in Canada were being watched with much interest by the neighboring states of the Union, such as Dakota, where there existed the extension of the same lignites that Canada is seeking to utilize in Saskatchewan and Alberta. The speeches made in regard to the lignite briquette by Sir George Foster and the Chairman were in jocular vein, but underlying was serious purpose, and the exhibition of a briquette—which presumably the Lignite Utilization Board is satisfied with—to the visitors, was understood to signalize substantial progress to meet the most pressing material need of Canada, that of internal fuel supply.

After the luncheon, the visitors were shown over the plants of the E. B. Eddy Co. at Hull, and witnessed what to a miner is always a sight for lugubrious reflection, namely the conversion of good mine timber into newspaper print.

Leaving Ottawa at six in the evening the Chemical Engineers arrived at Belleville shortly before midnight, and were greeted at the station by a brass band, much to their pleasurable astonishment, and under the guidance of the local member of the A.I.C.E., Capt. Lucius Allen, paraded to the Hotel Quinte.

## Visit to Deloro Smelter.

On Thursday morning, Dominion Day, automobiles took the visitors 40 miles by road through a picturesque and opulent countryside to the works of the Deloro Smelting and Refining Company, being greeted en route at Marmora by the local band. At Deloro, the manager, Mr. S. W. Wright, presided at a luncheon provided by the Deloro Company, served in the local church hall with the assistance of the ladies of Deloro, after which the engineers were shown over the plant,

the technical operation of which was explained at the luncheon by Mr. Wright, who said that his directors desired to withhold nothing from the visitors.

At the Deloro Plant high-grade silver-cobalt-nickel arsenides from Cobalt are treated, recovering silver, cobalt—as oxides and in metallic form—arsenic and nickel. Paris green is also made in a neighboring plant. The making of the alloy "Stellite" was seen in process, and particular interest was taken in Mr. Wright's announcement that machinery was approaching completion for the manufacture of table-knives in "stellite". The equipment for making blades was shown, and it was intimated that later the manufacture of forks was to be undertaken. "Stellite" does not lend itself to forging, and, after being cast, the blades are ground to shape, sharpened and polished. As the alloy is much harder than anything it is likely to come into contact with in domestic use, and quite stainless, there is no necessity for sharpening of the blade or the polishing that is required to keep ordinary steel knives in good order.

## The Talc Mine, Madoc

From Deloro the party went to Madoc and looked over the Henderson talc mine and the grinding plant of the G. S. Gillespie Co. Practically all the talc produced in Canada comes from the Madoc mines, the production in 1919 amounting to over 18,000 tons.

From Madoc the visitors returned to Belleville, calling on the way at the Corbieville distillery, now operated by the Industrial Alcohol Co., for the production of denatured alcohol from molasses.

In the evening a Dominion Day Dinner was given to the guests by the City of Belleville and the County of Hastings. During the course of the dinner announcement was made that Dr. C. K. Moore of Berlin, N.H., had been chosen as the recipient of the Institute medal for the most valuable contribution to chemical literature among the members of the Society during the year. The international felicitations which are usual upon an occasion such as this dinner were given unusual interest by its occurrence upon Dominion Day, and the fact that it was the first time that many of the visitors had been in Canada.

After the dinner the Institute resumed its itinerary and left for Shawinigan Falls, the most important centre of the activities of the chemical engineer in Eastern Canada.

## METAL QUOTATIONS.

Fair prices for ingot metals at Montreal, 8th July 1920:—

	Per lb.
Electro copper . . . . .	24c
Castings copper . . . . .	23½c
Lead . . . . .	10c
Zinc . . . . .	10¾c
Tin . . . . .	57c
Antimony . . . . .	10c
Aluminium . . . . .	37c

Dr. Michael Clarke says that war in the immediate future is an economic impossibility. So they said in June 1914. And can anyone say how many wars were going on in July 1920?

# A Review of the Gold and Silver Production of Northern Ontario During the First Half of 1920

(By J. A. McRAE, Cobalt).

A mid-year summary, based upon preliminary estimates from the mines, for the first half of 1920, would indicate a total production of silver and sold from Northern Ontario of approximately \$12,500,000; made up of a little over \$6,000,000 from the gold mines and approximately the same amount from the silver mines. The production of gold appears to be likely soon to definitely assume the lead, the only visible likelihood of the situation being reversed hinging upon the possibility of a big rise in quotations for silver.

The fixed price of gold, however, has prevented the gold from yielding profits equal to the silver mines. Verification of this may be gathered by turning to the annual statements for 1919 in which it is shown that the leading silver producer, the Nipissing, produced \$3,752,083 during the period and made \$2,717,311 net profit, while on an output of \$6,722,266 the leading gold producer, the Hollinger, realized only \$2,321,290 net profit. A re-adjustment of economic conditions appears to promise equal relief to both the silver and the gold mines in so far as material and supplies are concerned, while it promises greater relief to the mines in regard to labor supply in that during the past three years the silver mines have been fully manned, while the gold mines have only been able to procure a little under two-thirds of full requirements.

## Paying Big Dividends.

During the first half of 1920, the silver-mining companies paid \$2,237,905 in dividends. During the corresponding period, the gold-mining companies paid \$1,442,048, making an aggregate of \$3,679,953 for the half year.

For the last half of 1920, the present rate of dividends will probably continue at all the dividend-paying mines, disbursements for the year amounting to close to seven and a half million dollars. With dividends paid to the middle of 1920 having reached a total of \$99,437,321, the grand total up to the end of the year promises to amount to approximately \$103,117,274.

## Over Quarter Billion Produced.

The silver mine up to the end of July, 1920, have produced approximately 309,010,836 ounces valued at \$188,411,972. The gold mines of this part of Northern Ontario have produced approximately \$65,591,614. The aggregate output of silver and gold, since the discovery of silver in Cobalt in 1903 and the discovery of gold in Porcupine and Kirkland Lake in 1909, amounts to \$254,001,586.

Nor does the peak appear to have been reached in the production of precious metal from this field. The total ore reserves of the present actually exceed the total in sight at any previous time in connection with the industry in this country. This state of affairs offers at least the suggestion that production will increase to a corresponding degree.

Figures which show the total output of silver since the first discoveries in Cobalt is somewhat remarkable that from 1904 to 1911, both years inclusive, there was an increase each year in the number of ounces produced, while from 1911 up to the present there has been a decrease each year. Not in a single case was

this rule broken, showing the uniform manner in which the silver deposits have been mined. The value of the output, however, fluctuated. This was due to the rise and fall of quotations for commercial bar silver.

In reviewing the figures presented below, as representing the silver production, it is necessary to keep in mind the fact that cobalt metallies and cobalt oxide now play quite an important part in the output of the silver mines and the returns for this mineral are not included in the figures given. With cobalt valued at from \$2.00 to \$2.25 a pound at present as compared with very little value in the early years of the camp, the income is enhanced considerably.

## New Mines Developing.

While the Gowganda field appears to offer possibilities of stemming the tide of declining silver production from this province, yet in Cobalt, too, there are possibilities of new developments altering the situation for a time. During the last half of 1920 the Bailey Silver Mines and the Colonial Mine both of which have been idle for years promise to be added to the producing list. In addition to these are new properties opening up on which are encouraging possibilities, such as the Victory Silver Mines and the Oxford-Cobalt.

The Nipissing Mining Company continues to produce silver at a rate between \$4,000,000 and \$4,500,000 annually and is easily the leading silver producer in Canada.

Following is a table showing the silver output from the mines of Northern Ontario:—

## Silver Production.

Year	Average		Value
	Price cents Per ounce	Ozs. Produced	
1904 .. .. .	57.02	206,875	\$ 111,887
1905 .. .. .	60.4	2,451,356	1,360,503
1906 .. .. .	66.8	5,401,766	3,667,551
1907 .. .. .	67.5	10,023,311	6,155,391
1908 .. .. .	52.09	19,437,875	9,133,378
1909 .. .. .	51.5	25,897,825	12,461,576
1910 .. .. .	53.5	30,645,181	15,478,047
1911 .. .. .	53.3	31,507,791	15,953,847
1912 .. .. .	60.8	30,243,859	17,408,935
1913 .. .. .	57.8	29,681,975	16,553,981
1914 .. .. .	54.6	25,162,841	12,765,461
1915 .. .. .	49.69	24,746,534	12,135,816
1916 .. .. .	65.66	19,915,090	12,643,175
1917 .. .. .	81.41	19,401,893	16,121,013
1918 .. .. .	96.77	17,661,694	17,341,790
1919 .. .. .	111.12	11,224,970	12,747,621
1920 (first half) ..	118.03	5,400,000	6,372,000
Totals .. .. .		309,010,836	\$188,411,972

## The Gold Mining Industry.

Figures were presented in the "Journal" two weeks ago, showing the gold production from this district from the time gold was first discovered in Porcupine in 1909 up to the end of 1919. They may be brought up to date as of June 30th, 1919, by the addition of a little over \$6,000,000 for the first half of this year.

The mining situation in all its phases is sound. It finds no artificial support; but, instead, is standing on its merit alone. Over-enthusiasm is playing little or no part, even among the smaller and new enterprises, and the foundation of the industry is such as to assure longevity.

## Our Northern Ontario Letter

### THE SILVER MINES.

With the world output of silver estimated at about 180 million ounces annually, and the United States Government prepared to purchase at \$1 an ounce all the current output of that country, which amounts to 60 million ounces a year, it is obvious that only 120 million ounces are left to meet the demands of all the other nations of the world. Not only that, but the consumption of silver in the arts in the United States must be cared for out of foreign silver as it is only natural that silversmiths will turn to the foreign market for the metal just as long as it remains below the fixed price of \$1 as provided in the Pittman Act.

It is for these reasons, among others, that silver producers are resting easy in the belief that prices will again rise.

A notable instance of confidence in higher prices is the fact that the Nipissing Mining Company as of June 22, had \$1,685,406 in silver on hand or in transit. More than a million of this, in fact close to one and a half million is understood to actually consist of silver bars stored in the local vaults of the mine. In addition to this large liquid asset are \$3,376,497 in cash and war bonds, making a total net quick asset of \$5,061,903.

Another rich shoot of ore has been encountered on the Beaver Consolidated mine, making a total of six more or less important finds on this property since last Autumn. Current production is said to be running comparatively high, and the physical condition of the mine has been materially strengthened. This condition lends weight to current reports that dividend disbursements may be made at regular intervals of every three months from this date forward.

Output from the Kerr Lake mine is gradually declining, the May report showing a production of 48,834 ounces as compared with 61,512 ounces in April and 99,398 ounces in March. This falling off was expected, as intimated in recent weeks in the "Journal." It is due to the exhaustion of the high-grade ore, and signals a turn to lower-grade ore and consequent lower production. While a still further decline is expected, yet a uniform rate may soon be established, and it should perhaps be kept in mind that in low-grade are resources, inclusive of the large dumps which may be worked over, the Kerr Lake has an asset of big proportions. Also, the extent of the company's holdings in other countries lends added stability to the Kerr Lake.

In the boundary dispute between the O'Brien and the La Rose, the former company is favored in a decision just handed down. The judgment specifies that the O'Brien is entitled to possession of all that territory lying east of a straight line between the No. 4 post of the Colonial mine to the "Shaw" post, and is granted an injunction against the La Rose for trespass beyond that point with damages, if any. The text of the decision leaves cause for believing that O'Brien may enter some specified claim for damages,

in which case in the event of the contestants failing to agree upon the amount the point would have to be determined by the Master at Haileybury.

Arrangements are being made to explore the Mohawk-Cobalt property, situated near Mud Lake a few miles from the producing Cobalt area. In 1907 a shaft was driven to a depth of 200 feet at which point developments were suspended without doing any lateral work. In 1919 about 103 feet of cross-cutting was done, during the course of which three fairly wide veins were opened up in each of which heavy cobalt mineralization is said to occur.

Rich samples of silver have just been brought out from the Thompson claims, situated in the township of Van Hise in the Gowganda silver district. The deposit is said to be exceedingly rich and is attracting attention of the leading mining companies in other fields. It is intimated that the proposition has been placed before the McKinley-Darragh Company of Cobalt, and that the Temiskaming Mining Company is also desirous of making an examination of the property.

A deal is pending on the Cane Silver Mines, a property situated in the township of Cane in the Montreal River district. The object in view is to enlist the finances necessary to carry out a comprehensive exploration and development program. A number of veins on the property contain short but quite rich shoots of ore at surface.

During the past few days, prospectors in Haileybury have become more or less excited about a newly discovered silver deposit the location of which is as yet kept secret. Quite a number of prominent prospectors have disappeared as though by magic, leaving behind them among their intimate friends the mere suggestion that they are on the track of something new. The element of mystery surrounding the matter has created an atmosphere very similar to the early days when rushes of the kind were quite frequent occurrences. Whether or not anything of value will merge from the present mystery cannot be predicted at this time, but that it will become public information within a short time seems certain as recording will be necessary and will offer a "tip" to those now on the outside but with "their ears to the ground," so to speak\*.

\*A newspaper dispatch from Haileybury under date of 4th July states that bismuth, not silver, has been found in the township of Rattray by the rush of prospectors to the supposed new silver fields, and as bismuth is regarded as of no commercial value, the rush of prospectors has suddenly ceased. Men working on a lumber camp were supposed to have discovered a vein of almost solid silver.

Bismuth is quoted at from \$2.70 to \$3.00 per pound in New York but the dispatch does not state the extent or nature of the occurrence. The commercial production of bismuth has not yet been recorded in Canada. During the war the price of bismuth was increased owing to the shutting off of customary European sources of supply.

Important bismuth ores occur in Bolivia and Peru (where the San Gregorio Mine, east of Hauraucaca is stated to have sufficient ore in sight to supply the world's demand for many years (see Miller and Singewall "Mineral Deposits of South America"). In several instances in South America the bismuth ore occurs in association with tin ores.—Ed.

In view of the Nipissing not having included a bonus with its July 20th dividend disbursement, and in view of the current quick assets being now over five million dollars, the highest in the company's history, it is believed that it is not the company's intention to yield to the request of shareholders to increase the rate of dividend payments, but, instead, to make a substantial capital reduction by perhaps paying the shareholders \$1,200,000, an amount equal to \$1 per share, thus reducing the par value from \$5 to \$4 per share. This would appear to be a popular move for the company at this time.

**Ore and Bullion Report.**

During the week ended July 2nd, three Cobalt companies shipped an aggregate of four cars containing approximately 281,012 pounds of ore. The Mining Corporation with two cars was the heaviest shipper, as shown in the following summary:—

Shipper	Cars	Pounds
Mining Corporation . . . . .	2 . . . . .	129,370
Temiskaming . . . . .	1 . . . . .	65,584
Nipissing . . . . .	1 . . . . .	86,058
<hr/>		<hr/>
Totals . . . . .	4 . . . . .	281,012

During the corresponding period, no bullion shipments were made, the tendency still being to await higher prices for the metal.

**THE GOLD MINES.**

The greatest confidence is expressed by careful observers that the supply of labor for the gold mines will become adequate in a reasonably short time, on account of the great tide of men moving to this continent from the nations of Europe. This would eliminate the chief obstacle to maximum production and would probably result in all the leading mines increasing their net earnings.

In regard to the Porcupine V.N.T., concerning which there is a proposal to borrow \$50,000 with which to start work, and to grant a first mortgage against the mine, strenuous opposition is developing. It is pointed out by shareholders that the Porcupine V.N.T. has 750,000 shares still in its treasury, that the mine is well thought of and that with a small advertising campaign the money could be raised by selling only a small block of shares. General resentment is made manifest in connection with the mortgage proposal which is contended to be entirely uncalled for.

The head office of the Hollinger Consolidated has been changed from Toronto to Timmins, as provided for in a by-law passed at a meeting held in Toronto on June 29th. A number of other companies are reported to be preparing to take similar action.

At depth on the McIntyre-Porcupine, the result of operations continue extremely favorable, according to latest advice, and the year just closed on June 30th is understood to have been the most favorable so far in the company's history. It is intimated that total income exceeded \$2,000,000 and that net earnings amounted to well over \$1,000,000. This earning power is large as compared with the issued capital of \$3,600,000 made up of 3,600,000 shares.

In regard to the Lake Shore Mine at Kirkland Lake, it is officially announced to the "Journal" that the main shaft is to be continued from the present depth of 400 feet to a depth of 800 feet. In view of nearly a million dollars having already been produced by using the small mill of 60 ton daily capacity on ore

between the 400 ft. level and surface, chiefly from between the 400 and 200-ft. level, and with several years' ore still in sight at this horizon, it is quite evident that very considerable importance attaches to the announcement of the intention to get another 400 feet deeper. Success at the 800-ft. level would tend to the present mill being enlarged to double or perhaps treble its present size, according to official advice.

Owing to further delays in connection with the consolidation of the Tough-Oakes Gold Mines with the Aladdin-Cobalt and the Burnside, the belief has taken form that a situation has developed which is more serious than was at first supposed. It is believed the difficulty is in part at least due to a satisfactory arrangement in regard to the disposal of the treasury of one of the participating companies.

It is learned that a plan is being arranged with the object in view of working the Orr Gold Mines. The Wettlaufer interests of Buffalo and Hamilton B. Wills of Toronto, are said to be negotiating along lines mutually satisfactory. The plan includes arrangements to construct a mill so as to place the mine on a self-supporting basis as quickly as possible.

The main shaft on the Bidgood property at Mud Lake in the township of Lebel has reached a depth of 200 feet, and a cross-cut is being driven to the downward continuation of the vein. This was expected to be cut today, July 5th. At the first or 100-ft. level, the Bidgood vein had a width of about 12 feet, about eight feet of which was medium grade ore. After intersecting the body it is planned to continue the shaft to the 300-ft. level at which point extensive lateral operations will be carried out.

Good progress continues to be made at the Argonaut Gold Mines in Gauthier township, lying East from Lebel, and the belief has taken from that this is the eastward continuation of the auriferous zone along which the mines of the Kirkland Lake field are located.

During the course of performing assessment work on the claims owned by the Kirkland-Porphy company (now in voluntary liquidation), a wide vein had been opened up. The claims are situated in Teek township, south from the producing area. Whether or not the gold content of the vein is such as to offer more than ordinary encouragement is not yet announced.

A vein about ten feet in width has been opened up on surface on the Wood-Kirkland property in Lebel township. Gold tellurides are said to occur in the newly discovered vein.

A contract has been let to diamond drill the Porcupine-Miracle property in the Night Hawk Lake section of the Porcupine district. It is planned to cut the main vein at a depth of 300 as well as 500 feet. Former underground work was carried to a depth of 86 feet at which point some shoots of high grade ore are reported to have been found. The property is equipped with a mining plant as well as a small mill.

A good deal of interest appears to be developing in connection with the occurrence of oil shales in the vicinity of Long Rapids on the Abitibi River, and considerable local support may be given to enterprising individuals who propose to investigate the possibilities of the deposits.

In connection with the lack of a highway between this part of Northern Ontario and the older parts of the province, a proposal has been made by the Associated Board of Trade of Temiskaming suggesting that the government set aside ten townships, each six

miles square, the timber to be sold by tender and the proceeds to go towards paying for the construction of a macadam road from North Bay to Cochrane with branches to Porcupine and to Iroquois Falls. The road would be about 300 miles long and would cost at least \$3,000,000. It would link up the entire district of Temiskaming as so far developed, with the roads connecting with old Ontario.

## Manitoba Letter

C. S. MILLICAN.

### Pas Mineral Belt.

At the Flin Flon Property work is going on rapidly and the shafts have reached a depth of 100-ft. and 70-ft. respectively. Some trouble was encountered with water in one shaft, but that has now been overcome. In the more northerly shaft where the ore-body was struck native copper was found at the contact between the ore body and the country rock—apparently a concentration product. Drifting and cross-cutting will take place either at the 200' or 400' level in order that the whole ore-body may be fully prospected at one definite horizon during the summer. The total number of men in camp is approximately one hundred. Investigations are being carried on in the field with reference to fluxes and the development of the water power necessary for the operation of the property.

### Big Island Lake District.

Considerable interest has been aroused in this district which lies directly east of the Mandy Property owing to the occurrence of cobalt bloom over what is apparently a fairly wide zone of country rock. It would seem that the country rock at this point is mineralized with fine-grained smaltite in a zone closely connected with copper-sulphide mineralization. Not much work has yet been done to determine whether there is a possibility of silver mineralization connected with the cobalt but the ground is looked on as one of the best areas for prospecting in the territory.

### Copper Lake District.

Diamond drilling is proceeding on Gordon's Big Lode. The results of the assaying of the cores are not yet to hand. It is understood the mineralization at depth is heavier than on the surface. The total width of the lode as ascertained by diamond drilling is approximately forty-five feet. If the values are found to continue at depth this property will hold out great promise.

### Elbow Lake District.

In the district there has been considerable interest taken this Spring. A discovery made by T. Webb (an old-time prospector in the field) of very spectacular gold in quartz near the mouth of Webb Creek was followed by other discoveries by Forrest and others of fairly extensive lodes carrying apparently good values. These discoveries have caused an influx of prospectors into the territory north of Elbow Lake where there is likelihood of other discoveries of value yet being made.

### Second Cranberry Lake.

North-east of the Lake, work has been done by Rosen who is responsible for the discovery of cobalt bloom on Big Island Lake) in chalcopryite bands which show promise of giving workable values. This ties on the same belt of mineralization as the Copper and Brunre Lake territory. The whole field between Elbow Lake

the Cranberries and the east side of Athapuskow Lake is still open for prospecting and forms one of the most attractive areas in the whole belt.

### Herb Lake.

The Rex Mine is again in operation with some 20 miners under J. R. Campbell. Additional capital has been obtained to place the property on a working basis and careful management is assured. On the Bingo property there are some 12 miners. On the Northern Manitoba, work is being done preparatory to opening up the property again. Before the end of the Summer it is expected that there will be much further development in this area. The wagon roads from Sturgeon Landing to Lake Athapuskow, leading into the copper belt, and from Mile 82 to the south end of Herb Lake, leading into the eastern part of the gold territory, are being kept in repair by the Provincial Government.

The following names of mining companies having headquarters at Winnipeg, were omitted from the list that were given in this letter in the issue of the "Journal" of June 11th, (see page 486.)

Bingo Mines, Ltd., 315 Paris Bldg., Winnipeg.

The Pas Consolidated Mines, Ltd., 315 Paris Bldg., Winnipeg.

Northern Manitoba Mining and Development Co., Ltd., 711 Paris Bldg., Winnipeg.

### SILVER ISLET MINE.

#### Geological Survey of Vicinity Required.

By J. J. O'Connor.

The Silver Islet Syndicate are meeting with most satisfactory results in their investigation of the roof of the Silver Islet Mine. All reports indicated large bodies in the roof, and so far as the operations have proceeded, everything has been found as indicated. Another body of high grade ore has been uncovered in the east stope, above the first level. A few shots put in show it to be very rich, and of considerable extent, as yet not fully determined, but such as to be very gratifying to the operators.

Dr. T. L. Tanton, of the Geological Survey, Ottawa, has strongly recommended that a complete geological survey be made of the "Wood Location" (Silver Islet) together with the adjoining territory north and west, to Sawyer's Bay, including Thunder Cape.

The "Wood Location" comprises ten square miles. The adjoining territory recommended for survey, embraces and are of fifteen square miles, making twenty five square miles in all. If this survey be carried out, it will enable systematic prospecting of the area to be done in an intelligent and effective manner. This bit of ground has been too long neglected by the Survey, considering the large amount of silver it has produced in the past from one small speck of rock in Lake Superior on the "Wood Location". The whole area is cut by a series of dykes, and it does not seem reasonable that the only place silver will be found, is at the point where one of these dykes cut the Silver Islet vein. There are many such intersections known, and a survey would doubtless throw light on others, and place in the hands of prospectors the necessary information for opening up a prosperous silver-mining field. In any case, the dyke zone should have a thorough geological survey made of it. The necessary capital is at hand, on the ground, and immediate advantage could be made of any discovery resulting therefrom. It is hoped that the Geological Survey will accede to the recommendation.

## Nova Scotia Notes

The Minister of Labor announces that a Royal Commission will be appointed to enquire into and if possible adjust the questions connected with the demand of the United Mine Workers in Nova Scotia for an increase in wages effective May 1st. The Commission will presumably hold separate sittings to consider the wage question as it affects the several companies.

The Dominion Coal Company is making preliminary inspection of several mooted sites for new collieries to win the lowest seams in the Glace Bay district, but no definite announcement of the chosen locations has yet been made. Work is rapidly proceeding on the re-opening of the Morien seams.

The production of the Glace Bay collieries during June totalled 281,000 tons, which compares with 256,874 tons in May, and is 57,000 tons larger than the output of June 1919. The production for the first six months period of the past two years compares with 1920 as follows:

	Tons
1918 . . . . .	1,685,432
1919 . . . . .	1,539,328
1920 . . . . .	1,615,713

The production from the Glace Bay collieries in the first six months of 1914 was 2,254,043 tons, and in June 1914 was 452,279 tons, so that present production is approximately thirty percent below the pre-war rate.

The output of the Springhill Mines during June was 35,743 tons. The production rate at these collieries has changed very little from pre-war figures, the output for the first six months of the years noted below being as follows:

	Tons
1914 . . . . .	199,961
1918 . . . . .	201,852
1919 . . . . .	187,690
1920 . . . . .	220,000

An output at the tonnage rate exceeding that of 1914 is unique among the operating collieries in Nova Scotia—except for some recently commenced small collieries.

The production of the Acadia Coal Company for the first six months of 1920 was approximately 250,000 tons, comparing with 190,000 tons in the first half of 1919. An output increase of 25 per cent is notable.

The Intercolonial Coal Mining Company at Westville had a production during the first six months of the year of about 81,000 tons, comparing with 89,000 tons in the corresponding period of 1919. Production has been hindered by fire in a portion of the underground workings, necessitating temporary walling-off of the affected area.

Greenwood Coal Co. produced some 28,000 tons in the first half of the year, comparing with 17,770 tons in corresponding period of last year.

The Nova Scotia Steel and Coal Co. report output during June of 56,307 tons, about one thousand tons in excess of May production.

A well-known financial bulletin contains an article headed: "The Hope for Price Maintenance." This betrays one point of view, but it is not a general one. Hope in this instance is commingled with fears that prices may not come down yet awhile.

## British Columbia Letter

### THE METAL MINES.

#### Stewart, B. C.

The mining communities of Stewart and Hyder, as well as the scattered mining population of northern British Columbia and Alaska, were alarmed by a hurricane which swept up the Portland Canal about two weeks ago. Trees were torn up, houses were shaken, and small craft along the water front were swamped. There were no fatalities and not a great deal of material damage on which residents of the town are congratulating themselves.

Diamond drilling has been commenced on the Province Claim of the "Big Missouri" Group. Boyle Bros. have the contract. Last year the same form of development took place on the E. Pluribus Claim of the same Group. This property is one of the most extensive of the low grade prospects of the Salmon River Section, Portland Canal District.

Col. T. A. Hiam, the representative at Stewart of Sir Donald Mann, expects the Northeastern Railway up the Bear River, to be in operation this season. The bridges and right-of-way are being repaired and the gasoline locomotive to be used has arrived. As there are a number of properties up the valley to be developed Col. Hiam is confident that the road will be kept very busy.

#### Alice Arm, B. C.

The Taylor Engineering Co. is reported to have awarded a contract for the installation at the Dolly Varden Mine of a hydro-electric power plant. The cost is put at \$65,000.

#### Hazelton, B. C.

The Kitselas Mountain Copper Co.'s concentrator at Usk B. C. has been in operation for about a week, having started early in the month of June. It is giving satisfactory results. A considerable quantity of ore is being treated and development is in progress at the mine. The ore carries values in gold, silver and copper.

The Silver Standard Mine, New Hazelton, B. C., has been shipping steadily this year and important development is also in progress on the property. A new tunnel is being driven which has reached two veins and will continue until it crosscuts the main lead. Transportation to the concentrator is furnished by a large motor truck. It is used both summer and winter. Travelling in the winter is good after the snow becomes hardened, wires being wound about the truck wheels to ensure traction. Considerable high grade ore is being shipped direct to the Trail Smelter. Although the property is very promising it admittedly is yet in the development stage. The utilization of some of the water-power possibilities of the district is planned and with such a facility to hand the management look forward to placing the mine on a more productive basis.

#### Barkerville, B. C.

Placer miners are preparing for the season's work in the Cariboo District. John D. Galloway, government mining engineer, recently made a trip through a part of the section and, while it is impossible as yet to estimate the extent of the hydraulic mining to be

undertaken this year, the prospect generally is good. Owing to the unusually late spring and the heavy fall of snow there should be a plentiful supply of water and fall operations appear assured. The old channel on Grouse Creek, where the values are reported to be good, will be piped by the Waverly and there will be operations at Lowhee and Stout's Gulch. Generally it is expected that most of the old companies will be on their ground again and that some new leases will be worked. Notwithstanding lack of labor and high costs it looks as though the old Cariboo would seem more placer mining, both hydraulic and individual, than it has for some years and that the gold output will show an increase as a result.

#### Nelson, B. C.

Preparations are in full swing for the International Mining Convention to be held at Nelson from July 20 to 24th inclusive. Fred S. Starkey, Commissioner of the Associated Board of Trade of Eastern B. C., again is in charge of the arrangements. He proposes placing on display a representative exhibit of the ores of the Kootenays as well as outlining a programme that will furnish visitors both mental stimulation and diversion. One of the special features, it is understood, will be a trip through the mining sections of the eastern part of the Province for those of the delegates who care to make it.

The Mandy Mine, of Le Pas, Manitoba, is resuming shipments to the Trail Smelter according to authentic word received at Nelson. The first consignment for the year consists of 30 cars. Ten cars are to be shipped every two days throughout the season. It will be transported by water to Le Pas, by the Canadian National Railway to Calgary, and thence by C. P. R. to Trail. The Mandy last year shipped 8401 tons of ore to the British Columbia Smelter.

#### Rossland, B. C.

The faith of the old-time residents of Rossland, B.C., one of the oldest camps of the Province, that prosperity, which momentarily passed away when the mines of the Consolidated Mining & Smelting Co. were practically closed down, would return is about to be justified. At least such are the indications. The company's mines, it is stated, are to be put on a producing basis very soon, it being expected that shipments will be resumed early in July. The ore bunkers have been repaired, ore from the Mandy Mine, Manitoba, which the smelter management like to handle with the Rossland mineral, is coming, and all other conditions are satisfactory. The only element of doubt lies in the labor shortage. If the men are available there is no doubt that the mines will be made to yield without delay and that Rossland once more will take her accustomed leading place among British Columbia mining centres. That this will come about eventually is certain because the improvement of metallurgical methods of treatment of Rossland Ores and the construction of a concentrator for the application of these improved methods assures it. The Consolidated Mining and Smelting Co. will start work on this Mill shortly.

#### Trail, B. C.

Ore receipts in gross tons at the Trail Smelter of the Consolidated Mining & Smelting Co. for the week

ending June 14, totalled 6,913. For the week ending June 21 there were received 6742 tons. Two new shippers appeared in the latter list, namely, the old Whitewater Mine, of the Slocan, and the Sunnyside, Rock Creek. The total ore receipts at Trail Smelter for the year up to date are 135,068 tons.

#### Princeton, B. C.

W. P. Tierney, the contractor in charge of the construction of a railroad to connect the Copper Mountain Mine of the Canada Copper Co. and the Kettle Valley Railway, has stated that rails will be laid within 30 days. This 15-mile stretch of steel probably represents the hardest and roughest piece of construction undertaken in western Canada in recent years. The only work comparable to it is the road to the Dolly Varden Mine. The contractor states that the cost totals \$1,500,000. It describes it as having been heavy rockwork, bridges and trestles all the way.

#### Invermere, B. C.

Interest is keen in the work of the Toby Creek Mining Co., of Vancouver, B. C., in the opening up of their property, the Maple Leaf and Silver King Groups, situated on the Jumbo Fork of Toby Creek. On these claims is a large ledge of silver lead ore upon which there is active development. A 121 foot tunnel has been driven and it is to be extended. There is a quantity of concentrating ore already on the dump awaiting shipment. The government is constructing a road and with the completion of this work it will be possible to reach the properties by automobile.

#### Cranbrook, B. C.

With reference to the revival of placer mining activity on Wild Horse Creek, to which reference already has been made, it is interesting to note that the annual meeting of the Wild Horse Creek Gold Mining Co. was held recently at which the manager reported that the pipe line had been completed and that water would be turned on immediately. Officers were elected as follows: President, Lester Clapp; vice-president, A. Raworth, Secretary-Treasurer, W. D. Gilroy; Directors, C. R. Ward, Gustave Nelson, F. M. McPherson, F. A. Russell, and L. P. Sullivan; auditor, F. W. Burgess; Manager, A. J. Pamquist.

#### Victoria, B. C.

W. E. Ditchburn, Chief Inspector of Indian Agencies for British Columbia, reports that there have been a number of applications for permits to prospect on Indian reservations in this Province for the precious metals. This is allowed under an Order-in-Council passed by the Dominion Government giving effect to certain amendments passed by the Provincial Government to both the Mineral and the placer Mining Acts. While mining men consider the action of the authorities in throwing open the reserves for this form of mining a step in the right direction they do not consider that it goes far enough to do much good. A prospector may get a permit and may locate a claim on an Indian reserve but he cannot remove more than the gold and silver. These two minerals in British Columbia are usually found with other minerals so that the problem that the Dominion and Provincial Governments have left the miner to solve is easily appreciated.

**END DUMP MINE CAR.** Roller Bearings in dust-proof wheels. Made any size or capacity to suit.

**ROTARY MINE CARS.** Roller Bearings, dust-proof, easy running. Will dump at either side or end. Made in a large range of sizes and capacities.

We show here  
**FOUR TYPES**  
of our  
**MINE CARS**

**ROTARY SCOOP CARS.** Roller Bearings, with dust excluding device. Dumps at either side or either end. Made in any size you want.

We make many others.

We Make the  
Kind You Want.

Let us send you a copy of our new Mining Catalog of Mine Hoists, Cars, Cages, Buckets, etc.

**END DUMP QUARRY CAR.** With dust-proof self-oiling bearings. This is only one of our many types of End Dump Cars.

**Marsh Engineering Works, Limited, Belleville, Ontario**  
ESTABLISHED 1846.

Sales Agents: **MUSSENS, LIMITED, Montreal, Toronto, Winnipeg, Vancouver**

### Vancouver, B. C.

Dr. Edwin T. Hodge, formerly of the mining branch of the British Columbia University and who has accepted a lectureship on the faculty of the Oregon University, has bonded the Emancipation Group of Mineral Claims, situated on the Coquahalla river, near Dewdney Creek, about fifteen miles from the town of Hope. Some development has taken place on this property and ore has been shipped containing gold and silver values. Dr. Hodge is impressed with the possibilities of this property and, it is said, proposes giving his personal attention to its development.

That the sourdoughs of Dawson, Yukon Territory, scorn to permit, as far as it is in their power to prevent, the circulation in that part of Canada of dimes, nickles, and pennies is the purport of an interesting newspaper dispatch from the north. These old-timers, as well as those who date the commencement of their residence in those parts to more recent times, held fast to the principles laid down in the rush of 1898. The least that will be accepted in Dawson is a twenty-five cent piece and one grizzled old prospector thought the limit should be set at a dollar "as the dollar buys no more now than a nickel did a few years ago."

### The Coal Mines.

In view of the alarming reports in circulation as to the increasing shortage of fuel oil, and the possibility of important industries being forced to close down, at least until coal-burning appliances can be installed, anything bearing on coal production is of interest in the Canadian West. As it has just been stated that there is a likelihood of the several pulp manufacturing

plants of this province being compelled to cease operations for a considerable period because of lack of oil, a contingency that will have to be met by substituting coal as a fuel, it is especially noteworthy that the collieries of British Columbia are at present handicapped in their operations through difficulty in obtaining an adequate supply of labour. If the threatened added demand develops, while there is no doubt that there is plenty of coal to be got in this Province for all requirements, the problem of securing miners would assume a more serious aspect. As it is it is serious enough. Neither the Canadian Collieries (D), Ltd., nor the Canadian Western Fuel Co., the two large operators of Vancouver Island, have as many men as could be taken care of and the Pacific Coast Coal Company, which is under the new management of George Wilkinson, formerly Chief Inspector of Mines, is commencing extensive development both of its fields at Extension and at Squash is advertising for men in Victoria and Vancouver. The idea of inviting applications for employment from coal miners in the cities is sufficiently novel to furnish a striking indication of the conditions. The explanation is hard to find as the miners are highly paid unless it be that they no longer have the advantage of workmen of other crafts as to hours of labour, the eight hour day now being general. The suggestion has been made that coal miners who went overseas have not returned to their work underground. In the majority of cases, it is said, they have sought employment elsewhere. Whatever the cause there is no doubt that qualified coal miners are hard to find in such numbers as is necessary to place all the mines of the Coast and of the Interior on a basis of maximum production.

**PEAT AS A FUEL. A BRITISH INVESTIGATION**

The Department of Scientific and Industrial Research has published the lecture delivered before the Royal Dublin Society by Prof. Pierce F. Purcell on the Peat Resources of Ireland, as the second of the Special Report Series of the Fuel Research Board, the first being Mr. Leonard C. Harvey's report on Pulverized Coal Systems in America. The peat problem, although of venerable antiquity, becomes periodically rejuvenated in times of fuel scarcity. But the present virile phase of this much-debated question seems to present some points of difference, as compared with former waves of public interest in the subject—partly because the advance of knowledge has opened up new channels for its prospective utilization, but mainly because the pressing needs of land reclamation for agricultural purposes in certain countries has made it inevitable that many peat-covered areas should be stripped and made available for cultivation. From this standpoint peat has in some cases become a by-product of agricultural development, and its utilization for some purposes or other has therefore become an essential factor in the economy of these schemes. To cut peat for its own sake and to find a use for a secondary product are totally different questions; and it is necessary to bear this fact in mind when estimating the commercial value of some modern methods of utilization.

The Fuel Research Board have therefore been well advised to consider the peat problem in its present-day aspect, and no better exponent than Prof. Purcell, could have been found to expound it. At the same time, the old economic difficulty still remains that, compared with coal mining the working of a bed of peat 20 ft. thick, as Sir George Beilby reminds us in a prefatory note to this report, is somewhat like developing a 15 in. seam of coal. The labor involved in procuring one ton of dry peat involves handling once or oftener, at least ten tons of raw material, and this fact alone would seem to militate against any prospect of success in working peat deposits on a large scale.

The question arises, therefore, whether it is possible to overcome the labor difficulty in peat production to any extent, and this is answered by Prof. Purcell somewhat hopefully in the light of experience gained in Canada and in Germany of the application of mechanical methods of extraction of this extremely low grade fuel. The nature of the problem is aptly illustrated by the fact, pointed out by Prof. Hugh Ryan of Dublin, that there is a greater percentage of solids in milk than of peat in a drained bog. Air-drying can never by itself be an entirely satisfactory solution of the difficulty because of the hygrometric property of peat, which limits the final water content to about 16 per cent in theory, but to a much larger figure in practice, and so far no really economic process of artificially dehydrating it has been proved to be entirely successful, although the Ekenberk system, still in an experimental stage, is claimed to have given promising results.

It is not necessary to follow Prof. Purcell in his admirable survey of the area and fuel content of the countries. Neither do we need to dwell upon the many uses to which peat has been put apart from its value as fuel. It will be more to our purpose to follow Prof. Purcell in his remarks upon the utilization of this substance for power purposes. To this end, the gas producer certainly promises the best results, because

the presence of 60 to 70 per cent of moisture may not in this case prove to be prohibitive, since some manufacturers of gas producer plants already claim that this can be achieved. With regard to this point, however, Prof. Purcell is of opinion that the Italian practice, whereby the peat is first dried by exhaust gases to a moisture content of 33 per cent, is probably more economical, and in this view he is supported by Haaner, of the Canadian Departments of Mines, who maintains that with a moisture content of 60 per cent the quantity of heat generated is not enough to enable the producer gas reactions to take effect so as to enable power gas of the necessary heating value to be formed. But even when these criticisms are admitted it still remains true that peat with a moisture content of about 40 per cent can be effectively used in a specially constructed gas producer—a result which could scarcely be expected by direct combustion under a boiler.

Prof. Purcell examines in some detail the various ways in which the power gas from a producer could be used. It can be used in a gas-fired boiler or used in a gas-engine. Of these the latter is shown to be the more efficient in theory, but it is doubtful whether it can be employed on a large scale. As a matter of fact the best way of utilizing energy from peat remains still an unsolved problem, and it is hoped that the elaborate series of experiments about to be undertaken by the Fuel Research Board at the new research station in East Greenwich will definitely settle the question. There are many factors to be considered besides the over-all efficiency of any particular process. Questions of labor, depreciation, maintenance, capital charges and profits from by-products should also be taken into account, and in this connection it is a somewhat debatable point whether the end in view should be the maximum production of by-products or the greatest development of power gas, both of which cannot be achieved at the same time. It must also be remembered that the yield of sulphate of ammonia depends upon the percentage of nitrogen in the peat, which is by no means a constant quantity; so that while by-product recovery on one peat bog might be a payable proposition, on another it might prove a failure. Thus, as Prof. Purcell truly remarks, the problem is very complex. Hitherto, attempts to run peat power in Ireland have been limited to two only, one being in use at Clifden in Galway by the Marconi Company, and another, a producer plant, at Portadown, Co. Armagh, but these are on too small a scale to enable any general conclusions to be drawn from them. The wet-carbonising plant at Dumfries, run by the War Department for the production of briquettes during the war, furnishes another object lesson in the possibilities of peat utilization; and other projects have been under contemplation, nothing so far has been attempted in this country at all comparable with the work done in this direction in Canada, Sweden, Germany and Russia, where large scale plants, both experimental and commercial, have been installed, but for various reasons it is necessary to suspend judgment as to the results achieved. The largest peat power plant in the world, that of Bogerodozk, near Moscow, only began work in 1914, and its subsequent history is naturally obscure; and the great Fidesland project has been too intermingled with political considerations to be a trustworthy example of economical working. Moreover, in both these cases the peat is burnt direct under water-tube boilers.

## PAPER AND COAL

### A Curious Parallel to Our Newsprint Situation

(From the "Colliery Guardian")

Most of our readers have had so many worries of their own during the past few months that we have foregone the temptation to ventilate a trouble that has afflicted ourselves in common with all other periodicals. We refer to the shortage and high cost of paper. Modern industrialism, however, is so compacted that no trade can remain indifferent to the woes of its neighbors. Thus, when we called for an increased output of coal we were not entirely disinterested, for paper mills have been stopped for lack of fuel, and pulp boats from Norway have been detained for similar reasons. The prospect of a reduction in exports we view with the same mixed feelings. It shipments of coal are to be limited to 20 million tons, and 65 per cent of these are embarked from France and Italy, it will be possible to spare very little for our Norwegian friends, in return for their iron ore, timber and pulp, and the pits and the papers are, to that extent, in the same boat.

A short time ago one of the news agencies told us that the Norwegian Government were requiring makers of newsprint to supply Norwegian newspapers with their full needs of paper at a price below cost, otherwise they would not be permitted to continue their export business.

The Anglo-Norwegian Trade Journal characterises the whole story as a warped representation of the facts. The official organ of the Norwegian Chamber of Commerce in London says:—

By an Order in Council, in November 1919, the Government fixed the price of paper for home consumers at 55 ore per kilogramme. The price is due for a period running till the end of this year. At the time of the Order the price was quite sufficient to cover the cost. Since then the cost has increased, owing, particularly to dearer coal, and the mills, of course, have had to make good the loss by increasing the prices for later sales abroad. If paper contracts cannot be carried out at the originally agreed prices, the real cause is the increased coal prices. About the same time as the Norwegian Government, in November, fixed the price of paper for Norwegian consumers, the British Government in December, took off 10s. per ton of coal for British consumers. The loss was made good by enhanced coal prices for foreign consumers. The coal prices up till recently paid by British consumers are very much below cost price, so much below that if only 10s. had now been put on again the British consumers would still have had their coal below cost. Norway is one of the foreign consumers who have to pay the enhanced coal prices and the British Press is one of the home consumers who benefit thereby. No Norwegian news agency was stigmatised the British Press as being for this a "subsidised" Press. What moral difference is there between Norwegian paper and British coal? . . . . One can understand the feelings of British consumers paying the high paper prices, but what about the unhappy paper mills and other consumers in Norway paying the prices of British coal? In addition to the soaring prices there is the expensive delay of coal ships and the deficient delivery. As a typical instance can be mentioned that a Norwegian steamer, 3,000 tons arrived in the Tyne on January 31, and only on April 24 could she sail with a cargo of coal for one of the principal paper mills in Norway, and what stuff, at crying prices, can they get, these three months delayed steamers? They take small coal and duff and such inferior coal as the Coal Controller has no use for. How can anybody under such circumstances expect cheap paper from Norway? . . . It is just coal that can speed up production in Norway, but as a matter of fact, she gets even less coal from Britain this year than last year.

The argument is unanswerable. It little becomes us to sneer at a friendly nation, which has grave

troubles of its own, for doing things which we have done much more extensively and masterfully ourselves. Moreover, from the economic standpoint, these fiscal reprisals are deadly—to those who set them in train!

### TIME APPROACHING WHEN OIL-SHALE DEVELOPMENT WILL BE REQUIRED.

Pres. Alderson, of Colorado School of Mines, says the time has come when production of crude oil wells must be supplemented by production from oil shale. Position of the shale industry has been essentially changed in the last few years because of pronounced advance in crude oil. At present prices of crude oil, it is possible for oil from shale to compete profitably with oil from wells. This was not the case a few years ago, when oil in Mid-continent sold for as low as 40 cents a barrel, against present price of \$3.50. He says:

"Crude oil can be produced from shale under present costs at \$1.85 a barrel in Colorado and Utah. Crude oil in Wyoming, the nearest big field to Colorado and Utah shale-supplies, is selling at \$2.75 a barrel. Pennsylvania grade oil is quoted at \$6.10.

"The oil shale industry in relation to the oil business is similar to position of the porphyry companies to the copper industry. In Colorado and Utah there are 5,500 square miles of oil shale, which, with a yield of one barrel of oil to one ton of shale, will produce a practically unlimited supply of oil.

"Production of petroleum from wells in this country to date has been obtained from 4,109 square miles with estimated yield of 2,280,000 barrels to the square mile. One ten-foot seam of shale, yielding one barrel to the ton, will give 15,488,000 barrels of oil, or seven times the square mile output from wells. The 5,500 square miles of oil shale in Colorado and Utah will produce 255,000,000,000 barrels."

In his opinion the desirable minimum investment for the best operation of oil shale retorting plants is \$500,000. Under more favorable conditions in Colorado and Utah fields, as compared with Scottish fields, return on capital investment will be substantial.

Dr. Alderson points out that several oil fields in this country have passed their peak and are steadily declining in output. Fields in Wyoming, however, are still capable of greatly increased production, and the same is true of fields in Kansas and Oklahoma.

Scottish shale oil industry has been profitable over a long period and its record should be improved by the shale industry in this country, especially in Colorado and Utah, because of greater richness of shale strata and their more easily workable surface location.

Dr. Alderson will sail for England shortly, where he will investigate oil shale conditions—"Boston News Bureau."

Labor politics in Australia seem to be accompanied by much bitterness. The "Industrial Australian and Mining Standard" last to hand contains a sardonic cartoon, in which a gentleman of the traditional "capitalist" type as portrayed in American lampoons, is shown addressing an audience of apparent jailbirds as follows:—"Now boys, I will put the motion, Hands up the b. . . . scabs and traitors who want to continue doing a fair day's work for a fair day's pay. "Thank you, boys, not a single hand raised: I declare "the resolution to strike carried unanimously."

Gardenvale, P.Q.

**STRUCTURAL GEOLOGICAL FEATURE OR MORPHOLOGIC AGENCIES?**

There are two reverse faults and three erosion fault-scarps underground at the mine that are of great interest geologically and of much value mineralogically to the proposition. Two of the fault-scarps are normal and exhibit great importance to age disturbances or (dynamic) crustal movement and ore-deposit.

"After very technical investigations it is observed that these faults at the mine were developed from very early morphologic agencies; therefore will offer no serious obstacles to mining on the property, for the fault were long in progress and evidently complete according to the dynamic aspect before the formation of the vein; but have rather aided secondary enrichment."—Extract from a report on a property.

# Aladdin

## “Excellent Satisfaction”—The Cleveland-Cliffs Iron Co.

Aladdin Read-Cut Houses universally give satisfaction. The most difficult industrial housing problem can be simplified and solved by the Aladdin method and without the slightest slip or hitch.

It is customary in the Logan Field for the mining company to furnish housing for the employees. Therefore at the Ethel Mines, the Cleveland-Cliffs Iron Company had the usual precedent to follow. Their housing problems were solved with Aladdin Read-Cut Houses, regarding which they write,—

*“We shall be pleased to have you use our name as reference, as the houses which we have already purchased from you have given us very excellent satisfaction. As our operations expand more houses will be necessary.”*

This is but one of the many instances where the Aladdin service has solved the housing problem. Better houses, lower in price, more quickly erected, these are the expressions of satisfaction we hear from every customer.

## Aladdin

- expedites your building project—
- houses your men well and quickly—
- saves 18% of the cost of lumber—
- saves 30% of the labor cost—
- reduces the skilled labor required—
- guarantees complete shipment of material—
- guarantees the quality—
- carries material for 1000 houses in stock—
- ships from the nearest timber region—

—quotes definite prices on any order from one house up to a city of 3000, including churches, schools, offices, water and sewage systems, electric plants, street and house lights, heating plants, street parks, trees, lawns, etc., complete.

## EDITORIAL

### A Second Industrial Conference

Announcement is made that a second Industrial Conference is called by the Minister of Labor at Ottawa in the ensuing Autumn, provision for the expenditure which will be entailed having been provided in the parliamentary estimates. Complete unanimity of opinion regarding the necessity or the useful purpose to be served by a repetition of last year's conference is unlikely. The encroachment of the decisions of such a gathering upon provincial rights, and the tendency it fosters to the over-riding of local and provincial considerations by federal measures is something that politicians doubtless do not overlook.

The composition and form of procedure of the Industrial Conference of last Autumn were such as to place the representatives of employers at a disadvantage, and the spokesmen of organized labor were advantaged thereby. Employers in Canada are unorganized and lacking in cohesion, whereas the labor organizations are a unit.

The Canadian Manufacturers' Association is a powerful and necessary organization, but its usefulness lies altogether in caring for the commercial side of industry, which includes a careful watching of tariff and fiscal policies, imports and exports and judicious publicity. The Association is treading on dangerous ground when it becomes the representative of the employer in matters pertaining to labor and wages legislation, nor can it hope to adequately represent the individual employer so long as the laws of Canada permit—and encourage—the complete organization of trade unionists, and forbid similar organization of employers.

The union leader achieves his leadership through possession of oratorical and analytic gifts. His mind is saturated with facts, and apt phrases, regarding questions of which he has made a concentrated life study. As a platform speaker he is at his best, having arrived at leadership through a process of natural selection from amongst his fellows by virtue of ability to impress his sentiments upon others.

The employer represents the evolution of very different experience. Taciturnity has been praised as a business asset since the days of Solomon, and many successful executives suspect the man who can talk well, or is given to putting his thoughts on paper. Facts and figures are doubtless impressive, but they

lose their influence in the presence of a smiling union leader particularly when he jocularly impugns their accuracy.

If the Industrial Conference is to be repeated, and the employers wish to appear at less disadvantage, it is suggested that the employers should be represented by those managing and operating executives that have to deal day by day with their men, and that less reliance should be placed upon ponderous briefs dealing exhaustively, but unconvincingly, with academic phases of employment.

At the Conference last Autumn, the employers fought, on questions of academic principle, the introduction of changes that were accomplished facts of long standing in many industrial establishments in Canada, and in some instances were already incorporated in provincial statutes. In too many instances it was apparent that the employers were unacquainted with contemporary developments in labor matters, whereas the representatives of the men were posted up to the minute.

It should also be mentioned that there is today in the possession of the Department of Labour a mass of statistical information, representing the essence of a voluminous literature upon labour questions, most of which has been compiled and conceived from the natural standpoint of a department, instituted to care for the interests of Labour, as its name sufficiently indicates. The ammunition provided by the publications of the Department of Labour was skilfully used at the last Conference, to the discomfiture of speakers on the employers' side.

The useful work that was accomplished by the Conference of last Autumn could equally well, and with more expedition, have been achieved by a smaller gathering, and, as a matter of fact, any definite results obtained were got in committee. The desired end, namely, the mixing of employer and workman on a mutual footing of equality and tolerance, was not markedly achieved, and the rigid division of the two parties to the Conference, both in regard to seating and ideas was obvious, and had some element of humor, seeing that there were many on one side, who, but for the wheels of circumstance, might have well been upon the other side. The caste distinction between master and man in Canada is new, and fortunately not yet rigid, but that any amelioration of the

distinction was effected by the Industrial Conference last year is open to doubt.

If it is decided to assemble the Conference again this year, the public sessions should be reduced to a minimum length, and should be confined to little more than the appointment of committees. The average executive can ill spare the time necessary to travel to Ottawa and attend a lengthy and exhausting series of conferences necessarily wordy and argumentative, and dealing more with ethics and principles than with economic working conditions.

#### ONE PITFALL AVOIDED.

The Toronto "World," commenting on the Nova Scotia election shortly to take place, states that the "Liberal administration has been cautious and economical rather than progressive; all the mineral wealth of the Province, including the vast deposits of coal, are vested in the Crown, but no effort has ever been made to operate any coal mine by the Government. The result has been high-priced coal to consumers in Nova Scotia, and an absence in the mines of up-to-date machinery."

The Conservative newspapers in Nova Scotia say nasty things about the Liberal Government there, as is the wont of opposing political parties, but no one ever accused the Murray Government of sufficient lack of sense to undertake the operation of a coal-mine. If the opposition could by any means have inveigled the Nova Scotian administration into such an adventure it would have provided them with much campaign literature, and, if it should be regarded as a mark of progress for a local government to undertake coal mines operation, then Nova Scotia has much to be thankful for that the Murray Government has not progressed in this direction, but has preferred to be "cautious and economical rather than progressive." Governments have their uses, but coal-mining is not one of them. The foresight and fostering of coal mining is another story.

#### GOLD PRODUCTION IN CANADA.

In 1919, Canada was one of the few countries, if not the only country, in the world to increase its gold output, and, so far, the returns for 1920 indicate that the figures of last year may be exceeded. By far the greater part of the gold comes from Northern Ontario, and a very small part of that district. At a time when economic causes are causing shrinkage of gold output in other countries, it is significant that in Canada—where these same economic deterrents are not less active—an increase in production of gold should be found possible. This fortunate condition suggests that physical conditions under which gold is mined in Northern Ontario are conspicuously favorable to production at a profit.

#### MORE MEN NEEDED AT ONTARIO MINES.

Northern Ontario metal mines made a very good showing in 1919 and are capable of making much larger production this year. Ore has been developed and mining plant is installed for much larger than present output. This year's results will depend largely on the number of workers available and their willingness to work steadily. Wages are high, but the mines are not sufficiently supplied with labor to permit full utilization of the plant.

It is in the interests of the workers as well as of the shareholders that mines should be operated efficiently. Plants operated at full capacity make much larger profits than when producing smaller quantities. As wages paid to miners cannot be allowed to consume all the profits, the shortage of labor at our gold mines is a matter of concern to all interested in the industry.

#### ONE MAN TO CUT COAL, BUT TWO MEN TO HANDLE IT.

In our British Columbia letter some statements are quoted from Mr. G. W. Bowen, Managing Director of the Western Fuel Co. of Nanaimo, Vancouver Island. Mr. Bowen says with regard to the collieries in the Nanaimo district that "not more than 25 per cent of those employed were actually engaged in the production of coal," and states further, "The profits of the mines are not now so great as they were some years ago, when coal was cheaper on the market." Mr. Bowen's remarks are really a statement of cause and effect, and might with equal accuracy be applied to most coal-producing districts in Canada. The number of men engaged in cutting coal is too small in proportion to the number of men engaged in handling that coal. This unbalancing of the underground organization is the cause of that decrease in production which has as its effect the increasing of the unit cost of mining.

Commenting on the decision of Australia to use nickel for the penny and halfpenny coins issued in future, the "Engineering & Mining Journal" says that incidentally this will increase the demands on New Caledonia and "British America nickel mines." Does the term "British America" mean Canada? If so, there are many reasons to prefer the use of a correct territorial designation. "British America" is correctly used to cover Canada, the British West Indies, British Guiana and Honduras, from a geographical point of view, but applied to Canada today the term is archaic, if innocently used; and, if deliberately chosen, it is not well chosen.

CORRESPONDENCE.

Toonto, July 8, 1920.

Dear Mr. Editor:

I have read with great interest your article on page 538 of the issue of July 2nd on "The Unionization of Technical Men." I am in general sympathy with the ideas expressed in that article as far as I was able to understand them, but a passage that stuck me was as follows:

"We believe the safeguard against such dangers lies in the emanation of class legislation and a too processes, and would therefore endorse the recommendation already referred to that technical men should join their own organizations and assist in guiding along proper lines," etc.

Yours very truly,

WAKEFUL READER.

Note:—The passage to which "Wakeful Reader" properly calls attention should have read:

"We believe the safeguard against such dangers lies in the emancipation of the scientific worker's mental processes, and would therefore endorse the recommendation already referred to that technical men should join their own organizations and assist in guiding along proper lines a movement that is already important, and bids fair to become much more influential and widespread."

The error arose through editorial correction of a line which contained a mis-spelling, but the printer inserted the corrected line in the wrong place, throwing out the wrong line and retaining the original error (see fifth line from top). As printed, the sentence is, of course, meaningless. We apologize for the mystification of readers of the "Journal," whose annoyance is not unshared.—Ed.

**BRIQUETTE PRODUCTION EXPECTED AT BIENFAIT, SASK. BY SEPTEMBER—WILL NOT ASSIST FUEL SUPPLY GREATLY THIS YEAR.**

Output of briquette fuel from the Lignite Utilization Board plant at Bienfait, Sask., will have little effect this year on the coal market. The plant, which will be completed by the end of August, will have an output of 100 tons per day. Production will be continued for 90 and possibly 100 days during the present year, according to J. M. Leamy, power commissioner and a member of the board. Next year the production of fuel from lignite will be a real factor in the coal market, he stated. The briquettes will be sold at from \$12 to \$13 a ton, he said, and the price will at all times be as low as production costs permit.

Fuel sold this year, will be, as far as possible, distributed among representative dealers and a careful check will be kept to determine the actual value as fuel when put up to a variety of uses, according to Mr. Leamy.

**THIRD INTERNATIONAL MINING CONVENTION AT NELSON, B.C.**

From July 20th to 24th this now well established annual gathering of miners from British Columbia and the North Western States will hold meetings at Nelson. The Minister of Mines will open the Convention and in addition to addresses and papers, excursions through the neighboring mining centres will be arranged.

**THE WORLD'S PRODUCTION OF GOLD.**

Estimate for 1919 and 1920

The United States Geological Survey, Department of the Interior, has given out some preliminary figures showing the production of gold throughout the world in 1919. The production in the United States was \$58,285,196; Canada is reported to have produced \$14,687,000; India \$10,028,000; Australia (not including New Zealand or the Islands), \$29,268,000; the Transvaal, \$171,640,123; Rhodesia and West Africa, \$18,631,070. There was a probably large decrease in the production of gold in Russia and Siberia in 1919. Some increase was probably made in the output of Central America and South America, which, however, was doubtless offset by decreases in the output of other countries. The incomplete returns now available indicate that the world's production of gold in 1919 was between \$345,000,000 and \$350,000,000. The world's production in 1918 amounted to \$380,924,500.

The Geological Survey further states that information received during the first six months of 1920 indicates a still further decrease in the production of gold in the United States and that the output for the year will probably be less than \$50,000,000. The production in Alaska, Colorado, California, Oregon, and Montana will be much less in 1920 than it was in 1919, because water is very short for placer mining and many stamp mills are closed. Canada as a whole may increase its output, although the production of the Yukon districts will be smaller than last year. The output of Russia cannot be estimated. That of Australia will show a decrease. That of South Africa and South America will probably show no radical decrease. According to the Geological survey the indications are that the decrease in the world's production of gold in 1920 will not be so great as it was in 1919.

**ARTIFICIAL GRAPHITE**

Graphite is manufactured by the Acheson Graphite Co. at Niagara Falls, N.Y. This company utilizes the electric power generated at the Falls to manufacture graphite from anthracite coal or from petroleum coke. This product is used mainly in lubricants, but it is also used in paints, foundry facing, preventives of boiler scale, and fillers for batteries.

Artificial graphite may be used for any purpose for which natural graphite is employed according to the United States Geological Survey except in the manufacture of large crucibles. Patents have been issued recently, however, for methods of manufacturing crucibles in which artificial graphite may be used. Artificial graphite is peculiarly adapted to the manufacture of certain graphite products, among them graphite electrodes, which are not made from natural graphite and for which the demand has greatly increased in recent years. The table below, published by permission of the Acheson Graphite Co., represents only the manufactured graphite that comes into competition with natural graphite.

Graphite manufactured by the Acheson Graphite Co.,

1915-1919.

	Pounds
1915 . . . . .	5,084,000
1916 . . . . .	8,397,281
1917 . . . . .	10,474,649
1918 . . . . .	9,182,272
1919 . . . . .	8,163,177

**ELMER A. HOLBROOK APPOINTED ASSISTANT  
DIRECTOR OF UNITED STATES BUREAU  
OF MINES.**

Nova Scotia readers and members of the Canadian Mining Institute will be interested in the appointment of Elmer A. Holbrook as Assistant Director of the Bureau of Mines, succeeding Dr. F. G. Cottrell. Mr. Holbrook has spent much time in Canada, and has been a frequent visitor to the meetings of the Canadian Mining Institute.

The following account of Mr. Holbrook's professional career is taken from "Coal Age".

Mr. Holbrook was born at Pittsfield, Mass., forty years ago. His early education was obtained at the public schools of that place. His higher education was secured at the Massachusetts Institute of Technology, from which institution he was graduated in 1904, after having completed his course in mining engineering. Prior to his graduation from the Institute he worked in mines in Montana and was a member of one of the locals of the Western Federation of Miners.

Mr. Holbrook's first position after leaving college was with the Standard Ore Co. in Montana, where he

In 1911 he established headquarters at Halifax, Nova Scotia, where he designed and erected the mining laboratory for the Department of Technical Education of the Province of Nova Scotia. During the three years he was at Halifax he did a general engineering practice, most of which was in coal mines. For a time he was in charge of the mining department of the Nova Scotia Technical College.

In 1913 Mr. Holbrook joined the staff of the University of Illinois as associate professor in the mining department. Two years later he was raised to the rank of professor in the same department. During the several years he was associated with the University of Illinois he carried out important engineering and investigational work in the coal mines of the Middle West. In 1917 he was made supervising mining engineer of the Bureau of Mines and was placed in charge of the Middle West coal field station at Urbana, Ill.

The United States Bureau of Mines has at all times co-operated heartily with mining organizations in Canada and with our own Mines Branch. The co-operative mining investigations which have been undertaken at the Urbana Station of the Bureau and the University of Illinois at Urbana have made valuable contributions to coal-mining technical literature, to which Canadian readers have always been made welcome. Mr. Holbrook's acquaintance with diversified mining operations in several provinces of Canada, and his close connection with the co-operative technical investigations referred to will ensure a continuance of the helpful and friendly relationship between the Bureau and mining men in Canada, particularly as the new Director, Dr. Cottrell is no stranger in the Dominion, either in person, or through his technical attainments.

We wish both the Director and his Assistant all success in their positions.

**GOVERNMENT NAMES COMMISSION TO INVESTIGATE LABOR AND WAGES CONDITIONS AT NOVA SCOTIA COAL MINES.**

The Minister of Labor has appointed M. E. Quirk of Montreal, Sir William Stavert of Montreal and W. P. Hutchinson of Moncton, N. B. as a Commission to enquire into the questions attending the demand of the United Mine Workers of Nova Scotia for an increase of 25 per cent. in wages from May 1st 1920. Mr. Quirk is chairman. He was formerly Fair Wage Officer for Ontario, and has been entrusted on previous occasions by the Department of Labor with investigations in connection with coal mining disputes in Nova Scotia. Sir William Stavert is a well-known banker, with Maritime Provinces affiliations. W. P. Hutchinson is a train despatcher at Moncton, and has for many years been General Chairman of the Order of Railway and Telegraphers in connection with the Canadian National Railways.

The sittings of the Commission will commence at the earliest date that can be arranged.

A preliminary map of the International Boundary Region between Portland Canal and Stikine River, Alaska-British Columbia, has been issued by the International Boundary Commission of the United States and Canada. During the present summer there is to be a slight change in the line near Gracey Creek, south of the Unuk River and on the other portions additional monuments will be erected.

Entrance of the New Building of the U. S. Bureau of Mines

served as a sampler and underground surveyor. His next position was as superintendent of Ruby Gulch Mining Co. at Zortman, Mont. Later he served in the same capacity for the Gould Mines Co. at Gould, Mont. In 1907 he was made general superintendent of the Daly Reduction Co. at Hedley, British Columbia. At that time the Daly Co. was the largest producer of gold in the Dominion of Canada. After three years with this company Mr. Holbrook began a general practice as an examining engineer. He reported on properties in Nevada, South Dakota, Georgia, Ontario and Quebec, and was engaged for a time at Guanajuato, Mexico.

# Centrifugal Pumps and their Use

By F. A. McLEAN, Sherbrooke, Que.

(Concluded from page 563 of last issue).

## Some applications and Uses of Centrifugal Pumps.

Centrifugal pumps may be driven by means of belts or gears from steam engines, steam turbines, or electric motors, water wheels or any other sources of power available, most convenient or best suited to the location in which the pump is to be used. When operated by electric motors they readily lend themselves to the installation of automatic starting and stopping systems of the float-switch type. Driven by steam turbines they are more economical than steam pumps, operating on less steam and requiring less lubrication. The compactness of such units and their freedom from valves, more or less complicated motions, and sliding surfaces reduce the attendance costs to no small degree

### On Water Works Service.

During the last few years motor driven centrifugal pumps have been widely adopted for waterworks service in small cities, towns and villages. Where they are used to pump water to a standpipe or elevated tank they are often arranged to be started and stopped automatically by either a pressure regulator or float switch. When used with a system of the direct pressure type, they may be run continuously, maintaining the pressure and delivering only such water as may be drawn from the mains. In some locations where a part of the system is at a higher level or at some distance from the station, it is necessary to maintain sufficient domestic pressure at the pumping station to supply the greatest demand and to install a centrifugal pump to act as a booster in the line which requires the higher pressure. A booster pump may

be operated continuously and allowed to "float" on the line thus adding a fairly constant net pressure irrespective of the amount of water which may be taken from that line. A common practice is to use moderate pressure lines for domestic service and increase this largely in case of emergencies such as fire service, etc. Motor driven centrifugal pumps usually being fitted with constant speed motors are not adaptable for more than one pressure, and it is often necessary to install two or more duplicate sets designed for ordinary service which may be operated in series to obtain a larger pressure for fire service.

It is often desirable when installing centrifugal pumps for fire or other service where great reliability and freedom from interruption is essential, to either duplicate the equipment or to provide the pumps with more than one form of driving power.

An interesting instance of this kind is the installation at the Public Markets, St. Boniface, Manitoba, which comprises a No. 5 Cameron Class DV horizontal, double suction volute pump with a capacity of 500 U. S. gallons per minute, operating against a total head of 130 feet, at a speed of 1755 R.P.M. This pump is direct connected at one end to a 30 H.P. Westinghouse, 550 volt, 60 cycle, 3 phase induction motor, and at the other end to a 35 H.P. General Electric Steam Turbine, in such a way that either the motor or turbine may be used as desired thus making the equipment entirely independent of power failure. This arrangement is very compact and has proved very efficient and economical in operation.

Crank and flywheel pumps have been displaced in many localities by turbine driven pumps connected to condensers which have proved much more reliable and economical than the best triple expansion crank and flywheel pumps. Their low installation and yearly operating costs together with their compactness—permitting their use in small buildings and doing away with the necessity of special foundations—

Fig. 6—Cameron Double Suction Volute Pump, Arranged for Steam, Turbine or Electric Motor Drive. Installed at the Public Markets, St. Boniface, Manitoba

Fig. 7—Three-stage, Motor-driven Centrifugal Pumps in Series in a Mine Pumping Station

are some of the reasons why they are displacing other types for fire protection and water-supply services

#### Mine and Industrial Service.

In the last few years steam pumps have largely been displaced in station pumping service for the unwatering of deep mines where the installation is to be of a permanent nature. For temporary use the steam pump is well suited to this class of service, but where the equipment is to be operated continuously the same features of low maintenance and economy of operation which have led to the use of centrifugal pumps in other fields has caused them to be very widely adopted by many mining companies. Reliability is an essential feature of mine pumping equipment, and the ability of centrifugal pumps to operate continuously 24 hours a day with a minimum amount of care and attention, has resulted in their installation in many places in the mine where steam pumps were formerly used.

Where electric power is available, the motor-driven centrifugal pump can be obtained in portable units, of large capacity, which are very suitable for emergency requirements, such as inrush of water from drowned workings, or inundations from surface waters.

Fig. 8—Three-stage Turbine Pump, Driven by Steam Turbine

Emergency pumps of this type are very desirable at any mine exposed to danger of inundations, and, in many instances, the initial expenditure has been well repaid by the availability of portable pumping equipment when it was badly needed.

For handling slimes, tailings, acids and corrosive solutions in mine concentrating and reduction plants, the centrifugal pump has many advantages over other classes of pumping equipment. For this class of service it is possible to secure units designed to pump dirty and gritty water, or liquids containing semi-solids, and for handling chemical solutions.

The centrifugal pump is specially adapted to the use of corrosion-resisting materials in the construction of those parts that come into contact with the liquid being pumped.

#### Marine Service.

The steam pump has long been standard for use on dredges, barges, naval vessels and merchantmen, and still retains some supremacy in this field which, however, has recently been invaded by steam turbine, engine, or electric driven centrifugal pumps with so much success that it seems to be only a question of time until they will entirely replace reciprocating pumps of all classes of service on the larger vessels.

It is not hard to understand the preference for the centrifugal pump which occupies considerably less space than the best type of reciprocating pump; and space is always at a premium in ships. The centri-

fugal pump is higher in economy, simpler in construction, and delivers the water in a steady stream, resulting in quiet operation, and permitting the use of smaller piping.

#### For Boiler Feeding and General Mill Service.

Centrifugal pumps are ideal for boiler-feeding purposes and are usually either motor or steam-turbine driven. Motor-driven feeding pumps are generally allowed to operate continuously at full speed, maintaining a practically constant pressure in the feed line for a large range of capacity. The amount of water which is fed to the boiler can be controlled by a valve in the feed line without danger of creating a dangerous pressure in the boiler as centrifugal pumps will not build up a pressure greater than 5 or 20 per cent above normal even when the discharge valve is closed.

Steam turbine driven boiler feed pumps may be operated in the same manner, but are often equipped with pressure regulators similar to those used on ordinary steam pumps to maintain a fairly constant differential between the steam and feed line pressures, practically where the variation in steam pressure is considerable. The amount of water fed to the

Fig. 9—Motor-driven, Three-stage Turbine Pumps in Series

boiler by either steam or electric-driven centrifugal pumps can be regulated without touching the pump, and there are no valves, rods or large packings to be looked after. In case of loss of suction there is no danger of breakage by water hammer as is the case with the ordinary reciprocating pump.

For circulating and other low-pressure service, steam-turbine, steam-engine or electric-motor driven single-stage pumps are generally used while for higher pressures such as required in boiler feeding, etc., steam-turbine or electric-driven multi-stage pumps are more suitable.

#### Efficiency of Centrifugal Pumps.

The efficiency of a centrifugal pump is highest at only one combination of head and capacity for each change of the speed at which it is driven, and therefore if it is operated at a speed other than that for which it was designed, the capacity in gallons per minute and amount of driving power required can only be approximately determined. When run at other speeds the efficiency is likely to be low, making the equipment unsatisfactory for the purpose for which it was installed as well as expensive to operate.

Even though the increased power necessary to drive an inefficient pump is but small, it must be remembered that the excess power is continuously consumed while the pump is in use and will total up to a considerable sum in a year's time, often representing in money more than the difference in first cost between

the highest for any one year in the company's history, and that during 1920 with production at the rate of about half a million higher than in 1919 the net profit may reasonably exceed even that set last year.

Following is the June statement:—  
 "During the month of June the company mined ore of an estimated value of \$200,449 and shipped residues from Nipissing and custom ores of an estimated value of \$109,746. No bullion was shipped.  
 "There was no unusual development underground. All stopes continued to produce in a satisfactory manner. Development on several veins were generally encouraging. The usual amount of exploration was carried on.  
 The low grade mill treated 7,160 tons. The high grade plant treated 183 tons. Following is an estimate of production for the month of June:—  
 Low grade mill . . . . . \$120,967  
 Washing plant . . . . . 79,482  
 Total . . . . . \$200,449.

**Ore and Bullion Shipments**  
 During the week ended July 9th, three Cobalt companies shipped a total of eight cars containing approximately 583,206 pounds of ore. The Nipissing, with five cars headed the list, as shown in the following summary:—

Shippers	Cars	Pounds
Nipissing	5	390,147
Mining Corporation	2	128,679
O'Brien	1	64,380
Totals	8	583,206

During the corresponding period, the Mining Corporation and Nipissing both shipped bullion, sending out a total of 155 bars containing 175,943 fine ounces, made up as follows:—

Shippers	Bars	Ounces
Mining Corporation	99	100,564
Nipissing	56	75,379
Totals	155	175,943

**THE GOLD MINES.**

Interest swings again to the question of a bonus on gold, an explanation of the proposal having been made by Louis T. McRadden of Pennsylvania who introduced the Bill in the United States Congress. "It seems to meet conditions from all corners, is simple and not costly," says Mr. McRadden, "and provides for the immediate imposing of an excise of 50c. per penny-weight (\$10 an ounce) to be collected on the sale of all articles containing gold or gold used for other than monetary purposes, thereby creating a fund from which the gold producer is to receive \$10 for each ounce of gold produced." Opinion differs as to the possibility of the Bill becoming law.

At the Hollinger mine, an average of about 1,700 tons of ore is being treated daily and the indications appear to be that the final result for 1920 will approximate that of the preceding year. It is learned that among the necessities recently undergoing a change in price is high grade cyanide which advanced 2 cents a pound this month.  
 On July 13th the directors of the Forcupine V.N.T. Mines are holding a meeting. On the following day, a special general meeting will be held. The question of obtaining finances for the treasury is to be dealt with. Three proposals are to be considered, one of

which is an offer from the Associated Gold Mines of Western Australia to loan the V.N.T. some \$50,000, taking a first mortgage as security. This proposal is being opposed in the North. Another suggestion has been made that the company consider merging with the North Crown Mines, the company which recently took over the Forcupine Crown and the Thompson-Krist. This suggestion does not appear to be favored by the officials of the V.N.T. The third plan seems to find more general favor, and is the suggestion that in view of the company having 657,000 shares remaining unissued in its treasury, that these should be sold for the purpose of financing the treasury. It is pointed out that on the strength of the assurance that work is to resume, very little difficulty would be experienced in selling a block of perhaps 200,000 shares at around 25 cents a share. Later on, on the strength of the work going on it is felt that quotations would advance and enable the company to sell an additional block of 200,000 shares at a considerable higher price. This, it is thought would put the company in shape to produce in a pretty big way. Officials who have just concluded a visit to the mine, after making an examination of the plant, have announced to the "Journal," correspondent that by spending \$50,000 on the mill it could be so re-modelled and enlarged as to treat between 150 and 160 tons daily. Also, with about \$100,000 the main workings could be extended from the present depth of 600 feet to a depth of 900 feet, with main levels at 600, 750 and 900 feet, thus mining the ore in stages of 150 feet.

According to official advice, the Teck-Hughes in recent months has been able to increase its reserves about 30 per cent. This was accomplished at a time when operations were at about two-thirds capacity, by continuing effort to that part of the mine lying between the 400-ft. level and surface. Just now the mill is treating an average of 2,400 tons per month. It is found that greater efficiency can be established by operating at a uniform rate of two-thirds capacity than endeavoring to work at full capacity when in doing so the unsatisfactory supply of men would cause more or less erratic results. About 70 men are now on the payroll. In regard to the financial standing of the Teck-Hughes Company, while the mine itself is now producing a profit, yet the \$500,000 bonded indebtedness is a source of worry, some \$70,000 in interest falling due in October. Just what will be done to tide this over has not yet been determined, but the proposal has been made to increase the capitalization of the company.

Final arrangements are being made for the Kirkland Lake Proprietary, 1919, to take over all responsibility for the operation of the Tough-Oakes Mine, paying the Canadian Tough-Oakes Company a nominal rental for the plant so as to relieve this company from responsibility. The shares of the Tough-Oakes Mine are to be exchangeable for Kirkland Lake Proprietary on the basis of two of the former for one of the latter. It is intimated that the Proprietary has \$90,000 immediately available with which to re-open the mine, and to be exchangeable for Kirkland Lake Proprietary on with more in sight provided such is necessary.  
 From the rate of progress being made in the big construction programme at the Wright-Harcreaves Mine, the mill will be in readiness for operations some time during the closing quarter of the current year. The foundations are all completed, and the structure

off the line when not in use or when open for repairs or inspection. A centrifugal pump will revolve in either direction and there is nothing to prevent the liquid in the discharge line flowing back through it when not in operation. Consequently should the power be suddenly cut off, the impeller acting as a water turbine might be driven backward at a speed dangerous to both itself and its prime mover. A foot valve placed on the intake pipe or a check valve on the discharge line may be employed to eliminate this danger. Pumps operating at high pressure on which a foot valve is used, should be provided with a check valve on the discharge line to reduce the shock on the pump when the foot valve seats. It is a good plan to put a by-pass around the check valve so that the pump may be primed should the foot-valve start leaking.

Centrifugal pumps are usually fitted with heavy bed-plates so as to allow the use of a small foundation, which must, however, be of ample strength to bear the weight and support the pump firmly. The pump must be set level on its foundation and be carefully aligned before being put into service. The pump, motive power, and bed-plate of direct-connected units which are purchased complete are generally accurately aligned by the manufacturer before shipment, but this alignment is very likely to be disturbed in shipment or by carelessly tightening up the foundation bolts before assurance is had that the alignment is correct.

Some manufacturers ship their pumps with the coupling bolts packed separately, so that alignment may be accurately made by placing a straightedge across the rims of the coupling and measuring the distance between the faces of the coupling. The couplings should not be connected until one is sure that the prime mover is moving in the direction that the pump is intended to rotate which is usually indicated by an arrow cast or painted on the pump casing.

will be obtained by making the suction piping as direct as possible, and allowing the water to flow to the pump under a head of from 6 to 10 feet, to eliminate the formation of vapour.

As previously mentioned, the efficiency of a centrifugal pump is lowered by the presence of vapour, air or gas in the suction line. These collect in the suction opening of the impeller, being the point of least pressure, and interfere with the passage of the liquid, thus seriously reducing the capacity of the pump or even causing it to lose its suction altogether.

**Size and Arrangement of Piping.**

All connecting discharge piping should be arranged to place no strain on the pump and it is usually advisable to make this from one to two sizes larger than the nozzle on the pump, using reducers at these points to make the connections. This will cut down the friction losses and makes the installation more economical to operate. In consideration of the marked advantage of small suction fit the intake pipe should be of as large a diameter and as short and direct as possible. The piping should be so arranged that there are no pockets for the accumulation of air and where these are unavoidable, some means of exhausting them must be arranged. The principles on which the action of the centrifugal pump is based require the liquid to be handled at high velocity. The intake and discharge opening are much smaller than those of a reciprocating pump of the same capacity, and in determining the sizes of pipe to be used, it is well to refer to a standard friction table such as is generally published by the various pump manufacturers in their catalogues. In placing discharge piping it should be kept free of high spots and loops as any air bubbles which may be formed will interfere with the passage of the liquid being pumped.

A gate valve is usually fitted in the discharge line of centrifugal pumps so that the pump may be shut

A Battery of Turbine-driven, Multi-stage Marine Pumps awaiting Shipment to U. S. Navy Yards.

10465

loss of head within the pump itself. The efficiency of the pump is the ratio of the power theoretically required to raise a given quantity of water against the total head to the sum of this power, plus the friction in the bearing and stuffing boxes and the hydraulic losses in the pump due to leakage, etc. These latter figures when worked out for any given pump represent its pump horse-power, or in other words, the total driving power required.

**The Effects of Variations in Speed.**

Both the capacity and the total head of a centrifugal pump are affected by speed variation, and consequently considerable care must be taken to determine the speed at which a pump is to be operated so that its design may be governed accordingly. This is very essential in the case of pumps which are directly connected to constant-speed alternating-current motors which operate at slower speeds under no load than when fully loaded and cannot be conveniently regulated.

**Starting the Pump.**

The impeller of a centrifugal pump possesses no positive displacement of itself and when running in air cannot create sufficient suction to be self priming, and, therefore, both the pump and suction pipe must be filled before starting. This may be accomplished by placing a foot valve on the lower end of the suction line and filling the pump and suction piping from the discharge line allowing the air to escape through an air cock on the top of the pump casing. Another method is to close the discharge gate-valve and exhaust the air in the pump case by means of an injector allowing the foot valve to be dispensed with, provided the pump is started while it is primed. When the pump has been primed it is ready to be started and should be brought up to its proper speed and the discharge valve opened. After the pump has been started, it will require but little attention; an occasional inspection of the bearings, from which the oil should be removed and new oil substituted from time to time is all that will be required. The so-called dynamo oil is well adapted for use in the bearings of centrifugal pumping machinery. Pumps intended for use with corrosive liquids are made of special metal, but the case should be opened occasionally and all internal portions thoroughly inspected. The presence of air or gases in the suction pipe will considerably reduce the capacity and pressure of the pump and care should be taken to avoid this trouble by properly baffling the suction pipe.

**The Suction Lift.**

When a centrifugal pump is once under way it will handle water or other liquids of the same specific gravity at ordinary temperature on as high a suction lift as the best reciprocating pumps, or about 26 feet at sea level, provided the pump and suction piping are free from air and air leaks. It is usually difficult to maintain air-tight suction-glands and piping, and the maximum commercial suction lift is therefore considered to be about 18 feet, although some manufacturers advocate not more than 12 feet whenever possible. The limit of suction lift is decreased by a rise in temperature of the liquid being pumped, and when the temperature of the liquid to be pumped is over 150 Fahr. it is better to have the pump so arranged that the water will enter it by gravity. In the boiling point is to be handled, the best results concerns only the manufacturer of the pump is the

an inferior and a properly designed pump. Sometimes this amount will equal the interest and depreciation on the entire installation for a similar period of time. The saving made by the good pump when compared with an inferior type will pay back its cost in a very short time.

**Correct Design of Wearing Parts.**

There are a few parts of the enclosed-impeller type of pump that are subject to wear, such as the sections of the shaft which are carried in the stuffing boxes and bearings, as well as the portion of the casing which makes a running joint with the impeller. These wearing surfaces should be provided with renewable parts, easily replaced at small cost, and the main or more costly parts being thus well protected. The casing should be protected from wear around the impeller inlet by working rings secured on the impeller used to protect it from wear also. Bronze sleeves fastened to the shaft and passing out through the stuffing boxes will ensure the shaft against scoring and rusting. Centrifugal pumps of the highest grade are usually provided with self-oiling, babbitted shell-type bearings made in two pieces, spherically seated and so arranged that they may be removed when worn and either re-babbitted or replaced with a new set, so that the alignment of the impeller will not be disturbed and the close fit between it and the casing, which is so necessary to prevent leakage internally, will be preserved.

**Operating Conditions.**

In designing a pump for a particular installation, it is necessary that the conditions of head, capacity and speed be correctly determined and furnished to the builder together with information regarding any special requirements which may be involved if the highest efficiency is desired. It should be understood that the centrifugal pump is not an extremely sensitive affair that will be efficient at only one particular combination of head and capacity, and when it is not possible to obtain these ideal conditions. The efficiency remains constant for a small variation on either side of the normal capacity, varying inversely as the head, and consequently it is usually better to figure the head a trifle higher than normal and design the pump accordingly, and then if the head should be a little bit less, a slight increase in capacity will be the result, which in most cases will not be objectionable. Sometimes it is possible to obtain two or more conditions of head and capacity from a pump of special design running at a constant speed with satisfactory results, and when some provision is made for speed variation the possibility of designing an efficient pump for variable service is greatly increased.

**Explanation of Total Head.**

The make up of the total head on which a pump has to operate is as follows: the vertical static suction lift from the level of the liquid to be pumped to the center of the pump; the static discharge head which is measured from the centre of the pump to the point at which the liquid is discharged, and the friction in the piping, elbows, valves, etc., in both the suction and discharge lines, as well as the velocity head and entrance head. Another point to be considered, which concerns only the manufacturer of the pump is the

itself is now going up. The crushers, ball mill and one of the tube mills are already in place, and work is soon to commence on the construction of the tanks. All buildings including, power house, heating plant, dry, etc., are being brick-veneered inside and the estimated cost of heating the plant is perhaps the lowest in the North. The saving realized in heating is believed as likely to more than repay the cost of the heavier initial expenditure. Underground work is proceeding, the object being to connect shafts Nos. 1, 2 and 3 at the 400-ft. level. More than a dozen faces are in ore, and it is planned to operate the mill on ore coming from development work during the course of cutting the necessary stopes.

At the Bidgood property at Mud Lake in Lebel township, the vein has been cut and measures approximately 15 feet in width. This compares with a width of 12 feet at the 100-ft. level. As yet, average assays have not been announced from the 200-ft. level. The shaft is to be continued at once to a depth of 300 feet at which point the main development program is to be carried out.

Cross-cutting on the 500-ft. level of the Miller Independence mine at Boston Creek is nearing the point where it is expected to encounter the downward continuation of the "Adams" vein in which gold tellurides were found in spectacular quantities near surface. A number of highly mineralized stringers have been cut, and work during the balance of July is regarded as likely to be attended with important results. Work is also being carried on at the "D" or incline shaft.

#### PERSONALS.

O. G. Donaldson, shareholder of the Wright-Hargreaves and the Lake Shore Mines, has concluded a visit to the Kirkland Lake district and returned to his home in Buffalo, N.Y.

Major J. McIntosh Bell paid a visit to the Porcupine V.N.T. mine during the past week-end and returned to the Keeley Mine in South Lorrain early this week.

Wm. Gowans, assistant superintendent of the Castle property in the Gowganda district paid a brief visit to his home in Haileybury returning to Gowganda on Monday.

#### AMBER REPORTED FOUND BY MR. J. C. MURRAY IN NORTHERN MANITOBA.

A newspaper despatch from The Pas, Manitoba, states that Mr. J. C. Murray, formerly Editor of the "Journal" has arrived at The Pas, returning from Cedar Lake, with a gunny sack of amber of good quality. Mr. Murray reports a plentiful supply of amber scattered about the sand and the muck on the borders of the lake. He states that a canoe could be filled with it in less than an hour. The presence of amber at that place has been known for several years, but until Mr. Murray examined it for New York and Toronto interests, its value was unknown. Col. J. B. Miller, of the Parry Sound Lumber Company, and Major Craig, of Toronto, left here for the amber fields today.

The Poulin Asbestos property recently acquired by Mr. Samuel W. Cohen and associates has been organized under the name of the General Asbestos Company, Limited, with head office, Montreal.

## British Columbia Letter

### THE METAL MINES

#### Victoria, B.C.

The amendments to the Placer Mining Act of British Columbia, passed at the last session of the Provincial Legislature, came into effect on the 1st of July. Holders of placer leases, however, have until the 1st of January, 1921, to make such arrangements as are necessary to hold their property. They may do one of two things, viz., pay up arrears on their leases and continue annual payments as laid down by the old Act or consolidate the arrears and pay a proportion of the whole amount together with the current annual fees. Those failing to do either one or the other will be dispossessed of their holdings, the Act as amended providing for automatic forfeiture under such circumstances.

#### Stewart, B.C.

Arrivals from Stewart, B.C. declare that there is no mining boom in the Portland Canal District, but that there is much solid development. Nine diamond drills now are in operation, two on the Premier, two on the Northern Light Group, one each on the 49 Group, the Big Missouri, the Mother Lode, one on Goose Creek and one on the B. C. Exploration Company's property, Marmot River. It is stated that the snow is rapidly disappearing from the higher reaches and that there still is employment for good miners.

Activity is apparent through the country contiguous to the Bear River Valley. Men are engaged in putting the line of the Canadian Northeastern Ry., owned by Sir Donald Mann, in shape for operation, and a gas locomotive has been bought, together with some rolling stock, in order that the transport of supplies to the various camps may be undertaken as soon as the repairs to the road render it feasible.

Some of the mining operations in this section that may be instanced are the development of the Q & L Group held under bond by J. Tretheway, of Cobalt, consisting of surface stripping which has resulted in the exposure of a vein carrying good values and the driving of a tunnel on the vein the ore of which on assay gives return in galena, zinc-blende, and silver; the opening of the Red Top Group by G. Seivert; further work on the Tower Mountain Group by K. P. Matheson, who found promising leads of silver-lead galena last year; the exploration of the Goose Group by the Algonic Development Co., who have it bonded; the development of the L. L. & H. on Bitter Creek; and the vigorous development of the Lakeview Group, Glacier Creek, by P. Welch, of Spokane, and H. J. Fletcher, of Seattle, Wn.

#### Alice Arm, B.C.

The population of the town of Alice Arm is growing to such an extent that increased accommodation has to be provided with the result that there is much building in progress. A three storey hotel is under construction; also many homes in the nature of log cabins. The community radiates prosperity. Everyone is busy and the Dolly Varden Mine Railway is operating regularly, if not in the transport of ore from the mine in carrying supplies from tidewater to the camp. Reports continue to be received regarding the richness of the new ore being found on the development of the Dolly Varden Mine property. It is stated also that the Royal Group nearby is showing up well and that other

properties under development give encouraging indications of merit. Prospectors are going into the hills both up the Kitsault and the Illiance Rivers and much is looked for favorable to the district from the season's work.

#### Usk, B.C.

High grade copper ore is reported to have been discovered on the Nicholson Creek, near Usk, northern B.C., by Albert Baxendale a prospector. As a result the Crescent Group of Mineral Claims has been staked. Stripping is said to disclose a fissure vein, one foot to six feet wide, for a distance of 700 feet carrying bornite and chalcopyrite, much of which is of sufficiently high grade to ship.

#### Slocan, B.C.

That the Utiza Mine will be re-opened at once and by C. F. Caldwell, vice-president and managing director of the Utica Mines Ltd. The old Sunset property, situated near the Utica, also is to be developed. The latter has not been worked for fifteen years. During its operation over \$500,000 worth of ore was shipped, some 2,000 tons averaging over \$250 a ton at the former price of silver. It is proposed to continue the existing crosscut to strike the vein at new depth. The mine, it is hoped, will be shipping by fall.

Work on the Evening Star Mine, Dayton Creek, is proceeding with satisfactory results. The crosscut being driven for depth has reached an advanced stage, its face now being somewhere near the line of the shaft and below it. The workings will be unwatered before an attempt is made to connect the two. As the workings radiating from the shaft are quite extensive the latter work will take some time. Hugh Sutherland, of Winnipeg, Man., formerly executive agent for the Canadian Northern Ry., is the owner of the Evening Star and also of the Silver Nugget, in the same vicinity, which is to be developed.

#### Nelson, B.C.

The Florence Silver Mine, near Nelson, B.C., is in operation and the installation of another unit for the power plant is underway. The mine is working on a two shifts and the concentrator on a one shift basis. There is said to be an abundance of ore in sight, both the Fisher and Replacement veins looking splendid. About 150 tons of millfeed is coming down daily and it is expected that the mill will be able to ship 300 tons of concentrates a month.

Another deal is reported in connection with the Granite-Poorman Mine, Eagle Creek, it being stated that a syndicate has been formed to take over the property from the Vincent Development Co., As a result the Granite-Poorman property will resume operation immediately, a crew of men already having been put to work.

#### The Coal Mines

G. W. Bowen, vice-president and managing director of the Canadian Western Fuel Company, predicts that there will be a scarcity of coal all over the American continent during the winter of 1920-21 and attributes present conditions in the United States in this respect to the transportation problem. The increased demand for coal locally he explains by the shortage of oil and the greater population. The cost of production would govern prices, oil shortage and other contingencies

having nothing to do with the matter. Discussing the latter question he pointed to the fact that the Company was engaged in prospecting for coal, that what appear to be good body at the outset possibly would peter out in development, that in the Nanaimo Mines not more than 25 per cent of those employed actually were engaged in the production of coal, so that the average output of coal per day per person would not run more than a ton and a half. The profits of the mines were not as great now as they were some years ago when coal was cheaper on the market. Little coal was being shipped from Nanaimo to the United States whereas a few years ago the bulk of the output went to San Francisco, Cal. Now practically the only coal going south of the line was that required to fill small contracts with Seattle, Wn., dealers.

In an endeavor to produce satisfactory coking material the Granby Consolidated Mining & Smelting Co., is bringing coal from Brule Lake, Alberta, for mixture with the product of the Cassidy Collieries, Vancouver Island. As a result a considerable proportion of the output of the Cassidy Mine likely will find its way to the domestic markets of Vancouver, Victoria and other British Columbia centres.

T. A. Spruston, superintendent of the Extension Division of the Canadian Collieries (D) Ltd., pointed out to the miners recently the importance of their working more steadily than in the past. In the month of May out of 296 contracts miners employed only 85 worked full time. He figured that 906 shifts were lost which was the equivalent of working the mines one day a week with no miners. Reference was made to the high cost of producing coal at Extension under ordinary conditions. As matters stood there not only was the handicap of time voluntarily lost by employees but of actual lack of labor, there being places in the mines for 100 additional hands if they could be secured. Owing to the habit the contract miners had fallen into the earners of day wages were finding it difficult to get along as the Company had been compelled to close down each Saturday. There was a danger too, that, if production remained low, contracts entered into for the supply of Extension coal would have to be allowed to lapse, in which event, of course, the Company's customers would go elsewhere. Mr. Spruston emphasised the position by pointing out that loss of four days a month meant the loss to the community in wages of \$15,000 a month and resultant depression of trade and general business. He urged the men to work the full six days a week, thus increasing the productivity of the mines 3,171 tons a month. After discussion the miners passed a unanimous resolution urging the men to fill a full six days a week on the morning shift and five days a week on the afternoon shift.

The Chua Chua coal-bearing lands on the North Thompson River, near Kamloops, B.C., have been bonded to the Queen Bess Mining Corporation of Seattle, Wn., approximately \$500,000 being involved in the transaction. Glenville A. Collins, who was chairman of the recent International Mining Convention at Seattle, Wi., was instrumental in putting the deal through. Drilling is to commence forthwith and it is expected that the first shipments will be made next September.

## THE USE OF GYPSUM IN A NON-CONDUCTING ROOFING SLAB.

A paper read before the Technical Section of the Canadian Pulp and Paper Association at Sault Ste. Marie on June 23rd by Mr. H. S. Taylor, described the use of a non-conducting roofing with gypsum as its chief constituent, to overcome the decay and other troubles associated with roofing in paper mills caused by condensation of moisture on the underside of the roof. A moist atmosphere is inseparable from paper-making processes, which consist largely of the evaporation of moisture from a mixture of ground wood and water by passage over heated rollers.

After explaining the required characteristics of a roofing material as durability, non-conductivity and resistance to corrosion, and giving some instances of rapid decay in mill roofs attributable to interior condensation, with particular reference to the mill of the Spanish River Pulp and Paper Co., on Lake Superior, Mr. Taylor (who represents the Management Engineering and Development Co.) was asked to report on a suitable roofing to overcome the difficulties indicated. An abstract from the paper follows:

The result of a thorough investigation was the selection of gypsum for roof slab material combined with wood shavings.

This monolithic gypsum composition slab has long been used for fireproof floors and roof construction in the eastern United States and Canada under the trade name "Metropolitan." Some of the oldest of the large buildings of downtown New York city are of this construction 60 Wall Street, 42 Broadway, Beaver Bldg., Singer Bldg., etc., as well as hundreds of heavy manufacturing and loft buildings, apartments, hotels, residences and the like throughout the metropolitan district and in other communities. The first installation was made in 1892, and came into extended use in 1894. During this year a gypsum roof was placed on the St. Nicholas Skating Rink. I have for your examination a piece of gypsum knocked from the underside of the floor slab of this building just about the refrigerating machinery. The steel stable enforcement was found to be in excellent condition when exposed after 22 years. I also have for your inspection a piece of cable 32 years old, taken from the Horticultural Hall, Philadelphia.

This Metropolitan type of construction was placed on the Woronoco Mill of the Strathmore Paper Company in 1912; the Wayagamack Pulp and Paper Company at Three Rivers made an installation in 1915; Price Brothers have this type of construction over one of their machine rooms, the roof having been laid in 1915, and the Great Northern Paper Company, of Millinocket, Me., have a gypsum slab roof which was placed in 1913. For mills of the Escanaba Paper Company at Escanaba, Michigan, designed by the Management Engineering and Development Company, gypsum roofs are on machine room, boiler house and grinder rooms and the owners are well satisfied.

The slab is designed on the cantenary principle; cold drawn, twisted steel wire cables being figured to carry all the loads in suspension between beam supports. These cables are anchored to the end beams and brought into uniform deflection and tension by steel rods midway of each span.

Gypsum, more commonly called plaster of Paris, is mined as a moderately soft mineral, composed, in varying degree of purity, of hydrated calcium sul-

phate,  $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ . When gypsum is calcined at a temperature of  $100^\circ$  to  $120^\circ$  c.,  $\frac{3}{4}$  of the water of crystallization is driven off and the product obtained is the ordinary plaster of Paris. If calcined at temperatures between  $250^\circ$  and  $500^\circ$  C. but not sufficiently long to remove all of the water, a nearly anhydrous product is obtained which also forms a cement.

The product formed, as the result of the setting in either of the above cases, is practically identical with the original gypsum. This material is appreciably soluble in water. One part of the hydrated calcium sulphate at  $0^\circ$  C. dissolves in 488 parts of water; at  $35^\circ$  in 393 parts of water; at  $100^\circ$  in 460 parts of water. Its maximum solubility occurs at  $35^\circ$  C.

The gypsum composition, consisting of about 85 per cent. pure calcined gypsum, mixed with wood fibre to act as a binder and to toughen the finished slab, is mixed with water to a medium working consistency and poured into the forms. The set takes place within ten or fifteen minutes, and the forms are removed the same day if desired leaving a full live load capacity slab. The duty of the gypsum is to fireproof the steel, form a flat slab, and transfer the load from the surface to the cables in direct compression. Its work is analogous to that of the stiffening truss of a suspension bridge floor, for which duty it has proved itself amply strong in various authoritative tests as well as in actual service.

The chief advantages of the construction are:—

1. **Light Weight:** Composition weights 48 lb. cu. ft., or 16 lb. sq. ft. for a 4-inch slab, this weight being one-third that of concrete—less than the dead load of any other permanent, fire-proof construction, and no more than the ordinary wood sheathing. This light weight means a ten to twenty per cent. saving in steel framing supports, as well as reducing loads on foundations.

2. **Quick Setting of Slab:** As gypsum will set ten minutes after pouring, whereas four to ten days are necessary, depending on weather conditions, for concrete, this means a saving in interest and overhead charges by earlier completion. A full live load can be placed on the roof slab two hours after pouring, and forms are generally removed in from four to six hours. Of great interest and value in Canada, this quality permits progress in cold weather, as the slab may be placed without injury in zero temperature and below, the quick set taking place before the water can freeze.

3. **Heat Insulation:** Among the literature furnished you, are copies of the report of Prof. C. L. Norton of Massachusetts Institute of Technology. This report gives the B.T.U. transmission through various constructions used for roofs, together with a chart showing the possibilities of condensation under varying conditions. You will note that with the highly insulating gypsum roof, slab condensation will not occur under a very wide difference and indoor and outdoor temperatures, where the humidity is kept below 80 per cent. by means of ventilation. The dollar value of an insulating roof slab like gypsum as compared with wood of two or three times the conductivity, and concrete of five times the conductivity, may be readily determined from Prof. Norton's report. One heating engineer has established a  $7\frac{1}{2}$  to 10 per cent. reduction in heating equipment, and a 25 per cent. annual fuel saving as compared with concrete. (These tables showed mostly relative conductivities.)

4. **Resistance to Corrosion:** Gypsum is calcium sulphate and, being a salt of sulphuric acid, is not affected by any acids of this group. Beaker tests show corrosion by nitric and hydrochloric acids, but concentrations of these acids in a building are very rarely sufficient to affect a roof slab of gypsum. The same may be said of the strong alkalies, soda ash and caustic soda. In floors twenty years old, the steel has been found perfectly preserved by the embedding gypsum.

5. The fire resistive qualities of gypsum have been proved by many authoritative tests and fire experiences. In 1911 a fire occurred in the Knickerbocker Storage Warehouse, Newark, N. J.—an eight-story building with monolithic gypsum floors and roofs erected about 1900. The five floors were packed to the ceilings with furniture, and the fire raged over a period of eleven hours. The records of insurance and other inspections show the building was repaired and the floors restored, with the exception of two panels, by being plastered underneath with gypsum, the building then being used as a storage warehouse. The low cost of salvage is very apparent.

Gypsum slab was placed over the Lake Superior Paper Company's Sault Ste. Marie mill in the summer of 1919. Since then a new machine room at Espanola and a machine roof at Sturgeon Falls have been covered. A second machine room at Sturgeon Falls is now being constructed and will be covered with gypsum roofing. The roof has a pleasing appearance and is guaranteed for a period of ten years. This guarantee appears to be perfectly safe when considering the time this type of roof has remained in perfect condition on buildings constructed many years ago.

Other types of gypsum roofs will be found on many paper mill structures, the gypsum channel type and also pre-cast type. The channel type is made up in 8 ft. lengths, laid on steel supporting members and joints cemented. It has a pleasing appearance, but as reinforcement is not continuous there is a tendency to deflect under extreme heat. No doubt this deflection is aided by moisture. The pre-cast type we have not had experience with. The Thorold Mill of the Ontario Pulp & Paper Company is covered with this type of construction, but for mills that we have been interested in, the cost of pre-cast was greater than the monolithic slab, due to handling charges. I believe this Metropolitan type of roof construction ideal for machine rooms, grinder rooms, recovery plants, sulphite mills or for almost any paper mill building, as at the present time it is very little more expensive than wood, and from all indications will outlast wood many times over.

For a new mill the labor of placing a gypsum roof is very little more than that of placing a standard wooden roof, but for mills in operation a replacement entails great precaution. If properly planned and carried out, however, operation may be carried on without interruption. As an example of this statement we can take the Lake Superior Paper Company's machine room, a building 180 ft. x 270 ft. where the removal of their wooden roof and the placing of the new gypsum slab was carried on without an hour's shutdown of four paper machines running beneath.

For roofs over machine rooms, grinder rooms or other buildings, wherein moisture is excessive, all steel members directly embedded in the roof slab should be insulated by gypsum covering throughout their entire

surface, as, due to their high conductivity, low temperatures will be conducted to sections on the under side of the roof and on these sections condensation will form, with the resultant drip.

#### METAL QUOTATIONS.

Fair prices for ingot metals at Montreal, 15th July 1920:—

Copper, electro . . . . .	23 $\frac{3}{4}$ c
Copper castings . . . . .	23 $\frac{1}{2}$ c
Lead . . . . .	10 $\frac{1}{2}$ c
Zinc . . . . .	10 $\frac{3}{4}$ c
Tin . . . . .	57c
Aluminum . . . . .	37c
Antimony . . . . .	10c

Mr. Charles Camsell, the new Deputy Minister of Mines will make a flying visit to Vancouver the first part of August, when his friends will have a chance to see him for a short time before he takes up his home in Ottawa.

#### SQUARE CORNERED MOLECULES.

One of the strangest true stories that we have heard in some time was told at the summer meeting of the Technical Section. It seems that an oil salesman visited a pulp mill and in praising the quality of his oil to the superintendent remarked that the oils which were being used were decidedly inferior because in one of them the molecules were of cubical shape (and he drew a picture to show the form), while the other was not quite so bad as the molecules were pyramids, (and he drew another sketch), but that the oils which he was selling was far superior to any other on the market because the molecules were round. In fact the salesman, by misrepresenting something with which the superintendent was not at all familiar, convinced him that he was selling a ball bearing oil and consequently the best possible kind of lubricant. The curious part of this story is that we repeated it last week at the smoker of the American Society of Chemical Engineers and one of the gentlemen present was the chief chemist at the mill where the incident occurred and had overheard the conversation between the oil salesman and the superintendent. Another chemist from the same mill was also present and vouched for the truth of the story, else we would be strongly inclined to doubt it.

The superintendent in this case was not acquainted with even the rudiments of every day science and the salesman knew it. If the chemist had not been present, the wonderful new conception of the molecular state of lubricants would have been lost to the world, and this particular mill might have been induced to purchase a really inferior grade of oil, because a concern that permits its salesmen so grossly to misrepresent either his own product or that of others is not likely to be depended upon for a first class article. It is not necessary for a man to have a college education or to be an expert chemist or engineer to have a clear conception of such elementary science as would enable him to detect such misrepresentation and to perceive the principal qualifications of the materials required in his department. The man on the job must be depended upon for considerable advice in the purchase of materials unless the concern has a large technical staff which can carry out performance tests for the benefit of the purchasing and cost departments. From "Pulp and Paper Magazine."

# SAFETY FIRST HOISTS and CAGES

**ELECTRIC MINE HOIST**, with Drums keyed fast to shaft, so it cannot revolve in either direction except the power is applied.

This type Hoist is made also for Steam Drive.

Either kind, Steam or Electric, is offered in 7 sizes, from 10 to 50 Horse Power.

Send for our  
Catalog of Mine  
Hoists, Cars,  
Cages, Buckets,  
Etc.

It will interest you.

**SAFETY MINE CAGES** made to fit your shaft. We build these cages to suit you and your workmen. They are Safe, Strong and Reliable. We guarantee the Safety Device of our Mine Cages to be quick and positive in its action. It can be relied on to work and to hold the cage safely at any time in case of accident. The springs are strong, the dogs are properly designed and adjusted, and the whole device is made amply strong for any emergency.

**Marsh Engineering Works, Limited,** ESTABLISHED 1846 **Belleville, Ontario**

Sales Agents : **MUSSENS, LIMITED,** Montreal, Toronto, Winnipeg and Vancouver

## PORT ARTHUR NOTES.

(By J. J. CONNOR).

The Swedish-Canadian Mines, Ltd., operating the "Foley" mine, at Mine Centre, has been reorganized, under the following gentlemen: Senator George W. Fowler, Ottawa, President, H. R. Drummond Hay, Barrister, Winnipeg, Vice-President, J. P. Hanson, Chicago, Ill. Secretary-Treasurer, N. T. McMillan, Winnipeg, W. D. McKay, Toronto, and C. R. Fitch, Fort Frances. Directors, F. A. S. Carnegie, M.I.M.E. Engineer at the Mine, J. A. Johnson, Superintendent and Manager.

The work of sampling, and making mill runs is now in progress, with a view of determining the most efficient processes of recovering the maximum of values in the ore, before installing their permanent plant for treatment.

30 men are employed at present. This number will be increased to a full complement to operate the whole mine at an early date. The Company are not giving out the results of their operations, but are apparently well satisfied with the outturn, and are looking forward to active and continued mining and milling of ore.

The Silver Inlet Syndicate are meeting with continued success in uncovering fresh bodies of high grade macfarlanite ore in the roof of the East Stope. In this stope, the roof is of enormous extent. Vast cavities were mined out in the former operations that are without floors, and the operatives move about on rafts, in prosecuting the sampling. The walls and roof are so discolored with graphite, that it is impossible

to determine what is under it, without putting in shots. This is being systematically done, and expectations are being fully realized as the work proceeds.

## VANCOUVER NOTES.

A new cabinet of the minerals of Canada has just arrived at the Vancouver office of the Geological Survey in the Pacific Buildings, Hastings Street W. The minerals were assembled by the Dominion Department of Mines and are neatly arranged, numbered, and listed so that the name and origin of each mineral is easily located.

Prospectors and the public in general should make good use of this exhibit, which has taken much time and trouble to arrange.

The Publicity Committee of the B.C. Chamber of Mines is planning a Chamber of Mines exhibit, to be held in connection with the Vancouver Exhibition in September. All prospectors, associations and individual companies are invited to send exhibits of ores, photographs and interesting data to Chamber of Mines, freight and express prepaid, and such exhibits will be taken care of and placed in prominent positions. The exhibition directors have agreed to give every assistance toward making this the best mineral exhibit ever held in connection with the exhibition.

This is for all British Columbia and everyone is invited to help and make it a success.

### THE THREATENED BITUMINOUS COAL SHORT-AGE IN CENTRAL CANADA DURING NEXT WINTER.

The Board of Railway Commissioners, which is now charged with the supervision of coal imports and exports that were formerly vested in the person of the Dominion Fuel Controller, is completing the organization necessary to carry out this addition to the regular duties of the Commission.

On the 12th July, a Committee from the Canadian Manufacturers' Association was received by Dr. S. J. McLean, the Assistant Chief Commissioner and the possibility of averting the threatened increase in the existing stringency of bituminous coal supply in the provinces of Ontario and Quebec was discussed.

The Committee comprised the Fuel Controllers of Ontario and Quebec, representatives of the eastern and western coalfields, and members of the Special Fuel Committee of the Canadian Manufacturers' Association which has been collecting information on coal supply for the past two years.

In regard to the possibility of bringing coal from the Alberta collieries it was pointed out that the question was largely one of transportation and freight rates, as at the present time the capacity of the Alberta collieries was equal to the supply of any quantity of coal within the possibility of rail transportation, but the amount of coal that the railways could handle and the freight rate that could be arranged would have to be definitely ascertained by Alberta operators before extensive arrangements to meet future orders from Ontario could be made. The time between this date and the commencement of grain shipments eastward—the only period during which it will be possible to handle coal shipments of any volume—is limited, and the attention of the Commission was drawn to this point.

The probability of a coal shortage was admitted, and there was no discussion or questioning regarding a condition that now amounts to a certainty.

With regard to Nova Scotia coal, an actual shortage in production exists, practically identical in extent with the customary annual seasonal shipments to St. Lawrence ports before the decline in outputs which was a result of enlistments among the miners. No possibility of any appreciable assistance from Nova Scotia coal is likely unless additional miners can be obtained, and the advisability of assisting in every possible way the emigration of miners from European fields to Nova Scotia was suggested. The tonnage of coal exports from Nova Scotia to European points was stated to be almost negligible in comparison with the actual drop in production. The necessity to provide ships at reasonable freights was a first consideration in sending Nova Scotia coal to Montreal and St. Lawrence points.

It was further suggested that assistance would be obtained in connection with the coal supply of 1921, if the Nova Scotia collieries were enabled to work steadily and bank out coal during the Winter of 1920-1921. This is possible if an outlet for the coal is guaranteed by making railway contracts this year for next year's delivery, and if the coal companies are assisted by full release of their shipping from government control.

The Fuel Controller of Ontario is vested with the necessary powers to carry out his office, but in Quebec there are no existing regulations empowering the

office of fuel controller to take any effective action. It is expected that the necessary powers will also be revived in Quebec to meet the present emergency.

The Fuel Committee of the Canadian Manufacturers' Association is studying the fuel problem from the standpoint of a permanent solution by the enlargement of coal-mining in Canada, but this is of course a duty in regard to which there is no visible present likelihood of a discharge. The action of the Association at this time was taken because of the recognition of an existing emergency which requires immediate remedial measures. Such action does not, however, imply that present and emergent measures will be also those that promise greater permanent security in our domestic coal supply.

### THE BENDIGO GOLDFIELD, AUSTRALIA.

#### Rehabilitation of an old Goldfield by Consolidation of Properties and Profit-Sharing with Miners.

(Abstracted from an article in the "Industrial Australian Mining Standard" by "F.M.L.")

The following extract, taken from the above-mentioned source, is not without interest to Canadian readers, and has certain analogies in conditions existing in Canada—but not in gold-mining districts.—Ed.

Since 1851 the Bendigo field has produced over twenty million ounces of gold, valued at nearly eighty millions sterling. Of late years the annual yield has steadily declined, but it must not be imagined that the mining industry is by any means played out; it is still the largest industry by far in the district. It is true mine after mine has closed down on account of increased working costs, and the probability is that many mines now being worked would have been added to the list had it not been for the business-like methods and foresight of a few public-spirited business men, who brought about an amalgamation of a large number of companies, with the idea of running the mines on business lines.

#### Mining on Commercial Lines.

These men had seen the disadvantages that accrued from the gambling methods generally associated with mining throughout the State. Dividends were paid with money that should have gone to build up reserves, development work was neglected, and the heart taken out of a mine, with the result that it became a common thing for a mine to be making calls on its shareholders within a few months of paying its regular dividends.

The first step of the promoters of the new amalgamation was to remove, as far as possible, the gambling element, and place the stock on an investment basis; the next, to build up substantial reserves. Thus speculation was discouraged and steady investment encouraged. When it is remembered that a great deal of capital invested in Bendigo mines comes from outside the district, it can be seen that this policy must lead to increased security and confidence.

#### The Bendigo Amalgamated Goldfields Co.

The company was formed by the issue of 200,000 shares of 7s. 6d.; nominal capital £750,000, of which £479,848 is paid up. The amalgamation acquired a number of mines, and of these twenty are in full working, the number of men employed being about 800.

By the adoption of business methods, scrapping and disposing of old and worn-out machinery, installing new boilers in place of old and weak ones, thus saving

wages and firewood, taking advantage of the huge prices ruling for timber, secondhand machinery, and old metal, the cost of new plant was considerably reduced.

A number of the mines are at present being worked at a loss, but in these cases the prospects are such that development work is considered worth proceeding with; as a set-off to the mines on the non-paying list, there are those that pay working expenses, and others, notably the Constellation, in which rich stone is being obtained. This claim was amongst the non-payers for a long time, but the rich yields from it have enabled the directors to build up a fairly large reserve, and the question of a dividend to shareholders is now under discussion. The larger holders favor waiting until the annual meeting in July, when stock will be taken, and the exact position of the company known.

It is to the credit of the management of this company that it has never approached the Government for a grant.

#### Profit-Sharing with Miners.

Another unusual and important experiment that has been made, and which may yet cause an alteration in the working, not only of our gold but of our coal and other mines, and that is the granting of a share of the profits to the miners themselves. A co-operation, of association, of the miners employed by the B.A.G. Co. has been formed, and is known as the "Co-operative Alliance"; 250,000 shares, representing one-seventh of the company's present issue, has been allotted to the miners as profit-sharing shares. This gives the men employed an interest in the fortunes of the company, and their work; shares are paid up, and there is no liability. The shares, though profit-sharing, do not, of course, carry any interest in the assets of the company. At the present market value, these shares are worth about £25,000. Having a share in the profits of the mines, the men come to regard the company as one in which they have a vital and personal interest; for instance, a dividend of sixpence a share, declared by the company, absorbing £44,266, means that the Co-operative Alliance benefits to the extent of £6250. The miner receives a wage of £3 12s. a week of 44 hours, and, in addition, one-seventh of the profits earned.

This is a sound business-like arrangement. There is an inducement to work, as the men participate in the fortunes of the company. The stealing of gold will be less rife, as the men guilty are taking a percentage of what belongs to their fellow-workers. They are aware they are receiving a fair deal, and a go-slow policy would be almost an act of suicide. There is considerable allotment coming to the men, and a wise proposal has been made, and that is, that they should form a Co-operative Society along the lines of the one at Port Pirie, which has proved so successful. The miners alone would be shareholders, and with competent management, it should be a means of considerably reducing the cost of living for the miner and his family. The miners are also encouraged and assisted to buy their own homes. It is certain that the methods such as those described been introduced years ago, throughout the State, many a goldfield that lies deserted would be alive to-day.

The gold yield for the year is about 60,000 oz., which is much below the average, but there is no reason why, under the new conditions, it should not be maintained, and even increased.

The Bendigo Al Co. acquired the northern area from

the B.A.G. Co., and are actively carrying on development work, from which they expect good results at any moment. The New Argus and New Moon are in the same category.

The Lansell interest is small compared with what it once was, but they have a number of mines still working.

It will thus be seen that mining is still alive in Bendigo, and that the district offers in some respects a safe field for investment, now that the gambling element has been largely eliminated.

#### CHEMICAL INDUSTRIES EXHIBITION NEW YORK: WIDE RANGE OF TECHNICAL PAPERS.

For the sixth National Exposition of Chemical Industries which will be held in Grand Central Palace, September 20 to September 25, inclusive, there is being arranged the biggest Symposia on Chemical Engineering ever carried out in the United States. Up to the present four symposiums have been scheduled. One will be on Fuel Economy, one on Materials Handling, one under the general head of Chemical Engineering, and another on Industrial Management.

Many important topics will be treated upon when the Fuel Economy division holds its session. Among the papers to be read will be one on "Fluid Heat Transmission," by A. B. McKechnie, Parks-Cramer Co.; one on "Refractory Cement; Life Insurance for a Furnace," F. W. Reisman, Quigley Furnace Specialties Co.; another on Producer Gas and the Modern Mechanical Producer," by W. B. Chapman, Chapman Engineering Co.; and one on "Preventing Conduction and Radiation Heat Waste," by S. L. Barnes, Armstrong Cork Co. W. O. Rankin, of Quigley Furnace Specialties Co., will talk on "Powdered Coal" and there will also be an address by Conrad Dressler, of the American Dressler Tunnel Kilns.

The Speakers at the Industrial Management Symposium will include Harrington Emerson, on "Ultra Analysis of Costs; H. E. Howe, of National Research Council of Washington, on Research in Industrial Conservation,"; H. A. Ernst of Barret Co., Grinnell Jones, of Harvard University and others who have yet to select their topics.

The Chemical Engineering program consists of A. Hough and Wallace Savage on "Construction of Horizontal Stills; Thomas W. Pritchard, on "New Method of Destructive Distillation; W. D. Richardson, on "Corrosion and Galvanic Action in the Industries," and others to be selected.

The speakers for the Materials Handling program have not yet been announced, but F. G. Anderson, Chain Belt Transmission, will be among those who will occupy the rostrum for a time. Moving pictures have played a big part in previous chemical expositions but this year there will be a series of films which will far surpass anything before attempted. The majority of these are absolutely new, in fact some are still in the process of making.

In the U. S. Chemical Industries Series are included "The Story of Sulphuric Acid," General Chemical Co.; "A New Chemical Industry-Leather from the Sea-Fish Leather," Ocean Leather Co.; (Ford Educational Film Co.); "Perfumes for the World," Antoine Chiris Co.; "Modern Coke and Gas Manufacture," The Koppers Co.; "The Story of Petroleum Oil," Standard Oil Co., N.J.; "The Asphalt Paving Industry," Bar-

## *SIR JOHN WILLISON ON THE OUTLOOK FOR CANADA.*

Sir John Willison recently delivered before the Canadian Club at Halifax an address on the outlook for Canada in which he strikingly expounded the necessity to turn our raw materials into finished products in Canada. "Those who have ears to hear, let them hear," says Sir John, "for surely there is no other national policy for the Canadian people, whatever may be the fiscal faith which they have inherited, or the economic creed which they profess. It would be a blessing of the gods for Canada if we could forget that we ever had a tariff controversy and if we could approach the questions that are vital to national unity, national expansion and national prosperity without the fettering and narrowing incubus of old racial quarrels and party animosities. Through war, the debt upon the estate has been increased from \$336,000,000 to \$2,000,000,000, and if we are to reduce the obligation we must maintain and expand the industrial fabric and conserve and develop the natural resources."

"During the four years of war the half of our population which was not engaged in agriculture carried \$83,379,099 of the war taxation, while the half engaged in agriculture carried \$389,011—or only half of one percent. In this comparison I am not making any covert attack upon the farmers."—and here Sir John makes what we conceive to be his main point—"but only emphasising the heavy contribution of finance and industry and suggesting the heavier burden which must fall upon agriculture and industrial workers if these special sources of taxation should be restricted or destroyed. . . . We get only one-tenth of the value of natural resources if they are exported for manufacture in other countries."

We believe that the single vision which arises from the unrelieved and therefore necessarily selfish dominance of agriculture is gradually being enlarged as the peaceful penetration of agricultural communities by manufacturers proceeds in the West. One has only to glance over the provincial incorporations to see how persistent is this expansion, nor does it require great perspicacity to realize that the capital accumulation of many wealthy agriculturists is arousing a desire to have this money put to work.

The complete agricultural occupation of Canadian lands has not yet arrived, but it is closer to the event

than ever before. Agriculturally we shall soon have reached the frontiers of settlement in Canada, but there will still remain vast territories for the exploitation of the prospector and the miner, with future centres of population that will grow up around mining developments that may extend the agricultural limits in a circumscribed way. We are approaching the time when the repercussion of more or less complete agricultural settlement will enlarge the urban districts of the West, and there will then proceed to evolve that increase in industrialism and the intensive development of natural resources which will follow the appearance of the wealthy son of the farmer—himself not a farmer as will naturally happen—and the presence of an urban population from which to obtain the workers in manufacturing industries and mining and quarrying.

In other words, Canada is past the point where she is to be regarded merely as the northern storehouse of raw materials to be used in the industries of the United States. We have lived long enough on our capital in Canada. As Sir John Willison points out there is no ethnical or geographical obstacle between ourselves and our neighbors such as determine nationalities and divert the routes of industry into national channels in Europe.

In their decision to be and to remain a separate nation in North America the citizens of Canada, so Sir John intimates, have undertaken a great political experiment, which can not succeed unless we enlarge the development of those basic industries which will enable us to export a greater value of finished manufactures than we import. Volume of exports, if consisting solely of raw materials, is like to the action of a spendthrift heir which precedes the bankruptcy of the estate.

## *EMPIRE STEEL'S DONATION TO DALHOUSIE UNIVERSITY.*

The friends of education in Nova Scotia will be much heartened by the statement made by Mr. Roy Wolvin, President of the Dominion Steel Corporation, that \$250,000 will be given by the companies entering the British Empire Steel Corporation to Dalhousie University, with the idea of "definitely providing for professorships in research work in connection with 'the natural resources of the Province of Nova Scotia.' The justification for this munificent gift is best stated

in Mr. Wolvin's own words, namely that any subscription to Dalhousie University at this time "will be well repaid year after year". Mr. Wolvin said that men who first undertook the founding of a coal and steel industry in Nova Scotia were men of vision, a tribute both accurate and deserved, but to none of the predecessors of those who are now directing the allied industries has there been vouchsafed a clearer vision of the right action at the proper time. The large coal and steel companies in Nova Scotia have themselves been the victims of the meagre facilities for technical research existing in Nova Scotia, and they will be the chief beneficiaries of enlarged facilities.

Mr. Wolvin's statement was made after consultation with Mr. D. H. Mc. Dougall and Mr. J. W. Norcross. At the Toronto Meeting of the Canadian Mining Institute, Mr. D. H. Mc. Dougall, as the retiring President said: "Efficient and full use of our resources is dependent upon the progress of science, which, applied to their limitations, and supplementing their deficiencies, will have the effect of increasing their quantity and duration." Mr. Mc. Dougall pleaded for a recognition of the importance of applied science to our young nation, and expressed his belief that it was necessary that the Canadian people should "entirely revise their valuation of the scientific worker."

It is therefore heartening to observe that the most pregnant re-arrangement of industrial forces which has recently taken place in Canada is headed by men who have the desire, as well as the power, to practice what they preach. The gift to Dalhousie University is timely, wise and good business.

*A GERMAN COAL "KING."*

Cabling from Berlin, as correspondent of the New York "Times", George Renwick sends a character sketch of Hugo Stinnes, whom he describes as a "soul-destroying success, sinister as his looks," a man to whom power is as the breath of life, and whose remarkable influence in European politics is attributed to his realization of the basic necessity for coal in this age.

" 'I build on coal', Stinnes once said to me in the days long before the war. 'From coal you go on to iron and steel and then to the various industries, to ships to commerce; and coal will lead you to woods and forests, to wood pulp and paper. Coal is King.' "

One may dissent from the ambitions of Herr Stinnes, but, so long as private ownership is acknowledged in Germany, there is no disputing the power of any man, who, being the possessor of many groups of coal mines, has also the vision of the material power

that accompanies such possession when followed to its ultimate application in the arts of civilization.

There was no doubt in the minds of those who followed the course of the war, and realized the part that coal played in the ambitions of European nations, that the movement of Germany's armies was dictated as much by the hand of the mining engineer as by the military chiefs. Had Germany won the war, and imposed the terms which we now know had been drafted, and of which the peace of Brest-Litovsk was a mere forerunner, it is apparent how, with the aid of Hugo Stinnes and others like him in Germany, the conquered nations would have been scientifically relieved of their basic materials and industries by men who have devoted their whole being to the worship of material power. Once more, neither for the first nor the last time, the imponderables and the intangible things of life defeated the scientific calculations of an armed nation arrogant in its mightiness, but victory would not have been possible to the Allies, no matter how righteous their cause, had they not been able to marshal the coal production of their countries against their enemies.

Herr Stinnes's recital of the structure built upon coal has its exact parallel in the course of events in Canada today. From coal to steel, from steel to ships and commerce, with the by-path to wood-pulp and paper is curiously reminiscent of the chief items of discussion in financial and political circles in Canada during the past few months.

**ALBERTA GOVERNMENT ADVERTISES ALBERTA COAL IN WINNIPEG.**

The "Winnipeg Free Press" of July 17th contains a three-quarter page display advertisement published by the Alberta Government in the interests of Alberta coal, urging the use of western coal during the coming winter, and its immediate purchase.

"Whether for hot water, hot air, steam, direct or indirect heating or the good old-fashioned stoves and heaters, there is a coal from Alberta that will give you full satisfaction, and any responsible dealer can get it for you." So runs a portion of the announcement. Publicity of this kind is the very best kind of business and in every way to be commended. What the eastern coal man finds it difficult to understand, however, is why it should ever have been necessary to urge western people to burn western coal.

# Northern Ontario, Between the National Transcontinental Railway and James Bay, along the Abitibi and Mattagami Rivers

## ECONOMIC GEOLOGY OF THE PALEOZOIC AREA

(Illustrations loaned by the Ontario Bureau of Mines).

Part II of the 29th Annual Report of the Ontario Bureau of Mines, 1920, consists of a tri-partite description of that portion of Northern Ontario lying between the line of the Transcontinental Railway and the mouth of the Moose River in James Bay, as seen along the courses of the Abitibi and Mattagami Rivers, prepared by J. G. Cross of the Ontario Bureau of Mines. M. Y. Williams of the Geological Survey and Joseph Keele of the Mines Branch at Ottawa.

Mr. Cross has reported upon the pre-Cambrian rocks and iron-ore deposits in the Abitibi-Mattagami area, and Mr. Williams has described the geology of the Paleozoic area as seen in the cuttings of the two rivers. Mr. Keele deals with the clay and shale deposits.

The topographical character of the region is clearly recorded by Mr. Keele, as follows:—

### The Blanket of Glacial Drift.

A great sheet of glacial drift covers the whole region drained by the Abitibi and Mattagami rivers from James Bay to some distance south of the National railway. It is composed principally of boulder clay or till gathered in the Hudson Bay basin, moved southward by land ice and spread like a huge poultice over the land surface, completely obliterating the topographic inequalities of the underlying rocks.

This thick drift sheet was derived principally from the Paleozoic and Mesozoic rocks bordering the southern part of the Hudson Bay basin and possibly in part from the sea bottom, extends southward and covers the pre-Cambrian rocks from the Paleozoic border to a distance from 20 to 40 miles south of the National Transcontinental line. The only field data we have at present concerning the southern limit of this thick clay drift is the presence or absence of lakes. Where the drift is thick and persistent, lakes and rock ledges are practically absent, but where this drift thins out and disappears to the southward, lakes and rock ridges become numerous.

Photo by J. G. Cross.

### SMOKY FALLS, MATTAGAMI RIVER.

These beautiful falls, with a drop of 86 feet, receive their name from the mist which continually hangs over the crest.

The pre-Cambrian rock surface yielded less material than the more easily eroded Paleozoic rocks and very little clay during glaciation, hence when the southward moving ice sheet exhausted its load of fat northern clay it could not gather much more as long as it moved only over the old crystalline rocks.

The generally barren character of the pre-Cambrian upland when not enriched by the northern till, is exhibited along the Temiskaming and Northern Ontario railway line between North Bay and Cobalt, where the glacial drift consists of sand, gravel, and boulders only. The drift here is generally thin, so that it does not obscure the inequalities of the old pre-Cambrian surface, therefore rock ridges, small valleys or lakes are constantly in view of the traveller.

A very different aspect would open to an observer travelling on the proposed extension of the railway through the region north of Cochrane, where there is a marked absence of lakes and rocky ridges. So effectively has the till sheet levelled up the surface that if the whole area along and north of the National Transcontinental line were denuded of trees, it would be a rolling prairie country. The Abitibi and Mattagami rivers and their branches flow in roughly parallel trenches incised in the till sheet. These rivers occasionally lay bare a rock ridge which stands at a higher level than the general rock surface beneath the glacial till, and at these points rapids or falls occur.

The great mass of the unconsolidated surface materials originating from glacial conditions consists of till or boulder clay. In northern Ontario this till sheet is so thick and so persistent that it deserves a formation name, but none has hitherto been applied to it. It forms the greater part of the extensive clay belt over which the National Transcontinental railway is built, and includes a vast reserve of agricultural land. This till sheet is not entirely continuous, but is interrupted by minor areas of sand or gravel which are the result of the washing and sorting of the boulder clay by streams of water issuing at the water issuing at the edges of ice sheets.

There are no large areas of the till sheet entirely level in these regions, but the surface exhibits a series of gentle undulations. The hollows are swampy, owing to the fact that water collects in them, and cannot escape on account of the impervious character of the underlying boulder clay and the small amount of evaporation. The hollows accumulate a deposit of peat, and in time may support a thin growth of stunted black spruce. The higher portion of the surface is dry, and supports a forest growth of poplar and birch in addition to spruce. Travelling in any direction, then, one passes alternately from wet to dry land.

No definite evidence of multiple glaciation during Pleistocene time was found in the region examined. In places stratified sands and clays are overlain and underlain by till, but such occurrences are probably to be explained as the result of minor retreats and advances of the ice-sheet. No fossils were found in

the stratified deposits interbedded with till, nor was any other evidence obtained which would suggest that inter-glacial warm climate conditions prevailed at any time during the Pleistocene in this region. It was found that the clay beds which occur on the Mattagami river, and which have been referred to by previous workers as inter-glacial in age, are pre-Glacial in age.

#### Observation Limited to River Channels.

All that is accurately known regarding this part of Northern Ontario—which comprises approximately 26,000 square miles—is confined to the observation possible in the river channels cut through the all pervading mantle of glacial till, and in this regard it resembles the knowledge of Ungava and the North-West Territories in being tantalisingly incomplete. The portion of Northern Ontario traversed by the Abitibi and the Mattagami, as may be seen from the map, constitutes only a small part of the little known territory surrounding Hudson Bay, and when one reads the

Section of Onondaga limestone in cliff 50 feet high, Long rapids, Mattagami river. Photo by M. Y. Williams

statement of Mr. Cross regarding explorations in the muskeg along the Abitibi, where "an average of one mile an hour was considered good going," it is clear that little is known, and that little can be known for many years to come, either as to the feasible limit of economic settlement northwards in Canada, or of the mineral occurrences in unprospected continental areas.

#### Pre-Cambrian Rocks and Iron-Ore Deposits, Abitibi-Mattagami Area.

The mineral occurrences noticed by Mr. Cross's party are briefly noted as follows:

##### Metallic.

Numerous quartz and calcite veins were carefully examined for traces of gold and silver; none were observed.

Siderite.—At the head of Grand Rapids, Mattagami River, possibly in commercial quantities. Inferior metal at the foot of the Rapids.

Limonite.—Occurs sparingly with the above.

Chalcopyrite.—Occurs sparingly disseminated in a number of quartz veins examined, and similarly in the gabbro of the Abitibi Canyon.

**Non-Metallic.**

Peat.—Enormous areas of swamp and muskeg are underlain with peat. The depth is uncertain. The quality appears to be good.

Lignite.—Lignite beds occur along the lower stretches of the Abitibi and Mattagami rivers. These do not appear to have sufficient depth or lateral extent to be of economic importance.

Gypsum.—Gypsum similarly occurs along the Moose and Abitibi rivers.

Pyrite.—Pyrite, mixed with considerable quantities of pyrrhotite, occurs as irregular masses and lenses

ly north of Mattagami Station on the Transcontinental, is the most interesting part of the report of the Cross party, which gives the following particulars:—

**Description of the Ore.**

The ore is essentially siderite, although limonite is occasionally present. The limonite is found in vuggy or nodular masses in the siderite, and also occasionally forms a casing around the margin of the larger siderite bodies. On the whole the limonite forms only a very small percentage of the ore.

Wherever exposed the surface of the siderite has been oxidised to limonite; hematite is also probably present, judging from the streak. This oxidation is very superficial, being seldom more than three inches in thickness. In the inferior grades of ore, where there is much silica and clayey material, the oxidation is more pronounced; nowhere, however, was extensive oxidation observed.

In colour the siderite varies from dark brown to nearly white. The different shades of colour are probably due to finely disseminated limonite, or organic matter. Often the organic matter is visible in fairly large pieces, and appears to be of a lignite nature, having the appearance of charcoal. The structure is compact and finely granular. The fracture is uneven. A light coloured, coarse grained variety was observed as float, farther up-stream. No ore of this nature was found in place, and it is assumed that this material came from other localities, not yet discovered. Speculation as to the origin of this float will be presented later.

Siderite occurs at both the head and the foot of Grand rapids, but it is only in the former locality where ore of commercial quality exists. This showed on analysis the following composition:—

Sample (6) chipped, 600 ft.

	Per cent
Iron . . . . .	43.52
Silica . . . . .	5.40
Alumina . . . . .	2.63
Sulphur . . . . .	0.74
Phosphorus . . . . .	0.08
Manganese . . . . .	0.00
Water . . . . .	2.18
Carbon dioxide . . . . .	30.40

The chief impurities in the ore are silica, clay, limestone, sulphur and organic matter. The phosphorus is not abnormally high for this class of ore. Silica in the form of sand and gravel was often observed in the inferior grades. The clay content is also very high in places, the silica and clay frequently forming the greater part of the outcropping. Limestone is also present, often forming a breccia, the cementing material being siderite of inferior quality. Sulphur is present in all the ore. Often this can be observed as small pockets of pyrites in cavities in the siderite, and occasional specks of pyrite can be seen, with the aid of the glass, in nearly every specimen observed. Organic matter is also contained in all the ore, but in varying quantity; some of the siderite contains so much organic matter that it is almost black in colour. The best quality ore contained 1.27 per cent. carbon. This organic matter is probably lignite, as occasional pockets and seams of lignite were observed in the ore.

From the foregoing analyses it is apparent that samples Nos. 1 to 5 represent ore of very inferior quality, while sample No. 6 represents siderite of good

Photo by M. Y. Williams.

Deposit of iron ore on west side of Mattagami river at Grand rapids. The dark mass in foreground is the ore. Cliffs of weathered limestone rise in the background.

impregnating and replacing biotite gneiss, at the foot of Island portage, Mattagami river. The pyrite is not sufficiently rich to be considered an ore of sulphur. The sulphur content would probably not exceed 25 per cent.

Clay.—Clays of a refractory nature were observed, often associated with lignite along the Mattagami river, below Long portage.

Kaolin.—An interesting occurrence of highly kaolinized syenite gneiss, containing as impurities biotite and garnets, was observed in the Canyon of Long portage, Mattagami river.

**Siderite Deposits, Mattagami River.**

From an economic point the iron ore occurrence at Grand Rapids on the Mattagami, about 80 miles direct-

commercial grade. The latter will be referred to as the main body, and the former as ore of inferior quality.

The main ore-body has a maximum width of approximately 600 feet but the exact extent of workable ore was not determinable.

The ore occurs in cavities in limestone of Corniferous age, and the larger the cavity the better appears to be the concentration of iron content in the ore. It is suggested the iron was deposited in the cavities from solutions, iron being present in the neighboring rocks, and streams in the vicinity being noted as heavily charged with iron in solution.

Some work has been done on the Grand Rapids deposit by the original owners, but, interesting as this occurrence is from many points of view, its present economic value is small.

The conclusions of the Report are, in part, as follows:—

**Conclusions Regarding Ore Body**

The analysis of sample No. 6 shows that the ore is a siderite of very good quality. This material when calcined gave a product that analysed 61.22 per cent of iron. The sulphur and phosphorus content are too high for a Bessemer ore, but the material should be well adapted for the manufacture of steel by the basic open hearth process, and for the manufacture of pig iron.

Regarding the possible occurrence of similar ore bodies, it would appear, judging from a superficial examination only, that these siderites may be quite widely distributed. The following reasons are ascribed for this assumption:—

(1) The occurrence of siderite elsewhere in the same general vicinity.

(2) The similarity to this area, geologically and physically, of other large areas in the locality.

(3) The great abundance of siderite boulder drift for many miles along the Mattagami river. The deposits described would not seem of sufficient size to supply this profusion of boulders.

(4) The occurrence of siderite drift greatly in physical properties from any observed *in situ*.

(5) The existence of a talus slope of sideritic material four miles further up-stream than the deposits at Grand Rapids.

Attention is called to the presence of siderite on the Opazatika River in limestones, as indicating probable wide distribution of these siderites.

**Possible Occurrence of Oil in the James Bay Sedimentaries.**

Dr. Williams reports on the geology of the Paleozoic rocks as they approach James Bay with particular reference to the possibility of the presence of petroleum. The Onondaga limestone is present, but mostly it outcrops, and only in a few localities of restricted area is it covered by impervious shales such are presumed to be necessary for the retention of the oil in this section, which has been uniformly productive of oil in southwestern Ontario.

Dr. Williams suggests that nowhere in the district is it likely that there exists a greater depth of Paleozoic strata than 600 to 700 feet. The possibility of oil is suggested by the presence of formations which have yielded oil in southwestern Ontario, but, from reading the Report, it is not possible to gather that any definite indication of the presence of petroleum has as yet been observed.

The presence of oil-shales is noted, of low oil-content, samples from the Long Rapids, on the Abitibi river showing respectively 1.6, 3.9 and 5.5 per cent of crude oil. The outcropping beds along the Mattagami are of limited extent "but there is evidence they are of Portage age, and, if they are, the whole Ohio shale section may be present."

#### Clay and Shale Deposits of the Abitibi and Mattagami Rivers.

Mr. Keele, whose knowledge of the geology of shales and clays in Canada is well known as accurate and extensive, has dealt at length with the sorting and deposition of the glacial debris into sands, gravels and varying classes of clays. While there are in the district under review a number of clays, sands and gravels that would be valuable in settled districts, it is necessary that before any economic value can attach to such materials when situated so far from centres of population that they should possess unusual merit, and the refractory pre-glacial clays found in this part of Northern Ontario show such excellent qualities that they may become of industrial value. The clays of particular value, the presence of which is verified by Mr. Keele, occur on the banks of the Mattagami, about 55 miles north of Kapuskasing Station on the Transcontinental. One clay is stated to have the composition and physical properties of the fireclays of New Jersey, and another clay is stated to approach English ball clay in character.

With regard to the distribution of these clays, Mr. Keele writes:—

#### Prospecting for Fire Clays.

"Enough has been said about the qualities of these clays to show that they are of high grade and of extremely rare occurrence in the Province of Ontario, or indeed anywhere in Central Canada.

As already stated, small bodies of these high grade clays are visible at low water stages on the Mattagami river, and at about forty miles to the west of this locality on the Missinaibi river the most extensive known deposits of fire clays in the region are to be found.

There are no occurrences of fire clays reported from the Opazatika, a tributary of the Missinabi which intervenes between that river and the Mattagami, but then they have never been sought for on that stream.

In all probability the fire clays were originally spread over the large area extending between the two streams or beyond them, but glaciation must have removed some of the beds or scooped out the whole formation in places.

The clays as far as we know never overlapped the pre-Cambrian rocks, but are confined to the area underlain by Paleozoic rocks.

The persistent cover of glacial drift and forest growth retards considerably the prospecting of the

interstream areas, and the only thing to be done there is to put down borings at a venture in the hope of tapping the underlying fire clays, so this practically confines prospecting to the river banks for the present, until some nearer approach to the deposits is made by railway transportation.

Their distinctive colour is the principal clue to be used in prospecting for these clays, as they present a strong contrast to the monotonous drab of the ever present glacial clay. Dilute acid is a convenient field test, but it is not final, as some clays which do not show effervescence may not be fire clays. This test, however, prevents the burden of carrying useless samples.

The excessive overburden of glacial drift is one of the chief drawbacks to the exploitation of these clays. In regions where similar clays are mined it has been found that it is possible to remove one foot of overburden for every foot of good clay obtained, but it is not profitable to remove more than this."

#### Kaolin.

The presence of kaolin, or china clay, is not reported, but Mr. Cross discovered a kaolinized zone of rock below the Long portage on the Mattagami river, regarding which the Report comments:—"The discovery of a considerable body of rock well on its way to being a kaolin is of importance, as it may lead to the discovery of true kaolin in this region. The ever present burden of glacial drift, however, which makes prospecting so difficult has always to be reckoned with."

The presence of thin beds of lignite is several times mentioned in the report, but unfortunately there appears to be no possibility that in the region traversed any workable bodies of lignite exist. Peat-bogs exist in profusion, but their usefulness as a source of fuel supply is much smaller than peat-bogs nearer the frontiers of settlement, and, so far, experiments in the preparation of peat for use as a fuel have shown that it will not bear long-distance transportation.

#### GIFTS OF CANADIAN MINES TO PRINCE OF WALES ON EXHIBITION IN LONDON.

The Bulletin of the Imperial Institute states that the presents received by H.R.H. the Prince of Wales during his visit to Canada are now on exhibition in the Canadian Section of the Public Exhibition Galleries of the Institute. Included among the exhibits are specimens of cobalt, nickel and silver ores from Coniagas Mine, Cobalt; copper and gold ores from Drum Lummon Mine, Douglas Channel, British Columbia, native silver from the O'Brien Mine, Cobalt; gold quartz from the Hollinger Mines, Porcupine District, and coal from the Wellington Extension Mine, B. C.

The time has come for the people of this country to look the fuel situation squarely in the face and for public opinion to demand a course of action leading towards remedy. If any nation in the world cannot afford to trust to luck for the winter's coal that nation is Canada. Handling of the coal situation by frantic adjustments of succeeding crises ought to be a repugnant to the good sense as it is beneath the dignity of Canadians.—Montreal "Star."

## Our Northern Ontario Letter

### THE SILVER MINES

The mine operators in the silver producing areas of North Ontario, while free to admit that the decline in quotation for silver has been a disappointment, nevertheless are also mindful of the fact that even present quotations back in 1917 would have been sufficient to cause great enthusiasm. There is no sign of lessening activity, while the indications point to the likelihood of increased work in certain parts of the district.

During June the Cobalt mines shipped an aggregate of 1,497 tons of ore, as compared with 1,568 tons in May. The average price of silver during June was 90.95 cents an ounce, as compared with 102.58 cents in May. The lowest point reached in June was on the 16th when the metal was quoted at 80 cents an ounce. So far during July, the price has ranged well above 90 cents, and the July averages promises to exceed that of June. In addition to this price, the producing companies continue to receive payment in New York funds and are thus in receipt of an extra 12 or 13 per cent, making a total of more than \$1 an ounce for their product.

Negotiations between the Mining Corporation of Canada and the Penn-Canadian Mines, involving some 125,000 tons of tailings owned by the latter company, do not appear to be making much headway. The Penn-Canadian offered to dispose of the tailings at a time when quotations for silver were much higher than at present, having based its price on such figures. It is now believed that unless modified terms are presented, the negotiations will not terminate successfully.

For the first half of 1920 the properties of the La-Rose Consolidated are reported to have produced close to a quarter of a million ounces of silver, as compared with 269,000 ounces for the whole of 1919. At the present rate of output, the 1920 figures are expected to exceed 1919 by more than 50 per cent. It is also intimated that while production costs in 1919 amounted to \$1.05 for each ounce of silver produced, the reduction of exploration work this year is enabling the management to produce the metal at a much lower cost, and which leaves a satisfactory margin of net profit.

According to advice just obtained the mill of the Bailey Silver Mines, formerly the Northern Customs Concentrator, during the second quarter of the current year, earned \$50,477.65, made up of \$16,000 for April, \$17,000 for May and \$17,477.65 for June. It is also learned that the company is meeting with success in development work on the Bailey Mine itself, having opened up another rich ore-shoot in addition to developing additional milling ore. Prior to this development work, ore in sight was estimated at 23,000 tons of upwards of 20 ounces of silver to the ton. The higher grade ore is being assembled ready for subsequent shipment, while arrangements to install a railway siding and transport the milling ore to the Bailey Mill are proceeding satisfactorily.

Official advice to the "Journal" from the Canadian Light Railway Construction Company, of Toronto, conveys the information that twenty miles of the sur-

vey work from Elk Lake to Gowganda has been completed and that it is now possible to estimate the probable cost of construction work. It is also stated that survey parties are still engaged in making a survey of also tapping Boston Creek and the township of Kirkland Lake, and with the ultimate object in view of also tapping Boston Creek and the township of Skead. Financial arrangements consist of raising approximately \$1,500,000 for these projects, and the promoters of the enterprise appear to be confident of the outcome being successful. In the meantime, mining activity in the districts which the proposed lines are to serve is steadily increasing with indications of added impetus just as soon as rail transportation can be provided.

About 200 feet of underground work has been done on the property of the Cobalt 53 Mining Company, and consist chiefly of lateral work at a depth of 70 feet. The work is stated to have been financed personally by the promoters. The work done is for the purpose of endeavoring to open up the downward continuation of a vein which at surface contains encouraging quantities of silver.

The Thompson Powder Company is meeting with success in Cobalt and Porcupine in the sale of shares with which it is proposed to finance the manufacture of "Thompsonite," a comparatively new explosive. Former demonstrations were very satisfactory, so much so that quite a number of mining men in a position to pass on the merits of the explosives are stated to have subscribed quite liberally for shares in the company. It is planned to manufacture explosives in Toronto.

Although it was generally understood, at the time the deal was closed in which the Conigas Company took a working option on the Gamble-Thompson property at Gowganda that work would be carried on in an aggressive way, nothing much has so far been done. The property is rated as an excellent mining prospect.

In connection with the recent unofficial reports that the Nipissing Mining Co. contemplates making a capital reduction, in addition to regular dividend disbursements of 5 p.c. quarterly, it is learned by the writer in official circles that such a plan is not under consideration and that a circulation of such rumors merely serves to raise false hopes among the shareholders.

In recent years, the Nipissing has paid dividends at the rate of 5 p.c. quarterly, plus an additional bonus of 5 p.c. with the January dividend and a 5 p.c. bonus with the October dividend, making a total of 30 p.c. annually on the issued stock. In spite of this liberal rate of disbursement of profits, the company has accumulated a large surplus, the most recent financial statement showing over \$5,000,000 in quick liquid assets.

At a meeting this year, some of the shareholders made the suggestion that the rate of dividends should be increased. No action was taken on the suggestion, however, and, meanwhile, the treasury continued to grow. These facts appear to have been the basis of the recent reports that a capital reduction would be made. This report now receives official denial.

Following is an official statement from Arthur A. Cole, mining engineer for the T. and N. O. Railway, showing the total ore shipments from Cobalt over the railway for the month of June, in tons of 2,000 pounds:

**SILVER ORE**

Cobalt Proper	Tons
1. Conigas . . . . .	86.90
2. Dominion Reduction . . . . .	62.00
3. LaRose . . . . .	73.60
4. Mining Corporation . . . . .	301.52
5. McKinley-Darragh . . . . .	82.28
6. Nipissing . . . . .	793.22
7. O'Brien . . . . .	32.00
8. Temiskaming . . . . .	66.25

1,497.77

The above shipments were made to the following Companies:—

**CANADA**

Deloro Smelting & Refining Co., Deloro Marmora . . . . .	1,232.34
Conigas Reduction Company, Thorold	153.15

**UNITED STATES**

American Smelting & Refining Co., Chrome . . . . .	30.00
American Smelting & Refining Co. Perth Amboy . . . . .	82.28

**PRICE OF SILVER**

June 16th. Lowest . . . . .	80.000
June 2nd. Highest . . . . .	99.625
Average . . . . .	90.957

**ORE AND BULLION SHIPMENTS.**

During the week ended July 16th, six Cobalt companies shipped a total of six cars containing approximately 445,020 pounds of ore, a summary of which follows:—

Shipper	Cars	Pounds
La Rose . . . . .	1	90,666
Nipissing . . . . .	1	86,390
Temiskaming . . . . .	1	82,366
Dominion Reduction . . . . .	1	64,000
Coniagas . . . . .	1	61,305
Hudson Bay . . . . .	1	60,293
Totals . . . . .	6	445,020

During the corresponding period, no bullion shipments were made.

**THE GOLD MINES.**

A most optimistic turn has taken place in Northern Ontario in connection with the gold mining industry, and some of the most conservative mining men in the business are found numbered among those who are openly predicting interest and activity during the remaining months of the current year that may actually attain boom proportions. They base this belief on the strength of the facts that conditions are becoming less abnormal, that ore reserves are the highest in the history of the mines and that labor is becoming more plentiful, all of which promises to permit the mines to utilize their milling facilities to full capacity and thus add enormously to output and to the rate of dividend disbursements.

Not since the recent war laid its adverse influence in the way of the industry have gold mine operators seemed so optimistic. Speculation in mining shares is becoming more pronounced, and almost on every hand appears to be a spirit of pent-up enthusiasm which may reasonably find vent almost any day. Such mines as the Dome, Hollinger, McIntyre and Lake Shore are the favorites among the big producers, while among the lower priced shares the Dome Extension, Porcu-

pine V.N.T., Schumacher, etc., appear to be favorites. These mines are expected to lead the way, and to signalize general interest in all mining properties of promise throughout the district, to the end that great incentive will be offered for more intensified exploration and development work on properties as yet in the prospective or development stage.

A dividend of 5 per cent. will be paid September 1st to shareholders of the McIntyre-Porcupine of record August 1st. The disbursement will amount to \$180,514 and will be the third made so far this year. Up to date the McIntyre has disbursed a total of 55 per cent. or \$1,985,655. The company is capitalized at \$4,000,000 made up of 4,000,000 shares of the par value of \$1 each. Some 3,640,283 shares have been issued.

As a result of the special general meeting of the Porcupine V.N.T. Mines held this week, it is estimated that a plan to underwrite a block of treasury shares finds favor and may be adopted as a means of raising finances with which to remodel and enlarge the mill, as well as increase the scope of underground operations. The company has 675,000 unissued shares still in its treasury. It is suggested that about 200,000 shares may be underwritten at about 15 cents each 200,000 at 30 cents and 200,000 at 50 cents and with the funds thus made available it will be possible to completely finance the work in connection with putting the mill in shape to handle from 150 to 160 tons of ore daily as well as greatly enlarging the scope of underground operations. The outlook for the mine is considered very favorable.

It is apparently the quite general belief in the Porcupine district that the Dome Mines Company will, on or before September 15th, be justified in exercising the option which it holds on the Dome Extension mine. The indications that one of the main zones of mineralization will extend from the Dome onto the Dome Extension at a depth of about 1,150 feet seems to be the chief basis for such a belief. Great importance is attached to the latest official statement from the Dome in which it is shown that one of the main ore bodies, (the first so far opened up at the 850-ft. level) is believed to prove this body to be one opened up at various upper levels and having a sharp dip to the East, from surface to the 8th level, on the slope, having a depth of about 1,800 feet. The indications are that this orebody continues to dip to the East and probably enters the Dome Extension at a depth of 1,150 feet. Following is an extract from the latest official statement, relative to the big orebody found at the 850-ft. level:—

“A cross-cut was driven north from 803 drift (8th level) on the course of diamond drill hole 261. This drill hole showed an intersection of 65 feet averaging \$8.20 and is the first disclosure of payable ore on the 8th level. The cross-cut confirmed the results had from the drill hole and showed a principal ore body averaging \$7.61 over which a width of 43.5 feet. A stope is being cut in this ore body and is maintaining the grade disclosed by the development on the level, as well as showing some excellent specimens of free gold, this being the ore referred to in a previous paragraph, as the probable downward extension of the 723 ore body.

“We attach considerable importance to the finding of this ore on the 8th level as it should

prove the continuity of the east-dipping ore-shoot without a break from the surface to the 850-ft. level, a distance on the slope of 1,800 feet."

At the Kirkland Lake Gold Mines, additional rich ore is being opened up, recent developments having added a considerable tonnage containing average values somewhat higher than the former general average in the mine.

As a result of surface exploration, a vein has been opened up on the Kirkland Lake Townsite property. The vein or "break" contains considerable well-mineralized quartz, and occurs in a well-defined contact between the conglomerate and porphyry formations.

Delays have occurred in connection with delivery of equipments for the Hunton-Kirkland plant. It is learned, however, that the Elliot-Kirkland may loan its transformers to the Hunton so as to enable the latter to utilize its plant before the end of July, as originally planned.

Samples taken from a test pit six feet deep on the Wood-Kirkland property in the township of Lebel, are stated to have shown a high average gold content across a width of nine feet. Three feet is said to average \$65 to the ton, while six feet averages \$6 to the ton. The samples contain no visible gold, but gold tellurides are present, the ore also containing an average of about two ounces of silver to the ton.

Mr. Frank Henth, president of the Ontario-Kirkland Gold Mines, has issued the following statement to the shareholders, as of July 8th:—

"In my letter of May 15th, I advised you that the shaft on the Company's property had reached a depth of 450 feet, and that cross-cuts had been commenced to intersect the veins on this level. Since sending this communication, two veins have been cut on the 450 foot level showing ore of excellent grade. Drifting operations have proceeded along the veins with most satisfactory results, and the values so far encountered are considerably in excess of the values found on the 300 foot level directly above thus indicating an increase in the value of the ore with depth. These developments are rapidly adding to the ore reserves and greatly increasing the value of the property.

"As you were formerly informed, the Company has made a contract with R. C. Coffey to design and erect a mill suitable for the treatment of the ore. The preliminary work of clearing the mill site and excavating for the foundations is now under way, and it is our intention to proceed with the erection of the mill as fast as conditions will permit. We will be unable to make as rapid progress as we had hoped owing to the fact that the mines of Kirkland Lake have been unable to secure an adequate supply of efficient labor. The Ontario-Kirkland together with the other mines of Kirkland Lake, has granted an increase in wages amounting to an average of fifty cents per day, the effect of which has been felt, and we confidently expect a gradual improvement.

"The Shareholders and Directors who visited the property on the 7th of June, after carefully going over the entire situation and consulting with the Engineers in charge, decided that the best policy would be to continue the underground development work as rapidly as possible, and also proceed with the erection of the mill with all reasonable dispatch. This policy will mean the more extensive opening up of the ore bodies thus placing the property in a more advanced stage of development, which will greatly facilitate the extraction of ore in an economical manner when the mine is placed on a producing basis. Our progress must to a great extent depend upon the amount and efficiency of labor obtainable and, as noted above, the situation is showing signs of improvement.

"The amount of development work accomplished to date and the very favorable results are most gratifying, and places the Ontario-Kirkland in a high position among the mines of Kirkland Lake. Every effort will be made to continue the development work and advance the construction of the mill as above outlined. The success of the Company seems assured, and it is our intention to keep the shareholders duly informed of progress being made."

## British Columbia Letter

Victoria, B. C.

That the development of coal lands and the obtaining of accurate information regarding all reported oil fields are serious responsibilities under present conditions is recognized by the authorities of the United States would appear to be indicated by an announcement from San Francisco, Cal., to the effect that Josephus Daniels, Secretary of the Navy, together with Secretary Payne, of the Interior Department, and Governor Riggs of Alaska, have left to investigate coal and oil possibilities of certain Alaska lands. In this connection Secretary Daniels is quoted as follows:—"We have an appropriation of \$1,000,000 for development of the Matanuska coal fields for naval purposes and we also believe it possible that productive oil fields may be discovered. The oil, however, is only a possibility, but we will look into it."

Lists of Crown-granted mineral claims which have reverted to the Crown because of non-payment of taxes, and now are subject to leave under the terms of the "Taxation Act" have been forwarded to the Gold Commissioners and Mining Recorders throughout the Province. This publication is of surprising size, containing thirty odd pages. Every mineral district of British Columbia figures in the tables it contains. As would be expected, the sections best known to miners, because they have been longest prospected and have yielded and, it may be said, still are yielding the bulk of the mineral wealth for which the province is responsible every year, have contributed to the Crown the greater number of delinquent mineral claims. The Rossland Assessment District, for instance, has provided something over 800 such properties, all of which, as stated, may be leased after compliance with the statutory formalities, the particulars of which will be furnished on application to the Assessor. The Slovan Assessment District, also, is well represented with about 300 such claims advertised for lease. Nelson has about 328; Fort Steele about 90; Kettle River 170 odd, and, coming to Vancouver Island, it is found that Nanaimo has some 28 of these, presumably abandoned, claims; Cowichan, 18; Comox 33; and Alberni 45. It is safe to assume that many, if not the majority, of these properties, have not been sufficiently developed to conclusively prove their merit, and that sooner or later they will be further explored and opened up with, at least in some cases, satisfactory results. On this point it is illuminating to contemplate the success of Clarence Cunningham, one of British Columbia's largest individual operators, in the exploitation of several groups of claims which their previous owners thought had given up paying ore to the full extent of their resources.

W. Pellew-Harvey, of the firm of Pellew-Harvey & Co., London, England, is in Victoria, B.C., and intends it is stated spending some months in a general survey of the mining development and possibilities of the province. Mr. Pellew-Harvey is an engineer with practical experience in the Canadian West dating back some twenty years who subsequently made his headquarters in London. He is said to be here on a special mission on behalf of a syndicate of British capitalists and proposes, in pursuance of his commission, visiting all the mining camps and many reported promising prospects of the province.

Word received recently by mail from Dawson, Y.T., appears to confirm the recent report of a new silver strike in the Mayo District. The latest discoveries are on the slope of Mount Hinton, opposite Keno Hill. They are about five miles from Keno Hill, where was the first excitement, the water of Lightning Creek separating the two. When the news reached Mayo there was a stampede and the ground has been thoroughly staked. As to the Keno Hill properties, it is stated that the Yukon Gold Company have found a rich new silver deposit near where they have been working. A pioneer prospector, writing to a prominent resident, says: "I've been up Keno prospecting. I located three claims and hope to prospect for the remainder of the summer. I got in on the new stampede. It is located near the head of Lightning Creek and shows gold and galena. Everyone is away stampeding. Middlecoff Hydraulics are about closed, and the men are staking. They are opening up the biggest thing yet on Keno Hill, taking the ore out of the mud, five feet wide and got it stripped over 200 feet in length two days' ago. It runs 1,000 to 2,000 ounces to the ton, and they take it down to the frost about one foot deep, and there must be a big lead under. Words cannot express the big thing we got at Mayo. I believe it is going to astonish the world. Everyone who sees it says the same. The worst drawback at present is too many stakers and too few prospectors."

#### Stewart, B. C.

The Premier Mine, Salmon River, Portland Canal District, is the most talked of mining property of this province at present, and if the reports concerning the value of the ore shipped during the past winter and the results of diamond drill prospecting that has been under way are substantially correct, it is destined to continue to hold the attention of American mining men. As to shipments it is said that 1,500 tons have been extracted yielding an average of \$300 to the ton and that there is much milling ore on the dump awaiting treatment. Regarding development, the report is that the drills have cut the high grade ore at depth and that exploration in other respects is very satisfactory. The concentrator being installed is expected to be ready for operation next month.

The Provincial Department of Mines has sent two reconnaissance parties into the Unuk River country, north of the better known section of Portland Canal District, this summer. They were organized by Geo. Clothier, resident engineer at Prince Rupert, B.C., and will work along lines laid down by him. Commenting on the geology of this section, Mr. Clothier, in his report for the year 1918, says:

"Bordering the main granite mass on either side is a broad belt of altered sedimentaries, with unaltered sedimentaries farther away from the contact, through which have intruded dykes of all kinds, spurs, isolated peaks and short ranges from the main granite batholith, throughout which are ore deposits of every description. This district includes the west contact-zone, from Bella Coola north to the mouth of Portland Inlet, on the southern boundary of the Alaskan strip. The east contact belt extends from the Zymoetz (Copper) river near Terrace on the Grand Trunk Pacific Railway, north to the Alaska-British Columbia boundary line. The coast range is penetrated to the eastern contact by the Skeena river, the Naas River, Portland Canal and Observatory Inlet and through the Alaska strip by the Unuk river, the Stikine river (with its principal tributary, the Iskut) and the Taku river, admitting of a lot of prospecting north of the Portland Canal. The value of the eastern contact has already been demonstrated by the

discovery of such properties as the Hidden Creek Mines of the Granby Consolidated at Anyox the Dolly Varden Mines and others in the Alice Arm country, the Bush, Big Missouri and others of the Salmon River section of Portland Canal; and the Engineer Mine in the Atlin District. It should be noted that, almost without exception, the ore bodies occur in greenstones or andesites, more or less altered where mineralized, and carry all the mineral bearing metallics, such as gold, gold-silver, silver-lead, gold-copper, copper and silver."

One of Mr. Clothier's parties, on reaching the Unuk River, will work in a southeasterly direction, eventually meeting the other explorers, who will go in by the Salmon River, over the divide to the Naas Slope, and northwesterly along the line of contact.

#### Alice Arm.

Major J. A. McLennan, of Vancouver, B.C., president of a company organized to develop certain Alice Arm mining property, on his return from the North stated that work on the Royal Group of Mineral Claims, adjacent to the Dolly Varden, was giving satisfactory results. He asserts that the lead of the latter mine has been found on the Royal Group, that it has been traced for 400 feet, that a tunnel has been started on the 600 foot level where the vein is well defined. Major McLennan also states that while there still is snow in the gulches the season may be said to have opened. Every train leaving Alice Arm is well filled with prospectors bound for different parts of the interior.

#### Trail, B.C.

For the half year there has been received at the Trail Smelter of the Canadian Consolidated Mining & Smelting Co. a total of 147,389 tons of ore and concentrates. Receipts for the closing nine days of the month of June were 8,755 tons and five properties were added to the list of shippers in that period, namely, the Mandy, Le Pas, Manitoba, the Lookout, of Skagway; the Loon Lake of Loon Lake, Wn.; the Maestro of Ainsworth; and the Stemwinder, of Fairview, B.C.

Fifty-two claims have been made by farmers against the Canadian Consolidated Mining & Smelting Co. for damages to crops as a result of the injurious effects of the fumes from the Trail Smelter. The allegations of those who seek compensation of the company are being investigated by Judge J. A. Forin and a party of advisers, with some legal and others with agricultural experience as their qualifications. Before setting out on a tour of the farms said to have been affected Judge Forin and party made an inspection of conditions in an adjacent valley outside the smoke area.

Lonis H. Biggar, a flotation engineer of Montreal, P.Q., claims to have developed a process for the treatment by preferential flotation of the silver-lead-zinc feed of the Standard Mine, Silverton, B.C. He now is engaged in the construction of a six-cell plant, which will be ready for operation in conjunction with the Standard Mill in two or three weeks. The process will be used first in the treatment of a 5,000 ton slime dump averaging 11 ounces silver, 3 per cent lead, and 7 per cent zinc, which was accumulated before the adoption of flotation at the Standard. As this material averages 50 per cent of 200 mesh the only way the silver and lead can be separated from the zinc is by a process of preferential or selective flotation.

With reference to his plans at the Standard Mine, Mr. Biggar is quoted as follows:

"The process has been successfully developed and the testing completed and the Standard Silver-Lead Company is now constructing a commercial sized machine, duplicating the laboratory machine, and it is hoped to operate the Mill, treating the slimes, within a few weeks.

"As the sump as been exposed for several years some of the lead has become severely weathered and oxidized and cannot be recovered by flotation. However, it is hoped to recover 50 per cent of the lead, carrying 60 to 70 per cent of the silver in a concentrate carrying only 10 to 15 per cent of the zinc. The remaining zinc also will be recovered in the usual manner, carrying the remaining silver and practically free of lead, as the oxidized lead that does not concentrate at first is carried through with the tailings.

"This process has been tried in the laboratory on several crude silver-lead ores with very successful results and it is also hoped to apply to these in due course."

There promises to be a representative attendance at the International Mining Convention to be held at Nelson, B.C., from the 20th to the 24th of July, inclusive. Governor Emmet D. Boyle, of Nevada, is reported to have accepted an invitation, as have also L. K. Armstrong American Institute of Engineers, Spokane, Wn.; M. J. Carrigan and Glenville A. Collins, Seattle, Wn.; and Hon. Wm. Sloan, provincial minister of mines, R. F. Green, member of Dominion Parliament for the Kootenay District.

#### Vancouver, B. C.

The Vancouver Chamber of Mines is engaged in assembling an exhibit of British Columbia ores that will be as far as possible, representative of the mineral wealth of the various mineral districts of the province. The display will be ready for the Vancouver Exhibition next September. It will be made a permanent exhibit, however, being transferred to the quarters of the Chamber of Mines later. The Boards of Trade of different sections, the different branch Prospectors' Associations, and the individual prospectors and mine operators are being communicated with to the end that their co-operation may be obtained.

R. W. Brock, Dean of the University of British Columbia, has taken a party into the Francois Lake country, southwest of the Bulkley Valley, on geological survey work. He expects to be in the field some two months.

#### KIND WORDS.

Those who were fortunate enough to attend the Canadian meeting of the American Institute of Chemical Engineers had the pleasure of seeing modern Canada teeming with ambition. The future city of Belleville may be taken as an example. There cannot be the slightest doubt that it will forge ahead, endowed as it is with creative citizens. Shawinigan Falls has accomplished most, and credit for it should not be of less pride to Canadians because they must share it with their neighbors the citizens of the States. For the very greatest heritages that are theirs also belong to these kinsmen of theirs to the south. The ownership of North America perhaps forms the greatest of all partnerships and the dividend of a greater language, a richer literature and a finer race of men shall be reared from North America, Inc. and Ltd. by the co-operating peoples who loyally love the Maple Leaf or American Eagle.—"Chemical and Metallurgical Engineering."

## THE NOVA SCOTIA COLLIERIES.

### Reported Transfers of Coal Properties.

Rumor is very busy with the coal properties in Inverness Co. The Inverness Coal and Railway Co. is said to have been purchased by Halifax interests, but no definite confirmation of this is available. Statements as to the sale of the Mabou property are also made, but nothing definite has transpired. There is of course no blinking the fact that the only hope for a profitable and permanent coal mining industry in Inverness County lies in the possibility that eventually the separate properties, developed and undeveloped, may be consolidated and come under the control of parties with large capital at their disposal.

A further unconfirmed newspaper statement reports the acquisition of the Loch Lomond coal areas by the Dominion Steel Corporation. The small synclinal outlier basin of the Sydney coalfield, while its tonnage content is not large, is understood to be underlain by seams of low sulphur coal, very suitable for metallurgical purposes, and, while the immediate operation of the coalfield is unlikely, it has some importance for future metallurgical requirements.

### Coal Outputs.

Coal production is showing a disposition to increase in the Province, and an appreciable tonnage is likely to be added by the operations of small mines during the year. The coal mined by Malcolm Beaton and partners at Port Hood, Inverness Co., the contribution of the New Campellton Colliery at the Little Bras d'Or Entrance, and neighboring operations by a newly formed company on the Stubbart Seam, near Point Aconi, together with the enlarged production of the Indian Cove Coal Co., near North Sydney—all these being in Cape Breton Island—will in their aggregate amount to a substantial addition to last year's figures.

The Lanark Engineering Co. in the New Glasgow district and the Greenwood Coal Co. at Thorburn will both show a satisfactory output increase this year.

Later figures indicate that the estimated production of all the collieries in Nova Scotia, which in our issue of June 25th was placed at 5,400,000 tons, may, if present production rates are maintained and no labor troubles intervene, reach between 5,500,000 and 5,600,000 long tons, closely approximating the production of 1917, but still  $1\frac{3}{4}$  million tons below pre-war production. The significant fact, however, is that production has now an upward trend for the first time in five years.

### First Benefits of the Dominion Scotia "Merger".

Now that the Dominion Steel Corporation's shareholders have ratified the recommendation of the directors to enter the British Empire Steel Corporation, it is of interest to note that quick enlargement of production is possible from certain collieries in the Sydney Field where the working faces have for some years been prevented from advancing into the abutting solid coal because of the intervention of lease lines. This enlargement of the output capacity of the existing collieries without the necessity for additional or important capital expenditure will be the first benefit arising from single management of the coal properties. Anything that enlarges the "pit-room" of the collieries is important, because the restriction on development is one of the most serious effects of the reduction in the number of miners that was a direct result of heavy enlistments during the war. There are a

number of instances where quick access to favorably situated coal areas are possible under single management and harmonious policies which were not possible when, as the President of Scotia recently stated, the coal companies were "working at cross purposes along individual lines." The most striking advantages of the consolidation which now seems quite assured will proceed from the co-ordination and undivided purpose which it will be possible to attach to the technical operations of coal mining in the Sydney field.

#### Coal Outputs of the "Besco" Companies.

A review of the coal production of the proposed constituent companies of "Besco", which follows, indicates a probable increase in tonnage outputs of 400,000 tons in 1920 over the figure of 1919.

#### Dominion Coal Company.

	First Half 1919	First Half 1920	Year 1919 (Actual)	Year 1920 (Estimated)
Glace Bay Collieries:	1,539,328	1,615,713	3,087,638	3,300,000
Springhill Collieries:	187,690	220,000	393,441	430,000

#### Nova Scotia Steel Co.

Sydney Mines:	244,655	315,329	552,044	625,000
Acadia Coal Co.	190,558	251,000	407,326	490,000
	<u>2,162,231</u>	<u>2,402,042</u>	<u>4,440,449</u>	<u>4,845,000</u>

During the week ending the 17th July, following a meeting of the shareholders of the Dominion Steel Corporation in Halifax on the 15th., when approval of the recommendation of the Board of Directors to enter the British Steel Corporation on the terms proposed by the promoters was given, a number of directors of the constituent companies and others interested have visited the coal and steel plants in Cape Breton. President Wolvin intimated that a statement regarding the new policies would be given out after inspection of the properties was complete.

At a Directors Meeting held in Sydney on July 17th., Mr. D. H. Mc. Dongall, President of the Nova Scotia Steel Co. and formerly General Manager of the Dominion Steel Corporation, and Dr. W. L. Mc. Dougald, President of the Ogdensburg Coal and Towing Co., and of the Century Coal Co. of Montreal, were elected directors of the Dominion Steel Corporation. Mr. Mc. Dongall's appointment as a director of the Company with which he has had such long and intimate connection coincided fortuitously and significantly with his resignation of the position of General Manager on the 17th July 1918. Mr. Mc. Dougald made the following statement to the newspapers following the meeting:

"My return to the Dominion Steel affairs, coinciding as it does with the date of my departure two years ago, is peculiarly gratifying and interesting to me. The association of the Scotia and Dominion companies together in addition is a development fraught with the greatest possibilities, not only to the Maritime Provinces, but also to the Dominion and the Empire at large. Working together instead of at cross purposes along individual lines, the possibilities ahead of us are invaluable. The British Empire Steel Corporation and its success with hereafter be our joint endeavor."

#### DOMINION COAL COMPANY ESTABLISHES DEPARTMENT OF INDUSTRIAL RELATIONS.

Mr. Angus W. Macdonald, employment agent of the Dominion Steel Corporation, has been appointed superintendent of Industrial Relations of the Dominion Coal Company. The new department will supervise and compile statistics in connection with accidents, health of workmen, housing, first-aid and accident prevention.

Mr. Macdonald is a life-long servant of the Dominion Steel and Coal Companies, and has a unique knowledge of employment conditions in the coal and steel plants and the ore and limestone mines and quarries. At the last meeting of the Mining Society of Nova Scotia, Mr. Macdonald read a brief, but extremely suggestive paper on labor turnover in industrial plants, which dealt with the high cost of hiring and "firing" men, and represented the crystallization of a lifetime of observation of this process, so fraught with happiness or disaster to those who are the involuntary pawns in the game.

As a fisher, both for men and trout and information, Mr. Macdonald has a well-deserved reputation for carefulness and patience and ultimate success, and there is most certainly ample scope for such activities as may be properly conceived to come under the newly created department in the widely extended operations of the Dominion Steel Corporation.

#### NOVA SCOTIA COAL AT COCHRANE, ONT.

"An all-rail shipment of 2,000 tons of Nova Scotia coal to a pulp mill 32 miles west of Cochrane on the National Transcontinental cost, including freight, about the same as Pennsylvania coal, plus duty, laid down at the same point. This apparently demonstrates that if the duty on bituminous coal remains, Nova Scotia coal can be shipped to southern Ontario at a profit even by rail, and much more advantageously by water."—*Toronto Globe*.

Presuming this shipment came to Quebec by water, it would give a total distance transported of roughly 1,125 miles, and if by rail, possibly 1,300 miles. The bituminous coalfields of Alberta are distant from Cochrane approximately 1,500 miles. The bituminous coalfields of the United States from which Ontario draws its fuel are from 700 to 800 miles distant from Cochrane, depending on the source of the coal. The distances are not so vastly divergent that Canada could not take her own coal pretty much where it was thought necessary in Canada, should it be regarded as proper national policy. The reason why United States coal can be cheaply transported to Southern Ontario, and the Head of the Lakes, is because coal is "stealing a ride," being largely an outward freight from the Pennsylvania fields for cars—which would otherwise travel empty—going north for Lake Superior iron ore.

Sir Robert Borden, in almost his last appearance as Premier, told the House that a committee of the Cabinet had the question under consideration. An adequate and permanent supply of fuel is of such vital consequence to Canada that the Government ought to adopt a broad and statesmanlike policy to assure it.—*Toronto Globe*.

## Toronto Notes

Mr. Frank C. Loreing, of Toronto, is homeward bound on the S.S. Megantie, after having enlisted English capital for development purposes in the Canadian north country.

A. J. Bone, superintendent of the smelter at Anyox, B.C., who recently has been at Sudbury assisting in the starting up of the British-American Nickel plant, was in Toronto last week, and is now in New York.

Shareholders of Poreupine, V.N.T., held a special meeting in Toronto on July 14, when an offer was received from Hamilton B. Wills and a syndicate for 600,000 shares of treasury stock. The offer is 15c per share for the first 200,000, to be taken at once, an option of 30c for another block of 200,000 shares, and 50c for the third block of the same quantity. This would bring \$30,000 for immediate working capital and another \$160,000 later on. As the control of the company is held in England, news of the offer was cabled. The Poreupine V.N.T. has a 100-ton mill, and is regarded as a good property. It is a consolidation of the Vipond and North Thompson properties, and is situated adjacent to the Hollinger and Poreupine Crown Mines.

Announcement was made at the annual meeting of the Davidson Consolidated Gold Mines, Ltd., in Toronto, on July 15th, that operations would be discontinued at the mine for the time being, pending plans for carrying them out on a much larger scale later on, when present plans for financing have been completed. It was stated by President G. C. Crean that in the absence in England of the managing director H. H. Sutherland, the affairs of the mine had been under the supervision of F. C. Sutherland. The managing director, he said, had been in England negotiating to provide money to make large scale operations at the mine possible. "At the present time," he said, "I am not in a position to make a definite statement regarding the matter. However, I may say that the success of these negotiations seems assured. I feel confident that if you will continue to be patient for a little while longer, everything will work to the best interests of all concerned."

It was stated by the President that during the ten months since the Davidson Consolidated took over the property and plant of the Davidson Gold Mines, Ltd., results from development work had been highly gratifying. It is now proposed to sink a large compartment shaft to cut the ore body at a depth of 1,000 feet, and to provide facilities for handling a large daily tonnage of ore for milling, as well as permitting the carrying out of mining operations at the minimum cost. The old board of directors were re-elected and Col. Robert Starke of Montreal, who joined the board recently, spoke briefly, stating that he was in entire accord with the policy of discontinuing operations for the present.

La Rose Mines, Limited, have entered an action at Osgoode Hall, Toronto, against the Mining Corporation of Canada, Limited, and the Cobalt Reduction Company, to recover damages for the alleged conversion by the defendants of tailings from the plaintiffs' ore deposited by the Northern Customs Concentrator on the bed of Cobalt Lake or on lands leased by the Cobalt Townsite Mining Company, Ltd., and the Northern Concentrator, Limited. The lease of the property

was subsequently acquired by one of the defendants, and is now owned by the other defendant. In the alternative the plaintiffs ask that they receive a proper proportion of the tailings deposited on these lands.

According to an Order-in-Council just passed by the Ontario Government, the Gillies timber limit, on the French River, will shortly be thrown open to the mining prospector. These limits were withdrawn from prospecting, but practically the whole area, with a reservation in the south, may now be entered by prospectors after July 20th. The lands are added to the Timiskaming mining division. Those lands still withheld by the Crown against prospecting include the right-of-way of the Cobalt Power Co., and the right-of-way of the Cobalt Hydraulic Company's transmission line, both 100 feet wide. The Crown also reserves land one chain deep along both banks of the French River. There has been a constant demand for the opening of the area and some members of Parliament from the north have brought the matter up in the House.

### PROHIBITION—SOCIAL REVOLUTIONIST.

While ours may not be a voice crying in a very arid wilderness, it shall once more be lifted to record what we believe to be an indisputable fact—that prohibition is responsible in greatest degree for the acute labor unrest and growing world hatred that permeates certain productive strata of society. We believe that mining men, above all others, will appreciate the truth of that statement. Explain it as the prohibitionists may, there is no manner of doubt that labor conditions have grown worse since the eighteenth amendment became the law of the land. And, what is worse, hatred, deep and indefinable, seems to actuate a great majority of those forced to earn their living by manual work.

We think that the experience of one mining operator, in this particular vicinity will illustrate our point. He has been the victim of extensive sabotage throughout all departments of his operations. New hose has been left to be shattered by the blast; tools have been thrown down abandoned stopes; a machine drill was dumped into an ore shoot to emerge two weeks later when the ore was drawn, and many other vicious, persistent and contemptible outrages have been committed. One man was caught in the act, after three weeks' on the payroll, and given his "time." He truculently admitted that he was to blame and asked if his employer wished to know why. He did. And the explanation was that all the avenues of enjoyment, or what he considers enjoyment, had been closed to the worker and that he now had no choice but to sit around killing time until he hates the world and himself. No fault was found with the scale of wages paid; in fact, miners are earning six and a half dollars a day in that particular mine, but the monotony of the daily grind, coupled with the elimination of what has hitherto been held as the prerogative of every man who pays his way, has led to bitter and unreasoning hatred of so-called upper classes, that to all appearances still find fair enjoyment in life.

To us it seems that the time has come to meet the situation fairly and squarely and quit indulgence in idle theories that call for enforcement of sumptuary laws interfering with man's right to live as he pleases. The present condition of unrest is the greatest question before the American people. The employment of

# SAFETY MINE CAGES

MADE TO FIT YOUR SHAFT

We build these Cages to suit you and your workmen. They are Safe, Strong, and Reliable.

- ☞ The top doors permit the carrying of long timbers, or the escape of the men in case of accident.
- ☞ The hand rails are properly placed to safeguard the passengers in the quick ascent or descent.

- ☞ We supply these cages with either one or two sets of doors for inlet or exit, to suit your shaft.
- ☞ Rails are also laid in the floor, if required, for convenience in handling the cars.

TORONTO, Ont.

force or the imprisonment of a few misguided leaders will not eradicate the trouble, in fact will but make it worse. Better by far to meet it with the same recognition of the fact that human nature cannot be made to conform to the ideals of the fanatic of any breed, even if recognition leads to restoration of privileges now banned upon the statute books. Regulate the liquor traffic if you will, and as severely as good reason indicates, but restore to the working man that which he desires. Give him a chance to enjoy himself as he sees fit, so long as he does not encroach upon the rights of others, and brush from the statute books laws that make criminals of thousands of good citizens. Then, and only then in our opinion, shall we be on the way to real solution of the problem of industrial unrest.—Northwest Mining Truth.

### STATE IRON AND STEEL WORKS IN QUEENSLAND, AUSTRALIA.

In connection with the State Iron and Steel Works which it is the intention of the Queensland Government to install at Bowen, a seaport town on the Eastern Coast of Australia, about 600 miles north of Brisbane, the General Manager Mr. J. W. Brophy, accompanied by the Engineer for Harbours and Rivers, and the Chief Inspector of Mines for Queensland, have left Brisbane on a tour of inspection of iron lodes in Western Australia, the option on which was secured by the Government a short time ago.

These deposits are situated on islands contiguous to Yampi Sound on the north west coast of Australia, are very extensive, and are described by the State Mining Engineer for Western Australia, as "the richest and most accessible of their kind in the World."

The grade of the ore is 69 per cent metallic and it is estimated that there are nearly 100 million tons available above Sea level; while the mining problem present no difficulties as the ore can be quarried by the inexpensive open cut method, and delivered from the bins direct on the ship, the lode running right into the sea, and thereby offering every facility for cheap and efficient handling and shipping.

The Queensland Government is considering the recommendation of Mr. Brophy, that they should purchase for this trade, two steamers of the Lake Superior type, this class of vessels being specially built and equipped for the carrying of iron ores, and possessing great tonnage capacities.

It is the intention to blend those with the Queensland ores of 57 per cent metallic, which it is considered will make excellent iron, and enable the Queensland State Works to successfully compete with any other Iron Works either in Australia or elsewhere.

### THE BASEMENT COMPLEX.

Modern children are precocious, and it is only natural that they should pick up words and phrases used by their elders. The seven-year-old daughter of an erst-while geologist, playing with a bedraggled but cherished kitten, was asked what her pet was called. "Well," she replied, with a pedantic air, "there is considerable divergence of opinion. Daddy calls her a segregation from an intrusive magma of doubtful genesis; mother refers to her as the basement complex; sister Bessie insists that she is a typical example of secondary impoverishment; but I just call her my dear little Kitty."—"Engineering and Mining Journal."

### IRON ORE.

By J. J. O'Connor.

A notable forward step in the direction of utilizing Canada's vast deposits of low grade iron ores, has been made in the results obtained by Prof. Alfred Stansfield of McGill University.

The announcement, just made, by The Honorary Advisory Council for Scientific and Industrial Research, Ottawa, that the task allotted to Prof. Stansfield of determining the best method to pursue in bringing these ores to merchantable grades, has resulted so satisfactorily, and at such small cost, that if they had available funds at their disposal, they would undertake a demonstration on a commercial scale.

James W. Moffat, M.E.I.C., Toronto, has been experimenting along the same lines for some years, and is said to have perfected an extremely simple and successful process, that offers great possibilities in the future of low-grade iron ores. Mr. Moffat has taken out patents in Canada, and various other countries, on both the processes and apparatus.

The announcement of the Advisory Council, coming as it does, from the highest scientific body in Canada, should be sufficient warrant for the Government to furnish the money necessary to carry out this most important investigation. In lieu of this, they should make the whole question of the utilization of our low-grade iron ores the subject of departmental investigation. They have the necessary machinery in the Mines Branch, if the matter be not left to the Advisory Council to carry out.

This question has been urged upon the government by representatives of the mineral and industrial interests, by deputations of Members of Parliament, representing all classes. All has been said, that very well can be said, in urging some form of government assistance in developing an iron industry in Canada. It is now time for action. The results obtained by Prof. Stansfield clears the decks for that action, and it should no longer be deferred.

The Government that had the courage to stop borrowing, impose luxury taxes, and pay its debts out of its own resources, so as to make Canada and Canadians self reliant, should have the courage to take one more step, and make Canada independent in the matter of iron ore.

Operations are now being carried out on the eastern Mesabi range, in Minnesota, by the Mesabi Iron Company, on ores similar to much of our own, where millions are being expended in erecting a plant, and constructing the town of Babbitt. The first unit of this plant will cost three million dollars, and have a capacity of 3000 to 4000 tons of magnetic ore daily. All of this is being done after the most careful investigation, and the expenditure of over half a million dollars in a testing plant at Duluth, under the supervision of experienced engineers. This operation, of itself, should be sufficient stimulus to the Government to, at least, make the question a subject of investigation.

In Minnesota, where the greatest known deposits of high-grade ores in the world, are being exploited, the iron operators are taking steps to meet the conditions that are bound to arise as their high-grade ores near exhaustion. Every season sees an increased amount of beneficial ores shipped from the Minnesota ranges, until now it runs into millions of tons annually.

Skilling's "Mining Review," an authority on Minnesota iron ores, has this to say regarding the low-

grade ores: "Non-merchantable iron ore of the Mesabi range is the greatest potential tonnage asset of the State. The fact is that the known deposits of merchantable ore compose but a fraction of the tonnage that will be shipped from the range, unless some short-sighted policy, such as a tonnage tax, makes its appearance to discourage capital and inventive genius from converting non-merchantable ores into merchantable ores."

There is no question in the minds of Minnesota operators, but that their lean ores can be profitably converted into commercial grades, if they are not taxed out of the market by faulty legislation. What is true of the Minnesota ores of low iron-content, is equally true of Ontario ores of similar character.

Therefore, in the light of Prof. Stansfield's determinations, the Government should take this matter in hand without unnecessary delay, should pursue it to a definite conclusion, and settle the question of its commercial feasibility.

#### GUIDE TO NORTHERN BRITISH COLUMBIA.

We have received a copy of the Northern British Columbia Index and Guide and City Directory of Prince Rupert, published by F. S. Wright of Prince Rupert. This compendium of information regarding Northern British Columbia is printed on paper of extraordinary strength made from British Columbia timber in northern mills, and is of interest and value to any person concerned with the mining industry of the Prince Rupert District, as it contains a list of mining properties and companies, together with information on Post Offices, Banking points, telegraph offices and settlements. Names and addresses of owners of properties are given, and those mines that are shipping ore are indicated.

The Guide states that Northern British Columbia contributed 96 per cent. of the placer gold, 40 per cent. of the lode gold, 28 per cent. of the silver and 47 per cent. of the copper mined in British Columbia in 1919.

For a town which twelve years ago was a wilderness of bush and scrub Prince Rupert is making wonderful progress.

(in good order), 60 to 66 A 10 Edison Cells Preferred; Maximum overall length not to exceed 136"; width, not to exceed 42"; height, not to exceed 46"; 30 and 35 lb. rail; 24" gauge; Maximum Curve 20 ft. radius. Reply:—Box 505 South Porcupine, Ont.

#### GILLIES LIMIT TO BE OPENED FOR STAKING July 20TH.

##### Postponment of Date of Opening Urged by our Correspondent.

Despatches this week which carry the information that the Ontario Government has passed an Order in Council which will throw the Gillies Limit open for prospecting on July 20th comes both with welcome and disappointment to prospectors throughout Northern Ontario. It has been known for some time that this matter has been under consideration, but it had generally been expected that at least thirty days notice would be given. The first intimation of definite action came on Saturday, July 17, only three days ahead of the date of opening.

Many prospectors throughout Northern Ontario have spent more or less time in The Gillies Limit so as to be well posted as to its merit and prepared to stake claims at such time as it might be thrown open. A large number of these men who are giving the best part of their lives towards exploring the mineral lands of Northern Ontario are at this season scattered far and wide over the vast stretches of virgin territory in Northern Ontario as well as in Northern Quebec and Northern Manitoba. These men may not learn for several days and possibly weeks of the Limit having been thrown open, and are thus denied an opportunity to share in any advantage arising from such a step. These men, in preference to all others, appear to be entitled to at least an even chance. Therefore, in view of the circumstances, it may still be found possible for the Ontario Government to rescind the date set and to extend it for another thirty days.

General satisfaction is expressed that the new Minister of Mines, Hon. H. Mills, has been able to announce success in arranging to have the Gillies Limit opened, and it is plainly obvious on every hand that great appreciation would be added provided the minister is able to correct the unfortunate circumstances of a hasty opening and perhaps defer the date until August 20th instead.

The Gillies Limit is a large strip of territory lying immediately adjacent to the silver-bearing area of Cobalt. Its opening is expected to result in much added exploration work, and offers promise of commercial deposits of silver being opened up.

# They Work Intelligently

## HARDINGE

### Conical Mills

*Large Balls Work Only on Coarse Material, Small Balls Grind to Finish*

Notice the shape of the Hardinge Mill—conical, big at the feed end, tapering towards the discharge.

By the natural action of the mill the largest, heaviest balls concentrate at the point of largest diameter where they have the maximum drop; the smaller ones collect towards the discharge. The coarse material entering first meets the big balls and, as it is reduced and passed through the mill, is ground by the smaller balls.

That is common sense and true efficiency. No working hit-or-miss, banging away with big balls at small stuff or tapping at coarse material with small balls but, exercising almost human intelligence, automatically adjusting the grinding media to the material. That is the secret of Hardinge Mills and the reason they have so rapidly become the standard crushing and grinding for all modern plants.

We will be glad to give definite facts and figures as to what Hardinge Mills can do on your work if you will mail us a sample of your ore and let us know quantities to be handled, sizes of primary crushers, finished product desired, etc. Write for "Grinding Data" and our general catalog.

## PEAT FUEL IN CANADA.

The opinion of Professor Purcell of Dublin University upon the promising nature of the work done at the Alfred peat bog near Ottawa is one that is heartening because it is delivered by an authority on peat utilization. Professor Purcell's researches on the peat bogs of Ireland considered as a source of fuel have been published by the Department of Scientific and Industrial Research of Great Britain.\*

Complaint has been made that the results obtained by the Peat Committee have not justified the time and money spent on experiments, and it is possible that one cause of this feeling is that too much, in too short a time, has been expected from the trials. The manner in which the problem of the commercial utilization of peat as a competitive fuel against the best coal in the world has been handled by the Peat Committee has excited the admiration of those who appreciate the technical difficulties, and it is has in particular called forth much commendation from workers on a similar problem in Great Britain.

Every peat bog is not a suitable source of peat-fuel. Writing in the "Journal of the American Peat Society," Mr. Herbert Garnett of Minneapolis assumes that fifty per cent of the failures of peat fuel projects can be traced to selections of unsuitable raw material, and he states that the knowledge required for successful peat technology includes such studies as botany, chemistry, geology and an intelligent understanding of the functions of mechanical maceration. Peat fuel is not an experiment today, provided the raw material is suitable. In 1919, in the United States, 76,301 tons of peat were sold valued at \$860,841, which is less by 31,000 tons than the quantity marketed in 1918, in which year the value exceeded one million dollars.

If, as it is reported, the Alfred Bog has produced 20,000 tons of fuel, that is 20,000 tons to the good for Canada. The chief importance of the production of this by no means negligible tonnage of fuel lies, however, in the experience that has been gained. Facts have been learned concerning the suitability of raw material, its chemical and botanical characteristics, its physical behavior under the maceration process, and other things, trivial in themselves, but all important

in their aggregate, that will many times repay any expenditure so far made.

It is not quite fair to quote Dr. Haanel's estimate of sixteen billion tons of coal-fuel equivalent in the peat bogs of Canada, unless it is qualified by particulars of the locality of the bogs, and the nature of their contents, but Dr. Haanel has most properly called attention to the tremendous potentialities of this fuel source, and no doubt his point of view—like that of all who urge greater development of our internal fuel resources—is that we can call nothing our own that we have not got in Canada.

We would suggest that if the Peat Committee had given more publicity to their trials and successes through the technical press it might have assisted in disseminating knowledge of a very justifiable expenditure of public monies, and of experiments that have much technical interest which the "Journal" would have been glad to have described in its columns.

While we believe that nothing that can be done in Canada in regard to the utilization of water-powers, peat-fuel, or lignite utilization can ever be more than palliations of a chronic fuel inadequacy in default of more intensive development of the bituminous coals of Nova Scotia, Alberta and British Columbia; yet every little helps, nor is any good likely to come of disparagement of any branch of fuel engineering. We need full development in Canada of every available and local source of heat and power, not forgetting the necessity for fuel economy, a vast and only partially explored field of endeavor. We recommend the attention of the university faculties of Canada to the opportunities that Canada offers to graduates in fuel engineering.

When the American Institute of Chemical Engineers was entertained in Ottawa a few weeks ago, each visitor was presented with a lignite briquette. We wonder how many of those present realized the historical significance of that gift?

## TRIPLE FATALITY USING OXYGEN BREATHING APPARATUS IN ABANDONED MINE.

Our British Columbia correspondent states that the Minister of Mines has instructed the Chief Inspector of Mines for British Columbia to follow any investigation that may be instituted into the death of three men using oxygen breathing apparatus who undertook to explore an abandoned mine filled with black damp situated in Washington State. The despatch from

\*See "Journal," July 9th, page 572.

Seattle reporting this occurrence stated that an inquest had not been considered necessary. In default of exact information regarding this disaster—for it is not less than that—it is not possible to comment, any more than to express the opinion that the occurrence should be investigated in every detail. The statement made that the cause of death was the lack of an adequate supply of oxygen in the apparatus is not in any sense an explanation. The mine is more likely to have contained carbon monoxide than the mixture of inert gases usually called "blackdamp." For the sake of the good repute of the oxygen breathing apparatus it is to be hoped that the United States Bureau of Mines will enquire into this most unfortunate accident, and give the widest publicity to its report thereon. Mr. Sloan has rightly apprehended the importance to coal miners of correct information on this unprecedented triple fatality connected with the use of oxygen breathing apparatus, and no man using these devices will be satisfied until he knows just how and why the fatal results were caused.

#### *RELATIVE SAFETY OF GAUZES FOR MINERS' LAMPS.*

Investigations by engineers of the United States Bureau of Mines, quoted in this issue, have shown that the greater the protection from air-currents given to the flame of the oil safety-lamp the greater the relative safety against ignition of inflammable mixtures of mine air. The double-gauze is to be preferred to the single gauze, and the bonneted lamp to the unbonneted. To Canadian readers an interesting suggestion is that the properties of monel-metal or nickel in lamp gauzes should be investigated. Steel wire was proved by the investigators to be preferable to brass or copper, but it has the objection of susceptibility to oxidation. Monel-metal or nickel having a higher melting point than steel, and not being subject to rusting even under severe conditions, would seem suitable materials, and would have unusual wearing qualities.

#### *RADIUM.*

In view of the possibility that radium-bearing ores may be found in the pre-Cambrian rocks of Canada in sufficient percentage to allow of commercial concentration, the article published in this issue and extracted from "Chemical Age," on "The Business of Radium" shows how very specialized is the new industry of obtaining radium in a concentrated form. If radium ores containing the necessary quantity of radium element are found in Canada presumably the concentrate would be sold to parties in the United States possessing the necessary equipment to produce radium of high purity.

#### *HARNESSING AUSTRALIA'S GREATEST RIVER*

The "Industrial Australian and Mining Standard" of June 17th, contains an illustrated supplement which gives an account of a little known undertaking, namely the control and efficient distribution of the waters of the Murray River, the result of which will be a vast addition to the area of land capable of irrigation; security and regularity of water supply, establishment of new settlements; increased production, and the securing of a permanent navigable channel along the River Murray Valley of over one thousand miles in length.

The work, which when completed will cost £7,000,000, and will, it is believed make available for agricultural purposes a territory capable of supporting 5,000,000 people, is under the direction of a Commission composed representatives of the Commonwealth Government, and the three States interested, namely New South Wales, Victoria and South Australia.

The steel, concrete aggregate materials, and stone used in the construction of the impounding reservoirs, irrigation conduits, weirs and dams, together with the modern machinery for excavating and handling materials which are in use have provided an outlet for the growing steel industry of Australia, and for the utilization of local sources of concrete materials and granite, which are plentifully distributed.

To those who think of Australia as a land of heat and periodical droughts, there is pleasant surprise in reading of the snow-covered mountains that supply the waters of the great Murray River, and to read, in the advertisement of the Victoria Government Tourist Bureau, of the attractions of skating, tobogganing, and skiing in the Australian Alps, and of the mountain scenery and trout streams of the Grampians.

The endeavor of a sister Dominion to obtain the most efficient use of its natural resources arouses sympathetic interest in Canada, where our water-powers, so different in their physical and climatic characteristics to those of Australia, have always been a source of great solicitude and have seen much development; and are destined to be still more efficiently utilized.

#### *COAL SHORTAGE AN OUTCOME OF DEFICIENT TRANSPORTATION.*

Now that the real reason for the inadequate supply of United States bituminous coal coming into Central Canada is admitted by everybody to be deficient transportation, it may not be amiss if we recall that this fact was brought out and emphasised in the symposium of papers on the fuel problem read before the Canadian Mining Institute at the Annual Meeting in Toronto almost five months ago.

Mr. M. A. McInnis of Montreal in his paper on "Coal Transportation" pointed out that, under ordinary conditions of traffic movement, the province of Quebec was not badly situated in regard to coal sup-

ply, having, because of its superior transportation facilities, which apply both to the U.S. rail connections and the water-route for Nova Scotia coal, only seasonal difficulties to contend with in coal transportation.

"Our greatest difficulty in importing coal," stated Mr. McInnes, "occurs at what is known as the 'Niagara Gateway. Canadian roads at this point are 'unable to accept freight at the speed and in the 'quantity offered by American roads. Ontario points 'must take more coal by water, and adequate unloading and storage facilities must be developed to allow 'this to be done.'" "Transportation," emphasized Mr. McInnis, "is the weak link in the chain." Other papers in this symposium, which dealt with coal production in Alberta, Saskatchewan and Nova Scotia, made the same point. Unfortunately, no discussion took place on the group of papers, and the publicity which it was hoped to give to the fuel supply question was not obtained. The desirability of full discussion and adequate publicity of the Institute's proceedings is now apparent, particularly when these touch upon matters of public policy.

While civil peace exists in North America there is not, nor can there be, any actual physical shortage of coal. The capacity of the bituminous coal mines of the United States and Canada has never been tested. Few who know the facts will dissent from the statement that if the collieries in the United States and in Canada worked to their full output capacity they could produce bituminous coal at the rate of one thousand million tons annually.

The Canadian Manufacturers' Association, some two years ago, appointed a standing Fuel Committee, primarily with the idea of fostering the production of coal in Canada, and educating the public to the necessity of lessening, as far as that may be found possible, Canada's dependence on the United States for bituminous coal supply. In this respect the C.M.A. has shown the way to the Canadian Institute of Mining & Metallurgy, a body not less interested in securing a less hazardous supply of a commodity without which neither mining nor metallurgy could be carried on. Is not the Institute a fit and proper body to advise the Government as to the best means to bring about stability in our coal supply? The suggestion is made that the Government of Canada would probably welcome counsel and aid from the Council of the Institute—as did the Government of the United States welcome assistance from a sister society under like circumstances—in regard to a problem that will bother our children as much, if not more, than it bothers this generation.

We believe the fuel problem presents to the Institute not only an obvious opportunity for usefulness, but a pressing patriotic duty. Following up a

previous suggestion, if it should be that the Government at Ottawa sees the necessity to establish a permanent body to work out a solution to the problem that is actually our chief national handicap, the co-operation of the committee of the Manufacturers' Association with a committee of the strength and ability that the Institute could produce should provide that multiplication of counsel in which wisdom is reputed to reside.

---

#### GRAPHITE IN CANADA.

Report No. 18, Graphite, its Properties, etc., by Fritz Cirkel, has long been out of print and there has been much enquiry for an authoritative publication on graphite occurrences in Canada which is now met by the publication by the Mines Branch of a monograph by Hugh S. Spence that deals with the history, occurrence, mining, concentration and uses of graphite, all with particular reference to Canadian resources.\*

The production of graphite in Canada in 1919 was, with the exception of 1911, the smallest recorded since 1909. Inasmuch as graphite was one of the "war minerals" this was to be expected, but considering the demand for the mineral, which to quote the export, "is employed in so many branches of industry that the supply can hardly meet the demand," if concentration methods can be devised to take full advantage of the comparatively high graphite content of Canadian ores, the industry should prove permanent. The Report states the opinion of prominent New York graphite importers, that Canadian crucible flake graphite in order to compete with the American graphite market when normal conditions are restored, will have to be produced at a price of about five cents per pound.

---

\*Graphite, by Hugh S. Spence, Mines Branch Report No. 511, 1920.

---

#### LIMITATIONS OF GOVERNMENT ASSISTANCE TO A MINING ENTERPRISE.

Tin-mining in Cornwall reaches back to the beginnings of British history, but recently the industry has fallen on evil days. By a process that is becoming natural and well-recognized in mining circles the suggestion has taken form that rehabilitation of the industry could be effected by consolidation of operation of the mines, which would enable modern machinery to be installed and economy in crushing and concentrating of the ores. The Board of Trade was asked whether, in the event of such a consolidation being undertaken, which would involve the raising of new capital, the British Government were prepared to assist by a loan.

The reply of the board of Trade is interesting as stating in clear terms the extent to which a government is justified in granting monetary assistance to

a mining industry, and is, in essential part, as follows:

"Though more economy in working costs might be secured by a scheme of amalgamation, it appears to be clearly established that the only possibility of the maintenance of some of the Cornish mines on a remunerative basis lies in the discovery of new lodes as the result of development work; but it has been definitely stated by those concerned that it is not possible for them to raise any of the capital necessary for such development. His Majesty's Government fully appreciate the difficulties in which the industry is placed and the unfortunate consequences which may follow the closing down of the mines, but, after carefully reviewing all the circumstances, in view of the present position of the national finance, the unwillingness of private enterprise to invest further capital in the undertakings in question and the uncertainty as to whether any development work is likely to place the industry on a permanently sound basis, His Majesty's Government regret that they do not see their way to ask this House to vote financial assistance in this case."

It does not necessarily follow, however, that the refusal of government aid will mean the closing of those tin mines that possess intrinsic value.

### BOOK REVIEW.

**MINES AND THE SPECULATIVE INVESTOR.** J. A. Gallard. Publisher, Walter R. Skinner, 11-12 Clements Lane, London (Eng.). Price 7s 6d, 63 pp. Linen Boards.

This little book is the collection of a series of articles which originally appeared in the "Financial Times" of London from the pen of Mr. Gallard, the Mining Editor of that paper for seventeen years, and is intended as a guide to the mining share markets for the non-technical investors.

Mr. Gallard notes that recent years have seen a considerable addition to the ranks of those who participate in Stock Exchange operations with the object of increasing their capital. The reason for this development on a scale in excess of ordinary appears to lie in the increase in the taxation of incomes. Whereas in years gone by many people were content to invest their capital to yield them an income from dividends, the tendency of late has been to purchase shares in the hope of capital appreciation rather than for dividends since the former is not taxable.

The book has been prepared with the laudable object of elucidating the salient features of mining operations and methods of mining finance for the benefit of those "who being neither mining engineers nor mining financiers, have, so to write, only a casual acquaintance with mines and mining companies."

"Almost invariably" states the author, "mining share operators—at any rate among the public—are optimists, and many of them seem to have accentuated imaginative faculties; otherwise it would be difficult

to account for the values placed on some shares from time to time. 'While there's life there's hope' is evidently a favorite motto of the speculative investor in mines." Mr. Gallard is to be congratulated on his restraint.

The scope of the book is indicated by the chapter heads, which include such subjects as "Prospects and Mines," "Factors in Valuing Mines," "Ore Reserves," "The Life of a Mine," etc.

The chapter on "Engineers' Reports" includes a quotation from Mr. Walter McDermott regarding "old friends we meet in numberless reports, which seem to need a little protection against excessive wear and tear," to wit.

- a. A true fissure vein
- b. Increasing width in depth
- c. Increasing richness as depth is attained
- d. Junction of veins
- e. Ore in sight
- f. Proximity to a rich mine
- g. Failure from mismanagement

Mr. McDermott's penetrating comment on the correct and incorrect use of these familiar phrases is good reading.

Mr. Gallard pleads for more publicity of the affairs of mining companies, and with regard to periodical reports and statistics, correctly assumes that "if statistics are not provided the shareholders will know the administration is not anxious to be closely examined."

The author has had twenty years' experience of the journalistic side of mining and connection with the Stock Exchange, and his conclusions appear to be that the chief hindrance to mining investment and reputable mine promotion is lack of accurate publicity, a great part of which he attributes to the apathy of shareholders.

The opinions expressed with regard to the profitability of re-opening old mines, the usefulness of finance and exploration companies, and the good results of amalgamation and reconstructions, are not enthusiastically favorable.

### BRITISH FUEL ENGINEER FAVORABLY IMPRESSED BY ALFRED PEAT BOG.

Professor Pierce F. Purcell of Dublin University, says that the Alfred peat bog near Ottawa gives the greatest promise of commercial success of any plant he has ever seen. The enterprise is at present in the experimental stage. - Up to the end of 1919 the scheme had cost about \$110,000, the expenses being equally borne by the Dominion and Provincial Governments. Last year twenty thousand tons of peat were turned out, finding a ready sale in Montreal and Ottawa. The price in the latter city is \$6 per ton.

### PERSONAL.

Mr. H. Mortimer Lamb, the Secretary-Emeritus of the Institute, is fruit-farming at Burnaby Lake, near Vancouver City, and is much benefited in health by outdoor occupation. Mr. Lamb has recently been appointed Secretary of the British Columbia Division of the Institute, taking the place of Mr. Charles Cam-sell, the Deputy Minister of Mines, now resident in Ottawa. Mr. Lamb is still, as always, interested in advancing the welfare of the Institute and increasing its activities.

# Relative Safety of Gauzes for Miners Lamps

*Requirements of the United States Bureau of Mines Covering Flame Safety Lamp Gauzes—Description of Test of Steel, Brass and Copper Fabrics—Steel is Superior for High Temperatures—Comparative Efficiency of Various Lamps.*

Flame safety lamps have been used for about one hundred years in coal mines where a dangerous accumulation of explosive mine gas (methane) might occur, and thus render the use of ordinary unprotected flame lamps dangerous. Flame safety lamps are not only used for illumination, but also for detecting the presence of dangerous percentages of methane mixed in the air of the mine.

The safety of the lamp depends chiefly upon the cooling qualities of the wire gauze used to permit free circulation of the air through the lamp. If one enters a part of the mine where methane is present in the air, the methane enters the lamp and, coming in contact with the wick flame, is ignited, and continues to burn within the gauze without igniting the methane surrounding the lamp. If the air within the mine is travelling at a velocity of several hundred feet per minute the burning gases may be driven through the gauze by the air current. If the gauzes are properly designed and of the proper material these burning gases will be so cooled as they pass through the gauze that they will not cause an ignition of the gas surrounding the lamp. In order to test the effectiveness of a given safety lamp, tests are made in moving explosive mixtures of gas and air arranged to simulate mine conditions.

The Bureau of Mines investigated many features relative to the safety of flame lamps, and in 1915 established an official schedule known as "Schedule 7," whereby flame lamps having certain prescribed qualifications would be approved as permissible for use in gaseous mines.

Among the schedule regulations are the following requirements covering flame safety lamp gauzes:

"The lamps must be provided with double gauzes or with some other adequate arrangement serving the same purpose. Every gauze must be of steel or best charcoal annealed iron wire of not larger than 27 Brown and Sharpe gauge (0.014 inch in diameter), with 28 meshes to the lineal inch (784 to the square inch), nor less than 29 Brown and Sharpe gauge (0.0125 inch in diameter), with 29 meshes to the lineal inch (841 to the square inch)."

Frequently the use of brass or copper as a flame lamp gauze fabric was advocated, and one company thinking that the kind of material had no bearing on safety, without notifying the Bureau, substituted brass for steel in lamps stamped with the Bureau's approval.

The gauze specifications outlined above, relative to material and construction, were, in the main, based upon European experience and practice and upon reports of European investigations.

The purpose of the investigation herein reported was to conduct a limited number of check tests in order to determine to what extent European result should apply to American types of flame lamps and, conse-

quently, whether or not the present gauze specifications of Schedule 7, needed revision.

The selection of gauzes for the tests included steel, brass and copper. Steel is used quite widely in the American type of flame safety lamps, used in general service, brass has been used to some extent for lamps designed for the use of officials and inspectors, and copper has been used by surveyors because of its non-magnetic properties.

The tests chiefly involved the subjecting of the lamp, equipped with one of the several gauze materials under investigation, to currents of explosive gas and air moving in a horizontal direction, the lamp being suspended in the path of the air mixture. The lowest probable velocity at which an explosion would result was ascertained for each gauze material. This data was secured with respect to the several types of lamps and with respect to different percentages of gas in the air mixture. Tests were likewise made using the same gauze in successive trials to determine the effect of oxidation as affecting the safety of a given gauze material. Physical measurements were made to check the dimensions of the gauze material used, and measurements were made of some of the gauzes before and after tests to determine the change in physical condition due to oxidation. The tabulated results of the tests can be obtained on application to the U.S. Bureau of Mines.

The behaviour of the different gauze fabrics has, in a general way, checked the results obtained by foreign investigators. When the differences in the materials tested, together with possible differences in the test conditions are considered it is remarkable that these results, in so many cases, follow so closely the conclusions of European investigators.

For conditions of high temperature, steel proved superior to either brass or copper. For low temperatures, the advantage of steel over brass or copper is small. Brass or copper might be preferred by some, although one who knows the insecurity of such gauzes at high temperature might be unwilling to trust them even though the probability of high temperatures was remote.

Brass proved more satisfactory than copper. However, it should be remembered that the brass gauzes tested were of a good quality material, having a high proportion of copper and, therefore, may have given much better results than would have been obtained with some other brass.

In concluding the tests on the gauze fabrics under various possible conditions of service, there were certain points brought out very forcibly with respect to the comparative safety of different types of lamps. The least safe of all the lamps tested is the single gauze unbonneted lamp of the Davy type. In fact when compared with a bonneted lamp of modern design it should not be classified as a safety lamp. The condemnation of the Davy lamp as a safety device for present day conditions does not belittle the great work done by Davy. On the other hand almost every modern lamp uses for its protection principles advocated by Davy.

\*By L. C. Isley (Electrical Engineer, Bureau of Mines), and A. B. Hooker (Junior Electrical Engineer, Bureau of Mines).

The double gauze unbonneted lamp is somewhat safer than a single gauze lamp, but not dependable in high velocity air mixtures.

The single gauze bonneted lamp proved safer than either type of unbonneted lamp, the omission of a gauze being more than offset by the bonnet.

The safest lamp tested was the double gauze bonneted lamp. In such lamps there is the protective features of the single gauze bonneted lamp, with an additional safety or another gauze in case either gauze of a pair should become damaged in any way. (Although in this investigation the Hailwood combustion-tube type of lamp was not tested, previous tests by the Bureau have shown it to be equally safe as compared with a double gauze bonneted lamp of the Koehler type).

One object of the investigation was to determine whether the gauze specifications of Schedule 7 needed revision. The results indicated that present specifications, while perhaps not sufficiently detailed, were laid on a sound foundation and a lamp meeting these requirements would have a high standard of safety. It may later be deemed best to permit the use of brass gauze in bonneted lamps, but until the subject is investigated further that schedule lamps only should be admitted as permissible for use in gaseous mines could well be added as a step toward greater safety.

The possibility of using monel-metal or nickel for flame gauze has been suggested, since these materials have a higher melting point than steel, have about the same heat conductivity and resist oxidation at atmospheric and high temperatures. Whenever time permits these materials should be investigated.

#### SOME SOURCES OF HELIUM IN THE BRITISH EMPIRE

Early in 1915, Dr. J. C. McLennan, head of the Department of Physics in Toronto University, was requested by the Board of Invention and Research, London, to investigate the helium content of the various natural gas supplies within the Empire, it having been suggested that if a sufficient supply of helium gas could be obtained it would prove more suitable than hydrogen for use in lighter-than-air flying machines, owing to its inert character. The British Admiralty has authorized Dr. McLennan to make public his investigations, and the manuscript being offered by him to the Mines Branch for publication, on the recommendation of Dr. A. W. G. Wilson, the engineer in charge of investigation of chemical industries it has been published as Bulletin No. 31 (publication number 522). The Bulletin has several sections, the larger one dealing with the helium content of the natural gases of Canada. Section 2 is devoted to determinations of the radio-activity of the natural gases of Canada, and other sections deal with helium contents of natural gases from New Zealand, from various localities in England and with a gas from Pisa, Italy.

Dr. McLennan's investigations, which involved some new departures in physics, and the designing of new apparatus, have demonstrated that the natural gas from the Bow Island district of Alberta contained the highest percentage of helium observed in any of the natural gas samples tested, and these included every known source in Canada, and in addition the outside localities previously mentioned.

The possible uses of helium are only just commencing to be discovered, but in addition to its use in

aeronautics, it is suggested for use in gas-filled incandescent lamps and gas arc-lamps.

Dr. McLennan in his preface states:—"The solution of the problem of producing helium in large quantities was, before the beginning of the war, one which would have been considered by many visionary and chimerical, but through the enthusiastic support and financial aid received from the British Admiralty, and from the Bureau of Mines and Naval and Air Boards, Washington, the possibility of production on a large scale has been realized."

Incidentally, the Report is an excellent survey of the gas wells of Canada, and is fully illustrated by maps showing the petroleum and gas wells, and pipe lines established in producing districts.

Dr. McLennan's Report records a distinct scientific achievement, with very practical results in application. The prominent part taken in the investigation by Canadian workers is a matter for legitimate pride, and from this standpoint, as well as because the investigation has established the existence and availability of an entirely new natural resource in Canada, the Mines Branch has done well to give the Report to the public.

#### EXPLORING FOR RADIUM ORE IN BUTT TOWNSHIP

Last summer the announcement that pitchblende, an important ore of radium, had been discovered in Butt township, Ontario, caused a number of prospectors to visit the area. Several claims were staked, but comparatively little work was done on these claims because the most promising discoveries were still undeveloped. A number of the claim owners did some exploring work, but most of them have been unable to raise funds to thoroughly test the properties.

There being so little information available to prospectors for radium, it is not surprising that they are anxiously waiting for the results obtained when the known deposits are opened up. It is stated that some of the claims are now being thoroughly explored. If good results are obtained in developing one deposit, there should soon follow vigorous prospecting throughout the area.

The formations in which the pitchblende occurs in Butt township are not of a type that the Northern Ontario prospector regards highly. The rocks are granite and diorite gneisses. The pitchblende occurs in dykes of coarse pegmatite that cut the gneiss. Prospectors for precious metals in Ontario have had little cause to value highly such pegmatite dykes. In Eastern Ontario some such dykes yield feldspar or mica in commercial quantities, but the Northern Ontario prospectors cannot be expected to do much work on such dykes until one of them is proven to contain appreciable quantities of precious minerals. It is to be hoped that the results of development of the Butt pitchblende deposits will be satisfactory for it is very likely that there are many such deposits in Ontario.—R.E.H.

The Kingston Smelting and Refining Company, Limited, has been granted incorporation by the Ontario Government with power to lease or purchase mines and to engage in a general mining and smelting business. Among the incorporators are Alexander MacKinnon of Kingston and E. D. Chaplin, J. M. Israel, J. P. Aguayo and V. S. Gavito of New York. The authorized capital is \$200,000.

# The Business of Radium

By HAMILTON FOLEY,  
Standard Chemical Co., Pittsburgh, Pa.  
(From "Chemical Age.")

The United States is the foremost radium producing country in the world. This ascendancy has been gained notwithstanding that five hundred tons of American ore is required to produce the one gram of radium that has been obtained from five or six tons of European ore. A gram is about a thimbleful.

The recovery is made with regularity and precision. In the different steps in the process and in even the most general statement of the difficulties that have to be overcome, there is a new chapter of American contribution to chemical progress. There is also much to show why the market price of radium is \$120,000 a gram.

The radium ore fields of the United States are in the southwestern part of Colorado and south-eastern Utah. They cover a territory of about eight hundred square miles. This district is about sixty-five miles from any railroad and so mountainous that in many places there is a rise or fall in the local trails of two thousand feet in a mile.

Prior to the World War carnotite ores from these Colorado deposits were shipped abroad for French and German production of radium on a small scale. The embargoes on shipping stopped this export completely, although it had been falling off in quantity.

The recovery of radium in this country, as a commercial proposition, began in 1911, when the Standard Chemical Company, of Pittsburgh, was organized by Joseph M. Flannery, for the express purpose of mining carnotite ores and producing radium. Up to the present time it has produced almost one-half of the estimated supply of radium in existence.

## *Transport of Radium Ore.*

The infinitesimal radium content of the ore, making necessary the handling of enormous volume and weight of ore, the remoteness of the deposits from civilization and the long freight haul from Colorado to Pittsburgh, enforced efficiency methods to a high degree. Pack animals transport the hand-sorted ore in 100 lb. bags from the various chains to the concentrator. Here high grade ore is separated from ore of quality uneconomical to remove as such from the ore district. Milling reduces 500 tons of the hand-sorted ore to 125 tons in a pulverized condition, containing about 4 per cent of uranium oxide. The concentrate in 100-lb bags is transported by wagon, train or motor truck 65 miles to a railroad at Placerville, Colo.; thence 2,500 miles to Canonsburg, Pa., near Pittsburgh, where the Standard Chemical Co. operates a reduction plant for the recovery of the radium, uranium and vanadium.

The vanadium finds a ready sale as an alloy for high speed tool steel and the experimental work being done with it as an alloy for use in other classes of steel suggests that it may be more generally adopted.

## *Reduction.*

The chemical treatment of carnotite concentrates at Canonsburg, involves greater difficulties than the collection and first concentration of the ore. In part these difficulties inhere in the treatment of an exceedingly finely divided material; in greater part, they

involve working out efficient processes for the recovery of a material present in so small a proportion as one part in a hundred million, this being, approximately, the concentration of the radium in these concentrates. As they are further reduced chemically these concentrates yield what is called "raw sulphate." This consists, essentially, of silica together with sulphate of radium, barium, calcium, iron and aluminum. After freeing this mass from impurities and transforming to a soluble salt, there is obtained a soluble radium chloride.

## *Plant Control.*

The reduction plant keeps trace of the minute modicum of radium in the ore in process of reduction by the application of the most refined scientific measurements known. These measurements make it possible to know just where and in what quantity the radium is at all stages of the work. Remembering that when it reaches the reduction plant there is only one portion of radium for very hundred million portions of ore and that if this small quantity is not watched for very closely it may be lost and with it all the expense that has attended the shipment of five ear loads of ore all the way across the continent, the details by which it is followed may not be without interest. Every day the reduction plant sends to the laboratory at Pittsburgh, samples of each batch of ore it is proposed to handle for the first time that day, samples of each batch of ore in each stage of the reduction process and samples of each batch of residue it is proposed to discard. Chemists reduce these to solution. If there be any radium in any or all of these solutions it will generate the gas known as radium emanation. Inasmuch as this emanation emits the rays emitted from radium and as these rays carry electrical energy, each sample in turn is placed in an electroscope so the electrical energy it may liberate may be ascertained.

The electrical energy from equal quantities of radium is always the same by comparison, therefore, of the electrical energy obtained from any one of these samples with that obtained from a known quantity of radium, it is a matter of accurate calculation to know the quantity of radium in the batch of ore represented by the sample.

While scientifically trained minds know that the emanation from a gram of radium is not larger in volume than the head of a pin, it may surprise some readers to know that the measurements described detects with extreme accuracy quantities of radium as small as a billionth of a gram, or one five hundred millionth of a pound avoirdupois; and that such extremely minute measurements are made not once, but sometimes twenty and even thirty times a day in the laboratory of the Standard Chemical Company.

## *Radium Products.*

In the form of radium barium chloride the one-half ton of concentrates that is left after the Canonsburg reduction plant has eliminated the rest of each mass of five hundred tons of ore, is brought to the laboratory at Pittsburgh. Here by successive fractional crystallizations of the radium chloride, and at a later stage, of the bromide, most of the radium is obtained in a salt containing over 90 per cent of pure radium

bromide. A second or smaller amount of radium in the form of a salt of five to ten per cent purity is also obtained. By further chemical treatment the bromide is converted into the sulphate or the chloride and in the therapeutic use of radium these two salts find the largest use. The lower grade material, because of greater ease in handling and weighing out small portions with a definite radium content, finds use in the commercial world in the manufacture of the radium luminous compound more popularly known as luminous paint.

#### *Volume of Production.*

The first radium obtained in the United States was obtained in 1913 in the laboratory of the Standard Chemical Company. Since then the production of this company has been as follows:

	Grams (Radium Element)
1913.....	2.1
1914.....	9.6
1915.....	1.7
1916.....	5.0
1917.....	7.0
1918.....	13.6
1919.....	11.8
Total.....	50.8

Writing of the production of radium by this company, a scientific writer has recorded the opinion that:

"In the midst of industries whose output is measured in thousands or millions of tons, an industry whose total output in nearly five years is about one ounce, is likely to seem small, yet this production of radium by the Standard Chemical Company of Pittsburgh is the most notable in the world. This is more than a third of the estimated stock of the world's high purity radium, and to the efforts of this one company belongs the credit of starting and so establishing the manufacture of radium from low grade ore so that the medical and scientific professions may count upon an ever increasing supply."

In the ore fields the Standard Chemical Company maintains a force of several hundred men. Nearly as many are required at the plant at Canonsburg. In the laboratory at Pittsburgh there is another large staff. The activity of all of these men is necessary to make it possible for the radium in any quantity of ore to be obtained about three months from the time the ore was first mined.

#### *Radium Standards.*

Radium preparations in the United States are spoken of and measured in terms of radium element. Until recently European scientific men have adhered to the term radium bromide. Crystalline radium bromide when pure contains only 53.6 per cent of radium element. This fact and the method of measurement of radium preparations in Europe prior to the adoption of an international radium standard, had not a little to do with the earlier unsatisfactory work with radium. There was no common standard. The original method of measuring radium, consisted in comparing its activity with that of uranium. During the fourteen years this system of measurement prevailed scientific men spoke of radium as "two million times more active than uranium." Trained minds, of course, understood that what was meant was that the quantity of electrical energy emitted in the rays of the radium, small though it was, was two million times greater than that contained in the rays from uranium.

Such a ratio of comparison was entirely unsuitable for use especially with small quantities, and about 1912, by common consent, Madame Curie was asked to prepare what would be an international radium standard. This is deposited at Paris. Duplicates are in the leading capitals of the world, and radium preparations are now measured by comparing the electrical energy carried by the gamma rays from the preparation to be measured with the energy carried by the gamma rays of the international standard, or one of the certified duplicates of it. In 1914, the United States Bureau of Standards at Washington obtained a certified duplicate of the international radium standard and practically all quantities of radium in this country have been measured by comparison with it.

#### *Uses of Radium.*

In the industrial world interest in radium has always been limited by the small amount available. This was especially true of the ten years following its discovery. During that period some attempt was made to use the action of radium in causing a spontaneous and continuing luminescence in substances such as zinc sulphide, to make what is called luminous paint. In the United States attempts were also made to manufacture a similar product, but prior to 1913 this effort was practically negligible.

Radium and radium minerals are not generally luminescent. Tubes containing radium glow from impurities present which the radiations from the radium cause to give light. The World War created a most unexpected demand for radium. The necessity of illumination that would not betray presence to the enemy in the various branches of the fighting service made radium luminous material the most satisfactory and dependable light. The demand for the luminous watch dial alone raised one use for this material to a fair-sized industry.

#### *Radium Therapy.*

Therapeutically, there has been a gradual and steady increase in the use of radium since 1912. With this increased demand the production of radium has kept pace. The earlier over-enthusiastic statements of the value of radium in the treatment of cancer have not been wholly confirmed and radium is far from being the panacea in the treatment of diseases. Nevertheless the use of radium in certain types of advanced inoperable cancer gives palliation by the relief of pain and freeing from foul smelling discharges. This degree of palliation can be attained by no other treatment and, if used for this purpose alone, radium would be considered invaluable. In other types of cancerous growths radium has produced cures and surgeons throughout the world are gradually admitting that radium is a necessary adjunct in the treatment of cancer, giving in some cases more satisfactory results than any other treatment.

### **TAR SANDS RESERVED ALONG ATHABASCA RIVER.**

An Order-in-Council reserves the lands along the Athabasca containing the tar sand from sale, settlement or other disposal, the Order being based upon a recommendation made by Mr. Meighen when he was Minister of the Interior.

The Government's action is taken to indicate that some means of utilising the tar sands has been worked out, or that a solution of the problem of concentration is in prospect.

### REVIVED INTEREST IN COAL MINING IN INVERNESS CO., CAPE BRETON

A revival of interest in coal mining in Inverness County is being brought about by the heavy demand for coal and the high selling prices obtainable at this time.

Inverness County has for a good many years been slipping backwards in coal production, and it is a part of the Nova Scotia coalfields that more than any other has suffered from imaginative promoters, unwarranted capital investments and unskilful management. Much more money has been sunk in coal mining in Inverness County than has ever been recouped.

About ten years ago there were three companies working in the county, namely, the Inverness Coal & Railway Co., the Port Hood & Richmond Coal Co. and the Mabou Company. The Mabou Colliery was flooded in 1909 because an opening was made in the seam at a point where only 110 feet of strata intervened between the roof of the seam and the bottom of the sea. The strata was moreover not of a character to warrant the opening, even with a much thicker cover. The flooding of the Mabou mine was distinctly the result of poor judgment.

The Port Hood Colliery was flooded in 1911, the water entering at a point where pillars were being drawn in the lowest level, the solid cover intervening between the roof and the sea bottom being 942 feet. The inrush in its initial stages is estimated to have amounted to 3,000 gallons of water per minute. The water is salt, and there is a small daily rise and fall of the water in the time corresponding to a delayed reflex of the tidal action along the shore line. The connection with the sea is admitted, but the nature of the connection has always been a matter of debate and remains undetermined.

For some time, Messrs. Malcolm Beaton and associates have been mining coal from the Port Hood seam in a rise area above sea-level, and it is now reported that an attempt will be made to pump out the flooded mine. There is reason to believe that with pumps of large capacity the mine may be unwatered, or, in other words, the presumption of success is sufficient to warrant the attempt, if the financial arrangements can be made. The writer has never been able to credit the possibility of a vertical break 942 feet in depth communicating directly with the sea, or that such a break could occur from the extraction of a seven-foot seam of coal. The delayed reflex action of the tides on the water in the mine indicates that the point of initial entrance of the sea-water lies between high and low-water mark, and would also appear to indicate that the channel of entrance was a restricted one. The level above the one that was first flooded was very extensively robbed of its pillars, so much so as to raise the presumption of a "crush" and a shattered condition of the roof above. The stratification of the coal seam and the accompanying shale is inclined seawards, and the bedding planes of the strata lying immediately above the coal seam crop successively between high and low water mark along the shore. It is reasonable to presume a percolation of water along all the outcropping bedding planes, and the accumulation of a considerable body of water in the crushed area. When the pillar was drawn at a point which was approximately the lowest in the mine, this body of water continued downwards along the lines of stratification and under much pressure due to its head, broke through the weakened roof rapidly inun-

dating the mine, which was not provided with any water lodgment and had small pumps with a capacity of only 110 gallons per minute. It was not proved that the inundation was uncontrollable, and, writing solely from a technical standpoint without regard to financial questions, it has not been proved that the mine cannot be unwatered.

From a financial point of view, it is doubtful whether any large expenditure on pumping is warranted, and probably a new submarine winning in solid coal, leaving a barrier against the flooded workings, may some day be undertaken.

The Inverness Colliery has for some time been operated under conditions of much physical difficulty, and, in view of the financial condition of the company, which was for years in the hands of the bondholders, much credit must be given to the ex-General Manager, Mr. John Macgillivray, for keeping the property in operation through some very trying years. With new management, relieved of some of the heavy interest charges that were formerly carried, the property may do well so long as selling prices and demand remain good.

There are important undeveloped inland coal seams in Inverness County, and it is understood there is a possibility of a consolidation of these with properties already operating.

The same reasons that forced a consolidation of the independent companies in the Sydney coalfield exist in favor of a complete consolidation of the Inverness County companies, where, because of physical conditions, the costs of coal production must always be relatively higher than they are in the Sydney field. The chief market of the Inverness coals is the domestic trade of the Maritime Provinces, in particular of Prince Edward Island, a purpose for which the coal is better suited than for metallurgical uses.—F.W.G.

### COAL MINERS' WAGES IN NOVA SCOTIA.

The Royal Commission appointed to investigate wages and working conditions in the coal mines of Nova Scotia is taking evidence.

The demands of the miners were presented to the Commission at its opening session in Glace Bay on July 21st. Their far-reaching character may be gathered from the following summarised list.

*Closed Shop Conditions Asked.*—Under the term "self-determination" the men ask for a drastic form of the "closed shop," the clause reading: "That each local union shall have complete jurisdiction in union matters over the mine or plant where its members are employed, and may determine by the vote of its members at any of its regular meetings whether any new employee shall become a member of the union." A recent strike was called to force non-union men to join, so that refusal of the union to allow a new employee to join is equivalent to selection of workmen. The union asks that this right of "self-determination" shall not be abridged by any official of the employing company.

*Working Conditions.*—Better distribution of miners' tools, better air-pressure, abolition of "pushing," or manual movement of mine cars are asked. Four rooms to each machine cutter, and not more than two miners in each working place are demanded. The employer is asked to bear all onus of machinery breakdowns and accidents preventing work. Any man reporting for work, and not receiving work that day is to be compensated. If pit stops before 11 a.m. all day-paid

men are to be paid a half shift, and if pit runs till 12.30 before stopping, day-paid men to receive a full shift. Penalizing extra rates are asked for all night-work, and extra tonnage rates are asked for double-shifted places. Riding rakes are asked to be placed in operation in all collieries after twelve o'clock each day, so that men who finish early, that is after five hours' work, can go out of the mine. A maximum of 25 feet for shovelling down coal in a working place is asked. Time and a half for overtime and double time for Sundays and holidays is asked. \$6.00 per day is asked for new work, pending the agreement upon a tonnage rate, and men doing company work in default of ability to obtain a helper are to be paid \$5.50 per day.

*Increased Wages.*—One dollar flat increase for all day-paid men, and 24 cents per ton increase on existing tonnage rates is asked. Yardage rates, dead-work and timbering rates to be increased 25 per cent. Where through a shortage of men, two men do the work of three, it is asked that time and a half be paid.

This is probably the most drastic demand ever presented to the coal operators in Nova Scotia. The wage increases asked are not so important as the alterations asked in working conditions, particularly those clauses of the demands intended to prevent double-shifting of the mine and night work, and the other clauses limiting the number of men in a working place, and asking for four rooms for each machine cutter. These demands, in actual practice, involve an enlargement of the number of working places, or expansion of the mine workings; accompanied by a restriction upon production limiting the productive use of the mine workings and equipment to the working time of the individual miner, which, as is plainly contemplated by the demand for riding rakes after twelve o'clock, may not be more than five hours in each twenty-four hours.

In no other coalfield in the world do the conditions under which the mines are operated call for so large a number of working places, for so few producing miners, for so few hours in the working week. In the submarine districts, it is already impossible to keep the development work sufficiently in advance of the producing faces, and the extension of working territory has become a pressing problem, inasmuch as it involves greater expenditure in haulage, ventilation, upkeep, examination, transport of men and materials, and every item in underground costs. The submarine districts can only be profitably worked under a system that will concentrate the working area, reduce the haulage, pumping, ventilation timbering and upkeep to a minimum, and enable the mine equipment to be utilized for at least sixteen hours out of each twenty-four, not 30 hours a week, as is only too often the case today. If the Nova Scotia collieries are to compete against districts which more completely utilize the capital investment sunk in the colliery plant and development, it will be necessary to introduce similar methods in Nova Scotia; and, if the policy of the United Mine Workers should debar the local operators from adopting ordinary commonsense systems of mine operation, then the collieries cannot compete against districts which, in addition to more intensive production methods, have far more favorable natural conditions.

The increase in wages is the least of the burdens

that complete acceptance of the miners' demands regarding working conditions would entail upon coal production and its cost.

### SOME NECESSARY CHARACTERISTICS OF THE EFFICIENT MINE OFFICIAL.

By J. R. McNeill, Sydney Mines.

A great deal has been said relative to the efficiency of a mine official and still a great deal can be said. I wish to point a few characteristics that in my opinion go to make a successful and efficient mine official, and more specifically a man fitted to be an Underground Manager or Overman.

An efficient mine official must be a good organizer. He must have the knack of putting the right man in the right place. It is no small task to match men so as to give the best results working together. It requires the exercise of the best judgment on the part of the official. To succeed well with the men and avoid the many troubles that arise in mines, an official must have a mild temper and a way that will draw men to him and make them his friends. It must be recognized that all good workmen have minds of their own and do not relish being "bossed" by a man who makes this feature his most prominent characteristic. Men do not need to be "bossed" so much as to be acquainted with the details of the work to be done. An official who gives instructions in plain, simple language will get more and better work done than the "boss" who gives his orders in a commanding tone, designed to impress on the workmen the importance of his position.

Again an official should understand his manager or superintendent, learn his nature so as to interpret his ways and manner, which will often avert trouble arising from misunderstanding each other. There should be perfect harmony between the manager and his under officials. They should be in his confidence. When officials co-operate with one another they produce greater economy and increase the output of the mine.

The efficient mine official must understand and have a practical knowledge of mining methods and mining machinery. He should be able to judge of what a fair day's work is in coal mining. He must be strictly honest with his employer and with the men under his charge. While he must watch every cent of outlay, he must see that full time is given each man in the performance of his work; and faithfully fulfill all his obligations and promises. He must not fail to make improvements in ventilation, drainage and haulage, when he believes the outlay will bring good results for the money expended. In the daily operation of the mine he must keep his eyes constantly on every detail relating to the safety of the men. There should be no waste of material, which is often the case where the official is careless or inefficient.

To sum up my opinion of what constitutes an efficient mine official is: That he is one who can produce a maximum tonnage of clean marketable coal, of maximum quality at a minimum cost with due consideration for the safety and welfare of the men under his charge, and the safety, proper ventilation and maintenance of the mine under his charge. He must be fair, impartial and honest in all his dealings with everyone.

**MINERAL PRODUCTION OF BRITISH COLUMBIA. CANADIAN ABRASIVE CO., BRITISH COLUMBIA**  
**1919 and 1918 Figures Compared.**

That the monetary value of the mineral output of British Columbia for the year 1919 was \$33,296,313 as compared with \$41,782,474 for 1918 is shown by the official figures given in the Annual Report of the Minister of Mines, which has just been issued and is now available for distribution.

The decrease, while considerable, is not serious when placed against the greater decline in mineral production shown by returns from the various States south of the line where the mining industry is an important factor. In fact from this viewpoint it is indicated that this Province did not feel to the same extent the falling off in demand for metals following the cessation of war.

An interesting comparative table is published which, in part, follows:

**Quantities and Value of Mineral Products for 1918 and 1919.**

	1918		1919	
	Quantity	Value \$	Quantity	Value \$
Gold, placer, ounces . . . . .	16,000	320,000	14,325	286,500
Gold, lode, ounces . . . . .	164,674	3,403,812	152,426	3,150,645
Silver, ounces . . . . .	3,498,172	3,215,870	3,403,119	3,592,673
Lead, pounds . . . . .	43,899,661	2,928,107	29,475,968	1,526,855
Coper, pounds . . . . .	61,483,754	15,143,449	42,459,339	7,939,896
Zinc, pounds . . . . .	41,772,916	2,899,040	56,737,651	3,540,429
Coal, 2240 lbs. . . . .	2,302,245	11,511,225	2,267,541	11,337,705
Coke . . . . .	188,967	1,322,769	91,138	637,966
Miscellaneous Products . . . . .		1,038,202		1,283,644
		<hr/> 41,782,474		<hr/> 33,296,313

One interesting feature of the above is the interest shown in silver production, reflecting the increased quotations for the metal and, to some extent, the opening up of promising northern fields. Another worthy of note, but not of such an encouraging nature especially from an industrial standpoint, is the marked decline in coke manufacture. That, however, no doubt will be remedied as new mining projects, now in the development stage, are further advanced.

The report includes the usual detailed accounts of mining activity during the year in the several districts of the Province by the Resident Mining Engineer.

**THE GREAT CANADIAN WEAKNESS**

Ottawa reports refusal by Canadian manufacturers of huge orders from Australia and Brazil, owing to the shortage of coal. Canada's foreign trade, at the very period when the contest for world markets has begun steadily drops until the country soon may once more be creating debits abroad.

And Canada possesses undeveloped coal deposits of untold richness and value! A great source of wealth remains inactive, like money foolishly left buried in Canada's backyard, while factories throughout the Dominion take what coal they can get from the United States or go without.

Every new day brings its pointed reminder of the grave loss Canada suffers owing to her failure to use her own coal. It is the great national weakness which threatens this country with the loss of much to which Canadian war prestige entitles this generation.—Montreal Star.

The Provincial Department of Industries of British Columbia has loaned the sum of \$22,000 to the Canadian Abrasive Co., which will manufacture sand, emery and other abrasive papers. This industry has hitherto been controlled by manufacturers in the United States, and it is understood the industry is a new one in Canada. The abrasive materials used will be obtained locally, and the works will be in Victoria. Paper made in a local paper-mill will be used. The plant is regarded as an experimental one.

Natural abrasives, more particularly corundum from Ontario, have been produced in Canada during the past twenty years, and the production of artificial abrasives in electric furnaces is an important industry at Niagara Falls.

**ADVERTISING ALBERTA COAL**

The Government of Alberta is continuing its advertising of Alberta coal, and in a recent issue gives a series of common queries regarding Alberta coal with the correct answers. Some of the more arresting statements made are as follows:—The Province of Alberta uses Alberta coal entirely, Saskatchewan uses it for half its needs, and Manitoba is using more every year. Alberta has mines equipped to furnish 12,000,000 tons of coal a year. There is now mined about 6,000,000 tons year.

In years to come, if copies of such advertisements are in existence, they will be interesting proofs of what our descendants will find it extremely hard to believe, to wit, that it was once necessary to advertise that Western coal is suitable fuel for domestic use. After all, the Alberta Government is only taking a leaf out of the book of the anthracite operators, who not so many years ago, found it necessary to carry on a campaign of advertising to prove that anthracite would burn. In many western towns, the choice of fuel lay between domestic soft coals and imported anthracite, and the anthracite man got there first. It seems almost laughable now, but no later than the Spring of 1917, at a fuel conference called in Ottawa by Sir Geo. E. Foster, considerable incredulity was expressed by Winnipeg delegates of the suitability of Alberta coal for domestic purposes in Winnipeg, and the Alberta men waxed very wroth at an assumption which they frankly could not understand.

## Our Northern Ontario Letter

### THE SILVER MINES.

The prospective Cobalt silver area of Cobalt was added to on July 20th, when, by an Order-in-Council passed by the Ontario Government, the Gillies Limit was thrown open for prospecting. Intimation of the decision first came on July 17th, through press dispatches. This resulted in many prospectors not being on hand to share in any advantages that may result. The greater percentage of prospectors engaged in this part of Northern Ontario are either doing assessment work on their claims at this season or are on prospecting expeditions. The lack of due consideration for these most active of the prospecting fraternity has aroused a large amount of criticism in the North. It is common knowledge that during the war a movement was set on foot to have the Limit thrown open for prospecting, but a reconsideration caused these lands to be left tied up pending the return of the men from overseas, so as to give all an opportunity to share in whatever might be found. Only a small and practically valueless part of the territory was then opened. In spite of this early consideration for all concerned, the present government has in local opinion shown disregard for all and has dealt unfairly with prospectors. This, whether the Gillies Limit ever yields an ounce of silver, or not.

Production from the McKinley-Darragh is being maintained at an average of between 55,000 and 60,000 ounces of silver monthly. The indications are that output for the whole of 1920 will have a value of about \$800,000. Current net profits are adequate to meet current dividend requirements of 3 per cent. quarterly, in addition to which the treasury surplus amounts to more than a full year's dividend requirements. The mine, up to June 31st, has produced 18,907,250 ounces of silver, and has paid its shareholders \$5,821,591 which is equal to 262 per cent. on the company's issued capital. This output has been the result of doing a little over twelve miles of underground work, and from an area little more than fifteen-acres in extent.

Ore from the dumps of the Kerr Lake mine is now going to the Dominion Reduction plant for treatment. An average of from 125 to 150 tons are being treated daily. It is still too early to estimate the importance of this source of revenue, but from the returns so far the treatment of from 75,000 to 100,000 tons of this low grade material indicates a fair margin of profit. The price of silver will, of course, have a vital bearing on the extent of the profit to be derived from this source.

On August 1st the Coniagas will disburse a dividend of 2½ per cent., amounting to \$100,000. This makes a total of \$400,000 paid so far this year, and brings the grand total up to \$10,040,000. The mine is producing at the rate of between 800,000 and 900,000 ounces of silver annually, and has produced a total of over 28,000 ounces. Ore reserves are being maintained about three year's in advance of the present rate of output.

The Mining Corporation has commenced the erection of campbuildings on a group of claims in the township of Butt. It is planned to carry out a considerable amount of surface exploration.

Recent information from Butt township, tends to indicate that the radium-bearing material is high grade,

but that it occurs in more or less widely separated patches. The question of commercial success, it is said, will probably depend upon whether the pitchblende, which contains the radium element, occurs in patches close enough together to make mining feasible.

Premier Drury, having stated that the present Government has investigated the Department of Lands and Forests and found it "positively rotten", and that the Department of Mines may be the next in line for investigation, has aroused mining men to such an extent as to cause a general demand for the investigation to be made at as early a date as possible. The great majority of leading mine operators in Ontario stand sponsor for this statement to the Ontario Correspondent of the "Mining Journal":—

"Mining interests are strongly of the opinion that there is nothing to hide in so far as the mines are concerned and that all their operations and dealings with the Department of Mines has developed nothing that might be considered embarrassing on the widest possible investigation and are taking the stand that not only do they welcome such an investigation, but that, suspicion having been aroused by one in so responsible a position as that of the Premier of this Province, that necessity now demands an investigation and such is asked at the earliest possible moment."

The Ontario Mining Association, through Balmer Neilly, Secretary-Treasurer, has used the Government to institute a search of records and general investigation at once, mining men not desiring to remain under the stigma of suspicion created by the Premier's unreserved announcement.

Work is well under way on the White Reserve mine at Maple Mountain in the Elk Lake district. Work has been confined to close to surface, but it is now planned to re-open the 140-ft. level. A new motor boat has been placed under the water route from Latchford to Lady Evelyn Lake, and has improved transportation facilities.

It is stated that financial arrangements have about been completed for re-opening the Paragon-Hitchcock property at Elk Lake, some New York capital having been secured. It is also reported that the Laurier Mining Company with property in the township of James, is being re-opened and that a small steam-driven mining plant is being installed. The enterprise is backed by Saruia business men. The address of the company is Elk Lake, Ontario.

A Cobalt mining company as well as United States mining men have made an examination of the Delvin property in the Elk Lake district, and interested parties believe there is fair promise of this promising silver prospect being re-opened.

### Ore and Bullion Report.

During the week ended July 23rd, five Cobalt companies shipped six cars containing approximately 463,650 pounds of ore. Following is a summary:—

Shipper	Cars	Pounds
O'Brien . . . . .	2	129,795
Northern Customs . . . . .	1	96,800
La Rose . . . . .	1	87,400
McKinley-Darragh . . . . .	1	83,657
Coniagas . . . . .	1	65,998
<b>Totals . . . . .</b>	<b>6</b>	<b>463,650</b>

### Bullion.

During the corresponding period, the Mining Corporation was the only bullion shipper, sending out a large consignment containing 99 bars weighing 110,224 fine ounces.

### THE GOLD MINES.

Everything seems to point toward a continued increase in activity in the gold mining areas. Dividend disbursements from the leading mines continue at the usual rate, while work on outlying properties is taking on increased proportions. On August 11th the Hollinger Consolidated will pay its usual eight-weekly dividend of one per cent., amounting to \$246,000. Labor is still reported to be considerably below requirements.

Cabled advice is expected shortly from London in connection with the recent offer made by a Toronto syndicate to underwrite 600,000 shares of the Porcupine V.N.T. Mines treasury stock. The offer was graded, 15 cents each to be paid for 200,000 shares, 30 cents each for 200,000 and 50 cents each for 200,000 shares. It is believed the offer will receive favorable consideration, in which case the necessary working capital would be made available, and the property could then be placed on a producing basis.

At a depth ranging from 100 to 200 feet below the tenth level on the Dome Mines adjacent to the Dome Extension property, a large amount of ore containing average values of upwards of \$10 to the ton has been cut by short diamond-drill holes driven from the tenth level. The management considers it probable that this body dips easterly into the Dome Extension. From these facts, it is generally believed the Dome will take over the Dome Extension property in September. It is learned that a meeting of the directors of the Dome will be held in August. Provided the deal goes through the holder of Dome Extension shares will receive one share of Dome for each thirty shares of Dome Extension held. One of the diamond drill holes shows an ore body 17 feet wide and containing \$25.41 to the ton. Another hole shows the presence of an ore-body 19 feet wide and containing \$18.84 to the ton. One hole shows 40 feet of \$7.63 ore and nine feet of \$20.03 ore. These figures are all entirely official.

During the month of June, according to the regular annual report of Manager R. C. Coffey to the president and directors, the Lake Shore mine treated 1,535 tons of ore and recovered \$37,546, the average recovery being \$24.46 from each ton treated.

This compares with 1,636 tons in May from which \$41,187 was produced. In explanation of the slightly lower tonnage is the following note in the report: "The low tonnage was due to the electric power being off 8.2 per cent. of the possible running time."

For the first six months of the current year, the output from the Lake Shore mine has totalled \$244,710, or at the rate of nearly half a million a year, the average production being \$40,785 monthly. Complete official figures up to June 31st show that the mine has produced \$923,394 since commencing production in March, 1918, and that the million mark will be reached by about the end of August.

Capitalized at \$2,000,000 made up of 2,000,000 shares of the par value of \$1 each, and treating ore averaging over \$24 to the ton, and producing an average of \$40,000 a month, conservative unofficial estimates place the present earning power of the Lake Shore at

a little over one per cent. net profit every thirty days, one per cent. amounting to only \$20,000 or a little less than fifty per cent. of gross production.

Of outstanding importance in connection with the mine, is the recent decision to extend the underground workings from a depth of 400 feet to at least 800 feet, with an intermediate level at a depth of 600 feet.

On the Dome Mines, at a depth of 850 feet, some very spectacular ore is being encountered, some of the ore being equally as rich as that found at surface and which in the early days was called the "golden sidewalk."

One of the leading gold mining companies of Parcupine recently sent a representative to Montreal for the purpose of hiring newly arrived immigrants. It has been found, however, that nearly all of these men are coming from Europe to fill pre-engagements. One whole boat load had been previously engaged to work on one of the leading Canadian railways. It is believed, however, that as these new arrivals gradually work out their passage, they will begin to find their way into all lines of work.

During the fiscal year ended April 30th, the Teck-Hughes treated 17,277 tons of ore of an average grade of \$8.60 to the ton and recovered \$127,771. Before providing for financial charges on bonds, and extraordinary expense in connection with a labor strike, the operating costs amounted to \$6.01 a ton. The scheme to re-organize the company in such a way as to retire the \$500,000 bond issues as well as \$70,000 of defaulted interest, is progressing and is likely to take the form of a large increase in issued shares.

The Tough-Oakes mine is still idle, pending the arrival of scrip in the new company, the Kirkland Lake Proprietary, 1919. The stock was mailed from London early this month, and its arrival will enable the holders of Tough-Oakes shares to transfer into the new company on the basis of two shares of Tough-Oakes for one share of Proprietary. Once this transfer is made, work will be commenced.

Delayed equipment for the Hunton-Kirkland mine has arrived and is being installed, thus making it unnecessary for the company to borrow equipment temporarily from the Elliot. The new plant will be ready to operate within the next week or so.

The first diamond-drill hole on the Carveth property in the township of Thomas lying east from Night Hawk Lake has been completed, and the consulting engineer, Mr. Horace F. Strong is at the property making an examination and report.

A deputation of mining men from the Kirkland Lake, Larder Lake and Boston Creek districts presented a request to the Ontario Government to build a branch line of the T. and N. O. Railway from Swatiska to Kirkland Lake, with the final object in view of extending it east through Lebel and Gauthier townships to the Argonaut mine, and finally to Larder Lake. The premier told the deputation the Government would consider the matter provided the mine owners were willing to allow government engineers to enter the mines and report on the resources. If these warrant the road, it will be built. The Kirkland Lake companies appear to be agreed that such should be done, and the mines will permit inspection. As regards Larder Lake, however, the only operation is the Associated Goldfields, and it is known that this company on a former occasion ignored such a suggestion from the Ontario Government. In the meantime, the Canadian Light Railway Construction Company is endeavoring

to secure rights to construct a light narrow gauge line to Kirkland Lake. It is believed no definite action will be taken until such time as the mines grant official consent to the governments proposal to inspect all important properties.

### PERSONALS.

Mr. J. S. De Lury, professor and acting head of the department of geology in Manitoba University has been appointed to represent the mining industry on the Bureau of Industrial Research now being organized in Manitoba. Professor De Lury is a graduate of the University of Toronto. He was in 1906 on the staff of the Ontario Bureau of Mines. He resigned to accept an appointment as professor at the University of Idaho and was there for some years before returning to Canada and joining the staff of the University of Manitoba. He is at present making investigations in the Rice Lake gold area, Eastern Manitoba.

Mr. Jas. McEvoy is returning to Toronto after completing an examination of coal properties in Alberta. His address will be Gorge St. Arcade, Toronto, where he established an office before going west.

Mr. Cyril Knight of Toronto is one of the candidates for the position of secretary of the Canadian Mining Institute. He acted as secretary at the March meeting in Toronto. Mr. Knight is at present making geological investigations at Cobalt for the Ontario Bureau of Mines. Mr. Knight is well known here and in the United States for his work in Pre-Cambrian areas.

Mr. J. C. Gwillin, for many years professor of mining engineering at Queens University is reported to be still in poor health. His many friends, including a large number of former students regretted to learn that he has not sufficiently recovered to permit him returning to his former duties. He resigned the professorship at Queens sometime ago.

Mr. M. W. Hotchkin is operating the Colonial silver mine, Cobalt, under lease. Mr. Hotchkin was superintendent at the Tough-Oakes gold mine some years ago and recently in charge at the molybdenite mine at Quyon, Quebec.

Mr. John T. Stirling is reported to be recovering from his recent serious illness. Mr. Stirling is chief inspector of mines of Alberta and is one of the best informed persons in Canada on Alberta coal mines. He is an active member of the Canadian Mining Institute and has represented his district on the Council of the Institute for several years.

Mr. J. B. Tyrrell of Toronto is in the Rice Lake gold area, Manitoba. Mr. Tyrrell is consulting engineer for some of the companies developing properties in this area.

Mr. E. P. Mathewson is returning to New York after spending some time at the Anyox smelter, the Granby Company's plant which treats the ore from the Hidden Creek copper mine.

Mr. D. A. Dunlap, vice-president of Hollinger Consolidated Mines, has returned to Toronto.

Mr. H. H. Sutherland is returning to Toronto after being for some months in England.

Mr. Richard Pearce of Cobalt is in Toronto. He has been recently visiting the Lightning River gold area.

### TORONTO MINING STOCKS.

Following are the average quotations for gold, silver and miscellaneous stocks on the Standard Stock Exchange, Toronto, for week ending July 24:

Silver:	High.	Low.	Last.
Adanac Silver Mines, Ltd.....	3	2 $\frac{7}{8}$	2 $\frac{3}{4}$
Bailey. . . . .	4 $\frac{1}{2}$	3 $\frac{1}{2}$	3 $\frac{1}{2}$

Aluminum . . . . .	36
Antimony . . . . .	10

A Toronto newspaper states that coal-mining is a cumbersome process, and that the chief hope of relief lies in the development of electrical power and its application to heating purposes.

It is a faint hope. The application of electricity to domestic and industrial heating has a very limited field, and it is a most expensive and wasteful method of utilising even the electricity developed by water power.

**BRITISH COLUMBIA LETTER****Stewart, B. C.**

The road work to be undertaken by the Provincial Government in the Portland Canal District will be started and carried forward with all possible expedition under the supervision of G. A. Young, of the Public Works Staff. Perhaps the most important of his season's operations will be the construction of a road from the Premier Mine to provide transportation facilities for the Big Missouri and Mineral Hill Claims. Repair work on the Bear River Road already has commenced and there is much trail clearing and improving arranged for both in the Salmon River and Bear River sections, special attention being given the tributaries of the Bear, along which there is much prospecting and mineral improvement.

A strong lead of a good grade of ore is said to have been struck on the Unicorn Group of Mineral Claims, Salmon River, and ore of high grade has been brought into Stewart from the Glacier Creek Property. An open cut has been driven 20 feet on the latter and is in mineral carrying galena and iron sulphides.

**Rossland, B. C.**

The Josie Mine was closed temporarily recently, but only until another copper furnace was blown in at the Trail Smelter of the Consolidated Mining & Smelting Co. Considerable shipments of ore from the Mandy Mine, Le Pas, Manitoba, together with the usual run of company and custom ore, more than overtook the then furnace capacity of the plant.

**Trail, B. C.**

Vancouver (B.C.) Board of Trade recently arranged that a party of its members should make a tour of interior British Columbia in order that businessmen of the Coast City should be brought into closer touch with the activities of residents of other parts of the Province and the natural resources of other districts. The result is that an affiliation of the Boards of Trade of Eastern and Western British Columbia has been effected and one of the first joint efforts is to be to secure a market for the surplus zinc production of the Trail Smelter of the Consolidated Mining and Smelting Company.

During the war the Company went into the production of zinc on a large scale. Now, with an annual output of 20,000 tons of this metal and the total annual requirements of Canada not exceeding 10,000 tons, some profitable means of disposing of the excess must be found and, also, if possible, some avenue through which the greater output of the Company's plant, if worked to its full capacity, can be marketed.

Vancouver has promised its assistance in the solution of this problem.

The tourists included in their itinerary most of the mining centres of the Kootenays, among them Slocan City, New Denver, Denver Canyon, Silverton and Sandon. They found throughout the silver belt but little mining activity, in a comparative sense, because of the trouble still persisting between operators and miners regarding the recognition of the labor organization known as the One Big Union. Generally, however, the trip is having the important effect of creating a better spirit between the two sections of the Province and assuring, for the future, more co-operation and team work.

**Trail, B. C.**

The ore receipts at the Trail Smelter for the week ending July 7th were 9,035 tons. This creates a record for the year. Of the total the contribution of the company's properties amounted to 7,218 tons, which also is a record.

**Nelson, B. C.**

Four of the levels of the Blue Bell Mine, Riodel, B.C., are being unwatered by a pump just installed and constructed at the Nelson Iron Works from drawings furnished by S. S. Fowler, manager of the New Canadian Metal Co., Ltd. As soon as this is accomplished the levels will be actively mined. Last year the Blue Bell shipped to the Trail Smelter 1,249 tons of crude ore and 36 tons of concentrates. To date the property is credited with shipments aggregating 730 tons.

**Sandon, B. C.**

In order to side track the famous slide on the Cody road to the Noble Five Mine a "cut-off" is to be constructed, work on which will commence shortly. The Washington, Argo Fraction, Majestic, Hope, Black Colt, Silver Hill, Cinderella, Chicago and Climax are properties situated in the Sandon District on which development is in progress this season.

**Princeton, B. C.**

The Princeton Mining & Development Co. is proceeding with the work of placing its mine property, situated five miles east of Princeton on the Great Northern Railway, on a permanent shipping basis. There are three full claims on which the ledge has been opened by three tunnels, varying in depth from 48 to 480 feet. The vein is reported to have been traced for about 4,500 feet on the surface and the operators assert that they have a large body of concentrating ore averaging 4 per cent in copper and 1 ounce in silver. A three drill compressor now is in use by means of steam power and another is to be installed electric power to be secured from Bonnington Falls by tapping the line running to the Copper Mountain Mine of the Canada Copper Co. The intention is to instal a concentrator later on.

Considerable interest is evident in British Columbia in the annual report of the Canada Copper Co. This shows that, with a share capital of \$5,441,046 and a bonded indebtedness of \$2,920,650 there was a dividend distribution of \$622,518 for the year 1919, as compared with \$3,625,247 in 1918. The Company invested in nineteen properties in British Columbia last year. Both the Greenwood Smelter and the Motherlode Mine have been dismantled. On construction at the Copper Mountain Mine and the Concentrating Mill at Allenby \$1,112,000 was expended. Work on the Mill and the Railway to the Mine is making good headway. It was held up by labor trouble, otherwise it is likely that 2,000 tons of ore a day now would be coming from the Mine to the Mill. The ore will be concentrated to a 25 per cent. copper content and the concentrates will be shipped to Trail B.C. to be refined.

The quarterly report of the Chief Inspector of Mines for British Columbia shows that fatalities in the coal and metalliferous mines over that period totalled five, four in coal mines and one in the metal mines. In the corresponding period last year fatalities were two in coal mines and one in the metalliferous mines. For

the first six months of the year coal mine fatalities numbered eight compared with two in the same period last year and in the metal mines one as compared with a like number in 1919. Coal mine fatalities up to June 30, were distributed as follows:—Two in the mines of the Canadian Western Fuel Co. at Nanaimo, two in the Coal Creek Mines of the Crow's Nest Pass Coal Co., one in the Reserve Mine of the Canadian Western Fuel Co. and one in each of the mines of the Crow's Nest Pass Coal Co. at Michel, No. 4 and No. 6 Mines of the Canadian Collieries (D) Ltd. Four miners were killed by falls of rocks, two by falls of coal, one by mine cars and one by falling material in shaft. The single fatality in metal mines occurred at the Nickel Plane Mine, Hedley District.

To obtain first hand information regarding the accident which resulted fatally at least in two instances, to five men forming the rescue team of the Pacific Coast Coal Company's Black Diamond Mine, State of Washington, Hon. Wm. Sloan, Minister of Mines for British Columbia, instructed James McGregor, Chief Inspector of Mines, to visit the scene of the occurrence and to personally follow any investigation that might be instituted. The circumstances, as given by press dispatches, are that the team, equipped with rescue apparatus, entered an abandoned mine, known to be filled with black damp, to ascertain the depth of water necessary to be cleared and incidentally for the purpose of drill. As the men did not return within reasonable time another rescue party was called with the result that two of the first party were found fatally overcome and the other three in serious condition. Mr. Sloan explains that he is interested because it is of importance to the coal miners of this Province that all the available details should be known.

It as learned subsequently that there were three deaths, two being members of the first party to go underground and the other victim being a member of the second and the rescuing party. As to the former it is stated that the cause of their loss was lack of an adequate supply of oxygen in their apparatus. No explanation has been ventured as to the reason for the death of the third man. An inquest, it is understood, has not been considered necessary.

W. H. Armstrong, for the past three years director of coal operations for the Province of Alberta and the Southeast of British Columbia, denies the charge that the Dominion Government has been attempting to force the coal miners to enter a foreign (U.M.W. of A.) organization. Mr. Armstrong states that the United Mine Workers, which is in affiliation with the American Federation of Labor, three years ago entered into a two year agreement with the Western Canada Coal Operators Association. The agreement was carried out amicably on both sides and at its expiration was extended a year without formal renewal. On April 1st last the agreement was formerly renewed, but a provision for the "closed shop," which did not exist in the old agreement, was made. Formerly, the operators, if they so desired, could employ non-union men but under the new agreement the demand for the closed shop principle was recognized. An agreement between the men and the operators, such as is common in many other industries, was made for the collection of dues. The wage scale is based on the selling price of coal which is now, for instance, at Drumheller, Alberta, \$6.10 per ton at the pit mouth. This agreement was ratified by the

men by a vote of nearly three to one. "So far as the Dominion Government is concerned" said Mr. Armstrong, "it had nothing whatever to do with the arrangement between the United Mine Workers and the operators. The agreement was solely between the men and the employers and statement by the O.B.U. or others to the contrary was beyond the facts." Mr. Armstrong added that the mines were all working and the men apparently were satisfied with the scale of wages and the conditions.

The coal operators of the Province of Alberta resent the statement published in Eastern Canada that the mines of Western Canada already market all their product. They state that the facts are that all domestic coal mines of Alberta, owing to lack of orders, are working to only 25 per cent of their capacity. This applies particularly to Drumheller.

A reconnaissance party representing the Grand Trunk Pacific Railway is making a survey of a route of railway incidentally, would open Coal Fields, Northern B.C. Such a railway, incidentally, would open up a section rich in copper and silver-lead mineral resources. Its chief object, however, would be to develop the coal area which is extensive.

Mr. H. S. Monroe, the new General Manager of the Granby Consolidated Mining & Smelting Co., is quoted as stating that the coking ovens recently installed at Anyox for handling the coal of the Cassidy Collieries, Vancouver Island, have proved a success. From 420 tons a day of this coal there are being produced 300 tons of metallurgical coke and the by-products include 5,000 gallons of coal tar, 800 gallons of motor fuel and 5 tons ammonium of sulphate daily. The coal tar is shipped to a Vancouver Company for the manufacture of creosote, while the ammonium sulphate is available for the production of artificial fertilizer or the preparation of other ammonium salts for industrial uses. It further is pointed out that present rate of consumption of Cassidy coal, namely 420 tons a day, is the capacity of the ovens while the percentage of by products recovered is high. This statement sets at rest the assertions made that the Vancouver Island coal had proved a failure in the production of metallurgical coke in by-product ovens and that the Company had been compelled to resort to the importation of Eastern British Columbia or Alberta coal.

The appointment of John Macdonald, of Middleboro, B. C., and John G. Biggs, of Cumberland, B. C., to vacancies on the staff of the Chief Inspector of Mines of the Province is announced by Hon. Wm. Sloan, Minister of Mines.

These positions were thrown open, respectively, through the death of H. Lancaster, Inspector of Mines in the Fernie District, as a result of an automobile former Chief Inspector of Mines, and the promotion accident, and by the retirement of George Wilkinson, to his place of James McGregor, the present Chief.

Both the new officials possess all the necessary qualifications and besides are men of long practical experience in connection with mining in this Province. Mr. Macdonald was eleven year in the different coal fields of Scotland, two years in the State of Illinois, and has been identified with coal mining in the Nicola Valley Field, B. C., for the past ten years. Mr. Biggs started coal mining in the Newcastle District, England

as a young man, and for many years has been associated with the business in a practical way. In England he acquired a 2nd Class Certificate and on coming to this country was soon in possession of 1st and 2nd Class Certificates. He has been Secretary of the Board of Examiners in the Cumberland District for about five years.

#### WAGE INCREASE TO ALBERTA MINERS.

An agreement has been come to between the United Mine Workers in Alberta and the operators which is to remain in operation until March 1922. The increases are retroactive to April 1st 1920.

The details are arranged on the basic agreement of 27 per cent. increase in contract tonnage rates in the bituminous fields and 20 per cent. on dead work, which includes the occupation of timbering and handling of refuse; 24 cents a ton increase in the lignite fields and 20 per cent. on "dead" work, and all day wages increased 27 per cent. The miners are also to receive \$1.17 a day cost of living bonus. The increased rates will mean that a contract miner can earn between \$7 and \$10 a day, while day workers will run from \$2.97 to \$5.58 for boys and \$5.58 to \$7 for men.

The eight-hour day will be observed on the surface and eight hours from bank to bank in the mines.

#### INTERNATIONAL PULP AND PAPER ACQUIRE NEW BRUNSWICK COAL MINES

The International Pulp and Paper Co., has purchased the properties of the King Coal Co., the Northfield Coal Co., and A. D. Taylor near Minto, N.S., for a consideration reported to be in the neighborhood of \$150,000, and a first shipment has been made to the new pulp mill at Van Buren, Maine.

The New Brunswick coal seam—as there is only one—is an example of the relative value of coal in districts where its occurrence is scarce. The New Brunswick seam would not be looked at in one of the Nova Scotia coal fields, but occurring as it does at a point distant from any other source of coal, and, owing to its shallow depth being comparatively easy to mine, it is a valuable local asset, with a restricted zone of distribution, and, if extensively worked, not a long life, as coalfields go. The seam nowhere exceeds two feet in thickness, and is usually under this thickness, and the cover does not exceed fifty or sixty feet.

#### FIND NICKEL AND COPPER CLOSE TO LAC DU BONNET, MAN.

The Winnipeg Free Press announces that Nickel and the copper deposits essentially similar to the Sudbury type are to be found in the vicinity to Bear Lake, near the Maskwa river, not far from Lac du Bonnet, according to Dr. R. J. Colony, of Columbia university, who, with E. McDonald, also of New York, and J. S. De Lury, professor of geology, University of Manitoba, has just returned from an initial survey of the deposits.

No development work has been done, Dr. Colony said, but from what has been seen of the minerals, prospects appear unusually good. Many claims have already been staked and assessments made, and it is thought that development of the claims will be started before long. Dr. Colony and his party are leaving on another expedition into the Long Lake country in the early part of next week, to make further investigations.

#### TUNGSTEN ORES: IMPERIAL INSTITUTE MONOGRAPH.

The monograph on tungsten ores in the series of Imperial Institute Monographs on Mineral Resources, which has just been published by Mr. John Murray, has been prepared for the Mineral Resources Committee by Mr. R. H. Rastall, M.A., F.G.S., University Lecturer in Economic Geology, Cambridge, and Mr. W. H. Wilcockson, M.A., F.G.S., Lecturer in Geology in the University of Sheffield. It is divided into three chapters, the first containing a general account of tungsten ores, their characters, occurrences and origin, their mining and concentration, valuation and price, with a brief description of the metallurgy of tungsten and its employment in steel manufacture and other purposes, with a short discussion of the composition and characters of the remarkable non-ferrous alloys of which it is a constituent. The second chapter contains a detailed account of the geological features of tungsten deposits, and the mining and production of tungsten ores within the British Empire, including numerous statistical tables of output; while in the third chapter the tungsten resources of the rest of the world are treated in a similar manner. The relations of the British Empire and United States output to the world's total and the production of tungsten ores in the chief producing countries of the world are also shown by means of graphs,

The table giving the world's production of tungsten ores for the years 1910-1917, arranged by countries, shows that the British Empire produces a very large proportion of the total supply. Until about 1910 the United States headed the list, but about that time Burma rapidly came to the front and for several years showed the largest total. In 1916 the United States experienced an extraordinary tungsten boom, when prices soared to unprecedented heights and production was greatly stimulated. This in its turn stimulated the production in various South American States, especially Bolivia and Argentina. Before the war the smelting of tungsten ores was mainly in German hands, and the greater part of the British ore was sent to Germany for treatment. The enormous development of the manufacture of munitions in this country and elsewhere led to a great demand for high-speed steel for cutting tools, and a syndicate of thirty of the largest steel manufacturers at Sheffield formed a company to undertake the preparation of tungsten metal at Widnes. This company also acquired an important mine in Burma. The manufacture of metallic tungsten and of ferrotungsten was also undertaken on a large scale by several other firms in this country, in order to provide high-speed steel and other products for the needs of the British and Allied armaments. In order to ensure a sufficient supply of ore and to regulate the markets, the export of tungsten ore from within the Empire to foreign countries was forbidden by agreement of the various Governments concerned and the price was controlled. At first the rate was fixed at 55s. per unit (1 per cent of  $WO_3$ ) per ton for concentrates of 65 per cent, and upwards, afterwards raised to 60s. per unit. This usually worked out to about £200 per ton for good average concentrates. As was naturally to be expected, the world's production of tungsten increased largely during the war years, rising from 8,000 tons or thereabouts in 1914 to over 20,000 tons in 1917. One of the most remarkable features was the sudden development of output in

China, from sources of which little is known, the output for 1918 being over 4,000 tons.

In the British Isles wolfram is a by-product of the tin mines of Cornwall, and the big demand for it proved of great importance to many of these mines. Strenuous efforts were made to keep up the output of both metals in spite of scarcity of labour owing to the demands of the army authorities for men. Several promising new occurrences were developed, and old ones resuscitated. By far the most important feature of the Imperial production of tungsten in the last few years was the great development of the Tavoy district in Tennasserim, Lower Burma, which in 1917 exported no less than 4,553 tons of concentrates. The greater part of this appears to be from various forms of superficial deposits, though lode-mining is now making important progress. In the Malay States, both Federated and Unfederated, as well as in the intervening Siamese territory, the geological conditions are very similar, though here tungsten is subordinate to tin. An important quantity of ore also comes from Queensland and New South Wales, with lesser amounts from Tasmania and New Zealand, the latter Dominion producing mainly scheelite. Some unimportant resources have also been discovered in South Africa, especially in Rhodesia.

The chief European producer in Portugal, while large resources undoubtedly also exist in Spain, where the geological conditions are very similar. In both these countries methods are primitive and often wasteful, and a good deal of smuggling undoubtedly went on during the war.

The tungsten resources of South America are undoubtedly very large, the ore occurring in large quantities along with tin in the mineralised belt of the Andes, especially in Bolivia and Peru; this appears to be of Tertiary age, while the tin-tungsten ores of Western Argentina are of much earlier date, being associated with Palaeozoic granites. The mines of Argentina before the war were controlled by German interests.

The tungsten ores of the United States, situated mainly in Colorado, California and Nevada, show a remarkable contrast to those of the rest of the world, in that they are not associated with tin. The largest producing districts of all are Boulder County, Colorado, where the ore is wolframite, and the Atolia district of California, where it is mainly scheelite. The third producing State is Nevada, while smaller quantities have come from Arizona, Utah, Idaho, Missouri, Montana, South Dakota and Alaska. In the latter only the ore is associated with tin.

The foregoing brief summary indicates the sources from which at the present time supplies of tungsten ore are mainly obtained. Occurrences of little or no commercial importance in many other parts of the world are briefly touched on in the monograph, because in some they show points of scientific interest, and some of them may in the future be found worthy of further development. From a detailed study of the geological features of all known occurrences, one point stands out clearly, namely, that tungsten ores almost invariably owe their genesis to masses of intrusive igneous rock, in nearly all cases granite. Exceptions to this rule are few and important. Almost all the important occurrences are associated with tin, and commonly accompanied by ores of copper, arsenic and molybdenum. It is a curious fact that the world's largest producing districts in Colorado and California

should be almost the only exceptional and unusual occurrences.

The monograph concludes with a bibliography giving references to all the important publications on tungsten ores that have appeared up to the end of 1918.

## OBITUARY

### JOHN MACOUN, BOTANIST

The death at the age of ninety years is announced from Sidney, British Columbia, of Professor John Macoun, botanist, naturalist and a pioneer explorer of the Canadian West, and one of the old guard of the Geological Survey, in which for many years he was Assistant Director and Naturalist.

Prof. Macoun was born in Ireland in 1831 and came to Canada in 1850 with his mother and two brothers, settling near Campbellford, Northumberland Co., Ontario. From 1863 to 1879, Prof. Macoun was teacher of Botany and geology at Albert University, Belleville. In 1872 he accompanied Sir Sandford Fleming across Canada on the surveys for the proposed railway to the Pacific, and commenced a series of journeys and explorations that made him an acknowledged authority on the natural history of the West.

In 1875, on a second expedition to the Coast, Prof. Macoun nearly died of hunger, but was rescued near Fort Chipewyan by an Indian who gave him fish and potatoes. In 1882 he joined the Geological Survey.

Prof. Macoun was a Fellow of the Linnean Society, and an original Fellow of the Royal Society of Canada. His catalogue of Canadian birds is the authority on this subject. The Winnipeg "Free Press" in editorial mention of Prof. Macoun's death refers to him as "Canada's greatest botanist." The Victoria "Times" states that "His death leaves a vacant place among that brilliant roster of the men of the Canadian Geological Survey who gave to Canada the story of the West in the unvarnished lore of science." In the death of Prof. Macoun, writes the Victoria paper "the country has lost a distinguished public servant, the Province a highly esteemed citizen, and the cause of science a capable and zealous investigator."

### EMANCIPATION OF MINING COMPANY'S PROPERTIES BONDED BY VANCOUVER SYNDICATE.

Acting as the agent of a group of Vancouver business men, Dr Edwin T. Hodge was bonded for a sum said to be in excess of \$100,000 the properties of the Emancipation Mining Company.

The Emancipation Mine is situated a little over one hundred miles from Vancouver on the Kettle Valley Railway (C.P.R.).

The claims bonded comprise thirteen and a fraction surveyed claims situated between the upper portion of Emancipation Mountain and the valley of the Coquahalla River. Most of the development work has been done at an elevation of 2,670 feet, or 1,200 feet above the railway tracks.

A small amount of development on these properties has yielded very high-grade ore. Selected mining along the veins has yielded 1,250 tons of rock which has averaged \$28.57 per ton. Of the high-grade material, 118 tons is stated to have yielded values exceeding \$300 per ton.

The property is as yet only a prospect, but it is regarded as a promising one, and from a transportation point of view it is unusually accessible.

## ROLLER BEARING Rotary "Scoop" MINE CARS

Showing position when dumping at the side.

*This is only one of the many types of cars we make for the use of mines. We make these Scoop Cars any size or capacity you want.*

Will dump at either side or either end.

Showing car closed and ready for loading.

Showing the Roller Bearings supplied in all four wheels of our Mine Cars. Note the dust-excluding cap, with ample capacity for holding grease or oily waste.

*Send for your copy of our Mining Catalogue showing many other types of Mine Cars. It will repay you.*

**MARSH ENGINEERING WORKS, LIMITED,** Established 1846 **BELLEVILLE, ONTARIO**

Sales Agents:—MUSSENS, LIMITED, Montreal, Toronto, Winnipeg and Vancouver

## An Improved Self-Sharpening Bit for Coal-Cutter Chains

By C. E. KING.

Great progress has been made during the past fifteen years in increasing the efficiency of the coal-cutting machine, but little or no improvement has been made in the cutting chain. Realizing that the cutting ability of a mining machine depends largely upon the cutting chain, the Link-Belt Company's engineers have, during the past seven years, made a very exhaustive study of this method of mining coal, and have developed an improved cutting-chain which is proving successful.

The writer who has been active in the development of this chain, believes that the principles involved will be of interest to all engaged in the preparation of coal at the mine, and takes opportunity to describe the improved cutting-chain, only recently placed on the market.

The vital elements which govern a successful coal-cutting chain are:

(a) The angle at which the bit engages the coal. The bit must have sufficient cutting clearance to eliminate the excessive friction which is caused by a dull cutting edge dragging the coal. The bit should cut, and not scrape.

(b) The ability to hold the bit in this desired position.

(c) The chain must be so proportioned and manufactured that it will withstand the hardships im-

posed when encountering pyrite concretions, and hard dirt bands in or adjacent to the coal seam.

The principal feature of the Link-Belt chain is the self-sharpening bit. The angle at which the bit engages the coal is such that, while the top side of the bit is wearing from contact with the body of the coal, the bottom side of the bit point is being sharpened. A sharp cutting edge is always available by merely turning the bit over sidewise. This sidewise turning of the bit can be repeated until the point of the bit becomes quite blunt; and as the bits are double pointed, they can be turned endwise when one end has become dull.

Figure 1 shows the assembled lug in partial section. The edges of the bit are corrugated, and fit into corresponding corrugations in the lug, thus eliminating

all possibility of slip. An effective method of clamping the bit is the insertion of a malleable-iron wedge between the bit and set-screw. This wedge relieves the set-screw of the vibrating action of the bit, thus eliminating the annoying tendency of the set-screw to work loose. This is an important factor, since three to five per cent of the ordinary bits drop out of the lugs because of the set-screw working loose. Also, the point of the set-screw is not injured, as it is in cases where it engages in the hard steel bit. The set-screw is a snug fit in the lug, and a comparatively light pull on the set-screw is sufficient to hold the wedge and bit in place. The set-screw is not twisted off by the destructive pressure always required when it directly engages a smooth bit. Though very accessible for repairs, the wedges can not drop out of the lug, even if a bit is dislodged. There is ample room between the end of the wedge and the casting to release the bit, and the cutting dust finds a ready exit through the escapement hole provided for this purpose in the lug.

The advantages gained by this method of clamping the bit are:

1. Ability to hold the bit in its desired position.
2. Reduction of the loss of bits occasioned by set-screws working loose.
3. Prolonged life of the set-screw.
4. Increased efficiency of the machine men.

Figures 2, 3, and 4, show the bits in their working position. The bit shown in Figure 2 is in its forged condition, and ready to be replaced in the lug. Figure 3 show the same bit after it has cut approximately three times the amount of coal cut by the ordinary or curved type of bit. Note that the point has been worn similarly to a point obtained by holding the bit against an emery wheel. If the same bit be turned over, as shown, in Figure 4, a sharpened edge with renewed cutting clearance is presented.

The correct cutting angle is always assured, since its position in the lug link is fixed; and as the bit is straight, less of skill and time is required by the bit sharpener. The ability of the bit to sharpen itself is dependent entirely upon the angle at which it engages the coal. Steel of ordinary grade is used for the bits, and unusual tempering methods are required.

The lugs are cast from special steel. The chemical analysis and heat treatment of this casting have been developed by a very careful investigation of results obtained in actual service. The lugs are hot pressed to size (not machined), so as to improve the physical condition of the metal before heat treatment. The wearing surfaces are case hardened.

The strap links are made from a medium-carbon steel, drop forged. All engaging surfaces are accurately machined to fit the guides.

The chain has seven positions, the assembly or lacing of the chain being governed by the nature of the coal to be cut.

Chains can be supplied for all existing machines, and used without altering the cutter arm or sprockets.

It is claimed this chain will give greater production, with less power and prolonged life of bits and chain.

Coal is, and will continue to be, the main source of heat, light, power and fertilization of the earth, apart from the Sun. It is indeed fossil sunlight, and has no known substitute.

## FOR SALE

We offer for Immediate Shipment the following New Equipment at Prices Below Cost:

- 1—5' x 5' Ball Mill
- 1—5' x 16' Tube Mill
- 4—Bouchardt Concentrating Tables
- 1—Duplex Groch Flotation
- 1—Dorr Thickener
- 1—6" x 7" Aldrich Vertical Triplex Pump
- 1—3'-6" Allen Cone

**THE HALL MACHINERY COMPANY**  
SHERBROOKE, Que. 14 Phillips Sq.,  
MONTREAL, Que.

## American Zinc Lead and Smelting Co.

Purchasers of

# ZINC and LEAD ORES

Address

1012 Pierce Building, St. Louis, Mo.

## Exploration Department

For the purchase of

# MINES

Gold - Silver - Lead - Zinc - Copper

Address

55 Congress Street, Boston, Mass.

## NEWSPAPER ADVERTISING OF MINING STOCKS.

Humor is omnipresent to those who cannot divest themselves of the sense, and nowhere is it more often encountered than in reading the financial pages of our newspapers, and in the satellitic advertising it is usual to find on these pages, sometimes openly displayed for what it is, and at other times decently, or discreetly—as the reader prefers it—concealed.

As an example of advertising, naked and unashamed, and of humor also, to those who are merely watching but are not sitting in at the game, despite many invitations, we like the most recent announcement of the Little Gem Mining Company of Alaska, in Montreal's staidest newspaper. At the "instigation" of the brokers who are selling the stock of the company (the word is not ours, but we believe it is felicitously employed) a Mr. Robert Burns, whose qualifications for the work are not stated, but may be surmised, has been despatched to the mine in Alaska "for the sole purpose of definitely proving the value and prospects of the Little Gem Mine." Mr. Burns reports that the shipload of machinery is at Wasilla, from which it may be deduced that it escaped the earthquake that was suggested as being the only thing that could prevent the delivery of the machinery to the mine; and in his telegram states: "Miners enthusiastic over big developments and rich quality of ore found. Picked several pieces myself, no need to pan, can see gold plainly without glass piece. One inch square contained twelve pieces of gold on surface." Mr. Burns' acquaintance with gold-ore sampling and the use of the pocket lens may be deduced from internal evidence. The brokers state they do not consider it necessary to add anything to their client's report, and trustfully state: "We leave the matter in your hands as to whether you consider the proposition a desirable one or otherwise." The decision will be, as we imagine Mr. Burns' report to be, chiefly influenced by the reader's knowledge of the principles of gold recovery. There are gold mines in Canada, producing large quantities of gold monthly, where the most assiduous use of a "glass piece" would not reveal twelve pieces of gold on many inches of surface, and there have been mines also which have produced ore with "pieces of gold" as obvious as the plums in a pudding, but they did not pay dividends. We would not consider that Mr. Burns' telegram has "definitely proved the value and prospects of the Little Gem Mine."

As an example of discreeter advertising, is a paragraph in a Toronto newspaper regarding a property in Porcupine having "immense ore deposits which in size and formation greatly resemble those of the Hollinger Consolidated." Familiar phrase. "Considering the proven fact that values in the Porcupine Camp generally become more consistent, more evenly distributed and somewhat higher with depth," the paragraph enlarges on the possibility of greater values at depth than are indicated by assays of surface channellings. Is this feature of the Porcupine Camp a proven fact? If so, it is one of the most interesting developments of mining operations in that camp we have had occasion to come across.

A further piece of information is that the conditions in the Porcupine Camp resemble those of the South African fields, a fact that does not seem to have received previous prominence in Canadian circles, but, which, if admitted, would permit of much speculative comment.

Just below this upsetting paragraph is the advertisement of Peace River Petroleums Ltd., which takes comfort in the discovery of oil in the No. 1 well, Peace River Town, and in the fact that an enquiry for crude oil for local consumption has settled the question of "What will be done with the oil?" Is not that rather beside the question? The statement is made that No. 1 well "has oil and plenty of it" and that within thirty days a pump test will be made and the quantity of oil announced. The question that investors should ask following an announcement of this kind should be, not what will be done with the oil, but, how much oil will the wells yield? Any concern in Canada that has a well producing anything like a heavy flow of oil will not require to offer "last chances" on shares at fifty cents each.

There is something about the sale of mining and oil stocks in Canada that is distinctly repugnant, but is not easily definable in words. The nauseating mixture of reading matter puffs with apparent paid advertising is a procedure that does not enhance the good reputation of any newspaper, and it is in effect a fraud upon the reader who is credulous regarding those things upon which he is uninformed, and who is not in a position to distinguish between obvious advertising and reading matter that, whether newspaper men admit it or not, carries with it editorial endorsement in default of any notice to the contrary.

Any publication in Canada that attempts to give an opinion on the worth of mining stocks meets two dangers, the possibility of adversely criticising a potentially profitable offering, or of endorsing a flotation without merit, and therefore the task is—with some notable exceptions—shirked. But, apart from the very real difficulties of intelligently appraising flotation values, it cannot be said that many of our newspapers perceptibly discourage the appearance of dubious flotation advertisements, or exercise any rigid censorship in protection of their readers.

#### THE COMMISSIONER OF MINES FOR NOVA SCOTIA.

The result of the Nova Scotia provincial elections shows that still another part of Canada is disposed to try the political experiment of group government. The opposition will be composed of a Labor and Farmer group, but whether they will coalesce remains to be seen. There are some irreconcilable differences between the farmer and the trades unionist in Nova Scotia. There has for many years been a fight in Nova Scotia between the two schools of labor thought, namely those who believe in general representation of the people through a candidate not bound to any particular social group, and those who believe in a straight labor ticket, and the preamble of a union constitution which declares as its first principle that "all wealth belongs to the producer." Both federal and provincial politics will hear much of the miner-labor group in the next few years.

Disclaiming entirely any political bias, and expressing a viewpoint based entirely upon his personal qualifications for the office, we regret the defeat at the polls of Mr. E. H. Armstrong, the Commissioner of Mines for Nova Scotia. Not himself a miner, and representing the constituency furthest removed from active mining operations, Mr. Armstrong by devotion to the duties of his office and from a sense of its importance, has assiduously studied mining practice and mining laws, and has carried through some much needed reforms in connection with mineral holdings in Nova Scotia, where the mineral grants and reservations are much involved by reason of the long history of mining in this province. In particular is Mr. Armstrong to be thanked for his courageous and active attitude towards the undersea coal leases. This subject bristled with difficulties and dangers, but Mr. Armstrong studied the problem from the viewpoint of provincial interests, and it is largely because of his insistence that the life of the undersea coalfield should not be endangered by conflict of corporate interests, and the general acceptance of his viewpoint in Nova Scotia, that the Dominion Steel Corporation and the Nova Scotia Steel & Coal Company have merged their coal holdings, thereby solving a difficulty which would otherwise have had to be remedied by legislative enactment.

Nova Scotia has been most unfortunate in lack of continuity of administrative and technical direction of its mining problems, both in government and in corporate circles, and, if Mr. Armstrong's laboriously gained knowledge of the Department of Mines is lost through his failure to be returned as a member of the Legislature, it will be necessary for some other person to begin where he began, and all who know Nova Scotia will admit that already sufficient has been lost by the necessity to educate new men for positions in which training and experience are not less important than ability.

The management of technical departments of government by laymen is one of the weaknesses of our form of government, and we believe that the appointment of a mining engineer to the position of minister of mines, and of a farmer to the position of a minister of agriculture is as logical and necessary as the appointment of a lawyer to be attorney-general. The Commissioner of Mines for Nova Scotia has, however, earned initiation into the profession of mining, and his place will be hard to fill.

#### LENIN ON THE INTELLECTUALS AND THE ENGINEER.

The "Social-Demokraten" of May 14th, reports a conversation between Jakob Friis, a noted Norwegian socialist and Lenin. The proletarian autoerast is described as having brown eyes, "with a little touch of red." "He is a little deaf in one ear, and therefore talks loudly. When he wishes to bring out an important point, he closes one eye while he thinks, and at the same time a knowing smile comes over his face." There is no trace of humor in Friis's account of this engaging personality with the pensive wink, for he describes Lenin's doorway as the "entrance to the Holy of Holies," and remarks "one never for a moment notices Lenin being conscious of his own greatness. So great is he." Lenin criticises the intellectual doubters who "confuse the mass of workers." "Can you demand," asks Friis, "the same revolutionary clarity in other countries as in Russia?" "Ah!" replies Lenin, "the war has been such a teacher."

After further conversation, during which master and disciple discuss murder, revolution and the destruction of the fabric of society as it now exists in the academic and detached way that takes away the breath of the uninitiated, Lenin expresses himself thus:

"Revolution is coming unavoidably in every country. But it will be probably easier in the countries of Western Europe than with us. There they have entirely different organized forces in their hands than we have. Temporarily Russia has taken the lead. But when the revolution is over in Western Europe, Russia will quickly lag behind in development. How is it with the intellectuals in Norway, are they strongly reactionary?"

"They have become better recently. Especially the French *Clarté* movement has awakened much interest. When the French authors begin to be Bolshevist the Norwegian authors will follow close behind them."

"Hm. I don't suppose that such a following of the fashions is much to trust to."

"Perhaps not, but at least among the engineers I think that there is a real important movement discernible."

"Yes, they are more or less on our side everywhere. In Germany there is almost an engineers' proletariat, so to speak. It is of the greatest importance to get the engineers on our side. In this country they had, for the most part, purely capitalistic interests. It will also require many years to build up industrial life here anew. It is to be hoped that you will have an easier time of it in Norway."

Lenin looked at the clock. I got up and thanked him for all his kindness to me during my stay in Moscow."

We live in difficult times, and world currents are moving, the origin of which is not always known to those who are carried along by them. An "engineers' proletariat" strikes us as a phrase of evil omen, proceeding from an evil source. Should the engineer abandon the traditions of service, and those constructive ideals that have placed him in the forefront of progress and all that pertains to the welfare of mankind, and run after the strange gods of selfishness and greed, and consort with those who have adopted as the war-cry the equivalents of "More and still more" and "Ourselves alone," there would be little hope for the world. The entrance of the engineer into political life has been a significant event of recent years, and we believe that, if the best minds of the profession realize their responsibility and do not hold aloof from a duty of citizenship that is innately repugnant to the scientific engineer, the political influence of the engineer will be a cleansing and stabilizing element in the melting-pot of North America. There is just a danger, however, that minor and inferior elements in the profession, if not dominated by its intellectual leaders, may stray into the wilderness of chaotic thinking that has engulfed so many at this date, and has not by any means run its epidemic course.

#### SULPHUR IN ILLUMINATING GAS.

Much discussion is taking place in Montreal on the alleged sulphurous character of the illuminating gas supplied by the Montreal Light, Heat & Power Company, which the company attributes to the unusually poor quality of the coal it is forced to use, because of the shortage of suitable gas coal. It may be remarked that the question of sulphur in city gas is not new in North America. At the meeting of the American Institute of Mining & Metallurgy in Chicago last September a symposium of papers was read on the occurrence of sulphur in coal, and there was a general agree-

ment among the members who took part in the discussion—most of whom, of course, were coal operators or representatives of coal operators—that the gas companies could not expect much longer to continue to receive coal containing as little sulphur as was the case formerly. One speaker strongly advocated the enlargement of the purification plants to enable them to deal with a larger percentage of sulphur in the gas coal supplied. This is equivalent to stating that there has been much exhaustion of the coal seams with low sulphur content, and that with higher sulphur coal on the market operating conditions will have to be made to suit. The elimination of sulphur from coal gas is more or less complete, according to the extent of purifying surface over which the gas passes, and the frequency of the removal of the spent oxide, all of which means larger purification installations and large expenditure.

#### NEWS OF THE ASBESTOS MINES

By Courtesy of "ASBESTOS."

H. W. Edmonson, formerly with the Federal Asbestos Company has been appointed manager, and about 100 hands are now employed.

W. A. Janitsch, formerly with the Government survey, Ottawa, and having had four years overseas service, has been appointed as superintendent of the Federal Asbestos Company, as successor to H. W. Edmonson.

Asbestos Mines, Limited, East Broughton, have about finished repairing the milling plant on the Boston property and are commencing to produce fibre. The mill is, at present operated with steam power, but the intention is to change this to electric power immediately, this change to be made while the old steam plan is in operation.

As the mill is about three-quarters of a mile from the pit, a track and locomotive haulage is in contemplation, but until this is ready, teams and auto trucks are used to convey the rock to the mill. A steam shovel is being used to load the rock into the teams, and later into cars.

The Quebec Asbestos Corporation of East Broughton, have recently added another 1-½ yard steam shovel to their pit equipment. This will allow the mill to load enough additional rock to operate their mill to full capacity day and night.

They are also installing a new set of rolls, using them as auxiliary crusher, and it is expected this will materially increase their production.

The plant is one of the best equipped in the East Broughton district, and is under the able management of E. E. Spafford.

Jos. Poulin, who about three years ago built and equipped a small mill and plant in East Broughton, and has been operating this successfully since, has sold out to Mr. Samuel W. Cohen and associates.

This plant is situated near the Fraser Mine of the Asbestos Corporation of Canada. G. P. Angus, until lately engineer with the Consolidated Asbestos Ltd., has been appointed manager.

# GRAPHITE

## New Mines Branch Monograph on an Important Canadian Mineral

(Photographs kindly loaned by the Department of Mines)

From numerous enquiries for copies of Report No. 18, Graphite, Its Properties, Occurrence, Refining and Uses," by F. Cirkel, the "Journal" has known that there was a demand for an authoritative monograph on this important Canadian mineral to take the place of the previously mentioned Report, now, and for some time past, out of print. It is therefore a matter of some importance that a new and up-to-date monograph on graphite has been issued by the Mines Branch, and preliminary reference was made to Mr. Hugh S. Spence's Report in the editorial columns of the last issue.

The annual production of graphite in Canada, as recorded in the annual statistics of the Mines Branch, is as follows:—

### Annual Production of Graphite in Canada, 1886-1918.

Calendar Year.	Tons.	Value.
1886.....	500	\$4,000
1887.....	300	2,400
1888.....	150	1,200
1889.....	242	3,160
1890.....	175	5,200
1891.....	260	1,560
1892.....	167	3,763
1893.....	Nil	Nil
1894 (a).....	3	223
1895.....	220	6,150
1896.....	139	9,455
1897.....	436	16,240
1898.....	...	13,698
1899.....	1,130	24,179
1900.....	1,922	31,040
1901.....	2,210	38,780
1902.....	1,095	28,300
1903.....	728	23,745
1904.....	452	11,760
1905.....	541	16,735
1906.....	387	18,300
1907.....	579	16,000
1908.....	251	5,565
1909.....	864	47,800
1910.....	1,392	74,087
1911.....	1,269	69,576
1912.....	2,060	117,122
1913.....	2,162	90,282
1914.....	1,647	107,203
1915.....	2,635	124,223
1916.....	3,955	325,362
1917.....	3,714	402,892
1918.....	3,114	248,970
1919.....	1,322	92,241

(a) Exports.

The increased production during the war years came mostly from the Quebec mines, but during the year 1919 production from this source was virtually suspended, and the output came almost entirely from Ontario.

Imports of graphite into Canada are as follows:

Calendar Year.	Plumbago, not ground.	Ground and manufactures.	Crucibles, clay or plumbago.
1910.....	\$4,867	\$55,090	\$52,896
1911.....	4,940	51,192	56,814
1912.....	7,249	65,911	82,324
1913.....	9,375	72,887	73,971
1914.....	801	49,478	49,913
1915.....	3,436	41,681	106,761
1916.....	3,231	99,919	520,341
1917.....	47,218	123,991	798,004
1918.....	93,956	132,821	113,856
1919.....	6,604	80,970	59,914

The sharp increase in the imports of crucibles from 1915 to 1918 reflects the requirements of Canadian munitions industries, and the much increased value of graphite crucibles.

Attempts have been made to manufacture crucibles in Canada, in connection with which readers are referred to an article in our issue of January 16th last (see page 33) describing the plant of the Dominion Crucible Co. at St. John's, Quebec, a subsidiary of the Dominion Copper Products Co. The decreased demand for crucibles, and the lack of tariff protection, coupled with the 7½ per cent war tax on imported graphite (now removed) placed this young industry in a difficult position. The Dominion Copper Products Company is being wound up, having disposed of its assets to the Canadian Explosives Co., and the future of the crucible plant is uncertain. There is a possibility, however, that it may be used to manufacture foundry facings. It would be a pity to see the work of this plant discontinued, as it is so far virtually the only plant in Canada that has attempted to manufacture graphite crucibles.

### DOMESTIC CONSUMPTION OF GRAPHITE

From data furnished to the Mines Branch in 1912-13, the total annual consumption of graphite by Canadian manufacturers at that time amounted to 950 short tons. Of this amount, 192 tons represented domestic, and 785 tons imported graphite.

The bulk of the graphite used went to the foundry facings, stove polish and paint trades. The following table shows the consumption by industries:—

	Number of firms using Domestic graphite.	Domestic tons.	Imported tons.	Total tons.
Explosives. . . . .	2	..	9	9
Foundries . . . . .	267	78	351	429
Lubricants . . . . .	13	1	17	18
Stove polish . . . . .	12	20	270	290
Paints . . . . .	18	81	109	190
Rubber goods . . . . .	1	7	..	7
Various . . . . .	6	5	2	7
<b>Total . . . . .</b>	<b>319</b>	<b>192</b>	<b>758</b>	<b>950</b>

The above list of industries has since been increased by at least three, namely, dry battery, crucible, and pencil. The first-named uses chiefly artificial graphite produced at Niagara Falls, Ont. In crucibles, both domestic and imported graphite is used, and in pencils, imported amorphous graphite.

Prior to 1915, a certain amount of Ceylon plumbago was imported for use in the best grades of foundry facing, but the trade at the present time uses chiefly Mexican, Korean, American and domestic graphite.

The paint trade uses both artificial and imported amorphous graphite.

In powder and shot polishing, Mexican amorphous graphite is used.

Both flake and amorphous graphite is employed in lubricants. In addition, the Acheson Oildag Company, at Sarnia, Ont., manufacture so-called "deflocculated graphite"—a very finely divided artificial graphite—for use in their lubricating compound.

#### General Review of the Industry.

The great increase in the price of crucible flake, due to the war, did not lead, in Canada, to the increased mining activity that perhaps might have been anticipated. No new mines or mills came into operation, and a large proportion of the existent mills were idle or in only intermittent operation. This may be ascribed to a combination of causes, amongst which figures prominently the lack of success which has for years past attended efforts to evolve efficient mill processes for the refining of graphite in this country. This, coupled with great general increase in the cost of labour and materials in the last few years, has effectually discouraged the investment of capital in

an enterprise which, while offering possibilities during a period of excessive, war time prices, in ordinary times has yielded only slight returns and then only with the most capable of management and under exceptionally favourable conditions. In a number of instances, large mills, out of all proportion to the size of the ore-bodies as determined at the time of their construction, have been erected at great expense, and owing either to lack of ore, expense of running, or a combination of these causes, have been in only intermittent operation ever since.

#### More Efficient Concentration Processes Necessary.

Most of the mills erected in recent years have been equipped with a dry process of concentration, consisting is repeated crushing by rolls of flour mill type, with screening between successive crushing operations, as well as treatment on dry tables. Such an installation required an excessive amount of floor space and often an elaborate system of elevators, added to which the ore required to be kiln-dried prior to milling. The above called for a mill building of large size, relatively high power consumption and a large expenditure for fuel for firing the boilers, heating the plant in winter, and drying the ore. While wood fuel can usually be obtained in the vicinity of the mines, coal has sometimes been used for firing the boilers; this involved considerable expense for haulage, since many of the mills are situated at a considerable distance from rail.

#### Wet Concentration Displacing Dry Methods.

Dry methods for the concentration of graphite first came into prominence in Canada about the year 1906, and between 1906 and 1912 nine mills were installed with dry concentrating machinery. The process was

Open cut above workings of Globe Graphite Mining and Refining Company, concession V1, lot 21, township of North Elmsley, Ont. The banding in the limestone is well shown, and a well defined fold is exhibited in the cap rock above the shaft. Graphite bodies tend to occur at the crest of such folds.

adopted to supersede the wet system of buddles, originally employed in the older mills of the Buckingham district, in Quebec. Speaking generally, while there may have been some exceptions, dry concentration of graphite by the above methods has proved a failure in all respects. The expense involved has been high; a high grade of product has been obtained with difficulty and generally at the expense of an excessive loss of graphite in the tailings and the destruction of an undue proportion of the larger flake in the ore. Recent experience in the Alabama field, where a number of dry mills using similar or modified styles of concentrating machines have been erected in the last two or three years, has been along similar lines, and in various instances the dry installations have been discarded in favour of some form of wet concentration.

Some part of the failures that have attended efforts to develop the graphite industry in Canada has frequently been ascribed to the impersistence of the ore-bodies. While this is doubtless true in the case of a number of properties upon which mills have been erected, it is not to be inferred that all or even the majority of the known deposits are of such nature, and any such statement requires certain qualifications. For one thing, up to comparatively recently, few attempts to prove ore-bodies by diamond-drilling had been made, and opinions on the extent of deposits were based merely on outcrops or an insignificant amount of surface work.

The great majority of Canadian graphite deposits

originally bedded sediments, which have been subjected to an extreme degree of dynamic and contact metamorphism accompanied by intense squeezing, folding, fracturing, and intrusion, so that they together with the rocks intrusive into them, now form an exceedingly complex series with most involved structural relations. It is evident that little that is definite can be learned about the size and form of ore-bodies forming an integral part of such a complex from mere surface indications and even underground work will often fail to reveal anything of a really definite nature. Little underground mining has been carried out, however, the majority of workings being shallow and open-cast, so that our knowledge of the deposits is necessarily scanty. What holds good in the case of any one particular deposit, also, could probably not be taken as a criterion in the case of another, owing to local variations in the structural relations of the rocks.

#### Diamond Drill Prospecting Advocated.

Hence, apart from actual mining operations, diamond-drilling is the only reliable method of ascertaining the extent of graphite ore-bodies, and it is apparent that this fact is becoming recognized, five properties having been drilled during the past few years—three of them in the last half of 1918.

An additional feature that has some bearing on the question of the impersistence of ore-bodies is that Canadian graphite deposits, as a general thing, are apt to vary considerably in richness, and that operators usually confine their attention to the better class of ore (10-20 per cent grade) and regard the leaner

Graphite-lined bushings.

Section of mill, showing Krupp-Ferraris tables, slime-tables and hydraulic classifiers, New Quebec Graphite Company, Buckingham, Que.

Typical high grade, Canadian flake graphite ore, 15-20 per cent carbon, from the Buckingham district, Que.

Foliated plumbago, range III, lot 18, township of Low, Que. This plumbago is of good quality, but is hardly as dense as that from Ceylon.

portions of an ore-body as not worth taking out. This practice has arisen through the difficulties and expense attending the concentration and refining of graphite, it being found that ore running over 10 per cent of graphite might be considered of commercial grade, while anything much under this percentage was too expensive to treat. Frequently, in the case of the graphitic gneiss ore-bodies, the rich ore occurs as a succession of streaks or lense-shaped bodies, that gradually merge into the adjacent non-graphitic country rock, and are separated along their strike by patches of lower grade ore or barren rock. With cheaper methods of concentration, much of this lower grade ore (5-10 per cent graphite) might very well be utilized; in this connection, it may be noted that the milling ore in Alabama does not average over 3 per cent of graphite, the Pennsylvania ore from 3 to 5 per cent and the New York ore 5 to 6 per cent. The two former are, however, soft and extremely easy to

crush, whereas the Canadian gneiss ores are unweathered and hard.

While, therefore, the statement that Canadian graphite ore-bodies are generally small and impersistent is correct in the sense that what has heretofore been considered milling ore is apt to occur in rather small and irregular bodies, such bodies are often bordered or connected by masses of ore of lower grade, representing material whose graphite content may possibly be capable of profitable recovery by improved methods of concentration.

#### Oil Flotation.

Much interest has been shown in the last year or two in the possibilities of oil flotation for the concentration of graphite ores, and it has been demonstrated that by this system flake graphites can be treated both cheaply and efficiently. The elimination of the preliminary drying of the ore, necessary in all methods of dry concentration and in surface tension or film flotation, is an important consideration from the standpoints of expense and mill capacity. Additional features are, that a much smaller mill building, involving less initial expenditure, is required to treat an equal tonnage of ore as compared with dry concentration; that there are fewer machines and appliances requiring constant attention and repairs, and that a smaller force of men is required for operation of the plant. A number of the graphite mills in Alabama are employing oil flotation machines of one type or another at the present time, and the system has also been applied successfully to Pennsylvania ore. In both cases, the ore treated is of relatively low grade, carrying only 3 to 5 per cent of graphite. Oil flotation has also been installed recently (September, 1918) at the mill of the American Graphite Company, in New York state, and is reported to be giving every satisfaction. The New York ore is similar in its general characteristics—hardness, texture and associated minerals—to the Canadian graphitic gneiss ores. A number of tests with oil flotation have lately been made on Canadian ores, and a Callow plant was installed in August, 1914, at one of the mines in the Buckingham district. Unfortunately, however, the mill was destroyed by fire before the system had had an opportunity of being properly tried out. Three Canadian mills have since been equipped with this system of oil flotation.

Thus, while it must be admitted that graphite enterprises in Canada in the past have been attended by numerous failures, this result has, in many cases, been due

Fibrous or columnar plumbago, range VII, lot 21, township of Buckingham, Que.

largely to inefficient and expensive methods of concentration that rendered profitable the treatment of only the richer portions of ore-bodies; could not be depended upon to produce either a clean or a standard grade of product; made poor recovery of the graphite in the ore; necessitated frequent shut downs of the mills to effect repairs. In not a few cases, also, capital was expended on the erection of mills without proper investigation of the amount of ore available.

A pronounced recrudescence of interest in the possibilities of Canadian graphite has lately been evidenced, and it is to be hoped that, with efficient management and a proper appreciation of the difficulties attending the development of deposits and the treatment of graphite ores, the industry may recover from its depression, and the production of flake graphite proceed on more profitable lines than heretofore. The fact, however, must not be ignored that the prices that have been obtained for crucible flake graphite during the war period have been abnormal, and that with reduced ocean freight and insurance rates, Canadian and American graphite generally may expect to find a serious competitor in Madagascar flake. The production of this material has risen rapidly during the last four years, despite embargoes and transportation difficulties, and the resources of graphite appear to be very large. Cheap native labour, also, even with the somewhat crude concentrating and refining methods that are largely employed, enable the Madagascar product to be placed on vessels at a very low cost.

The fact, too, that in steel melting, electric furnaces have in recent years come into decided prominence in the United States (hitherto, the principal market for Canadian graphite) and that there are indications that in the brass industry, also, electric melting may ultimately largely supersede crucible melting, must not be lost sight of when the development of the Canadian graphite industry is considered.

#### Review of Market Conditions, 1914-1918.

Graphite, at the present day, is employed in so many branches of industry that the supply can hardly meet the demand. At the same time, any one particular type of graphite (crystalline, flake, amorphous, or artificial) is particularly adapted to certain lines of work, and thus the various industries have come to utilize

only that kind which best suits their needs. A case in point is the crucible industry. In the first crucibles made, Bavarian flake graphite was used, but, with the discovery of the Ceylon plumbago deposits, flake graphite was largely discarded in favour of the crystalline form. In the same way, pencils were formerly made from either crystalline or flake graphite, but are now manufactured almost solely from amorphous graphite. During 1918, in the United States, curtailment of imports of Ceylon plumbago led to the use of an increased proportion of flake graphite in crucibles, and experiments have been undertaken by the Bureau of Standards with a view to

Main pit of Miller mine, range V, lot 10, township of Grenville, Que. The ore-body is stated to have followed the well defined slip face on the far side of the pit

determining whether plumbago cannot be replaced to a still larger extent by flake without any serious detriment to the quality of the crucibles so made.

Thus, while in many of the industrial uses of graphite, a certain type of graphite is considered essential for best results, in those industries which consume the bulk of the graphite used, some one of the other forms of graphite than that at present employed could probably be substituted, either wholly or in part, without serious detriment. (See A. V. Bleininger, *Chemical and Metallurgical Engineering*, Sept. 27, 1918, p. 467.)

The Report points out the dependence of Canadian producers of graphite on the United States market, and reviews at length the war-time restrictions intended to discourage the importation of foreign graphite and encourage domestic production in the United States and Canada. The two countries seem to have worked as a unit, and, whether domestic producers in North America can hold their own against importations from Ceylon and Madagascar or not, it is certain that as a result of the war a great deal more is known about the graphite deposits, and their economic possibilities than was the case before the war.

All restrictions governing the importation of foreign graphite and the required use of twenty per cent or more of Canadian or Domestic flake in the United States were removed in January, 1919. Restrictions against importation of foreign crucibles were also removed.

#### Limitation of Economic Possibilities of Graphite Deposits.

Summarizing the economic possibilities of graphite deposits, in which, of course, local factors such as transportation, fuel costs and labor supply play an important part, the Report states that commercial flake graphite ores may be said to range all the way from 3 per cent carbon content upwards, although 3 per cent ore would be of exceptionally low grade, and only to be regarded as of economic importance in the case of large ore-bodies. The average content of the ores worked in Canada is 10 to 15 per cent, which is considerably higher than most of the deposits in the United States.

"The economic importance of a flake graphite deposit is in very large degree dependent upon a cheap and efficient concentrating process. Should oil flotation prove the solution of the difficulty which has long embarrassed the flake graphite industry in this country, large quantities of material, hitherto considered of too low grade to work will be converted into milling ore."

#### Graphite Occurrences and Mines in Canada.

The Report deals very fully with every graphite occurrence, mine and mill in Canada, and, as is proper because of the dominating position of the property in the industry, pays considerable attention to the Black Donald Mine in Renfrew Co., Ontario. The occurrences as summarized are referred to as follows:

100-foot level at mine of Globe Graphite Mining and Refining Company, concession VI, lot 21, township of North Elmsley, Ont. The pillar indicates the thickness of the ore-body in the east workings.

The graphite occurrences in Canada that have hitherto received any measure of attention lie in the eastern portion of the country. The disseminated flake deposits are found in the Provinces of Ontario and Quebec, and within a radius of 150 miles of Ottawa. The Canadian graphite industry at its inception (1866-70) centered in the more or less immediate vicinity of Buckingham, Que., about 25 miles east of Ottawa, but the earlier mills in this district have long been out of operation. In recent years, some half dozen mills have been in more or less intermittent operation in the Buckingham area, all engaged in the production of flake graphite. Crystalline graphite, or plumbago, also occurs in this region, but the veins, as a general thing, have been regarded as too narrow for profitable development. In more recent years, several flake graphite properties have been exploited in Ontario, in the region lying immediately to the west of Ottawa, and five mills have been erected in this section. Little, if any, crystalline graphite has been reported to occur in this district, the graphite all being of the flake variety. The occurrence on concession I, township of Brougham, in Renfrew county (Black-Donald mine), of a mass of high grade flake ore is noteworthy, since such a graphite body is probably unique among known graphite deposits. The ore consists of rather small flake, the greater part of which is too small for the requirements of the crucible trade, but containing local streaks of larger flake. The richness of the ore varies from 0 to 80 per cent graphite carbon, and the ore-body, which dips approximately

vertically and is enclosed in crystalline limestone, has an average width of about 40 feet.

Flake graphite has also been reported from several points in British Columbia, but none of the occurrences have been worked. Crystalline graphite has been found at various localities in the Northwest Territories and Labrador, and a deposit of this material was worked during 1917 and 1918 on the south side of Baffin island. A small tonnage was secured during these operations and shipped to the crucible trade. The material is reported to be equal to the best Ceylon plumbago for this class of work.

Amorphous graphite was worked a number of years ago near St. John, New Brunswick. The ore here consists of impure, graphitic shales and slates, and the material found employment in foundry facings and paint stock.

The number of graphite mines and mills in operation during the last few years has averaged about half a dozen; in addition to which there has been intermittent work on a few deposits which, for one reason or another, have not reached the producing stage.

#### Mining Methods.

There is nothing unusual about the mining methods at Canadian graphite mines, and no really deep openings or shafts have been undertaken. Detailed particulars, with sections of the mine workings in illustration are given of the mine of the Globe Graphite Mining & Refining Co. North Elmsley Ont. and of the Black Donald Graphite Co.

Foliated plumbago, from near Lake harbour, Baffin island. This material is reported to be the equal of Ceylon plumbago for crucible work.

**Concentration and Refining of Graphite.**

Concentration of graphite is different to the concentration of metals from ores inasmuch as the value of the concentrate depends largely on the shape and size of the individual particles or flakes, and while the percentage of carbon content is, of course, an important consideration it is not more important than the separation of graphite from the ore in the form demanded by commerce.

The Report goes so fully into the various methods of concentration used that condensation is not possible, and those who are interested should obtain the Report for perusal. Film flotation, which is practised in the Alabama field, has been tried in Canada, but the presence of associated mica particles lessens the selective efficiency of this method in many Canadian ores. A desideratum appears to be the minimum amount of coarse grinding and the least possible attrition of the graphite particles in the separation processes.

**Uses of Graphite.**

The outstanding physical properties of graphite, namely its refractoriness, inertness, high electric and thermic conductivity and resistance to attack by chemical agents render it of extreme importance in a variety of modern industries, while its lustre, complete opacity even in the thinnest flakes, softness and slipperiness, are additional properties that have extended its usefulness to several important branches of industry.

In order of present importance, the principal uses of natural graphite are in the manufacture of crucibles, lubricants, pencils, foundry facing, paints, stove polish and dry batteries while small amounts are also used in electrotyping and as a boiler scale preventive. According to a competent authority, the world's production of natural graphite is divided among the more important of the industries mentioned above, approximately as follows:—

	Per cent.
Crucibles . . . . .	75
Lubricants . . . . .	10
Pencils . . . . .	7
Foundry facing and stove polish . . . . .	5
Paints . . . . .	3

It is obviously impossible to ascertain the proportions with strict accuracy, and the consumption of several of the minor industries will doubtless reduce the above percentages slightly, without, however, materially altering the ratio.

The Report goes very fully into the manufacture and uses of graphite crucibles, but mentions that the growing use of electric furnaces is displacing the crucible process.

The pencil industry, now firmly established in the United States to the displacement of Austrian and German goods, is a considerable user of graphite, most of which comes from the Santa Maria Mines, near La Colorado, Central Sonora, Mexico. The Report states that there are no known Canadian deposits of graphite that provide a material for pencils comparable with the Mexican product.

Both in quantity and richness of the ore, the Black Donald Mine excels all other reported Canadian deposits, and the Report states that the annual production of refined graphite of all grades from this source has greatly exceeded the combined production of all other Canadian refining plants. The deposit "is the richest

and largest body of flake graphite so far known in either the United States or Canada." The average graphitic content of the ore of 65 per cent, but zones of material ranging as high as 80 per cent occur locally. Much of the ore secured, therefore, has been pure enough in its natural state to find employment in foundry work.

**Artificial Graphite.**

Artificial graphite is made on a very large scale at Buffalo and Niagara Falls by the Acheson Graphite Co. in electric furnaces from anthracite. During the last three years the Acheson Co. has made an average of ten million pounds of artificial graphite annually. (See "Journal," July 16th, page 577.) This quantity represents only the manufactured graphite that comes into competition with natural graphite, and is used chiefly in the manufacture of graphite, electrodes, graphite brushes, and in the filling of dry batteries.

**Summary.**

The conclusions indicated by a perusal of the Report are that the domestic producers of refined graphite in the United States and Canada, if the production is not to still further decline from 1919 figures, will require tariff protection against imported materials; and that, comparing the United States and Canada only, the Canadian producer is not unfavorably situated because of the relatively higher graphitic content of the ores in Canada.

The bulk, if not almost all of the various grades of refined graphite produced in Canada, is exported to the United States, and Canada herself is required to import a not inconsiderable quantity of manufactured goods in which graphite plays an important constituent part. The extension of our graphite industry to include a modicum of domestic manufacture of such goods is plainly suggested, the graphite mining industry being in this respect analogous to asbestos mining. There are, indeed, several instances where graphite and asbestos are combined in articles imported into Canada, both materials being in all probability of Canadian origin.

**PERSONAL**

Hon. Robert Drummond, Editor of the Maritime Mining Record, has sailed for England, and expects to visit the mining fields of Scotland and England, to obtain first-hand knowledge of conditions. The "Journal" wishes Mr. Drummond a pleasant visit and a safe return to Nova Scotia.

**METAL QUOTATIONS**

Fair prices for Ingot Metals in Montreal, August 4th, 1920:

	Cents per lb.
Copper, electro . . . . .	24½
Copper castings . . . . .	24
Tin . . . . .	55
Lead . . . . .	10¼
Zinc . . . . .	10½
Aluminum . . . . .	9½
Antimony . . . . .	9½

## Northern Ontario Letter

### THE SILVER MINES.

Although the price of silver has strengthened considerably, the silver hoard at the mines of Cobalt continues to increase. The leading producing companies apparently are not yet satisfied that quotations have found the high level which appears to be warranted by the law of supply and demand.

Early in the week, intimation came from New York that the antagonism of those interests which have been "bearing" the price of silver had been withdrawn, but the advice did not leave an altogether favorable impression at the mines of Northern Ontario, where it is generally conceded the antagonists are confined to Great Britain and her far-flung influence in the Far East.

In regard to the silver situation, however, mining men who claim to be in touch with the activities of British metal brokers and metal authorities are not quite sure but that a gamble in silver may yet materialize that might reasonably send quotations to a higher level than ever before reached. This, of course, is conjecture on their part, and cannot be offered as a prediction. Attracted by reports of a new silver discovery in the Harricana River district south from Amos in Northern Quebec, a large number of prospectors from the Cobalt and Haileybury district joined in a rush to the new field. Returning prospectors allege that the so-called find consisted of some neat silver placed by artificial means in a crack in the formation. They are thoroughly convinced that the thing was "salted," and have accordingly returned without staking any claims. A number of those who joined in the rush, however, have remained in the district to prospect for gold, the formation being attractive.

Flotation equipment is being installed at the Temiskaming mine for re-treating the large pile of sand tailings which has accumulated from past operations. With the present improved methods of treating the material and with silver at the present high price, it is believed the margin of profit per ton treated will be considerable and that by late September the work will be well under way.

Quick liquid assets of the Nipissing Mining Company as of the middle of 1920 were \$5,065,211. This is the highest on record for the company. It is made up of \$3,362,214 in cash and United States and Canadian war bonds, together with \$1,702,997 in ore in transit on hand and in process as well as bullion stored at the mine. It is the plan of the company to accompany its October dividend of 5 per cent with a bonus of equal amount. The January dividend will also be accompanied with a 5 per cent bonus. This is the usual custom and will call for the disbursement of \$1,200,000 in the two distributions—October and January.

Considerable activity is taking place in the recently opened Gillies Limit. The number of mining claims recorded is not large, but quite a number have been staked and are being systematically prospected before being recorded. Those interested in the new field are quite optimistic about the outlook.

A discovery of peculiar interest has been made at a depth of 800 feet on the Crown Reserve mine. It consists of gold in quartz, occurring in quantities of as

high as \$12 to the ton. There is not much of the gold-bearing ore and the find is not regarded as of any material importance. This is the second similar freak occurrence in Cobalt, a small showing of gold having been found some years ago on the Kerr Lake mine.

It is learned this week that the Crown Reserve Company is extending its activities to the Harricana River district in northern Quebec, and has a number of men engaged in exploring a prospective gold property south from Amos station on the Transcontinental railway. The property lies on the mainland at a point close to the Siseoc property which is located on an island.

Published reports in such papers as the "Toronto World," "Mail & Empire," Toronto, and "Northern Miner," relative to a big new silver find having been made on the Miller Lake O'Brien at Gowganda are not correct, according to authoritative advice to the correspondent of the "Journal." It is stated that the company recently shipped a large specimen of silver ore to the Royal Museum, Toronto, the sample having been taken from the main vein which has been worked for a number of years. This appears to have given rise to the erroneous and misleading reports concerning a big new discovery.

Good headway continues to be made on the Keeley Silver Mines in South Lorrain, where the installation of an 80-ton mill should be completed within the next two months or so. Underground developments are satisfactory and the indications appear to be that the mine will be on a steady producing basis before the year is out.

At the Dickson Creek property, situated about seven miles from Cobalt and located along the shore of Lake Temiskaming at a point about half way between Haileybury and New Liskeard, a station is being cut at the 250-ft level preparatory to carrying out lateral operations. The vein dipped from the shaft at a depth of 200 feet, and it is estimated to lie about 25 feet from the shaft at the 300-ft. level. Work is confined to conglomerate formation, the underlying diabase being estimated to lie at a depth of about 350 feet. The operation is conducted by English interests, the address of the mine office being Haileybury, Ont.

The Mining Corporation of Canada is negotiating for the purchase of a certain part of the Right-of-Way Mines lying adjacent to the McKinley-Darragh, Princess, Silver Queen and Mining Corporation territory. It is believed the deal will reach successful consummation. It does not involve any very great amount of ore, and it is believed that the purchase price will be moderate.

At the 150-ft. level on the Oxford-Cobalt property, the cross-cut has reached the vein and drifting operations are now under way. The vein is about eight inches in width and contains smaltite together with other mineral. Silver values at the present point are low. It is planned to drift about fifty feet each way continuing the shaft another 100 feet in depth.

#### Ore Bullion Shipments.

During the week ended July 30, two Cobalt companies shipped an aggregate of four cars containing approximately 311,388 pounds of ore. The Nipissing alone sent out three cars containing nearly a quarter of a million pounds.

Following is a summary:

Shipper.	Cars.	Pounds.
Nipissing . . . . .	3	245,388
Dominion Reduction . . . . .	1	66,000
Totals. . . . .	4	311,388

During the corresponding period, no bullion shipments were made, from which fact it is clearly evident that the great hoard of silver in the vaults of the local mines is steadily increasing.

The policy is one which if adopted in a general way by producers in other countries would probably quickly break the attempt of big financial interests to hold the price of silver down. The vaults at the mines of Cobalt actually contain an aggregate of around three million ounces of silver, which is equal to about 125 tons or more than four carloads of silver.

### THE GOLD MINES.

The acute shortage of labor at the leading producing gold mines is being relieved only gradually, although the next few months promises to bring greater relief in this respect than any previous period since the war caused general curtailment.

As a result of the increased pay which the mining companies gave to their men last spring, the cost of mining has shown a substantial increase at the big producers where large forces are employed. The indications are that mining costs at the Hollinger Consolidated for this reason may show an increase of between 50 cents and \$1 a ton. At the same time, however, it was only because of this increase in pay that the company has been able to secure forces with which to work the mine at two-thirds capacity. Had the old wage scale been continued, it is obvious the operations would have been reduced to perhaps well under half capacity, with a corresponding decline in profits. The increase in pay is generally believed to have been wise and has assured the company of net profits adequate to cover dividend requirements at least at the rate of seven per cent annually and is tiding things along until such time as general readjustment takes place.

Official announcement is made that the Porcupine V.N.T. directors have accepted the offer made by Toronto and London interests to underwrite 600,000 shares of treasury stock. A block of 200,000 shares were immediately taken up at 15 cents each, and the recommendation has been made to resume work at once on the strength of the \$30,000 thus secured. The syndicate has an option of six months on the second block of 200,000 shares at 30 cents each, and an option on the remaining 200,000 shares for ten months at 50 cents a share.

August promises to prove a vital period for the Dome Mines as well as for the Dome Extension. With the Dome option on Dome Extension up for consideration and final decision by September, the August meeting of the directors of the Dome promises to be of much importance.

As a result of the extensive deposits of ore being opened up at depth on the McIntyre-Porcupine, the physical condition of the mine is being added to at a rapid rate. The mine is firmly established as the third largest producer in the Dominion and may even be a close contestant with the Dome Mines for second position. At a depth of 1,125 feet an ore shoot nearly

one-quarter of a mile in length has been opened up in vein No. 5. At the succeeding levels, 1,250 and 1,375 there is every reason to believe similar results will be achieved. In addition to this, recent diamond drilling operations have indicated rich ore at a depth of 1,600 feet. With one main haulage level established at a depth of 1,000 feet to which all the ore from the upper levels falls through chutes, the McIntyre management is establishing another main haulage at a depth of 1,375 feet for the purpose of handling all the ore between that depth and the 1,000-ft. level. By this method of mining, the ore falls through chutes, is drawn off into cars, conveyed by miniature electric railway to the main shaft and hoisted to surface from where it passes over an aerial tramway to the mill with a minimum of manual labor, plus that required to operate the mechanical equipment.

A deputation of Kirkland Lake and Larder Lake mining men which waited upon Premier Drury recently, requested the Government to construct an extension of the Temiskaming and Northern Ontario Railway to Kirkland Lake with a view toward extending it right on to Larder Lake by way of the Argonaut mine in Gauthier township. The Premier told the deputation the Government would build the railway provided the property owners permitted a Government appointed engineer to enter the mines and report to the Government as to the resources, and to form an estimate of the amount of traffic indicated. The Kirkland Lake mining men, as well as the manager of the Argonaut Gold Mines appear to be satisfied that the offer is a good one, and are content to let the Government engineer enter the mines. Such does not appear to be the case, however, in regard to the Associated Goldfields. It is reported that Dr. McKay, of the latter company, does not desire to submit the property to an independent examination and is understood to have told the Premier that if the Government would build the railway to the Argonaut, the Associated Goldfields would itself build the line from that point to its property at Larder Lake. Just what attitude the shareholders will take in this matter is difficult to say, but it seems obvious that suspicion will be aroused in connection with the property if the President turns down a chance of having the Government build a railway, the cost of which would be at least \$40,000 a mile. Several miles separate the Goldfields from the Argonaut, and the cost might reasonably amount to close to half a million dollars. It is pointed out that if the recent annual report of the Associated Goldfields is correct, the attitude of the President is difficult to understand.

Construction work on the Wright-Hargreave mill at Kirkland Lake is progressing rapidly, the building itself being almost completed. The work of installing equipment is also well advanced, and the earlier estimates promise to be fulfilled and the mine placed on a producing basis during the last quarter of this year.

Reports are current that a consolidation may be arranged between the Orr Gold Mines and the Hunton-Kirkland. The negotiations have not advanced very far at the time of writing, but the prospects of something of the nature being done are said to be favorable.

During the course of continuing the main shaft of the Bidgood Gold Mines from the 200-ft. level toward the 300-ft., a large vein has come into the shaft from

the south, and is believed to be a 24-foot vein which shows on surface a short way south of the point where the shaft was commenced. Channel assays are being taken and the mineral content of the body will be ascertained within the next few days. Once a station is established at the 300-ft. level, it is proposed to carry on lateral operations along this wide vein as well as on another vein some seventy-five feet farther north and which at the 200-ft. level had a width of close to sixteen feet.

The directors of the Lightning River Gold Mines have just concluded a visit to their property and are optimistic over the outlook.

With regard to the shower of writs which farmers in the Sudbury district have issued against the International Nickel Company with a view to recovering various amounts for alleged damages from sulphur fumes, considerable discussion is heard among mining men.

One prominent mining man who has had experience in other countries, stated to the writer that without any intention on his part to venture an opinion as to the justice of any or all of the claims entered against the International Nickel Company, he nevertheless was of the opinion that the matter should be quite easily adjusted. His opinion and comment was thus:—

If the claims entered are found to be unjustified after having been thoroughly investigated, then a general dismissal of the writs will be in order. On the other hand should these claims be justified in whole or in part, the Government might indeed be well advised to turn to New Zealand for an example as to how to deal with the matter. This mining man stated that in New Zealand, the holder of land values his own property, and is taxed on his own figures. In turn, the Government has the right to redeem this land at such valuation, plus moderate addition for inconvenience caused. At times when such a dispute arises over alleged damage, the owner of the land is prevented from presenting unreasonable claims by reason of that fact that the assessed value of his land is accepted as its value.

It might not be unreasonable to suppose that the assessed value of the Sudbury farms might be averaged up for the past five years, and with a moderate addition for the increased value of land at present might be found to constitute a basis from which to calculate the measure of damage done, if any.

This method, it is thought, might go a long way to cur, any attempt on the part of owners of more or less worthless land, turning "sulphur farmers" and imposing an unjust penalty upon the nickel industry, which is of very great importance and benefit to this country.

In referring to this, the gentleman interviewed did not mean to infer that such unjust claims would be made, but events in the past have tended to show that where one individual might have reason for some complaint, others have not been adverse to attempting to profit by entering alleged similar claims for damages.

The MacLeod River Coal Mine is shipping regularly to Prince Rupert. It is located about 800 miles from the Coast on the Grand Trunk Pacific Railway. The present production is 4 carloads a week which is being marketed in Prince Rupert and Edmonton.

## BRITISH COLUMBIA LETTER

### The Metal Mines

The season's work has been well underway in the Portland Canal district for some weeks. With the snow gone and prospectors and miners in the hills the towns of Stewart and Hyder are almost deserted. On the various properties along the Salmon and the Bear Rivers, however, activity prevails. The only notable new discovery reported is on the Georgia River, a few miles down the river from Stewart, where a number of gold bearing claims have been recorded. Samples indicate that they are rich but their possibilities must yet be established by development. The Marmot River also is being well prospected and many promising claims have been located. For the rest development work is continuing on all the better known mines and prospects of the Portland Canal and road construction is in progress to assist in the opening up of the mineral zone. The Unicorn Group is to be drilled, a contract having been awarded to Lynch Bros., of Seattle, Wn., and F. P. Stewart, familiarly known as "Pap," has returned to the camp to supervise plans for the opening up of the Mountain Boy Group of Crown Granted Mineral Claims. "Pap" is a pioneer of the Portland Canal District, being credited with responsibility for directing the attention of Sir Donald Mann to the potentialities of the district.

### Invermere, B.C.

The Silver King Mining Property, operated by the Toby Greek Mining Co. Ltd., of Vancouver, B. C., and situated near the Jumbo Fork of Toby Creek, is showing up extremely well. At about 90 feet from the surface a cross-cut is being driven towards the overhanging wall of the lead to the south of the tunnel. This cut has opened up a ledge about 80 feet wide of high grade silver lead ore, which is reported to range in value up to \$100 a ton, the most important of the mineral content being silver. There is considerable shipping ore already on the dump. From what now is apparent and from the general indications it would seem to have been established that the Silver King Shortly will become one of the regular shippers of the Province. A road is under construction the completion of which will solve the question of transportation.

### Trail, B. C.

Ore receipts at the Trail Smelter of the Consolidated Mining and Smelting Co. for the week from July 7th to 14th totalled 4,810 tons, making the aggregate for the year to the latter date 159,368 tons.

### Kimberley, B. C.

The mineral resources of southeastern British Columbia and Alberta is the subject of an article recently published under the name of P. A. O'Farrell who declares that "in the Kootenays, the Kettle Valley, and on the Island of Vancouver there are copper mines which can easily supply all the copper which the British Empire May need for a century to come; that there is more and better coal in Southern Alberta and the Kootenays and Similkameen than in the whole of Europe, including England and Russia; and that there is more iron ore and valuable standing timber in Southern British Columbia, including the Island of Vancouver, than in all Europe." He asserts that "had the Kootenays been located in Europe, Prussia

Sales Agents:—MUSSENS, LIMITED, Montreal, Toronto, Winnipeg and Vancouver

and other pirate nations would have spent billions in treasure and rivers of blood for their possession." Dealing with the mineral resources of the Kimberley District specifically Mr. O'Farrell states that here are found deposits of lead and zinc and iron sulphides which are extensive enough to supply all the zinc and lead which Canada and the Empire will need for a century," for beneath five, six or seven square miles of land on the eastern slopes of the Selkirks a blanket of mineral lies embedded between two layers of quartzite at an angle of 22 degrees from the horizontal." He then goes on to describe operations at the Sullivan Mines. He says, in part:

"The Consolidated Mining & Smelting Company owns 2,500 acres of this mineralized territory. It is driving two long tunnels into the mountain to find how far the blanket of mineral extends. It also is boring two a half miles lower down the valley to tap it at a depth of 2,500 feet. How far this great mineral deposit extends to the east or to the north cannot be fully determined for years, but enough has been done to demonstrate that from Kimberley alone Canada and the Empire can draw all the zinc and lead they require for a generation or two. If this phenomenal continue as constant and as regular as they are under mineral deposit extends five miles down the slope and five miles to the north, and if the ore values the 500 acres already proved up, these ore deposits at Kimberley will make Canada a supreme factor in the lead and zinc markets of the world.

"I have already stated that one stope which I examined, 8,000 feet from the portal of the tunnel, would yield 30,000 tons of ore to the acre. In the other two

stopes, 2,200 feet higher up, the distance between the hanging wall and the floor was occasionally 150 feet. From each of these stopes they broke down 150,000 tons of ore, or 300,000 tons from about six acres. In other words, 60,000 tons to the acre.

"In one stope the ore ran 50 per cent lead and 10 per cent zinc, and 8 ounces of silver. In the other 30 per cent zinc and 10 per cent lead and 3 ounces of silver. The gross metal and silver values of this ore, therefore, for 800 pounds of metal and 5 ounces of silver at current prices would be \$70 to the 2,000 pounds of ore. Under each acre, therefore, were \$3,500,000 worth of metals and silver, but the general run of the ore is not so rich nor much more than the average of 20 feet between the hanging wall and the foot-wall. An average for all the ore extracted will be little over 500 pounds of zinc and lead and three or four ounces of silver to every 2,000 pounds of ore. Sixty per cent of the whole deposit so far proved will furnish ore of this average.

**WANTED.**—Mine Foreman for Nova Scotia mine; must be experienced in drifting, shaft sinking, shaft timbering, etc.; one who can train men to do such work or who can bring a following of experienced men with him. Single man preferred, as mine is twenty miles from railroad and no family houses available. Camp has electric light and good bunk houses. Good board is provided. Write giving references and salary desired, which will be supplemented with bonus in proportion to results achieved. Address—Canadian Mining Journal, Box 17, Gardenvale, P.Q.

"The other third of the deposit is a sulphide of iron containing smaller quantities of lead, zinc and silver which the management does not reckon as of any present value. They mine and ship the iron pyrites to make the sulphuric acid needed in the Company's metallurgy or in the western markets. No effort is made to find and work the big stopes and the rich ore. All the ore is extracted and the whole, as I have already said, will yield 500 pounds of lead or zinc out of every 2,000 pounds of ore. It has taken eleven years of constant research and metallurgical experiment to find the chemical reagents and metallurgical equipment necessary to segregate the zinc, lead and iron sulphides contained in these ores. The Broken Hill ores of Australia are of similar character and the Germans who controlled them made fair recoveries through oil and water and alkali concentration but they never succeeded in making a really pure zinc or pure lead out of the concentrates.

"But the Trail metallurgists have succeeded in making pure electrolytic zinc and electrolytic lead out of the Kimberley ores. At Tadnac (Trail) the zinc sulphide is calcined and then dissolved in dilute sulphuric acid and recovered on plates by electrolysis. If the mineral operation is not complete and particels of lead and zinc sulphides get into the sulphuric acid they remain as tailing or slimes but a way has been found to segregate the zinc in these tailings.

"I am giving these details to show that Canadian and American electro-chemical metallurgists are achieving better results in the recovery of metals than the Germans were able to effect with all their boasted knowledge of chemistry, and it is also interesting to know that at Tadnac was built the first metallurgical plant which manufactured electrolytic zinc for the world's markets."

#### Hedley, B. C.

There are employed at the Nickel Plate Mine, Hedley, B. C., about 150 men, two third of whom are at work underground and the remainder either at the mill, situated at Hedley, or the power plant. The Company is extracting gold bearing ore running, on average, \$9 to the ton. As it costs about \$8.50 a ton to mine, the profits are not large, in fact they are so negligible as to be scarcely worth mentioning. This was not so when the ore approximated \$12 a ton, and it is stated that considerable development is planned in expectation that a body of richer ore will be encountered. Ore is taken out of the Nickel Plate at several levels, the upper one being six hundred feet lower still. Ore cars holding two tons run on a narrow gauge electric railway for a mile out of the mine. Then the ore is dumped into a tripple at the top of a steep side hill. From the tripple the gold-bearing ore is dumped into cars operating on long steel cables and running down a side hill that seems almost perpendicular. The long slide to the mill in the town itself is made in two sections and passengers who go up or down on the ore trams sit tight and fervently hope that nothing breaks. A trip to the Nickel Plate in one of the little ore cars beats anything in the roller coaster line on any midway.

#### Victoria, B. C.

That oil has been discovered in commercial quantities in the Peace River Country is the effect of reports, apparently well authenticated, from Peace River Town, near where the Peace River Petroleum Ltd. is oper-

ating. Crude oil, it is said, will be delivered to customers before the end of the present season. In No. 1 Well the bore is being enlarged from six to eight inches, which work has progressed beyond the 1,000 foot level. No. 2 Well, two and a half miles below Tar Island, has been started. Drilling equipment is being installed at Hudson's Hope, and on the Upper and lower Smoky River. At the San Joaquin Well it is said that 20,000,000 cubic feet of gas is escaping daily, that it is a wet gas containing a good deal of gasoline, and that the Well will be capped and provisions made for the recovery of the gasoline and the saving of the gas.

The Department of Mines, Ottawa, claims to have discovered a process by which crude oil may be recovered from the tar sands which occur so extensively in the neighborhood of Athabaska River, near Fort McMurray. A reserve of 55,000 acres of such land has been created.

#### Nelson, B. C.

The Blue Bell Mine, Riondel, B. C., is the largest property to come under the interdiction of the One Big Union. This organization has demanded for the workers in that mine a scale of wages which, it is said, to amount to an increase of 40 cents per day over what was being paid. The Blue Bell is the oldest mine in the Kootenay, dating back to 1865, and is operated by the New Canadian Metal Company, the manager of which is S. S. Fowler, one of the most highly respected metal mine operators of the Province.

#### TORONTO NOTES

Mr. Frank C. Loring, Sun Life Building, Toronto, has just returned to the city after an extended stay in London, Eng. in the interests of Northern Ontario mining properties. Mr. Loring states that he has sufficient faith in the standing and reputation of Canadian mining amongst British investors and promoters to return to England and open an office in London, which he proposes to do shortly. Mr. Loring pointed out that South African production was falling off and that Canada seemed to be the only country left in the way of a gold producer. Canada is becoming increasingly popular amongst the financiers in the Old Land, as is evidenced by the space being devoted to Canadian mining and other industrial affairs in the British journals and he predicts that Canadian mining investments are destined to occupy a large place in the British financial world. Mr. Loring will remain in Toronto till October and will then return to London where he will open an office as consulting engineer. He will, of course, retain his office in Toronto, which will be looked after by his son.

At a special meeting of the shareholders and directors of the Porcupine V. N. T. Mines, held in Toronto on Tuesday of this week the offer by Hamilton B. Wills, on behalf of a syndicate he has formed, for the purchase of 600,000 shares of treasury stock of the company at an average price of 31¾ cents a share, was accepted. The scheme has been adopted as a substitute for the mortgaging of the property to the Associated Gold Mines of Western Australia to the extent of \$50,000, which had originally been proposed. English interests agreed to the proposition so that fresh funds for development purposes will come both from Canada and overseas. It is expected that actual mining operations will be under way by Oct 1st.

# They Work Intelligently

## **HARDINGE**

### Conical Mills

*Large Balls Work Only on Coarse Material, Small Balls Grind to Finish*

Notice the shape of the Hardinge Mill—conical, big at the feed end, tapering towards the discharge.

By the natural action of the mill the largest, heaviest balls concentrate at the point of largest diameter where they have the maximum drop; the smaller ones collect towards the discharge. The coarse material entering first meets the big balls and, as it is reduced and passed through the mill, is ground by the smaller balls.

That is common sense and true efficiency. No working hit-or-miss, banging away with big balls at small stuff or tapping at coarse material with small balls but, exercising almost human intelligence, automatically adjusting the grinding media to the material. That is the secret of Hardinge Mills and the reason they have so rapidly become the standard crushing and grinding for all modern plants.

We will be glad to give definite facts and figures as to what Hardinge Mills can do on your work if you will mail us a sample of your ore and let us know quantities to be handled, sizes of primary crushers, finished product desired, etc. Write for "Grinding Data" and our general catalog.

Night and Day they grind away

# Massco Mill Equipment

## The Marcy Mill

Crushing in one **easy step** means lowest cost per ton output. The reason lies in the Marcy grate and the low pulp-line carried. Marcy balls are always crushing ore, their impact being unretarded by any superfluous cushion of water. Marcy grate openings run with the movement of the mill, enabling the rapid discharge of fine material.

## Perfection Oil and Acid Feeder

Adjustable friction drive and detachable cups enable an almost unlimited range of speeds and feeds. Permits accurate regulation of the amount of reagent fed, resulting in great savings.

## Pierce Amalgamator

Saves all the fine, flake, rusty, and "flour" gold. Higher recovery inevitably results from the use of the Pierce Amalgamator. It is simple, compact and easily taken apart for a clean-up.

## Scobey Tailings Sampler

Reduces a full day's run of pulp at any part of your mill to a 10 lb. sample, accurately and without attention. The Scobey is thoroughly practical and reliable.

## The Wilfley Table

The history of the Wilfley is the history of concentration. Over 22,000 have been sold during the last twenty years for use in all parts of the world. Simple, substantial construction, trouble-proof moving parts, have kept the Wilfley to the fore-front of all concentrators. Manufactured in Canada by Wabi Iron Works, New Liskeard, Ont.

## Massco Service the World Over

Brings the *best* of all lines of Mill, Mine and Smelter equipment within easy reach of every operator. Special bulletins on any part of the Massco line will be mailed on request. Massco engineers will gladly assist in the working out of any problem.

## Government Loan to Coal Mining Companies Suggested to Increase Production of Coal

The Government, through the Sub-committee of the Railway Commission, to which has been entrusted the movement of coal at this time, has placed an embargo on export shipments of coal from Nova Scotia, except to the United States and to Newfoundland. This action may have seemed to be unavoidable, but leaving this phase of the matter on one side, it is not constructively helpful inasmuch as it does not in any way tend to increase the production of coal. Actually, it will discourage production by debarring the coal operators from the most profitable market in the history of bituminous coal demand.

During the war period, and without losing sight of the valuable services rendered by the Dominion Fuel Controller or the embarrassments of the Government, we believe the authorities were always much more pre-occupied with the idea of reducing the price of coal and controlling its distribution than they were impressed with the necessity for increasing the coal output. The word "control" was in itself a misleading word, and responsible for much misconception. What the coal industry of Canada has required in the past, and urgently requires at this time, is not control, but encouragement. Although coal is much more costly than ever before, it is nevertheless one of the cheapest of raw materials, considering the labor and risks involved in its production. A little shortage reveals that coal is cheap at any price, and, where the root of the problem of fuel supply is—as it is in Canada—a question of deficient production, cost is a secondary matter.

The general attitude of the Canadian public towards the coal producing industry—of which the policies of the large purchasers and any government which happens to be in power is a natural and necessary reflection—has been that when American coal is to be had in plentiful quantity and at low prices the domestic producers must put up with the inexorable functioning of the laws of supply and demand. When a national emergency arises the cry is raised that domestic resources should be reserved for domestic needs, and "control" of the industry is at once instituted. Briefly, this means that in slack and easy times the coal industry must take its chance of making money, and in good times it must not be allowed to make profits.

A continued course of this treatment cannot but result in enfeeblement of any industry, and is responsible for the present entirely unsatisfactory condition of domestic coal production in Canada.

In Nova Scotia there exists a shortage of coal production that is between two and two-and-a-half million tons annually. The export embargo will affect possibly from 300,000 to 400,000 tons of coal, for which good prices are obtainable. If coal production had been sustained, Nova Scotia could have supplied both Canadian and foreign markets. If the Government prohibits profitable export of coal in order to fill domestic requirements—which it is always admitted is a proper proceeding—it thereby assumes responsibility for the financial condition of the industry which it takes control of, and if, in order to serve a national need, the coal industry is deprived of profitable business the proceeds of which would provide much needed capital for development, then it devolves upon the Government itself to find the capital.

The President of the Dominion Steel Corporation has announced that a sum of \$4,500,000 or thereabouts is to be expended on the extension of the collieries controlled by this Corporation, but it must not be assumed that this sum, comparatively large enough it may be, in anything but a small degree represents the capital expenditure necessary to enable the Dominion collieries to produce an output commensurate with the extent of the coal areas, or the domestic demand for coal. An expenditure of \$20,000,000 could be conservatively and profitably made upon these collieries, but a really adequate expenditure would be so large that it could not possibly be undertaken by any private corporation.

There are a number of considerations which, cumulatively considered, indicate that financial assistance in the development of new collieries should be given by the Federal Government. These considerations include the following. During the war period the enlistment of miners was relatively greater than that of any other class, and enlistments from amongst these most essential munitions-workers were not restricted as they should have been. The praiseworthy desire of the miners to be recognized as war workers—which would have lessened the number of enlistments—was

never acknowledged, although badges were granted to munition workers of far less importance. The coal-freighting steamers of the coal companies were requisitioned for a length of time that has occasioned a discontinuance of coal shipments from Nova Scotia to Montreal of about five years. During the war period the price of coal was controlled in a manner that limited the profits of the companies, but at no time did the Government undertake to increase the coal output by financial assistance as was done in the case of other munitions. The Government did not during the war period, nor has since the Armistice, given tangible aid, or adopted any other attitude but a critical and watchful one, towards the coal industry. We submit that it would have been much better for Canada if the resources of the Government in the shape of financial assistance, of relaxation of immigration regulations, of assisted immigration, of freighting vessels and railway conveyance, and indeed every possible form of state encouragement and aid had been given to the coal industry. The millions of dollars lost in adverse exchanges would have been much better expended on the opening of new sources of coal supply. There is no corner of our national life where endeavor has not been restricted and expansion throttled by the insecurity of coal supply. The problem is not, however, an insoluble one. It may be that only a par-

tial solution will be found possible, but, in that event, the sooner we know it the better.

There are two phases of the coal supply problem before this country today. One is a pressing immediate emergency, requiring emergent measures. The other is a problem that will always be with us, a condition that is part of our national heritage, a congenital weakness that if we do not take steps to end, will eventually end Canada, as a national entity. The actions of the Sub-Committee of the Railway Commission at this time are temporary expedients to avert a threatened crisis, but will not the Government earn the lasting gratitude of our people by forming a permanent body charged with unremitting study of the fuel problem so that we may find out whether or not there is a permanent solution to a permanent problem?

There are a thousand and one loose ends in connection with our fuel question that need tying up. No concentration of the thought and advice of competent men actually engaged in the production, transportation and sale of coal in Canada has ever been attempted, except for snap judgments in emergent situations, and this does not count. It can never be accurately stated that any problem is insoluble until a concerted, determined and prolonged effort has been made to solve it, and this is precisely what has **not** been undertaken in Canada.

## Demands of United Mine Workers in Nova Scotia Discourage Increase of Coal Production

The United Mine Workers of Nova Scotia at their own urgent request were granted a Royal Commission charged with enquiry into all phases of the working conditions at the collieries, and in particular with reporting upon the request of the union for a general wage increase in addition to the adjustment of January last. This Commission is sitting, and newspaper reports indicate it is going into matters thoroughly. A session is to be held in Halifax on August 9th, when, it is announced by the U. M. W. leaders, the first demand for an increase of one dollar a day will be replaced by a fresh demand for an increase of two or maybe three dollars a day. It is stated unequivocally by the President of the union that whether the decision of the Commission is favorable or not, it will either be entirely repudiated, or regarded as merely a temporary arrangement. Each successive demand of the United Mine Workers in Nova Scotia has been based on increases in the cost of living, but the actual adjustment made has included many other things, having to do with conditions of employment, that are even more irksome than wage increases inasmuch as they are deterrents to production. The newest demand is like previous ones in this respect.

The President of the union has made some most extraordinarily misleading statements to the newspapers. For example, he is reported as stating that he has the statement of the President of the Dominion Steel Corporation that the Dominion Coal Company can produce coal in Nova Scotia cheaper than either the American or Canadian operator by two dollars a ton. Such a statement could not have been made because it is not true. If it were stated that the American operator can produce coal at from two to three dollars a ton less than the Nova Scotia mines it would be about correct.

It is further stated that the coal companies are reaping vast profits on the world coal shortage. As to this, the Dominion Steel Corporation did not quite earn six percent last year, and any chance it had of making a little more this year has been spoiled by the embargo on export coal.

The new demands of the miners are not forced by necessity to keep up with the increased cost of living. Each agreement with the operators contains machinery for such adjustment as may be required by a continued mounting of commodity prices. The attitude of the men is based on erroneous ideas of the

profits of the operators, and a desire to share in the returns. At the same time the union is doing its best to kill this profitable business by its general policy to restrict production, not as is erroneously proposed by reduction of the individual efficiency, but by opposition to any attempt at intensive production, such as night-work, double shifts, and concentration of workers underground, by the introduction of shorter hours of work, and by determined resistance to any lessening of the number of non-productive workers or the importation of miners from abroad. Increased output of coal, an increase adequate to the demand, would enable the coal companies in Nova Scotia to pay adequate wages, to accumulate adequate financial reserves, to make adequate financial expenditures on new openings and to lay the foundations for steady employment for an increased force for many years ahead. But the present inadequate production, and the inadequate production of the last six years has placed the companies in the weakest position they have been in for many years. The business of a coal company is to produce coal. It is only functioning properly to the extent it produces coal. If the miners would manifest a genuine desire to increase production they would afford an opportunity to the operators to increase wages, but, unfortunately, while they protest with their mouths against alleged deterrents to production arising from lack of equipment, the greatest deterrent of all consists in their own attitude which imputes all possible blame to the operator, but assumes no tittle of responsibility on the part of the workers themselves.

#### CERTAIN POST-TIMISKAMING IGNEOUS ROCKS OF ONTARIO FOR WHICH THE NAME HAILEYBURIAN IS PROPOSED.

By Willet G. Miller and Cyril W. Knight.

In the pre-Cambrian of Ontario there is a widespread series of igneous rocks, of greater volume than formerly recognized, that intrudes the Timiskaming sediments but is older than the Algoman granite and gneiss. Descriptions of these rocks have been given in various papers and reports by the authors and their age relations have been discussed. For instance, in a paper published in 1915 the authors said<sup>1</sup>:

"It may be added that basic rocks of the age of sudburite are widespread and have frequently been mistaken for Keewatin<sup>2</sup>. They are represented by the peridotite and augite lamprophyre of the Porcupine region, one hundred miles north of Sudbury, and by the lamprophyres and other rocks of Cobalt, 90 miles to the northeast of Sudbury. For economic purposes, at least, some age name should probably be applied to these basic rocks."

<sup>1</sup>Journal of Geology, Vol. XXIII, p. 590.

<sup>2</sup>Sudburite is a lava, often with pillow structure but frequently schistose, that occurs in considerable volume in the Sudbury area. It has the same relation to norite as that of basalt to gabbro or rhyolite to granite. (Ont. Bur. Mines, Vol. 23, Part I, p. 215).

Diabase that appear to be of this age occur in considerable volume in the vicinity of Cobalt and elsewhere and at times are confused with the later Nipissing diabase. Gabbro-diabase and basic lavas of Hastings and other countries of southeastern Ontario are also of this age. The Correlation Table that accompanied our report in 1915 shows the occurrence of these rocks in several districts<sup>3</sup>.

Since the publication of that report and other papers in which we have described and referred to these rocks we have found an age name for them more necessary, especially in connection with structural geology of the mines at Cobalt. In this area lamprophyres and the so-called "older diabases" are of common occurrence and reference has frequently to be made to them. While we are loath to introduce another age name, still as a matter of convenience we now propose to employ the name Haileyburian for these post-Timiskaming and pre-Algoman igneous rocks. The name is taken from that of the capital of the District of Timiskaming, the town of Haileybury. Dikes of certain of these rocks occur in the environs of the town.

Certain of the rocks that we class as Haileyburian are older than others but they are all post-Timiskaming and pre-Algoman.

The following table, with the addition of the name Haileyburian, gives the age classification employed by the geological staff of the Ontario Department of Mines, the names of the igneous systems or series being enclosed in parentheses, thus: (Laurentian intrusives), to distinguish them from the sedimentary systems<sup>4</sup>.

#### Pre-Cambrian Epochs of Ontario and Their Metal Production.

**Keweenawan.**—Epoch, following basic intrusions, of (a) silver, cobalt, nickel, and arsenic at Cobalt and elsewhere, (b) nickel and copper at Sudbury, and copper elsewhere. Certain gold deposits, not now productive, appear to belong to this epoch.

**Animikean.**—Epoch of deposition of "iron formation" as a chemical precipitate. Includes the Cobalt and other series of sediments.

**(Algoman).**—Epoch, following granite intrusions, of gold at Porcupine and at many other localities, and of auriferous mispickel. Deposits of galena, zinc blende, fluorite, and other minerals appear also to have been derived from the granites, but some of them were not formed till post pre-Cambrian time.

**(Haileyburian).**—Preceding the intrusion of the Algoman granites, basic intrusives, of post-Timiskaming age, give rise to nickel and titaniferous and non-titaniferous magnetite deposits and chromite.

**Timiskamian.**—Epoch of minor deposition of "iron formation" as a chemical precipitate, with conglomerate and other sediments.

**(Laurentian).**—Granite intrusions probably gave rise to ore deposits which have been removed by excessive erosion as is known to be the case with deposits of later origin.

**Loganian (Grenville).**—Epoch of deposition of extensive "iron formation" as a chemical precipitate, with limestone and other sediments.

**Loganian (Keewatin).**—Composed largely of basic volcanic rocks, many of which are now schistose.

## Third International Mining Convention at Nelson. B.C. July 20th to 24th, 1920

(Reported by Robert Dunn, Victoria, B.C.)

With a large number of delegates in attendance, both from the different mining sections of the Province and from a number of the adjacent mining States, the third annual Mining Convention of Nelson, B.C., opened on the 20th of July and continued until the end of that week.

Those attending were welcomed on Wednesday morning (July 21st) by J. A. McDonald, the Mayor; Dr. W. O. Rose, member of the Provincial Legislature for the city; Hon. William Sloan, Minister of Mines for British Columbia; and R. F. Green, Member of the House of Commons for West Kootenay, the two latter speaking on behalf of the Province and the Dominion respectively.

The feature of the morning session, outside of the formal addresses, was a paper by A. G. Langley, resident engineer for the Kootenays, on general mining conditions in the Eastern Districts of British Columbia.

Mr. Langley reviewed the history of prospecting in British Columbia from the first discoveries of placer gold near Fort Steele by prospectors from the United States, and said that to one who had travelled the rugged mountain regions of the Kootenay district it was really amazing to see the places into which the pioneer prospector has penetrated, without the aid of trails and with his grub and blankets on his back. He advised search for fissures and crushed zones, and a careful look-out for float. He thought the average prospector went out into the hills to look for gold, silver-lead and copper ores and seldom gave the rarer metals a thought. He suggested it might be well for prospectors to familiarize themselves with the appearance of these minerals, and said that each resident engineer had a cabinet of specimens provided by the Government which could be inspected. He referred particularly to platinum, tungsten, pitchblende, tin and molybdenite. As pegmatite veins were often the source of rare minerals, he described the characteristics of these veins. He advised prospectors to get the best terms for properties, but not to hold them too long. Quick action was necessary, and he suggested that the prospector should ask cash for ore in sight, but that for further payments he should allow the purchaser sufficient time to develop and prove the property.

J. W. Mulholland, President of the B.C. Prospectors' Protective Association, gave a short talk on some of the problems affecting prospecting in the Canadian West. He emphasized the need of trails to facilitate the opening up of prospects; spoke of the need of exhibits of the rarer metals in order that those going to search for minerals might become conversant with those varieties not commonly found in B.C.; also referring to the organization of branches of the Prospectors' Association and the good work being done by the same.

In the afternoon, with S. E. Fowler in the chair, Nichol Thompson of Vancouver, gave an address on the possibilities of the Iron and Steel Industry in this Province. Iron, he said, was the basis of all industry and had been so looked upon from the very

dawn of History, "for we find that when Croesus, in his ostentatious way was explaining to Solon the riches of his palace, including the gold in the treasury, the philosopher with a prophet's vision said to him: 'My friend, when a man comes along with better iron than thou, he will be master of all thy gold.'" Mr. Thompson pointed out that time had proven the truth of this for it not unfrequently happened that the surest way to a gold mine was through an iron mine.

The speaker traced the development of the iron and steel industry during the past sixty or seventy years, and then dealt more specifically with conditions in this province. He stated that the magnetites of the Pacific Coast were of a considerably higher grade than were found elsewhere in the world, as far as he knew. This was a point that did not seem to be generally appreciated. The statement that the magnetites could not be treated without haematite, was not correct. Such a theory had been exploded.

It seemed to him that the only question now was that of markets, and he did not think that there was any serious need for concern on that score. On this point he had been commissioned by capitalists considering investment in such an industry in the North-West, to make a thorough investigation of local market conditions. The results had been most satisfactory. There seemed to be no reason to doubt that it would be possible to absorb the output of a 250 ton furnace. He mentioned specifically the large consumption in British Columbia of tin plate for canning purposes.

Concluding, Mr. Thompson said, "Get the steel industry started and many other industries will follow. We have the ore and the coal to make coke, and failing coke we have the water power to generate electricity and the timber to make charcoal. All we require is capital and labour to co-operate in making this magnificent province the Greater Britain of the future."

Glenville A. Collins, who was Chairman of the International Mining Convention at Seattle, followed with an address on financing the prospector.

Mr. Collins said the prospector was a man of high ideals, and persistent faith, but he advised that he should learn more of the principles involved in raising money. "If prospectors knew how to deal with business men along business lines, there would be twice as many mines, and as many more mining fortunes owned by their discoverers. Business men lacked confidence in the prospector's knowledge of business principles, and asserted his belief that "any time a prospector approaches a live business man of capital, and demonstrates his knowledge of business principle as applied to mining, he may be sure of his backing."

The speaker said that the old stock company principle was on the wane. "To stock a mining prospect "today with the expectation of raising any considerable sum by sale of shares is almost to guarantee "its failure." The speaker objected to corporate stock issues, and preferred unincorporated joint stock associations with non-personal liability, and proposed

a plan of co-operative prospectors' syndicates. The concluding part of Mr. Collin's novel and suggestive remarks are quoted in full, as follows:

#### Prospectors' Groups.

In these days of co-operation and collective bargaining, I am going to venture to suggest a plan of finance that so far as I know is new to mining.

Usually in any worthy district there are a number of prospectors working that are more or less accessible to one another. Say any number of such men meet together and organize themselves into a prospectors' joint syndicate. For the purpose of illustration, say there were five prospectors, and they all had several claims each; maybe some were better than others and possibly their idea of values of ore and property were inconsistent. These men come together and associate themselves (not their property yet) into a joint syndicate as trustees, whose object was to work to develop these properties and district. They jointly get together an accurate statement of the district represented, and its resources—this statement to be verified in so many ways as possible, one by the other, if need be, or by a reputable engineer if possible.

Such a joint syndicate could collectively bargain for grubstake, development capital, or sale of property, for any one of its individual trustees without tying up the claims. The syndicate could then apportion to each of its member trustees, on a specific claim or piece of work, such money as seems wise and needed in the judgment of the trustees, and with the proper legal and technical advice.

This kind of syndicate would represent a better speculation for capital than the ordinary individual property, because one would be assured of the honest collective judgment of several prospectors, their attorney and engineer, in making investment of syndicate funds, as against one individual, against one proposition, as in the present method of syndicate.

There are instances where such a plan can be worked out with success and in the financing of a whole group of prospectors, at one time, in ample proportions, and with many advantages as to legal protection, engineering assistance, dealing with smelter, and towards an honest and intelligent winning from nature of its coveted possessions.

These joint syndicate groups could in many instances become factors in a central association, such as your Prospectors' association here at Nelson. And where this is possible a Prospectors' association could work out a syndicate plan of group financing so as to supply funds to these individual prospector groups, thereby greatly strengthening this mode of finance and protection to the prospector at less cost all around.

#### Prospectors' Musts.

Now gentlemen, I have talked a lot, and said very little; but, to summarize before closing, let me repeat:

The prospector must learn more about business in order to interest capital.

He must be more careful about making his deals by securing proper advice.

He should hesitate before going in on a corporate plan of stocking a prospect.

He can wisely call together his neighbor prospectors and organize a co-operative joint syndicate.

He can work out a plan by such co-operation so as to finance not only himself but his neighbors, and at the same time provide for legal and technical advice and protection, and make better bargains with smelters and stores furnishing supplies.

He can advertise his district or encourage development, promote transportation and do many other such things.

Co-operation among prospectors in an organized manner cannot help but be beneficial to the mining industry, as well as the individual prospector.

On Thursday morning, the Chair was taken by L. K. Armstrong, Secretary of the Columbia Branch, A.I.M. & E., Spokane, who made a few introductory remarks relative to the various problems confronting industrial advance at the present time. He mentioned the development apparent throughout the Kootenays in connection with the lumber business, and emphasized the need of conservation in this connection. He thought it would be well if, in America, some system of re-forestation were adopted. The labour question

was one very prominently before all classes, and he did not find it hard to understand the cause of this in view of the fact that the dollar now was purchasing only what two dollars purchased not many months ago. His opinion was that for the sake of the country, for the sake of industry and the general welfare, it would be advisable for employers and employees to get together wherever possible, discuss their differences in a sane and reasonable way and effect an amicable settlement. How they were to do this was a matter he would leave to them, it being his desire merely to give expression to his conviction that the spirit indicated was most necessary.

"Oxidized Lead Ores," was the subject of an address by S. S. Fowler, General Manager of the new Canadian Metal Co., Ltd., Riondel, B.C. When first coming to British Columbia, Mr. Fowler had given some attention to this matter and had concluded that there were no oxidized ores in this province, the action of glaciers having made their existence impossible. Subsequently however, his theory in this respect had been proved erroneous by the discovery of oxidized lead ore at the Bluebell Mine and the Paradise, the North Star and the Electric Point, the latter being situated just south of the line. The shipment of ore from these properties since had become rather an important contribution to the Trail Smelter of the Consolidated Mining & Smelting Co.

In the Bluebell mine he had found oxidized lead ores at a depth of four hundred feet below the level of Kootenay Lakes. His explanation of this, and he took credit for originating the theory, was that the weathering of the deposits preceded the existence of the lakes, there than perhaps having been an inconsiderable river, where now there is a very large body of water.

"Some years ago," Mr. Fowler said, "I found an area utterly barren of vegetation. Not a tree on it more than a foot high. It was about half the size of this hall, and I became curious as to what was underneath it. I opened it up and discovered a body of ore, lead-bearing and decided to ship some of it. It is strange looking ore, showing no signs of value, and when it was shipped the road-master on the railway said whoever sent it ought to be in an asylum, and that he knew where there were millions of tons of such rock. Well! the shipper is still out of the asylum." After giving some account of the development of the Bluebell mine, one of the best known operating properties in the province, Mr. Fowler told something of what he is now doing in experimentation to the end that a greater recovery of the values of this material may be secured.

T. W. Bingay, Comptroller, Consolidated Mining & Smelting Co., of Trail, contributed a paper on the advance in metallurgical practice, with special reference to the Trail Smelter plant for increased production. Much of the information given has already been made available to the public. He told the story of the Trail Smelter, of its efforts towards zinc production during the war; of the additions recently made to the copper refinery; and of the plans in view for the treatment of the ores of the Rossland plant.

Nichol Thompson occupied the chair for the afternoon session, the feature address of which was that by the Hon. William Sloan, Minister of Mines for British Columbia.

### Speech of the Minister of Mines.

Mr. Sloan referred to his pleasure at attending the last Convention, expressed his renewed pleasure at being present at a third annual gathering and heartily welcomed the delegates to British Columbia on behalf of the Provincial Government.

He reviewed the mineral production of the province for 1919, which, although showing a reduction of twenty per cent from the figures of 1918, he considered was a good showing under the circumstances and required no explanation, instancing greater reductions in neighboring metal-producing states.

Mr. Sloan drew the special attention of the delegates to the decline in gold production, and he believed that everything possible should be done to stimulate gold output. He explained the changes in the Placer Mining Act designed to open up large areas now idle, and mentioned the removal of the fifty cents royalty formerly collected per ounce of placer gold recovered.

The policy of the Department of Mines in re-division of the mineral survey districts, and the expenditures on opening up trails was enlarged upon, the Minister mentioning that since the enactment of the legislation there had been expended on road and trail construction and on repairs to mines and promising mining properties the sum of \$280,000, and that up to date \$355,000 had been authorized on similar work. Mr. Sloan said that no application for road or trail construction to a mine or mineral property made to the Mines Department that had received the endorsement of the District Engineer, but was given favorable consideration, and he renewed his assurance to the delegates that this would be the constant policy of the Department under his direction.

The Minister of Mines denied that, as had been stated, all iron ore in British Columbia had been put under reserve. Only a small area carrying iron in the Clinton district had been so reserved under the powers granted him. The large area of iron-ore (limonite and hematite) in the Taseko or Whitewater district, estimated by the Government Engineer to contain possibly fifty million tons of ore had been so reserved, the Government believing that this body of ore, so suitable to be mixed with magnetite, should be held out of possible speculation so that nothing might interfere with the initiation of an iron and steel industry in the Province.

### The Possibility of an Iron and Steel Industry in British Columbia.

On this important matter the Minister spoke at length as follows:

It seems to me that the time is propitious for action on the part of capital. There is no question that we have the magnetite ores necessary for the maintenance of a 300-ton a day plant and, if the exploration now in progress in the Taseko River district results as favourably as Mr. Brewer's report would indicate, we will have all the fluxes required. There now are two parties in this district—one having been sent into the field by the Provincial Government, Mr. F. J. Crosland, B.Sc., the well known mining engineer and geologist, being in charge—and the other under Mr. J. D. MacKenzie, of the Canadian Geological Survey. Mr. Crosland's work is to establish as far as possible the tonnage of ore available, and that of Mr. MacKenzie is to make a geological and topographical survey. There also are some high-grade red hematite deposits on the Bull and Sand Rivers, Kootenay District. This ore is known to be of excellent quality, and last year Mr. Langley, District Mining Engineer, was instructed to make an examination of the property. Owing to his many duties be-

cause of the extent of his territory he was unable to get the work done but, now that he has an assistant, the inspection will be made and we will await the report with interest.

Six years ago the development of the magnetite ores of British Columbia and their actual commercial utilization involved problems which seemed insuperable because of the advantages of the East over the West in respect of cost of materials, labour, etc. Pig-iron, I am competently advised, now can be produced as cheaply in British Columbia as in Pennsylvania and other industrial centres of America. Ores cost roughly \$7.00 a ton at the lower Lake Superior ports, or approximately \$7.50 a ton at the Eastern furnaces; the cost of British Columbia magnetites landed at some point within easy reach of fuel could not be more than \$4.50 a ton—in fact such a figure would allow those delivering the ore a good profit. As to the cost of fuel—the former difference favoring the East has been eliminated, as coke which before cost the Eastern manufacturers from \$2.00 to \$2.75 a ton, is now costing them between \$11.00 and \$12.00 a ton, at which figure it should be possible to secure it in British Columbia.

Two tons of iron ore approximately are required to produce a ton of pig iron. In the East this ore is worth at the furnaces about \$15.00, while in this province it could be had for about \$9.00, which is a liberal estimate. One and a quarter ton of Eastern coke is necessary to produce one ton of pig iron, which means an expenditure on fuel at present prices of about \$13.75, while before the war it cost something like \$4.00. Under these circumstances it would appear that British Columbia now would not be at a disadvantage in respect to the production of pig iron.

The cost of production in this province of one ton of pig iron, by blast furnace and under existing conditions as sketched, has been placed at \$33.00 as follows:—

Two tons of ore at \$4.50 .....	\$ 9.00
One and a half tons of coke at \$10 .....	15.00
Three-quarters of a ton limestone at \$4 .....	3.00
Labor and Overhead Costs, etc. ....	6.00
	<hr/>
	\$33.00

For purposes of comparison it is interesting to note that the last Eastern quotations available follow: Bessemer, \$42.50; basic, \$43.00; foundry, \$43.00 to \$45.00. While there are no official figures at hand regarding the Western market price of pig iron there is no doubt that with freight and cost of handling added the material would be much more expensive on the Coast. This is proven by the fact that the Purchasing Agent of Yarrows, Ltd., Esquimalt, on inquiry, stated that they paid \$75 a ton for their last shipment of pig. As to freight rates per ton of pig from Ontario it runs to \$14.80 a ton; from Quebec \$15.80; and from seaboard and U.S. points, \$16.60 a ton.

As to the market possibilities, which of course is a matter of the utmost importance, it seems to me that there is no doubt that the product of say a 300-ton blast furnace could be absorbed in the Canadian and American West. If there is any doubt of the market now available taking care of this product it seems to me that the time is opportune to ask the Dominion Government to assist by the installation at one of the Pacific Coast terminals of the two National Railways of car shops and all the manufacturing plant that that implies. Hon. J. D. Reid, Minister of Railways and Canals, is in British Columbia this week, and it seems to me that he should be approached to this end. I know that it was the fixed policy of the Mackenzie and Mann interests, had they been able to discharge the vast financial obligations they shouldered, to provide such car shops. Should the Dominion Government do this it would mean that a large part of the product of a 300-ton a day iron blast furnace would be taken care of and, no doubt, the establishment of the industry assured. This would be an indirect, though effective way for the Federal Government to discharge the responsibility it unquestionably has to assist in the opening up of our iron ore resources. As you know, it was mainly through the bounties and bonuses granted by the Dominion that the Eastern Canadian iron and steel industry was put on its present flourishing basis. If we cannot get this treatment it seems reasonable to ask that their railway policy be shaped along such lines as will result in the encouragement of the same industry in the West, where the native resources are of just as high quality and just as extensive. This, too, would

appear to be the moment to strike from the fact that the launching of the British Empire Steel Corporation merger, with a capitalization of \$500,000,000, has been announced within the past few weeks. Included in this combination are the iron and steel manufacturing interests of Eastern Canada, and the question occurs in considering the move, whether this tremendously powerful industrial and financial combination will retard or hasten our ambitions for an iron and steel industry in this province. Certainly it is not a time for sleep and British Columbia should not hesitate to strongly press her claims for recognition.

I draw attention to the fact that the Provincial Government has not overlooked or shirked its responsibility. This is evidenced not only by the fact that a bounty now is offered on the production of pig iron from British Columbia and which was last session extended for a period of five years, which, in the case of a 300-ton plant this bounty will entail an outlay of about \$1,000,000, but as well by the activity of my Department in the obtaining of all possible information regarding the resources of the province. We have had many applications for assistance for the establishment of an iron and steel industry from private enterprise, but thus far all have required the endorsement of bonds to from 50 per cent to the full value of the plant. The Government's position is that, if it is necessary to go that far, it would be better that the industry should be vested in the people and operated for the people's benefit. The assembling of data is continuing to the end that, if it becomes necessary, the Government will be in a position to give serious consideration, basing the same on authentic information, to the advisability of the announcement of some such policy.

Further remarks of the Minister dealt with the Government's policy to aid returned soldiers, and mentioned that 25 parties of soldier-prospectors are now in the field on a Government grubstake.

Lectures to prospectors during the winter months, and exhibitions of mineral specimens were part of the Government's plan to help intelligent prospecting.

At the request of the B.C. Prospectors' Protective Association the Resident Mining Engineers have been instructed to furnish brief preliminary reports of properties examined to the owners.

To stop "wild-eating"—which was the Government's aim—legislation has been passed providing that promoters of mining properties shall submit copies of prospectuses and advertising matter to the Resident Mining Engineers.

Mr. Sloan's evident thorough knowledge of the work of his department, and his references to the Government's policy in respect to the iron and steel industry, occasioned much enthusiasm, the Minister of Mines being accorded three hearty cheers on the motion of Mr. Carrington, of the Seattle Chamber of Mines. Mr. Sloan returned the compliment by calling for three cheers for the delegates from the United States.

C. B. Beale, His Majesty's Trade Commissioner, Winnipeg, delivered a very illuminating address, especially in regard to the splendid effort Great Britain is making to recover trade lost during the war, on the subject, "inter-Empire Trade Development." He dealt with the need of close co-operation with the Mother Country in the establishment of stronger inter-Empire trade ties.

W. Pellew Harvey, a former resident of B.C., when he was prominent in connection with the mining industry and for many years established professionally in London, England, addressed the Convention on the question of his mission to B.C. He said that it was generally admitted that the province possessed great mineral wealth, and he was here for the purpose of ascertaining as closely as possible, the position at the present moment; not for the sake of rashly investing,

but for the collection of data and where these justified, making recommendations to his clients who might feel justified and willing to come to the support of those interested in mining in the Province. Mr. Harvey referred to the geographical conditions of Kootenay, particularly in the matter of transportation, and compared it with Siberia, where all is open country and transportation, therefore, an easy matter. After complimenting the Department of Mines on what it had done to make the obtaining of accurate information an easy matter, and also on what was being done for the encouragement and assistance of the prospector. Mr. Harvey spoke of the Trail Smelter and the tremendous work it was doing for the mining industry in this part of the Dominion. This plant handled 66 per cent of the total mineral production of the province. It might help, he suggested, if a subsidiary interest could be created, possibly supported by the Consolidated, whereby local camps and districts producing small quantities of ore, although probably large in the aggregate, could have a customs concentrator. Something also might be done in the way of establishing test centres to grade the ores for future treatment by smelters.

A number of resolutions were passed. One of these has reference to the activity of the One Big Union in the Sloean and other interior districts. It puts the delegates on record as emphatically condemning any species of radicalism which is a menace to the prosperity of the mining industry of B.C., and calls upon the Dominion Government to make immediate investigation of the baneful effect of these activities, and to take such action as will restore prosperity by guaranteeing to every law-abiding citizen, "the right to work where, when, and for whom he pleases, safe from the unlawful interference of any kind whatsoever directed by those who seek destruction of the free institutions under which we live, and to which we hereby pledge our continued and unyielding allegiance. And it is further Resolved," the Resolution continues, "That we condemn in unqualified terms any employer of labour who, in furtherance of selfish interests, panders to any organization of disloyalty whether flying the banners of One Big Union, or I.W.W. or the plain red flag of Anarchy."

Copies of this are to be forwarded to the Ottawa authorities.

Another resolution was submitted by the B.C. Prospectors' Protective Association petitioning the Minister of Mines, Ottawa, to throw open the Indian Reserves in B.C. to mining operations for all minerals. It was pointed out that the Provincial Government has amended the Mineral Act and the Placer Act permitting the mining of gold and silver on these Reserves. As, however, the precious metals almost invariably are found associated with the base metals, the privilege granted by the said amendment means very little, if anything.

No account of the Convention would be complete without a reference to the mineral exhibit and to the indefatigable and successful efforts of Fred A. Starkey, who was in general charge of the arrangements and the conduct of the programme, for the entertainment of the visitors.

As to the exhibit, it may be said to have been one of the most complete of the varied ores of the Kootenays it has been the privilege of the writer to inspect. Practically every shipping mine, whether large

or small, was represented, and it was an education in the mineral resources of Eastern British Columbia to make the circle of the tables containing the samples, all of which had been clearly labelled. A large specimen of the Mandy Mine, Le Pas, Manitoba, and a small cabinet of the rarer minerals, many of them not as yet discovered in British Columbia, which has been loaned by A. G. Langley, District Engineer, were among the many features accorded special attention.

Fred A. Starkey and his energetic assistants are to be congratulated on the success of the Convention from whatever angle it may be viewed.

### BOOK REVIEW

A STUDY IN CANADIAN IMMIGRATION. By W. G. Smith. The Ryerson Press, Publishers, Toronto. Linen Boards. 5 by 8 inches. 406 pages. Price, \$3.00

The preface of this book announces that it has many defects, but a perusal of the work reveals that its defects are not those of its author, but reside in the incomplete character of our vital statistics, and the difficulty of interpreting figures that are incomplete, and of too short a duration to enable critical elucidation and analysis. Not that the mass of statistical information in this work is meagre, for it contains sixty-one tables that must have cost the author tremendous labor to compile.

As an example may be mentioned the attempt to trace the percentage of infirm and defective persons in Canada among the various contributory sources of our population. Statistics of this kind are useless unless they contain data as to the ages of the persons considered, and the large percentage of infirm persons shown by the statistics to be of native Canadian origin is doubtless due to the number of elderly persons included, whereas the immigrant population, at any given time, naturally contains persons that are, in the phrase of the insurance actuary of "effective age," and are, by natural selection, neither very young, nor very old.

The author is an optimist on the ability of Canada as a "melting-pot" of nationalities, but he points out with clearness the dangers of indifference towards the strangers in our midst, and the undesirability of allowing foci of extra-national culture to multiply in our midst. He says, with fine fervor, and much truth, "What is needed is a new crusade of young Canadians 'in whom the fires of patriotism burn, who will man 'the outposts of Canadian nationality.'" He points out the hardships suffered by the immigrant, who he describes as "the lineal descendant of the forgotten pioneer, and like the pioneer achieves competence and prosperity." The problem of the immigrant is the problem of the Canadian people, who through their Government have advertised abroad and solicited the emigrant at home. The author points out how many millions of money have been spent in solicitation of emigrants, and how little in comparison has been spent to retain and incorporate the immigrant into our national fabric when arrived.

We have always considered that the work of the "Reading Camp Association," now known as the Frontier College, one much needed in Canada, and those who have read "A Handbook for New Canadians," by Mr. Alfred Fitzpatrick, will find in it the

answer to many of the questions raised by Mr. Smith's book. As Mr. Fitzpatrick pointed out, and as Mr. Smith intimates also, the newly arrived immigrant in Canada is the prey of his environment and too often of his own countrymen, who because of their knowledge of the immigrant's language are too complaisantly allowed to control their compatriot's housing, supplies and general destiny in Canada. Tutelage in Canadian institutions, in the English language, and in citizenship is required to assimilate the immigrant, and Mr. Smith says truly: "A thousand new teachers in as many teacherages would mean the beginning of a new day."

"In time of war a half million of our best were enlisted in a gigantic struggle of destruction. In times of peace can there not be a brigade or two of equally ardent spirits who will engage in the work of construction?" The Frontier College would seem an organization ready to hand for a work that recent events have revealed as desperately necessary.

Mr. Smith advocates restriction of immigration in lean times, and stricter supervision of incomers in good times. He asks for inspection of emigrants at the point of departure, and suggests the throwing of greater selective responsibility upon the steamship and other agencies that earn dividends by bringing emigrants to Canada. He pleads for a large and adequately equipped institutions like Ellis Island at several points of main entrance into Canada, and asks that regulation of immigration shall be planned with a view to the tremendous scale on which it may be expected in years yet to come. Due credit is given to improvements in the Immigration Law, but it is suggested that larger measures are required in the proportion that immigration may be expected to be larger in coming years.

Mr. Smith has presented a lot of problems that he has not attempted to answer, but his book contains many statistics in understandable and convenient form which may lead enquirers to a better grasp, if not a solution, of the individual problem they themselves are faced with in connection with immigration.

We commend the work to officials of Canadian corporations who desire the foreign workman, to employment and welfare officers.

After perusal of the volume we would summarise the desirable conditions in connection with immigration to include the following. Careful selection of the country in which emigrants are to be solicited. Some countries—Finland for example—seem to yield undesirable elements in large proportion. Agreement with the government of the emigrant's country on the lines laid down by the Italian government and designed to protect against exploitation of the emigrant by his own compatriots both during his journey to Canada, and after his arrival there. Examination of intending emigrants at or previous to embarkation for Canada. Enlarged and centralized examination and detention facilities at the point of debarkation in Canada. Continued interest in the immigrant in his sojourn in Canada, and a deliberate and widespread campaign for his Canadianization, including discouragement of all forms of national segregation and the formation of communities in Canada detached from Canadian influences. Unless we Canadianize our immigrants then we risk the un-Canadianizing of Canada.

# Coal Supply and Prices in Canada

By The EDITOR

In Nova Scotia the coal companies are selling coal for local domestic consumption at prices which are reasonably low, and netting only a small margin of profit over cost of production, namely at from \$5.50 to \$6.00 per ton for run of mine coal, with a differential of 35 cents for screened coal. There is no shortage of coal in the Maritime Provinces, and an increased quantity of coal is being produced from small mines having a local sale, particularly in the vicinity of New Glasgow and Amherst.

The cost of coal in Newfoundland is unprecedentedly high, running up to \$35 per ton delivered in the consumer's cellar. Prospecting for coal is being actively carried on in Newfoundland under pressure of the demand and high prices, and, while coal mining in Newfoundland can never be a very large industry because of the small and contorted character of the deposits, it will eventually, like the coal deposit of New Brunswick, develop into a valuable local source of supply. Newfoundland, like the mainland is suffering from lessened efficiency of transportation, and during the war suffered a great decrease in the number of vessels available for coal freighting.

The Nova Scotia coal companies have been able to keep Halifax and St. John well supplied with coal, and at Halifax there has recently been a decided falling off in the demand for steamship bunkers.

The situation in Montreal is singular. Many of the local coal merchants have contracted with their customers for coal supply at comparatively low prices, figures in the vicinity of \$3.75 at the mine being general. The coal companies are unable to deliver coal at the contracted prices, but there is no difficulty in obtaining "spot coal" at prices double and treble the figures at which deliveries were promised. This refers to bituminous coal.

Anthracite is selling retail at \$16.50 per ton in Montreal, and an increase of fifty cents is expected immediately.

The condition of affairs in Montreal is understood to be general in the New England States, where the same complaints as to non-fulfilment of contracts and the availability of "spot coal" at enhanced prices are heard.

In Toronto, retailers to domestic customers are quoting run mine bituminous at from \$14.25 to \$14.50 per ton delivered. Anthracite is quoted at from \$8.00 to \$11.50 per ton at the mines in American funds.

Many of the larger manufacturing concerns in Ontario and Quebec are uncertain regarding their operations during the coming winter. Stocks are non-existent, and a considerable amount of unemployment is even now being caused by curtailment of operations caused by coal shortage. The position of manufacturers is illustrated by the published remarks of the Purchasing Agent of the Canadian Consolidated Rubber Company, who states that this Company's requirements of coal run to about 80,000 tons annually, and that this quantity will cost approximately \$1,000,000 more than it did last year—if purchased. This official stated that he had bought Dominion Coal Company's coal throughout his Company's history, until the supply ceased.

Indication of the cost of U. S. coal in Manitoba is

given by the prices at which the provincial government has let contracts for its winter supply. Ten thousand tons of Yougheogheny slack have been contracted for, 7,000 tons for the Government powerhouse at \$15.25 per ton delivered and 3,000 tons for the Manitoba Agricultural College at \$12.75 per ton delivered. For other provincial establishments at Brandon and Portage la Prairie, Souris run mine is being purchased.

In British Columbia, the collieries are not being pressed for coal so hardly as in the East. In Alberta, notwithstanding the appeals of the Government and an extensive advertising campaign, the collieries are not working to capacity, and the members of the coal trade there are very justly indignant at a report which was given wide circulation in the East that the western collieries had a local market which was absorbing all the production. Nothing of course could be further from the truth. Alberta collieries never at any time, even in the strenuous period of 1917-1918, worked to full capacity.

High as coal prices are throughout Canada, they will certainly go very much higher as the result of the new wage agreement in District No. 18, the pending demand of the U. M. W. in Nova Scotia, and the general wage increase in the bituminous and hard coal districts of the United States, added to which there will be the freight rate adjustment required to enable the railways to pay the increase recently granted in the U. S., and the corresponding increase which will be given to railway men in Canada.

There is a phase of the coal question in Canada that is not fully understood, namely, that coal has not in recent years been used as freely as it would have been if supplies had been easier to obtain, and prices lower. There are a great many manufacturing enterprises mooted that have not been able to proceed because the promoters could not see their way to a stable coal supply. It is moreover not appreciated that the capacity for coal consumption, and the per capita use is a growing one. Many past calculations on coal supply have been falsified by neglect to take into account the growing factor of per capita consumption, and it may surprise many persons to know that the consumption capacity of Ontario alone is 12,000,000 tons of bituminous coal annually, or almost equivalent to the entire coal production of Canada. Calculations based on coal consumption rates of several years ago are entirely out of date, and will certainly lead to erroneous conclusions.

With regard to the efficacy of an export embargo in assisting the present crisis it is necessary to take both a backward and a forward view. The outstanding necessity in connection with our coal supply in Canada is to greatly increase the output capacity of the existing collieries, and to provide new collieries. The financial weakness of Canadian coal operators is due to the inconsiderate and almost contemptuous treatment they received at the hands of large coal consumers in Canada in years gone by. They were compelled, in order to hold their organizations together, to sell coal at prices which were actually below the ultimate cost of production, although possible they slightly exceeded the aggregate cost of labor and material at the time of purchase. Today, owing to con-

ditions in Europe very high prices can be obtained for export coal and the coal companies have a chance to make money. The profits thus obtained are vitally necessary to the provision of capital for the increase of production. The actual assistance in tonnage that will be obtained by an export embargo is utterly negligible in comparison with the actual shortage in production. The shortage of production outweighs the export tonnage ten to one, and if, as intimated by the Railway Commission, is should be considered that not only an export embargo, but price control, is to be imposed on Nova Scotian coal producers, it should not be forgotten that the crisis of this year will be the the crisis of 1921, and every year thereafter, so long as Canadian coal production does not appreciably increase.

There has recently been a turn in production in Nova Scotia, and what is more important than anything else, the Dominion Coal Company has announced the resumption of capital expenditure that has been deferred seven years.

This journal has on many occasions pointed out that what is required in Canada is not a coal "controller," but a coal "booster." More men engaged in coal-mining, more money invested in coal mining, more coal produced from Canadian mines, are things earnestly to be desired.

**WORLD'S COAL OUTPUT.**

The monthly **Bulletin** of statistics of the Supreme Economic Council for May states that in the case of coal the latest available figures for the United Kingdom, Belgium, France, and Germany indicate on the whole progress in the direction of the rate of production of pre-war days. The following table compares the aggregate average quarterly output of these four countries as a whole in 1913 with their quarterly output during 1919 and 1920:—

Period	Excluding Comparison German Lignite with 1913.	
	Metric tons	Per cent.
Quarterly average, 1913 ..	132,000,000	100.0
1st Quarter, 1919 . . . . .	98,100,000	74.3
2nd Quarter, 1919 . . . . .	90,900,000	68.9
3rd Quarter, 1919 . . . . .	92,100,000	69.8
4th Quarter, 1919 . . . . .	105,000,000	79.5
1st Quarter, 1920 . . . . .	107,100,000	81.1

In the case of the United States the quarterly production of coal has increased from an average of 129 million tons in 1913 to 142 million tons in the first quarter of 1919. In consequence of the inability of the United Kingdom to export as freely as formerly, European countries have turned to the United States for supplies, and are now obtaining about 1,400,000 tons per quarter from that source.

**TORONTO COAL PRICES.**

Toronto, August 11.—Toronto coal dealers have been advised that on August 16th there will be an advance on the freight rates on all classes of coal on the United States side of the line. The new anthracite wage scale has not been announced but reports indicate that it will amount to one dollar a ton under the new scale. The freight advance for the Canadian market will probably be one dollar a ton on anthracite and from 50 cents to 75 cents a ton on soft coal. Prevailing quotations at Toronto; Mine run \$14.25 to \$14.50 f.o.b. Toronto; smokeless coal \$14.50 to \$15.00; hard coal \$8.00 to \$11.50 gross tons at mines, American funds.

**STATISTICS OF ANNUAL PRODUCTION OF ANTHRACITE AND BITUMINOUS COAL IN THE UNITED STATES.**

The following figures of the annual output of anthracite and bituminous coal in the United States, taken from "Saward's Journal" New York, form a useful reference.

It should be mentioned that the anthracite figures, showing as they do the total production, and being reported as they are in net tons by the Geological Survey, differ materially from the report of tonnage shipped as reported in gross tons by the Anthracite Bureau of Information. Roughly speaking, the Survey figures will be found to be about 25 per cent. more than the Bureau figures, the difference increasing in recent years because of more coal being used at the mines.

**Coal Production—Net Tons.**

	Coal Production Net Tons	
	Anthracite	Bituminous
1890 . . . . .	46,468,641	111,302,322
1891 . . . . .	50,665,431	117,901,238
1892 . . . . .	52,472,504	126,856,567

1914 . . . . .	90,821,507	422,703,970
1915 . . . . .	88,995,061	442,624,426
1916 . . . . .	87,578,493	502,519,682
1917 . . . . .	99,611,811	551,790,563
1918 . . . . .	98,826,084	579,385,820
1919 . . . . .	86,200,000	458,063,000
1920* . . . . .	42,780,000	257,010,000

\*Six months.

**NOVA SCOTIA COAL INACCESSIBLE TO ONTARIO BY RAIL.**

In reply to the enquiries sent out by the Windsor, Ont. Board of Commerce, three Nova Scotia coal companies have stated that their coal output is covered by enrrtent commitments. The replies received also suggest that the rail carriage from Nova Scotia to Ontario points would make the delivered costs prohibitive.

The Nova Scotia Steel Company, in its letter, stated: "Ontario has never given proper consideration to the coal question, as it has heretofore been able to obtain all the coal it required from the United States at a low cost, and therefore, gave little heed to developing the Canadian coal industry."

**NOTES FROM THE NOVA SCOTIA COLLIERIES.****Changes in the Mines Office Staff.**

Mr. R. D. Anderson, an official of long service in the Mines Office at Halifax, has taken a position as technical adviser to the Inverness Railway and Coal Co., as newly organized. Before going to the Mines Office Mr. Anderson was connected in official positions with the Glace Bay collieries, and is well equipped for his new position.

Mr. Michael Mc. Intosh, for a number of years Inspector of Mines for the Waterford District, has resigned from the service of the Government, and has been appointed to special duties connected with the cost of colliery materials by the Dominion Coal Company. Mr. Mc. Intosh is returning to the Dominion Company, having previously been manager of one of the Waterford collieries.

Another official of the Mines Office, Mr. J. J. Mc. Neill, recently returned to a position as colliery manager with the Dominion Company after having for several years been Inspector of Mines in the Glace Bay District.

**COAL PRODUCTION.**

The Nova Scotia Steel and Coal Company's collieries in July raised 51,472 tons, which compares with 43,713 tons in July 1919. For the seven months ending July the production for 1920 is 315,329 tons, being 82,000 tons in excess of the corresponding period of last year, equivalent to an increase of one third.

The Dominion Coal Company's production from the Glace Bay collieries during July was approximately 268,000 tons, or 13,000 tons below the output for June. For the seven months period the production during 1920 has been 1,883,000 tons, or slightly less than 100,000 tons higher than for the corresponding seven months of 1919. June production of 268,000 tons compares with 224,000 tons in June 1919. The production for August is unlikely to exceed that of July.

**British Columbia Letter****THE COLLIERIES**

The Cassidy Collieries of the Granby Consolidated Mining & Selting Co. have been closed down for over a week. Just what the trouble is cannot be said although it is known that it has its source in demands of the men. Whether these demands are for increased wages or for recognition of an organization the employers do not care to have anything to do with is the question. It is denied, however, that more wages are asked for and it cannot be that better living conditions are being sought for the Cassidy Collieries are a model in this respect. The only possible difference, therefore, would appear to be in respect of the recognition of some organization among the men. Operation of the mine stopped when the men called a holiday to formulate their demands. The management, thereupon, met the miners by making the desire for a holiday appear unanimous and formally closing down the property. Their explanation is that the bunkers were full and that difficulty was being experienced in marketing the product. Among those familiar with the situation this is not taken too seriously, especially in view of the fact that all the other coal mines of Vancouver Island are working as near to capacity as the labor conditions permit

and also having in mind that the orders for the product are far in excess of the output. There, however, still is a holiday at Cassidy. The deputy Minister of Labor is investigating the trouble and it is hoped that his intervention will result in a settlement.

The first British Columbia coal to be shipped to Europe left Vancouver Island on or about July 28th. It consisted of 4,500 tons of the product of the Canadian Collieries (D) Ltd, and is being carried by the motorship Pacific of the Johnson Line to Sweden. J. M. Savage, general manager of the Canadian Collieries, states that many inquiries are being received from Europe as to the possibility of securing coal from the Pacific Northwest. The present prices here are said to be comparatively low and, as the shortage on the continent is acute, purchasers are driven to all possible sources of supply. The development of this new trade between British Columbia and Europe will be watched with interest.

A mass meeting was held recently at Fernie when the question of ratifying the new wage agreement in U.M.W. District No. 18 was considered and the question of allegiance to the U.M.W. of A. and the One Big Union was debated. In view of the fact that the agreement was negotiated between the Operators and the U.M.W. of A. this organization appears to have had the best of the argument. The miners afterwards marched en masse to the office of the Crow's Nest Pass Coal Co. and conferred with the management. What occurred has not been announced, but the mines have up to the time of writing have been working without interruption.

The Wellington—Nanoose Collieries, operating the Nanoose Bay Mine, has been completely re-organized and the mine henceforth will be known as the Lantzville Mine. X. Louis Williams is the chairman of the Board of Directors; F. H. Lantz, the managing director; and J. A. Coleman, the secretary. Over \$100,000 has been spent during the past year in improvements to the pithead equipment. New wharves have been built, a new "Link-Belt" screening plant installed, and a new washery capable of handling 500 tons a day erected. The slack from the washery is used for firing the boilers and electric power and light is generated from a 250 volt Robb dynamo, while an Ingersoll Rand Compressor of 150 lbs. capacity also has been installed. Edward Floyd, an English mining engineer with experience in the coalfields of Northumberland, has been appointed superintendent. The Lantzville Mine is situated on a beautiful townsite and it is proposed starting immediately on the construction of such houses as are necessary for the comfortable accommodation of officials and men.

Extensive coal deposits situated in the Copper River District, Northern British Columbia, are being inspected by engineers and representatives of Canadian financial interests with a view to their development. This field is located on Chettleburgh Creek, a tributary of the Zymoetz River, about thirty miles from the town of Smithers. There are seventy-five leases on which two good seams of coal have been exposed, respectively nine and six feet thick. The latter have been slightly developed by short prospect tunnels. A lot of exploratory work has been done and the

measures are exposed on Chettleburgh Creek for a distance of two miles. A diamond drill was taken to the property in 1913 but was never used.

British Columbia's production of coal for the month of June aggregated 239,566 tons, of which the Vancouver Island mines were responsible for 149,973 tons and those of the Mainland for 89,593 tons.

The detailed figures follow:

<b>Vancouver Island Field</b>		Tons
Canadian Western Fuel Co., Nanaimo . . . . .		56,474
Canadian Collieries (D) Ltd., Comox . . . . .		41,426
Canadian Collieries (D) Ltd., S. Wellington . . . . .		6,887
Canadian Collieries (D) Ltd., Extension . . . . .		14,087
Pacific Coast Coal Co. . . . .		8,662
Nanoose-Wellington Collieries Ltd. . . . .		1,427
Granby Collieries, Cassidy . . . . .		21,010
		149,973
<b>Mainland Fields</b>		
Crow's Nest Pass Coal Co. . . . .		62,770
Corbin Coal Co. . . . .		15,048
Middlesboro Collieries . . . . .		7,882
Fleming Coal Co. . . . .		2,730
Coalmont Coal Co. . . . .		1,163
		89,593

Some interest has been created in Southern Vancouver Island through the publicity given to the recent experience of a resident of Victoria in the person of James Rennie who, while exploring the Sooke River Country happened upon the remains of the once thriving mining town of Leachtown. Recalling stories of the placer excitement of the locality half a century or more ago Mr. Rennie decided to put in some otherwise idle moments in testing the sands. Searching he found what appeared to be virgin ground and a little panning brought surprising results. He returned with seventeen nuggets, none very large but some were very much worth while. It is understood that the ground is to be staked and that an effort will be made to perfect arrangements for placer mining operations on a considerable scale.

#### PERSONALS.

Mr. J. B. Tyrrell has returned to Toronto after visiting gold properties in Northern Manitoba.

Mr. H. H. Sutherland has returned to Toronto after several months absence in England where he has been enlisting capital for the development of gold properties in Northern Ontario.

Mr. J. S. DeLury who has completed an examination of the Rice Lake gold area for the Manitoba Government has returned to Winnipeg.

Mr. Jas. McEvoy has not yet returned from Alberta. His address there is c/o Cadomin Collieries, Cadomin, Alberta.

Mr. A. G. Burrows is in Toronto for a few days. He will return shortly to Gowganda where he is making examinations for the Ontario Bureau of Mines.

Mr. P. E. Hopkins of the Ontario Bureau of Mines staff is working in the vicinity of Schrieber, Ontario. He will later visit some Western Ontario gold areas.

Prof. M. B. Baker of Queens University is making geological examinations in Leeds Co., Ont., for the Bureau of Mines.

#### INTEREST IN GOLD MINING QUICKENS.

Increased activity in gold mining in the Porcupine district is indicated by recent announcements concerning properties that are not at present producing. Arrangements have been made for the resumption of work at the Porcupine Crown, Vipond and North Thompson which are in the vicinity of the Hollinger and developments at the Dome mine are awakening interest in the possibilities of the neighboring property, Dome Extension. A Toronto syndicate headed by H. B. Wills has undertaken to supply the treasury of the V. N. T. company with a sum that should put it in a position to operate the mine. The shareholders have accepted the offer made by the syndicate and it should not be long before the result of the financing is apparent at the property. It is announced that the syndicate will take of the treasury stock 200,000 shares at 15 cents, 200,000 at 30 cents and 200,000 at 50 cents.

The interest in Dome Extension is a result of the increased likelihood that the Dome company will exercise its option on the Extension property and develop it. The announcements concerning these mines is reflected in the stock markets. The trading in V.N.T. and Dome Extension is much more active than for some time.

The Kirkland Lake gold district is also attracting more attention now than for some time. Good progress has been made in exploring the surrounding area; but the more advanced properties have for many reasons been delayed in development and the outlying properties have not received the attention that they will when the older mines are operating at capacity. There are now rumors that a merger of some of the mining companies is likely to be effected and this is taken to mean that very considerable advantages will accrue to all the operators in the district. Vigorous development of the mines in this area will give new life to the prospectors working in the district.—R.E.H.

In Northern Ontario, the announcement made by Hon. Harry Mills, Minister of Mines in the Ontario Cabinet, that short courses for prospectors would be carried on in a half a dozen northern centres during the coming winter, has been greeted with interest among mining men. The courses are one of the units in the Provincial Government's plan for greater development of the mineral resources of Ontario. Schools will probably be opened in Haileybury, Sudbury, Timmins and one or two other centres. The course will last about six weeks and prospectors who attend will be taught the elementary principles of geology, to provide them with a sufficient knowledge of rock formations to enable them to judge the possibilities of a district with greater facility. General training will be given in sampling ores, testing values, etc. All courses will be free to prospectors. The Ontario Government will probably establish an assay office at Kirkland Lake, miners and prospectors will be able to obtain free assays of any ore they may discover.

The Denver Rock Drill Manufacturing Co., manufacturers of rock drills and accessories, of Denver, Colorado, will open an office at 421 Manhattan Building, Duluth, Minn. It is expected that the branch there will be ready for business on Aug 1st.

# Northern Ontario Letter

## THE SILVER MINES.

### The Cobalt Field.

From available figures, the indications are that silver production from Northern Ontario is now a little under one million ounces monthly. At 95 cents an ounce which is the quotation at the time of writing, and plus 13 per cent premium on New York funds, the value of the output is at the rate of over \$1.07 an ounce in Canada, or not far under million dollars monthly.

For the first half of the current year, due to silver having averaged a fraction over \$1.18 an ounce, the indicated output had a value of over six million dollars, but with the lower average now prevailing, it is believed the total for 1920 may not exceed eleven million dollars.

Under the circumstances, and in view of the mines being about sixteen years old, the decline above noted is not heavy. The indicated output of \$11,000,000 for this year compares with \$12,747,621 for last year. Indeed in 1914 the value of the output amounted to only \$12,765,461, while in 1915 it was valued at \$12,135,816 and in 1916 at \$12,643,175. From these figures, it is to be noted that the measure of prosperity being enjoyed in a general way is being well maintained.

Production from the newly opened Bailey Silver Mines has not materialized at as early a date as had been estimated. During the past week, A. J. Young, president of the company, visited the property, and was apparently pleased with the progress made, however. Among other things, financial arrangements have had to be made, and it is now estimated that ore will be going to the company's mill within the next month or six weeks. In the meantime, the Bailey mill, which was formerly the Northern Custom Concentrator, is realizing quite large gross earnings, and net profits are said to range from \$2,500 to \$5,000 monthly from treating customs ore.

The La Rose Consolidated will employ a diamond drill for the purpose of exploring certain parts of its Cobalt property. It is planned to move the machine to the property at once, and although the more promising parts of the mine have been pretty well explored, the past history of these old Cobalt properties leaves much room for additional zones of enrichment to be encountered. Those who have followed the history of such mines as the La Rose are not yet convinced that all the ore bodies have been opened up, and any exploration work that may be carried on presents possibilities of new favorable developments.

Reports recently in circulation that the Mining Corporation might purchase a part of the Right-of-Way Mines, lying beneath the railway adjacent to the Mining Corporation, are said to have been unfounded.

A diamond drilling contract is being let on the Cobalt-Mohawk property, situated near Gillies Depot, in the vicinity of Mud Lake. Veins opened up in the early days of Cobalt, contain considerable smaltite, with low silver values. It is planned to tap these veins at depth. Petrolia business men are involved in the enterprise.

Drifting operations are under way at the 150 ft. level of the Oxford-Cobalt. The values at this point are comparatively low, although the vein itself has a width of about eight inches and contains some smal-

tite. It is learned that the plans are to continue the shaft to a depth of perhaps 300 or 350 feet, at which point further lateral operations will be undertaken. It is believed the chances of finding silver at this lower horizon will be much greater than at the present point for the reason that such work will be fairly close to the contact. The Company has studied the lesson learned at the Temiskaming mine where over 75 per cent of the silver so far mined came from within 100 feet of the contact of the overlying Keewatin with the underlying diabase.

Reports that the Beaver Consolidated has over a quarter of a million ounces of silver bullion stored at the mine, have received official denial, it being stated that the report has no basis in fact.

### Ore and Bullion Shipments.

During the week ended August 6th, three Cobalt companies shipped an aggregate of six cars containing approximately 514,123 pounds of ore. The Nipissing, with four cars was the heaviest shipper.

A summary follows:—

Shipper	Cars	Pounds
Nipissing . . . . .	4	346,718
McKinley-Darragh . . . . .	1	84,950
La Rose . . . . .	1	82,452
Totals . . . . .	6	514,123

During the corresponding period the Mining Corporation and the Nipissing shipped bullion, the Mining Corporation sending out over a hundred thousand ounces on the closing day of July.

Following is a summary:—

	Bars	Ounces
Mining Corporation . . . . .	99	100,573
Nipissing . . . . .	15	20,533
Totals . . . . .	114	121,106

### The Elk Lake Field.

In the Cane and Auld township section of the Elk Lake district, renewed activity is taking place. This includes the Cane Silver Mines, the Triangle Silver Mines, and the Legault property. On the Triangle, a plan is being carried out to have 400,000 treasury shares underwritten, and to use the proceeds in further development as well as putting in a mill of small capacity to treat the medium grade mill rock being encountered. On the Cane Silver Mines, the company is said to have bought the original Elk Lake owners out, and to now be preparing to do considerable work. Work was commenced this week on a moderate scale, Jack Byrne, formerly associated with the Bourk's Gold Mines being in charge of the work. An endeavor is being made to interest one of the Cobalt Mining Companies in helping to finance the work. On the Legault property, lying about one mile south from the Cane property, an examination is now being made by J. Houston, and a deal is said to be pending.

In the immediate vicinity of Elk Lake, the Paragon-Hitcheock property is preparing for aggressive work. It is planned to perhaps secure a small plant for handling the ore right at the property. This company may be reached by mail to Elk Lake, Ont., while the address of the Triangle Silver Mines is Kenabeek, Ont.

### The Gowganda District.

Uneasiness is made manifest in the Gowganda dis-

trict in connection with the slow progress being made in regard to the proposed light narrow-gauge railway from Elk Lake to the Gowganda field. With the Ontario Government having discontinued work last spring on the macadam road which had been commenced during the previous year, and with no definite assurance as yet of a light railway, the property owners are left to bear the full weight of totally inadequate transportation facilities.

The amount of work being done quietly in the Gowganda district is very considerable. With the Miller Lake-O'Brien serving to spur on to greater extent the hope of other property owners, and with success being met with on the Castle property of the Trethewey Company, and with the Reeve-Dobie on a fair way to make a success of producing silver, together with other favorable results in various parts of the field, it is regarded by mining men as a great pity that the Ontario Government has adopted a policy of indifference to the transportation difficulties of this partially proven and extremely promising silver field.

Another demonstration of confidence, and a real exhibition of that spirit which is conquering the great new problems which confront the pioneers of the mining industry of Northern Ontario is contained in official advice from the Dominico Mines Co. Inc., of Rochester, New York, regarding the Big 4 Mines of Gowganda.

Last spring this company launched a scheme to develop their 155 acres of mining lands in the Gowganda field. More than one year's wood supply having been cut, the company commenced the installation of a steam-driven mining plant. The spring proved to be one of the driest on record, and bush-fires in that district got out of control, completely destroying the plant, as well as burning up the fuel supply. In doing this, the fire appears to have made the property safe from a re-occurrence of such a fire, and has led the company to decide upon installing more modern equipment. Accordingly, an oil-driven mining plant is to be purchased at once.

The directors have just concluded a visit to the property and were highly pleased with the outlook. The main vein is stated to contain a large amount of the metal cobalt, this running as high as nearly 20 per cent. Silver values are said to amount to around 26 ounces to the ton.

A more or less peculiar occurrence is a large dyke of iron sulphides on the property in which the sulphur content is said to amount to from 40 to 44 per cent. It is believed this deposit may also be worked at a profit.

Among those visiting the Big 4 were the following:

Dr. Carl H. Huber, who is president of the company, together with John C. McCurdy, James J. Withall, J. Wilson McCleary, all of Rochester; as well as W. W. Jones, of Albany, N. Y., who is State Mine Inspector, and H. L. Holmes, of Buffalo, N. Y.

### THE GOLD MINES.

A matter of very considerable concern to gold mine operators in Canada is the announcement to the "Canadian Mining Journal" that the two leading gold mines of Poreupine, namely, the Hollinger and the Dome, have each ordered a carload of low-grade cyanide from the American Cyanamid Company, from Niagara Falls, Ont. These companies will conduct a thorough test with a view to determining whether or not it would be possible for this cheaper material to

replace the high-grade cyanide which the mines are now importing from Glasgow, Scotland.

It is estimated that the Dome could save about \$15,000 annually by using the low-grade material, while the Hollinger might save at least double that amount, provided, of course, satisfactory recovery results from its use. The recent increase of two cents a pound for Cassel cyanide appears to have caused the Hollinger and Dome to decide to give the American Cyanamid product a trial.

The Hollinger Consolidated being one of the largest gold mines in the Western Hemisphere, and the Dome being the second largest in Canada, the attention of cyanide consumers in general are directed to the result of the experiments now to be undertaken.

Another matter of much interest, although local in its scope, is the decision of British interests to carry on extensive diamond drilling operations on property lying west of the proven Poreupine gold zone, in that part of Mountjoy township lying adjacent to Tisdale. The property to be explored is covered with a heavy overburden of sand, in fact is a veritable sand plain. The diamond drill is expected to show whether or not the geological conditions peculiar to the Hollinger-McIntyre part of the Poreupine field extend west south-west beneath the sand plains. A maximum of ten thousand feet of drilling may be done as the first part of the scheme. The drilling is to be done by Mr. Reid, a diamond drill operator of Timmins, while Ernest Loring of Haileybury will supervise the work.

Rumors are current that the Bewiek-Moreing mining interests may re-enter the Poreupine gold mining area, and this time indulge in active mining operations. The plan of procedure has not yet been definitely stated. It will be recalled that this company of speculators entered the Poreupine field in the early days and that had their lead been followed there might be no producing mines in that rich district. One of the chief pieces of work done was to build an elaborate office on the shore of Pearl Lake. The other was to purchase a block of Hollinger stock, which was held until the price went up a few dollars, and then to throw the whole lot on the market. Whether or not the Bewiek-Moreing interests expected stock to break in price and then buy in the amount sold is not clear. At any rate, such an opportunity did not develop. Their next line of attack at this late date is expected to be of a somewhat different nature and be along the lines of real development work.

### The Kirkland Lake District

Hamilton B. Wills, stock broker of Toronto, is asking the Orr Gold Mines to contribute 810,000 shares to him in return for nearly \$200,000 which he claims to have spent through the now liquidated Kirkland-Porphry Company during the currency of an option held by that concern, and the assets of which have now been purchased by Mr. Wills and Conrad Wettlaufer of Buffalo. It is not stated whether or not the request is based upon legal merit, or finds support in moral right. The Orr treasury contains only a little over 900,000 shares, and such an issue of 810,000 shares to the Wills' interests would leave the treasury in a depleted condition and would perhaps lead to a capital increase of perhaps another 500,000 shares with which to finance work and build a small mill.

The Hunton-Kirkland plant is completely installed and mining operations are commencing this week. It is planned to sink the shaft to a depth of 300 feet at which point lateral operations will be undertaken. This depth has been selected for the reason that at

this horizon all the operating mines have found some of their richest deposits. Due to the surface showings on the Hunton being exceptionally rich, although narrow, the work to be carried out during the next few months promises to be the center of more than ordinary interest.

There is said to be no truth in rumors about the Hunton-Kirkland joining the Orr Gold Mines in a scheme of consolidation.

Final details are being arranged in connection with transferring scrip in the Kirkland Lake Proprietary, 1919, for old shares in the Tough-Oakes mine. Once this is completed, the new company will proceed with taking over the control and operation of the Tough-Oakes mine.

#### Steady Work at Boston Creek.

Cross-cutting at the 500 ft. level of the Miller Independence Mines is proceeding unremittingly, and the face of the cross-cut is now nearing the point where the downward continuation of the main vein is expected to be encountered. The cross-cut is now in more than 300 feet and is going ahead at the rate of 100 feet a month.

Some rich ore has recently been bagged on the Peerless Gold Mines, about twenty sacks of this material being ready for shipment. The ore is said to contain high silver values, as well as gold.

Good progress is being made on the work of building a wagon road as well as a bridge over the Blanche river so as to provide improved transportation facilities for the Skead township gold area.

#### At Fort Matachewan.

It is learned that there is very little likelihood of the Matachewan Gold Mines resuming operations for some little time, and that work may be deferred until such time as electric energy is assured following the harnessing of a water-power on the Montreal River. This power development scheme is not making very rapid progress.

On the Thesaurus property situated in the township of Baden some little distance north of Fort Matachewan, sinking is being done with hand-steel and the shaft is down 28 feet. The property is sometimes known as the "Jim" Nelson claims. The pay-streak, though not very wide, is said to be quite rich.

#### WHY ORE IS WHERE IT IS

The old saying—that gold is where you find it—implied that theory and knowledge were of no value in the search for ore, and that its presence could be made known only by actually finding it. The idea is still maintained by many, particularly by the practical mining man. However, it is being continually demonstrated by the economic geologist, or mining geologist, that not only is ore where you find it, but in considerable part its discovery depends on where and under what conditions search is made for it. As our previous conception of percentage of copper or of iron necessary to constitute ores of those metals has changed, due to added knowledge of treatment of ores, so our conception of **why ore is where it is** has changed with increased geologic knowledge supplied by field and laboratory work. The old adage must now be discarded, and give rise to intelligently directed research, based on geologic principles, whether for increasing ore reserves in regions already being exploited or for mineral in new regions. The research work of our of

our universities and of Government, and endowed laboratories, and the field work of our geological surveys and independent geologists, has produced a host of valuable data which gives greater probability of reward for intelligently directed search for ore or oil based on an understanding of geology. The economic geologist who avails himself of all phases of this knowledge is enabled to decipher more readily why a particular ore is where it is.

Ore is where it is, not purely by chance, but by the result of definite processes which operated under certain conditions within the crust of the earth. The economic geologist is like a detective, in that he must search for his clue and diagnose these processes which gave rise to a certain deposit. For example: is a certain ore deposit located in a particular place because of a pre-existing fissure, or a certain favorable rock formation, or its proximity to an igneous intrusion, or to a combination of all of them? Economic geology is not an exact science like mathematics, yet there are certain fundamental principles which underlie the formation of most ore deposits. No two ore deposits are alike in all respects, but with a knowledge of the principles and processes of ore deposition, one is in a better position to ferret out the problems of the particular ore body.

Such a knowledge of principles and processes is required to answer scientifically the question of **why ore is where it is**.

The answer involves, among other things, a knowledge of the different processes which result originally in the concentration of minerals or mineral products which may be valuable; of the source of the materials and the agents of transportation; of the shapes and distribution of pre-existing cavities and their control over ore bodies; of the shapes and characteristics of ore bodies formed by making their own cavities; the effect of the host rock; the action and results of secondary processes, and the tale that may be unfolded by the minerals that make up the deposit. The final careful answer to be the question tells most that need be known of the deposit. The answer, in turn, often enables similar places where conditions exist, and where similar processes operated to be determined, and search for more ore to be directed accordingly. For example, should it be found that an ore body originated by solutions given off from a nearby intrusive, that fissures of a certain system acted as channelways for the solutions, and that where the fissures intersected certain beds of limestone, replacement ore bodies resulted, then, if the same congenial bed of limestone be formed, and fissures of the same age be recognised and projected to cut the bed, the intersection of the two may be a locus for ore. Exploration may then be directed to that place with the reasonable expectation of the search resulting in the finding of more ore. This is one phase of the work of the trained economic geologist.

While the above example applies to the search for more ore in districts already partly developed, the answers to **why ore is where it is**, gained from a number of places, may also be applied to undeveloped districts. It is a generally accepted fact that most ore deposits susceptible to relatively easy discovery have already been found. Most regions have now been at least superficially prospected. The incentive for prospecting on the part of the old-time prospector is not as great as it used to be. Much credit is due to him

for bringing to light a large number of ore deposits, and his passing is much lamented. This, coupled with the fact that more attention is directed to the exploitation of large low-grade deposits, and in the acquisition of new properties, investing capital now gives more weight than heretofore to the expected possibilities of prospects, requires for the discovery and development of more mineralised regions that there should be enlisted all the knowledge and experience gained by economic geologists. The old prospector was a self-trained man, and more often not trained at all, but the economic geologist has his own training gained from answer as to why ore is where it is. In addition, he has the advantage of the experience of the prospectors, and of other countless trained men who have contributed their knowledge to the science.

With the decreasing chances of discoveries by prospectors, and the consequent waning incentive for them to prospect, has not the economic geologist an opportunity to increase the world's mineral reserves by supplementing, or even supplanting, the work of the old-time prospector? His field may be not only to examine and report upon the prospect found by the prospector, but specifically to direct the prospector in his search for new mineral areas, and to guide and advise him about his discoveries.

The old saying "Where ore is, there it is," may then fade into historic interest in the light of the application of the geologist's answers to why ore is where it is.—South African Mining & Engineering Journal.

### INTERNATIONAL NICKEL.

#### People Intimate With Company's Affairs Say Business and Earnings Are Much Better.

Sentiment among people conversant with affairs of International Nickel Co. has taken a decided turn for the better. The company is said to have definitely rounded the corner and its business is considerably better than for some time. This condition may be expected to be reflected to some extent in report for three months ended with June.

While surplus stocks of nickel, held abroad, and difficulties of transportation in this country materially reduced demand in fiscal year ended March 31, officials are said to be much encouraged by better business since that time.

It may be presumed that plant operations are at a higher rate than the 60 p.c. of capacity averaged during three months ended March 31. That 60 p.c. of capacity represented 80 p.c. of former capacity, as the Port Colborne plant was included in percentage for March quarter.

Not a little of the improvement is the result of new markets the company is constantly developing for its Monel Metal, an alloy made up of the same component parts as found in nickel ore. One of the uses for Monel Metal is in construction of racing yachts. A large amount of Monel Metal was used in construction of the Resolute, as well as in Vanitie. Another wide use is in golf clubs, where non-rusting qualities are important.

Nickel company's financial position was greatly strengthened in the last fiscal year and at March 31 it had a working capital account of nearly \$9,500,000, against \$9,779,645 March 31, 1918. Working capital March 31 last was larger than in any of the previous three years.

Possibility of resuming common dividends is be-

lieved somewhat remote, although the company is in a strictly liquid position, with earnings showing real improvement. One thing which might delay dividends is that additional plant facilities will be required to take care of expansion in Monel Metal. Such facilities, undoubtedly, would be financed from earnings.—"Boston News Bureau.

### GRANBY CONSOLIDATED.

#### Securing Greater Efficiency—May Build A Concentrator.

Although it has spent in the neighborhood of 10,000,000 during the past few years in expanding its operations the Granby Consolidated Mining Smelting & Power Co. may eventually spend \$1,000,000 additional in the construction of a concentrator.

The company has among its ore reserves at least 10,000,000 tons of silicious ores not amenable to direct smelting treatment. A 2000-ton plant would probably cost between \$1,000,000 and \$1,500,000 and would at once add substantially to the company's productive capacity. To handle the output of such a mill the present smelter could be increased in size if necessary.

Since the change in mine management was recently effected, greater efficiency has been accomplished. Considerably less coke and lime have been used to get the same results. The metallurgical end of the company's operations at Anyox has been thoroughly over hauled under the direction of E. P. Mathewson.

Granby has been producing about 500 tons of coal daily from its own property. A portion of this has been made into coke for the company's own use while the balance has been shipped to Vancouver for sale in the open coal market. Production could be increased to 1000 tons daily should market conditions warrant.

Boston News Bureau.

### REORGANIZING CANADA COPPER CO.

#### \$500,000 Assessment Underwritten.

The Canada Copper Corporation will be reorganized; a \$500,000 assessment which has been underwritten.

Upon payment of an assessment of 50 cents per share stockholders will receive a share for share exchange of stock in a new company with same capitalization.

Should the stockholders not care to pay assessment they may exchange their holdings on basis of ten for three new shares, leaving the seven shares for the underwriters.

Heretofore, the Canada Co. and its predecessor the British Columbia Copper Co., have operated under American charters but the new concern will take up a Canadian charter, thereby effecting some saving by eliminating dual taxation.

The Canada Copper Corporation has practically completed a 2000-ton mill and production, after many delays, should be started before the end of the year. It has taken about three years to build the plant which can treat 2500 tons of ore daily.

Costs have greatly exceeded early estimates in constructing the 2000-ton plant. Instead of \$2,500,000, covered by an issue of bonds, construction and equipment to date has cost over \$3,000,000. The company claims reserves of 10,000,000 tons of developed ore.—"Boston News Bureau."

Mr. Geo. R. Rogers, manager of the Wasapika mine has returned to Toronto after a visit to the property.

**INCREASING DEMAND FOR HIGH-GRADE ASBESTOS.**

**Canada Controls American Market.**

The demand for asbestos spinning fibre has in late years grown usually strong, and this demand, coupled with the fact that the United States is largely dependent on Canada for high-grade asbestos, has enabled the asbestos syndicate of Canada, which controls most of the world's supply, to fix prices for the raw material that are so high as to make the manufacture of textile fabrics of asbestos profitable. Thus American manufacturers who do not own Canadian mines are at a great disadvantage. For these reasons much attention has been given to the search for spinning fibre in South Africa and in the United States to meet the increasing demand. The results are encouraging. Three varieties of asbestos are found in the Transvaal, and at some places the mineral occurs in abundance. The imports to the United States from South Africa are increasing.

**Arizona has the Most Promising Deposits.**

Arizona is the most extensive producer in the United States, although its output of spinning fibre is not large as compared with that of Canada. The growing interest taken in Arizona fibre by asbestos manufacturers in the United States is encouraging. The total quantity of asbestos sold in the United States in 1919 was 1,002 tons, of which 420 tons came from Arizona, where there are two promising areas, one in the Grand Canyon and the other about 40 miles northwest of Globe. The route to the deposits in the Grand Canyon has recently been changed, and a small output was made in 1919. Part of the output was sold to customers in America, and the remainder was sent to Japan. Nearly all the asbestos mined in Arizona, however, comes from the region northwest of Globe, where the Arizona Asbestos Association, on Ash Creek, and the American Ores & Asbestos Co., in the Sierra Ancha at the head of Pocket Creek, are the principal operators. A number of smaller producers and shippers considerably increased the total output in 1919.

**Government Surveys for Asbestos.**

Thus far asbestos has been mined only in the western part of the Arizona asbestos field, on Ash and Cherry creeks, and in the Sierra Ancha. The formations that contain asbestos lie nearly flat and extend eastward into the Fort Apache and San Carlos Indian reservations, where asbestos mining is not yet permitted, although steps have been taken by the Government to make these deposits available to meet the needs of the country. A party sent out by the United States Geological Survey, Department of the Interior, is now examining these deposits to determine their availability as a national resource. Two valuable deposits of asbestos on Indian lands are already known, one on Cibecue Creek, in the Fort Apache Reservation, and the other in Bear Canyon, in the San Carlos Reservation.

**Georgia and California May Help.**

Georgia ranks next to Arizona in quantity of asbestos produced, but the fibre is of very low grade. The grade of the fibre from California is better, and the mineral is more abundant there, so that the general outlook for production in the United States appears to be good.

**Total Output in 1919 and 1920.**

The total output for the United States in 1919 was about as follows: Arizona, 420 short tons, chiefly spinning fibre; California, Georgia, North Carolina, Maryland, and Wyoming, 582 short tons, most of it of low grade. Wyoming reports the sale of a small quantity that had been mined in 1918. The production of 1920 will be larger than that in 1919, and the most notable feature of the production is the fact that most of the fibre produced in Arizona is of spinning grade. Nearly 237 short tons was shipped from mines in Arizona alone during January, February, and March, 1920. If mining is continued at this rate throughout the year the output of Arizona in 1920 will be about 1,000 tons.

**Imports.**

The asbestos imported into the United States in 1919 is tabulated below. More than 99 per cent. of it comes from Canada and is entered free of duty to compete with our domestic fibre, greatly to the advantage of the Canadian producer.

**Asbestos Imported Into the United States in 1919.**

Country	Quantity (short tons)	Value	Unmanufactured	
			Average value per short ton at port of origin	Manufactured
British Indies	1	\$80	\$80.00	.....
British South Africa	900	132,465	147.18	.....

—U. S. Geological Survey.

**NEW MAP OF PRAIRIE PROVINCES.**

A new edition of a map of Manitoba, Saskatchewan and Alberta giving the number of quarter-sections available for homestead entry in each township with the boundaries and offices of government land agencies has been issued by the Natural Resources Intelligence Branch of the Department of the Interior. This new edition clearly indicates all railways, forest reserves, parks and Indian reserves, also the land which has been reserved for soldier settlement purposes. The size of the map is 24 in. x 36 in., and the scale 35 miles to one inch.

The importance of the new edition at the present time is apparent to prospective settlers, officials of banks, railway companies and land agencies, in fact everyone interested in the development of land in the Western provinces. A copy of this publication which is known as the "Small Land Map of Manitoba, Saskatchewan and Alberta," may be obtained free of charge by applying to the Superintendent of the Natural Resources Intelligence Branch of the Department of the Interior, at Ottawa.

## THE SEARCH FOR PETROLEUM.

By Mr. E. H. CUNNINGHAM CRAIG.

(From the "Petroleum Times.")

### Western Canada.

The vast regions which may be included under the title of Western Canada have been prospected for petroleum fairly extensively, and in several districts speculative drilling has been active at one time or another. But up to the present there has been no very pronounced success achieved.

That oil does occur in the region is not a matter of doubt, but the conditions under which it occurs have, perhaps, not been fully appreciated, and conditions that will concentrate it in sufficient quantity to give rise to prolific oil fields can hardly be said to have been proved yet. Difficulties of transport over enormous distances and wild country have no doubt kept back development, but these are being steadily, if slowly, overcome, and the time cannot be far distant when it will be possible to transport plant to any desired location without any excessive danger or delay.

Geologists and prospectors have traversed the country from the international boundary to the Arctic Circle, and there is a mass of information available for the student of petroleum to study and form his judgment upon.

There are several distinctly and entirely different propositions presented by different districts, and each has its adherents.

There are those who believe in the possibility of the foothill country of the Rocky Mountains, part of which was exploited during the short-lived and somewhat crazy Calgary oil-boom of 1914. Much of the drilling done at the time was quite justifiable on scientific grounds, much was mere "wild-cat" work, but the result in the end was that only one or two localities were tested adequately and only in one has a workable field been developed. It is not a large field, the drilling is deep and expensive, but the oil is of high grade and the small productions that are being obtained from half a dozen wells are sufficient to be remunerative.

Again there are those who favor the prairie lands, where the great gas-fields are situated on very broad and gentle anticlinal structures. In the Viking field where the flexure is slightly less broad a little oil accompanied by very strong gas has been struck.

It seems very doubtful, however, whether there has been sufficient concentration of oil to give lasting productions, though the gas supply may be ample for many years.

Then there are the exploiters of the tar-sand area of the Athabasca River, where the basal beds of the Cretaceous formation consist of very thick asphaltic oilsands that extend in an almost horizontal position over thousands of square miles. If a method of tapping these deposits in shallow and cheaply drilled wells can be devised, and if such ground be worked like a low-grade ore proposition, it is possible that a commercial success might be achieved. But small production of rather heavy oil will be the rule, and only work on a very large scale with special precautions can give any hope of successful development.

Finally there are those who look to the Devonian formation for petroleum, and believe that the impregnation of the basal Cretaceous beds with oil is the result of seepage upwards from Devonian strata.

This theory, though subscribed to by several geolo-

gists, is the nucleus of much controversial writing, but field evidence may be said without exaggeration to be very heavily against it. The holders of this theory advocate drilling in anticlines in the Devonian formation in localities from which the Cretaceous asphaltic oilsands have not long been denuded, and where filtered residues of oil now make fairly conspicuous surface shows. That a certain amount of oil can be obtained under these conditions is obvious, but it has yet to be proved whether a commercial yield can be maintained over a period of years.

These are the four main classes of petroleum propositions that western and north-western Canada afford, leaving out more speculative ventures in British Columbia. Oil can be, and has been, struck under all those different geological environments, but as stated above, no great success has been made, up to the present, in any one of them. But there are still very many localities that have not been tested, there are many that have partially but not adequately been tested, and there are modified or slightly varied examples of those four fundamentally different environments that have not been fully studied.

For instance, it is said that by drilling many miles from the tar-sand outcrops, these strata will be found still fully impregnated with oil, but preserved from inspissation, and great productions under high gas pressure are predicted.

There is admittedly some evidence for this, e.g., the famous gas well at Pelican River, but the difficulty is to find any structure that will suffice to concentrate petroleum towards any one locality and so maintain a supply of oil to the wells. By careful and elaborate levelling it is stated that such structures have been detected, but the evidence is meagre and the structures so discovered are too gentle to have had any appreciable effect upon the underground migration of a heavy petroleum.

In the foothill country there are many localities with excellent structures and all essential conditions for an oilfield, so far as can be ascertained from surface evidence, where no drilling test has been made. Most of such localities would require deep drilling, and there is always the fear that the adverse condition discovered in the Calgary district, i.e., the lack of a porous reservoir rock of sufficient thickness, may militate against profitable production. Deep drilling necessarily requires prolific production to make it pay, but as oil becomes dearer this objection tends to become less formidable. There are areas west of Edmonton that appear to be worth careful and scientific exploration with the drill.

Then, as already suggested, a bold and comprehensive policy of handling the shallow tar-sand proposition merits attention. No small scale work will suffice here, for no prolific production in any one well is possible.

Detailed and painstaking work in the prairie area may result in the discovery of small oilfields, but it is more probably as gas-fields that these areas must look for commercial prosperity.

The believers in oil of Devonian age in this western and north western territory are perhaps taking the longest odds, but such enterprises are not to be condemned off-hand because the bulk of the evidence points to the oil belonging really to the Cretaceous Series. Light shows of secondary filtered oil can be made to pay if there be sufficient concentration, which depends naturally upon large and well-defined geological structures.

Considering the whole subject it may be said that the verdict at present must be "not proven." There is no doubt whatever about there being a vast volume of oil in the country: the only question is—can it be found sufficiently concentrated under favourable conditions for development. The conditions are known over very large areas, it is not a case of drilling mere "wild-cat" wells in the hope of discovering something phenomenal. Any company undertaking exploitation work must start with most of the essential facts known and a fairly accurate estimate of the depth to be drilled. Modified success or partial or even complete failure has been up to the present the result of all development work done. But a clear case can be made out to justify further attempts in several well defined districts. All the cards can be put upon the table at once. It must be stated at what horizons oil is to be expected, what depth has to be drilled and what area of concentration each well can be expected to drain.

Also, and this is really the most important point of all, what production of oil per well will constitute a success.

The investor or speculator in oil-shares must consider every point carefully and weigh every condition in the light of previous experience before he risks his money. No vague generalities should suffice to induce him to subscribe capital to any scheme, however enticingly put forward.

This perhaps may be said: in the foothills the chances of large productions are greatest, but the expenses of development work and the risks of failure are high.

Among the gentle structures of the prairies or the tar-sand areas the striking of gas or oil respectively are excellent, so long as wells are located on simple scientific principles but the yields may be small. In the Devonian strata drilling is more purely a gamble, but not without hope of substantial results. There is a very confident feeling in the West that big results will be obtained some day, and though booms are always to be deprecated, they are often useful in drawing more than local attention to development work.

But there is no excuse now-a-days for anyone entering upon a venture in oilfield development in western and north-western Canada with his eyes shut. The main facts are known, the possibilities may be estimated; it is only necessary to balance the calculated expenditure against the class of result that can be expected, and if a margin on the right side be indicated to go ahead boldly. The high grade proposition, big production per well and a fortune made in a day, is naturally the most attractive to anyone with a speculative instinct, but the low grade proposition, consisting of a large number of wells cheaply drilled and pumped, may in the end prove the more remunerative. The oil is wanted, and wanted badly; in the opinion of the writer it may be got, but there cannot and will not be any successful development by prospectors or companies that shut their eyes to the material facts.

Mr. G. C. Bateman, manager of the La Rose mine, has returned to Cobalt.

## Now Issued in One and Two Volumes

The **Ultimate** Book for Every Engineer Whose Work Brings Him in Touch With Any Phase of Mining.

"**PEELE**" is at once reliable, thorough and practical—the one complete, up-to-the-minute source of all mining engineering facts.

One-Volume Edition—2375 pages, 4½ by 7—flexibly bound—\$7.00 postpaid.

Two-Volume Edition—Vol. I—1225 pages—Vol. II—1216 pages—flexibly bound—\$8.00 postpaid.

Send the coupon for the edition you prefer.

## THE COPPER INDUSTRY IN 1919.

### Conditions and Prospects.

(From U. S. Geological Survey).

The principal features of the American copper industry during the year 1919 are shown in an advance statement on the production of copper in the United States by H. A. C. Jenison, of the United States Geological Survey, Department of the Interior.

The smelter output in 1919 was about 1,310,972,000 pounds, a decrease of 597,561,000 pounds from that of 1918. The production of refined primary and secondary copper from domestic and foreign ore and metal was 1,863,580,000 pounds, which was 612,497,000 pounds less than the production in 1918. Refined primary copper amounting to 326,043,000 pounds was produced from ore or other material imported from foreign countries, principally Chile, Peru, Mexico, and Canada.

The discrepancy between the smelter production and the refinery production is due to the fact that 562,000,000 pounds of blister copper and other material was in process of refining at smelters and refineries or in transit on January 1, 1919, and though it was smelted in 1918 it was not refined until 1919.

In 1919 the imports of copper in all forms amounted to 429,388,000 pounds, and the exports of copper in all forms amounted to 516,628,000 pounds, which was 231,062,000 pounds less than the exports in 1918 and 616,205,000 pounds less than those in 1917. The exports in 1919 were less than in any year since 1907.

On January 1, 1919, the stocks of refined copper were 180,000,000 pounds, and on January 1, 1920, they were 631,000,000 pounds, an increase during 1919 of about 451,000,000 pounds. The stocks on January 1, 1920, were several times greater than they have ever been before.

In addition to the stocks of refined copper in hand about 310,000,000 pounds of blister copper and material was in process of refining at smelters and refineries or in transit on January 1, 1920. This estimate does not include blister in foreign smelters destined for the United States for refining nor material in transit to the United States from such smelters.

The apparent domestic consumption in 1919 was about 876,564,000 pounds, which is 785,106,000 pounds less than that in 1918 and less than the domestic consumption in any year since 1914.

### Causes of Decrease in Output.

Many causes contributed to decrease the smelter and refinery production, the domestic consumption, and the exports, and to increase the stocks, but the principal cause was a poor market. The industry was working at maximum capacity when the war demand for copper ceased, and it was then, of course, forced to continue production only at the rate required to supply the ordinary commercial and industrial demand. The war demand was stopped so suddenly as to disturb greatly the trade and industrial conditions, and the prospects for the immediate future appeared so uncertain that few industries were able to continue production without first decreasing it greatly and reorganizing, to some extent, their industrial mechanism.

### Prices and Costs.

Under the peace-time conditions the demand for copper was small and the average price soon fell from 24.7 to about 15 cents a pound. This price was far below the actual cost of the production of a very large

part of the previous year's output. All smelters and mines were forced to decrease production. Some were shut down entirely; others were operated at the minimum capacity that would keep the organization intact and the equipment in proper order. Much of the copper in stock could not be profitably held, and the placing of a large part of it on the market kept the price down, though it showed a tendency to rise when the readjustment set in.

The price during the year showed many fluctuations but averaged only 18.6 cents a pound, which was about 24 per cent less than the average price in any year since 1915, though the cost of labor and supplies had risen as much as 150 per cent during that time.

The labor troubles in other industries decreased the cost of supplies used by the copper industry, and materially increased the cost of production.

### Decrease in Foreign Demand.

By the time the price of copper had risen high enough to permit the industry to meet these unfortunate conditions foreign exchange began to fall so rapidly that foreign buyers were unable or reluctant to purchase American copper, and finally the exchange between the United States and foreign countries dropped so low that they could no longer buy it. These conditions almost ruined the foreign market for American copper, and the demand and the price in the domestic market were less than they had been at any time for several years. On the whole, the year was an unsuccessful one, and in view of the conditions it is remarkable that the industry remained as stable as it did.

### Prospects for 1920.

It is hard to foresee what improvement can be expected in 1920 but the quantity of copper sold in the early part of 1920 indicates that the year will be better than 1919. Any improvement, however, will be temporary and no stability or security can be found until existing troubles are settled and industry and trade become more stable. The prosperity of the copper industry is peculiarly dependent upon the establishment of stability in other industries, and before the industry can receive any great stimulus the condition of labor and of trade generally, not only in America but in Europe, must be greatly improved. When that time comes the industry will undoubtedly be as prosperous as ever.

## METAL QUOTATIONS.

Fair prices for Ingot Metals in Montreal August 12th 1920.

	Cents per lb.
Copper, electro . . . . .	24 $\frac{1}{4}$

### PERSONAL.

Mr. E. V. Neelands, Mining Engineer, of Toronto left for Venezuela on August 9th and expects to return to Toronto about October 15th.

# SAFETY MINE CAGES

MADE TO FIT YOUR SHAFT

We build these Cages to suit you and your workmen. They are Safe, Strong and Reliable.

We guarantee the Safety Device of our Mine Cages to be quick and positive in its action. It can be relied on to work and to hold the cage safely at any time in case of accident. The springs are strong, the dogs are properly designed and adjusted, and the whole device is made amply strong for any emergency.

If you do your part by keeping the timbers in proper condition, and the bearings lubricated and reasonably free from rust, the Safety Device will do its work every time.

We supply these Cages with either one or two sets of doors for inlet or exit, to suit your shaft.

Rails are also laid in the floor, if required, for convenience in handling the cars.

The top doors permit the carrying of long timbers, or the escape of the men in case of accident.

The hand rails are properly placed to safeguard the passengers in the quick ascent or descent.

HAVE YOU SEEN A COPY OF OUR NEW MINING CATALOGUE?

If not, drop us a card, and one will be sent at once.

## FORESEES ELECTRO-CHEMICAL INDUSTRIES IN THE NORTH.

(By the Northern Ontario Correspondent of the Journal).

Among those who have given the matter considerable study, and from results accomplished under somewhat similar conditions in other countries, the belief is taking form that Northern Ontario may reasonably be counted upon to develop another important industry, which may rank favorably with the three chief industries of the present,—mining, farming and pulp-timber products.

It is in the water-powers, and the probable establishment of electro-chemical industries that careful observers claim to foresee new and important developments, and it is to the Des Quinze falls at the head of Lake Temiskaming, to Kettle Falls on the Abitibi River, as well as to the numerous great water-falls which occur on all the rivers tributary to James Bay that immediate attention may be turned.

It has been stated by the British Water-Power Commission that the world's annual consumption of nitrogen amounts to approximately 750,000 tons, having a value of at least \$250,000,000. About four-fifths of the total has previously been produced from nitrate deposits, but with this source of supply nearing depletion,

great importance attaches to nitrogen fixation from the air.

In Northern Ontario it has for some time been recognized that the rivers could be harnessed for this purpose, and that their economic value thus employed would be enormous. It has been pointed out that while no suggestion is made to copy the methods employed by the Germans before the recent war, it should nevertheless be kept in mind that Germany actually made great progress in the establishment of electro-chemical industries, including nitrogen fixation, and that these industries had their beginning from Government subsidies.

When last year's survey was made of a possible route for the extension of the Temiskaming and Northern Ontario Railway from Cochrane to tidewater at James Bay, considerable attention was given to the feasibility of utilizing Kettle Falls as a means of establishing an electro-chemical industry which might contribute to business for the proposed railway.

The diminution of the fertility of wheat and cotton-growing areas as well as general agricultural lands in many parts of the world creates a national necessity for establishing some system where artificial fertilizers may be obtained in large quantities, and it is believed that the favorable local aspect may attract the attention of the advisory bodies of the Imperial authorities, and that a solution of the nitrate problem may actually be found in the water-falls of Northern Ontario, an opinion based on existing official data.

### COKE DISPOSAL.

The growth of the by-product coke industry independent of the iron and steel industry and the prospects for developing it primarily, as a source of gas without necessity for relying on the needs of blast furnaces, depend almost entirely on the question of coke disposal. The extension of the domestic coke market is of great importance in this connection, and much progress has recently been made in this direction. The situation bears close relation to the condition of anthracite coal supply which is yearly becoming poorer in quality and more inadequate in amount. Just as the availability of natural gas has accustomed millions of American people to the use of gas fuel for domestic purposes, so the wholesale use of anthracite coal as domestic fuel has paved the way to introduction and substitution of coke.—**Gas Age.**

### Royal School of Mines Frecheville Research Fellowships

The Imperial College of Science and Technology, South Kensington, London, S.W. 7, with which the Royal School of Mines is incorporated, is offering two Research Fellowships of £300 a year each, tenable for one year and possibly renewable for a second year, to aid in carrying out any investigation or research connected with Mining, Mining Geology, Metallurgy, or Technology of Oil, which in the opinion of the Selection Committee is of sufficient use or promise.

Applicants, who may be Associates of the Royal School of Mines or others, and preferably men with some practical experience, if resident in Canada should apply in writing to the Secretary of the Canadian Mining Institute, Montreal, (from whom further particulars may be obtained), before 1st September, 1920, giving the nature of the proposed investigation, qualification for the work and references.

It is anticipated that the Committee will make the awards by the end of November, so that the Fellowships and work may begin on 1st January, 1921. Holders will be expected to devote their whole time to the work which may be conducted at the Imperial College or in special circumstances elsewhere at the discretion of the Committee.

## *SOME FIRST-HAND DEFINITIONS OF THE THEORY OF THE O.B.U.*

The newspapers have contained little about the notable debate which took place in Winnipeg on August 6th between exponents of the rival doctrines of the O. B. U. and the American Federation of Labor, but it occupied the attention of three thousand persons for three hours in hot weather, and elicited some definition of O. B. U. theories that will bear quotation.

Jos. Knight, who opened the debate for the O. B. U., and who was more remarkable for his venom than his logic, said: "The O. B. U. is not a national organization. That is absurd. An organization of the working classes as a class cannot be national. . . . What has the O. B. U. done? It has permeated the mind of the working classes of Canada in a manner that they will not get over, and tomorrow the O. B. U. will have the whole thing."

The representative of the American Federation of Labor, W. H. Hoop, defending the policies of the allied craft unions said this form of organization supplied "that merit which enables the worker to pool and use his economic power within the limits of the constitution, and carries with it the dictatorship of the proletariat whenever they desire to express it at the ballot box; whereas the O.B.U., throwing aside all weapons other than the big stick of direct action, treats society as an enemy, seeking to subdue various sections by dictatorship."

John Houston, speaking for the O. B. U. quoted a conversation with a tramcar driver, who advised "All you have to do to win that debate is to point the attention of the audience to the fact that the bosses, the politicians, the newspapers, and all the organizations and institutions of society are against the O. B. U. If the working class cannot see that an organization which meets with all that hostility is in their interests, then they cannot see anything at all." Mr. Houston's own point of view he stated to be a firm belief "that when a man takes part in the Labor movement, and while doing so he enters into relations or bargains or receives any favors from the bosses, he is a traitor to the working class."

The speakers of course said much more, but the quotations selected sufficiently disclose the fatal gulf between those who desire to mend society as it is now constituted, and those who desire to end it. Mr. Knight and his confederates have correctly diagnosed the O. B. U. movement as the deadly enemy of "the institutions of society" and as anti-national. This

gentleman, in his rebuttal speech, said further: "Oh fellow-workers, the simplicity of the whole thing! Here you are, the workers of Winnipeg. You organize in your own units. Express yourself through your Council, and the workers of Winnipeg will have control of their own affairs. There it is in simplicity—the O. B. U."

"Their own affairs"—and, everybody else's. We grant the simplicity, but there's the rub.

Those who advocate the complete domination of the "working classes" also arrogate to themselves the definition of the term, accompanying their advocacy with a denial of the right of any other class to exist. When they also postulate that all those are traitors who enter into communication with those inhabitants of the world that are not included within the self-determined definition of workers, they disclose themselves as the relentless and irreconcilable enemies of society. Can society, the general community of mankind, which includes the workers and all others be blamed if it recognises its would-be assassin and defends itself?

The A. F. L. speaker said the O. B. U. was "out to smash the State," and that when "the nature of the real thing was seen by the State, there could be no compromise." Which seems to be a fair expression of the position and responsibility of the State towards "all the organizations and institutions of society" that the O. B. U. conceives to be the enemy of the worker.

## *INCREASED RAILWAY CHARGES.*

The apologists for increased railway charges are making use of rather far-fetched instances to illustrate how lightly the increases of railway rates will be felt. Elaborate calculations are being made on the increased freight charges upon a tailored suit of woollen goods, and other finished articles whose value consists much more in labor than in material cost.

It is not in package freight and express shipments that increased railway rates will be most fundamental and widespread, but in the effect of increased rates upon heavy raw materials shipped in bulk, such as coal, iron-ore, petroleum, and bulk foodstuffs.

An increased freight charge upon coal will successively and cumulatively add to the cost of every manufactured article at every progressive stage of manufacture. The manufactured articles into which the cost of coal does not enter, and enter very largely, are completely negligible. In fixing freight rates, therefore, it is desirable that the least possible increase shall

be made in the carrying charges of raw materials, and in particular the transportation costs of coal.

No reasonable person will deny that the railways must have more revenue if they are to continue to fulfill their proper function. The mining industry, as the great producer of raw materials, stands to lose more than any other branch of industry if our transportation system break down through lack of financial strength, and all who understand the elementary requirements of prosperity in mining industries include efficient transportation facilities among them. The railway companies will not meet with any biased or thoughtless opposition from mining men to such rate increases as the Railway Commission may concede to be required to meet increased wages and increased costs of material, but there seems a possibility that the use of finished manufactured articles as typical instances of the effect of the expected increase of railway charges discloses a solicitude for manufactured goods in relation to freight charges that may imply a lack of realization of the far-reaching effects of freight increases on raw materials, and, in particular, on coal.

These remarks refer, of course, to those instances where it is necessary to transport coal by rail. Whenever it is possible coal should be transported by water. The railways admittedly do not like freighting coal, and regard it as a necessary nuisance, and—wherever a competitive or alternative water-route exists—the objection of the railways should not be disregarded. There are indeed railways in Canada whose running costs would be much lessened if they developed water transportation for locomotive coal to a larger carrying capacity than it has yet reached.

#### BRITISH LABOR AND POLISH FREEDOM.

Despite the biased and incomplete cabled reviews on which Canadian readers have to base their opinions of British politics, it has for sometime been clear that Britain would not declare war upon Soviet Russia. Britain has other fish to fry, she is dead-tired of war and war's consequences, and there is a widespread disinclination in Britain to interference in other people's political experiments.

Therefore the hysterical demand of the Laborites that there should be no war with Russia has fallen rather flat, and the country is generally amused at one section threatening revolution to obtain what is the very general desire of all the people.

The action of the Labor Party is not logical. They state first: "We are not concerned with the form of the Russian Government. We have no concern about the merits or demerits of Bolshevism." Later the Council of Action was instructed to remain in being until, among other things, "recognition of the Soviet Government" is secured. Recognition and approval

of a constituted government are usually regarded as inseparable. It is one thing to protect against military interference in national affairs, and another thing to solemnly approve a foreign government.

These phases of the event should not however obscure the gravity of the step taken by organized labor, which, as it is characterised by H. J. Thomas himself, is "a desperate and dangerous method" and a "challenge to the whole constitution of the country."

The danger consists in acceptance by the Labor Party of a theory that was precisely enunciated by Robert Williams, who said to the assembled delegates: "I tell you solemnly and seriously that you are infinitely more representative than the House of Commons, and you may be summoned to sit permanently as a Committee of National Safety." Those outside the ranks of organized labor may challenge this statement as being untrue, and the issue will then be straitly drawn. The interpolation of the Russian situation will then be recognised as distinctly irrelevant and merely confusing the true issue.

The decision of organized labor to form a Council of Action, which is merely another term for a Revolutionary Committee, doubtless is a reflex of the Miners' Congress at Geneva, and is a sign of the growth of the international movement in labor politics, and the temporary discount of national sentiment that is a natural result of comparing of notes between representatives of European nationalities after the dreadful experiences of war.

If the labor groups in all civilized countries unite in denouncing war they will find few opponents of their course, and there is no doubt that a general strike of coal miners would most effectually paralyse all war effort. Labor has a long way to go yet, however, before it can guarantee national rights and national independence against aggression by autocrats, either monarchial or ostensibly proletarian, or against the armed forces of uncivilized races and those nations that while they have accepted Western civilization have not accepted Western ethics. The British workman is secure in his nationality and in his island, but closer proximity to chaos and the kindergarten of child races that are at this time experimenting with forms of government in eastern Europe and western Asia would modify his enthusiasm in the singing of the "Internationale."

The taste of British laborites for Russian methods is as mysterious as the bygone enthusiasm of certain literary circles for Russian literature, and it is a singular turn of events that links Ludendorff with the British worker against Poland and Lloyd George. Considering the momentous nature of the laborites' decision to adopt direct action one could wish they had chosen a more definite issue, but, for the peace of Britain, it is perhaps fortunate the issue is clouded and not urgent.

## ASSOCIATED GOLDFIELDS.

The proposal to give railroad facilities to the Larder Lake gold area is one that especially interests shareholders of Associated Goldfields. This company has issued a report on its property which would indicate that the company has resources for conducting mining operations profitably and on a large scale. A railroad covering the area would derive much business from an industry of the magnitude contemplated.

The Ontario Government owns the railroad from North Bay to Cochrane, the Temiskaming and Northern Ontario Railway, and a branch line from this railroad is asked for. The railway commissioners have indicated a willingness to consider the proposal provided a report on the property is made by Government engineers. Up to date there has been no announcement as to whether the company is willing to have the mine examined by the Mines Department. The usual examinations by inspectors of mines and geologists of the Bureau of Mines do not include sampling systematically of properties or the expressing of opinions as to their commercial possibilities. The examination called for would be of a different character from that of the customary ones.

In view of the expenditures involved in the construction and operation of branch lines the stand taken by the Government officials seems a reasonable one. It is to be hoped that the company will so regard it.—R.E.H.

## ORIGIN OF THE SUDBURY NICKEL ORES.

The origin of the nickel-copper ores of the Sudbury district has been much discussed. Those who are interested in the subject will do well to read the opinion of a recent worker on the problem published in an article in the July bulletin of the Canadian Mining Institute. This writer states that geological work at the mines has disclosed facts that indicate the origin of the ore by its intrusion in molten condition along a plane of shearing in the footwall rocks adjacent to the norite, after the latter had solidified. The writer presents some evidence in support of his view, but does not discuss the subject fully.

The evidence offered is hardly sufficient to shake the faith of those who believe the localization of the orebodies to be primarily the result of differentiation in the norite magma. It is reasonable to suppose that the cooling of the molten mass would take a very long time and that during that period there would be much cracking of solidified portions and subsequent sealing of the cracks by dyke-like masses.—R.E.H.

Leland D. Adams of the Weedon Mining Company is visiting Canada. Mr. Adams, who resides in California, expresses himself as well satisfied with recent developments at the mine.

## CORRESPONDENCE.

To the Editor of the Canadian Mining Journal.  
Dear Sir:

In your issue of July 30th inst. you have an article on the Graphite in Canada. You have had a number of articles on this mineral during the last year or two. I do not think any of the writers of the articles are well posted about this mineral, especially in the Province of Ontario. I know that there is in Ontario, as yet virgin, mountains of sand and gravel, carrying silver flake graphite for the purposes you mention, that is for the making of crucibles and for pencils and for powder, just as pure as any found in Ceylon and I am sure as any found in the United States, and superior to the Black Donald of Renfrew, but up to the present no one seems to want them. Then you go on to say if concentration methods can be devised to take full advantage of the high graphite content of Canadian ores, the industry should prove permanent. Well sir, I own and control four patents, patented in Canada and in the United States. With any of them I can clean and separate Graphite, Gold, Silver, Lead, Zinc, Molybdenite, as easy and perfectly as blowing chaff out of wheat—I have a perfect process.

And I can clean and concentrate for cents per ton what by any other process costs as many dollars per ton. My process and my machine have no equal in the world, but Sir do you know that some of our mine owners, and mine managers, know so little about minerals, and the machinery required to clean and separate the minerals from the matrix that they think there is no machine will do it?

And they are using that rotten filthy dirty process—the Hun's process—oil flotation or still worse, cyanide, that is both dangerous and unhealthy. Any of your readers can see my Patents at any time, and they are in a class by themselves, as there is nothing yet patented in their class. Hoping you will find a place in your valuable paper for this.

I am very truly,

M. J. Paterson, Sr. E.M.

66 Churchill Avenue,  
Toronto, August 9th, 1920.

## BOOK REVIEW.

THE MINES HANDBOOK. The Mines Handbook and Copper Handbook for 1920, Vol. XIV, 6 by 8½ by 2½ inches. 1992 pages. Cloth Boards. Price \$15.00. Published and compiled by Walter Harvey Weed, New York City.

The latest edition of this standard compilation covers the mining industry of the world for 1918, 1919 and the first quarter of 1920. It is announced that the Handbook will hereafter be published annually, delay in issuing the 1920 volume having been caused by labor troubles and paper shortage.

The Handbook contains statistical information regarding the production, consumption and United exports and imports in all commercial metals. The scope of the work is comprehensive, covering as it does the metal mining industry of the world, and the information, so far as we are in a position to check it from the references to Canadian and Newfoundland mining operations, is complete and accurate.

This Handbook is a necessity in the library of consulting mining engineers, metal brokers, dealers in mining equipment and supplies, and all who are interested in mining, more particularly in America.

# The Concentration of Graphite Ores--Past and Present

By R. C. ROWE, Buckingham, Quebec.

## I.—Introduction.

Some day, someone may write a complete history of the graphite industry of this country. The result will be interesting, and instructive, inasmuch as it will illustrate the remarkable and devious wanderings of the human mind in search of a certain definite result.

It is quite beyond the scope of this paper to attempt to explore the various backways and byeways of metallurgy that graphite has, in the past travelled. Only generalities can be dealt in.

Canadian graphite occurs principally in more or less flat flakes ranging in size from one-eighth of an inch in diameter to microscopical dimensions, disseminated throughout the rocks of its occurrence. Its specific gravity is in the vicinity of 2.2. That of its accompanying gangue is around 2.6.

Refined graphite enters into many phases of our everyday life; but its chief use is in the manufacture of crucibles. Only the largest flake is used for this purpose, and, as this material is the most valuable, the efficiency of a process for concentrating graphite is, to some extent, governed by the amount of crucible flake produced.

For example: Consider two mills each operating with a recovery of 85 per cent. One, however, produces 110 lbs. of crucible flake per ton of ore treated, while the other produces only 100 lbs., the remainder of the production, in each case, being made up of finer grades. The mill producing 110 lbs. of crucible flake would be considered the most efficient and, would probably remain a better paying proposition, even if its recovery dropped 5 or 10 per cent below that of the other. Thus it is obvious that a high recovery figure does not always mean a paying graphite proposition.

The small difference in the specific gravities of graphite and its accompanying gangue, makes it difficult to concentrate the mineral by any methods that have gravity as their underlying principle, and it will be readily understood that it also aggravates certain problems that are familiar to all mill men. In fact, the average millman, inexperienced in the mineral, upon tackling its concentration, finds himself in a veritable land of topsy turveydom where precepts and precedents often fail. He finds concentrates where he is used to finding tailings. He finds settling tanks that don't always settle. He finds values, to alarming amounts, in overflows, and other places where they have no earthly reason to be. He finds his elusive mineral floating in the air about him, and polluting the country side. In fact, after a while, he begins to think that there is graphite everywhere in the wide world, except in the one place where it should be, namely, the bags at the end of his often intricate pulp flow.

These introductory remarks will show, to some extent, the obstacles that have had to be overcome by the old operators. Couple to the physical characteristics of the mineral, erratic market conditions, and less modern machinery, and, in the light of latter-day knowledge, one can see that the whole thing was more or less futile.

It is to be regretted, however, that those who have

gone before, have left us little record of their endeavours, and apparently few, if any, records of results have been kept.

Thus it is that, doubtless, much of the futile ground covered once, has been covered repeatedly since, and the bitter lessons of failure have had to be relearned again and again.

## II.—The Past.

Briefly, all efforts in concentrating graphite, up to the introduction of the flotation process, may be considered commercial failures.

The first graphite mill in this country apparently started to operate about fifty years ago. I have talked with an aged individual who remembers that his first job in life was to carry whiskey for the mill crew of this particular venture. From local tradition, and Government records, we learn that there was a considerable amount of activity in graphite about this period.

The concentrating device used was the well known buddle, and, as this was a more or less standard machine, graphite, in its infancy, did not stray far from the well beaten paths of common practice.

The flow sheets in use may be broadly described as follows: The ore was broken in crushers and stamps, and roughly classified. The resulting products were then fed to buddles. Buddling resulted in three products: Concentrates, middlings, and tailings. Middlings were re-treated in buddles, concentrates were treated with buhr stones and screens.

The use of buhr stones and screens has survived, and still forms a part of graphite milling practice; but the use of the buddle has died completely. It is obvious that, with such a small difference in the specific gravities of values and gangue, the buddle could never be an efficient concentrating device for graphite; but in one case its use survived until a short time ago, when it was superseded by oil flotation. Only remarkable local conditions, however, rendered this possible.

The general use of the buddle persisted for some years before it was finally abandoned as a failure, and, after its abandonment, graphite for a time departed completely from accepted practice. Each operator appeared to follow his own particular line of experimentation, and the ramifications to which fancy lead are extraordinary.

It would be useless to attempt to describe all the machines and devices employed. Some worked on the gravity principle, among which might be listed, air jigs, air float machines, and various wet concentrators. Some operators delved into electrostatics. In one case a bulk oil process was tried. Mr. H. P. H. Brumell evolved a surface tension machine. This apparently was not successful, though the use of devices, employing surface tension, continued in use, largely in Alabama, right up to the advent of the flotation process.

One operator, in the Buckingham district, tried for two years to design, and perfect, a machine that depended upon the flat shape of the flake for concentration. In other words, he endeavoured to make every individual flake follow the particular laws of dynamics that govern aeronautics. The outcome of

numerous experiments is shown in Figure I, and it is given here as an illustration of this phase of the graphite industry.

The ore pulp, rendered fairly dilute, was fed at the point A, and, forming a thin film, ran down the incline B. During the journey the flakes of graphite were presumed to acquire, and maintain, a position parallel to the surface B, and, upon striking the water level C, they were supposed to volplane as it were across the space G to the overflow lip D, where they were discharged to the small screen E, and removed by any suitable means. The gangue particles, being granular, sank in the space G, and were discharged through the valve F. Water level was regulated by the tailings valve.

Theoretically, the principles involved were fairly sound, and in practice some of the flakes did volplane across the clear space, and were duly collected; but, again, some of them didn't, and the proportion that did was very, very much smaller than the proportion that didn't.

About this time a dry process of rolling and screening was receiving a good deal of attention, and its adoption in Canada became almost universal. Here

FIG. 1.

again the shape of the flake was taken advantage of, and here again the principles involved were fairly sound—up to a point.

The broad lines of the flow sheets usually adopted were somewhat as follows:—The ore was dried in either kilns or rotary driers, and was ground by the usual dry methods to minus 20 mesh. In this form it was fed to small high speed flour rolls. The theory simply was that, the flake, being flat and tough, would pass through the rolls uninjured, while the gangue being granular, with the exception of any mica present, would be pulverised to dust, and could thus be removed by screening. The rolled material was passed over a forty mesh screen. This yielded a fairly clean flake. The throughs were dusted over an eighty mesh, and then passed to another battery of rolls, after which the material was scalped over sixty mesh, the throughs being again de-dusted, and further treated with rolls and screens.

The principles upon which the process rested have long been recognized. The first graphite mill in Canada used buhr stones and screens for the final treatment of concentrates, and the latest uses rolls and screens for the same purpose; but there is a vast difference between treating a high grade concentrate, and a ten to twelve per cent ore. In the first case the destruction of valuable flake is small, and the wear and tear on rolls and screens is negligible, while in the latter the destruction of flake is enormous, and the cost of wear and tear becomes a most formidable item. In practice it was found that, with the roll and screen method, a large proportion of the graphite

was broken up, and therefore passed out with the dust. The large quantities of floating dust in the air of the mills caused trouble with bearings and belts. Recoveries were low, operating efficiencies were low, costs for repairs and renewals were high, and so the process inevitably languished, and eventually died.

While the roll and screen process was dying out, a plant using wet crushing, grinding, classifying, and tabling machinery was designed and built. In this process the very slight difference between the specific gravities of graphite and its gangue caused many troubles; but the plant may be considered the most successful one working on disseminated ores up to the advent of the use of oil flotation on graphite ores.

The flow sheet was roughly as follows: The ore was broken in jaw crushers, and ground in a ball mill and tube mill. The resulting product was then sized in screens and hydraulic classifiers, and passed to a series of tables, which produced concentrates, middlings, and tailings. Middlings were re-ground and re-tabled. Concentrates were filtered, dried and then passed to a finishing plant consisting of rolls and screens.

The recovery of crucible flake was high, and the operating efficiency was high. The plant, consequently, has run fairly continuously for some years, and latterly flotation has been installed. The construction of this plant marked the return of graphite to the more or less beaten paths of milling practice, and during the war several other plants adopted the gravity process. All other plants, however, installed dry gravity tables, and the processes were dry throughout.

Reports of the results of these mills differ; but they all eventually closed down. It is the opinion of the writer that the enormous cost of repairs and renewals was largely responsible for this. High costs, and low operating efficiency appear to be factors accompanying every dry process.

The use of gravity methods for concentration, brought into discussion a point that had, apparently, escaped notice before, or if it had not escaped notice had, at least, not been raised, namely the intimate intercrystallization of graphite and its accompanying rocks. It was found, through careful examination of table middlings that, even at most minute subdivisions, graphite and gangue were still to be found clinging to one another. This is a most important point in considering the application of the flotation process to graphite ores, and it will be treated in a subsequent portion of this paper.

The use of standard gravity tables, for the concentration of graphite, marks the last phase of the past. The use of the oil flotation process belongs to the present; but before passing from the past to the present it might be remarked that it is singular that the flotation process was never discovered by the early graphite operators. Fine graphite will often float without the aid of oils, and on every tailing pond big blobs of graphitic froth may be seen. It seems remarkable that, to none of the numerous operators came that flash of inspiration that would have bridged the gap between those floating blobs of mineralized froth and a new process.

Frank Elmore saw the imprint of an oily hand marked out by collected copper slime, and from this germ of thought one phase of the flotation process was born. Graphite operators, for years, actually saw the mineral laden bubbles that were, eventually, to

revolutionize metallurgy, and they, even though searching for a process to solve their troubles, failed to grasp the significance of what they saw. So are epochs born—and so are they lost.

### III.—The Present.

The flotation process is now being generally adopted for the concentration of graphite ores. Its adoption has, however, been somewhat slow, and graphite is probably one of the last of the amenable minerals to which the process has been applied.

It was probably the remarkable results obtained by flotation upon molybdenite that first drew wide attention, in this country, to the possibility of applying the process to graphite. Concentrates running ninety per cent  $\text{MoS}_2$  were obtained by flotation, and, as graphite much resembles molybdenite in appearance, a widespread idea became prevalent that graphite concentrates running ninety per cent graphitic carbon could be obtained by oil flotation in every day milling practice.

If such were the case, the milling of graphite would be a very simple operation. This idea still persists in some quarters, and the writer ventures to assert at this point that a graphite concentrate averaging ninety per cent carbon, obtained by flotation alone, in ordinary milling operations, is a myth. Such a concentrate has been obtained in the laboratory, and it will, undoubtedly, be obtained again; but anyone hoping to produce such a result in milling practice is pursuing an ignis fatuus.

In a very broad sense, it may be stated that the flotation process presents a solution of the vexing problem of economically concentrating graphite. The operator contemplating the installation of the process has one solid rock to cling to: Froth flotation produces a clean tailing. Given the correct ore pulp conditions, he may rest assured on this point; but from here on nothing is stable.

Mechanical or pneumatic machines give practically the same results. The former giving a shade better tailing, while the latter generally shows a slightly better concentrate.

Mr. Chas. Spearman remarked in a recent article upon graphite published in *The Canadian Mining Journal*, that the problem was more one of grinding than of concentrating. I, for one, agree with him upon this point. As pointed out previously, Canadian graphite, as a general rule appears to be very intimately associated with its accompanying rocks, and no system of wet grinding appears to free the particles of graphite completely from the accompanying gangue. It must be borne in mind, when considering this point, that sliming must be avoided. Preservation of flake is one of the graphite mill man's chief objects.

Under existing methods the product of any grinding plant may be roughly classified as follows:—

- a. Free flakes of graphite.
- b. Flakes of graphite with small pieces of attached gangue.
- c. Particles of gangue with small pieces of attached graphite.
- d. Free gangue.

This classification is more noticeable in undecomposed ores. Decomposition appears to free the flake in a manner impossible to duplicate mechanically. Tests run on such ores often give remarkable results that cannot be duplicated upon undecomposed ores, and, for this reason, it is desirable that all tests, in

connection with flow sheet design, should be run on ore taken from below the zone of decomposition.

According to flotation practice, classes "a" and "b" and part of "c," of the above classification, will float. This is entirely desirable from a recovery point of view; but it tends to produce a dirty concentrate.

Thus, it will be gathered that the purity of a graphite flotation concentrate is in direct proportion to the degree of liberation of flake accomplished by grinding, and that the degree of concentration attainable by flotation is governed by factors which are, in themselves, quite apart from the process under discussion.

The ideal machine for preparing graphite pulp for flotation would be one that would pulverize all gangue and yet leave the flakes of graphite intact. Such a machine does not exist, and probably never will. The only remaining alternative is to pick the machine that will accomplish the grinding with a minimum destruction of flake. Here a diversity of opinion is met with. Some engineers prefer ball mills, some rolls. Among those preferring ball mills there is a further split; one faction favouring peripheral discharge mills, while the others can only think of centre discharges. It is therefore impossible to lay down any rule in connection with this most important point. The ultimate scheme to be adopted by any operator can only be determined by tests, and local conditions; but in any case grinding and classification should receive very careful consideration, and nothing should be left to theory, every step being tested out, if possible, by mill scale tests.

Rougher, or primary concentrates, will generally run from thirty to forty-five per cent carbon. Three methods of raising these present themselves:

- (1) Successive floatings, returning tailings for re-treatment.
- (2) Stage grinding and floating.
- (3) Tabling.

The first consists of a series of cleaners, and is undoubtedly the simplest; but it is doubtful whether it will, under any circumstances, result in a really high grade concentrate.

In the second method the entire primary concentrate is reground in a pebble mill, and refloats, the concentrate obtained by refloating being again ground, and further floated. This may be carried on indefinitely, as the successive regrindings and refloatings are all operated in closed circuit. A high grade concentrate is the inevitable result; but the destruction of valuable flake must be tremendous. The destruction of flake occurring during tube mill grinding is a much debated point. Many claim that the loss is negligible; but the writer has found that, in a thirteen foot mill, fourteen per cent of the flake was ground to minus 150 mesh. This with a dilute pulp, and a special large discharge.

The third alternative—tabling—appears to be best suited to general requirements. Theoretically, the free flake, having a different specific gravity to flake carrying attached gangue, would be taken off, and thus saved from the chances of tube mill grinding, while the tailing containing unfree flake would be returned for regrinding and refloating. But practice does not altogether bear out theory. It is difficult to quite break the primary froth, and an oil streak, which passes straight down with the head water on the table, is the result. This oil streak looks rather fine; but it entraps a proportion of unfree flake and gangue and a lowering of the table concentrate is the

direct result. Careful selection of flotation oils may do much to alleviate this condition; but, in any case the old troubles, due to slight differences in specific gravities, are present.

By any of the above methods a concentrate ranging from sixty-five to eighty-five per cent graphitic carbon may be obtained. A fair average is 75 per cent.

After dewatering, and drying, the usual finishing methods may be followed. The plant employed usually consists of a series of buhr stones and screens. In some cases rolls are substituted for the buhr stones.

Apart from the general lines touched upon in the foregoing, many difficulties crop up. Froth collects, and builds up, in all sorts of odd and unexpected places, and it is particularly difficult to dispose of overflows without losing graphite.

It will be observed, from the foregoing, that no golden rules have been laid down. One can only generalize, and that all too broadly. It cannot be too strongly emphasized that every graphite ore is a problem. Two ores, that appear exactly alike, will yield vastly different results with the same treatment. For this reason, every contemplated step in a flow sheet should be thoroughly tested, and nothing should be left to theory, and nothing to chance.

To continue our generalizations:—Treatment 1. should yield good results on a soft friable ore.

With undecomposed gneissic ores treatments 2 and 3 should yield good results. Either might be advantageously used, or a combination of both.

Treatments 1 and 3 undoubtedly yield a higher proportion of No. 1 flake, while No. 2 probably results in a higher grade combined concentrate.

As stated elsewhere in this paper, it may be found justifiable to sacrifice a small percentage of recovery, if the sacrifice involves an increase in the amount of crucible flake produced per ton of ore treated. In this connection it may be remarked that, the finer the grinding, the higher is the flotation recovery. The amount of grinding best suited to commercial and metallurgical requirements can only be determined by careful observation over periods, though careful testing will indicate the limits within which the ideal must lie.

In conclusion it may be remarked that the trend of thought, regarding graphite and the flotation process, is distinctly optimistic; but it must be pointed out that the graphite industry on this continent has, in the past, suffered through an acceptance of certain optimistic lines of theory. Mills have been built on theory alone, and it was not until the mill failed that the weakness of the theory was shown. The application of the flotation process to graphite is a tricky thing, and a too easy acceptance of theory may easily end in failure.

The advisability of testing has been emphasized in this paper, and, in conclusion, it may well be emphasized once more. Prove every step, if possible by mill scale tests. Look upon theories with suspicion. Remember that a few hundred dollars spent in tests may save many thousands—and failure.

## SALT MINING AT MALAGASH, NOVA SCOTIA.

About twenty tons of salt daily are being produced here. The deposit of potash-bearing mineral which was reported occurs near the surface, and while its analysis is promising, it is not considered as representative of the continuation of the deposit when it reaches a depth where atmospheric and surface influences are not felt. Sinking is being carried on in the salt vein itself, and the possibility of finding more valuable material is regarded as quite probable.

## THE IRON ORE MINES AT WABANA, NEWFOUNDLAND.

The Scotia Mine is producing 1100 tons daily, of which 98 per cent is machine-loaded ore. There are now eight mechanical loaders in the submarine territory, namely, four Thew shovels, two Myers-Whaley loaders, and two Armstrong loaders. The use of mechanical loaders is being found of much advantage in advance work, the rate of progress of headings and leading places being much helped thereby.

The sale of ore for outside shipment has not yet resumed pre-war volume. It is reported that the Dominion Steel Corporation is about to ship ore to Middlesboro, England. This Company has not hitherto sold much ore to outside parties, but the Scotia Company was in previous years a heavy outside shipper. There is little doubt that with the reduction of freight rates likely to take place the shipment of ore to Europe, and to the United States, will assume important proportions once more.

## COAL SHORTAGE AND PRODUCTION.

### A Glace Bay Viewpoint.

Papers in Montreal and other parts of the upper provinces are urging upon the Dominion government the importance of increased production at the Cape Breton collieries in view of the shortage of coal which threatens to assume famine proportions before the winter is well under way.

It would be interesting to know how the government would proceed about getting more coal out of the mines in Cape Breton. The various managements have been trying to do that for the last couple of years and have not yet succeeded in making any appreciable headway. By the Dominion coal company, the principal producer, a steady average of 10,000 or 11,000 tons a day is being maintained and with the utmost exertions it seems to be impossible to get above that figure, taking it month by month. Once a week or so it rises to over 12,000 but this hardly ever happens two days in succession. Before the war production at these collieries often rose to over 20,000 tons a day.

If the government could provide the management with several thousand skilled mine workers it would be doing something practical to help out the coal situation as it would enable the management among other things to open new mines or speed up production at those in process of development. But if Montreal is depending on increased production in Cape Breton, as things look now it will go without fuel this winter.—Glace Bay "Gazette."

The U. S. Geological Survey reports 2,430,000 tons of gypsum mined in the United States in 1919, an increase of 373,000 tons over the production of 1918, reflecting the resumption of building construction.

# Coal Export Embargo will Injure Nova Scotia Coal Trade

Inverness County Especially Threatened.

By The Editor

The circumstances under which the S.S. "Lord Dufferin" loaded with coal at Port Hastings, Cape Breton Island, has been allowed to proceed to Holland illustrates exactly the possibilities for injury to the Nova Scotia coal trade that accompany the export embargo now in force. The cargo in question was loaded by the Inverness Railway & Collieries Company, a re-organization of the Inverness Coal & Railway Company with some added properties. This reorganization was planned and has been carried out to take advantage of the favorable export market now existing, and the willingness of foreign purchasers to send ships for loading. Just previously to the re-organization there seemed every likelihood that the Inverness Colliery would be compelled to close down, and, as everybody in that district knows, if it once closed down, it would not be re-opened. There is one other coal mining operation in Inverness County, also the result of the existence of an export market. Neither operation is large enough to permit of the ownership of large steamers, and the rail shipment from the Inverness collieries places them at a great disadvantage as compared with f.o.b. cash business.

During the war the profits of the Inverness Coal & Railway Company were most rigidly held down by the Fuel Controller. The property is a most difficult one to work, the face of the deeps being some 6,000 feet out to sea, and the haul from the workings to the surface is one of the most difficult in Nova Scotia. The survival of the property in an operating condition has been possible only through most rigid economy and the existence of a good demand for coal in recent years. Under these circumstances the re-organization of the property, the coming in of new capital, the acquisition of adjoining properties, and the excellent export market offering has caused much rejoicing in Inverness County, where during recent years, the inhabitants have seen mine after mine disappear from the operating list, and have seen once prosperous mining towns full of empty houses with boarded-up windows.

The assistance which can be given to the Canadian domestic coal supply by the production of Inverness County is entirely negligible, and the entire output of the county in recent years has not exceeded 200,000 tons annually.

Apparently the authorities have seen the injustice of enforcing the embargo in the case of the Inverness collieries, and it is to be hoped that not only will it be removed so far as these mines are concerned, but that the Government will encourage the intensive mining of coal in Inverness County for export purposes. It is not for the good of Canada, nor will it appreciably assist in relieving the existing bituminous coal shortage in Canada, that an industry that has declined for many years should be throttled at the first signs of revival. Neither will the people of Inverness see the justice of a policy that threatens to impoverish them in the day of opportunity to relieve the needs of a market that in other times has not afforded the local industry any help.

If the Government at this time prevents the Inver-

ness collieries from undertaking profitable business that will enable it to lay aside reserves against the evil times that are coming, then it should assume financial responsibility for the future of the properties, and should undertake to dispose of the output of the collieries at a price that will yield them a fair profit for an indefinite period ahead.

During the coming Winter and particularly during the Spring season, when the drift-ice will prevent water shipments of coal, the collieries will either have to bank out coal or remain partially idle. If the collieries, as was suggested by the Fuel Controller, can be given long-term advance contracts for railway coal by the Government, with a guarantee that the coal will be taken away in the shipping season, then it would be possible for the mines to work all winter without interruption, thereby largely increasing the annual output of coal.

Any Government that undertakes to control an industry must accept concomitant responsibility for that industry. It is pertinent to recall that the issue of the "Canadian Mining Journal" of this date in 1919 quoted the plea made by Mr. D. D. Mackenzie, M.P., for the larger allotment of the coal purchases of the Canadian National Railways to Nova Scotia coal mines, which was withheld because United States coal was cheaper. Mr. Mackenzie wrote to Mr. Hanna, in part, as follows:

"I must with all respect, yet with all insistency, impress upon you the necessity of coming to the assistance of these men by purchasing the article which they produce, whether or not it may be more expensive than the same article imported from a foreign country."

It is this policy of ignoring domestic coal mines in favour of the United States when coal is cheap and plentiful, and of restricting the profits and expansion of these mines when coal is dear and scarce that has brought the Nova Scotian collieries to their present state of low production tonnage, high production cost and a generally unstabilized condition.

It is quite certain that if the Inverness Collieries had been required to depend upon the Canadian National Railways or upon the Montreal market for a market and disposal of their coal output there would have been neither new capital or re-organization of old properties, but, just so soon as under the stimulus of good demand at remunerative prices, the interest of investors is quickened it is discovered that domestic requirements must take precedence of all other demands.

Any and every course that will stimulate coal production in Canada is commendable. It seems an elementary proposition that the way to relieve a coal shortage is to produce more coal, but it is nevertheless a proposition that has never been grasped by the successive governments of Canada. Any and every course that restricts coal production is to be condemned, and restriction of production, both present and future, will result from the export embargo. At the same time the domestic situation will not be greatly helped.

**NEW YORK ADVICES ON ASBESTOS MARKET.**

Since our last letter regarding the Asbestos situation, prices have advanced for all grades, some grades only slightly and others to a greater extent. This is only natural when one stops to consider the enormous demand which is evidenced by the fact that there are to-day 7,750,000 passenger cars and trucks on the roads, and the fact that automobile manufacturers expect a production of 2,000,000 cars and trucks for this year.

In addition to this, the enormous building construction going on all over the world is almost double what it has ever been before at any time. This is due to the fact that practically all building construction both here and in Europe was stopped during the war. Besides the extraordinary building construction that is going on in this country, England, France and Italy, there is additional reparation and construction work going on in the devastated districts of France, Italy and Belgium.

The steamship trade is also consuming large quantities. Not alone for the new tonnage which is being produced, but also owing to renewals of practically all the steamers that were operated during the war. Owing to the scarcity of steamer space from 1914 until the Armistice was signed nearly all steamers were kept in service continuously and renewals and repairs were put off until recently.

Considering that the output at the Mines has decreased instead of increased it is readily understood that the Asbestos market is going to hold firm with the probability of prices still going higher for a considerable period.

**TORONTO COAL PRICES.**

Toronto, August, 18.—Prevailing coal quotations are as follows :

Mine run \$14.25 to \$14.50 f.o.b. Toronto; smokeless coal \$14.50 to \$15.00; hard coal \$8.00 to \$11.50 gross tons at mines. American funds. The demand is not stiff but practically no coal is coming in, the shipments being diverted to the Great Lakes for consumption in the North West.

**METAL QUOTATIONS.**

Fair prices for Ingot Metals in Montreal August 19th 1920. (For shipment from stock, and in less than ear-load lots.)

	Cents per lb.
Copper, electro . . . . .	24 $\frac{1}{4}$
Copper castings . . . . .	23 $\frac{3}{4}$
Tin . . . . .	55 $\frac{1}{2}$
Lead . . . . .	10
Zinc . . . . .	10 $\frac{1}{2}$
Aluminum . . . . .	35
Antimony . . . . .	9

**A NEW USE FOR MAGNESITE.**

It is reported by the Engineering and Mining Journal of New York that Mr. H. F. Wierum has been experimenting with ground magnesite as a substitute for lime in making egg shells. He finds that hens using magnesite produce a very superior grade of shell, having superior insulating and wearing facilities. Those who found magnesite useful in the shell industry during the war will be pleased to find that it is also useful in the original shell industry. It is another example of how the old established industries, have been helped by the hunt for substitutes.

**Our Northern Ontario Letter**  
**THE SILVER MINES.**

In the silver mining fields of Northern Ontario, as a result of success achieved in the South Lorrain, Gowganda and Elk Lake districts, the output of the metal may be maintained for a much longer period than had the industry depended entirely upon the Cobalt mines alone.

At Cobalt, too, the new developments on such properties as the Bailey Silver Mines, the Colonial, Prince Davis and Lumsden offers promise of adding to the number of producing mines.

According to official advice to the "Mining Journal" an ore shoot just encountered at the 350-ft. level of the Bailey Silver Mines shows a width of from four to five inches and contains high silver value, some of the ore containing from 2,000 to 4,000 ounces to the ton. The high grade is being bagged, while the lower grade material is being made available for treatment in the company's own mill. The work of transporting medium-grade ore to the mill will commence just as soon as the short railway siding is completed. This should not be later than about the middle of September.

Perhaps the most interesting official advice received during the week is that dealing with the success being met with on the Keeley Silver Mines, in South Lorrain. Although this property remained idle for a number of years, and was not re-opened until a few months ago, it is understood the ore in sight is estimated to contain close to \$1,000,000 in silver. Not only has the ore encountered been found to contain high values, but the ore-shoots are comparatively wide. One main ore-shoot is stated to be from four to five feet in width, and contains average silver values ranging from 30 to 100 ounces to the ton. In the meantime, the work of constructing a new mill is making satisfactory progress and the company expects to be treating ore at the rate of 80 tons daily some time during the closing quarter of the current year.

During the month of July the Nipissing mine produced silver at the rate of close to \$6,000 every twenty-four hours. In his regular monthly report to the president and directors, Hugh Park, manager, states that during the period, the Nipissing produced \$182,111, and shipped residue and bullion from Nipissing and custom ores of an estimated net value of \$129,315. Mr. Park states there were no unusual underground developments, but that the usual success was achieved in opening up new narrow veins.

A new order issued by Hon. Beniah Bowman, Minister of Lands and Forests, grants general working permission on all mining claims staked on the Gillies Limit. The Limit was thrown open on July 20th, with the understanding that the holders of claims would have to make application for and receive permission to do assessment work before undertaking any development work, but the new order directs that on and after July 20th it will not be necessary to make such application. Incidentally this will tend to shorten the time within which the first instalment of work falls due.

Up to the present only two mining disputes have resulted from staking of claims which occurred in July on the Gillies Limit. This is in sharp contrast to 1912 at the time a small part of the territory was

thrown open when as many as half a dozen disputes arose in connection with one claim.

Some small nuggets of native silver have been found in a narrow vein on the Garvey claims in the Gowganda district, in the vicinity of Smoothwater Lake. The find is characteristic of many others made in this field.

A large number of mining men will attend a general meeting of the members of the Ontario Mining Association to be held this week at Sudbury. The meeting commenced August 17th and will last for three days. Mine managers and presidents of mining companies representing perhaps ninety per cent of the mines of the Province will attend the meeting. In view of this being the first general meeting since the new organisation became fully established, it promises to be of outstanding importance. From this rate forward, the activities and the influence of the Association appears destined to be extensive. Not only will it serve as a means of comparing mining achievements, but the organisation aims to cooperate with the Ontario Government in such a way as to make available much valuable data, and stands ready to offer suggestions which may be considered beneficial to the industry.

#### THE GOLD MINES.

What is considered to be one of the most hopeful signs in connection with the gold mining industry of Northern Ontario is the report this week that the Hollinger Consolidated has secured fifty English miners. It is believed that if a slack period in mining has actually set in in England, and if the Hollinger has secured fifty men, it is not unreasonable to suppose that many more may be obtained in the same manner. Should such prove to be the case, it will remove the only obstacle standing between the gold mines of this country and maximum production.

The gold mines in the aggregate have a greater quantity of ore in sight than ever in the past, and their milling facilities will permit them to treat more than 6,000 tons every twenty-four hours. These two factors would come into full play in the event of an adequate number of men being secured. For this reason, therefore, too much importance cannot be attached to the reports that men are being obtained from the British Isles.

An announcement of importance to the shareholders of the McIntyre-Porcupine has just been made, and conveys the information that the company has decided to enter into another venture, this time in a coal mine in Alberta. It is stated by president J. P. Bickell that one property has been purchased and an option has been secured on another, and that the Temiskaming Mining Company may also be asked to take part of it. The Blue Diamond property at Brule, Alta, has been purchased, and a fifteen year option is held on the Canadian Coalfields property. Just how the report will be received by the shareholders of the McIntyre-Porcupine and the Temiskaming Mining Company remains to be seen and will be governed largely by the report presented prior to voting on the question.

The Miller Independence Mines of Boston Creek announce a stock offering of 46,000 shares, and restricts the right to participate in it to the present stockholders. This company received permission from the Department of Securities of the state of Ohio, about one year ago to sell not more than 100,000 treasury

shares at \$3.80 per share. Of this amount 54,000 shares were sold at that figure. The present offer is calculated to again strengthen the treasury and at the same time offer an opportunity for the present stockholders to reduce the average paid for shares.

Work at the mine is proceeding in a satisfactory way and the face of the main cross-cut at the 500-ft. level is believed to be within about 70 feet of the downward continuation of the main orebody. In the meantime, work has been resumed in the inclined shaft at a point closer to surface with the object of blocking out the high-grade ore shown at that horizon.

#### KIRKLAND LAKES ANNUAL MEETING.

That a fine body of ore had been recently discovered on the 400-foot level was an announcement made by President Frank L. Culver, at the annual meeting of the Kirkland Lake Gold Mining Company, Limited, held in Toronto on Tuesday of this week. The development has not proceeded sufficiently as yet to indicate the extent of the ore body, but it is believed to carry values ranging from \$200 to \$300 a ton. In the President's survey of the operations it was pointed out that the principal development consisted in the sinking of the main shaft to the 900-foot level. In this respect Kirkland Lake is the pioneer in the way of depth operation in the Kirkland Lake Camp. The results obtained are most encouraging as the porphyry formation is found to exist at the 900-foot depth. Mr. Culver made it clear that the company had never carried on what is described as selective mining, and stated that such a policy would always be avoided. It was also stated that the proposed amalgamation between Kirkland Lake, the Orr and Teck-Hughes Mines would receive consideration at the hands of Kirkland Lake only on the basis of actual values. All of the old board of directors were re-elected.

#### CARTWRIGHT GOLDFIELDS.

Surface exploration of the property of Cartwright Goldfields, Limited, which lies north east of Matheson, Ontario, is bringing good results. Last week another vein carrying free gold was discovered. It lies near one of the veins that is now being stripped. Work on the latter vein was begun a few weeks ago and good values have been found in the samples taken as the work progresses.

The Cartwright property is close to Painkiller Lake. It is easily reached by wagon road from Matheson on the L. and N. O. Railway.—R.E.H.

#### THE PREMIUM ON GOLD.

At a meeting of the Commercial Club in Salt Lake City on July 23, Mr. H. N. Laurie of the American Mining Congress outlined the proposal which would provide for a premium of \$10 per ounce on newly mined gold. This proposal is being placed before U. S. Congress by Representative McFadden.

At present Canadian gold producers are benefitted by a premium on gold arising from the fact that gold can be sold in Canada on the same basis as U. S. currency. This means that gold in Canada is worth considerably more than the \$20.67 per ounce at which it is quoted.

## Putting Canadian Iron Ore on the Map

By J. J. O'Connor

If Canada is to keep place with her competitors for world trade, if her great fleet of merchant ships are to be kept employed in carrying our own products to world markets, if she is to pay her debts out of her own resources, she must develop her enormous deposits of iron ore, in order to occupy that industrial independence that will enable her to compete successfully for the foreign trade that is so vitally necessary to her future.

A glance at the past shows that all that is needed to make Canada a leader in mineral production, is well directed, and sustained effort on the part of Government and people, in the exploitation of her vast store of mineral wealth. In 1886 Canada's mineral production amounted to \$2.23 per capita, in 1917 it had reached \$23.12 per capita. If iron ore production had made the same advance as all other minerals; if imported iron ore had been displaced by domestic ores, and if the enormous importations of iron and steel products—now in the neighbourhood of \$175,000,000 annually—had been displaced to a great extent, by our own manufactured articles, as they very well might have been, our mineral production would show a vastly increased sum per capita.

That this industrial independence may be brought about, is but reasonable to suppose, in the light of what is being done in other iron fields, by our neighbours in Minnesota, where millions of tons of iron ore are being beneficiated annually, and millions of dollars are being expended in the installation of plants for the magnetic separation and concentration of low grade iron ores, similar to our own.

The province of Ontario is wholly dependent on United States ores, with the exception of the extremely small percentage of domestic ores now being charged to the furnaces of this province.

The Ontario Government is directly interested in the industrial development of its own estate. The Federal Government is equally interested in the up-building of an iron and steel industry in Canada, adequate to its needs, therefore, they should co-operate in demonstrating the commercial feasibility of converting our low grade ores into a desirable product for furnace use.

The Bureau of Mines, Toronto, and the Mines Branch, Ottawa, should make a joint, and thorough investigation of what the Mesabi Iron Company have done in their experimental plant, at Duluth, and what they are now doing at Babbitt, Minn., as a result of the experiments carried on at Duluth, where they produced thousands of tons of ore that met the highest furnace requirements.

Skillsings' Mining Review, an outstanding authority on Minnesota iron ore, in a recent issue, says, in part: "The work of pouring concrete for the foundations for the first mill unit of the ore treating plant of the Mesabi Iron Company, at Babbitt, Minn., will be begun early next week, and the work of erecting the steel for the superstructure will be begun about August 15th. Four hundred men are employed by the company at Babbitt, and the immediate vicinity, in the extensive preparations necessary to whip this new and important iron mining enterprise into shape for production. The company will enter the shipping list

with its product at the opening of navigation next spring. This initial unit has an estimated capacity for treating 3,000 tons of ore per day, but it will occasion no surprise if the over-run is considerable. The size of the new mill will be total length 1350 feet, and width 130 feet. The plant consists of five sections laid out to give continuous process. But to return to the mill that is being erected out there in the wilderness of the Eastern Mesabi. The Minneapolis Steel Machinery Co. has the contract for the steel. While people are vastly interested in the fact that the Mesabi Iron Company is spending about three million dollars on the Eastern Mesabi, the real basis of this interest lies in the fact, that the expenditure is being made to establish on a broad commercial basis, an advanced principle in magnetic separation. Magnetic separation is the principle on which this costly development is being founded, and this Company has produced separators that are expected to do their work more efficiently than any heretofore built. The modus operandi is as follows: Mine, crush, grind to powder and separate the ore from the rock, and form the concentrate into clinker by the sintering process, for blast furnace use. The final clinker will be a very high grade iron ore, free from moisture, free from all deleterious elements, such as sulphur or titanium, and dust. There are billions of tons of low grade magnetic ore, or taconite, on the Eastern Mesabi. The Mesabi Iron Company alone controls, or owns outright, many hundreds of millions of tons itself, in the 20 square miles it has taken over. It would seem that the Mesabi Iron Company had fully worked out its problems in metallurgy, when one considers the success of the first cargo of the product of the low grade magnetic ores, which was produced in the experimental plant at Duluth. As far as can be seen all problems of the future were met in the production of the first cargo. Assuming that to be the case, the Company seems destined to become one of the chief factors in the future of the iron ore industry of Lake Superior. It has brought into being an enormous mass of iron bearing material that gives every promise of lengthening for a very great many years, the life of the iron, mining industry of Minnesota. W. G. Swart, general manager, in charge at Babbitt, Dwight E. Woodbridge, of Duluth is in charge of the company lands."

With this experience before us, and the success it has met with, it would seem idle to not take advantage of the opportunity of investigating this great enterprise, and determining its adaptability to our own ores. Both Governments have the necessary machinery at hand, for making such an investigation. Added to this, is the highly satisfactory results in magnetic separation, obtained by Prof. Stansfield, of McGill University, recently. It is to be hoped that this matter may not be longer deferred, and that immediate action may be taken. The Tariff Commission would do well to look into the question of the vast tonnage of iron ore, and iron and steel products imported annually, and its effect on the commerce of the country.

Pottery products in the United States during 1919 are reported to have reached a value in excess of any previous year. The value of manufactures in 1919 is estimated at \$76,140,000 comparing with \$63,911,793 in 1918. The increase over 1918 is of course largely made up of higher values as measured by cost, but no figures are available regarding quantities.

## British Columbia Letter

### Stewart, B. C.

R. K. Neil, part owner of the Premier Mine, Salmon River, Portland Canal District, in discussing operation on that property, stated that cyanide plant, with a capacity of 00 tons a day, is being installed and would be ready for use early next year.

There are some 100 claims staked in the Marmot River section of Portland Canal and on many development work is in progress. George Clothier, government mining engineer, recently made a tour of inspection through the district with a view to ascertaining the extent of the necessary road and trail improvements. The B. C. Exploration Company is heavily interested in this section and Dr. W. L. Uglow, geologist for the Company, has completed an examination and is preparing a report, together with maps, describing his investigations and giving his conclusions. P. D. I. Honeyman, for the same Company, has a small crew of men at work on the Salmon River Lode Mining Co's property, situated near the Big Missouri Group.

Among the properties under development in the Bear River Valley, Portland Canal, are the Bayview, situated just back of Stewart, from which a trial shipment is to be made soon; the Lakeview, which is being worked by Al. Harris on behalf of P. Welch and associates; the Fitzgerald Group, which is to be explored by diamond drill by the Algonic Development Co.; and the Nabob and Redtop Groups.

### Alice Arm, B. C.

The Dolly Varden Mine is shipping an average of 150 tons of ore a day and preparations are being made for the extension of the railway to the Wolf Group of the Claims situated a short distance north of the mine. The Toric, Tiger, Musk, Silver Horde, Climax and other prospects are being opened up, Surface stripping is taking place on the La Rose Group with satisfactory results and good showings are reported on the Wild Cat, North Star and Royal Groups.

### Hazelton, B. C.

John D. Galloway, resident engineer at Hazelton, B. C., has left on a tour of inspection of various mining properties in the Cariboo District. He is engaged incidentally, in the collection of an exhibit of the minerals of northern sections of the Province which is to form a part of a large British Columbia mineral display in England.

There is considerable placer mining work in progress in the Dease Lake, McDame's Creek, Thebert Creek, and Telegraph Creek districts of Northern British Columbia this season. On Thebert Creek George Adams, a well known hydraulic operator of the Atlin Camp, has been at work since early in the year. A. St. Clair Brindle, a mining engineer, has returned after accompanying a party representing the Princess May Mining Co., of Vancouver, to McDame's Creek. They took in an hydraulic outfit.

### Quesnel, B. C.

Once again R. T. Ward, of the Bullion Placer Leases, Cariboo, has been heard of in connection with litigation. Having won his long drawn out suit with John Hopp it was thought that the operation of the

long disused property would follow without delay. Some of Mr. Ward's associates, however, challenged his right to retain control or the management of the project. For a time it looked as though there might be another sustained fight through the courts. However it now appears that a settlement, said to be generally satisfactory, has been reached and that the famous property soon will be put on an operating basis.

### Prince George:

Good reports have been received concerning the showings obtained on a property situated near Prince George and known as the Hole-in-the-Wall. Samples have been brought in containing values in gold, silver and copper and it is said that the two outcrops from which these were taken have been uncovered by stripping. The property is to be inspected by a competent engineer.

### Nelson, B. C.

Considerable development is taking place on mining properties situated on Lightning Peak and the Provincial Government is having a road surveyed from Deep Creek to the Peak. It is likely that a trail will be constructed and prospectors and operators interested are confident that it will not long before the mineral resources of the section are sufficiently well proven to justify the building of a wagon road.

The possibilities of the development of gold mining on a considerably larger scale than at present in British Columbia was the subject of an address by Dr. Edwin T. Hodge, formerly professor of geology in the University in British Columbia, delivered recently at Nelson. To a number of interested mining men he explained that there was a belt in this Province similar to that of California extending from Bridge River in the north southwards across the Fraser River into the Skagit basin in the State of Washington. It is cut by numerous dykes and in places quartz veins have been prospected and shown to contain gold. Only in a few places have been mined to any extent. One of these places is in the Coronation and Pioneer Mines on Bridge River and another in the International Group on the boundary line. Dr. Hodge, however was of the opinion that the richest showings were in the central portion and in this connection he mentioned the Emancipation Mine, which was bounded recently and is to be developed. The British Columbia Belt was described as similar to the Motherlode Belt of California and "whether considered in a generalized way or considered from the standpoint of the minute and detailed study of the individual deposits there are a good many reasons to believe that within the Province a series of gold mines will be developed which will rival those of California.

Among the properties under development on Lemon Creek, Slovan, is the Barnett, where a force is engaged in stripping the vein and driving a tunnel. There are two of these, that on which work is in progress, being in a distance of 80 feet and the other 70 feet. Both are in ore which carries values in gold and silver, chiefly the former.

The Silversmith Mine, formerly the Slovan Star, promises to be one of the heaviest producers of the

Kootenays. The annual report, just issued, shows that the gross receipts from the sale of ore for the year ending May 31st were \$205,996.68, the margin over operating expenses being \$14,358.83. It is pointed out that this latter showing may not appear to be adequate but its comparative meagreness is explained by the necessity "to spend large sums for timber, raising and opening up various stopes in order that the ore could be economically mined." Perhaps the most significant statement is that "it is estimated that sufficient stoping ground has been developed to last seven years at the present rate of production."

#### Kaslo, B. C.

On his return from a tour of the Kaslo District, R. done preparatory to a thorough examination of the conditions are improving. George H. Aylard and Associates have taken a bond on the old Wellington Mine and the tunnels are being cleaned out and other work done preparatory to a through examination of the property. On the South Fork of Kaslo Creek the Silver Bear is being opened up by a small crew of men. Not only is development being carried out underground but a considerable amount of surface work is being done. Some ore is being taken out at intervals and at present a car load is sacked and ready for shipment. The Index, Revenue and Liberty Hill Groups also are receiving attention. The Cork-Province at present is idle but it is understood that the owners expect to be able to complete financial arrangements shortly for the resumption of operations.

R. A. Grimes, manager of the McAllister Mine, Three Forks, is responsible for the statement that the labor trouble which has been interfering with mining activity in the Slocan and other parts of the Kootenay is being overcome. Illustrating the improved conditions he points out that a considerable force is engaged on the Noble Five; that the same is true of the Queen Bess; that the Rambler-Cariboo again is the scene of real work; and that the Rosebery-Surprise is operating. He has been able also to increase his crew on the McAllister and the threatened walk-out at the Blue Bell, Riindel, is said to have been averted. There is as a result, Mr. Grimes asserts, a feeling of renewed confidence and optimism among the operators.

#### Trail, B.C.

Ore receipts at the Trail Smelter of the Consolidated Mining & Smelting Co. for the final 10 days of the month of July were the greatest for any similar period this year. They totalled 12,862 tons, bringing the aggregate for the year to date up to 181,157 tons.

#### Nelson, B.C.

The Provincial Prospectors' Protective Association continues to gather strength. Local organizations representing the Grand Forks and Smithers Districts have made applications to the central body for copies of the constitution, and there is every reason to believe that they will become affiliated. It has been decided that the Provincial Attorney General shall be asked what action will be taken to protect prospectors' cabins and caches from the depredations of thieves. It appears that members of the Association have been put to expense and annoyance in many instances by finding their headquarters in the hills rifled on returning from their periodical trips.

The Perrier Gold Mines, Ltd., of Nelson, recently incorporated with a capitalization of \$250,000, announces that the development of the Perrier, situated on Cottonwood Creek, will be proceeded with. The property has been opened up to the extent of two shafts, one being 120 feet deep with a northerly drift 200 feet in length from the bottom. There are two feet of good milling ore in the shaft and a similar width in the face of the drift. The smaller shaft, 40 feet deep, has been sunk in four feet of milling ore. The latter is said to be similar to the product of the Athabasca and the Granite-Poorman, from 60 to 70 per cent of the gold being free milling. While there is a considerable body of ore blocked out, no stoping has been done as yet, the ore shipped having been taken out in the course of development. The present equipment includes a 150-ton milling plant, a compressor, a friction hoist and an hydraulic pump, this being operated by water power brought through a 2,500-foot eight-inch wooden pipe.

#### Stewart, B.C.

Word from the Salmon River Section, Portland Canal, indicates that a fresh body of ore has been uncovered at the Premier Mine. The strike has been made in No. 2 Tunnel at a depth of about 600 feet and assures the active operation of the mine for an indefinite period. It is believed that this development is responsible for the recently announced decision to install a cyanide plant on the property. There now are more than 150 men employed in and about the mine, and good headway is being made with the concentrator foundations and the pipe line.

One of the two diamond drills on the Big Missouri has been closed down, that at work on the E. Pluribus Claim being continued. This is the claim on which high-grade ore is being opened up.

The Northern Light and Spider Groups on Salmon River and the Fitzgerald Group on the Bear River are being thoroughly explored by the Algonic Development Co., whose operations are the most extensive of any other one concern interested in the district, with the exception of the Premier Mining Co.

#### Vancouver, B.C.

John Hopp, well-known as an hydraulic placer operator in the Cariboo, states that, while British Columbians interested in this phase of mining appreciate the Provincial Government's action in relieving them partially from taxation and the payment of royalty, they still are seriously handicapped. With camp supplies, fuel and wages doubled in cost, the gold mining companies are hard hit at being compelled to market their product at an arbitrary figure. "We miners," he said, "only wish that gold would be left free to have its price fixed by the law of supply and demand. The arbitrary price of \$20.27 an ounce for fine gold hits us very hard. Only the best conducted plants can afford to operate, and many placer men are just holding on and not operating." Dealing with the season's conditions he stated that the water has been late this year, and that to make it worse there is a very rapid run-off which probably would limit the season to 90 days. Usually he gets his plant in operation by May 12, but this year work did not begin until June 1.

#### Victoria, B.C.

The Geological Survey of Canada has issued its an-

nual summary report of the geological survey work in British Columbia, and the Yukon during 1919. It contains an account of the explorations of W. E. Cockfield in the Ogilvie Range, Yukon, who also writes of the Mayo District in the same area. J. J. O'Neill deals with the Salmon River District, B.C.

Apropos of the new monograph on Graphite by H. S. Spence of the Dominion Mines Branch, it may be noted that in British Columbia graphite has been discovered at Alkow Harbor and on Dean Channel in the Bella Coola District. In the Fort Steele District it has been found on Matthew Creek, Marysville. A vein about two feet wide and running 25 per cent graphite was uncovered there about four years ago. In neither body nor values, however, is the vein a commercial proposition. Some years ago two carloads were shipped from Harrison Lake, but nothing further has been developed there. These are the only reputed discoveries. In the Bella Coola District the mineral occurs in minute flakes associated with pinites in a matrix of heulandite. In runs 23 per cent. in graphite. The Marysville deposit occurs on a contact of diorite and mica schist in a disseminated matrix of earthy silicates.

#### Moyie, B. C.

It again is reported that the St. Eugene Mine is to be put on a shipping basis by the Consolidated Mining & Smelting Co. The heavy tonnage from the Sullivan at Kimberley to the Trail Smelter is said to necessitate wet ore from the St. Eugene to act as a flux. The St. Eugene has produced over 5,000,000 ounces of silver and 229,000,000 lbs. of lead, valued at more than \$10,000,000. When the St. Eugene closed down in 1910 it was reported that the ore deposits had played out but it is said that there are big bodies of ore still in reserve. A small crew of men is at work.

#### Trail, B. C.

Ore receipts at the Trail Smelter of the Consolidated Mining & Smelting Co. of Canada for the week ending July 21st were 7,061 tons, bringing the total receipts for the year up to 168,295 tons. For the first time for some years the Velvet Mine of Rosslund appears among the list of properties shipping ore to the smelter. The Silver Bear, of Kaslo Creek, also is one of the shippers.

#### Grand Forks, B. C.

The Copper Farm Group, situated about five miles below Princetown on the Great Northern Railway, is being developed by the Princetown Mining & Developing Co. and is expected to become a regular shipper. There are three full claims on which the ledge has been opened by three tunnels. The vein has been traced for about 4500 feet on the surface and the operators assert that they have a large body of concentrating ore averaging 4 per cent. in copper and one ounce in silver. A three drill compressor has been installed and is now operating by means of steam power and another is to be installed shortly.

#### Vancouver, B. C.

J. W. D. Moodie, for many years general manager of the Britannia Mines, has resigned. He has been succeeded by B. B. Nieding, a well known mining man of the Pacific Northwest.

T. C. Botterill, formerly assistant superintendent of the Surf Inlet Mine, has accepted the superintendency of the Emancipation Mine, operated by the Liberator Mining Company.

### THE COAL MINES.

The Canadian Collieries (D) Ltd., has adopted a forward policy in connection with the development of its coal holdings on Vancouver Island. J. M. Savage, General Manager, and Thomas Graham, General Superintendent, have decided that the Extension field shall be opened up to a greater extent than at present. There is coal at Extension and coal at the head of Oyster Harbor and there is every reason to believe that there is coal under the Haslam flats lying between these points. Several boreholes have been put down in this territory and all have shown coal or coal indications. A workable seam, however, has yet to be found and the Company will make another effort to this end, it being the intention that new boreholes shall be commenced without delay. The Company's new mine at South Wellington now is a regular producer and it also possesses a coal field at Sable River, near Union Bay, which will have attention soon. Messrs. Savage and Graham declare that the factors that have prevented the Company's aggregate output mounting very materially are lack of labor and uncertain market conditions. At present, however, there is no doubt about the market. The demand for the fuel produced by the collieries of Vancouver Island is brisk, in confirmation of which may be instanced the recent shipments to Sweden and other foreign parts and the prospect of further development of this overseas trade. Therefore it is the intention to proceed with development and to produce to the maximum capacity of the field having regard to the labor available.

With reference to the recent indications that a strong European market is about to be established for British Columbia coal it is interesting to note that the "S. S. Robin Goodfellow," of the Robin Line Steamship Co., a subsidiary of the Skinner and Eddy Corporation, of Seattle Wn., after loading at the bunkers of a Vancouver Island Coal Company will leave for a South American port.

Following the reaching of a settlement of wage and other questions between the Mine Operators and Employees in Eastern British Columbia and Alberta Coal Fields it was thought that a period of industrial peace was assured. Broadly speaking there is no reason for believing that this assumption will not be justified. There already has been, however, one slight rift in the lute. It occurred at Fernie, B. C. All the men with two exceptions had signed up with the U.M.W. of A., as it was through this organization that the agreement had been made with the Operators. When the two referred to it is stated that the U.M.W. of A. refused to accept them as members. Whether this is correct or no there is no doubt of what ensued. The miners refused to go to work the next day as a protest and a deputation waited on the management of the Crow's Nest Pass Coal Co. to make known the grievance. The next day, however, they went back to work pending an adjustment of this difference. The mines at Michel are in full operation, which statement applies to most of the mines of District 18 (U.M.W. of A.) which takes in a part of Eastern B.C. and the whole of the Province of Alberta.

The Coalmont Collieries, in the Nicola-Princeton Coal Field, mainland of British Columbia, soon will be well equipped with the plant necessary to permit a greater output and regular shipments to the waiting Vancouver and other adjacent domestic markets. The stations for the tramway that will bring the coal from the pitmouth to Coalmont are erected with the exception of the terminals. The little town at Coalmont will house the families of the miners and the married men will be able to spend their week-ends at home, bunks and meals being provided in addition for all hands near the pitmouth. At present some 150 tons a day are being produced, transport being furnished by motor truck over the hill road.

In a recent address to the members of the Vancouver (B.C.) Board of Trade W. R. Wilson, president and general manager of the Crow's Nest Pass Coal Co., Fernie, B.C., emphasized the desirability of the businessman having a clear knowledge of the fundamental basis of the chief manufacturing industries of the Country and in this connection referred to the conditions under which the iron and steel industry was operated in Canada and the United States. He spoke of the lamentable duplication of transportation and the high costs that were added to the finished product as a result of these charges. He said:—

“The iron ores that are smelted in Pittsburg are chiefly produced in the State of Wisconsin and are brought to Pittsburg by these stages of transportation: First, by rail to the lakes from the mines; second, across the lakes by steamer to the different points on the east side of the lakes; then, again, distributed by rail to different smelter points. Then, after these three stages of traffic manipulation, the ores are smelted in various forms of crude iron and steel are shipped from Pittsburg to various points in Ontario and Manitoba for further manufacturing processes.

“Following this manipulation of transportation of iron ores and iron those engaged in the iron trade production in Ontario and Manitoba, through the lack of fuel in these Provinces, again go to Pennsylvania or Virginia to purchase the coal and coke fuels they use in the finishing processes of reducing the crude iron to marketable form.

“In these duplicated processes of transportation of the crude metals and transportation of fuels the manufactures of Ontario and Manitoba possibly absorb about \$12 excess per ton in all the finished products they make, which can only be regarded as a serious economic handicap to those engaged in these particular industries in provinces which do not possess suitable fuel deposits for these purposes.

“Then the people of the West, who have so far failed to take advantage of their own natural resources are called upon to purchase the products of iron and steel that are manufactured in the East, not only at excessive cost of production, as just illustrated, but to pay for repeated mileage costs of transportation, which have become involved in a system of production that is founded on either an oversight or a misconception of the sound basic principles of industry.

“In the Fernie District we have coal deposits that are, at least equal to the best coals on the continent. The coal bedding, in some instances, is accompanied with exigencies that I have never seen in any other coal fields on this continent, which peculiar characteristics may be briefly referred to as follows:

“When these mountains were lifted from the original lines of formation, which upheaval approximately lifted the structural bedding in some parts of the areas of the district from 500 to 3,000 feet higher than they were originally, considerable crushing and contortional twisting in the structural mass occurred, which violent forms of crushing developed dynamic heat of various degrees of intensity. These forces volatized the coal beds to a certain extent, also volatizing the beds of shale that intervene between the different beds of coal. These violent crushing mass pressures, acting upon the sandstone, shale and coal measures of the district may be estimated at 2500 to over 3000 feet in thickness, also developed indefinite and artificial rent lines in the whole structural mass.

“In some portions of the fields, rent lines appear to have been formed, thereby making it possible for the intense gas pressures to escape as the process of volatization went on. In other portions this form of relief fracture does not appear to have occurred, hence in certain districts of the field intense pent-up pressures of the gas appear to have been formed in the small voids and cracks and cavities that have been created during the general upheaval.

“In some instances these small pent-up pockets of gas may be estimated to have assumed a pent-up force of about 210,000 pounds per square foot, or about 1458 pounds per square inch. These difficulties, while of a very unusual nature in coal mining, are carefully approached and through the medium of excessive care may be safely dealt with.”

Coal mining operations will be commenced at the new coal field near Lampman, Saskatchewan, Canada, within the next sixty days. This field is being developed by the Farmers Coal Mining Co. Ltd., a company owned and operated by the farmers of the district. The shaft already has been sunk to a depth of 170 feet and the coal bed lies at a depth of 210 feet. This coal has been shown from analytical tests to have a calorific value of more than 12000 British thermal units, and is of high grade. When fully developed the mine will have a capacity of 1,000 tons a day. This will take some time, however, as it will be necessary to do a large amount of work in channelling and tunnelling away from the shaft before maximum capacity can be reached. In the meantime the work is being hurried and coal will be brought to the surface within the next two months.

Coal production returns for the month of July, as far as are available, indicate that the collieries of British Columbia apparently are satisfactorily meeting recent heavier demands of the trade. The figures follow:

**Nicola-Princeton Field.**

	Tons
Middlesboro Collieries Co., Middlesboro . . . .	6,918
Fleming Coal Company, Merritt . . . . .	2,626
Coalmont Collieries Co., Coalmont . . . . .	1,984

**Vancouver Island Field.**

Canadian Western Fuel Co., Nanaimo . . . .	55,399
Canadian Collieries Ltd., Comox . . . . .	41,089
Canadian Collieries Ltd., So. Wellington . . . .	8,904
Canadian Collieries Ltd., Extension . . . . .	15,342
Pacific Coast Coal Mines, So. Wellington . . . .	7,680
Nanoose-Wellington Coal Co., Wellington . . . .	3,079
Granby Cons. M. S. & P. Co., Cassidy . . . . .	9,019

**JOHN STEWART MacARTHUR.**

A TRIBUTE BY DR. W. A. CALDICOTT.

(In The Journal of The Chemical, Metallurgical and Mining Society of South Africa.)

The members of our society will learn with much regret that J. S. MacArthur, whose name is familiar throughout the mining world as the inventor of the cyanide process, has recently died in consequence of complications following upon a chill.

John Stewart MacArthur was the son of a Scotch clergyman, and began work early in life as an apprentice in the laboratory of the Tharsis Sulphur and Copper Company of Glasgow. Later he entered the service of the Cassel Gold Extracting Company as chemist (1871-86, eventually becoming its technical manager (1886-93), and subsequently managing director until 1897. It was during his service with this company that he, with Dr. Forest and others, undertook during his leisure hours the series of systematic researches for a hydro-metallurgical process of lixiviating gold ores, which resulted in the first practical application of a dilute alkaline cyanide solution as a gold solvent, and of zinc shavings, at first plain and later lead-coated, as a precipitant of the dissolved gold.

Apart from patent specifications, the first published authoritative account of the MacArthur-Forrest process of gold extraction is contained in an article published by J. S. MacArthur in the "Journal of the Society of Chemical Industry" on 31st March, 1890. After describing the practical application of the process, the paper concludes with the following words:—"I confidently predict that cyanide of potassium, hitherto used only to polish amalgamated plates, will take front rank as chief agent in gold extraction." The events of the last thirty years have amply fulfilled this prediction; and further, most silver ores in Mexico, which is the chief source of silver, have for years been treated by means of the cyanide process. The many million ounces of gold and silver yearly extracted by means of the cyanide process have, apart from their direct influence upon the mining industry, produced wide and far-reaching effects upon the whole monetary and economic systems of the civilised world.

The cyanide process was demonstrated in South Africa upon a variety of gold ores, concentrates and tailings in 1890 at the battery of the Salisbury G. M. Co. Later this pioneer work of the Cassel G. E. Co. was taken over by the African Gold Recovery Syndicate, which eventually became the African Gold Recovery Company. Following these novel and successful demonstrations, the use of the process rapidly extended in the Transvaal and the whole mining world, as its superiority over competitive methods became realised. To the gold mines it meant the conversion of embarrassing tailings into dividends, and the payability of mines otherwise unprofitable. Some of MacArthur's reminiscences of this period were given in the December, 1908, issue of our journal.

Subsequently, in 1896, the Transvaal patents were the subject of an historical lawsuit, which resulted in their cancellation on the ground of prior scientific knowledge, although no gold had ever been previously extracted on a commercial basis from ores by means of cyanide solution. A recent tribute to MacArthur's work in this direction is contained in Dr. H. H. Green's

presidential address before the last meeting of the South African Association for the Advancement of Science in the following words:—"Thus the development of the whole mining industry of the Witwatersrand, and the very coming into existence of the city of Johannesburg, was conditioned by a laboratory observation made originally by a pure chemist, and developed by a mineralogical chemist—who, it may be added, did not get enough out of his patent to enable him to abandon his practice. The cyanide process for the extraction of gold from low-grade ores and tailings makes just that difference between profitable and unprofitable production of gold in South Africa, and without it the industries of the Witwatersrand would never have reached their present development."

Following on the last of his visits to the Rand, MacArthur engaged for many years in ordinary professional work on gold and copper as a consulting metallurgist. His practice involved repeated visits to Portugal and the United States, as well as numerous investigations and researches. In January, 1913, he published a paper in our journal on winz wafer precipitation, and during the war until his death he devoted himself to the extraction of radium at Balloch, on Loch Lomond, for military watches and compasses.

To his sturdy independent Scottish characteristics and chemical knowledge MacArthur added a remarkable insight and tenacity of purpose and a kindly consideration for those with whom he was associated. The world is the poorer through his death in the loss of a good chemist, a famous inventor, and an honorable, upright man.

In addition to having been for many years an honorary member of our society, MacArthur was awarded in 1902 the gold medal of the Institution of Mining and Metallurgy, and the well-known text book, "Rand Metallurgical Practice," was dedicated to him by the authors in the following terms:—

To

JOHN STEWART MACARTHUR.

Whose pioneer researches and introduction in 1890 of the Cyanide Process as an essential feature of Rand metallurgical practice have rendered possible the successful treatment on scientific principles of low-grade banket ore, and have been a prime factor in establishing the Witwatersrand Goldfields as the premier gold producer of the world.

**GOWGANDA.**

The revival of interest in the Gowganda silver area, due in part to the development of the Castle property by the Trethewey Company is still dampened by the lack of suitable transportation facilities. The proposed light railway would help the district considerably, but there seems no prospect of it being built this summer.

The reported new discovery at the Miller Lake-O'Brien, the premier mine of the district, doubtless originated with the shipping to Toronto of a large specimen of very rich ore.

The high price obtainable for silver should encourage those interested in Gowganda properties. They have however had many difficulties to contend with.

It is rumored on the street that an English company has acquired a large interest in the Trethewey on the strength of developments at the Castle property.—R.E.H.

# MINE CARS

We make the kind of Car you want, and  
make it just the way you want it made.

MADE IN MANY SIZES

**ROTARY**—Will dump at either side or either end

This is only one of the many styles of Mine Cars we offer. Let us know the type of car you prefer, and we will give you attractive prices.

Write for your copy of our new Mining Catalogue. Just off the press.

We have been designing and building cars for a quarter of a century. Our designers know their business, and are at your service free of charge.

**STEEL SKIPS**

For use on Mine Tipples. Made any size to suit your work, and if desired, with double bottom, and rivets countersunk and flush on the inside, to facilitate easy dumping.

**HEAVY BUILT PUSH CAR**

A good general purpose car for any kind of heavy work. Heavy steel frame work decked with 2½ in. or 3 in. planking. Self-oiling babbitted boxes. Made for any gauge of track, and any required weight to suit the load.

If you use Wood Cars we can supply you with the wheels, Axles, Boxes, etc., so you may build your own cars. You will save money by so doing.

**MARSH ENGINEERING WORKS, LIMITED,**

Established 1846

**BELLEVILLE, Ontario, Canada**

Sales Agents:—MUSSENS, LIMITED, Montreal, Toronto, Winnipeg and Vancouver

## FOR SALE

We offer for Immediate Shipment the following New Equipment at Prices Below Cost:

- 1—5' x 5' Ball Mill
- 1—5' x 16' Tube Mill
- 4—Bouchardt Concentrating Tables
- 1—Duplex Groch Flotation
- 1—Dorr Thickener
- 1—6" x 7" Aldrich Vertical Triplex Pump
- 1—3'-6" Allen Cone

**THE HALL MACHINERY COMPANY**  
SHERBROOKE, Que. 14 Phillips Sq., MONTREAL, Que.

## This Trade Mark on Your Belting

Guarantees satisfaction under Mining conditions, intense Heat or below ZERO. Wet or Dry, Steady or Intermittent. Will outlast from 4 to 6 Rubber Belts on Bucket elevators.

We also make Conveyor Belts, any width or thickness,

SOLE MAKERS:

F. Reddaway & Co., 653 St. Paul W., Montreal

## MANGANESE STEEL CASTINGS

FOR

All Kinds of MINING MACHINERY,  
CRUSHER JAWS, HAMMERS AND  
HAMMER TIPS, LINERS FOR  
CYCLONE BEATERS  
BUCKET TIPS, STAMPS AND DIES,  
DREDGER POINTS

Mild Steel Castings for all purposes

BALLS FOR BALL MILLS RE-  
DUCE COST OF ORE PER TON  
CRUSHED

**CANADIAN BRAKESHOE CO., LIMITED**  
SHEPPOOKE, QUEBEC

## THE SECOND INDUSTRIAL CONFERENCE.

### Views of the Canadian Institute of Mining and Metallurgy.

In all probability, the Minister of Labor will call a second Industrial Conference, to meet at Ottawa during the autumn. Few will gainsay that it is, in theory, an excellent plan to bring together periodically in gatherings of this kind representatives of industrial employers, of employees, and of the general public. In practice, however, the usefulness of such a conference must depend very largely on the degree to which the various delegates can really speak authoritatively for the class they are supposed to represent. The labor delegates, representing organized and unionized labor, can be depended upon to act as a single unit. They are agreed upon what labor wants, and by their life's training and practical experience in such matters, they are both prepared and qualified to state their views or demands of labor upon any question which may arise. On the other hand, at last year's conference it was evident that the employers' representatives were in a position to speak only for themselves, or at most for the one particular industry in which they were engaged, and it must be admitted that, in general, they did not display a sufficiently intimate knowledge of the wider aspects of the various labor problems that came up for discussion. The delegates representing the general public, also, could do no more than express their opinions as individuals, and in no sense did they fairly represent the class for whom they appeared—a class that surely is as vitally interested in the establishment of harmonious industrial relations as are either the employers or the employees. A conference so constituted cannot possibly go very far towards solving permanently the problems underlying industrial unrest. It might be compared with a match in which a team of amateurs, who have never previously played together, is pitted against a well trained professional team. No matter how able and resourceful the former may be individually, their lack of understanding and combination places them at a great disadvantage, and the game must suffer. So with the conference, and unfortunately there is, on very important points, sufficient antagonism between employers and employees to render the parallel all the closer. Since there must be two sides, let them be evenly matched and determined to play the game. As was stated in the *Bulletin* in commenting on last year's conference, "if industry it to benefit to the fullest possible extent from such meetings as the recent Conference, it is essential that representatives of employers as well as employees should be in a position to speak authoritatively for the interests for whom they appear."

### NOTES ON MINING OF MICA, GRAPHITE AND MAGNESITE IN QUEBEC.

(From Bulletin of C. I. M. & M.)

The demand for Canadian mica continues to be good; the prices are quite satisfactory, and in consequence the mines of the Lièvre-Gatineau region are very active. The Blackburn mica mine, at McGregor lake, one of the very few underground mica workings in the country, has now reached a depth of 250 feet on a slope of 60 deg. The Wallingford mines, at Perkins, are getting out some remarkably large sheet-mica, a great proportion of which is shipped to Eng-

land. Canadian mica is of the variety phlogopite, possessing elasticity and dielectric properties unattained in the other varieties. The province of Quebec produced last year over 80 per cent of the Canadian output of this mineral.

The graphite industry is showing signs of resuming activity. After a year of inactivity, the Quebec Graphite Company, Ltd., has re-opened its mines and completely remodelled its mill, which is now working with the Callow process as the basis of its concentration practice. Oil flotation methods appear to be the process to which the Buckingham ores are most amenable. The Quebec Graphite Company has also gone into the manufacture of graphite products, such as flake lubricants, graphite pastes, pipe-joint compounds and foundry facings, and they intend to extend this list to include graphite greases, stove polish, electrodes and paints.

All the magnesite quarries are in operation in the Grenville district. The Scottish-Canadian Magnesite Company, which has installed a very complete and modern plant for the production of dead-burned magnesite, is now turning out a product that finds a ready market in the United States, in Canada and in Europe. The North American Magnesite Company has also built a very complete mill at Calumet, but, unfortunately, the starting has been delayed by the non-delivery of some of the machinery. In the meantime, the quarry has been active and the rock shipped, as in the past, to the Longue Pointe cement plant, where it is dead-burned in the rotary cement-kilns. The International Magnesite Company, operating in Harrington township, is producing calcined magnesia, used in the manufacture of flooring cement. The consideration, by the Senate of the United States, of the Magnesite Bill, which passed Congress in October last, imposing a duty of  $\frac{3}{4}$ c per lb. on dead-burned magnesite entering the United States, has been postponed until next December.

### TALCUM FIGHTS FIRE.

Talcum powder, a leading ingredient of vanity cases, was recently used in putting out a fire which otherwise would have burned down a coal tar products plant in Cincinnati, Ohio. The blaze which had caught a huge tank of naphthalene was smothered by dumping upon it fifty-pound sacks of the well-known complexion aid.

In a yard near the burning plant where tanks containing 300,000 gallons of oil, but as the fire was checked they were not touched by the flames, according to an account in the current number of the *Journal of Industrial and Engineering Chemistry*. This is the first time that a cosmetic has been applied with puffs to the bright face of danger.

A large deposit of metallic arsenic is reported on Alder Island, one of the smaller islands of the Queen Charlotte group. Several claims have been staked covering the entire island, and samples taken indiscriminately give returns from 18 per cent, to 24 per cent, arsenic, while the locator states it is possible to obtain specimens of the almost pure mineral. This is the first deposit of the kind on record in British Columbia, although for years arsenic has been produced as a by-product from the arsenopyrite ores of the Hedley Gold Mining Company.—From the *Journal of Industrial and Engineering Chemistry*.

Address .....

C.M.J. 8-20-20.

The Independent Labor Party in Britain believes in talking to the man at the wheel. They also have a fondness for rocking the boat. Premier Lloyd George's hatred of a causeless or unnecessary war led him in the past to brave the yelling of the mob, and as skipper of the Ship of State he put her past some nasty rocks between 1914 and 1918. If the old boat wobbles today it will not be because the skipper has lost his skill, but because there is a mutiny in the fo's'cle.

**WANTED**—Mine Foreman for Nova Scotia mine; must be experienced in drifting, shaft sinking, shaft timbering, etc.; one who can train men to do such work or who can bring a following of experienced men with him. Single man preferred, as mine is twenty miles from railroad and no family houses available. Camp has electric light and good bunk houses. Good board is provided. Write giving references and salary desired, which will be supplemented with bonus in proportion to results achieved. Address: Canadian Mining Journal, Box 17, Gardenvale, P. Que.

**POSITION WANTED**—Mining Executive, married, 30, technical graduate, 8 years in responsible positions as Mining Engineer and Superintendent in Canada. Also European mining experience. Well recommended, proven ability and capacity. Apply, Box 18, Canadian Mining Journal, Gardenvale, P. Q.

## FOR SALE

- 1—20 x 42 Jenckes First Motion, Double Drum Mine Hoist, Friction Drums 72 x 30, Corliss Twin Engine complete with 1200' 1¼" Cable.
- 1—14 x 20 Jenckes Geared Double Drum Mine Hoist, Friction Drums 72 x 48 with special Reduction Gears and extra 6" Shaft for Electric Drive.  
(Note. Was operated at times with 150 H.P. Motor since removed.)  
1200' 1" Cable on Drums.
- 1—36 x 24 Jenckes Jaw Crusher, Bolted Pitman, Manganese Jaw Plates.
- 1—300 H.P. C.G.E. Variable Speed, Slip Ring Motor, 2000V., 3 phase, 60 cycle, 300 R.P.M., Type 1, Complete with outboard bearing, Resistance Frames and 60 x 24 C.I. Sheave for Rope Drive, Starter, etc.
- 2—300 H.P. Westinghouse Type 'C' Constant Speed Motors, 2000V., 490 R.P.M., complete with Starters, outboard bearings, 36 x 24 C. I. Pulleys and adjustable sliding Bases.
- 1—Briquetting Mill complete, rated capacity 5 tons per hour, manufactured by The Henry S. Mould Company, Pittsburg, Pa.
- 1—24" S. & A. Type A.C. Troughing Belt Conveyor. Distance C. to C. Head and Tail Pulleys 102'.
- 1—24" Link Belt Company's Troughing Belt Conveyor, C. to C. Pulleys 116'.
- 4—Standard Gauge Slag Cars, capacity of Bowl 225 cubic feet.
- 1—5 1-2 x 8" C.B. B.V. Canada Foundry Vertical Triplex Plunger Pump, Direct Geared to 25 H.P. C.G.E. 550V. Motor.

We have a large assortment of Mine Cars and Steam Pumps and miscellaneous equipment, and will gladly send booklet on request.

Immediate Shipment. Write or Wire for Prices and Information to:

## THE ASBESTOS INDUSTRY.

An account of the endeavors made in the United States in recent months to find asbestos deposits of good quality (which we copied—with due acknowledgment—from the Bulletin of the U.S. Geological Survey) has been twisted in Ontario newspapers to the attempted detriment of Canadian asbestos companies. The asbestos companies are stated to be "even worse than the International Nickel Company" that *bête noire* of a section of Ontario politics, which we take to represent the ultimate depth of perfidy. The inside story of nickel is soon to be exposed, so we are told. We are under the impression it had already been told, and quite voluminously. The suggestion is made that the inside story of asbestos would be equally redolent of iniquity. The International Nickel Company will we believe welcome the fullest enquiry into its affairs. The "inside story" of asbestos will be found written in the Annual Reports of the Quebec Department of Mines, but, fortunately for Quebec, that province is not so given to corporation baiting as some other provinces in Canada.

The fact that asbestos is not as yet spun and manufactured into finished articles on a larger scale in Canada is not perhaps entirely a matter for congratulation, but it represents a phase through which most primary industries have to pass. This phase will not be shortened by ill-advised railings against the conduct of an industry that has passed through some very evil times and has only recently obtained a position of financial stability.

The recent large and rapid increases in the selling price of various grades of Canadian asbestos are stated in the 1919 Report of the Quebec Department of Mines "to be due to an extension and development of the known uses rather than to new applications and utilizations." In many cases, asbestos is but a single component in a manufactured article that consists of a combination of materials, as, for example, in the case of steam packings of various patented makes, where asbestos, graphite, metallic wire, rubber, and possibly a lubricant enter into the fabrication of one article.

The criticism to which we take exception speaks of the "refining" of asbestos, but no analogy can be properly instituted between the extraction of metals from their ores, and the working up of the thousand and one specialized articles of which asbestos is a component. The most accurate analogy in Canadian life may be drawn between asbestos and pulp-wood, and

when the time is ripe, Canadian enterprise can be trusted to supplement the production of crude asbestos by its further utilization in manufactures in Canada, as is being done in the case of pulp-wood and paper.

The existence of an avid market for asbestos in the United States cannot be considered as a reproach to Canada, as has been intimated. The Quebec Mine Report mentions that two mining industries in that province, namely the production of chromite and magnesite, are threatened in their future prosperity by possible closing of the United State's market consequent upon the mooted imposition of a protective import tariff. The export of these two minerals has not been objected to, and in Quebec it is regarded as desirable. The export of asbestos differs only in degree, but not in principle.

It is not desirable that the export of any Canadian minerals to any friendly nation shall be discouraged, because such a policy involves a restriction of mineral production in Canada. Canada needs the largest possible export of mineral products, combined with maximum use of domestic mined minerals within our own borders. The last-named desideratum is not, however, one that will be obtained by government regulation of exports—as is suggested—but by private manufacturing enterprise.

To mine the minerals we possess to the fullest extent would be—as in the classic cases of coal and iron—the best possible way to diminish unnecessary imports; and to mine and export to the fullest extent the minerals that we uniquely possess would be the best way to reduce our adverse trade balance. The mining industry in Canada does not require control, but it does require aid and comfort from our governing bodies, and a readjustment of that jaundiced view which assumes that because an industry is big and efficient it is therefore evil.

## CORPORATION BAITING.

Those of our readers who see that excellent weekly, "Chemical and Metallurgical Engineering" may have noted a rather interesting piece of detective work which led to the arrest of clever thieves who had stolen platinum from the Old Hickory Powder Plant at Jackonsville, Tennessee. The chemical analysis of the stolen material was a determining factor in the detection of the thief, and a feature of interest to readers in Canada was the statement made by one of the accused men that the sponge platinum in their possession

had been obtained "by placer mining on an unregistered claim in a region about one hundred miles north of Parry Sound, Ontario." The authorities ascertained by enquiry from the Department of Mines that the total annual production of platinum in Canada did not exceed 25 ounces, and that no placer mining of platinum was carried on in Ontario.

This quite interesting account of chemistry applied to the detection of crime has been reproduced in the "Literary Digest" as being of general interest, but the Toronto "World" finds the account "very suspicious" and, rather ungrammatically, states editorially "You'd almost think the long and exact account of 'the trapping of the thieves was printed in that paper for some special reason.'" This "special reason" the "World" surmises is because the International and Mond Nickel Companies wish to convey to the Canadian public the impression that the "whole annual output of platinum does not exceed 25 troy ounces."

We remember on a previous occasion that an article advocating the electrification of the Canadian National Railways which appeared in this journal, which suggested the use of the slack coal from a colliery with an annual output of 180,000 tons, was discovered by the "World" to be inspired by the "coal barons of Nova Scotia." At that time we thought it was impossible that Torontonians perspicacity could go further, but apparently there are no limits to the penetrating vision of those who have chosen corporation baiting as a vocation.

A full and complete account of the platinum production of Canada will be found in the Report of Mineral Production for 1919 issued by the Mineral Resources Division of the Mines Branch at Ottawa. The Toronto newspaper states that the Ontario and Ottawa Mines Departments "have been forced by the long campaign 'of the 'World' to at last begin to express their suspicion that a very valuable amount of platinum has 'been taken out of the nickel ore from the Sudbury 'Mines'". We would not consider the definite statements of the two Mines Departments as "expressing a suspicion". Ottawa states that the International Nickel Corporation reports for 1919 a recovery, in Canada of 25 ounces of platinum and 62 ounces of palladium, with also a small quantity of fine gold and silver. It also is stated in the Ottawa report that recoveries in New Jersey during 1918, as reported by the Annual Reports of the United States included 649.7 ozs. of platinum, 786.6 ozs. of palladium and 472.5 ozs. of rhodium. While it is not possible to state exactly how much of this recovery of platinum group metals originates in Sudbury mattes, it is believed, states the Ottawa report, "the Sudbury mattes have been the source of the greater part of the platinum group metals recovered."

We can conceive of no reason why the International

Nickel Company desires to convey to the public any other impression than is given by the published reports of the provincial and federal Mines Departments, and if, as the "World" states, the Mond Nickel Company in a recent London prospectus referred to the possible recovery of platinum group metals, it is merely a proof that there is no desire on the part of the Mond Company to conceal a thing that is common knowledge.

To use Lloyd George's most recent epigram, the "World" is flinging a sledge hammer at an open door. Its criticisms are not important, being based on erroneous surmises, but the attitude of this newspaper is important to the extent that it reflects unjustified criticism of large investments of United States capital in Canadian mining ventures. The greater the number of United States investments in our mining fields the greater will be their development. The larger the number of refining and manufacturing plants that United States interests can be induced by fair means to operate in Canada, the better will Canadians be pleased, and we take it to be a proper and laudible policy to bring this about by legitimate means—to which our friends in the United States as shrewd business men will be the last to sincerely object. Nevertheless, there are most pressing reasons to deprecate the use of jaundiced innuendo, and the perversion of national loyalties to effect commercial ends. There is no more dangerous citizen abroad today than he who deliberately stirs up strife between Canada and the United States, and this in effect, if not in intention, is what the "World" is doing.

#### LENIN'S IDEA OF A STABLE GOVERNMENT.

The most intelligent and richest bourgeoisie are those of England and America. The English are the most experienced and the best administrators. They afford us the best examples of personal dictatorship in its highest form, the most stable kind of a government which has consolidated power in the hands of a single class. . . . I believe that if you will keep in mind this English example you will comprehend this question of personal control better than from any number of abstract resolutions and preconceived theories. . . . I hope the gentlemen present, who are experienced Water Transport Workers and therefore know what good management is, will appreciate that we must first of all be good business men, and must dispense with our industrial Soviets and run things without them. Every branch of administrative work calls for special training and qualifications.

The foregoing is not an extract from a capitalistic organ, nor the opinion of a bourgeois professor of political economy. It is an extract from a speech made by Nikolaie Lenin before the Third All-Russian Congress of Water Transport Workers. From all accounts Lenin is in a position to compare at first hand the results of administrative work by men without special training and qualifications, and his opinion is for that reason a weighty one. It coincides fairly exactly with the opinions expressed by Mrs. Phillip Snowden and Bertrand Russell on their return to England after a visit to Russia.

### OUR "CURIOUS PLEA FOR PATERNALISM."

The Sydney "Post" takes exception to our suggestion that a federal loan should be made to the Nova Scotian coal companies to assist in the development of new collieries, and believes that any millions the Government has to spend can be laid out "in a million better ways than that suggested by the 'Mining Journal.'"

The objection of the "Post" is apparently based on an assumption that our "curious plea for paternalism" is advanced in the interest of the coal operators, whereas the basis of the argument is that deficient production of the bituminous coal in Canada is a national menace requiring definite aid and a definite policy on the part of the Government to remove. No criticism is made of the existing government of Canada that is not applicable to all previous governments, for none of them have ever grasped the fundamental importance of coal production to Canada. It may serve as an illustration of the very general inability of the public—and its reflection, the government in power at any given time—to understand the true national position of coal production, when a newspaper circulating in a community that depends for its daily bread on coal production, deprecates a suggestion that the government should assist coal production by loans to be devoted to the extension of output.

We suggested that the expansion of the production of the Nova Scotia collieries to a point commensurate with the potentialities of the coal deposit, and adequate to meet the domestic needs of Canada, involved a capital expenditure entirely beyond the ability of the coal companies to handle, and we believe this statement will be found to stand unimpugned, once it is admitted that coal production is a national necessity. Any possible difference of opinion lies in the admission or non-admission of the paramount need for a domestic source of coal production in Canada.

Coal production on a much enlarged scale is a principle condition of the persistence of the Canadian nation. It is more important than agriculture or any other form of industry, because without coal production neither agriculture or any form of manufacturing industry could exist. The Province of Ontario alone requires 12 million tons of bituminous coal annually, or more than twice the production of Nova Scotia. Every form of industry in Canada has in the past few years been throttled and prevented from attaining its possible development by coal shortage or fear of coal shortage.

The Canadian Government itself, as owner of the National Railways and as owner of a fleet of merchant steamships, is very intimately interested in the availability of coal. The Provincial Government of Nova Scotia depends on coal royalties for its revenues almost entirely. The export trade of Canada depends entirely on the availability of coal for its existence.

The adverse balance of trade with the United States against Canada is largely made up of imports of coal and steel, and things made with the aid of coal. Is it then quite correct to say that there are a million better ways in which the Government could spend money than in loans to increase the production in Canada of the most important raw material known to civilization?

It is intimated that our suggestion will appeal to none "but the interested operators". That is to be doubted. It may well be entirely unwelcome and objectionable from certain standpoints of the operator.

In making the suggestion, the "Journal" did not have in mind either operators, operatives or politics. There is no body of men more interested in the preservation of Canada's capacity for bituminous coal production than the Canadian Federal Government for the time being, because the continued existence of that government and the persistence of Canada as a separate and independent political entity in North America hinges on whether we will or will not take steps to stop this decline in domestic coal production, and thereby assure this country of some modicum of industrial independence.

The coal problem in Canada is a permanent one, and we shall not approach a solution until it is studied from a national standpoint by a permanent body appointed for that purpose. The "Canadian Mining Journal" holds no brief for the coal operator, but being a periodical devoted to the progress of mining and metallurgy in Canada, it conceives that it is carrying out a proper function in calling attention to the unsolved condition of the problem of coal supply, on which all mining and all metallurgy depends.

### THE COAL EXPORT EMBARGO.

Our contemporary "Coal Age" suggests that the embargo on export coal is unfair to the coal producer unless a proportionate embargo is placed upon the export of manufactured products which consume coal in the making. The point is well made. "Coal Age" suggests that the coal industry in the United States would be willing to participate in a curtailment of coal export "in like degree with the manufacturers of any other commodity that consumes coal in its making and that requires transportation in the process of getting it out of the country. Any other programme for increasing the supply of coal for home consumption by decreasing exports is as unfair to the home coal industry as it is to the foreign consumer."

It would be interesting to see a list of the things that do not consume coal in the making and do not require coal for transportation to seaboard. It would be indeed a list of things that "aint". The tendency is for large manufacturers to acquire their own coal areas, to be operated for their own manufacturing uses, and a large part of the coal producing capacity

of all countries is in this way passing under the control of interests that are not primarily engaged in the supply of house and ordinarily marketed coal. Coal mining as the base of a manufacturing industry occupies a proper place, and the manufacturer who acquires coal mines is wise in his day. Coal mining, prosecuted singly as means of commercial profit, has not, however, been remarkably successful. It will not be surprising, in the future years, to see the "coal operator" as he is now known, disappear, to be replaced by men who are not willing to act the part of a common laborer for industry in the digging of coal, but will follow coal into all the ultimate profit-making uses that ramify throughout the entire fabric of the modern world.

### THE INTEREST OF THE COAL PRODUCER IN COAL DISTRIBUTION.

Evidence was recently given before the Board of Commerce sitting in Victoria, British Columbia, that a coal dealer was accustomed to pay \$7.50 for a long ton of coal at the pithead, which he retailed in Victoria at \$12 per short ton, the equivalent of \$13.44 per long ton. After allowing for cost of handling the coal and delivering it into the customers' cellar, this dealer concluded that his average profit had been \$2.50 per ton.

From the records of the Fuel Administrations of the United States and Canada we believe that the figure named by the Vancouver dealer does not represent fairly even the profit made by coal dealers upon sales of domestic coal in small lots to private customers. Transactions in car-load lots, and contracts for large quantities of coal for manufacturing purposes and large buildings are conducted on a smaller spread. The extent of the profit of the dealer upon domestic business is, however, one to cause the coal producer to think.

Those who have had experience of the operating costs of coal production know that very large expenditures, both of money and of mental and physical energy, are required to effect an economy of a few cents in the unit cost of coal production. They also know that a profit of \$2.50 per ton is a possibility that does not enter into the most rosy dreams of a coal mine operator. If the financial risks and the scale of the coal mine operator's undertaking is compared with that of the coal dealer the disproportion will be found to be striking, and the proportionately smaller reward of the coal operator equally striking.

These considerations give point to a suggestion, previously urged on several occasions in the "Journal", that the coal mine operator, wherever it is found possible, should control not only the comparatively thankless and unremunerative operation of coal production, but should control further the handling and distribu-

tion of the coal to the point of ultimate destination in the customers' cellars or storage bunkers.

Unless the coal mine operator is prepared to do this, he is likely to continue to bear unjustly the odium of a "spread" in coal selling prices with which he has nothing to do, but for all of which he will be blamed by the uninformed public, certain of no pertinent facts except the ever-rising price of coal.

The basic nature of coal in fixing prices of all commodities is little understood, and is least understood by those who control the mining and sale of coal, otherwise their carelessness of what happens to the price of coal after it leaves the pitmouth is not understandable. We doubt whether any condition would be more potent in reducing commodity prices in Canada than a plentiful supply of coal at moderate prices and the coal producer is the person most interested in seeing that the price paid by the ultimate consumer is as low as it can be made.

Up to the point of leaving the colliery yard every possible device of economy is made use of to lower the unit cost of coal production. Production costs are dissected minutely and discussed in cents and fractions of cents, but as soon as the colliery premises are left behind—or just as soon as the handling and transportation of the coal ceases to be controlled by the producer — inefficiency, with its corresponding cost, commences and continues to the point of ultimate destination.

It is advisable, in the interest of the producer of coal and the consumer alike, that wherever possible the producer should control every revenue-producing stage of coal handling and transportation from the coal face to the consumer's cellar.

The coal producer, who spends half a million dollars to take five cents a ton off coal haulage costs, cannot, if he appreciates his own interests, view with disinterestedness the carriage of coal along city streets in winter weather in half-ton lots.

We are pleased to note the whole-hearted manner in which the Canadian collieries (Dunsmuir) Limited go about arranging a picnic for the employees. Free transportation for five thousand people to the seashore, fifteen thousand ice-cream cones, chocolates, oranges and sports for the children, are some of the items noted in a Vancouver Island paper. The presence of all the officials, from the President down, and a general spirit of good feeling is in marked contrast to times happily gone by. The fashion is one that it is to be hoped may spread.

The death is announced from Ottawa of Dr. William James Wilson, for many years the paleobotanist of the Geological Survey at the age of 69 years. It is hoped to make more extended reference to Dr. Wilson's scientific attainments in a later issue.

# Mining Operations in Quebec During 1919

In the first issue of the "Journal" in 1920 we were able through the courtesy of the Superintendent of Mines, Mr. Theo. Denis to give a summary of mining operations in Quebec during 1919, with approximate figures. At that time it was thought that the total value of the mineral production of the Province, as was the case in all other provinces of Canada, would be appreciably less than the figures for 1918, whereas the exact figures now available show that in 1919 the curve of aggregate annual values of the mineral production for Quebec continued its uninterrupted rising course and reached the highest figure yet recorded. The 1919 value was \$2,105,908 or 11.3 per cent. in excess of the value of 1918, and the unremitting progress of Quebec as a mineral producer is shown by the following table, taken from the Report of the Superintendent of Mines, now to hand for 1919, viz.,

**Table of Value of Annual Mineral Production of Quebec from 1900 to 1919.**

Year	Value
1900	\$ 2,546,076
1901	2,997,731
1902	2,985,463
1903	2,772,762
1904	3,023,568
1905	3,750,300
1906	5,019,932
1907	5,391,368
1908	5,458,998
1909	5,552,062
1910	7,323,281
1911	8,679,786
1912	11,187,110
1913	13,119,811
1914	11,732,783
1915	11,465,873
1916	13,287,024
1917	16,189,179
1918	18,707,762
1919	20,813,670

The industry employs 8,930 workers, with wages totalling \$7,341,619. Asbestos is by far the most important single branch of mining in Quebec, seeing that it employs 45 per cent. of the workers and disburses 54 per cent. of the wages of the total industry. The quarrying and preparation of building materials and cement is an increasingly valuable feature in Quebec, employing 37 per cent. of the workers and disbursing 32 per cent. of the wages. The manufacture of cement contributes 21 per cent. of the total mineral production value of 1919, comparing with only 16 per cent. in 1918.

The Superintendent of Mines properly congratulates the Province of Quebec on so favorable a showing in the disturbed period which has followed the Armistice, and is the more worthy of note in Quebec because that province contributed notably to the output of minerals such as pyrites, molybdenite, magnesite and chromite that were in unusual demand during the war period and ceased to be in demand when the war ended.

The striking freedom of Quebec from social disquiet is attributed by Mr. Denis to the confidence of the people of the province in "the judgment and the ad-

vice of the 'directing' classes" and their indifference to "the insinuating, and often plausible, urgings of theorists who have panaceas to bring about the advent of utopian conditions, and of the Millenium."

It is pointed out that the increase in mineral production value is to be attributed to higher unit prices rather than to increases in tonnage for the same items. For example, the main product of the Provinces, asbestos, shows an increase in value in 1919 of 279 per cent., but a tonnage increase of only 33 per cent. Cement shows an increase of 33.6 per cent., but a decrease in quantity of 20.5 per cent. Brick value is increased 7.8 per cent., but quantity production is decreased by 31.3 per cent.

The Report includes a description of the gold-bearing area on Lake de Montigny in the Abitibi Region, and on the molybdenite deposits of La Corne Township, in the same region by Adhemar Mailhiot of the University of Montreal, and accounts of investigations made by Mr. Denis on the alleged discovery of a new goldfield in the unsurveyed portion of Gaboury Township, to the south of Lake des Quinze and on an occurrence of serpentine near Lake Mackenzie in the same township.

Attention is called to the large unknown area of Quebec and the dearth of trained geologists, and the use of the areoplane to aid prospecting is suggested.

Again, and not unnecessarily, the Quebec Mines Report warns against fraudulent mining-stock offerings. It would be well if Quebec newspapers would give as much publicity to Mr. Denis's warning as they do to the advertising of dubious mine stocks.

### Asbestos.

The following statistics regarding the mining of asbestos are condensed from the Report:

	1919 Tons	1918 Tons
Rock mined and hoisted during year	3,061,690	2,445,745
Asbestos produced	154,378	159,225
Pounds asbestos per ton rock	101 lbs.	117 lbs.
Value per pound	\$3.88	\$4.08
Total value	\$10,995,300	\$9,053,945

There is in Canada only one manufactory of asbestos products, namely that of the Asbestos Manufacturing Co., at Lachine, where there are produced asbestos slates, shingles, sheathing, mill-board, paper and pipe coverings. Eighty-nine per cent. of the Canadian shipments of asbestos go to the United States, seven per cent. to England and the remaining three per cent. to other countries.

Operations are reported by sixteen companies in the Black Lake, Thetford, Coleraine, Danville, Robertson and East Broughton Districts. An interesting development is the progression of open-pit mining to the "glory-hole" method in the operations of the Asbestos Corporation of Canada, and the use of shafts for haulage of rock and in some instances of men,

See "The Upper Harricana River Gold Area," issue of 14th Oct. 1919 page 765. A. Mailhiot.

See "Molybdenite Deposits of La Corne Township, Abitibi, P.Q." issue 18th February 1920, page 135. A. Mailhiot.

thereby doing away with ladders, and eliminating interference with operations by weather conditions.

#### Chromite.

Production of chromite fell to 8,184 tons valued at \$223,331 compared with 23,000 tons valued at \$770,955 in 1918, and the future of the industry depends largely on whether the United States imposes an import duty on chrome.

#### Copper and Sulphur Ores.

Production in 1919 was 53,965 tons valued at \$447,623 comparing with 125,446 tons valued at \$1,319,690 in 1918. Copper contents of ore shipped amounted to 5,751,188 pounds, a substantial portion of which is to be credited to the re-opened Huntingdon Mine<sup>3</sup>.

Activities of all the mines were affected during the early part of 1919 by the lack of demand for pyrites and the low price of copper.

#### Molybdenite.

Only one production of molybdenite is reported for 1919, namely 83,002 lbs. of molybdenite from the Moss Mine of the Dominion Molybdenite Co. Operations ceased at this mine on March 10th 1919 owing to market conditions. The deposit is not exhausted, and the mill equipment is described as remarkably efficient. Should the demand arise, the Quebec deposits will be able to produce moderate quantities of molybdenite for an indefinite period. Prof. Mailhot's report on the La Corne deposit is published in this section of the Report.

#### Zinc and Lead.

Shipments were confined to the Port Neuf District, and totalled 5,318 tons valued at \$103,138, a decrease of 2,320 tons of ore and of \$71,956 value compared with 1918.

The Federal Zinc and Lead Co., which is developing the promising deposits of zinc and lead ores in the region of the Cascapedia River<sup>4</sup>, devoted most of its energy to road-building during the year.

#### Gold and Silver.

The production in 1919, as formerly, came from the treatment of the copper-sulphur ores of the Eastern Townships and the zinc-lead ores of Portneuf Co. Gold so recovered totalled 1,446 ozs. and silver 127,223 ozs.

A description of the development work in the Lac de Montigny District is given in Prof. Mailhot's report, but no gold production is recorded in the 1919 figures from this newly discovered occurrence.

#### Magnesite.

Magnesite to the extent of 9,940 tons was produced in Quebec in 1919, being a considerable decrease from the figures of 1918. Important shipments of dead-burned magnesite were made during 1919 to most of the steel mills in the Eastern United States and in Canada, the Report mentioning the following concerns who have used Quebec magnesite with satisfaction, namely, Bethlehem Steel Co., Carnegie Steel Co., Jones and Laughlin, Atlas Crucible Co., Halecomb Steel Co., Ludlum Steel Co., and all the Canadian steel plants. Like chromite, the future of the Quebec magnesite industry depends on whether or not a prohibitive protective tariff is imposed on importations from Canada into the United States.

<sup>3</sup>See issue of August 6th 1919, page 582. "The Huntingdon Mine". R. E. Hore.

<sup>4</sup>See issue of 6th February, 1920, page 102. "Zinc and Lead Deposits of Gaspesia. J. C. Beidelman.

#### Graphite.

There was no commercial production of graphite in Quebec during 1919. The industry is in a waiting condition, and much depends on the possibilities of improvements in concentration practice, which have been very fully dealt with in recent number of this journal<sup>5</sup>.

#### Mica.

Mica production is valued at \$224,988 an increase of eleven per cent. on 1918 value. As so much depends on the grade of the mica placed on the market quantity comparisons are not especially valuable. The 1919 production is estimated at 3,853,265 pounds. Eighty-two per cent. of Canadian mica is credited to Quebec.

#### Miscellaneous Mineral Products.

Production of iron oxide and ochre is valued at \$111,645, a reduction of 30 per cent. in quantity, but of equivalent value to the figures of 1918.

Silica and vein quartz production is valued at \$50,161, a decrease from 1918 figures being due to the lessened demand for silica used in the manufacture of ferro-silicon.

Peat, for the first time, is recorded in the Mines Report of the Province. The producers are the "Tourbieres des Laurentides" with head office at Grand Mere, who work the Garneau Junction Bog, peat being delivered for domestic uses at Grand Mere by auto-truck, a haul of four miles. The peat is cut and stacked for drying in the old-fashioned way. The Bog is said to be 500 acres in extent with a depth of peat varying from 5 to 11 feet.

#### Wages and Accident Statistics.

The average wage of workers in the mineral industry has increased from \$593 annually in 1915 to \$968 and \$1,025 respectively in 1918 and 1919.

Fatal accident rate in 1919 was, for all branches of the industry, 1.67 per thousand workmen. Very complete statistical information on the incidence of accidents is given.

The Report of the Superintendent of Mines for Quebec is a carefully compiled volume. Wherever information of a scientific or commercial nature seems desirable it is included in a form likely to be helpful to mining men. The Province is to be congratulated on its unique position in 1919, as being the only province in Canada to report an increase over 1918, and on the comprehensive and accurate nature of the Annual Report.

<sup>5</sup>See issue August 20th 1920, article by R. C. Rowe, page 676. Also issue August 6th, 1920, page 636. and articles by Chas. Spearman, issues 12th Feb., 6th Aug., 1919, and 16th Jan., 18th June 1920.

#### Oil Found by Imperial Oil Company North of Great Slave Lake.

Oil has been struck by the Imperial Oil Company Limited, at a point just within the Arctic Circle, north of the Great Slave Lake, and close to the Mackenzie River. The flow of oil is small, and possibly cannot be made use of economically, but it is regarded as significant that oil has been found there. The flow is ten barrels a day. At Czar, Alberta, the Company's drill is down 2,000 feet.

## THE BLACK DIAMOND MINE FATALITY WITH BREATHING APPARATUS.

Report by the British Columbia Chief Inspector of Mines.

Coal Mine Operators and Coal Miners will be interested in a report, which has been issued in bulletin form by the Provincial Department of Mines, on the accident to members of Mine Rescue Teams which occurred at the Black Diamond Mine of the Pacific Coast Coal Co., State of Washington, on Saturday, July 10th, 1920.

Hon. Wm. Sloan, Minister of Mines, on being informed of the serious character of the accident, three men losing their lives and others having narrow escapes, instructed James McGregor, Chief Inspector of Mines, to investigate.

Mr. McGregor's report, together with some supplementary official comments, are included in the aforementioned Bulletin. The former details the circumstances very fully and the latter make a number of pointed references to the happening that are particularly instructive and interesting reading.

These follow :

"This accident in no way discredits the efficiency and safety of the apparatus when handled properly.

"The plain facts of the case are that this team (that is the Black Diamond Mine Rescue Team, which last year won the championship in competition with teams from the entire Pacific Northwest and two of whose members were lost on this occasion) attempted a feat in ordinary practice that any sane man would have given very serious consideration before permitting even in a case of emergency.

"The place to be travelled was dangerous being full of carbonmonoxide gas, (CO<sub>2</sub>). There was no need to take the risk in ordinary practice work.

"The roadway to be travelled by the team was the worst possible for men wearing mine rescue apparatus, being of heavy grade and very rough.

"To go in with such a supply of oxygen (the tanks were shown to have been only partially charged), knowing the conditions, was suicidal.

"The slope to be travelled by the team is 1400 feet in length and pitches 35 degrees and with the rails being lifted was in very dangerous and rough condition for walking. A person in good physical condition without mine rescue apparatus would have his work cut out to make this return trip in 30 minutes, yet the men attempted to make it with one of their number only having 45 minutes supply of oxygen, two having 50 minutes supply, one 60 and one 90 minutes supply.

"It is notable that the one with the 45 minute supply was one of the survivors, the machine he was wearing being a Gibbs. This can be attributed to the automatic feed, which would function according to the wearer's demands. Both men lost were wearing the Draeger type of apparatus, 1916 model, which are not equipped with the automatic feed arrangement, the machines giving a constant supply of oxygen and not functioning according to the wearer's demands. After the accident the machines were all found to be in good condition and if they had been properly charged before going in the mine there would have been no accident.

"The rough conditions encountered on the slope can be imagined when it took five teams of four men each to get out the bodies of the victims."

## PORT ARTHUR NOTES.

By J. J. O'CONNOR

### Territory near Thunder and Black Bay to be prospected for Oil.

In 1911-12, Mr. J. A. Beam, of New Bethlehem, Pa., visited this district and made a thorough examination of the formation and physical features of the territory adjacent to Thunder and Black Bays, with a view to its oil and gas possibilities. His long experience, as a gas and oil operator in other fields, forced him to the conclusion that there was more than an even chance of finding both oil and gas in paying quantities in this territory.

As a result of his investigations, the Nepigon Prospecting Company, a close corporation, has been formed with J. A. Beam, of New Bethlehem, Pa., as operator in a large way of oil, gas, coal and railways in Pennsylvania, as President, Jobe Burton, of Pittsburg, Pa., manufacturer, as vice-president, and A. E. Annis, of Orangeville, Ont., contractor, as Superintendent of operations.

The company have secured through A. E. Annis, leases covering 30,000 acres of land, in Dorion, McTavish, McGregor, Pearson and Sibley townships, including the Woods Location, (Silver Islet) excepting the Silver Islet Mine. The leases are the usual form in use in the oil fields of Lambton County, Ontario, and other oil fields. The owner of the fee is to receive one-eighth of the oil, and \$100 per well, after the first year. If no drilling be done, the owner of the fee is to receive ten cents per acre after the second year, and if no drilling be done at the end of five years, the company forfeits all rights under its lease.

It is the present intention to have the drilling done by contract, if suitable arrangements can be made. If not, the company will bring in its own drills from Pennsylvania, under experienced drill operators. The first hole will be put down on the Woods Location. It is expected that no results will be obtained under 1700 feet, and possibly at a much greater depth. However, it is intended to pursue the drilling until the formation has been thoroughly tested. The drills will be in operation by October 1st, next, and continue through the winter. The old road from Silver Islet to Sawyer's Bay, will be cleared out, and motor trucks used in taking in supplies from Sawyer's Bay, during the winter, so as to avoid going round Thunder Cape, at seasons when the passage by ice is difficult and dangerous, in the early Winter and Spring. The Head Office of the company will be at Port Arthur.

### Grace Mine on Eagle Lake to Resume Work.

The Grace Mining Company, George J. Blake, 300 Broadway, Buffalo, N. Y., President, with Head Office at Toronto, Ont, and 300 Broadway, Buffalo, N. Y. is resuming active mining operations after nearly a decade of inactivity.

The Grace mine is situated 21 miles south of Eagle River station, on the Canadian Pacific Railway, on the shore of Eagle Lake. The present development consists of a complete camp equipment, and a ten-stamp mill. The main shaft is down 150 feet, with considerable drifting and cross-cutting, on a strong highly-mineralized quartz veins, yielding an average of over \$23 per ton in free-milling gold ore. Arrangements are completed for continuous operations during the coming Winter, with a full staff of miners.

The organization is composed entirely of American

capitalists, who are expected to visit the property when the engineer in charge gets the work of mining underway.

Captain Walpole Roland, with a crew of men, two car-loads of machinery, a gasoline launch, a scow and a general outfit of supplies arrived at Vermillion Bay, Eagle Lake, on August 12th, and on the following day proceeded by launch to the mine, where the preliminary work of unwatering will begin, directly pumps can be installed. On the completion of unwatering active mining will be proceeded with.

#### NOTES FROM THE NOVA SCOTIA COLLIERIES.

##### Springhill Mines.

Several days idleness has resulted from a dispute between the management and the boiler firemen, which has been adjusted. Disputes in connection with the development work at the No. 7 Slope and in connection with underground rates at No. 2 Slope have also been adjusted by increasing the rates.

A new slope, to be known as No. 8 Slope, has been commenced by the Dominion Coal Company.

##### Increase of Benefits in Relief Association.

The several branches of the Dominion Coal Workers' Relief Association have agreed to increase the weekly subscription from 25 cents to 30 cents. The relief payment will be raised from \$6.00 to \$9.00 per week. The Dominion Coal Company, which pays on a fifty-fifty basis with the employees, is also increasing its payment. This society deals entirely with cases of sickness and death not arising out of employment.

##### The Royal Commission on Wages.

The Commission, which has been taking evidence in the Minto District, is expected to hold final sessions in Sydney, before filling its decision.

##### Dominion Coal Bankhead Escapes Fire.

By prompt measures the Reserve Bankhead of the Dominion Coal Company, which serves Nos. 5 and 10 collieries, was saved from destruction by fire on the 26th August. A previous bankhead at Reserve Collieries was destroyed by fire in October 1906.

##### The Hiawatha Coal Co.

This new coal company is opening up a mine on the General Montgomery Moore areas at False Bay Beach, in the Morien Basin of the Sydney Field. The take of the company is stated to cover two square miles of the Tracey Seam, estimated to contain ten million tons of coal. At the shore crop, the seam shows a thickness of 4 ft. 8 ins., but inland it is believed to increase in thickness. Some dredging will have to be done to obtain a berth for loading vessels to open up a passage from the sea to False Bay Lake. Coal may be shipped during the remainder of the year, but it is not expected that operations will be large until next Spring.

#### ASBESTOS NOTES.

An English invention is a pulley made of asbestos and cement, designed to run at very high speeds. It is said to be satisfactory in operation, with good balance, and costing much less than aluminum pulleys.

"Asbestos" states that reports come from Luzon, Philippine Islands of a property yielding considerable quantities of Nos. 1, 2 and 3 qualities of asbestos, with some fibres three feet in length. "Asbestos" is investigating these reports and more definite information may be forthcoming.

#### ASBESTOS TRADE CONDITIONS IN EUROPE

"Asbestos" for July contains a resume of the asbestos situation in Europe by Mr. B. Marcuse, President of the Asbestos and Mineral Corporation who has recently visited Europe.

Mr. Marcuse reports that there are a great many plants making shingles, textiles, sheet packings and mill boards and that, while all these plants have been seriously hampered by inoperation during the war, and by the terrific drop in exchange since the war, they are gradually and surely resuming operation. It will, however, in Mr. Marcuse's opinion, be quite some time before their production will be sufficient to care for home consumption. Hence it is unlikely that much of the foreign made product will appear in the world market for some time to come.

It is interesting to note that in France, as well as in Germany, the manufacturers are associated in a syndicate or Groupment, which to a large extent buys and allocates raw material, exchanges trade information, and presents a united front to outside competition. In Germany this Groupment is directly under Government control, and has charge of all imports and exports. Practically no exports are now permitted, since Germany was quite barren of all Asbestos during the war and has not yet caught up with home demands.

During the war the United States was exporting to Europe quite large quantities of Asbestos goods but, now that the European plants are again producing, that market will automatically be closed to United States shippers. Since the foreign plants cannot do much more than care for home requirements, it is evident that the one big foreign outlet is South America. Tremendous development is going forward in South America, and at least one United States manufacturer has been fully alive to the possibilities there, for he has maintained several direct representatives in South America for the past few years, and records of exports furnished by the U. S. Customs Office indicate that the market is a good one.

#### Asbestos Products—Prices Current July 1920.

(From "Asbestos.")

Average market prices paid by consumers for average quantity, quality and freight haul from producer, were about as follows:

Asbestos Air Cell Covering, 4 Ply	35% to 40% off
" Air Cell Paper in Rolls . . .	\$10.00 to \$12.00
" Cement . . . . .	\$.175 to \$3.00 cwt.
" Cloths, 10s Commercial . .	\$.150 to \$2.00 lb.
" Listings and Tapes . . . .	\$.175 to \$1.90 lb.
" Millboard . . . . .	\$12.00 to \$18.00 cwt.
" Packing, Steam, High Pressure . . . . .	\$.125 to \$2.00 lb.
" Packing Sheet . . . . .	\$.100 to \$1.50 lb.
" Wick and Rope . . . . .	.65 to \$1.00 lb.

#### SALT FOUND AT FORT McMURRAY.

Announcement is made from Edmonton that salt of good quality has been discovered at a depth of 523 feet at Fort McMurray.

**OBITUARY.**

**J. C. Gwillim.**

Mr. J. C. Gwillim, for several years professor of mining engineering at Queen's University died in Kingston on Thursday August 19. Funeral services will be held in Kingston on Saturday. The body will then be shipped to Winnipeg for burial.

Professor Gwillim was well known in mining circles throughout Canada. He was not only an able engineer but a successful teacher of mining engineering. He was one of the most popular professors at the School of Mining and the many graduates of that Institution will learn with regret of his demise. He leaves with them memories of a man worth knowing.

For some time Professor Gwillim had been suffering from the serious illness that resulted in his death. He spent several months in British Columbia in an endeavor to win back his health, but recently was compelled to resign his position on the staff of the University.

**Dr. ELLIS DEAD.**

Dr. William H. Ellis died on Monday, August 23, at Lake Joseph, Muskoka. He was for some years, Dean of the Faculty of Applied Science at the University of Toronto, succeeding the late Dean Galbraith in 1914. Previously he was professor of chemistry in the same Institution, having been identified with the School of Science since 1878. Before that he had been instructor in chemistry in the College of Technology, Ontario's first technical college.

School of Science men all knew and liked Prof. Ellis. He had a great part in building up the Institution that now ranks with the best engineering colleges. He served well and long.

Dr. Ellis was born in Derbyshire. He graduated from the University of Toronto in 1867. He died in his 75th year.—R. E. H.

**PERSONALS.**

Mr. Dwight L. Woodbridge has returned from a trip to the Belcher Islands, Hudson Bay. Mr. Woodbridge was examining iron ore deposits there for American interests.

Mr. Murray Kennedy has been appointed manager of the Trethewey silver mine at Gowganda. Mr. Stewart Thorne who was manager at the Trethewey mine at Cobalt when he left for overseas has been in charge of the Gowganda property for some months, but has resigned owing to poor health.

Sir Charles Wright and Capt. Leighton Davies are in Toronto inspecting the Toronto plant of Baldwin Ltd. This company will soon be producing iron and steel sheets and tinsplate at the Ashbridge bay property taken over from British Forgings.

**METAL QUOTATIONS.**

Fair prices for Ingot Metals in Montreal August 26th 1920. (For shipment from stock, and in less than car-load lots:

Copper, electro . . . . .	24¼
Copper castings . . . . .	23¾
Tin . . . . .	53
Lead . . . . .	9
Zinc . . . . .	10½
Aluminium . . . . .	35
Antimony . . . . .	8¾

**THE FINANCIAL RESULTS OF GOLD MINING IN NORTHERN ONTARIO.**

The following brief analysis of the result of gold mining operations in Northern Ontario, dating from the time the first dividend was paid, up to the middle of the current year, gives a fair idea of the results achieved to date.

One feature not dealt with in detail at this time is the ore reserves at the various mines. In this connection, the broad statement may be made that ore actually in sight at the proven mines amounts to close to 70 million dollars, while that indicated in the mines both prospective and proven amounts to close to 100 million.

Following are figures showing production from year to year, as well as the amount of dividends paid during each twelve-month period:—

**Gold Production from Porcupine.**

Year	Value produced \$
1910 . . . . .	35,539
1911 . . . . .	15,437
1912 . . . . .	1,730,628
1913 . . . . .	4,294,113
1914 . . . . .	5,190,794
1915 . . . . .	7,480,901
1916 . . . . .	9,397,536
1917 . . . . .	8,229,744
1918 . . . . .	7,833,966
1919 . . . . .	9,941,803
1920 (est. first half) . . . . .	5,500,000
<b>Total</b>	<b>\$59,650,461</b>

**Kirkland Lake Production.**

Year	Value produced <sup>†</sup> \$
1913 . . . . .	26,232
1914 . . . . .	74,590
1915 . . . . .	555,539
1916 . . . . .	702,761
1917 . . . . .	404,356
1918 . . . . .	636,667
1919 . . . . .	486,809
1920 (est. first half) . . . . .	570,000*
<b>Total</b>	<b>\$3,456,955</b>

Note:\* The output for the first half of 1920 from the mines of the Kirkland lake district has exceeded the whole of 1919, during which year a labor strike caused the mines to close down for over four months.

**Dividends from Kirkland Lake Camp.**

Year	Value produced \$
1915 . . . . .	65,187
1916 . . . . .	260,750
1917 . . . . .	(nil)
1918 . . . . .	100,000
1919 . . . . .	100,000
1920 (first half) . . . . .	50,000
<b>Total</b>	<b>\$575,937</b>

**Dividends from Porcupine Field.**

Year	Value produced \$
1912 . . . . .	270,000
1913 . . . . .	1,182,000
1914 . . . . .	1,410,000
1915 . . . . .	2,360,000
1916 . . . . .	4,166,000
1917 . . . . .	1,699,542
1918 . . . . .	1,771,000
1919 . . . . .	2,083,028
1920 (first half) . . . . .	1,299,028
<b>Total</b>	<b>\$16,240,598</b>

**Summary of Gold Production.**

Porcupine . . . . .	\$59,650,461
Kirkland Lake . . . . .	3,456,955
<b>Grand Total</b>	<b>\$63,107,416</b>

**Summary of Dividends.**

Porcupine . . . . .	\$16,240,598
Kirkland Lake . . . . .	575,937
<b>Grand Total</b>	<b>\$16,816,535</b>

It should be noted that while only \$16,816,535 has been paid out of a total gold production of \$63,107,416, the producing mines have all built up large treasury surpluses, as well as spent a large amount of current earnings on building up ore reserves which assures larger dividends than ever before, and means that as the mines become older the total dividends paid will represent a larger percentage of the total production than has been the case up to the present.

**DAVIDSON CONSOLIDATED GOLD MINES, LTD.**

For several months the directors of Davidson Consolidated Gold Mines Ltd., have been negotiating with English interests to make the mine a big producer of gold. The directors have now announced to shareholders that a satisfactory conclusion to these negotiations has been arrived at. The shareholders are now asked for their approval of the deal and co-operation in making it possible.

According to the letter just sent to shareholders arrangements have been made for the sale of 1,500,000 treasury shares at 75 cents per share; the proceeds of this sale in principle to the applied towards the carrying out of an extensive plan of development, which has been decided upon by arrangement between the English interests and the Davidson directors. A condition of the offer is that the English interests shall receive an option on 2,000,000 shares—1,000,000 at \$1 and 1,000,000 at \$1.25, the option to remain in force for nine months after the first 500 ton unit of the mill is completed, but in no event to exceed a period of two years. In order to carry out this arrangement it will be necessary for each shareholder to contribute 50 per cent. of his holdings towards the option.

The development planned includes the sinking of a 3 compartment working shaft to a depth of at least

1,000 feet, the construction of a mill with a daily capacity of 1,000 tons, the first unit of which (500 tons) shall be undertaken in the immediate future.

President G. C. Crean in his letter points out that the report on the property made by Messrs. Bert and Loring for the company is fully confirmed by the examination and report of Colonel Fielding of London, who was sent out by the English interests to examine the property.—R.E.H.

**TORONTO NOTES.**

The mica mine at Blue Mountain, near the head of Stoney Lake, Peterboro County, Ontario, which was unsuccessfully operated about a quarter of a century ago, has been purchased through the Supreme Court of Ontario, from the Bradford estate, which was being settled in that court by two American engineers, C. L. Nicholson of New York and Norman Miller of Michigan. It is expected that the mine will be in operation by the middle of September with an output of about 100 pounds a day. The machinery and equipment are now on the way to the mine and labor has been arranged for. The output is contracted for until after Christmas and three firms are trying to contract for the mine's total output. The most serious difficulty that will confront the new operators will be that of transportation. The mine is located about four miles from the head of Stoney Lake, which is about twenty miles from the terminal of the Grand Trunk at Lakefield. The mica will have to be hauled over poor roads to the head of the lake and there towed down Stoney and Clear Lakes to the railway at Lakefield. During the winter sleighs will be used to haul the mica over the lake to the railway. It is stated that the former operators of the mine failed to make it a paying proposition because they spent too much money on road construction. The new enterprise, however, is confident of success and claims that the mine is rich.

According to the quarterly report issued by the Bailey Silver Mines, Limited, the gross earnings of the Bailey Custom Mill at Cobalt for the first quarter were in excess of \$50,477, and the net profit from milling operations were \$22,951. It is stated that the mine has a large tonnage of ore actually developed and with the completion of the railway siding at the mine will commence immediate shipment of its developed ore to the mill, which should then show a net profit in excess of \$1,000 daily.

**THE FINISHED WORK OF THE BOLSHIEVIKI.**

The following opinions on the results of the applied doctrine of the Bolshevists are extracted from an article contributed to a Parisian newspaper by H. B. Shiozberg, a lawyer of Petrograd, who was so fortunate as to escape from that devoted city.

"The Bolsheviki wanted to destroy the bourgeoisie; instead of that they have merely strengthened and increased it."

"They attempted to introduce agriculture on a communistic basis; instead of that they have developed in the peasantry a still stronger desire to own land."

"The Bolsheviki attempted to subject the industrial life of the country to the government, but instead of that they merely destroyed and disorganized it."

"The Bolsheviki attempted to spread enlightenment in the masses, but instead of that they have paralyzed science and art."

### GABRIELLE MINES PROPERTIES UNFAVORABLY REPORTED UPON.

Although a discouraging report has been received from J. B. Tyrrell, mining engineer, of the value and quality of the quartz from the Gabrielle Mines, Ltd., directors of that company are determined to carry on the work next year. Lieut.-Col. A. C. Gray, president, announced that a report had been made to him by Mr. Tyrrell, one of the most competent mining engineers in Canada, showing that assays showed little promise of returns from the property, but that the officers, directors and shareholders were so confident of the value of the mine that they propose to go on with the operations next year if it is at all possible.

The Gabrielle properties consist of the Gabrielle, the Gabrielle Fraction and the Cartwright claims. The Gabrielle was the first mine discovered in the Rice Lake district, the discovery being made in March, 1911, by Maj. E. A. Pelletier, now vice-president of the company. The first assay in 1911 showed a yield of \$130 a ton. Up to the present time there has been constructed 120 feet of shafting and 130 feet of drifting. A survey was made in 1919 by Mr. Tyrrell and in his report he said: "I believe you are justified in making arrangements to sink one or both of the shafts to depths of 100 feet at least and in drifting on the veins from these shafts. The property appeals to me as sufficiently attractive to warrant risking a reasonable amount of money in the hope of developing it into a paying mine."

His report to the directors concludes with the following: "There are four gold bearing veins known on the property. Two of them designated Nos. 2 and 4 respectively, are too small to deserve serious consideration. No. 1 vein is close to the shore of Rice Lake. Gold may be found in it in many places, but a careful sampling showed that the surface, the vein in the drift, and the dump taken from the drift all yielded assays varying from \$4.80 to \$4.87 in gold to the ton. No. 3 vein, near the north side of the Gabrielle claim, is the strongest and most continuous of any on the property but on the best exposed portions of its surface, for a length of 100 feet, it showed an average value of \$3.88 in gold to the ton, while in the drift, at a depth of 64 feet below the surface, and for a length of 75 feet, it showed a value of \$3.35 in gold to the ton. A dump beside the shaft, which had been taken from the shaft and drift, was sampled and yielded \$4.80 to the ton. The results of the assays here quoted show vein-matter of much too low grade to be mined at a profit, and as there is no reason to believe that the veins contain more gold in some other places that have not yet been uncovered or explored, or that other and richer veins may be discovered, I recommend that all mining work on the property be discontinued."

"The country does not deserve the blow that this report will give it," said Col. Gray. "We are just as enthusiastic as we were before over the mine and indeed over the whole Rice Lake district."

He said that although the directors were upset by the report they are making arrangements to go on with the work next year. Pending further negotiations to carry on the work the mine will be closed at the end of this season. Old prospectors who have been over the ground carefully, he said, had faith in the claims. Some of them pointed out that four or five of the largest mines in the world were once condemned to be closed by competent engineers, but the "bull-

headedness" of their owners kept them going. Major Pelletier has a claim adjoining the Gabrielle site, and he has announced that he intends to spend \$5,000 there this winter in developing it.

Col. Gray states that a meeting of the shareholders will be called on September 14. At that time another report will be presented by Capt. C. A. Millican and by Col. Gray.

Since the claim was opened there have been 1,500 tons of rock removed and half a ton of this has been used for sampling. The average value of the samples has been about \$60 a ton, it was said. Timber on the property is valued at \$150,000. The claims are held under crown grants.—"Winnipeg Free Press."

### SAFETY METHODS IN BUILDING CONSTRUCTION REDUCE ACCIDENTS.

An innovation in making provision for the safety of workmen engaged in building and construction work has been introduced in the erection of large extensions to the plant of the American Rolling Mill Company at Middletown, Ohio.

At 2 P. M. each Tuesday a committee composed of foremen, mechanics and laborers inspects the entire job from sewers to roof with the one purpose of seeing that proper methods are taken to safeguard the employees against accident. This committee makes a detailed report of each inspection to a representative safety committee, which considers and puts into effect the recommendations of the inspection committee.

The plan was introduced and is being carried out by Dwight P. Robinson & Company, Inc., a large engineering and construction organization which has been making careful investigations of various plants for protecting its employees.

The success of this program is being closely watched by various safety societies which are now encouraging day laborers as well as trained men to speed up their work. Experts in all types of building construction are agreed that the first marked reduction in building cost will come through increased production. The best features of this new safety plan are being copied by many large construction companies in the United States and Canada. The public is interested in the plan because indirectly it will lower rentals by reducing construction costs. This applies equally well to industrial constructions, large building projects and homes.

### THE TORONTO EXHIBITION.

Canada has no institution which better reflects the national spirit than its National Exhibition, which stands a monument to the civic progressiveness of Toronto, a triumph of loyal, vigorous citizenship and one of the Queen City's greatest contributions to the educational service of the nation, and to her industrial efficiency and agricultural advancement. The paramount reason for the majority of Fairs and Exhibitions is primarily the exploitation of the immediate locale. Not so the Canadian National, with its annual attendance of 1,000,000 people, drawn from all parts of the continent. It is the arena for the display of the strength and enterprise of the whole nation and the testing ground for much that other nations have to offer, a giant kindergarten, where the hundreds of thousands go for relaxation and enjoyment and are taught, enlightened and elevated in thought without being conscious of the many influences at work. A year of travel in Canada can here be condensed into a few days' sight-seeing.

## British Columbia Letter

### THE METAL MINES

#### Hazelton, B.C.

In his report for 1919, John D. Galloway, resident mining engineer, referring to the Rocher de Boule Mine stated that it was a formerly big copper producer but had remained inoperative all year. There was considerable milling ore available but no shipping ore pending further development. It now appears that the Mine is not likely to figure this year among the shippers it having been announced by J. D. Williams, who recently returned from the property, that there was no prospect of immediate resumption of work, as the copper market was not very active and the labor situation uncertain.

The Delta Copper Co's property, Rocher de Boule Mountain, is to be subjected to some exploration by means of the diamond drill. There has been some tunnelling in progress, but this has been found too slow and a drill will be put on the ground as soon as possible. If the results are satisfactory a permanent working tunnel will be driven.

The encouragement of the production of gold is a problem which is giving the Provincial Mines Department considerable concern. The amendments to the Placer Mining Act passed at the last Session of the Legislature by reducing rentals and other expenses attached to leases and by permitting the payment of arrears annually in comparatively small amounts it was thought would make it easy for those sincerely desirous of operating their holdings and at the same time squeeze out those who have been holding merely for speculation. Attention now is being turned to a more direct, and perhaps a more practical form of aid, J. D. Galloway, resident engineer with headquarters at Hazelton, having been authorized to continue Keystone drilling operations on the placer areas at Harpers Camp. This week was started last year, but, for various reasons, could not be finished. An expert crew of men has been engaged by Mr. Galloway and operations have been underway for some weeks. It is hoped that it will be possible to report satisfactory results at the end of the season. Mr. Galloway, in his 1918 report, gives detailed attention to placer mining conditions on the Horsefly River. First explaining that the important productive ground near Harpers Camp was an area lying in and about a bend of the Horsefly River, consisting in all of not more than 10 acres, and that the estimates of the amount of gold taken out of this area vary from \$500,000 to \$1,250,000 he proceeds to deal with the theory of the rich old channel, which the drilling now underway is expected to establish or disprove. It is pointed out that the character of the gold taken from the ground known as Ward's Horsefly was uniformly "fine, flat and well-worn" making it clear that it had travelled some distance and probably had its origin at some unknown point far up the Horsefly. The Horsefly River, both above and below Ward's Horsefly, has been fairly thoroughly prospected and a little gold has been taken out in places but no place has been found comparable in richness to the Ward ground. "The conclusion" Mr. Galloway continues "has therefore been reached

by many that the gold in Ward's Horsefly did not get there by following the present channel and an old channel of the river is postulated to account for this remarkably rich spot." There has been considerable prospecting for this presumed channel, but the work has not been well organized nor sufficiently exhaustive to satisfy those who have examined the ground that it does or does not exist. Mr. Galloway then tells of operations down the Horsefly River at a point known as "Hobson's Horsefly", where the deposit of gravel worked was a short distance from the river and represented a former channel. In this connection he says: "The project was unsuccessful owing to the outside gravel changing to a cemented gravel, which is virtually a conglomerate. Hydraulicking therefore was of no avail and a small stamp-mill was erected to grind the cemented gravel. It was obvious that unless the ground was extremely rich placer-ground it was not pay to operate in this way. The mill was operated only a very short time when the work was stopped."

#### Stewart, B. C.

The Provincial Government, through the Mines Department, is making considerable expenditures in road and trail work in the Salmon and Bear River sections of the Portland Canal Mining Divisions this summer. The extension of the road to the Premier Mine in order to furnish a ready means for the transportation of supplies from the Coast to the many claims under development in that region, and later to provide a means for the shipment of ore to tidewater, is making good progress. It was started as soon as weather condition permitted and is being hurried because of the shortness of the season. Hon. William Sloan, Minister of Mines, is expected to visit the Camp in the course of a few weeks and it is possible that he will take the opportunity to inspect this work as well as to give his personal attention to some of the operations and requirements of the Bear River area. Lucien Danoel, a mining engineer and a professor of the University of Liège, visited the district recently accompanied by Théo. Collart, Belgian Consul at Vancouver. He paid special attention to the several properties in which the Algonic Mining & Development Co., a Belgian syndicate, is interested. On the Spider, one of these prospects, a tunnel has been driven 360 feet with good ore all the way and it is planned to ship ore next winter over the snow. The visitors commented favorably on the activity of the Provincial Government in opening up the country and on the great work being done by the United States authorities in the construction of a sixty-foot road from Hyder to the border.

#### Trail, B. C.

Four men were more or less seriously hurt recently while at work in the Copper Refinery of the Consolidated Mining & Smelting Co. All were burned about the face and one, Gordon O'Connor, may not recover his sight. Molten copper splashed between the moulds and into running water used for catching the drip. The copper was shot 40 feet into the air.

Ore receipts at the Trail Smelter of the Consolidated Mining & Smelting Co. for the week July 21 to 31 aggregated 12,862 tons and for the week August 1 to 7, 10,221 tons.

**Nelson, B. C.**

The Emma Mine of the Consolidated Mining & Smelting Co. will resume operations immediately with a force of 50 men. This property formerly shipped about six cars of ore a week, but work ceased last year when production was discontinued at the Rossland Mines. Now that the latter have been placed on a shipping basis the ore of the Emma is required as it makes a good flux for the product of Rossland. It is understood that its output will be about the same as before the close down. The ore is low-grade gold, silver and copper.

**Vancouver, B. C.**

Conditions at Keno Hill, Mayo District, Yukon Territory, where rich discoveries of silver are reported, are described by George F. Johnson, a mining man recently returned from the North. He says:

"Preliminary prospecting has uncovered evidence of as many as nine separate leads of silver-galena shipping-ore. The present known depth and length of these are such that shipping ore now in sight will require many years of considerable activity to mine.

"Taken from one of the "leads" on the plateau of Keno Hill is what the miners call the "War Baby Silver-Galena Nugget." It is one oblong piece of solid silver-galena, similar in shape to a large potato, weight estimated by experts to be 1200 pounds. From the same vein or ledge from which this piece came are four other nuggets or slabs. These are nearly solid silver-galena and by comparison the weight of the smallest is easily 800 pounds.

"On either side of these slabs, and also below and above the "ore vein" is in evidence, with manganese capping, carbonates and footwall, all of such character as to induce the prediction that further development may prove the district to possess the largest and richest silver deposits in the world.

"Owing to the surface character of some of the "leads" it has been possible to develop with comparatively little effort to a point where ore can be shipped. In places one man can "pick down" or mine a quarter of a ton of shipping ore per working day. Estimating this ore to be worth \$200 per ton it is clear that some individual claim owners will be able to mine profitably."

It is stated by Mr. Johnson that the holdings of the Yukon Silver-Lead Mining Co. were located and partially developed before the discovery of the Keno Hill properties. The former are situated on Mount Haldane or Lookout Mountain and are in direct line with Keno Hill and the Silver King, from one pocket of which silver is said to have been taken valued at \$500,000. Much development has been done on Lookout Mountain, tunnels and shafts having been driven aggregating 1200 feet. It is stated that the vein has been followed for 400 feet perpendicularly, disclosing good shipping ore. Development on such properties as the Silver King, Mount Rambler and others in the section, as well as in the Twelve Mile area, should prove the extent of the area of the silver-galena bodies in the Yukon.

Considerable work is being done by the Canadian Geological Survey in British Columbia this year. Charles Camsell, until recently in charge of the western survey station and now Deputy Minister of Mines for the Dominion, states that there are twelve parties in the field. The topographical branch of the Survey

is making two fine maps of the Vancouver area and other parties are at Salmon Arm in the Coquihalla District, at Bridge River on iron deposits, in the Lardeau and in the Eutsuk Lake areas, and on the west coast of Vancouver Island. There is another party at the mouth of the Fraser River studying the sedimentary deposits of the river.

Mr. Camsell announces, too, that important work is being done in the Province of Alberta, D.B. Dowling is continuing his oil investigation. Another party is examining the Peace River Coal Fields and another is mapping out the extension of the Crow's Nest Pass Coal Fields to the north. A further party is in the McKenzie River country working out the structure of possible oil bearing rocks.

Oil drilling rigs are actually installed and working in two areas, one in the Great Slave Lake region and another near the Arctic Circle, the latter being the scene of the most northerly oil drilling in the world. There is much oil drilling going on around Peace River Crossing and much gas and some oil has been found. The latter is heavy oil and is a pumping proposition.

The gold receipts at the Dominion of Canada assay office, Vancouver B.C., from January 1st to July 31st, 1920, are valued at \$1,073,451.17. From April 1st to July 31st, 1920, they aggregated \$819,216.72, or about \$200,000 per month for the four months of the fiscal year 1920-21.

**THE COLLIERIES**

When the Board of Commerce of Canada held sessions recently in Victoria, B.C., evidence was submitted by what is known as the United Co-operative Society that there was a combination among the local Retail Coal Merchants as a result of which the former's demand for delivery of coal by the Collieries was refused. It also was charged that the retailers were charging unwarranted prices for the fuel. In reply the dealers denied that there was a combination, asserted that their influence with the Coal Operators was not sufficient to enable them to dictate to whom coal should be delivered, and that the prices asked for coal were reasonable. One firm admitted a profit of 90 cents a ton which was not considered excessive and others claimed their profits were not as great. It also was declared that coal was cheaper on the Pacific Coast than anywhere else in the world. Coal costs the consumer in Victoria, and it is approximately the same in Vancouver and elsewhere in British Columbia, from \$7.50 a ton for slack to \$14.50 for lump for domestic use.

It is announced by Dominion Government authorities, Ottawa, that although the embargo which came into effect on August 1st almost completely prevents the export of coal from the Eastern Canadian Provinces, it applies only to the Atlantic Coast. The Pacific Coast Collieries may still export coal. The Canadian Collieries (D) Ltd., and the Canadian Western Fuel Co., Vancouver Island, and possibly the Crow's Nest Pass Coal Co., Eastern British Columbia, are in a position to export considerable quantities. As the prices in this province are lower than in most parts of the world, and as the market and prices in European and other overseas parts, are satisfactory it is likely that this trade will grow. Already, as has been reported same shipments have been forwarded to Sweden and

elsewhere and, as there are many orders on hand and others are constantly coming, a material development of the business is promised.

The output of coal in Western Canada continues to be satisfactory. There was produced in the Province of Alberta during the first six months of 1918, 2,897,950 tons of coal while for the corresponding period of 1920 the output was 3,043,940 tons. The increase demand, however, has kept pace with the greater production as Alberta coal now is being used almost entirely as far East as the head of the Great Lakes. This, of course, is relieving very substantially the pressure on the supplies of Eastern Canada.

The negotiation of an important mining transaction, involving control of some of the greatest coal fields of the Province of Alberta, has been reported. As a result these properties are to pass into the hands of the McIntyre and Temiskaming Mining Companies of the Porcupine and Cobalt District, Ontario, respectively.

The Ontario companies are purchasing the Blue Diamond Coal Mines Ltd., of Brule, Alberta, a concern with an acreage of some six square miles and producing 500 tons of steam and domestic coal a day, and have optioned the Canadian Coal Fields Ltd., whose holdings cover a large tract of coal lands lying along the Hay river some thirty miles from the Blue Diamond. The Blue Diamond is capitalized at \$1,500,000 and the Canadian Coal Fields Ltd., at \$10,000,000. The option on the latter is understood to be for 15 years. The seller of the Blue Diamond is Messrs. McKenzie, Mann & Co., which concern also is a large holder in the optioned property. The purchaser of the property is the McIntyre Company, whose intention it is to share the deal with the Temiskaming Company on a fifty-fifty basis at the purchase price.

Engineers already are planning for considerable further development of the Blue Diamond Mines, it being the intention to install the mine plant and equipment necessary to permit an increase of production of from 600 to 2000 tons a day.

The production of coal in British Columbia for the month of July, 1920, follows:

#### Vancouver Island Field.

	Tons
Canadian Western Fuel Company, Nanaimo, B.C. . . . .	55,399

Corbin Coal & Coke Co., Corbin . . . . .	15,763
Total . . . . .	76,008

### COMBATING RISING COSTS BY REDUCING OPERATING EXPENSES.

Coal strikes, coal shortages and increasing prices have taught coal dealers and large consumers the wisdom of stocking and storing large amounts of coal. In that manner big reserves of fuel can be held against times of lessened production, blockaded traffic and increasing prices.

Such a plan is very advantageous but it encounters difficulties presented by the problems of handling the coal within the yards or storage space. Labor is scarce and wages high. These factors, coupled with the increasing prices of coal, make it very difficult to keep down rising costs.

However, it is the only way out. Coal prices cannot be reduced—they will go up instead of down. Nor

Disc Feeders of Loaders.

can cheaper labor be secured—it is difficult to get at any price. The only way left to combat coal costs is to reduce operating expenses.

This question of lower operating costs also applies to business having large quantities of bulk material to handle which can no longer afford to use obsolete and expensive hand methods—a fact proven by the tremendous growth in the past few years of labor-saving machinery of all kinds.

For different operations, specific machines have been developed which perform that one operation at great savings in time, labor and money. Each type of machine has its particular place and function, but it is unusual when one machine can be used for a multitude of different tasks.

Old Type Barber-Greene Self-Feeding Bucket Loader with Traction Wheels.

The Barber-Greene Company of Aurora, Ill., have however, with their Self-Feeding Bucket Loader proved the exception to this general rule for the B.G. machines can do many jobs with equal ease and equal economy.

Being comparatively small and moving from place to place under their own power, they can move around a factory, yard, sand or gravel pit, road or paving job just as a gang of shovellers would change from job to job as needed. The difference is that only ONE man is required to operate the Loader, and this one man can move about 75 cubic yards per hour.

The distinguishing feature of the B.-G. Self-Feeding Bucket Loader is the Rotating Double-Disk Feeder (patented) at the base of the elevator. The feeder does the work of one or two men and gives the machine a range that is otherwise impossible. It enables the machine to dig to a width of six feet rather than to the bucket width, and the operator consequently has little difficulty in keeping the loader continuously up to the capacity.

The digging or feeding device consists of a pair or horizontal discs, set almost flat on the ground, but with a slight pitch toward the pile. The rotation of the two discs carries the material to the centre where it is picked up by the buckets digging from the smooth surface of the discs. The wide digging face of this loader enables it to handle a large quantity of material with very little movement and it also enables the machine to advance without obstruction into the pile.

The construction of the machine in general enables it to use the Disc Feeder to best advantage. The Discs deliver a large capacity to the Bucket Elevator and this in turn is of a size consistent with this capacity. It is designed for handling heavy materials and for very severe service. The frame construction and the crawlers embody strength; the chains and buckets are selected for wearing qualities; and the drive is designed to enable the operator to keep the machine at productive work for the maximum amount of time. A differential provides for turning sharp corners. A slow reverse feeding-speed is provided to enable the loader to be readily spotted on the job.

MODEL 20, the "last word" in Loader design and construction—the result of 18 months' study and ex-

Old Type B. G. Bucket Loader handling Coal from Stock Pile and delivering to B. G. Portable Belt Conveyor.

perimentation. It is simply a new and better model built along the same general lines as the hundreds of older B-G. Self-Feeding Bucket Loaders in daily operation all over the world.

The Barber-Greene Co., extend service to customers through their Branches and Agents, Mussels Limited, being their Canadian representatives.

### WHY FRANCE WANTS COAL.

Maximilian Hardin, in a recent number of *Zukunft*, enforces upon his German readers a few wholesome truths regarding the coal deliveries demanded of Germany under the Treaty:

The *Bulletin de l'Association internationale des chemins de fer* has just published the following report: 'The new president of the Society of French Civil Engineers, Mr. Eduard Gruner, in his inaugural address, discussed the destruction and reconstruction of the coal districts in the North and Pas-de-Calais. Citing the records left by the German engineers themselves, he showed that Germany's work of destruction in these regions was thoroughly planned and carried out with all resources of expert engineering science. In August of 1915 they had ascertained scientifically the height of the ground water line in every shaft then working, and beginning with the advance shafts in Courrières and Lievin they started their work of destruction. The engineers in charge of this crime have themselves explained that they dropped into each shaft a small beam to the end of which was attached a mass of high explosive. The quantity varied from 80 to 200 kilos according to the estimation of the amount required in each particular instance to destroy the casing and cement work of the mine. The underground passages and excavations were filled with water. Around the pillars they assembled all conceivable material: barrels, gratings, cable, basketry, human corpses, bodies of animals, and whatever they could lay their hands upon to foul the water and prevent the mines from being pumped out. In the midst of this débris, they sank shells and boxes of dynamite, hoping thus to prevent salvaging the mines by causing constant explosions. First of all they dealt with the property of the Lens Mining Company. They did not spare one of the twenty shafts. This explains why a district which used to produce more than 4,000,000 tons of coal annually could be flooded to the very top of the shafts.

Equally methodical was the destruction of the works above ground. Every building, machine, piston rod, crankshaft, shaft, with its bearings and brackets, was cut up and broken into pieces completely with dynamite. It would have been considered a very serious oversight to leave a boiler intact. All the steam boilers, winches, and other pit head apparatus, were completely destroyed with explosives. Of 12,000 laborers' houses in Lens and thousands of small houses in the neighboring villages and country, not a single one was left intact. In October, 1918, the irresistible general advance of the Allied Army swept through these regions. Thereupon every shaft of the Mining Companies of the North, from Escarpelle to the gates of Douai and the collieries of Anzin on the Belgian border, was destroyed. In regions where a cannon was never heard, thirty or forty kilometers from combatant troops, by the 12th of October there was not a steam engine, a winch, or a pump, or a ventilating fan left. Everything was completely ruined. A few fig-

ures will show the extent of this destruction. For years to come 220 mines will be useless. The water is from 60 to 80 meters deep in them. Double or three times this quantity will have to be pumped out before the first breaches in the mine walls will be uncovered. A production of 20,000,000 tons of coal, which was increasing annually by far more than a million tons, and by 1920 would have reached at least 26,000,000 tons, has been stopped completely and cannot be resumed before 1920, at the earliest. This destruction was never justified on the ground of military necessity.—“Living Age.”

### A RE-ALIGNMENT OF TRANSPORTATION ROUTES.

A re-alignment of transportation routes in North America is assuming definite shape, some of the causes being undeveloped, and as yet not clear, and other causes more apparent.

The more general use of the Panama Canal is following upon the great port improvements on the Pacific Coast, Seattle having taken the lead and reaped the initial benefits of its expenditures, with Vancouver not far behind. More and more does it seem likely that the trade of the Orient will flow towards the Pacific ports, and that Vancouver will increase in importance and volume of shipping interchange. The growing strength of Japan, and the commercial impetus and increase in population which is likely to follow her occupation and administration of Eastern Siberia, Manchuria, Sakhalin, Corea, and the long heralded renaissance of China, which seems likely to take place under Japanese tutelage forecast much coming enlargement of the commerce of the Northern Pacific. The political changes which these future developments may give rise to are momentous and may force some re-adjustment of the attitude of North America towards Japanese and Chinese ambitions, but they point indubitably towards greater importance of the Pacific ports and the railway lines that serve them. The presence in China of great deposits of anthracite, bituminous coal, iron and alloy metals, is one of the significant facts indicating world destinies.

The great bituminous coal reserve of Canada lies bordering the crest and to a great extent on the Albertan side of the Rockies. This deposit is so large and unique in Canada that it must at some future date become the dominating centre of Canadian industry, and the focus from which transportation lines will radiate. Inspection of the map will show that the western coalfield is relatively near to the Pacific Coast, and that in days to come Vancouver will become a great coal-exporting port, and the point from which manufactured articles, made with the assistance of western coal will go out.

The recent conferences on the St. Lawrence waterway indicate quite unmistakably that the future will see ocean-going vessels going to Duluth and Port Arthur, which will not displant but will supplement the existing east to west rail lines, and others that are yet to be built. Such a route will mitigate those sea-

Electrically Operated Mine Hoist

Steam Driven Mine Hoist

## 7 OF OUR MINE HOISTS IN USE BY ONE N.B. MINER 7

and this is not the only firm in Canada using seven of our Hoists.

Would these customers continue to purchase our Hoists from year to year as their business grows without a good reason?

Quality and service count for much more than price in the long run, and while we can assure you that the price of our Hoists is reasonable, the price alone would not have secured us these many repeat orders. These customers were satisfied with the quality of the Hoists, the honest workmanship and material put into the machines, the skill exercised in their design, and their comparative freedom from premature breakdowns or repairs.

Our Mine Hoists are built right, and give the best of service—that is why our customers stay with us, and continue to order more machines as their needs increase.

Choice of seven sizes in either Electric or Steam Hoists, ranging from 10 H.P. to 50 H.P.

**Marsh Engineering Works, Limited,** ESTABLISHED 1846 **Belleville, Ontario**

sonal crises in transportation which the periodical accumulation of crops combined with climatic conditions must always cause in North America, and it will be time to talk about redundancy of transportation facilities and competition of facilities when it shall be demonstrated that existing routes are adequate. Most people will be of the opinion that their complete inadequacy has been proven.

From the viewpoint of the coal and steel industries of Canada, the importance of the St. Lawrence waterway—should its possibility be favorably reported upon by the engineers who are studying it—is that it will enable Nova Scotian coal and Newfoundland ore to be brought to steel plants and metal-working establishments in Ontario and Quebec, and thereby lessen a dependency upon our neighbors that has become a national menace.

There is the further consideration that the north-western states of the Union are about as dependent upon British Columbia and Alberta for bituminous coal as Ontario is upon United States sources of supply. Quebec cannot be said to be dependent upon the United States for bituminous coal, as there is an amply sufficient potential source of supply in Nova Scotia, and the St. Lawrence waterway has for many years carried millions of tons annually from Nova Scotia to Quebec centres of consumption. When the coal fields of Alberta and British Columbia be-

come the main source of bituminous coal supply along the Pacific coast the international exchange of coal between Canada and the United States will not be so humiliatingly lop-sided as is the case now.

There seems therefore emerging from today's readjustments a possibility that at some point in the Canadian West, perhaps not far from the Saskatchewan-Albertan border, there will be discernible the "water-shed" of traffic, from which on one side the stream will flow to the Pacific ports, and on the other side to the Atlantic ports of the Dominion. The shipment of manufactured articles from the East to the three provinces of Saskatchewan, Alberta and British Columbia will lessen as the coalfields provide a domestic source of articles that now originate so largely in the East, and to the southwards, and instead of being exporters of wheat and beef, and importers of mostly everything else, the prairie provinces and British Columbia will become exporters of manufactured articles, in addition to agricultural products, and importers of very little.

The one drawback to industrial eminence in the prairie provinces is the apparent lack of an iron-ore deposit. It is a little too soon, however, to assume that such a deposit may not yet be discovered within transportable range of the western coalfields. In British Columbia this difficulty is not so marked, and, on Vancouver Island, the necessary conditions for iron

smelting and steel manufacture seem to be present.

The inadequacy of rail transportation in North America is generally admitted at this time, and whether it is a breakdown of executive or operating conditions, or simply a reflex of social adjustments, it is difficult to form an opinion, but it is probably a combination of them all. Leaving this aside, the condition of rail transportation is causing much speculation on modes of improvement, prominent among which are proposals of electrification of steam roads, and long-distance motor-truck transportation, which is becoming more and more feasible with improvements of highways and truck design. It appears very likely that much development in both these directions will take place in the immediate future. The marked increase in motor manufactures in Canada shows that our manufacturers are reading the signs of the times, and this field has many possibilities in Canada, and is of interest to the steel trade in particular.

—From "Iron and Steel of Canada."

#### CAPTAIN J. G. ROSS.

Chairman of the Montreal Branch of the C. I. M. & M.  
(From the August Bulletin.)

Captain J. G. Ross was born in Embro, Ontario, and obtained his early education at the Embro public school and at Woodstock Collegiate Institute. Later he entered McGill University, and, after taking the

CAPTAIN J. G. ROSS

mining course, graduated in 1903 with the degree of B.Sc.

During his student days, Captain Ross had acquired his first mining experiences in British Columbia and Cape Breton, but during the two years following graduation, he was employed as resident engineer on the northern division of the Grand Trunk Railway. He returned to mining work, however, during the Cobalt "boom", and from Cobalt he went to New York as superintendent of construction on the Hudson River tunnels. In 1907 he was superintendent of the Worthington mine for the Mond Nickel Company, and during 1907 and 1909 he was examining mining properties in many parts of the world, including New Caledonia, Australia, South and Central Africa, Asia Minor, etc. After returning to Canada he spent the next year on examination work in Porcupine and British Columbia and in 1911 accepted the appointment of consulting engineer with the Milton Hersey Company, Limited., Montreal.

When war broke out in 1914, Captain Ross was already on the active list of the Canadian Militia and proceeded overseas with the 1st Contingent as Lieutenant in the 13th Battalion (Royal Highlanders of Canada). As battalion machine-gun officer he went through the strenuous fighting of the Second Battle of Ypres in April 1915. Subsequently he was appointed adjutant of the 13th and promoted on the field to Captain. During the next month at Festubert, Captain Ross was badly wounded by shell fire while the battalion was attacking on May 21st. He suffered a compound fracture of the right leg which confined him to hospital in England for many months. After leaving hospital he returned to Canada and was discharged with the rank of Captain. He resumed his consulting work with the Milton Hersey Company in 1916 and at present holds the position of consulting mining engineer for the company.

Captain Ross joined the Institute in 1911 and much of his spare time is devoted to its affairs. He was elected to the Council in 1919 and is also chairman of the Montreal Branch as well as a member of various committees.

#### ORNAMENTAL MARBLES FROM ST. JOSEPH DE BEAUCE, QUEBEC.

The British Canadian Marble Co., Ltd., of St. Joseph de Beauce, Quebec, financed by British capital, and owing extensive deposits of beautifully artistic green and red marble near St. Joseph village have just completed a mill for the treatment of red slate for the ready roofing trade. This slate is found adjacent to the marble. The mill has a capacity of 100 tons per day and is the first of its kind to be erected in Canada. It was designed, and built by Chas. Spearman, M.E. of Montreal. The marble quarries have been in operation since last April and are shipping to various points in Canada where new buildings require this material for interior finish.

It is understood that St. Joseph marbles will be used in the annex to the King Edward Hotel in Toronto, now building.

The Company has an experienced quarry foreman, Mr. M. Kelly, who comes from the Vermont marble district.

The Premier of Canada says the tariff policy of this country should be to keep Canadian workingmen in Canada, to make goods in Canada, and to give Canadian industries just enough advantage in the Canadian market to make it pay them better to stay here and expand, than to diminish their plants and leave. Mr. Meighen announces his Government intends to revise the tariff to secure these ends; that wherever a tax exists that is not necessary, it will be wiped out, that no interests, however powerful, will get more; and that no wreckers or theorists, however enthusiastic, will be permitted to imperil the well-being of the country by blindly fixing less. Whether Mr. Meighen's government can carry out this programme or not time alone will tell, but that Mr. Meighen has outlined the specification of national well-being few will deny. The phrase "wreckers or theorists" is a very happy one. Only too often the terms are synonymous, and while the theory is beautiful, the result is most dire.

The statement has been made by Senator Gideon Robertson, Minister of Labour, Ottawa, that there are at present vacancies for 600 men in the coal fields of the Province of Alberta, where miners are paid \$10 and laborers \$5 and \$6 a day.

## THE NICKEL INDUSTRY.

At the sixth annual meeting of the Mond Nickel Company held in London towards the end of July, Mr. Robert Mond, the Chairman of the Company set forth the Company's position with regard to the excess profits tax imposed on British incorporations, and among other things said :

"I do not think that any of the shareholders realise how difficult and complicated taxation has become during the war for a business like ours, which is carried on not only in this country, but also in Canada. Our profits are subject to taxation in this country, in the Dominion of Canada, and in the Province of Ontario, and as a matter of fact, we have to deal with the following taxes: Income tax, excess profits, and now the corporation tax in the United Kingdom, Dominion Income tax and business profits war tax in the Dominion of Canada; and mining tax in the Province of Ontario."

This is a formidable list of taxes, and would suggest that the Mond Nickel Company, at any rate, has undergone very considerable "investigation" if the tax-collectors have run true to form.

It is encouraging to know that the cumulative imposts that large mining companies with international interests have now to face does not discourage the enterprise of those who have the direction of business policies, and it is interesting to note Mr. Mond's announcement of the purchase of the firm of Henry Wiggin & Company of Birmingham, England, the oldest established firm of nickel and nickel-silver manufacturers in that country. This Company owns three works in Birmingham, well equipped with rolling mills, wire-drawing plant, refining plant, and other machinery. The Chairman stated that there was an increase of over half a million dollars in nickel stocks in the Company's possession, and that production had been curtailed owing to lack of outlet. The Company was doing everything possible to increase the industrial uses of nickel by making such goods as sheets, nickel coin, wire, and blanks, the purchase of the Birmingham firm being a part of this policy.

The continued demand for nickel will depend, as has been the experience of asbestos, upon the creation of a variety of uses, and one of the most encouraging signs of the times in regard to the nickel industry is the already long list of new applications of nickel, and metals of the nickel group, to everyday implements that is being daily added to by the enterprise of the nickel companies.

## MANUFACTURING IN WESTERN CANADA.

Elsewhere in this issue is an excerpt from the monthly Bulletin of the C. P. R. which deals interestingly with the expansion of manufacturing in the West. A single statement is sufficiently remarkable to attract wide attention, namely that since 1900 the value of the produce of western manufactories has increased from 34 million dollars to over 400 million dollars, or by twelve times. Astonishing as this rapid growth may seem, it may be very confidently predicted that it is but small compared to that which the near future holds for the West.

The value of the manufactured articles of Canada to that of the value of field crops was in 1919 about as three is to one. Up to the present time the ratio between agriculture and manufactures has in the West been disproportionately in favor of agriculture, and has not conformed to the general average of the country. This has in large measure accounted for the traditional attitude of the west towards protective tariffs in aid of domestic industries. We venture to predict that the time is coming when the ratio of manufactures to agricultural production will be more pronounced in favor of manufactures in the West than in the case of the general Canadian average, for the reason that the West possesses the essentials for manufacturing on a scale that the East does not—and in particular it possesses an abundant supply of that indispensable and destiny-disposing material which is the basis of all manufactures—coal.

The possibility of the presence of oil in the Canadian West is one that properly excites much interest, and some justifiable hopes, but we would point out that in its coalfields the West has a more permanent supply of motor-spirit than can ever be looked for from the unknown sources that produce petroleum.

## BRITISH COAL MINERS THREATEN STRIKE AS POLITICAL WEAPON.

The threatened coal strike in Britain, the possibility of which has been before the country since before the appointment of the Sankey Commission, will shortly assume a menacing aspect. It seems certain that the miners have voted for a strike, and it seems if anything more certain that the Cabinet will resist the demands of the miners' leaders, so there is every likelihood that a long-deferred issue is about to be fought out.

The disguise of a demand for higher wages, and the other familiar accompaniments of a labor dispute, has

been attempted in this the latest stage of the campaign for "nationalization" of key industries, but this disguise has recently been virtually discarded, and the real objective of the miners' leaders is admitted—both by those who favor and those who do not favor it—to be political rather than primarily connected with a desire for higher wages and shorter hours of labor.

"Nationalization" is one of those mysterious words that mislead the public while concealing the aims of those who invented the term. It is an example of the nickname in politics, used to gain approval instead of opprobrium. It is much to be doubted whether any but a small and selected group of the mine workers understand what nationalization of coal mines means in the interpretation of the miners' leaders. Their objective is to destroy private ownership, of every nature, substituting the apparent ownership of the State, but always with the proviso that the worker shall comprise the State.

As controlling the workers in the most essential industry of a modern state, the industry without which continued existence of such a state is unthinkable and quite impossible, the coal miners accepted, at their international convention at Geneva, the leadership of that school of thought which advocates the destruction of private ownership, and the employment of "direct action" to bring about its most speedy consummation.

The strength of the miners, and their selection to lead the frontal attack upon society as it now exists, arises from the absolutely essential and entirely irreplaceable nature of the commodity which they produce, a circumstance that gives to united action of coal miners a greater importance than their numbers would entitle them to under the most representative form of government that could be designed.

It is not, therefore, the legitimate political representation to which coal miners as members of the state are entitled, that they purpose to use, but their control of a necessity of human existence. This is the feature of the miners' policy that will bring their whole strategy into disrepute, and will marshal public opinion so strongly against it, that, if a strike occurs, the probability is it will meet with the failure it deserves.

The policy of the miners is to translate into actuality the principle embodied in the preamble to the constitution of the United Mine Workers of America, namely: "All wealth belongs to the producer." Their demand at this time is that all the apparent profit made in the coal mining industry in Britain shall be absorbed in the payment of increased wages to the miner and by a reduction of the selling price to the domestic consumer. That is to say, it is proposed the industry shall break even, and that coal mining shall show no apparent profit to any person, or to any constituted body—the State not excepted. The accuracy of the book-keeping of the miners' advisers is not admitted, nor have these advisers suggested what should be done in

the not unlikely event of the industry showing a net loss on operations. Presumably the State would be asked to absorb this.

To discuss the rectitude or otherwise of this doctrine would require a re-statement of the science of political economy, and will not be attempted here. Suffice it to say that the granting of the miners' demands would mean admission of the principle that the State can decree abolition of private property rights with discriminatory application to a selected section of its citizens. A further admission would be necessary, namely, that the political power of any group in the State must be measured, not by voting power, but by the industrial importance of the product of a selected group of workers.

It would probably also be admitted by the leaders of the miners that there is no industry in Britain to which the same arguments for "nationalization" cannot be applied.

The miners are presumably counting upon the assistance of the transport workers and other trades union bodies in Britain, but the financial loss and physical suffering which a prolonged strike will occasion to all classes of workers, makes it unlikely that such support will be forthcoming.

It is apparent to all that the paper profits of the industry cannot be absorbed by increased wages to the miners without depleting the revenues of the State—thereby requiring additional revenue. If on the other hand State revenues are to stand undiminished, a further increase in the cost of coal will be required—thereby increasing once more the cost of living to the general public. The idea that any industry can be continued with a profit accruing to some person, or some association of persons, is one that is unlikely to find general acceptance in Britain.

If it becomes generally realised—as seems fairly likely—that the miners are acting as the vanguard of Communism, under orders from a central organization, and assisted by undertakings for an international coal strike, the British Government is certain to be supported in resisting the use of the strike weapon to enforce a political theory that has not received the approval of the nation through the ordinary channels of the ballot.

The British public is unlikely to concede to the miners as a class the preferential treatment they demand, not—and they are quite frank about this—as an inherent right, but because they believe they possess the power to enforce this essentially selfish demand.

#### BRITISH MINERS ASK PREFERENTIAL TREATMENT.

The demand of the British coal miners is for an increase of two shillings a day in wages, with lesser graded increases to junior workmen, to be accompanied by a decrease of approximately \$3.50 per ton in the selling price of domestic coal. That is to say the

miners ask for the establishment of a condition that will simultaneously increase wages and decrease revenue.

The cost of producing a ton of coal in Britain was (using an approximate Canadian equivalent) \$1.52 per ton in 1913, and in May 1920 had reached \$5.45 per ton, an increase of 218 per cent.

The rate of production is now twenty per cent below that of 1913, notwithstanding that some 73,000 additional persons are now employed in the industry when compared with 1913.

The wages of mineworkers have increased since 1913 by 155 per cent, the increase in the cost of living being estimated by the British "Labor Gazette" at 152 per cent. The wages now earned by the miner remunerate him for seven-eighths of the daily period of labor, and for four-fifths of the daily product of his labor before the war.

The exports of coal from Britain for the period of six months ending June 1913 totalled 37,048,000 tons. Those for the corresponding period of 1920 totalled 16,493,000 tons, a falling-off of 57 per cent. In the meantime coal from other countries is displacing former British markets, such as Norway, Sweden, South America, Spain and the Levant. Britain must continue to import heavy tonnages of iron ore from Spain and grain from the Argentine, and the lack of coal to make an outward cargo is responsible in large measure for the high delivered prices of these essential commodities.

During the war coal proved more potent than gold to maintain the parity of British exchange abroad. The tardiness of the recovery of sterling exchange, and its failure to fulfill confident expectations of renewed strength is largely due to the non-availability of British coal for export to countries which have an adverse balance against Britain.

A most potent weapon to reduce living costs and deflate currencies would be the increased production of coal. The policy pursued by the leaders of the British miners is a major factor in keeping up the cost of living, and an increase on present rates of wages would have the effect of reducing production and increasing living costs.

In the earlier part of the campaign for nationalization, the leaders of the miners expressed themselves as strongly opposed to working for private profit, which was a fairly understandable viewpoint. Now they express themselves as opposed to working for the profit of the Government, notwithstanding that any surplus of profit is applied to the relief of general taxation. It is not so very long since the miners in South Wales threatened a strike if they were asked to pay income tax as other citizens are.

The miners at this time possesses the following advantages over his position in 1913, namely: shorter hours of labor, a greater margin between his income

and his necessary expenditure than ever previously, a larger say in the management of the industry and undiminished extent of the privileges as to free or cheaper coal and house rentals.

As a result of all these concessions to the miner, the country at large pays more for coal and gets less than ever before; the cost of commodities is increased directly as a result of increased wages, and indirectly as a result of decreased exports of coal.

Now the miner asks for a further intensification of these contrasted advantages to himself and the disadvantages to his neighbour.

Meanwhile, production in the United States is increasing. In 1913 the British exports of coal were five times those of the United States. Now the export of coal from the United States far exceeds that of Britain.

The miners are prominent in that group of laborites that desires to direct the foreign policy of Britain, and are offering gratuitous advice, commingled with dire threats, to a Cabinet that does not contain the meanest intellects in Europe. They are amusing themselves passing resolutions regarding state policies, and announcing new and untried theories of political economy and representative government, while rapidly and surely the foundation of Britain's political and military strength is being taken away. No one knows better than the coal miner the national importance of coal, or realises what a powerful weapon he controls as the producer of coal, but, unfortunately for Britain, and in flat defiance of his ostensible desire to save the pockets of the domestic consumer, the miner prefers to put first of all his own sectional desires, and asks for preferential treatment.

It would be desperately unfair to impute such unworthy motives to the individuals amongst the miners, because they number some of the best citizens of Britain. The war record of the miners' regiments is an inspiration, and a source of enduring praise, and is probably the best index to the real worth and ideals of the miner. Unfortunately for Britain, the men who carried the miners' banner in less opulent and more conservative times, and laboriously laid the foundations of the existing power of the miners' unions, have been superseded by men who are using that power with less wisdom and less rectitude than their predecessors.

#### THE ONTARIO MINING ASSOCIATION.

The Ontario Mining Association held its first Annual Meeting at Sudbury from the 17th to 19th of August. This association of operators is a necessary and logical outcome of the scattered and diversified nature of mining operations in Ontario, a province of Canada that lacks only coal to give it the most all-round importance in mineral production in Canada.

The temporary dominance of agrarian interests in Ontario was probably the deciding factor in bringing

about the formation of the Association, but, in any case, it is a necessary body, and properly directed, it cannot fail to be beneficial to the mining industry, and a potent force in preventing misapprehensions among the general public, for doubtless it will be the policy of the Association to undertake the dissemination of accurate information. There is nothing that the mining industry in Ontario requires so much as accurate and first hand information regarding the industry, which is, and has for many years, been the plaything of ill-informed and interested propagandists.

The first meeting was of a "get-together" character, and entertainment and business were combined through the hospitality of the International Nickel Corporation, whose guests the members of the Association were for the first two days. Visits were made to the Creighton Mine, to High Falls, the Eddy Dam and Copper Cliff. On the concluding day of the meeting the visitors were shown over the British-America Nickel Corporation's mines and smelter at Nickelton.

Among the most important business discussed during the meeting was the unsatisfactory position of Canada as a producer of iron ore, in which respect this country has gone from bad to worse during the past decade.

A Commission was appointed, composed of Colonel R. W. Leonard, Mr. A. J. Young and Mr. G. S. Cowie, to assist the Ontario and Federal Governments in any enquiry they may set on foot into the improvement of Canada's position as a producer of iron ore.

The case for the iron ore industry in Ontario has been given much attention in the columns of the "Journal" during the past year, particularly the question of beneficiation, to which attention has been drawn from time to time by our Port Arthur correspondent, Mr. J. J. O'Connor. Of equal significance to the stand taken by the Association in regard to iron ore, is the belief expressed by the members that Alberta coal could be used as a fuel in metallurgical processes.

The Ontario Mining Association is to be congratulated on dealing at its first session with the weakest link in the industrial position of Canada, namely this country's dependence on outside sources for coal and iron.

#### PEACE RIVER PETROLEUMS, LIMITED.

In an advertisement of the stock offering of Peace River Petroleum, Limited, which appears in a Sudbury newspaper, there is quoted an article from the Toronto "Star" of August 7th, written by Dr. Sven Lawrence of Copenhagen, described as formerly a geologist and operator in the oilfields of Baku, on the Caspian Sea. This article contains some statements regarding oil occurrences in Canada that are new to

this journal, and seem to have escaped the attention of Dominion geologists engaged on elucidation of the economic geology of oil in Canada. With regard to Alberta it is stated: "The tales of its trappers and prospectors sound like fairy tales." (Perhaps they are). "Oil is oozing out of the ground, natural gas wells supply the fuel for their tea kettles, (a weak beverage for such a country) and burning mountains that have been ablaze for perhaps centuries, roll their pall of smoke down the valley of one of the tributaries to the Peace River."

This imaginative writer proceeds to state that in Canada "we have twenty times the oil-bearing area of Mexico; that is, the third largest oil producer in the world, and a larger area than the United States, and still thousands of unknown square miles to explore."

All of this is the purest presumption. Western Canada has not yet been proved to be an oil-bearing country comparable with either Mexican or United States oil regions. All that can as yet be stated with accuracy regarding the oil prospects of western and north-western Canada is that there is a fair presumption that oil is present, and that scientifically directed search with the drill may be rewarded by the discovery of oil in commercially payable quantities. Such search is now being made. The presence of oil has been revealed in the Peace River country and north of the Great Slave Lake, but nothing in the nature of a gusher has yet been encountered.

Mr. H. E. Cunningham Craig, whose opinion is quoted as being a fairly independent one, says: "Considering the whole subject it may be said that the verdict at present must be 'not proven'". There is "no doubt whatever about there being a vast volume of oil in the country; the only question is—can it be found sufficiently concentrated under favorable conditions for development?" \* This opinion corroborates the best informed opinion of Canadian geologists, and in particular the conclusions of Dr. Dowling as set forth in our issue of April 9th last.

Peace River Petroleum, Limited, advertises that it has a paying flow of oil in one well, and it offers shares at fifty cents each in what its advertisement states to be "the best Canadian proposition ever offered the Investing Public". This may be all true, and again it may be quite untrue. The project is the purest gamble. Be this as it may, the promoters do not add to the attractiveness of the offer made by quoting such imaginative and misleading accounts of the oil possibilities of the Canadian West as that of the Copenhagen geologist referred to. The quotation of this article, with apparent approval, is in itself an indication of ignorance of essentials in the advertisers that does not recommend them as guides to safe investment in oil mining.

\* See page 668, issue August 13th.

## CORRESPONDENCE

14 Place Royale,  
Montreal, Canada.  
August, 14th, 1920.

The Editor,  
Canadian Mining Journal.  
Dear Sir,—

In your issue of the 13th. inst. I note with interest Mr. E. H. Cunningham Craig's "The Search for Petroleum" in Western Canada, being a copy from the "Petroleum Times."

Man is apparently quite as capable of a change of mind as the fairer sex. If Mr. Craig had inculcated into his reports and papers during 1913 and 1914 such information and conservatism he would not have gained the reputation of trying to out-do the writers of the dime novels, and much money would have been saved and a great deal more honest development work would have been performed.

The exploiting of the Southern Alberta Oil Fields during the years mentioned by boomers backed up by engineers of reputation should be a lesson to Canadian engineers in the future. Engineer's reports should be above all honest and not in any way influenced by possibility of material gain.

We should welcome sincerely such changes of opinion and the courage to in black and white record the change.

Yours faithfully,  
G. M. Ponton.

The Editor of the "Canadian Mining Journal."  
Sir,

This characteristic titbit has been given extended space on both sides of the Atlantic :

London, Aug., 20.—(By Canadian Associated Press.)—The Daily Mail's financial editor, discussing the possibility of the introduction of more Canadian mining shares on the London market soon, remarks that it can hardly be claimed that such investment up to the present, have proved so satisfactory that there is likely to be any great rush for new schemes. The writer says that the Canadians seem to have kept for themselves the best of the mines or let Americans finance them."

The verities were not outraged when that was put into the types.

Had the writer reasoned introspectively, he could have been more interesting—and instructive—and might have explained why "the London market" ought not to be indiscriminate—and how it is that Canadians either have "kept for themselves the best of the mines, or let Americans finance them."

The paragraph is opportune in that "more Canadian mining shares" are about to be introduced "on the London market." Presumably some of those are suspect. Perhaps they are unfit for London consumption. If so, then London should not attempt their "introduction", since it is perfectly true that "Canadians" do not have to go so far afield with "the best" of their mines. Really there is force in the intimation that "Canadians", or "Americans" are sufficiently absorbitive for immediate requirements; because "London" is preoccupied.

In rare instances "the London market" has been sought with deserving mining propositions. As rarely has "the London market" participated in what promised profits. As a rule, the preference is for the

sovereign rather than the "almighty" dollar—and yet the experience has been that London was wedded to its ritual—it has "left undone those things" it "ought to have done"—and "done those things" it "ought not to have done."

Homilies, however, will not rectify errors of commission or omission—on either side of the Atlantic. "London" waited too long, was unresponsive—or entertained propositions in which "jobbers" had precedence. At Porcupine, "London" did not rise to the occasion. At Kirkland Lake, the cooperation of "London" was involved in discredit and litigation. Excepting the Townsite property "London" never got nearer than the fag ends of the real Cobalt situation. "London" could have had a larger share of the Nickel Country and defaulted. The "Flin Flon" was preferred to "London" and New York got it to be joined later by the British-Canadian Mining Corporation. The Consolidated Mining and Smelting corporation commands the British Columbia position—but "London" would rather take on something more speculative.

"Canadians" welcome the "Daily Mail's" remarks—if they will serve as the introductory to a more intelligent, active interest in our "best" mines—or prospects. "London" mining financiers thoroughly comprehend the economics of Mining. Why they are more in touch with the actualities of Canada—when their representatives "on the spot"—and not catch-penny promoters—are authorized to deal—instead of having to await the termination of the grouse season, "London" will get more that is worth having. "Canadians" greatly prefer "London" co-operation in the "best" mining speculative ventures.

ALEXANDER GRAY.

Montreal, 23 August 1920.

## PERSONALS.

Mr. J. W. D. Moodie, general manager of Britannia Mines, Howe Sound, B.C., has resigned. He is succeeded by Mr. B. B. Nieding.

Mr. John Stirling has gone to Scotland. Mr. Stirling, who is Chief Inspector of Mines of Alberta was seriously ill this summer and he will take a much needed rest before returning.

Messrs. Ross and Cassie, Limited, with offices in Sudbury, Cobalt and Timmins, have been appointed Northern Ontario representatives for the Federal Engineering Co., Ltd., handling their conveyor and transmission belting

Mr. Charles Camsell, Deputy Minister of Mines has arrived in Ottawa, bringing his family with him from Vancouver.

Mr. John McLeish of the Mines Branch, Ottawa, has been called to Toronto by the illness of his father.

Mr. J. T. Kerr, of Detroit, is in Toronto making arrangements for doing some work on the property of the Golden Summit Mining Co., at Sesekinika.

**T. J. BROWN LEAVES NOVA SCOTIA STEEL AND COAL CO.**

Mr. T. J. Brown, for many years Superintendent of the Sydney Mines operations of the Nova Scotia Steel and Coal Company, has resigned that position and becomes General Manager of the Inverness Collieries, Limited, a Company recently organized to work the properties formerly belonging to the Inverness Coal and Railway Co. at Inverness, Cape Breton.

# British and Colonial Petroleum Resources

## A Review of the Present Oil Situation

By HENRY B. MILNER, M.A., F.G.S.

Oil Technology Dept., Royal School of Mines.

(From "Discovery" for August)

Nowadays, when public attention is so easily attracted by any matter in the slightest degree sensational, or by one which promises to provide something out of the ordinary for popular diversion, it is not difficult to appreciate the cause of a certain liveliness in that particular section of the daily Press which exists solely for the purpose of supplying its readers with articles calculated to inspire the requisite feelings of satisfaction or apprehension. No matter what the subject under discussion, exaggeration and imagination are called into play in the production of the most misleading paragraphs, and the resulting distortion of fact is only equalled in magnitude by the shameless extent to which scientific or economic principles are ignored.

Quite apart from the complexity of international politics (which surely provide food enough for the most insatiate literary appetite), since the Armistice we have had a succession of Press "scares," some with a foundation of fact, but most without any. The varied aspects of the present shortage of many of the necessary commodities of everyday life can be attributed, reasonably enough, to one of the more disagreeable legacies of the War; but the startling predictions of a world-famine in such vital essentials as wheat, coal, water, and oil—to cite only a few examples—require a somewhat closer scrutiny of their "bona fides" than the prophets of these disasters would be willing to admit. Articles of this kind, so long as they are confined to the requirements of advertisement or enhanced sales, are harmless enough, for the reader who allows himself to be influenced by their purpose assuredly deserves all he gets. It is only when they are written with the calculated intent of disturbing international relations that they assume a dangerous character; and in such circumstances, no amount of comment and censure should be spared which may proclaim or deny the validity of a particular case.

In the present oil situation we have a cogent example of Press propaganda of the very worst type, whose ulterior object is not so much the creation of an alleged oil famine scare, as the possibility of disturbing our political and economic relations with other countries; in particular the United States. It will have been apparent to those who follow carefully the happenings in the oil world, that the present agitation for a definite Imperial oil policy, to conserve our resources and relieve the tension of possible famine, is but a cloak to hide an attack on American tactics, rather than an honest attempt to review a situation which may or may not have arisen. Briefly, the arguments may be summarised as follows. On the one hand, we are told that the United States, knowing that we are very largely dependent on her for the bulk of our oil-supply, is adopting somewhat the attitude of a "profiteer" in making us pay extremely high prices for a commodity which she could easily afford to sell for less. Against this, we in turn are accused of adopting a "dog-in-the-manger" policy in other fields in which we are interested, especially in Persia and Me-

sopotamia, our aim being, it is alleged, the elimination of American capital and interest in future developments in those countries. And so as to bring the whole matter to the point of ebullition, the "experts" responsible for these indictments have dexterously juggled with statistics in order to demonstrate a universal decrease in oil output, an ever-increasing demand, and, in consequence, an ultimate famine in what has now become a vital asset to modern civilised life.

It is with the object of inquiring into the true state of affairs that these paragraphs have been written: and, without endeavouring to solve any of the recondite problems of British and foreign politics, it is proposed to present the reader with a survey of the position of our Imperial Oil Resources as it appeals to the petroleum technologist. This entails, among other things, an inquiry into the nature and extent of those resources and the possibilities of future development. If this be achieved, it can safely be left to individual intelligence to decide how far a political and economic impasse may or may not have been reached, and what precisely are the probabilities of an oil famine in the near or distant future.

In order to appreciate the first disturbing element in the matter, it is necessary to gain some idea of the present position of the oil resources of the United States. Writing in 1916 on the subject, Arnold, in the "Annual Report of the Smithsonian Institution," adduced important statistical evidence showing that the total consumption of oil in the United States per year amounted approximately to 265,000,000 barrels. After surveying the possibilities of further development in the principal oilfields, he estimated the probable future supply at about 5,763,100,000 barrels, from which it is evident that in about twenty-two years from that date the United States production of oil would be exhausted. This is a somewhat pessimistic view to take of the situation, and it would seem that he has allowed the barest minimum of supply for unprospected areas in Texas, Wyoming, and other fields. If the bulk of the land to be prospected, not only in the Mid-continent but in the Gulf, Rocky Mountain, and other large fields, is only half as productive as that already proven in those fields, then his estimate of future supply falls short of the probable one by several thousand million barrels. This makes no allowance whatever for possible developments in such States as Alabama and Mississippi, which are regarded favourably in some quarters as potential oil-producers. But even admitting Arnold's figures, he himself states that the estimated supply would probably "spread over a period of from fifty to seventy-five years", mainly on account of the restricted use of petroleum as a fuel, and the gradual rise in price of a commodity of which the supply fails to satisfy the demand. Further, that before the supply of natural petroleum was exhausted, the Colorado, Utah, and Californian oil shales would be fully utilised, and artificial substitutes would largely take the place of petro-

leum as a fuel. From which it is seen that, while there is no need for immediate alarm in connection with the United States oil resources, there is every need of some national scheme of conservation whereby the internal resources of the country may be utilised to the greatest possible efficiency.

The appreciation of these eventualities has led to a good deal of agitation for the introduction of a scheme of this nature, and the Press has, with its customary zeal, seized upon the opportunity to spread the news of famine in furtherance of its own particular propaganda. This, together with the unsettled state of international commerce, has been sufficient to create the feeling of tension in the oil world to which we have alluded.

Whatever the issue, it is obvious that to any policy which America may feel it necessary to adopt ultimately, having for its aim the preservation of her natural oil resources, no sane person can take exception. We have to realise that, like ourselves, America has received an enormous impetus to her motor and aeroplane industry as a direct consequence of the War, and the demand for oil fuel was never so great as at present. To meet this demand she has, perforce, to call on her own resources to a greater extent than before; and consequently, if the limit of wise output be reached, her export trade is the first to suffer, with corresponding effect on those countries mostly dependent on her for their oil-supplies. This possibility constitutes the true danger of the position, and in foreseeing it, it is only reasonable that England should be prepared to meet such a contingency with a policy calculated to relieve any strain to which the British oil industry might suddenly be subjected.

It is common knowledge that we are largely dependent on United States oil for our requirements; and in view of the fact that that country is responsible for nearly 70 per cent. of the world's supply of crude oil, and that we at present only control about 4 per cent., the possibility of the cutting down of American supplies is one to be guarded against. Fortunately, on this occasion at least, we are not content to await eventualities; and although a definite Imperial oil policy has so far not been made manifest, a movement in one direction has resulted; namely, the immediate development of our colonial oil resources. To these must be added our interests in Persia and our ultimate policy in Mesopotamia, concerning which our own Government has been consistently vague. In a contemplation of these possibilities, then, our petroleum experts have been and are being employed, and already some highly interesting data have been forthcoming. For our present purpose, it will help in the understanding of the position if we review the progress made in the past and the developments possible in the future, in the various productive areas within the Imperial Dominions. And for reasons quite apart from natural precedent, it is convenient to deal with the British Isles first.

In selecting our own country as an "oil-producing area", we at once take rather an anomalous step, since although, as mother-country, England must form the ultimate political and economic keystone binding our colonies into one united whole, as a crude oil-producing centre she is sadly insignificant, a statement which will doubtless meet with severe criticism from many quarters. It must be evident, however, even to the non-technical public, that the results of the recent boring operations in Derbyshire and elsewhere have

not so far justified the flowery statements of confidence which characterised the scheme in the first stages of its initiation last year. "Hardstoft" is scarcely the great success which it was destined to be, a few tons of crude oil per day (according to the latest reports) being the usual rather meagre yield. Doubtless, with more powerful plant and greater pumping this yield could be raised somewhat, but even then the result could not possibly justify the outlay of capital necessary.

Little good could be served by reiterating the text of the several warnings uttered by expert geologists, both before and after the Derbyshire enterprise was commenced last year. It is a very able article dealing with the geological reasons which render it unlikely that England will ever furnish a commercial supply of oil, Mr. V. C. Illing discussed this aspect of the question in the "Geological Magazine" of July 1919, to which the reader is accordingly referred. Writing just a year later, we have to admit that his admonitory predictions have not only been fully justified, but that the search for subterranean oil-pools not only in the Midlands, but in the whole of the British Isles, is a policy only dictated by those for whom scientific principles have little or no meaning.

"Hardstoft" and kindred propositions were defended by their supporters principally on the grounds that the requisite geological structures for the preservation of oil-pools were present in the areas, and the dangerous word "anticline" was flung hither and thither as an offset to the adverse criticism which the scheme met with from high scientific quarters. To the general public, and unfortunately to many so-called oil experts, the terms "oil" and "anticline" are almost synonymous, certainly inseparable. It does not follow, because subterranean anticlines can be proved in Carboniferous strata, that there, necessarily, oil will be located. It takes a man with an "eye for country" as the saying goes, to understand three-dimensional stratigraphy; and, unfortunately, such men are the exception rather than the rule in the technical world. However, it is easy to be wise after the event, and one can only hope that this unnecessary waste of money, in conducting what is at most only an interesting experiment, will be speedily terminated; and, further, that it will be a lesson to those who anticipate similar schemes for other parts of the British Isles in the future.

We cannot leave the survey of English oil prospects without reference to the oil-shale industry, which is certainly rather a different proposition from that referred to above. It is a well-known fact that at certain horizons in the stratigraphical series, carbonaceous rocks occur from which, by artificial distillation, a form of petroleum may be obtained; but at present only one large field in this country has been worked for any length of time with success, and that is situated in the Midlothian Carboniferous field of Central Scotland. These shales have yielded over forty gallons of oil per ton in the past—though this is by no means a phenomenal amount for good oil shale—whilst the by-production of ammonium sulphate to the amount of 50 lb. and over per ton has been a contributing factor of no small importance to the success of these operations.

There seems to be no reason why the production of shale oil from this centre should not be a standard industry for many years to come, as the deposits are by no means exhausted. On the contrary, further ex-

tensions of the field should be possible within the confines of the main tectonic trough in which the Calcareous Sandstone series lie in this region. While, on account of certain complexities of structure, there may be an element of risk in putting down trial boreholes for the location of deeper seams, it would not be anything like so hazardous an undertaking as that to which the country gave almost tacit assent last year in Derbyshire.

Another field has come under the public eye of late, and one which promises to afford interesting results; namely, the Norfolk oil-shale field. Very little in-

formation has been forthcoming in connection with the development here, though the reader is referred to Dr. Forbes Leslie's paper, read before the Institute of Petroleum Technologists in January 1917, for general details. Geologically, this subterranean occurrence in Norfolk is of great interest, though in the present writer's opinion the structures are difficult of elucidation without adequate borehole data, and Dr. Forbes Leslie's explanations thereof do not always seem to him conclusive. Apart from that, it is certainly a possible field, and as such, a potential asset to our home oil industry.

Map prepared by Mr. D. B. Dowling, showing how possible oil-bearing rocks in North America have been affected by continental stresses.

Other occurrences of oil shale, such as those of Kimeridge in Dorset, the so-called "Kimeridge Coal", have been worked in the past with intermittent success. The Kimeridge shale yielded at times as much as 70 gallons of crude oil per ton, with a rather small amount of by-products. The extent of the shales, however, is extremely limited, and any mining of them would necessitate working thin and probably discontinuous seams over a wide area, a process which is seldom a profitable one.

For the rest, small oil-pools probably will be met with from time to time in various parts of the country during boring operations, particularly in Carboniferous formations; but the public would be well advised to receive such reports with the scepticism, they deserve, and to realise once and for all that oil, in sufficient quantity to make it a commercial proposition, is certainly not one of the many blessings which Nature has seen fit to bestow upon us.

Crossing the Channel into the main continent of Eurasia, the oilfields can be divided into two main groups for present purposes: those in which we have financial interest, and those in which we have or may have both financial and administrative interests. With the former group we are not here concerned; it includes the important fields in Russia, Roumania, and Galicia, and so long as political and economic conditions allow, constitutes an open market from which we, in common with other countries, may draw large quantities of oil for home consumption. The other group includes our own colonies in Asia and the East Indies, and our interests in Persia and Mesopotamia.

In the countries of Burma and Assam occur probably the most valuable oil resources that we possess, the Upper Burma fields being already famous for their oil-production, while the Assam fields only await development on a large scale. The comparatively recent prominence of the Burma fields is largely due to the progress made in overcoming difficulties of transport, which formerly necessitated conveyance of the crude oil for over 300 miles via the Irrawaddy River to Rangoon. With the installation of pipelines, the production has naturally increased and further developments may confidently be expected, particularly in the Minbu and Yenangyat districts. The Assam fields have yet to be fully prospected, but no doubt exists as to the great possibilities of the Tertiary deposits of the Brahmaputra and Surma basins. The petroliferous beds are here often associated with coal seams, and are located along a belt of country stretching from Chittagong approximately N.N.E. for a distance of over 800 miles. At present the Digboi field, near Debrugarh, on the Brahmaputra, is the best-known region actually working; but the results of geological survey at various points along this belt have shown most favourable indications for the location of new sites, though in some places the structures are exceedingly complex, owing to the disturbed character of the strata.

Of the Malay Archipelago, British North Borneo, Brunei, Labuan Island, Sarawak, and British New Guinea (Papua), all show indications of oil to a greater or lesser extent, though little is at present known of the commercial possibilities of the fields. North Borneo and Sarawak are perhaps the most important countries, and drilling is proceeding with a view to locating further supplies. In Papua, petroleum has been found along the same line of earth movement on which are situated the oil-bearing horizons of Java and

Sumatra, and Dr. Wade has shown that the oil indications are extremely good, though conditions of climate and native labour have hitherto prevented prospecting on a large scale. Reported occurrences of oil in many parts of the Malay Peninsula have engaged the attention of geologists from time to time; but in the writer's opinion, the knowledge that we have of the geology of this region points to unfavourable conditions for the location of oil in quantity, although certain horizons in the restricted Tertiary formations may give a small yield from time to time.

The economic and political problems with which the future of the Persian and Mesopotamian oilfields is bound up still remain to be solved, and until conditions settle down from the present deplorable state of flux resulting from the War, it is a little premature to venture upon any suggestions as to developments of the petroleum resources of this part of Western Asia. Whatever our future policy with regard to these countries may or may not achieve, once the fields are better known and more widely prospected, the resulting influence on the world's supply of oil fuel will be far-reaching. Our knowledge of the Mesopotamian possibilities is largely based on reports and opinions gained during the War, and, geologically, on analogy of structure and conditions to those obtaining in the better-known Persian field to the east. Here the petroleum deposits lie along a belt of country extending from the Persian Gulf to some miles north of Baghdad, in a direction running parallel to the Turko-Persian frontier. The best-known field is that of Maidan-i-Naphthun on the River Karun. Other districts include Dalika, Zohab, and Loristan, all of which show great promise.

Passing now to the continent of Africa, our most important field is that of Egypt, where on the coast of the Gulf of Suez, at Jebel-Zeit and at Gernah, a few miles to the south, operations are in active progress. The oil is chiefly found in the Miocene deposits, which are still undergoing energetic examination with a view to locating further pools. Latterly, the lower limestone horizons of the Miocene series have been the subject of detailed investigation, but so far no definite results have been forthcoming. Prospecting is also in progress to the east, in the Sinai Peninsula, where geological conditions are somewhat similar to those of the main Egyptian fields, while one or two islands in the Red Sea have been surveyed, but with negative results from a commercial standpoint. Other regions in Africa have from time to time been searched for oil, notably the Ivory Coast, Gold Coast, Nigeria, and Somaliland, but in all cases the results were extremely poor and unimportant. In Central Cape Colony there have been several petroleum indications in the past, connected with the carbonaceous Karroo shales, and owing their origin to the destructive distillation of those rocks as a consequence of igneous intrusion. In Northern Cape Colony similar occurrences are found in the Dwyka series, while carbonaceous shales, with occasional show of oil, are known from the Orange River Colony and in several other regions of South Africa. A great deal of prospecting has been done in these areas, but, as far as present knowledge goes, the geological conditions are entirely unfavourable to the preservation of oil, and it is unlikely that any important supplies will ever be obtained from this part of the world. There are still large areas in Africa unknown to us, geographically, geologically, and economically; and though in mineral

resources she is probably one of the richest countries in the world, the prospects of locating large oilfields are, from geotectonic considerations, essentially remote. Africa, like India, is a fragment of a "lost continent", in which we find no indications whatever of those great post-Carboniferous orogenic movements which have so fundamentally affected the continental mass of Eurasia; in it we are unable to trace the results of such tangential earth stresses as were responsible for the production of structures similar to those obtaining in the important Eurasian fields.
