In the amendments to the Mining Tax Act, as finally enacted by the Ontario Legislature, it is a source of considerable satisfaction to the mining industry to note that the clauses increasing the rates of taxation on mines have been deleted by arrangement between the Government and the Opposition, which means that there will be no change in taxation of any of the mines. Clauses 7 and 8 are of interest to mining companies and operators and are given below in full:

7. Notwithstanding anything contained in this Act, lands or mining rights forfeited to and vested in the Crown hereunder since the 29th day of June, 1920, which are not included in a valid subsisting claim under *The Mining Act of Ontario*, or which have have not otherwise been disposed of by the Crown, may be regranted to the owner or lessee at the time of forfeiture, or his heirs, executors, administrators or assigns, upon payment to the Minister on or before the first day of January, 1922, of the amount of taxes, costs, expenses and penalties, if any, which have accrued or have been incurred, or which would have accrued or have been incurred except for such forfeiture, and the sum of ten dollars for each and every parcel of land, but every such grant shall be subject to any lien or encumbrance existing at the time of the forfeiture and shall be so expressed.

8. Where lands heretofore forfeited to and vested in the Crown under this Act have been prior to such forfeiture assessed for school taxes and sold for the nonpayment of such taxes, the Minister may cause an examination of such lands to be made, and where it is found upon such examination and report of an officer of the department thereon, that such lands are in use and occupation for agricultural purposes, or are suitable for the same, and are not valuable for minerals, the Minister of Lands and Forests, upon report of the Minister of Mines, may deal with such lands and dispose of them under *The Public Lands Act* to the purchaser thereof, if any, under such tax sale, or his representatives or assigns, freed and discharged from all claims for taxes imposed under this Act, but every patent issued for such lands shall be subject to any undischarged lien or encumbrance created by such tax purchaser, his representatives or assigns, and the mines and minerals in such lands shall be reserved, and the patent shall be so expressed.

PORT ARTHUR NOTES.

By J. J. O'CONNOR.

The Port Arthur Duluth & Western branch of the Canadian National Railway is undergoing a complete rebuilding preparatory to the carrying of a heavy iron-ore traffic from the Palatine Mining and Development Company's mine, in Minnesota to the company's furnace at Port Arthur. A large gang of workmen are employed in this construction work. The road-bed will be entirely rebuilt, and laid with 80 pound rails throughout its length. There is a link of about four miles to be reconstructed on the Minnesota side, to connect with the Canadian portion of the road, and this work is also underway. Active open-pit mining will be commenced at an early date, and shipments will begin during the coming Summer.

The company's furnace at Port Arthur will be doubled in capacity. This work has been commenced and will be actively pushed to completion. It is the intention to have the furnace in blast before the close of the present season.

Arthur Mitchell, is managing director, and Thomas Krakowiak, of Chicago, is engineer in charge of the mining operations.

It is the intention of the company to build up an extensive iron and steel industry at their plant in Port Arthur.

OIL AND GAS IN WESTERN CANADA.

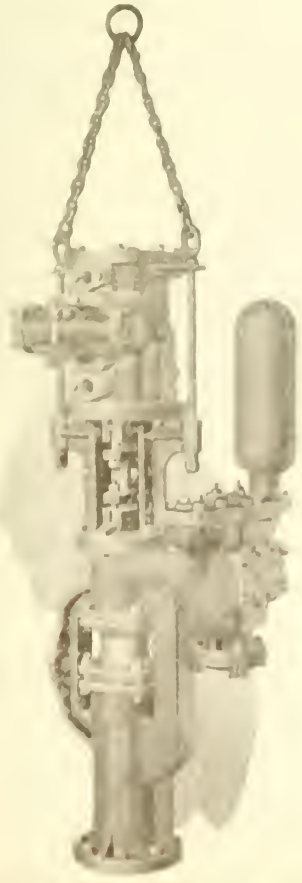
In response to the numerous enquiries that have been received since the discovery of oil in Western Canada, the Department of the Interior at Ottawa has just published a report entitled "Oil and Gas in Western Canada."

This report contains a description of the area, a resumé of the progress of development in the oil and gas fields, a synopsis of the Petroleum and Natural Gas Regulations governing the disposal of rights on Dominion Lands, and information regarding Provincial Legislation and Regulations governing the sale of shares, stocks, bonds, etc. It is accompanied by a map of the oil regions of western Canada showing railways and steamboat routes.

The Board of Public Utility Commissioners for the Province of Alberta, the Department of Mines, and the Mining Lands and Yukon Branch of the Department of the Interior, contributed valuable statistical information which has been embodied in the preparation of this report by the Natural Resources Intelligence Branch, of the Department of the Interior.

That specific and authoritative information on the subject may now be had, will appeal to the prospector, capitalist, and student of conditions in western Canada.

Copies of this report may be obtained free of charge from the Superintendent, Natural Resources Intelligence Branch, Department of the Interior, Ottawa.



THE HEPBURN SINKING PUMP

TORONTO FIRM MAKING MINE PUMP WITH SPECIAL FEATURES.

John T. Hepburn, Limited, of Toronto, has placed on the market a mine pump which is meeting with much favor owing to its special adaptability to mine duty. It is known as the "Hepburn Patent Sinking-Pump" and the feature that strongly commends itself to the mining industry is that the pump is operated without the aid of tappets, levers or any other loose parts. It is very strongly designed, and constructed to withstand the roughest kind of usage without sustaining injury. It is capable of handling gritty water, and is free from extraneous valve-gear lessening its liability to external damage. The pump is certain in action, and always makes a full stroke either under full of partial loads, and the steam piston is perfectly cushioned at any speed or pressure, even without water in the pump.

The ram has only one packing gland instead of two. The pump valves are hard rubber; the pump valve seats, valve plates, stops and springs are of brass. Doors are provided to give easy access to the pump valves and a convenient chain sling is attached for lowering the pump.

Equipment includes air chamber, lubricator, drain cocks and packing for the glands.

PERSONALS

Mr J. J. Ashworth has been appointed general manager of Canadian General Electric Co. Ltd. and Canadian Allis-Chalmers Ltd., Toronto. He has been for several years assistant general manager and now fills the vacancy created by the resignation of Senator Frederic Nicholls.

EDITORIAL

UTILIZATION OF OIL SHALES.

The Fuel Committee at Ottawa has had before it witnesses that have recommended the utilization of oil-shales, of peat, and of electricity developed from water powers, to aid in the solution of the fuel-supply problem in Canada. The necessity to make use of these three potential sources of light, heat and power is greatest where flowing petroleum and bituminous coal are absent, or in insufficient supply. This condition is one that obtains in the provinces of New Brunswick, Quebec, Ontario, Manitoba and Saskatchewan. In these provinces every available source of power supply should be tapped, and even at that, would be found to be insufficient, so far as the three central and most populous of these provinces are concerned. It would be invidious to exalt any one of the three power sources named into the position of a complete remedy for our fuel insufficiency, as even with the aid of bituminous coal from Nova Scotia, and such importations of bituminous coal and anthracite from the United States as the future may see, the requirements of Ontario—for example—will not be so easily met as to induce a feeling of security.

With particular regard to the utilization of oil-shales, history records it as an industry that many years ago had great promise of success, but was killed in Canada, and in the United States, by the discovery of apparently unlimited supplies of flowing petroleum. At one time there were between fifty and sixty oil-shale distillation establishments in the United States, most of which, according to Sir Boverton Redwood, were not more than fairly started when "the discovery of petroleum prostrated the whole business and threatened its projectors with overwhelming loss, from which they were happily rescued by converting their oil factories into refineries."

The oil-shales of New Brunswick and of Nova Scotia, and in particular the "Stellar" oil-shale seam in Pictou were mined for distillation around 1860. About the same date, according to R. W. Ells, the Utica shales in Quebec and Ontario were used for the distillation of oils "until the discovery of the oils of the Petrolia district put an end to the industry."

The oil-shale resources of the United States are believed to be truly immense, but the mineral statistics of 1919 do not record any mining of oil-shales in the United States, notwithstanding the supposed avidity of our neighbours for oil-bearing deposits.

In face of these things, the status of oil-shale utilization is revealed as being entirely secondary to the availability of flowing petroleum and bituminous coal. The situation is made clearer when it is recognised that the coal companies of Nova Scotia are themselves the lessees of areas which contain carbonaceous shales and inferior coals capable of distillation for oil and sulphate of ammonia, and, as was pointed out some years ago, these companies have also "access to large quantities of inferior coals, coaly shales, and screenings, which, at some future date, may very conceivably be found to yield a sufficient percentage of hydro-carbons to justify the extraction of these."

The possibility of making use of the oil-shales of Canada depends chiefly on the availability and the price of petroleum, and it would not seem unreasonable to suppose, in view of the remoteness of the Norman field, that should this vicinity yield petroleum in generous quantity, the delivered cost of such oil will be one with which the distillation of the oil-shales of New Brunswick and of Pictou Co., Nova Scotia ought to be able to compete, having in view the quality and the accessibility of the shales.

In England, the mining and distillation of oil-shales is becoming quite important. This is a reflex of the growing scarcity and cost of bituminous coal, as the existence of the oil-shales has been long known, but up to this date the cheapness of bituminous coal, and the abundance of petroleum imports, has kept the oil-shale industry from developing.

It may further be remarked that the commercial success of oil-shale utilization depends on the completeness of distillation and recovery of valuable constituents, and that if the use of coal were accompanied by the same thorough-going utilization of its constituents the secondary character of oil-shales as a source of light, heat and power would be very apparent. Nevertheless, in a country where bituminous coal is absent, oil-shale assumes a value of the first rank.

The Editor of this journal is accused of having "pronounced" that coal is an absolute necessity for the industrial prosperity of a country. The belief is not a singular one. Prof. Henry E. Armstrong, before the

Royal Society of Arts, recently said: "if we were reasoning beings we should worship coal as our most priceless possession, as the greatest of heaven-sent blessings." The belief is quite common, and the Germans recently took desperate chances with a victorious enemy, because of this obsession.

It would be extremely foolish, however, to deny the necessity we are under in Canada to use every available source of power, coal, shales, peat, water-powers and wood and vegetable fuels. With full utilization of all these we cannot hope to avoid the necessity of importing fuel, but we can do much better than we are doing.

THE BUDGET.

Canadian newspaper comment on Sir Henry Drayton's Budget is virtually identical with English newspaper comment on Mr. Austen Chamberlain's Budget. They are both referred to as "humdrum" and "colourless", and as marking time. Paying debts is not a colourful proceeding, and convalescence after serious sickness is a humdrum and tedious process. A through-going revision of the tariff was, as expected, not attempted. It became evident during the course of the tour of the Cabinet Committee on Tariff that there was much unreality about the whole proceeding, and that the country as a whole was disposed to let well alone. The complexity of the questions raised by the Committee's questionings warranted the assumption that when these gentlemen attempted to make recommendations the task would be found too great, and that this consideration, added to the general state of flux in human affairs, would counsel inaction. In the meantime, the United States has undertaken tariff experiments, trade depression has supervened, commodity indexes and currency discounts have altered international relations, the country does not know whether to regard our national railways as white elephants or wise capital expenditure. Public opinion did not expect, and therefore did not favour, tariff revision at this time, and as Parliament is popularly supposed to reflect the people, everybody should be happy.

So far as the mineral industry in Canada is concerned, it is faced with so many uncertainties that relief from tariff unsettlement is very welcome.

CANADIAN HONOURS.

The recent Convocation of Queen's University was notable in that honorary degrees were conferred upon three representative mining men of Canada, namely, Mr. C. V. Corless, President of the Institute; Dean R. W. Brock, of the University of British Columbia, and Mr. J. J. Denny, of the Nipissing Mine, gentlemen whose contribution to the advancement of science and education is so well known as to render further mention unnecessary.

The compliment paid by Queen's University to the mining profession is one that will be appreciated by them very generally, and in particular by the Canadian Institute of Mining & Metallurgy, which claims all three of the gentlemen honoured as its own members.

The incident serves once more to demonstrate that there is no means in Canada by which service to the nation, in any capacity, can be honoured except by the conferring of scholastic dignities. Canada, by the action of its legislators, is without a central fountain of honour. The necessity for some means by which a Canadian can be honoured in Canada for service to his country is evidenced by the function which the universities have assumed. It is quite evident, however, that scholastic institutions must confine their recognition of national service within traditional limits, and they cannot encroach upon, nor can they adequately fulfill the duty which now and then devolves upon a grateful country of rewarding a citizen by singling him out for titular honour. Canada may be represented, through its legislatures, as a country that yearns after republican simplicity, but it is a land that is neither republican by tradition, actuality, or the opinion of its citizens. Canada is a truly democratic country, and it has always been the desire and privilege of all true democracies to honour individual citizens when the occasion arose. Canada's legislators have deprived this country of access to the traditional fountain of British honours, something that no other Dominion has been sufficiently snobbish to do, but Parliament has provided no substitute to act as Canada's dispensary of honour. By doing so they violate a sentiment that has been engrained in our race since the first warrior was lifted on his shield and acclaimed a hero.

FROTH FLOTATION IN COAL WASHING

This issue contains a paper, taken from the transactions of the Institution of Mining Engineers, describing the adaptation of the selective principle of froth flotation to the preparation of coal for certain industrial purposes, and in particular to fit slack coal for use in by-product ovens to make coke for iron blast-furnaces.

The transactions of the mining societies in Britain have in recent months been rich in records of advances in knowledge of coal substance, and in economic applications of the researches of Stopes, Lessing and others into the separable constituents of coal. Miss Stope's division of the constituents of coal into four substances, separable by mechanical means, and having specific characteristics, has led to search for methods of preparing coal based on selection of the most valuable constituents and on rejection of those containing the largest proportion of undesirable and incombustible substances; and, once more, a line of research that seemed theoretical to the point of fancifulness, has led to definite economic applications.

For example, it has long been held that recovery of all possible fines in coal-washing was a feature to be sought after, and a minimum rejection, or, as it was usually phrased, a minimum loss, in the process of coal-washing was strained after. Dr. Lessing's recent studies on the distribution of mineral matter in coal have led

him to the conclusion that the dust and dirt in unwashed coal consists largely of fusain, which is wholly devoid of coking properties, and yields a small percentage of by-products. The elimination of this dust from washed coal intended for coking would seem desirable, and its reincorporation as fines into the washed product, merely to avoid loss of weight in washing, is shown to be a mistaken policy, if good coke is the desired end. Thus an extremely practical conclusion is the result of pure research that in its inception was not taken altogether too seriously by practical men.

There is an intimation, also, in recent British and American literature on the question of coal substance, that it may be found possible to remove pyrites from coal more thoroughly than has yet been achieved by a washing process, and this anticipation is based chiefly on a clearer understanding of the manner in which sulphur exists in coal substance.

Methods of coal-washing hitherto adopted have depended on a rough-and-ready separation by specific gravity, but froth-flotation introduces great refinement in selection of particles. It has long been recognised that only very fine grinding would make it possible to reject undesirable substances from coal where these existed in a state of fine division or dissemination, but the difficulty has been to treat fine-ground material by ordinary gravity-washers. Flotation would therefore appear to have a future in coal preparation not less important than its place in metal separation, now that it is recognised that coal is a complex ore containing many substances it is desirable to separate and concentrate.

* See "Studies in the distribution of mineral matter in coal", R. Lessing, Trans. Inst. Min. Eng. vol. lx, p. 288, 1920-21

IS COAL CHEAP?

Commenting on the easiness of the demand for coal at this time, the Toronto "Globe" states there is a singular callousness about the future "and a general belief that coal prices will come down. Either the public is sensing the situation correctly or there is going to be a lot of trouble and discomfort later on."

"Coal Age" points out that last year the U. S. public between June 1st and December 31st put into storage 25 million tons of bituminous coal, on which they paid premiums of five dollars or more per ton. "The cost of this coal and of the storage" states "Coal Age" "was of minor consideration in the mad desire to accumulate reserves. It seems fairly clear that the problem of stabilizing the bituminous coal industry largely revolves around a diversion of intense consumer interest in coal at high prices to more interest in coal when it is to be had at lower prices, in order that there may not be the necessity for such high prices."

This is most excellent advice. Bituminous coal will not go any lower at the pitmouth in the United States districts, and, so far as the Canadian buyer is concerned, his only hope of lower prices for bituminous than hold today is in whatever possibility of reduction in freight charges and exchange discount the future holds.

The Toronto "Globe" expresses surprise that the segregation of coal-carrying railroads from coal companies in the United States has not brought down the price of anthracite. No one who understands the economics of the anthracite industry expected such a result, and there is little doubt that the abolition of the working economies which such co-operation made possible will increase all working expenses and raise the cost of producing anthracite. The chief cause for the high cost of anthracite at the mines is the exhausted nature of the reserves, and although there may be some recession in the price of anthracite corresponding to the decline in commodity indexes, yet relative to the index, the price of anthracite will increase with cumulative rapidity as the reserves diminish. The sooner the central provinces of Canada prepare themselves to use some substitute for anthracite the better.

PALATINE MINING AND DEVELOPMENT CO'S. ENTERPRISE.

By J. J. O'CONNOR, Port Arthur.

Robert E. Hogan, representing the Palatine Mining & Development Company, the purchasers of the Atikokan Iron Company's blast furnace at Port Arthur, has arrived in the city, and has opened offices at the furnace plant. He announced officially that all matters pertaining to the acquirement of the blast furnace, from the former owners, had been closed, and that negotiations with the Canadian National Railway management had been satisfactorily concluded, whereby his company are to rebuild that portion of the P. A. D. & W. Railway, between North Lake and Gunflint, a distance of sixteen miles, and from Gunflint to the Paulson Mine, in Cook County, Minnesota, a distance of five miles, twenty-one miles in all. The Palatine Mining and Development Company will operate this portion of the railway under a ten year lease from the Canadian National Railway. The latter company has undertaken to relay with eighty-pound steel, and otherwise put in shape that portion of the P.A.D. & W. Railway between its junction with the C.N. Railway main line, and North Lake, and to have it completed and ready for heavy traffic in two months. In addition to the new steel, this undertaking entails the relaying of the entire distance with new ties, the construction of new bridges, and a general lining up of the road bed.

Mr. Hogan gave out the statement that the mining company would be in readiness to begin the shipment of iron ore over the railway, on the completion of the above undertakings, and that at least two, and probably more, trains of ore would be sent over the road daily.

The daily capacity of the furnace will be 500 tons of ore, when the enlargement now underway is completed. It is the intention of the company to have a large reserve of ore in stock pile at the furnace.

That portion of the railway between North Lake and Gunflint skirts on the shores of lakes for the entire distance, instead of building construction camps, for the accommodation of the men on construction work, the Palatine M. & D. Co. have constructed house-boats on scows, that may be conveniently moved from point to point, as the work proceeds. Labour is plentiful at thirty-five cents per hour, with board and lodging at one dollar per day. It is the intention to have this enterprise fully underway by July 1st next.

The Work of the Honorary Advisory Council for Industrial and Scientific Research

When the Research Council Bill, now enacted, was before the Houses of Parliament, a statement of the work done and planned by the Advisory Council was given to each member of parliament. By the courtesy of a member of the Council the "Journal" has received a copy of the statement, which is herewith reprinted insofar as it pertains to matters of interest to the mining industry. In addition to these matters, the Council is investigating the prevention of rust in wheat, the most suitable method of reforestation in Canada, the prevention of the destruction of concrete by alkaline waters peculiar to the West, the breeding of foxes, utilization of fish-waste, the separation and liquefaction of helium, and a number of other matters, such as fog signalling, materials for insulation of high-voltage electric currents, sulphite-liquor waste, vanadium ores, vitamines, bacterial content of cream and butter, and more efficient methods for heating houses.

The Constitution of the Research Council.

The Research Council consists of eleven gentlemen chosen from the Universities, the Engineering Profession and the Industries of the Dominion, who have been appointed to advise the Government with reference to the best means of applying the great discoveries and advanced methods of modern science to the further utilization of the natural resources of the Dominion of Canada, to the development of new industries in the Dominion and to the extension of those which already exist.

With the intense competition which exists in the industrial world at the present time and which promises to become even keener in future years, those nations which have the resources of science at their command will have, of course, an enormous advantage over those which have not.

This fact has already been so clearly realized by Great Britain, France, the United States of America, Japan, the Commonwealth of Australia and the Dominion of South Africa, that each of these has established a Research Council similar to that now in existence in Canada for the purpose of applying the methods of Science to their industries.

In order that its work may be made efficient over as wide a field as possible, the Research Council has secured the active co-operation of no less than 109 of the leaders of science and industry in Canada who are organized into Associate Committees.

All these gentlemen, with the single exception of the Administrative Chairman of the Research Council, give their services to the Government without payment.

The Manner in Which the Research Council Carries Out Its Work.

The council has been in existence a little over four years. The first year and a half of this period was devoted to the development of its organization, and to a thorough study of the whole field of Canadian resources and industries.

This study showed that certain great problems now face the Dominion which must be solved if the country's industrial development is to be furthered or even maintained.

The council then proceeded to make a detail examination of each of these problems, calling in for purposes of consultation the most expert advice that could be secured. When it was convinced that a problem was one which might be solved, it selected a group of experts, or sometimes a single individual and appointed them to carry out the work, arranging at the same time for the provision of the funds necessary for this purpose. In this way the various investigations were carried out by the men most competent to undertake them and under conditions most favorable for success.

Fuel Investigations.

The fuel problem is one of the most important which Canada has to face.

Enormous sums of money are paid to the United States every year for coal.

All the coal used in Central Canada comes from the United States, and should this supply—for any reason—be cut off even for a single winter, it is well to contemplate what would happen to the people and industries of this part of the Dominion.

The first investigations, therefore, undertaken by the Research Council dealt with the provision of a supply of fuel from Canadian resources to replace that imported from the United States. Tht two following investigations were arranged to this end.

The Utilization of the Peat Deposits in Canada.

The Department of Mines reports that there are at least 37,000 square miles in Canada covered by peat bogs. These bogs are from 5 to 10 feet deep. Many of them lie in Central Canada where there is no coal. About 1-8 tons of air dried peat are equal to one ton of coal for heating purposes. One square mile of peat bog contains an amount of peat equal to 430,000 tons of coal. Attempts have been made at intervals for the past sixty years or more to utilize this Canadian peat, but without success. The best results were obtained by the Federal Department of Mines in their operations a few years ago on the great peat bog at Alfred on the line of the Canadian Pacific Railway between Ottawa and Montreal.

The Research Council after a careful study of the situation decided that it should be possible to cut down the cost of producing air dried peat, and thus put this material on the market at a price which would make it readily saleable. They therefore arranged with the Dominion Government and the Provincial Government of Ontario for the appointment jointly of a Peat Commission, and for the provision of grants for the carrying out of the work of the Commission in question.

The Peat Commission decided to undertake work at the Alfred bog, and have carried on operations there for two summers. They have used a machine similar to that formerly supplied by the Department of Mines, and have designed a new machine of greater efficiency.

They have succeeded in greatly reducing the price of manufacture.

Last summer, they made 5,900 tons of excellent air dried peat at this bog. This was sold under commercial conditions in the city of Ottawa, and in some 25 smaller cities and towns of Central Canada. It was found to meet with a ready market everywhere in competition with coal, and ten times as much could have been sold had it been possible to produce it. Offers were received from individual companies

to take the whole output of the bog. The peat was sold at varying prices, which, however, in every case left a good margin of profit.

The Peat Commission believe that a still further reduction in the cost of production may be made by further improvements in the machines now in use, and in order to bring their work to a final conclusion with a view to the delivery of peat at the lowest possible cost to the community they have asked the respective Governments for a continuation of their grant for another season.

If this is done there is every reason to believe that a great new and profitable industry will in the immediate future develop in Canada as the result of the work of this commission.

The Briquetting of the Low Grade Lignites of South Eastern Saskatchewan.

The only fuel which occurs in Eastern Saskatchewan and Manitoba is the low grade lignite which falls to pieces when mined and has, therefore a very restricted use. This fuel, however, occurs in enormous amount.

The Research Council took up the question of the manufacture of a high grade fuel comparable to anthracite from the abundant supplies of this low grade material. The deposits were visited and a complete study of the whole subject was made with the help of Geologists and Engineers from the Department of Mines, the Commission of Conservation, as well as with the help of other experts who were called in for consultation. This study embraced an examination of the character and extent of the lignite deposits, the possibilities of carbonizing this fuel and the best method of briquetting, the question of suitable binders for the briquettes and all other details of manufacture. Extended experiments were then made on carload lots of the lignite, which resulted in the production of excellent high grade fuel in the shape of small briquettes which are clean, easily handled and convenient to burn. An extended test just completed of this briquetted fuel in comparison with the Pennsylvania anthracite imported into Canada, shows that the briquetted fuel has a heating power practically identical with that of anthracite coal.

Consignments of this fuel have already been supplied to the Prime Minister of Canada and the Premiers of the Provinces of Manitoba and Saskatchewan.

The Research Council, in order to carry out this research, arranged with the Federal Government and with the Provincial Governments of Manitoba and Saskatchewan, for the joint establishment of a Fuel Research Board, under the Chairmanship of a member of the Research Council, and for the provision of adequate grants to enable the Board to build a commercial plant at Bienfait (near Estevan) Saskatchewan, capable of turning out 100 tons of briquetted fuel per diem, the raw material being mined in the immediate vicinity. This plant is now nearly finished, and will be manufacturing this new briquetted fuel next June. The whole plant would have been in operation last August as originally scheduled, had it not been impossible — owing to the conditions in Canada during the past year — to obtain delivery of the necessary machinery for the plant.

There is every reason to believe that this fuel can be placed on the market at a price considerably lower than is now paid in Manitoba and Saskatchewan for anthracite imported from the United States, and that another large and profitable industry will be started in Canada which will at the same time supply the people of this portion of the Dominion with a fuel made in Canada, thus doing away with the necessity of sending millions of dollars to the United States each year for the purchase of coal in that country.

The Use of Canadian Iron Ores in the Place of Iron Ore Imported from the United States.

Realizing that Canada is paying annually millions dollars for steel products purchased in the United States, and that steel plants in the interior of Canada have been dependent on the United States for their supplies of iron ores, the Research Council has, through committees, been making a thorough investigation of the iron ore resources of the country. These researches have been conducted along two lines (one) to determine if our low grade ores could be treated by beneficiation so that they can be used commercially in blast furnace practice, and thus relieve our furnace operators of importing their ores from the United States, (two) investigation of electric smelting methods of our low grade ores.

The committees have accomplished much, and as a result of their investigations have made a preliminary report to the Research Council. They are convinced that Canada possesses large bodies of iron ore which however requires treatment or beneficiation to put it in shape for commercial reduction to pig iron, and also that the time has arrived for this work to be undertaken. The decreasing iron value or content of the Minnesota ores, proportionately increases the value of Canadian ore, and promises to create another Canadian industry in which our transportation systems will take part.

It is hoped during the present year to arrange for a commercial test under actual blast furnace operation of a sufficient quantity of Canadian low grade ores, 10,000 to 15,000 tons, to determine the value and usability of our enormous ore deposits.

Training Research Workers.

By the foundation of Bursaries, Fellowships and Studentships, tenable in Canadian Universities, provision is made each year for the training of a certain number of young gradnates who have shown ability and promise in the methods of scientific investigation, thus providing workers for the prosecution of research in the Dominion.

Education of the Public in the Necessity of Research for the Advancement of Canadian Industries.

Several members of the Research Council have at various times since its establishment visited the important centres of industry in all parts of the Dominion and addressed Boards of Trade, Canadian Clubs and other important and influential bodies, on the value and importance of Scientific Research and the plans of the Government of Canada to meet their needs.

The Need for a National Research Institute in Canada.

While many researches must necessarily be carried out in the field or be located at certain special centres and while others can with advantage be carried on at Canadian Universities, there is a great body of research work which now needs to be carried out in connection with the various industries of the Dominion which is too varied, too elaborate and too technical to be well done in our Universities which are primarily teaching institutions.

The Research Council believes that the time is now ripe for the erection of a National Research Institute

under the management of the Research Council in which the necessary laboratories and appliances for scientific and industrial research — with an efficient staff of workers — will be provided. Such an Institute would be equipped and ready to undertake the study and solution of the great number of special problems and difficulties which present themselves in all advancing industries, and the solution of which is necessary to the highest industrial success. The Research Institute would render to Canada and Canadian Industry the services which are now being given to the Industries of the United States by the National Bureau of Standards at Washington and the Mellon Institute at Pittsburg, although these are planned on a much larger scale to meet the need of a much larger population.

The Bureau of Standards which is maintained by the Federal Government at Washington, employs about three hundred scientific workers and handles the greatest diversity of problems. It tests papers, textiles, structural and other steels, building and roofing materials, cements, paints, inks, chronometers, thermometers, barometers, electrical apparatus of all sorts, radioactive preparations, and in fact anything and everything to which a mechanical, physical or chemical test can be applied. It tests the supplies purchased by the various departments of the United States Government. It has eliminated all fraud in this connection and has saved the country many millions of dollars. It is studying the telephone service, street railways, gas, electric light and power, etc. It furnishes manufacturers' chemists with standard samples of chemicals with which to compare their own product. It is investigating the magnetic properties of iron and steel. It is studying the properties of materials at low temperatures. It is engaged on the problem of standardizing radium. It is carrying on researches in connection with wireless telegraphy. It is conducting experiments on rubber in order to determine, if possible, the relation of its commercial properties to its chemical constitution. It is laying the foundations of an American ceramic industry by its study of native clays.

With the provision of a Research Institute of this type — adapted to Canadian conditions — it is believed that the industries of the Dominion would receive invaluable assistance and direction.

U.S. COAL MINE FATALITY RATE HIGHEST IN WORLD SAYS STATE REPORT.

The coal mines of the United States have the highest fatality rate per 1,000 miners employed of all the principal coal-producing countries, it appears from a table covering a ten year period published in a report of the Safety Board of the State of Washington on the coal mining industry. According to this table the death rate in American coal mines over a period of ten years was 3.74 men killed per 1,000 employed. Great Britain, with almost 50 per cent more men employed in its mines had a rate of only 1·36 men killed per 1,000 employed, and ranks sixth highest in the fatality rate table.

The report on coal mine accidents in the State of Washington shows that fatal accidents have been reduced from a total of 34 in 1918 to 18 in 1920, or from a rate of 5·81 men killed per 1,000 employed to 3·75 per 1,000 employed. Non-fatal accidents have been reduced from 1,116 in 1917 to 502 in 1920.

PERSONAL.

Mr. D. H. McDougall, president of the Nova Scotia Steel & Coal Co., has been appointed vice-president of the British Empire Steel Corporation, in full charge of operations. The business of the Corporation and its subsidiaries is now being conducted in the Transportation Building, Montreal (where the whole of the seventh floor has been taken for this purpose), and the staff of the Dominion Iron and Steel Co. and the Dominion Coal Company has been moved from the offices at 112 St. James St., occupied by them for the past twenty years. Mr. McDougall will have his headquarters in Montreal, and it is understood will reside there in future.

Mr. Roy M. Wolvin, President of British Empire Steel Corporation, is in England.

Dr. W. F. Ferrier, of Toronto, leaves this week for Vancouver. He will be in British Columbia for some time on professional business.

Mr. A. G. Burrows and Mr. P. E. Hopkins, geologists of the Department of Mines of Ontario have left Toronto for Boston Creek. They will spend a month in Skead Township.

Prof. J. W. Russell, of Woodstock, is at Cobalt. He is in charge of development work at the Oxford Cobalt Company's property.

Mr. Balmer Neilly is making arrangements for a meeting of the Ontario Mining Association to be held at Cobalt in June.

A number of McGill University mining students in charge of Dr. John B. Porter, have been studying mining methods at iron mines on the Marquette Range, Michigan.

A large number of mining students from Canadian Universities will be employed by gold mining companies in Northern Ontario this Summer.

Professor Waldemar Lindgren of Boston, a leading authority on gold deposits, will spend the summer in Bolivia.

The American Mining Congress annual meeting and the National Exposition of Mines and Mining Machinery will open in Chicago on Oct. 17.

Mr. S. E. Thompson, consulting engineer for Kirkland Lake Proprietary, Ltd., is at Haileybury. Mr. H. G. Latilla, chairman of the board of directors of the company, is expected to arrive from London shortly.

Mr. A. F. Brigham, general manager of Hollinger Consolidated, has returned to the mine after being in Toronto for a few days.

Mr. S. R. Jones, formerly manager of the Buffalo mine at Cobalt, is on a visit to Kirkland Lake. Interests formerly identified with the Buffalo mine are interested in the Teck-Hughes gold mine at Kirkland Lake, and Mr. Jones has had much to do with the development of the gold mine.

Mr. A. A. Cole, mining engineer of the T. & N. O. Ry. has been visiting mines at Kirkland Lake.

Mr. G. R. Mickle, mine assessor is at Cobalt. He will visit several mines in the north during the next few weeks.

Mr. Wm. Wright, who is interested in several properties at Kirkland Lake, is visiting the mines.

Mr. M. B. Baker, professor of geology at Queens University, will spend the field season in Leeds county, on work for the Ontario Mines Department.

The Importance of the Mining Industry to Old Ontario

An Address to the Toronto Board of Trade, May 3rd, by G. C. Bateman.*

I have been asked to speak to you to-day on the importance of the mining industry to Old Ontario. When we speak of Old Ontario we are covering only one section of the country, and the subject might just as well have been the importance of the mining industry to Canada. However, as Ontario is the richest mineral province in the Dominion, and as it brings things more nearly home to us, I shall deal chiefly with it.

I am afraid that with many of you, knowledge of mining in Ontario is confined to the purchase of mining stocks, some good and some bad, but I have no hesitation in saying that to no body of men is the industry of more real importance than it is to yourselves, and there is no body of men who should be more interested in the industry than yourselves.

Mining is a science which demands the highest ability. Our mineral resources must be developed. Capital and labor must be intelligently directed toward that end. Without this our undeveloped resources can have no value and can contribute nothing to the prosperity of this province.

The two great basic industries in Canada are agriculture and mining. Everyone is so familiar with the importance of agriculture that it is not necessary for me to say anything, yet it may surprise you to know that for the five years preceding the war, of the total tonnage carried by Canadian railroads 35 per cent originated from the mines as against 20 per cent from the farms. The T. & N. O. Railway was projected purely as a colonization road to develop the great clay belt of Northern Ontario, but, for the same period as mentioned above, 44 per cent of the tonnage carried came from the mines as against only 11 per cent from the farms. The American railways report that for the seven years preceding the war 52 per cent of their gross tonnage originated in the mines as against 13 per cent from the farms. While our friends, the Farmers, with a little help from Labor, run the government of this province, we feel that in some particulars at least we can ask them to take a back seat.

The government records show that to date the total value of the metallic production of Ontario amounts to $647,681,000. The dividends paid by successful mining companies from this production amount to $125,000,000 and deducting one from the other we get $525,700,00 as representing the cost of production. The aggregate amount of capital invested is approximately $160,000,000 which gives us a total of $682,700,000 as the total expenditures of the successful companies. However, all companies are not successful, as many of you no doubt are aware, and a very modest estimate of the amount paid out by these latter would be 10 per cent of the above figure, or $68,000,000, giving a total of $750,000,000 disbursed by the industry of this province.

This vast sum represents the money paid out by mining companies of Ontario, for labor, supplies and equipment. A large portion of it has gone to the farmers and business men of Old Ontario. These profitable mining companies have about 250,000 shareholders and these shareholders have received in dividends $125,000,000,000. It certainly does not seem unreasonable to assume that with expenditures by the mines amounting to $750,000,000 that the business men and farmers of Ontario have profited to at least as great an extent as the shareholders.

In considering what the industry means to the province, it is also necessary to mention the collateral benefits which the province derives. Mining is the pioneer industry in the unsettled sections, and it opens the way for others to follow. It provides a ready market for the homesteaders' produce, and labor at those seasons in which he might otherwise be unprofitably employed on his farm. It leads to the development of otherwise useless water-powers and to the opening up of the country and the establishments of prosperous towns and settlements.

Eleven years ago gold was discovered in what is now known as the Porcupine district, but which was then a virgin wilderness, 30 miles from the nearest railway. To-day it is one of the most prosperous and progressive sections of the province and its prosperity and its importance are only in their infancy.

Timmins, with a population of about 6,000, is the most important town, and from the 1920 report of the Timmins Board of Trade the following figures were obtained:

(1) Freight receipts for the year were $725,000 and were exceeded by only one town of equal size in Ontario.

(2) Payrolls amounted to $4,500,000, assessment had reached a figure of $2,225,000 and revenue from taxes, royalties and rates came to $170,000.

(3) Bank clearings for the year amounted to $7,000,000 and were considerably in excess of the best town in Ontario having a population of 10,000.

Prosperous settlements have also been built up in other places throughout Northern Ontario and there can be no question but that the development of the mines has done more to encourage the opening up of the farms than any other single factor.

There also seems to be little doubt but that the mining industry in opening up the country and providing labor centres, has been instrumental in the establishment of extensive pulp industries in this country.

The industry is a great colonizer. The earliest history of Britain is connected with the visits of the Phoenicians in search of tin. Mexico and South America would not have been developed by Spain had it not been for the treasures in gold and silver which these countries possessed. The treasure ships of the Americas sustained Spain in its proud position long after she should have fallen and so profoundly affected the destinies of the world. The discovery of gold and diamonds in South Africa led directly to the Boer War and to the acquisition by Great Britain of one of its greatest colonies. The discovery of gold in California was responsible for the development of Western America and the Cariboo placers in British Columbia was the greatest single factor in opening up that province. The Yukon to-day would probably have been known only to the trappers had it not been for the great gold rush of '98, and coming back to where we started from the discovery of precious metals in Northern Ontario

*Manager of the La Rose Mine, Cobalt, and consulting Engineer of the Bailey Silver Mines.

is directly responsible for the development of that great area.

So far we have considered only the purely commercial aspects of the industry, and while it may not be my province to discuss what some may consider its broader aspects, it may not be out of place to say that the advance of mining and civilization have been intimately connected since the dawn of the world's history. Our modern civilization, our cities and methods of transportation would be impossible without this industry, and so dependent have we become upon it that it is hard to conceive of any single article which we use in our daily lives, in which the product of the mines has not played some part in either its production, manufacture or transportation.

Coming back, however, to the commercial phase, with which, I presume, we are most interested, we will now consider the industry from some of its national aspects, because whatever affects the country as a whole will affect Ontario.

To-day among problems facing the country there are two outstanding ones.

The first is the correction of our depreciated currency, and the second is the solving of our railway problem. We might also say that there is a third, the payment of our national debt, but the solution of the first two will go far toward taking care of the third.

The discount on our money with the United States is due to an adverse trade-balance. On account of our geographical position to that country our trade will always be greatest with it, but it remains with us to change its present direction, and to do that we must find where our adverse trade is largest in products for which this country produces the raw materials. The government returns for the first ten months of this fiscal year show the following imports and exports under certain headings,—

Imports.

Iron and its products	$216,329,442
Non-Ferrous metals and products	48,922,337
Non-Metallic minerals and products	177,213,100
	$442,464,879

Exports.

Iron and its products	$68,657,207	
Non-Ferrous metals and products	40,447,435	
Non-Metallic minerals	35,804,372	
		$144,909,014
Representing an adverse balance of		$297,555,845
or at an annual rate of		$357,067,014

Exchange alone on these items would cost approximately forty to fifty millions.

It is apparent that this indicates an opportunity for improving this condition by the development of our mineral resources. To-day, due to a large measure to the bounty paid for this purpose, Canada has a number of large and efficient iron and steel furnaces, which are a great national asset. Every ton of iron ore, however, that goes into those furnaces is imported. Ontario draws its supply from a friendly foreign country, but imagine what our position would be if that country were unfriendly.

In 1900 Ontario's mineral production was valued at only $10,000,000, and there was comparatively little mining going on in the province. The only operations of any magnitude were in the nickel field and they had, by no means, attained their present proportions. In Eastern Ontario a few small operations were being carried on in a desultory sort of way. Gold mining was in particularly bad odor and it was believed that there were no gold mines of any importance in the Province. In those days the T. & N.O. Railway was just being built, and most of that section, now called Northern Ontario, was practically a wilderness known only to the Indian, the lumberman and the trapper. Yet in 1918 our mineral production had grown to a value of $80,000,000.

Mining had, of course, been carried on in the older portions of the province for many years before 1900, and, as a matter of fact, we find regulations governing the staking of claims back in 1864, when this province was known as Upper Canada. A prospector was then required to stake a mining claim embracing 6,400 acres as against an area to-day of 40 acres. He had to pay for it at the rate of four shillings an acre, and in order that he should not become too wealthy at the expense of the country's natural resources, all rights to gold and silver were reserved to the Crown.

The first important silver discovery in Ontario was made on Silver Islet, a small, low-lying, barren island of only a quarter of an acre in extent, near the north shore of Lake Superior. Almost the first blast carried below the water level, but the island was built up and a prosperous industry established. Prospecting was carried to the mainland and led to the development of a large number of properties and the expenditure of millions of dollars.

The next development was that of the Bruce Copper Mines, where the ore was shipped in barrels to England for treatment. In the early 'eighties the copper-nickel mines of the Sudbury field were discovered, and were first worked only for the copper. The nickel in the ores was at that time a handicap as there was practically no market, but the development of scientific practices for the treatment of the ores, and the expenditure of great sums in developing a market, conditions have been reversed and now the nickel is the important metal, while the copper is a by-product. To-day this industry have been developed into one of vast importance, and this district supplies practically 90 per cent of the world's production of nickel. Last fall there was completed for one of the companies operating in that field a storage dam in connection with their hydro-electric development. I suppose it is safe to say that very few of you have heard of this installation, yet it cost approximately $3,000,000, and is one of the large dams of the world. I believe it is larger than the famous Roosevelt dam in Arizona, of which we have all read. This same company contributes more freight than any other individual customer the Canadian railways have.

The Cobalt camp was discovered in 1913 and is more or less familiar to everyone. While small in extent, it is the richest silver camp the world has ever known, and it contains the largest silver-mines in the British Empire. In 1911, which was the banner year from the point of view of production in ounces of silver, although not in value, Cobalt, with a producing area of approximately seven square miles, had an output of 33,000,000 ounces and was the third largest silver-producing community of the world, being exceeded only by the whole of Mexico and the whole of the United States. Incidentally, to provide Cobalt mines with compressed air, the largest natural compressor in the world was built.

The success attending the development of this rich area led to exploration in other fields, and the develop-

ment of the Elk Lake, Gowganda, Porcupine and Kirkland Lake camps followed. To-day, Canada, through the Ontario mines of Porcupine and Kirkland Lake will this year produce about one-third as much gold as the whole of the United States. In Porcupine we have what is possibly the first, but if not the first, then certainly the second greatest gold-mine in the world.

Ontario also holds an important position with regard to other minerals, and metals, about which we hear less. Through Ontario smelters treating our Cobalt ores we have reached a point where we control the worlds market for cobalt and its alloys and produce 90 per cent of the world's supply.

In Eastern Ontario we have the largest talc industry on the American continent. In the same section there was, a few years ago and probably is still operating, a mine which produced the largest sheet mica in the world, while the feldspar mined north of Kingston sets the standard of quality for America.

From the mining industry thus developed, the province has derived in direct revenue something over $11,000,000, or approximately one-half of the amount of capital expenditure on the T. & N. O. Railway. Practically all of this revenue came from camps in the northern portion of the province, which would lie within a circle of less than 150 miles in diameter. This represents only a very small part of the province and a very small portion of the vast area of pre-Cambrian rocks in which the mines are found, and which lie within the boundaries of the Province.

Ontario, however, is known to have at least 500,000,000 tons of iron ore, although it is of such a character that it needs beneficiation before it can be smelted. Those who are interested in its development believe that a bounty of 50 to 75 cents a ton would make the industry self-supporting and would yield a moderate profit. A production of 1,000,000 tons of ore a year would require government assistance of from $500,000 to $700,000, which may seem a fairly large sum of money for any one particular industry, but it is small in comparison with the $5,000,000 which would have to be paid out for labor and materials to produce this annual output. Is there anyone who would say that the profit to the country from this $5,000,000 of new money would not be greater than the bounty granted?

It is the possibilities of this new money which I want to emphasize and while I have spoken particularly of the iron resources because they run into such large tonnages, the same conditions apply to other metals and minerals, although they would not need to be subsidized. The exploitation of these natural resources is a matter of national importance and should receive the attention of the government, as well as of every man who is interested in the welfare of this country.

We have recently had our attention drawn very forcibly and unpleasantly to the conditions of our Canadian government owned railroads. To correct this condition we need lower operating costs and greater tonnage. The McAdoo award has created one of the worst conditions this country has to face. It affects every man, woman and child in this Dominion. Railroads wages practically set a standard for the rest of the country and we cannot hope to get back to normal until this condition is changed. Its ramifications lead into every department of our industrial life. It not only helps to maintain the high cost of living, but it increases labor costs all over the country and automatically decreases the tonnage which our railroads should carry.

To instance this, we might mention the manufacture of sulphuric acid, which has always been an important industry. Sulphuric acid is very largely manufactured from iron pyrites, of which we have large quantities and during the war, shipments from Canadian mines ran into hundreds of thousands of tons a year, practically all of which went to the States. After the war the demand, of course, fell off, but there has always been a good market for Canadian ores. They must, however be able to compete with Louisiana sulphur, and with the cheaply produced, although low-grade, sulphuric acid from Western zinc-smelters, but if labor and transportation costs are too high, they are unable to do so. That is the condition to-day and Ontario mines, equipped for an output of approximately 250,000 tons a year, are practically idle.

We find this condition affecting even our gold and silver mines. In Cobalt a certain grade of concentrates is produced which, in some instances, costs for marketing alone as much as 35 per cent of the gross value of the product, and in this cost transportation is the big item.

In the last annual report of the Hollinger Gold Gold Mines, all ore below a grade of $6.00 a ton was dropped from the estimate of ore reserves as having no immediate value. A small profit per ton would be sufficient to justify its treatment, and such treatment would result in five dollars for every ton of ore, which is now considered of no commercial value, being paid out for labor and supplies.

During the past two years we have, each winter, faced an acute coal-shortage. Unfortunately, Ontario has no coal, but we have large supplies in the Eastern part of Canada and immense quantities in Western Canada. It might perhaps be too much to ask that this country should become entirely self-supporting in the matter of coal, but there is absolutely no reason why it cannot become much more nearly self supporting than it is at present. It is, however, almost impossible with freight rates as they are, and with wages and working conditions such as our paternal government has forced upon the coal operators of the West, to move coal for any great distance East or West through our own country.

In Ontario to-day we have in our undeveloped mineral resources a great source of potential wealth, which would materially assist in correcting our adverse trade balance, and which could provide immense tonnages for our railroads. Their development would open up the country, establish new industries, give employment to thousands of men and provide a very large market for manufactured goods.

The development of these resources would be of much greater benefit to the country as a whole, than it would be to the owners of the properties. It is very doubtful if in the past the average shareholder has received a return commensurate with the risk involved. This risk itself is large, and in addition to the risk there is the difficulty and expense of establishing an industry in a new country. Roads must be built at private expense, and much material for construction brought from a distance and transported to the ground under financially difficult conditions. Connections to railroads must be financed and power for Hydro-electric plants often have to be provided at

private expense, and all boarding and living houses must be built by the company.

Contrast this with a new company locating, and often subsidized to locate, in an industrial centre where material for construction is obtainable at the door, roads and schools are constructed at the public expense, power is obtainable to a minimum cost, telephone and telegraph connections can be obtained for a nominal sum, and the company is under no expense for housing and boarding its employees.

The people of Ontario own the mineral resources and we sometimes hear it suggested that they should be developed by the Province. Aside from the fact that it is advisable to risk the public funds for the purpose, our present view of Government ownership does not encourage us in this direction. The Ontario Government once undertook to go into mining, but the results were not such that we would wish to see the experiment repeated. It is, however, the duty of the people and the Government of this province to encourage capital to undertake this work, and to see that it is permitted to earn a liberal reward, which is essential in view of the nature of the undertaking.

During the past two decades the value of the mineral production of this province has increased 800 per cent. This is a large increase, yet it does not require much of an optimist, and I am decidedly one of them, to believe that the record of the next few years will far surpass that of the past. To obtain the fullest measure of success, however, it is necessary that we should have from the people, and particularly the business men of Old Ontario, not only a greater knowledge and appreciation of the problems of the industry, but their co-operation as well. With this co-operation and assistance, mining should rapidly take the position to which it is entitled of being the second greatest industry in our country.

LONDON OPINION ON SILVER MARKET OUTLOOK.

Bullion brokers and others in close touch with the silver market admit the difficulty, if not the impossibility, of forecasting the likely course of values in the immediate future.

In conversation with a representative of The Financier, a well-known authority said he would not care to take on the mantle of the prophet and attempt to predict whether the price will rise or fall in the near future.

"The outlook," he said, "is admittedly too obscure and no one can see clearly a day ahead. I think that the price is more likely to fall further than to rise, if only by reason of the growing stocks of the metal here and especially in China.

"As regards China, that country is more likely to be a seller of the metal than a buyer, because of the enormous stocks held there and because of the condition of the export trade and the uncertainties of revival. You will notice that in the past week there has been very little business either way and the price has accordingly been remarkably steady. It looks, therefore, as if buyers and sellers alike have been holding aloof waiting upon developments, but exactly what developments must be left to individual conjecture."

The price of the metal during the course of a week has varied between 34⅝d. and 35d., a variation that has been a somewhat rare phenomenon in this market for a long time past, the fluctuations, as a rule, being much wider. This comparative steadiness is sufficient to show that business has been smaller than usual, the Indian bazaars, generally big absorbers of the metal, having taken little. For a long time the trade has merely purchased, as it were, from hand to mouth, because the jewellery trade is not greatly flourishing at the present time, thanks largely to the obstinacy of the miners.

Supplies have been but moderate, the Continent sending but little to the market, but owing to the recent slightness of demand stocks have increased. It is because of the largely artificial conditions of the market that it is not possible to make any accurate forecasts of the immediate future.

Messrs. Samuel Montagu and Company remark that "if the proposal, forming part of the latest German offer, to hand over some silver as part reparation is ever embodied in the final terms accepted by the Allied Powers, the question will arise whether or no the metal will be placed on the market for realization."—London "Financier."

ENGINEER'S LICENSING MOVEMENT BEING PUSHED IN UNITED STATES.

The movement for licensing engineers has gone further than is realized by most mining engineers. A synopsis of recent legislation as given in the last number of the official organs of the American Association of Engineers notes that the Arizona bill is a law, having been signed by the Governor on March 19; also the Colorado bill, signed by the Governor on April 4, "through efforts of the Colorado Section of Engineering Council." The Minnesota bill has become a law since the writing of the synopsis in question.

On the other hand, the Montana bill, introduced by the A.A.E. chapter, met with the opposition of the Montana Society of Engineers and was killed. The New Mexico bill passed the Senate but failed in the House; and the same fate befell the Missouri bill on March 18. In California a bill sponsored by the A.A.E. was withdrawn from the Legislature. In Nevada, the bill met with the opposition of mine operators and died in committee.

Passing from the distinctly mining states, a bill for this purpose has become a law in North Carolina; in New Jersey the bill became a law April 1; in Indiana on March 10; in Tennessee, on April 19. In Arkansas and South Dakota the bills have failed. In Texas the bill passed the Senate, but failed in the House. In South Carolina the bill failed in committee, "due to opposition from the farmers." Bills are pending in the legislatures of North Dakota, West Virginia, Ohio and Connecticut, being opposed in the latter two states by the Manufacturers' Association. In Pennsylvania, the bill pending in the Legislature is being opposed by various engineering societies in the state, and also by the Scranton Correspondence School, "it being their contention that the law might be construed against the so-called practical engineer." It has passed the House. In New York, there now exists a licensing law, and a fight is on to so amend it as to permit corporation license. In Georgia, Nebraska, and Oklahoma, the movement is being pushed.

We have taken no editorial stand on this important question, but are watching its developments with interest. It behooves all mining engineers to do the same. We know that many are on each side of the question. The rest should ponder, and in their respective states frankly thrash out the merits and demerits of the plan. —Engineering and Mining Journal.

Froth Flotation as Applied to the Washing of Industrial Coal

By ERNEST BURY, WALTER BROADBRIDGE, and ALFRED HUTCHINSON.

(A paper read before the Institution of Mining Engineers, Manchester, September 15th 1920.)

Introduction.—In the autumn of 1919 Sir Arthur F. Pease suggested to the Skinningrove Iron Company that the froth-flotation methods, as practised by Minerals Separation, Limited, for the recovery of fine metalliferous ores from slimes, should be investigated as a possible means for the separation of fine coal from shale and other impurities. The authors accordingly erected at the works of the Skinningrove Iron Company several small washers working under Minerals Separation patents for the experimental separation of crushed coking coals, washery wastes, fine coal-sludges and the like. The object of this paper is to indicate to the members of the Institution the results of the experiments so obtained, and to suggest the importance of this method of treatment to the fuel and metallurgical industries as a whole. The paper will include a short description of the principles of froth flotation, followed by a somewhat detailed account of the operation of the froth-flotation process, and a few remarks on the application of the process to coal treatment in general. Representative results obtained on various types of material will then be included, and the paper will conclude by indicating the economic aspects of the process, especially as applied to the preparation of coal for the production of metallurgical coke.

Principle of Froth Flotation.—When certain reagents are added in small quantities to water, and the whole is agitated violently, a multitude of very minute air bubbles are formed. On allowing the liquid to come to rest, the bubbles do not coalesce, but remain distinct from each other, and rise slowly to the surface, where a more or less permanent froth is formed. The reagents that may be used for this purpose are many and various, and include certain oils (such as turpentine), soluble organic substances (such as cresol), certain alcohols (such as amyl-alcohol), and soaps. The proportion of reagent required is small, amounting in most cases to a fraction of a pound of reagent to a ton of water.

If solid particles are suspended in the water, these particles may or may not become attached to the bubbles; if they do so, on allowing the liquid to come to rest, the bubbles rise to the surface and form an extremely stable froth, in which the solid particles are supported. Particles of metallic sulphide, coal, and graphite can be readily floated by this method; on the other hand, sand, clay, and similar earthy materials do not adhere to the bubbles, and therefore sink to the bottom of the liquid. It follows that, if a mixture of floatable and unfloatable particles in water is subjected to agitation in the presence of a suitable frothing agent, the floatable particles will be included in the froth, while the earthy matter will sink to the bottom. Thus, if coal containing a proportion of clay or similar material is ground to pass a 1/10 inch screen, and the product is mixed with water to which a suitable reagent is added in small quantities, the coal can be separated in a pure state from the clay. If the coal comprises pure coal, carboniferous shale, and clay, the pure coal can be recovered in a pure state, after which, by adding a small quantity of oily reagent, the carboniferous shale can be recovered, the clay being finally left behind.

It should be noted that the froth-flotation process does not depend on the specific gravity of the substance, since some substances (such as galena), which are most readily floated, possess a high specific gravity.

Operation of Froth-flotation Process.—The operation of the froth-flotation process is broadly similar for all types of material treated, and involves the three stages of (1) crushing, (2) flotation, and (3) disposal of products. The details of best practice vary, of course, with the material treated and the type of product required, and the treatment of coal will differ somewhat from that of metallic ores. As the process is now estimated to treat 70,000,000 tons per annum, we can expect considerable help from this sister branch of the industry in rapidly developing the best methods to employ on coal treatment. We have made ourselves conversant with the methods employed in metallurgical practice, and have investigated the question of applying them to coal treatment.

Taking the three stages in their natural order, we wish to explain our conclusions as follows:—

(1) **Crushing.**—As it is already standard practice to crush coal for bye-product coaking, flotation introduces nothing of a revolutionary character in this respect. The material should be crushed to a degree sufficient to ensure—

(a) That the largest particle of floatable material is sufficiently small to be held in the froth; and

(b) That the floatable material is freed sufficiently from adhering waste for efficient separation to be possible.

In cases where the valuable material and the waste occur distinctly separate as large crystals or broad bands, (a) will be the deciding factor; whereas fine and intimately-associated crystallization or narrow stratification render (b) most decisive. The process treats the finest as well as the coarsest floatable material, and no classification of the crushed material is necessary or advisable.

As a result of investigation, it has been established that the most suitable crushing for coal is for it to pass a screen of 1/10-inch aperture.

In ore-dressing, the practice now generally employed is to crush everything smaller than about 1/2 inches in a watery pulp. For coal-crushing we advise that the material be kept dry throughout.

In metallurgical practice, the use of screens is avoided as much as possible, their place being taken by classifiers; for coal treatment we believe that the use of screens is advisable.

These variations from metallurgical practice are rendered advisable simply because coal is a "light" material, whereas metallic minerals are "heavy." Unfortunately, rolls, ball-mills, and the like do not grind to the required degree in the first operation with the guarantee that no oversize will be produced, and control by screen or classifier is necessary. Efficient wet

screening entails the use of large quantities of water, which in turn requires the introduction of dewatering tanks; the only alternative is water classification.

As the shale is of greater specific gravity than coal, control by classifier results in the shale being crushed to a finer degree than the coal. This is economically undesirable: crushing costs money, and shale is the hardest constituent to crush. In this connection it is interesting to note that the work at Skinningrove proved that the ash is largely concentrated in the oversize, as the figures in Table I. demonstrate:—

Table I.—Coal Received from Crusher and Screened on a ⅛-inch Screen.

No.	Ash in total coal Per cent.	Percentage through screen.	Ash in undersize. Per cent.	Ash in oversize. Per cent.
1	18.2	77.8	10.6	44.5
2	13.0	71.4	7.7	26.2
3	13.5	73.7	8.7	37.0

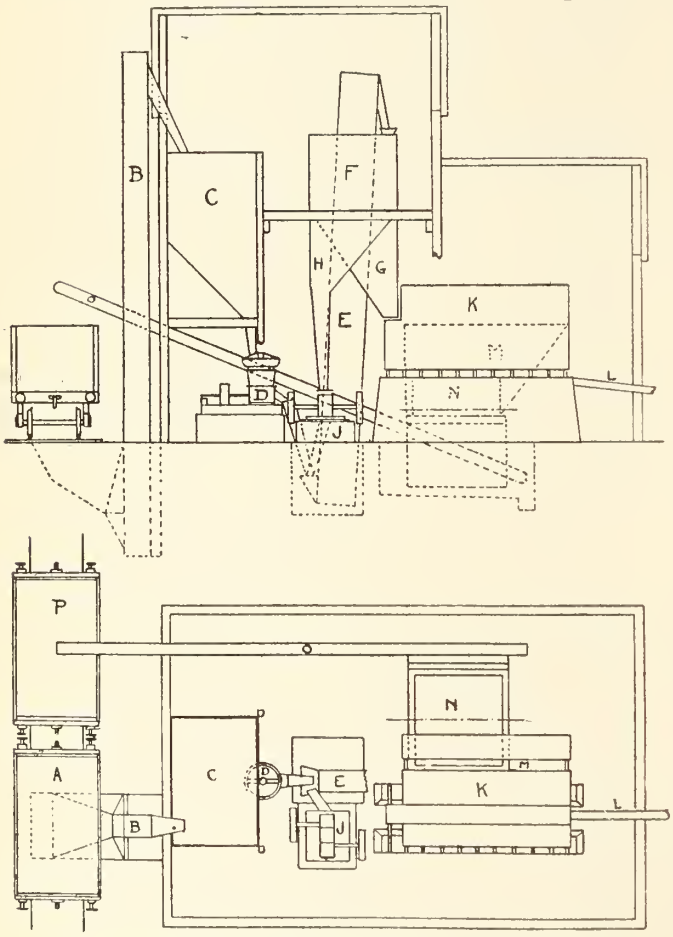


Fig. 1.—Diagram of Testing Plant at the Powell-Duffryn Colliery, Aberdare.

In such a case it may be decided to pass the undersize direct to the ovens without further treatment, leaving only the oversize for the flotation process, although, in view of the still better quality of the flotation product, the wisdom of this course is questionable.

Once the general principles are decided, it is not difficult to suggest a flow-sheet for crushing to flotation size. Our own idea is to crush in gyratory, jaw, or sledge-mills to about ½ inch, screens through vibrating screens of 1/10-inch aperture, pass the oversize through crushing-rolls, and return the product to the screens; the undersize from the screens to pass to the fine storage-bins, and thence to the flotation plant, the washed coal passing to the dryers. Fig. 1 illustrates a testing plant on these lines now operating at the Powell-Duffryn Colliery, Aberdare, whilst Fig. 2 is the flow-sheet relating to the plant.

We believe this method to be both efficient and economical, inasmuch as the material is crushed just fine enough for the purpose, and no finer.

That the product obtained approaches this ideal is indicated by the screen analysis of flotation product made from coal thus treated shown in Table II.

Table II.—Screen Analysis of Coal Concentrates from Oliver Filter, Skinningrove.

Mesh on	Under	Weight percentage Direct	Weight percentage Cumulative	Ash percentage Direct	Ash percentage Cumulative

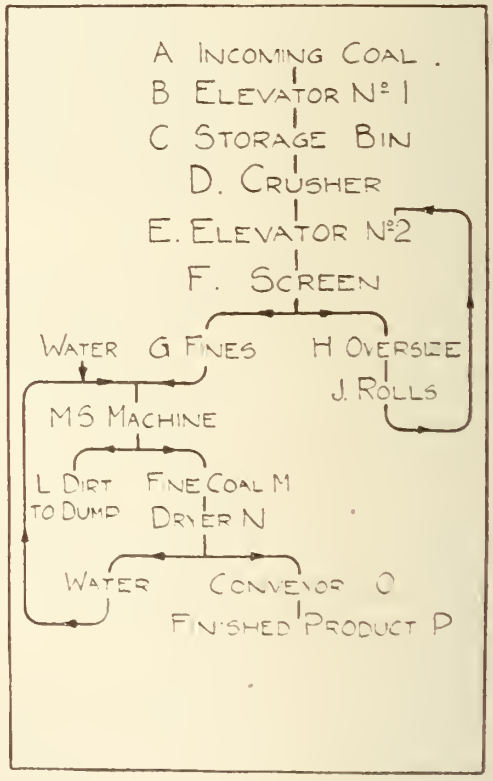

Fig. 2.—Flow-sheet of plant shown in Fig. 1.

(2) **Flotation.**—Concerning the actual operation of the flotation process, nothing is more remarkable than its extreme simplicity in practice, once the proper reagents have been found. Given a steady flow of pulp of suitable water-solid ratio, and a regular feed of reagent, a modern flotation machine will produce a clean product on the one hand and a remarkably value-free residue on the other, in fashion automatic, regular, and persistent. So simple is the process that a large number of different machines have been designed and worked with success in the metallurgical field. Very few, however, are of universal application; and after a close study of their points of advantage and disadvantage, and after practical tests on the subject, we

have come to the conclusion that the type known as the "M.S. Standard" is the one best adapted to the treatment of coal. The machine is usually constructed largely of wood, although other materials, such as sheet-iron or concrete, can be substituted. It is designed to alternately subject the coal-water pulp and reagents to sufficiently violent agitation to entrain air, and then bring it to a state of comparative rest. During agitation the air-bubbles collect and attach themselves to coal-particles, and when the pulp is brought to rest the air-bubbles, heavily charged with their collected load of coal, rise to the surface to form a thick, heavy, stable froth, whilst the remainder of the pulp continues in circuit for retreatment. The machine is a combination of a number of sets consisting of an "agitation-cell" and a "froth-box" placed in series side by side so that the sets have a common wall and the vertical agitators are all in line. Agitation box No. 1 is connected by a slot through the common wall to "froth-box" No. 1, and this is connected by a pipe to "agitation cell" No. 2, the said pipe connecting the bottom of the "froth box" with the centre of the bottom of the "agitation cell." The pulp passes from mixing cell to frothing-box, and from frothing box to the next mixing cell, until all the coal has been removed from the froth. The number of sets required depends upon the character of the coal, four or five being sufficient in most cases. It may be advisable in certain circumstances to add one or two mixing cells, without corresponding froth boxes, at the head of the plant, the flow in that case being from mixing box to mixing box through slots in the common wall.

The accompanying photograph (Fig. 3) shows an 8 mixing cell 8 froth-box plant; whilst Fig. 4 illustrates the flow of the pulp through the machine.

The crushed coal and water in proportions of 4 to 5 parts by weight of water to one part of coal, are fed into the first cell, where is also added the necessary proportion of reagent. This proportion is of the order of half a pound to each ton of dry coal treated, and varies slightly from this according to the particular material. At Skinningrove it has been found that the water used for washing the naphtalene from coke-oven gas is, after the separation by settlement of all the naphtalene still sufficiently rich in suitable reagents to treat all the coal required for the coke ovens; in other words, the production of high grade coke oven coal will cost nothing for reagents.

The coal-water mixture, which we technically term "pulp," then circulates, as previously mentioned, in what may be described as a horizontal spiral curve, discharging washed coal at each forward bend. Such discharges may be taken off individually or combined into one, two, or more qualities, according to requirements. By proper adjustment of the quality and quantity of reagents, the low-ash, high-grade coal is thus early separated from the bone-coal (high fixed ash) and the shale or clay. When this point is reached, as is readily determined in practice, a small quantity of paraffin or similar oil is added to the appropriate mixing cell in the proportion of about one-third pound to each ton of dry original coal. By this addition, the bone-coal, which has hitherto remained with the shale or clay, is induced to float, and is removed as a separate product. Such bone-coals obtained in practice contained from 2 to 15 cent. of ash.

The tailings or residues run to waste from the last froth-box consist of clay, shale, or other gangue material with which the coal was originally contaminated, and have an "ash" content varying from 60 to 85 per cent., according to the nature of the gangue.

(3) **Disposal of Products.**—In the treatment of a coking coal, therefore, three separate products result, namely, the "tailings," the "high-grade coking coal," and the "bone-coal."

(a) **Tailings.**—The tailings in some cases may be of no value, but may in others consist of high-grade fire-clay, in which case recovery might be worth consideration. The proportion of water to solids will be approximately 30 to 1 in the treatment of a coking coal, and the pulp readily flows by gravity to any convenient dumping-ground, where the shale rapidly settles out, leaving the clear water, which is quite innocuous, to pass to the drains.

Where the water is scarce and re-use desirable, the tailings may pass to a continuous-discharge Dorr Thickener, or similar contrivance, which delivers a clear overflow to the pumps, and discharges a thick pulp at the outlet-valve.

(b) **High-grade Coking Coal and Bone-coal.**—Either washed product, which forms as a thick, stable, heavy scum on the water surface in the froth-boxes, is made to overflow gently, as formed, by the aid of revolving paddles, which move it slightly forward at each revolution they make. As discharged from the lip of the froth-box, the product contains about 50 per cent. of moisture. The further draining or drying of this material in the most economical and efficient way is a problem to which we are now paying close attention.

In metalliferous ore-dressing practice, the concen

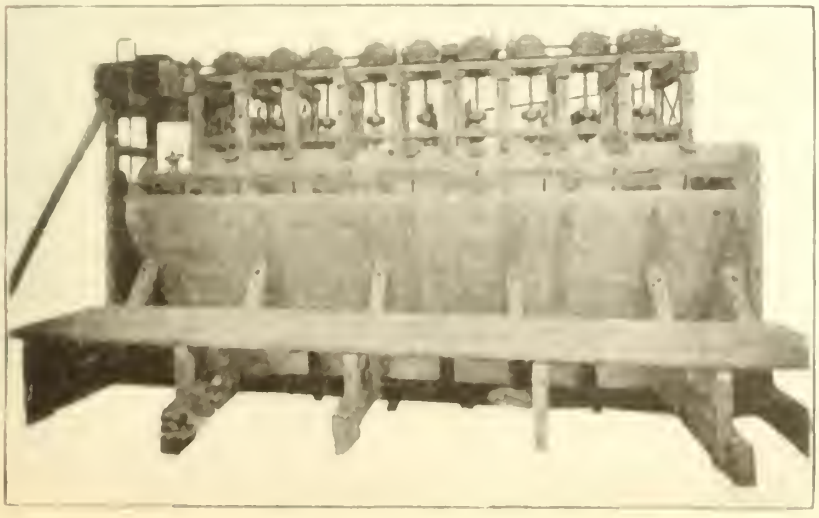

Fig. 3. Photograph of an 8 mixing cell 8 Froth-box Plant.

trate is washed into thickening tanks, discharged into revolving filters of the Oliver type, drained under suction, and discharged as a filter cake containing from 10 to 15 per cent. of moisture. Further drying by heat is part of the smelting process, and does not adversely affect the value of the product.

We have applied this type of treatment with success to coal concentrates, and, by suitable arrangement of the plant, have succeeded in discharging the concentrate directly into the filter, and have thus discarded the thickening process.

Already we have succeeded in reducing the moisture from 50 to 10 per cent., a figure which is comparable with the moisture content in crushed coking coal treated by gravity washers. We consider, however, that this degree of draining from either type of washer is inadequate, average coking practice being deficient in this particular.

An alternative method of mechanical drainage is to employ continuous centrifugal driers, and we are informed that there is such a machine on the market guaranteed to give a product containing 8 and possibly only 7 per cent. of moisture.

It is fully realized in this connexion that there is a limit beyond which the removal of water, as water, is practically impossible, as thin films of water are very persistent. The removal of further moisture beyond this limit necessitates evaporation.

Whether it would be profitable to approach this limit too closely by mechanical means is a question we hope to settle in the near future. In order to supplement these means, or even replace them, we have the possibility of utilizing waste-heat in many ways. Obviously, by proper application, any degree of dryness can be produced, but careful consideration to all proposed methods must be given, because dusting, with its attendant loses and explosion risks, and also overheating, must be avoided. Another disadvantage of such methods lies in the inevitably bulky nature of the apparatus.

Scope of the Flotation Process in Coal-washing.—So far we have discussed the question of coal flotation chiefly from the point of view of its application to the production of blast-furnace coke. The same process, however, with little or no modification, is equally applicable to the treatment of (1) low-grade coals for fuel purposes, (2) washery waste, (3) dump waste, (4) stock duff, and (5) slurry or other coal-bearing material.

The application of the process to the treatment of such materials is now well established, the results shown in Table III. having been obtained from waste material (Powell-Duffryn Aberaman tip):—

Table III.—Results obtained from Waste Material.

	Product.	Weight. Percentage.	Ash. Percentage.	B.Th.units per pound.
(1)	Raw coal	100	70.4	2,280
	Washed product. .	15	15.6	12,450
(2)	Raw coal	100	67.6	5,230
	Washed product. .	21	10.5	12,280
(3)	Raw coal	100	48.5	4,390
	Washed product. .	30	10.5	12,680

The chief difference between treatment of high-grade coal and low-grade waste lies in the different proportions of product to waste — a factor which is readily allowed for in designing the plant. In our experiments we have succeeded in obtaining perfect separation of coal from shales and other impurities, in whatever proportions the minerals may be mixed, and we have met with equal success in the treatment of all types of material as above-mentioned. These include the finest coal-dust found on colliery roads, at pit-heads, and in the slurry ponds to which the fine untreatable discard of gravity washers is led.

Arguing from general principles, it might be maintained that the presence of pyrites in a coal would bar its treatment by flotation, since pyrites is one of the metallic minerals readily concentrated by the process. As a matter of fact, however, the reagents employed to treat coal are of a different character from those

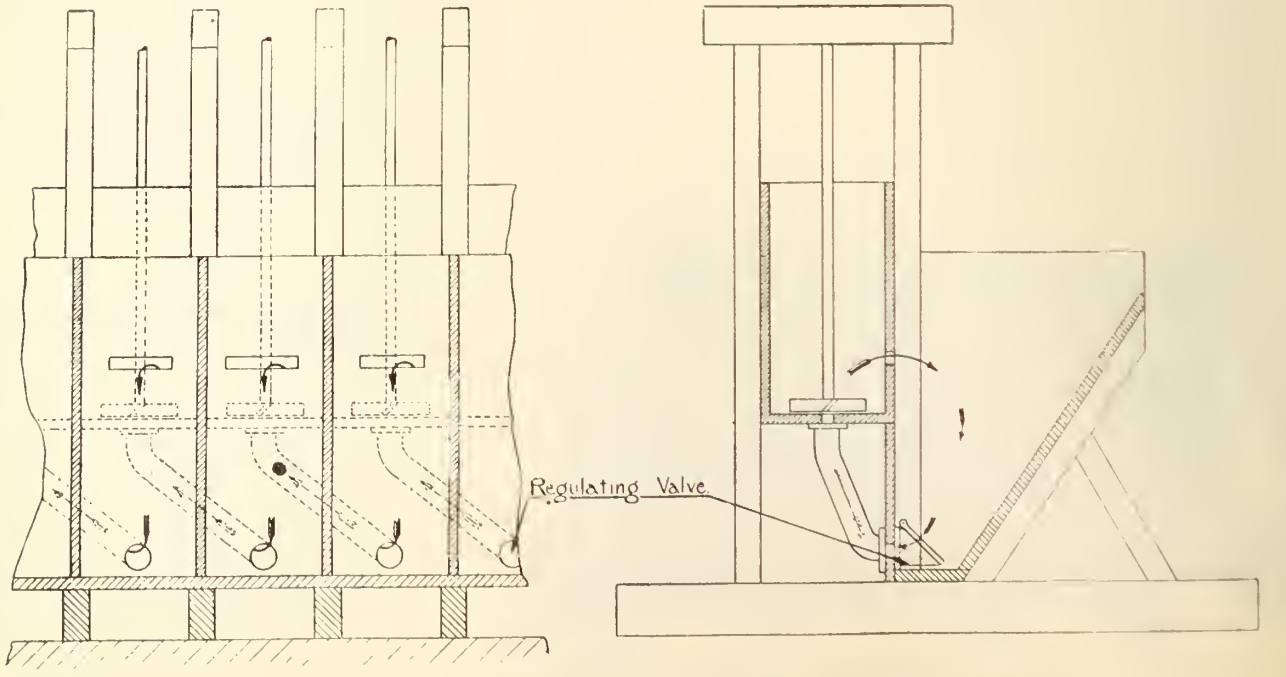

Fig. 4.—Diagram illustrating the Flow of the Pulp through the machine.

necessary for pyrites, and it is found that in the treatment of pyritic coal the coal floats for preference, with the result that the product obtained contains less sulphur in proportion than the raw material. Gypsum and other sulphates are, practically speaking, totally eliminated by the process.

If we were asked to state the most striking fact in the application of this process to coal-washing, we would refer without hesitation, to the facility with which it separates one grade of coal from another merely by the simple control of reagents, and without the aid of any form of screening or classification. This property renders the process so elastic in regulation that it requires only elementary skill and a little intelligence on the part of the operator in charge to produce the most profitable separation into (1) fine, high-grade, low-ash coal; (2) band, bone, or bastard coal of dull appearance, and high combined ash; and (3) shales, clays, gypsum, etc., compatible with the type of coal treated, and the purposes for which the products are intended.

The separation of the bone, band, or bastard coal, as shown above, is new in the annals of colliery practice, since this cannot be removed by gravity treatment, its separation in this case being entirely a matter of surface tension. The ash-content in band-coal may be said to be almost entirely molecularly mixed with the carbonaceous substances, and no degree of crushing and washing would effect its purification. The fact of its removal by froth flotation means that the true coal is thus available for the manufacture of fuels of a new standard, and indicates a probable revolution in blast-furnace practice. We have succeeded in making coke from this concentrate containing 4·8 to 5·0 per cent. of ash, whose physical strength was beyond anything in our experience.

Results.—In the course of our investigations we have made a very large number of tests, the majority of which were made with objects outside the scope of the present paper. To enumerate these results would be tedious, and we content ourselves by giving in tabular form (Table IV.) a selection which illustrates the points we have discussed.

Economic Aspects of the Process.—From a technical point of view we were convinced, by our experience, that the new process was a distinct success, and a careful enquiry into the economic aspect of the question assured us that flotation, applied to coal-washing, could in no way be compared to the use of a Dreadnought as a ferry-boat; quite to the contrary, examination shows that its introduction will bring a comfortable margin of profit in the one case we have investigated, namely, the production of clean coal for making blast-furnace coke.

It may be argued that the rejection of the band-coal could not be economically supported by the colliery industry, and, indeed, we cannot afford to reject anything in the trade which is combustible. We hold, however, that in the preparation of metallurgical coke this band-coal should be isolated and applied for purposes of combustion where its high ash-content cannot materially interfere with the economy of such processes. We suggest that this material should be better employed, say, for combustion purposes in raising steam and the manufacture of producer-gas, rather than be charged into the blast-furnace to make slag, with its concommitant extravagance. Accepting as an axiom that nothing should be charged into the blast-furnace but materials which would make for the most economic manufacture of pig-iron, our investigations into froth flotation have brought us to the decision that only coke made from true coal should be utilized for the manufacture of pig-iron.

Some of the most obvious advantages accruing from the flotation of coal for the production of blast-furnace coke for the smelting of iron and steel may be categorically summarized as follows:—

(1) **Ash Reduction.**—Saving in cost of handling, particularly where the place of the production of the material to be coked is situated at some distance from the coke-ovens.

(2) **Economy in Coking.**—The product is more highly bituminous, yields a richer gas and a larger quantity of bye product, whilst the ash reduction admits of a larger efficient charge to the coke ovens.

(3) **Production of Superior Coke.**—The coke produced is, for blast-furnace purposes, superior to any other. It is harder and denser, yet highly porous; it contains a minimum of ash, sometimes under 4 per cent.; it resists the crushing effect in the blast furnace, and offers all those advantages which only such a coke could offer.

(4) **Economy in Furnace Space.**—There is more room for an increased quantity of iron ores and fluxes.

(5) **Minimum of Silica owing to Ash Reduction.**—Less coke consumption required and less limestone flux per ton of ore.

(6) **Economy of Thermal Efficiency of Blast-furnace.**—The production of slag is reduced. Fewer thermal units are therefore employed in its formation, and fewer taken from the furnace by the molten slag.

(7) **Density of Coke means less Fines.**—The very dense coke means a greater quantity of large coke and the screening out of a lesser quantity of fines. The **total value** of the product of the oven is thus raised.

(8) **Maximum Thermal Efficiency at Critical Zone of Furnace.**—The resistance of the hard coke to the crushing effect of the furnace burden minimizes the tendency towards coke consumption in the upper cone of the furnace, and the maximum number of heat units

is developed at the tuyere lines, or, in other words, at the point of highest thermal effectiveness.

From long experience with a given plant, we are prepared to resolve the foregoing economics into a reduction in cost of manufacture, working upon ordinary Cleveland ironstone, as between gravity washing and flotation washing as follows:—

For the Production of 1 Ton of Pig-iron.

	Cwts.
Burden of coke with 10 per cent. of ash from modern washery product coal	23
Burden of coke with 5.5 per cent. of ash from flotation product coal	21
Economy in coke	2

	Cwts.
Economy in limestone	1.5

Saving per ton of Pig-iron produced.

	s.	d.
2 cwt. coke at 62s. 9d. per ton	6	3.3
1.5 cwt. limestone at 9s. 6d. per ton	1	2.4
Saving in coke and flux alone	7	5.7

This is equivalent to—

	s.	d.
Saving per ton of coking coal	5	8.40
Allowing for ash discarded at 41s. per ton	1	10.73
	3	9.67
Less royalty	0	6.00
Net gain per ton of iron	3	3.67

In our calculations we assumed that the bone-coal, which is of similar ash value to the raw material, will be utilized at its purchase value for processes outside the manufacture of pig-iron coke.

As the cost of flotation is practically the same as that of jig-washing, it is clear that the economics of the process are perfectly sound.

The extraordinary flexibility of the flotation method of washing coal, which permits of the treatment of all grades of fuel down to the smallest dust, will, in our opinion, become an asset of national importance. There is no pit-heap containing coal, or washery heap, or fine dust, or other colliery waste, from which the coal cannot be completely recovered by this method of treatment. It may prove that valuable business can be established in the purchase of waste-heaps, which colliery firms have hitherto neglected. The adoption of this process will render available for use in the iron and steel industries, and other consumers of coal, large quantities of fuel which have hitherto been regarded as valueless, or even, in some cases, been thrown to waste.

The flotation method does not, of course, compete with washers treating nut-coal for sale on the open market for boiler-firing, etc.; it can be employed only where the original coal is fine or where crushing is part of the normal treatment—that is, for coking, gas-making, briquetting, coal-dust firing, colloidal fuel, etc.

We desire to record the very able services of Mr. F. Butler-Jones, Mr. A. Bicknell, and Mr. Arnold Bury, whose experimental work has been indefatigable in this research.

Northern Ontario Letter

THE SILVER MINES.

The Cobalt District.

A rich silver strike has been made at a depth of 360 feet on the Keeley Silver Mines in South Lorrain. Lateral work has been under way for some time at that level where a large tonnage of good milling-rock has been blocked out. It has been officially estimated that over half a million ounces of silver are in sight as a result of former work in ore containing an average of upwards of 25 ounces to the ton. Further lateral work has been proceeding along the main vein at a depth of 360 feet during the past two or three weeks and has resulted in the discovery of high-grade ore which is stated to be very similar to the rich ore taken from the adjoining Wettlaufer mine some years ago, which property produced upwards of two million ounces of silver from a small area. It is too early to estimate the extent of the find on the Keeley until further work is done but, occurring as it does at a point not far from the lower contact, it is regarded as being important.

Another favorable factor in connection with the silver mining industry of this district is that the Mining Corporation of Canada will probably re-open its mines in Cobalt within the next few days. The Company, prior to closing down during the first week in March, was the second largest silver-producer in Canada. In the meantime, the work of increasing the capacity of the plant about 50 per cent over its former rate has been carried on and this work is just receiving the finishing touches. Also, a small force of men has been engaged on the company's Buffalo Mine which it purchased a year or so ago, and all is now in readiness to draw a large volume of ore from this property. The Mining Corporation employes about 250 men when working at full capacity.

Work has been commenced on the Victory Silver Mines, situated in the vicinity of the Temiskaming and Beaver mines in the south-eastern part of the township of Coleman. The operators are optimistic over the appearance of the property as shown during the course of getting the work started. In the early days of the camp, attention was directed largely to the high-grade ore shoots and many valuable veins appear to have received too little attention. It is believed Victory Silver Mines may be numbered among these in that the geological structure is quite favorable, and with veins showing native silver at surface.

Current reports would indicate that there are fair possibilities of the old Silver Cliff mine being re-opened within a reasonably short time. Tentative negotiations with this object in view have been under way for some little time.

It is also reported that work may be resumed this summer on the property of the Casey Mountain Syndicate, situated in the township of Casey in the vicinity of the Casey-Cobalt mine. Some of the interested parties appear to have formed themselves into a body known as the Casey Mountain Co-operative Syndicate for the purpose of providing funds with which to carry on the desired exploration and development work.

In a general way, activity is increasing in the silver-mining areas of Northern Ontario. This includes Cobalt, Gowganda, Elk Lake, Casey township and South Lorrain. The increase seems to be due in part to an improved economic condition, as well as to the belief that with the world now producing silver at a rate lower than any previous year since 1890, there is

small likelihood of the price declining to any great extent below the present quotations. Indeed, now that the great volume of silver released during the recent war seems to have settled down into grooves of general demand, the belief is taking form that prices may reasonably work to higher levels.

In the regular monthly statement issued to the president and directors of the Nipissing Mining Company, Hugh Park, manager, states that during the month of April the company mined ore of an estimated net value of $142,610 (including $14,424 of Cobalt) and shipped bullion from Nipissing and custom ores of an estimated net value of $177,762. The value of the silver production was estimated at 61 3-8 cents an ounce. "Underground work was suspended for part of the month on the town side of the Lake, due to the destruction of 73 shafthouse by a fire on April 11th. Operations at the low-grade mill were not interfered with to much extent, the tonnage being obtained from the township side of the lake. Temporary hoisting arrangements at 73 shaft were completed on April 22nd and underground work and production is going ahead as usual. A permanent headframe is now being erected. "There were no unusual developments underground during the month. The low-grade mill treated 6,633 tons. The high-grade plant treated 91 tons. The refinery shipped 301,075 ounces of bullion.

J. P. Bickell, president of the Temiskaming Mining Company states that the property will not be re-opened under present conditions. A lower cost of operation or a higher price for silver will be necessary before an attempt is made to place the mine on a producing basis. This statement was made in response to unofficial rumors that the property might be opened at an early date.

ORE STATEMENT.

Following is a statement of ore shipments over the T. & N. O. Ry. for the month ended April 30th:

(In tons of 2,000 lbs.)

SILVER ORE.

Cobalt Proper—	Tons.
1 Coniagas	65·64
2 LaRose	62·94
3 O'Brien	64·00
	192·58

The above shipments were made to the following Companies:

Canada—	
Deloro Smelting & Refining Co., Deloro	64·00
Coniagas Reduction Co., Thorold	95·59
United States—	
American Smelting & Refining Co., Perth Amboy	32·99
	192·58

Price of Silver.

	Cents per Oz.
April 12th—Highest	62·875
April 1st—Lowest	56·125
Average	59·337

During the week ended May 13th, ore shipments from the mines of Cobalt were heavier than for some time, the Coniagas and the O'Brien sending out a total of four cars containing approximately 291,366 pounds. Following is a summary:

Shipper.	Cars.	Pounds.
Coniagas	2	162,396
O'Brien	2	128,970
Totals	4	291,366

During the corresponding period, the Nipissing mine shipped 30 bars containing 51,082 ounces.

THE GOLD MINES

The Porcupine District.

Large additions to the mill on the McIntyre-Porcupine Mines promise to mark the last half of the current year. The company is working its present equipment at full capacity of not far under 600 tons of ore daily, and is producing gold at the rate of from $175,000 to $185,000 every thirty days. In spite of this, the ore reserves are such and the result of development work at depth so favorable that a further big addition to the plant appears to be warranted at once. Accordingly, the grinding equipment is stated to have been placed on order with a view to having the additional milling facilities in operation by about December 1st, at which time it will be possible to treat 900 tons of ore daily and produce $250,000 monthly.

In an interview with A. F. Brigham, general manager of the Hollinger Consolidated, the Journal correspondent was informed that some of the recent reports about the capacity of the plant had been over optimistic in that the rate would not exceed an average of about 3,300 tons of ore daily, as compared with an intimated unofficial estimate of 3,500 tons daily. Mr. Brigham also left the impression that the unofficial estimate of a monthly yield of a million dollars was over-optimistic. As to this, were the plant to average 3,300 tons daily, and recover $10 per ton which is below the average as estimated in the ore reserves, the daily yield would amount to $33,000 or at the rate of a little over a million a month. From this, therefore, it may be gathered that mill heads may be slightly reduced now that the plant has been brought up to the full capacity. With recovery of $9 a ton on the basis of full operations, the annual yield would approximate $10,810,500, not including the premium received as a result of the exchange rate as existing between Canada and the United States. Concerning the question of when the Hollinger would take up the matter of developing the Kettle Falls water power, Mr. Brigham merely remarked that something must be done to assure the mines of ample hydro electric power as a precaution against the possible recurrence of such a costly shortage as that which occurred during the closing weeks of 1920 and the first four months of the current year. There has been some publicity given to the fact that the Hollinger is to make a close bid for the world record in point of annual production. This publicity has brought some criticism. As to this, neither the publicity nor the criticism has come from officials of the company, but the facts of the case are these. The company has no selfish motive to set out for a world record but the truth is that the resources of the property are such that in the natural course of their conservative development they offer promise of ultimately surpassing in point of annual yield any other gold mine in the world. In fact there are so many known but as yet undeveloped ore bodies and such great resources in the veins already developed that within a reasonably short time as gold mining goes this enterprise could conservatively win the distinction of world leadership

—all the criticism and meaningless uncalled-for questions of "Why?" notwithstanding. "Why a 'world' record?" asks one writer. To which it may be replied: A world record for the reason that it may be impossible to avoid such an achievement during the natural course of operating this gold property upon a scale which its resources warrant.

The outlook for the Porcupine V.N.T. Mines, in regard to the likelihood of this property being re-opened on a large scale, is becoming more favorable and there are now excellent prospects of the necessary arrangements being made within a reasonably short time.

At a meeting of the shareholders of the Moneta-Porcupine Mines, it was stated that arrangements are being made to finance a scheme of exploration work. A block of treasury stock is to be sold and additional funds to be loaned to the company for this purpose. The property lies immediately to the west of the Hollinger Consolidated.

The Kirkland Lake District.

Developments on the Lake Shore mine during the past two or three weeks have been exceedingly favorable, both No. 1 and No. 2 veins being found to contain high-grade ore at the 600-ft. level. The opening up of these bodies at that depth, and the driving of a raise through to the 400-ft. level promises to make it possible for the company to estimate large ore-reserves by the close of its fiscal year at the end of November, next. Heretofore, owing to development work not being sufficiently advanced, the management has refrained from any definite estimate of reserves. In one stope at the 400-ft. level there is between 18,000 and 19,000 tons of ore actually broken and ready to draw out for the hoisting to the mill. This ore is high-grade, averaging upwards of $28 to the ton.

The Wright-Hargraves mill is giving excellent satisfaction and is treating all the ore as it comes from the lateral work at the levels where drifts are being extended for the purpose of opening stopes.

By the late Summer, the mill on the Kirkland Lake Gold Mines will attain full capacity operations at an average rate of between 150 and 160 tons of ore daily. This rate is occasionally reached at the present time, although the average is slightly below that figure. The ore shoots at and below the 700-ft. level are found to be extending in length as compared with the upper levels of the mine.

Good headway is being made on the Kitchener-Kirkland property, situated in the northwestern part of the township of Teck, and adjoining the La Belle-Kirkland and the Fidelity. A shaft is being sunk on a vein some ten feet in width in which an encouraging gold content occurs.

At a meeting of the shareholders of the Elstone-Duncan Gold Mines, holders of property in the township of Ganthier, it was decided to remove the head-office from New Liskeard to Toronto. Arrangements are being made to carry on quite an extensive program of exploration and development work on this promising gold prospect.

The Boston Creek District.

A spectacular gold discovery has been made on the Walsh claims in lot 5, concession 3, in the township of Catherine. The find was made by Hugh Walsh, a well-known prospector. Two large veins have been opened up, the pay-streak in one being 15 inches in width.

British Columbia Notes

BRITISH COLUMBIA LETTER.

Stewart, B.C.

The Red Cliff Group of Mineral Claims situated on Bear River is reported to have been taken over by Messrs R. W. Wood and A. B. Trites, who proposes doing development work this year. The outcrop on the Montrose Claim is said to contain good gold values with a small percentage of copper and a greater one of iron pyrites.

P. H. Graham, who has charge of the installation of an eleven-mile aerial tramway for the Premier Mining Co. which will transport ore and concentrates from that company's property, Salmon River, to tidewater near Stewart, has taken over personal direction of the work. The tramway, the route of which parallels the wagon road and is approximately 11½ miles in length, the second longest of its kind on the American continent, will require enough lumber to keep the Hyder and Stewart Mills busy for some months. There are to be 150 ordinary towers and twelve tension towers as well as three angle stations and two terminals. The stationary or carrying cable will be one-inch steel and the travelling cable five-eighths of an inch in diameter. Mr. Graham also is to supervise the construction of ore bunkers at the wharf at Stewart with proposed capacity of 4,000 tons.

Hudson's Hope, B.C.

The Provincial Government has let a contract to Lynch Brothers, of Vancouver, B.C., to sink three test holes by diamond drill, there to be a minimum of about 3,000 feet of drilling done, in the Boulder Creek District, about 24 miles northeast of Hudson's Hope. The party already has set out for the locality and expects to commence work very soon. This action is in line with the policy of the government of definitely ascertaining the oil possibilities of the Peace River Country. Mining engineers have been in this territory for two years on behalf of the Provincial Administration and their reports have been of such a character that the time now has arrived for practical prospecting. The drilling of this season, it is hoped, will demonstrate the presence of oil and possibly prove that it is in paying quantities.

The placer gravels of the Ingenika River, Peace River District, are to be prospected this year on a considerable scale for gold and platinum if the plans of R. D. Fetherstonehaugh, mining engineer, and his associates are carried through successfully. Mr. Fetherstonehaugh has done much preparatory work. His sampling of the locations that have been acquired is said to have given returns extremely satisfactory both in respect of gold and of platinum. He will be assisted in his enterprise by William Hubbrough, mining engineer of San Francisco, Cal. The company's claims are on the Peace and on an old river bed not far from Hudson's Hope. They will be worked by the draw line scraper system, the capacity of the scraper being 1,000 yards of gravel daily. There will be two engines of 30 horse power, two boilers and a ten-inch centrifugal pump, in addition to other plant adjuncts. Generally the method to be adopted is the same as that lately used in California and other fields. Mr. Fetherstonehaugh estimates that the gravel can be handled at the rate of 10 cents a yard and that the gold and

platinum contents will run from $1 to $1.50 for the same quantity. Operations will continue until about the middle of October. Officials and workmen will be housed in tents, there being no intention at present to construct a permanent camp. Supplies will be obtained at Hudson's Hope.

Nelson, B.C.

At the annual meeting of the Standard Silver-Lead Mining Company the following were re-elected directors for the ensuing year: W. J. Wakefield and George H. Aylard, of Victoria, B.C.; L. K. Larsen, of Nelson, B.C.; William A. Carry and Charles Hussy. Mr. Wakefield is the president, Mr. Aylard, vice-president; and Mr. Hussy, secretary-treasurer. Mr. Hussy announces that the same policy will be followed, viz., the payment of no dividend and continuance of the search for available mining property in which to invest. Receipts for the year ending December 31, 1920, are given as $216,609 with disbursements of $143,197, giving an operating gain of $73,412. The net gain for 1920 is $69,162 while the balance on December 31, 1920, was $367,173. Cash in banks and government bonds are given as $316,104 and $56,800 is invested in term mortgages.

The Silversmith Mines, Ltd. has effected a deal with the Minnesota Silver Company and F. W. De Foe, et el, of New York, by which the management of the Silversmith secures the use of the Ivanhoe mill site, mill, and water power at Sandon. In order to utilize the mill it is necessary to construct a 4,000-foot tramway from the lower workings of the Silversmith Mine to the mill. The latter also will be thoroughly overhauled and remodeled to meet the requirements of the new users. It is estimated that, with the completion of this work, the plant will be capable of treating 150 tons of ore in a 24-hour day. The Silversmith now will be able to mill its ore the year round. The old mill, owing to water shortage, has been able to operate only seven or eight months in each year.

An action has been brought against Clarence Cunningham—the well-known Kootenay mining operator, by Robert Insinger, of Spokane, Wn., manager of the Northwestern and Pacific Hypotheek Bank, acting also for associates in the ownership of the Hewitt Mine. It is sought by the plaintiffs to recover $37,500 claimed to be due as payment on the Hewitt Mine operated by Mr. Cunningham on an option to purchase. Much evidence has been heard and a great deal of legal argument. The judgment has been reserved.

Trail, B.C.

Ore receipts in gross tons at the smelter of the Canadian Consolidated Mining and Smelting Co. from April 21st to the 30th totalled 12,056 tons. Of this the company mines contributed 12,023 tons and the Sally, Beaverdell, 33 tons. This brings to total for the year up to 139,816 tons.

Vancouver, B.C.

A Vancouver branch of the Yukon Order of Pioneers has been formed. Membership is limited to those who entered the Northland prior to 1909. At the first banquet of the organization there were present many who had "mushed" over the historic Chilcoot and White Pass trails to the goldfields. The company included three ex-governor of the territory, Mr. F. T. Congdon, K.C., Mr. Alex. Henderson, K.C., and Capt. George Black; two ex-mayors of Dawson City, Messrs. Henry C. McAulay, the first to hold that office in the centre of the Yukon, and R. P. McLennan; and other former northerners of distinction. One of the outstanding oratorical incidents of the affair was the declaration by Edward C. Russell, Seattle, Wn., grand president of the Y. O. O. P., that greater things than have been are to come out of the Yukon in the way of commercial development when "the solid-silver ores of the Mayo and other sections are exploited."

William Elliott, a well-known Canadian returned soldier and a prospector, writes from the Mayo District that the Guggenheims are opening up new rich claims and are striking good ruby-silver. He says that the Northwest corporation, a subsidiary company of the South American Consolidated Gold Fields, has secured fifty claims. The opportunities for obtaining ground with small capital will be limited after next Summer. The Canadian Pacific Ry. Co. is looking up property on the Christable Creek slope of Keno Hill and others are investigating the Rambler, Lookout, Stand To, Patterson and Cameron Mountains. Prospectors are pushing towards the north and south forks of the McQuestion river. Martin Ravey, of Vancouver, describes the first prospecting that was done where now is Camp Mayo. In '98 he packed in the first miners equipment to test the silver of Mayo. "At that time" he says "any man looking for quartz in that country was looked upon as one proposing to live 1,000 years, that is if he thought of profiting. I made my last trip with an old husky dog, fully 90 per cent wolf. I could pack 60 pounds on that old fellow and took in a drill, hammer, dynamite caps, pick and shovel. After firing my first shot I sat..... picking up beautiful blocks of galena wondering at the wealth that fellow prospectors had said would never be developed..... According to a government report issued in 1918, Louis Bauvette "discovered" silver in July of that year. I might state that it is probable that the blazes of trails, the remains of camp, and the very discovery-holes of the first silver strike were grown over with moss when Beauvette staked Keno Hill."

SUDBURY DISTRICT NOTES.

D. E. CUSHING.

Schreiber District.

The Schreiber Mining District bids fair to add another chapter to the mining history of Canada. Gold discoveries, with subsequent high assays are attracting the prospectors from various other mining camps. Forerunners of the trek have reached the district. They are of the type who made the Yukon, Porcupine and Cobalt possible.

Prominent among the first arrivals were R. E. Wilson and Hugh McEachren. Both are old timers in the mining game. Mr. Wilson was in the Yukon rush of 1898 and has mined in Siberia, Cobalt and Porcupine. McEachern also numbered among the first in the different camps. Both are impressed so far with what they have seen in the Schreiber area.

Mr. McLaughlin, another arrival, has not only been a pioneer in the many different camps but has also been in the various Australian and South African camps.

Many claims have been staked in the Schreiber area. Perhaps the best are in the vicinity of Duke Lake, and the surface showings there are reported to be of high promise. One prospector, named Longworth, recently sent a number of samples to New York interests and they report that the assays show consider

able platinum. Longworth is starting work on his claims, and will have a number of other assays made to ascertain whether the platinum content is of commercial value.

A second gold-bearing vein has been located some 225 feet from the main vein on the McKeller mine. This vein is over fifteen feet wide.

West Shining Tree Camp.

Men and material is still going into the West Shining Tree camps, and there is every indication of a real mining boom, and something a little different from the other booms attempted for this camp. Hitherto the advance has been retarded materially by lack of transportation, but the Ontario Roads Department has about completed its road in from the railway and the situation is much better.

There are many signs pointing to a boom.

The Wasapika Consolidated is well financed now and is pushing development. A two-hundred-ton mill is to be erected, the contract having been placed. The first unit of 100 tons will likely be in operation before the end of the year.

On the White Rock, Sudbury controlled, the construction of a five-stamp mill is already far advanced, and this mill hoped to be the camp's first producer.

The Atlas is also reported to be in better shape now to go ahead as a mining company. It is understood that this was made possible by the purchase of a block of stock by the U. S. interests. It is planned to undertake extensive operations. A. M. Bilksy, former manager, has transferred his interests and I. Singer, Toronto, is now secretary.

The Herrick is developing and also the Wekenda, and the Churchill Company should soon start.

Besides the foregoing, there are many other promising properties in the camp. Thre is a bright prospect of a large gold-production and a great many old prospectors continue to work on claims. Many of these hold much promise and as soon as money eases, it would not be surprising to learn of the launching of several new companies.

Good Ore at Dome Mines.

During the past few weeks there have been persistent rumors that a very large body of high-grade ore has been opened up recently at the Dome mine. No official statement concerning it has yet been given out; but shareholders expect to find in the report to be issued this month confirmation of the statements that developments of major importance have taken place.—R. E.H.

EDITORIAL

CANADA'S INTEREST IN ASBESTOS MANUFACTURE.

Elsewhere in this issue will be found an excerpt from the remarks of the Chairman of Bell's United Asbestos in London, which are of serious import to Canada as the principal producer of the world's asbestos. The high tariff which is proposed by the United States against importations into that country of manufactured asbestos has led this leading English manufacturer to seriously consider the opening of a factory in the United States. Canada can hardly remain a disinterested spectator of a condition which permits of such a proposal. This journal has not hitherto been able to see clearly how Canada could profit, as the country certainly should profit, from its predominant position as a producer of high-grade asbestos. The difficulty of manufacturing finished products from crude asbestos in Canada consists in the fact that it is a process of assemblage rather than making a uniform product from a raw material. So far as this journal is aware, the only working up of crude asbestos in Canada—with the possible exception of one small textile-making branch of a United States firm—is in the manufacture of tiling and corrugated sheeting at Lachine, near Montreal. In the three year period 1917 to 1919, Quebec produced 89 percent of the world's asbestos and it is therefore understandable that the government of Quebec should have contemplated an export tax on crude asbestos for the purpose of encouraging the manufacturing of finished asbestos goods in Canada. This is a procedure, however, which will require very careful consideration as it is not at all certain that it would have the effect desired. If asbestos manufacture is to grow up in Canada it will have to do so as the result of private enterprise a development that would logically intimate with the Canadian asbestos companies themselves. The spectacle of one of the largest and most experienced asbestos companies in Britain building a factory to utilise Canadian asbestos in the United States is, however, not one that the Province of Quebec can be expected to view with equanimity. The place for such a factory is in Quebec, and the proposal is one that is likely to focus attention in a very definite way upon a matter in which public opinion in Quebec has as yet been only mildly interested. The asbestos companies in Canada, if they are wise, will take the initiative, as by doing so they may avoid the embarrassment which will follow when the public has apprehended the meaning of a squabble between United States and English companies over the profitable uses of a product that the world must have and which Canada controls in virtual entirety at this time, although benefitting therefrom only as an exporter of raw material.

THE BRITISH COAL STRIKE.

George Roberts, a British labour member of Parliament, and former Food Controller, has stated the coal strike in Britain is being prolonged by the cowardice of the miners' leaders in not telling the miners the truth. Mr. Roberts, however, told the truth.

The irresponsibility of the miners' leaders has been not only the cause of the prolongation of the coal strike, but of its inception. The right of the leaders of the miners to pose as plenipotentiaries of the men they undertook to advise and represent never existed, and the tragedy of the situation today is that the necessity of the leaders to save their own faces is the obstacle preventing immediate compromise of the strike.

The leaders of the miners in the first instance, knowing the impoverished condition of the union treasury, advised against a strike. Later the leaders advised against withdrawal of the maintenance forces at the mines. In neither instance were their wishes followed, and they are afraid now to advise dropping of the pool proposal and acceptance of a wage basis that will give the lowest class of labourer in the poorest mine district a wage of ten shillings a day, and the opportunity to earn wages over one hundred percent greater than pre-war wages, and much in advance of other classes of manual labour in Britain.

The inability of any responsible government to pool the revenues of private owners without authorisation of such a revolutionary innovation by vote of a general election, must have been fully realised by the miners' leaders, yet they preferred to place a political demand of this nature ahead of any consideration of questions of wages and hours of work, on this untenable ground advised a strike of all coal miners in Britain, and asked the assistance of all organized labour through the pressure upon the voters of that most desperate expedient

of modern times, the general strike. The miners' leaders, proved by the actions of their own followers to be capable of initiating policies only, but not of controlling the union membership; were actually prepared to imperil the life and comfort of every individual in the State to impose acceptance of an untried economic theory applicable to one industry only out of many thousands of industries. They proposed this dangerous experiment, they hazarded a strike of miners, attempted a general strike, and have appealed for outside assistance, and each successive step they have taken has been to save themselves from the consequences of the initial error. It is a pity to see so loyal and worthy a membership as comprises the Miners' Federation following policies they do not understand; forced to expend their undoubted powers of endurance and fighting abilities in an untenable cause, and debarred from a settlement that they eagerly desire, because the leaders dare not expose their errors.

Britain is at this time a much-harrassed country. Had the justice of the miners' cause been admitted by the public the strike would now have been over, but the silence of the public and the unusual reticence of the British press regarding the inconvenience, financial hardship and physical suffering, that the public is now undergoing, is in itself a most significant public condemnation of the miners' attitude. The situation, is however, in nothing more serious than in the absence of responsible leaders among the miners themselves, dominant enough to tell the miners the truth and to advise a compromise that will admit the initial error of the leaders.

The British coal miners' strike was not a strike for wages and working conditions. It was a strike to compel acceptance of a new political principle, by duress of a blockade of all production and transport in Britain. There is another term for this kind. of action. It is possibly better not to name it, but the British public has interpreted it correctly, and is now anxiously waiting the representative of the miners who will expound it to them also, and will be courageous enough to trust the undoubted good-sense and patriotism of the miners to abandon an unjustifiable course as soon as they are told the truth.

THE COMMISSION OF CONSERVATION.

In cancelling the Commission of Conservation it would have been much better had the Government's spokesman refrained from some very unkind and unnecessary aspersions upon the Commission's conception of its duties and its zeal in carrying them out.

There is a very considerable inconsistency in the action of the Government in simultaneously destroying the Commission of Conservation and establishing the Research Council. The scope of the work proposed to be done by the last-named body does not replace nor conflict with that done by the Commission of Conservation. If it is considered necessary at this time to abolish the Commission of Conservation it is an admission that the original appointment was a mistake. The statement is made that the publications of the Commission duplicated those of permanent government departments, but reference to the actual publications will show that the Commission in many cases has coordinated and collected in readable and impressive form much information that was scattered throughout the technical literature of years, and was in large part inaccessible to the public. The work of the Commission in regard to water-powers, forest resources, fisheries and fuel resources, is very largely responsible for the more intelligent interest of the public in natural resources, and this is due to the viewpoint of the Commission, which loyally interpreted the scope of its parliamentary warrant. Its work was to awaken public interest, to decry waste, to urge efficient use of resources.

The opinion of the Senate on a matter of this kind is always valuable, because it proceeds from a mature and detached vision, and when Senator Nicholls recently stated that the Commission "had rendered signal service to Canada" he spoke, as did Senator Edwards, as a man of affairs and some achievement in technical enterprises.

The scope of the work proposed to be done by the Research Council was outlined in a memorandum that was published in our last issue, and on persuing the memorandum it is impossible to avoid an uneasy feeling that if this body devotes itself to its duties with the conscientious zeal that marked the policy of the Commission of Conservation, some future government exponent will one day arise and criticise a future Research Council much as the Commission of Conservation was recently read out.

Any criticism that is justly levelled at the Commission of Conservation should be put upon the persons that created that body and charged it with certain duties, because the contention of those who have abolished it is not that the Commission did not function, but that its functions had become too provocative and were stirring things up too relentlessly. To be the keeper of the country's conscience in regard to natural resources will always be found to be a thankless task, bringing to those who keep reminding us of our economic sins, more kicks than halfpence.

THE GOLD PRODUCER SHOULD NOT BE TAXED.

Increase in gold production is, beyond question, very much to be desired. It is in the interest of Canada that we should develop all our promising gold deposits and extract from them all the gold that can be profitably mined. Any burden placed on the producer must result in the loss of much potential wealth. Every cent added to the cost of mining operations means that tons of ore must be left unworked. The gold miner, unlike the dealer in most commodities, is not permitted to increase the price of his product to meet tax impositions and is simply forced to discontinue producing gold that the tax makes unprofitable.

Taxes affect production of gold at all mines in the same manner. To lessen the profits of the most successful mining companies can only result in thousands of tons of ore being left unmined. Even in cases where very large profits are being made it is unwise to tax the producer, for the recipients of the profits and of the millions spent by the operating companies will be subject to taxation like any other citizen. Where large profits are being made the removal of taxes will always result in additions to the production of gold, for in every big gold-mine there is partially developed many tons of ore that might be mined if taxes were removed, but which will never be mined if it cannot be profitably done while the extraction of the higher-grade ore is proceeding. The utilization of such ore would bring comparatively little profit to shareholders for it would barely pay the cost of extraction; but so long as it pays its cost, hundreds of workmen would find profitable employment mining ore which will be of no use to anyone if burdens are placed on the producers.

The proposal to increase taxes on mining company profits has been strongly opposed and the Ontario Government has evidently been convinced that it would be unwise. If the subject were fully understood by the general public there can be little doubt that Governments would find it a wise policy to come out strongly in favor of proposals to help to increase gold production, by removing all taxes on profits of gold-mining companies.

Ontario is particularly favored with gold deposits and will derive great wealth from the industry if the Government will realize the possibilities and will encourage production. It is often claimed by Governments that they are desirous of encouraging production, but cannot easily find ways of doing so. The Ontario Government can give a great impetus to gold mining, make greater use of the known resources and stimulate development of others by freeing gold producers from taxes. This will not mean that the necessary revenue will be lost, but that it will be derived indirectly from gold mining, just as it is from our manufacturing and other industries. The individuals who share the disbursements of the operating companies whether they be shareholders, employees, manufacturers of mining machinery or supplies, merchants, or others who benefit from mining operations, will not be relieved from taxation, but the industry will be developed on a much larger scale and every mine now operating will be given a longer and more productive life.

Casual attention to the subject will not likely result in departure from the present tax gatherers' method of taking money from those who have it, regardless of the future. If a careful study of the possibilities increasing gold production were made, however, and of the resulting benefits to the community, the probable result would be a declaration in favor of removing all tax burdens from gold producers.—R. E. H.

ENGLISH ASBESTOS MANUFACTURERS CONTEMPLATE FACTORIES IN THE UNITED STATES.

At the annual meeting of the shareholders of Bell's United Asbestos, being the 33rd ordinary general meeting in London, the Chairman, Mr. J. Alfred Fisher mentioned that the Company's export trade was being threatened by high protective tariffs in most countries, and in lesser degree by some of the self-governing Dominions. In regard to the United States, the principal absorber of Canadian crude asbestos, Mr. Fisher stated:

"The most striking case, however, is that of America where an attempt is now being made to impose an entirely prohibitive tariff in place of the existing import duty of 20 per cent. ad valorem. This is high enough indeed, and practically shuts out trade, but the new tariffs proposed are so remarkable as to be worthy of mention. Take, for instance, asbestos yarn of ordinary quality selling here for two or three shillings per pound. American manufacturers are urging that a duty be put upon this article of $1.75 and/or 50 cents per pound, or say from 100 to 300 per cent. The supporters of this extraordinary proposal, however, give manufacturers on this side a good advertisement when they base their claim upon the statement that while they have to pay their workers higher rates than are paid in Europe, they can only spin yarn from the longest asbestos procurable, costing them $3,000 per ton, or 6s. 3d. per pound at the normal rate of exchange. This class of fibre represents less than 1 per cent. of the total Canadian production.

The prices charged by American manufacturers for asbestos goods even now are very high. Is it conceivable that they wish to persuade their Customs authorities that they are unable to utilize less costly grades of spinning fibre that are available and from which they must surely know that it is quite possible with proper skill to make goods of the best quality?

It would appear to be their object not to protect themselves from loss, but to make sure of keeping British manufacturers out of their market altogether (although they have a free market here), and to increase their already large margins and make American consumers pay the bill.

If their proposals are adopted this company would be justified in seriously considering the question of starting a factory in the United States where we have important connections. The difference in labour cost is not serious having regard to the high rates now paid here to asbestos workers.

It is obvious that the present ad valorem duty of 20 per cent. should be ample to cover the increased wages cost in the States, and if we are so much ahead of our American friends in the art of spinning asbestos fibre as the statements to the Customs authorities imply, then we should have a good prospect of success, and I purpose sailing for New York in a few days to go into these questions.

GOLD OCCURRENCE AT KAZUBAZU, QUEBEC, UNCONFIRMED

The Superintendent of Mines at Quebec, [illegible] ing the location of the reported gold occurrence at Kazubazu, is unable to confirm the [illegible] at this point and states that [illegible] did not disclose other gold or silver minerals.

The Mackenzie Oilfield of Northern Canada.

A Résumé of the Paper presented on 27th April, 1921 before the Institution of Petroleum Technologists, in London.

By Dr. T. O. BOSWORTH, M.A., F.G.S., F.R.G.S.

(From "The Petroleum Times.")

Some years ago I had the privilege of saying a few words before the Institution about the prospective oilfields which had been outlined in Northern Canada during my geological exploration in 1914.

The Mackenzie oilfield, which is now the subject of so much attention, was the most northern of those fields, and the flowing well which was recently "brought in" is the No. 1 test well which was located there seven years ago.

This "Discovery Oilwell" is situated on the right bank of the Mackenzie River, some 45 miles beyond the little trading post known as Fort Norman, and within about 90 miles of the Arctic Circle. It is the first well drilled in the North-West territory, and the most northern oil well in the world.

From Edmonton, the nearest large town, the distance to the oilfield is about 950 miles north-westward, in a straight line.

Almost immediately north of this city begins the great forest of spruce and poplar—one of the largest forests in the world—extending to the Arctic Ocean, and covering half the North American continent.

Three hundred miles beyond Edmonton the roads and railways terminate, and travel is almost entirely restricted to the great lanes through the forest which the rivers provide.

These rivers—the Athabasca and the Peace—unite to form the Mackenzie River, which flows northward to the Arctic Ocean.

It is only during the summer months that these northern rivers are open.

On both the Athabasca and the Peace the ice goes at the end of April, and on the Mackenzie it breaks up in the latter part of May. It is the ice on the Great Slave Lake which delays the transportation, for this generally remains until the middle of June.

The Mackenzie River remains open for navigation for about four and a-half months, but during October the winter is advancing from the north, and those who do not wish to stay must hasten southward to avoid being frozen in.

These great rivers are much alike in character—all being wide and shallow. At low stages of the water their channels are not to be depended on for boats of more than six feet draught.

Until the oilfield is further proven and developed the oil will be brought southward along the waterway to the railroads of Alberta. For this purpose motor barges of several hundred tons capacity can be employed. Two fleets of these vessels will be required—one operating north of the Smith portage and the other south of it.

If the oilfields fulfils present hopes and expectations, the transportation of the oil doubtless will in due course be accomplished by pipeline, and already several schemes are under consideration for piping the oil to one of the inlets on the Pacific Coast. The shortest distance to tidewater is 550 miles. Such a pipeline would not be longer than some of those already operating in the United States, but owing to the wild country to be traversed, the cost is estimated in millions of dollars.

The Devonian formations are spread over a large part of Western Canada, but about three-quarters of the area is thickly overlain by the Cretaceous deposits.

The eastern margin of the sheet of Devonian rocks crops out in the Palaeozoic escarpment of Manitoba. The line of it passes northward by Lake Winnipeg, Lake Athabasca, Great Slave Lake and Great Bear Lake, to the Arctic coast.

On the west side of the Devonian area the beds are upfolded in the Rocky Mountains.

Between their escarpment on the east and their folds on the west the Devonian strata are thought to be more or less continuous and undisturbed.

Thus in southern Alberta and southern Saskatchewan, the great sheet of Devonian strata underlying the Cretaceous is believed to be practically horizontal.

In northern Alberta, as we travel northward down the Athabasca or the Peace, where the Devonian is here and there exposed to view, we see that here too the limestones have a general horizontal attitude, though they also show many small gentle undulations.

Farther northward, in the North-West territory, the same general horizontality is observed in the scanty exposures around the western end of Great Slave Lake.

Continuing on the Mackenzie River, the first 250 miles of the valley, from Great Slave Lake to the mouth of the Nahanni, apparently are occupied by horizontal Devonian rocks. In this part of its course the river flows W.N.W. between low banks, in which only a few small exposures of greenish shales are seen.

There seems to have been a general idea that this horizontal attitude of the Devonian was maintained throughout all the Mackenzie Valley. This, however, is far from being the case.

At Nahanni River, about half-way between Fort Simpson and Fort Wrigley, the river had closely approached the Mackenzie Mountain range, and is sharply deflected northwards. At this place folded rocks of which part presumably are Devonian, are visible from the river in Mount Camsell and other hills.

Proceeding northward a further 70 miles down the river to Fort Wrigley, the Mackenzie Mountains recede from view on the west side, whilst on the east side we see, and soon approach, the Franklin range.

At Fort Wrigley, Rock-by-the-River-Side, etc., the river is in contact with outlying parts of these mountains, and here again folded Devonian rocks are visible.

From Fort Wrigley to Fort Norman the river proceeds on a N.N.W. course for some 130 miles, gradually drawing out of sight of the Franklin range.

After passing Fort Norman the river comes in contact with another mountain system—referred to here as the Limestone Mountains.

These mountains, which consist of anticlinal folds of

Devonian rocks, are encountered by the river for a distance of a hundred miles.

It is in this territory that the favorable indications and structural conditions were found which have led to the recent strike of oil. This is the site of the new oilfield.

Beyond the Limestone Mountains the river passes on to the Ramparts, and through them to Fort Good Hope. Here, and for more than 100 miles beyond, the Devonian is much exposed, but the beds lie horizontally, and no further folding is discerned.

A few miles beyond Fort Norman the Mackenzie turns sharply to north-westward, so as to flow along the south-west flank of the Limestone Mountain range.

This straight course, known as the Long Reach, is maintained for 75 miles, parallel with the range and a few miles from it. The river then turns northward, and in a distance of 25 miles it cuts across the trend of the mountains at their western end.

The Devonian strata of the Limestone Mountain district have been thrown into a series of bold asymmetrical folds, whose axes plunge up and down, steeply and frequently.

In the synclines the soft Camp Creek Series and Fort Creek shales give rise to low ground. But wherever the upward pitchings of the anticlinal axes bring the arches of the Beavertail limestone up above the general level of the land, the denudation has developed out the arches as conspicuous anticlinal hills.

Four main anticlines are thus revealed where the Mackenzie River crosses the folds. At this place all of them are pitching down toward the west. In order from south to north, they have been named (by the author): Wolverine Anticline, East Mountain Anticline, Bat Hills Anticline, and Beavertail Anticline.

The four axes lie roughly parallel, at intervals of about seven miles. Their direction, where the river crosses them, is slightly north of east; but on the east side of the river they bend round to a E.S.E. course, which is perhaps their more important direction.

These four main anticlines are very much alike, each forming a line of more or less discontinuous limestone hills, exceeding 1,000 ft. in height.

In each of these anticlinal ranges a core of the grey barren limestones, or the Fort Norman limestones, is laid bare in the parts where the axis rises to its maximum height.

On each of them the bituminous Beavertail limestone forms steep dip-slopes, and generally it is also seen forming conspicuous arches on some parts of the crests.

Low down on the flanks the Fort Creek shales are found followed by the soft Camp Creek beds.

Near the axes the strata at the core are very steeply inclined, but a mile or two away, on the flanks of the anticlines, the dip is 15° to 35°.

It was the remarkable character of the Fort Creek shales and Beavertail limestone, rather than the oil seepages which led to a favourable view of the prospects in this field. For here, extending over a large region, we have 1,000 to 1,500 ft. of highly bituminous rocks, which obviously are a potential source for the generation of a great quantity of petroleum. These limestones and shales are black with bituminous material, which appears to be present, not as a migratory but as a fixed constituent. In some places where these beds are much exposed the bituminous odour is so strong that it may be noticed at a distance of half a mile. The bituminous shales are undergoing slow combustion at their outcrop, and often they are burnt to a bright brick-red colour, or even to a grey colour, becoming so hard that they clink when struck. In several localities there are conspicuous cliffs of these bright red rocks over 100 ft. high.

Fluid oil is not visible in the bituminous rocks, though where they pass under water some liberation of gas is seen. But the oil might reasonably be expected in the porous beds of the overlying thick series of clay shales and sandstones, and also there was a good chance that at depth, and under favourable structure, accumulations of petroleum might occur within the black shales and limestones themselves.

After study of the bituminous beds the sand of the overlying Camp Creek Series were searched for oil. At each place examined, either seepages were found or the presence of oil was detected on crushing the rock under water.

The principal seepages occur on the shores of the Long Reach, where the river flows for 75 miles along the outcrop of the Camp Creek Series.

Near the mouth of Camp Creek (which at first we called Oil Creek) the seepages are conspicuous for a distance of two and a-half miles. On digging in the river gravel the outcrops of the green oil-sands are exposed, and the oil could be collected in considerable amount. Further out in the river much oil rises up to the surface of the water, and in winter it collects, forming pools in the ice.

Extending over many thousands of square miles, we have 1,000 ft. or more of richly bituminous beds. And overlying these rocks there are 2,000 ft. of shale and sandstones, from which seepages of oil arise. Further, this mass of petroliferous deposits is traversed by large anticlinal folds.

The high parts of the anticlinal hills are not now favourable territory, for there the oil-bearing beds have been denuded away. But on the flanks of the folds and on certain low parts of the crests, and also on the minor structures, the petroliferous beds are more or less intact.

Thus there are many places where satisfactory structural conditions occur and pools of oil are likely to be found.

The oil has a paraffin base and is of high quality. The seepage oil, obtained on digging in the outcrop of the Camp Creek beds, has a greenish black colour and a strong paraffin smell. The specific gravity is .905. The crude oil from the well is of light colour, low specific gravity, high gasoline content, and low cold test.

An analysis made at the Alberta University has been quoted as follows:

Specific gravity	845	Baumé
Distillation 70–150° C.	22.5	per cent
150–300° C.	38.5	"
300–350° C.	33.9	"
350–375° C.	4.1	"
Loss	1.0	"

Thus in commercial terms the oil consists of—

Gasoline	22.5 per cent
Illuminating oil	38.5 "
Light lubricants	33.9 "
Medium lubricants	4.1 "

Within the region here discussed the petroleum appears to have been first recorded about a century ago by Sir John Franklin, who saw, near Bear Mountain, "sulphurous springs and streams of mineral pitch."

It was not until 1919 that a drilling outfit was conveyed into the North West territory, the oil claims hav-

ing been acquired by the Imperial Oil Company, who were conducting an exhaustive search for oil throughout Canada.

The location of this first test well was chosen in 1914, as a site where a hole of moderate depth could not fail to penetrate the several petroliferous formations which had been found.

The well is on the river bank about half-way down the Long Reach, near the mouth of Camp Creek, where there are copious seepages of oil.

The well was drilled during the summer of 1921. Almost from the start oil was coming into the hole, and before a depth of 100 ft. was reached a yield of five or ten barrels a day could be obtained.

After passing from the Camp Creek Series into the dark Fort Creek shales the oil showings still continued, until at a depth of 738 ft. a string flow of oil was encountered which spouted to a height of 70 ft. After about ten minutes the well was capped. Some hundreds of barrels of oil issued from the well before it was finally shut in, but no dependable estimate of its capacity can yet be made. It is thought that the initial output will be at least 500 barrels a day.

But progress in the West is swift. A number of drilling machines already are on their way to the north —and during the coming summer the Mackenzie oilfield will be the scene of much activity.

COAL DUST IS GOLD DUST.

At the conference arranged by the Higher Production Council at the Efficiency Exhibition at Olympia, the subject of "Fuel Efficiency," with special reference to coal and gas, was discussed.

Sir Richard Redmayne chairman of the Imperial Mineral Resources Bureau, and late Chief Inspector of Mines, presided, and said the object of the conference was to consider the best method of using our greatest national asset — coal. Many people were hoping and expecting to see coal fuel at the price it was before the war. It might fall temporarily, but that it would remain for any length of time at a pre-war price he did not for a moment believe. The air and object of scientific men was to endeavour to work out some method of commercially possible low-temperature carbonisation by which by-products could be recovered, and a fuel left which was capable of being used for domestic purposes. He referred to the system of pulverised fuel which had been so largely applied in America and to the still more recent mixture of pulverized coal and oil known as colloidal fuel. There was no doubt that from the tests he had himself seen, colloidal fuel had come to stay. Bulk for bulk it gave practically the same results as oil, and one of its advantages was that it enabled vast deposits of coal of low calorific value, which existed in some of the Dominions, to be utilized.

Mr. John Drummond Paton (Manchester), in a paper on the subject, said that in 1919 and 1920 coal dust had become gold dust and as gold was the basis of British industry and coal was the nearest approach to gold we should utilize every ounce of coal to the extent of its maximum value. If coal dust could be utilized in many cases inferior coal might be found even of higher value, because of the oil it contained, than the coal which was looked upon as good coal. Eventually, he remarked, we might possibly get all the industrial power we needed from the coal mines in this country.

PORT ARTHUR NOTES.

J. J. O'CONNER.

The Palatine Mining & Development Company have filed an application with the city Council of Port Arthur, for the purchase of two hundred acres of land, owned by the city, and situate adjoining the Provincial Paper Mills, on the waterfront, for the purpose of erecting a modern ore-dock, and other facilities required in the carrying out of their iron and steel undertakings at this point.

The Company's engineers are preparing plans showing the proposed improvements contemplated, when these are completed it is altogether likely that the Council will transfer the property to the company, on the terms of their application.

A number of prominent mining men have visited Port Arthur during the past week, in connection with various mining enterprises now underway. These include Edward P. Scallon and W. R. Doell, of Crosby, Minn, both of whom have proceeded to the Atikokan Mine. A. E. Annis, of Orangeville, and F. Hazelwood, of Latonia, Fla. representing the Nepigon Developement Company. This company has over thirty thousand acres under oil and gas leases in this district. Their drilling-rigs have been shipped and are expected to arrive here in a few days, when drilling operations will be commenced. Prominent among these visitors were Joseph Mieynzinski, President of the Palatine Mining & Development Company, Stephen J. Napieralski, a leading iron-master of Des Plaines, Ill., and Mr. Vose, of the Hunt Engineering Corporation, Chicago. Mr. Vose is now at the Paulson Mine, in company with Arthur Mitchell, of Duluth. Thomas Krakowiak, metallurgist, of Chicago, was also among the number.

OXYGEN BREATHING-APPARATUS USED AT NEW GLASGOW FIRE.

The New Glasgow Hospital was recently the scene of a fire which was extinguished after a hard fight by the local fire brigade. Dense smoke in the upper floors hindered access to the seat of the fire, and the trained rescue corps from the Acadia Coal Company, equipped with oxygen breathing-apparatus, were of great assistance under these conditions. The Acadia Coal Company has probably made more effective use of oxygen breathing-apparatus in mine fires than any in Canada, and in this instance the apparatus seems to have been used in what is undoubtedly its chief function, namely, to give access to the seat of a fire in its initial stages. The location of such a fire, whether underground or on the surface, is, in principal, merely incidental.

NORTHERN PRODUCTION CO.

A meeting of shareholders of Northern Production Co. was held in Edmonton May 16, and it is expected that the outcome will be the reorganization of the company. The following were elected directors: Col. G. B. McLeod, president; Dr. Raymond Ghostley, J. E. Lundy, George Mills, Dr. John Jackson, F. Blake, and Wm. R. Angel. The name of the new company will be Edmonton and Athabasca Oil, Ltd.

PEACE RIVER OIL CO.

It is reported from Edmonton that the pioneer oil company of the Peace River district is preparing to begin operations again. This company, commonly known as the McArthur, has drilled three wells.

Enquiry by the British Columbia Government into the Production, Distribution and Sale of Coal.

(Digest by our Victoria Correspondent.

All phases of the coal mining industry of British Columbia and particularly that part of it centering in Vancouver Island and the lower Mainland, are dealt with exhaustively in the reports of Alexander Henderson, Commissioner appointed by the Provincial Government under the "Public Inquiries Act"; General R. G. E. Leckie, who was selected as a mining engineer to investigate the mining methods of the various collieries, the cost of production, etc.; and A. P. Foster, chartered accountant, who was commissioned to scrutinize the records of the companies upon whose product the people of Vancouver, Victoria, and other provincial cities are chiefly dependent for the fuel needed for industrial and domestic fuel.

Recommendations of the Commissioner.

After a summary of the proceedings of the commission Mr. Henderson makes the following recommendations:

1. Introduce the use of the short ton in all Government compilations and endeavour to secure its use in all sales.

2. Require coal operators to furnish monthly returns of operating cost and sales realizations of their several mines. Forms could be furnished by the Department of Mines and the persons covered should be the same for all mines. The correctness of such returns should be verified by government audit assisted by government inspectors familiar with mining operations and costs. The balance sheets of the operators should be furnished to the government and examination should be made to determine the capital actually invested, upon which dividends and interest should be properly allowed.

3. Dealers should be licensed, not for revenue, but to compel compliance with conditions contained in the license safeguarding the public. They should also be required to make returns showing capital engaged, coal handled, operating cost, sales realizations, and profits received. These returns should be uniform and be subject to government audit and examination in the same way as in the case of the operators.

4. Dealers and all large users should make collection of stocks of coal in the summer season, when transportation is cheap and municipal bodies should encourage such collection.

5. Tests should be made and published, showing the analyses and characteristics of coal from all the mines of the Province. Endeavours should be made to see that one class of coal was not put on the market in the name of another. Further there should be established a standard by which to grade coal by its physical form. General Leckie in his recommendations has suggested how this should be done.

6. Dealers should be required to issue to the public regular lists setting forth the different grades of coal, the tests relating to them, the several uses to which the different coals may best be applied, and prices.

7. Consideration should be given to the advisability of appointing a fair weights and measures officer for the Province and he might be given supervision over similar civic officers and jurisdiction as to grades. Provincial police and civic police should be authorized to supplement the authority of the fair weights and measures officer in every possible way and a determined effort made by every means available to stamp out the practice of deception in weights and measures.

8. Supervision of construction of new buildings might include regard to convenience for accepting delivery of coal wood and other goods in bulk.

9. Combines which keep up the price of coal should be dissolved and the offenders prosecuted.

10. An enactment to compel the operators to furnish coal to any person demanding a quantity, not less than one carload of 40 tons and tendering payment therefor at the correct price, provided that the operators should not be required to furnish coal to such person in priority to orders previously given bona fide.

11. Study should be given to the question of introducing uses of coal that would obviate the waste of by-products and the public nuisances now suffered.

12. Consideration of the use of pulverised coal and the establishment of central plants for its production and introduction of automatic stokers.

13. An endeavour should be made to reduce freight rates both rail and water, from Nanaimo and other coal-shipping points to places taking coal and also to reduce rail-freights on coal from the Interior thus aiding in securing cheap coal from all sources.

It will be noted that in his ninth recommendation, Mr. Henderson makes rather a drastic suggestion in regard to action against combines, suspected of acting in such a way as to keep up the cost of coal, beyond a reasonable figure. On this point he says that it is his opinion that evidence adduced before him "clearly establishes that the prices paid by consumers have been excessively high". The price of $15.00 per ton for lump coal has never been justifiable.

He continues:—

"The evidence shows very clearly a combine among coal dealers in Vancouver to fix the price of coal. The Dealers Association does not appear to have discharged any other function which it might, except the function of keeping up the price of coal. The association could render invaluable aid in reducing the price of coal, if it adopted a regular system of transporting coal from the Island to Vancouver and also an economical system of delivery.

"There is further evidence that the coal operators will not usually sell coal to persons not coal dealers. This is a great aid to the dealers' combine and makes a steel-clad coal ring. The operators and dealers justify refusal to sell coal to others than dealers on the ground that it would not be fair to the dealers after having stocked up, to have the operators sell to those who otherwise might be customers of the dealers. They say that their practice in this regard is the same as generally prevails between wholesaler and retailer.

"There is undoubtedly some force in this argument but it must be pointed out that it operates as an aid to the dealers in keeping up prices and, if it does not bring the operators within the provisions of Section 498 of the Criminal Code under which the dealers are liable, it comes very closely to one of the offenses, against which that section is directed. If licenses are imposed on the dealers and returns required as I suggest, the evil probably would be removed. It might therefore be unwise to prosecute for past offenses but I certainly would recommend that any future infringement of the enactment should be properly proceeded against.

"A member of the Dealers' Association at Vancouver endeavoured to show that if the mine operators had restricted the sale of coal to a limited number of coal-dealers, an advance of one dollar per ton between pre-war days and the present would have sufficed to cover the increased cost of handling coal from mine delivery to delivery to customers, instead of the increase of $2.50 which actually has taken place. If this is correct, it is difficult to avoid the conclusion that the Dealers' Association has had it within its power to relieve customers of at least $1.50 increase by adopting correct methods of handling coal.

"The dealers have fixed uniform prices and have fixed them apparently not to meet the requirements of the most efficient among them but to ensure a profit to the least efficient. The public has lost the advantage of close competition in prices and the dealers who conduct their business intelligently and well while making improper profits have lost in the end by giving up the advantage to be gained by them in an open market from larger sales at lower profit.

"The evidence conclusively shows further that dealers frequently deliver short weight to consumers. This does not necessarily mean that there is a design to deliver short weight although in some instances there is evidence of that but it does show that the consumer suffers from short weight delivery whether the dealer and carter is in fault. The practice of short weighting should be put a stop to by a rigid prosecution of the offender, whether dealer or carter. A very few convictions would cure the evil."

Consultation of Miners, Dealers and Consumers Recommended.

Reference was made by Mr. Henderson to a suggestion made before the Commission that operators, dealers and consumers should meet and consult together with regard to the whole question of cost of coal production, transportation delivery, etc.

This idea he considers a good one, stating that it is not too much to hope that there could be devised "a delivery of coal by operators to dealers and by dealers to consumers, that would be more satisfactory to consumers and much cheaper without imposing on operators or dealers undue losses. The practice of endeavouring to reform by stormy methods, is, I believe, less likely to accomplish its object than reasonable consultation.

Mr. Henderson remarks that the operators and dealers are willing to enter into such consultation and expresses the opinion that the result would be reformation of some of the ways not only of operators and dealers, "but also of those of us who are consumers". He points out that the consumers would get new ideas on the subject of the best coal to use, the best mode of securing delivery and also the best mode of using it, particularly in furnaces. "No other communities in Canada", he asserts, "have such expensive modes of delivering coal, as Vancouver and Victoria".

Cost of Production.

Under cost of production, Mr. Henderson refers to the affairs of the two leading collieries of Vancouver Island, The Canadian Collieries (Dunsmuir), Limited, and the Canadian Western Fuel Company. He observed that a scrutiny of their financial records certainly shows that while the companies are doing fairly well now, their operations have not been highly remunerative in the past.

The following particulars are given with reference to these two companies:—

(*a*) *Canadian Collieries (Dunsmuir), Limited* :

This Company was incorporated originally with the following capitalization:

Common shares	$10,000,000
Preference shares	5,000,000
First Mortgage Gold Bonds	10,000,026
	25,000,026
Accrued Bond Interest	3,799,888
	28,799,914

The Company was re-organized recently as follows:

Common shares	1,127,000
Preferred shares	4,900,000
"A" Debenture Stock	5,000,000
"B" Debenture Stock	5,000,000
	$16,027,000

Up to date the Company has paid no interest on bonds and no dividends.

The operating figures of this Company for the year named are as follows:

1914-15	Loss	$316,036
1915-16	Loss	378,647
1916-17	Loss	348,222
1917-18	Loss	102,129
1918-19	Loss	3,804
1919-20	Profit	52,489
1920-21 (8 Mos.)	Profit	168,814

No provision has been made in the above figures for bad debt, head-office expense, bond interest, income-taxes or other charges not directly chargeable to operations.

Details of Coal Production Cost.

The cost of a ton of coal is stated as follows:

	1920-21 (8 Mos.)	Year 1919-1920.
Total mine-cost	$6.243	$5.600
Depreciation	.$00	.496
Depletion of coal area	.129	.126
Transportation, surface	.619	.596
Other charges (less credits)	.173	.035
Total cost per ton	7.664	6.783
Sale price per ton	8.095	6.870
Net profit per ton	.431	.087
Tons commercial coal sold	391,411	605,425

(*b*) *Canadian Western Fuel Company, Limited.*

This company was incorporated under the laws of British Columbia on May 9th, 1918. It purchased the assets and assumed the liabilities of Western Fuel Company, Limited. It has a capitalization of $3,250,000, and in 1920 made a profit of $388,555. Its sale of coal was 638,264 tons, of which 493,795 tons were sold in British Columbia. It sold at an average price of $7.125, made up as follows:

	Tons.	Average price.
Lump	380,961	$8.598
Nut	55,756	7.994
Pea	59,754	5.152
Slack	90,031	3.692
Washed Slack	51,762	3.590
	638,264	7.125

The cost of a ton of coal is stated as follows:

	Year 1920	Year 1919.
Total mine-costs	$5.951	$5.664
Depreciation	.279	.271
Depletion of coal area	.093	.123
Transportation, surface	.528	.509
Other charges (less credits)	.137	.147
Total cost per ton	6.988	6.420
Sale price per ton	7.718	6.383
Net profit per ton	.730	Loss .037
Tons commercial coal sold	531,695	483,157

Referring to the Granby Consolidated Mining, Smelting and Power Company, Limited the Commissioner points out that this Company only recently commenced production, that its coal operations are but ancillary to its smelting operations, that the major part of its output is used by itself and that only a small quantity has entered the market. Of the Middlesboro, Princeton, Fleming and Comox mines, it is stated that while they ultimately may be expected to send coal in quantities to the Vancouver market, their production at present is not large and much of it is taken up by the railroads and does not reach ordinary customers.

Wages and Management Not Open to Criticism.

In discussing the wages paid to coal miners, Mr. Henderson said "The wages paid are high, but there

is nothing connected with mining in this Province that is fixed on a fairer basis. Wages are re-adjusted at regular quarterly intervals by the High Cost of Living Commission, and rise and fall according to the rise and fall of the price of commodities essential to life.

"If all wages were fixed in the same way, that is to say, a fair basic wage to start with and then increase above that wage or reduction towards it as prices of commodities rose or fell, it would become evident very quickly that workmen were not unreasonable because their wages were very high but that those who controlled the prices of commodities were responsible.

"In this connection it must not be forgotten that coal mining in British Columbia, even more than elsewhere, is of a somewhat intermittent character and that employment is frequently not for the whole time, but is interrupted by idle days, often several in a week. This is trying for the workmen and bad for the operators, and probably can be cured only by increased demand for coal. It is mentioned as an incident, perhaps inevitable, and certainly resulting necessarily in higher wages than would be required were the employment constant for full time.

"I cannot refrain from remarking upon the evidence respecting conduct of mining operations on Vancouver Island. This evidence shows that the management is excellent, that the superintendents and others in charge are most experienced and intelligent men, and are familiar with the best and latest modes of mining, that the operations are well and efficiently conducted, and it reconciles one slightly to high prices, to learn that the provisions for the safety and welfare of the workmen are of the very best and that improvements are being constantly made. The evidence of this phase of the subject seem to me most satisfactory and convincing and is supported by General Leckie after a thorough investigation by him.

Supplies and materials have been and still are high in cost for mines as for other requirements. It must not be forgotten, however, that there is not much inducement to the operators at the present time to reduce operating costs. They are getting an extremely high price for their coal, and as long as that continues, they have little reason to complain of high wages or high prices for supplies.

Effect of Railway Freight Rates.

Taking up the question of cost of transportation, Mr Henderson observes that the freight charges, whether by rail or by water are high. By rail the rate is $1.65 per long ton, and by water about $.75. The water rate varies slightly, as transportation is carried on by independent tow companies and also by a number of dealers on their own account. Rail transportation has one advantage over the use of scows, in that it involves less handling of coal and occasions less pulverizing. It is suggested in this connection that transportation companies so far as concerned in the moving of coal in British Columbia, might be required to make returns showing operating costs, quantities carried, distances travelled and amounts realized for services.

"No constitutional difficulties", Mr. Henderson says, "would arise in the case of provincial companies. There might be great difficulties in exacting such returns from federal railways or navigation companies. My conclusion from the evidence submitted from this phase of the question, is that towing rates could be materially reduced."

It is explained that the report does not deal extensively with railway freight-rates affecting coal, as these, if too high, must be attacked before the Railway Commissioners. There was evidence, however, to show that without a reduction in freight rate really cheap coal cannot be obtained from the Interior mines.

Dealer's Spread.

As to the cost of coal to the dealers, the prices of the different grades F.O.B. the mines, are given as follows:

Prices	Lump.	Short tons.	Nut.	Pea.
On January, 1917.....	4.75	4.24	3.75	3.00
On December 1, 1920....	9.75	....	8.75	8.25
On February 6, 1921....	9.46	8.44	8.46	7.96

The additional cost of a number of Vancouver firms dealing in coal then are given and the Commissioner points out that from these the wharf, yard, and delivery expenses of the concerns mentioned varied in 1920 from $1.47 to $2.30, per short ton, and overhead expenses from $0.55 to $1.23. "The consumers", it is stated, "received no advantage by reason of this variation."

After referring to the fact that coal, when delivered by rail, is frequently short weight, and that while difficulty may have been experienced in obtaining redress, the railway companies, no doubt, would correct such shortages, if it were possible to have their attention called to it immediately. Mr. Henderson deals with the question of the cost to consumers, which comments already have been enumerated.

Industrial and not Domestic Coal-Consumption of most Importance.

In his introductory remarks, the Commissioner refers to the importance of the subject matter of the inquiry, because it must be recognized "that upon a cheap supply of bituminous must be built practically all industries". He points out that the great markets for this coal are the railroads, manufacturing industries, steamship bunkers, and coke and gas plants. These create the demands that make the market steady; the domestic consumption of coal is seasonal; the others are steady throughout the year. He says that as the interest of all those who consume coal, whether in large or small quantities, is advanced both directly and indirectly by cheap coal, he has endeavoured in his study of the subject to look at it from the larger and broader viewpoint.

Concluding this section of his report he says:

"Competition on the Pacific Coast in coal is apt to become very intense and this affords an additional reason for taking all legitimate steps in the direction of securing by every possible means cheap production, transportation and distribution.

"I have not gone into the great expense of an inquiry into the operating costs, output, sales realizations, and other matters connected with the coal mines in the portion of District 18 in British Columbia and under federal fuel control, further than to obtain prices of coal to consumers and railway rates to Vancouver. My reasons were that the special matters of inquiry arose, as I understand, on the complaint of citizens of Vancouver whose supply of coal does not come to any appreciable extent from District No. 18, and all the matters of inquiry have been or are being investigated by Federal authority and a duplication would be useless expense."

Comments of General Leckie, the Mining Engineer.

General R. G. E. Leckie, the mining engineer appointed in connection with the Commission, submits in his report recommendations which may be summarized as follows:

1. That legislation be enacted to deal with any combine formed for the purpose of maintaining a high price for coal.

2. That dealers should be licensed so that their operations may be conducted in the best interests of the public and that they should be limited in number, according to the requirements of the district they serve. This would eliminate unnecessary overhead expense.

3. That an effort should be made to secure special freight-rates for coal, in order that there might be closer competition in the larger markets between the different coal-fields.

4. That an effort should be made to eliminate the system of delivering coal in sacks, compelling consumers to make provision to receive coal in bulk.

5. That the calorific value, analyses, and the important characteristics of the different coal-seams mined in the Province should be officially established and made public for the benefit of the consumer.

6. That standard sizes of coal should be established officially. It is suggested that these sizes should be classified as Lump, Stove, Nut, Pea and Slack. The size of screen through which each of the first four mentioned should pass, is given, and as 25% ash, if unwashed and not more than 15%, if washed. Coal containing more than 25% ash should be sold as such without any restriction. It is further recommended in this connection "coal sold as per above classification and which on arrival at destination is found to contain more than 10% by weight of a size less that the classified coal which was ordered, shall be examined by some person, appointed for the purpose, and such rebate allowed the purchaser as occasion directs. By destination is meant delivery place, where the coal is delivered in bulk, by carload or scow, and any examination where such is demanded, must be made before the coal is unloaded from the car or scow."

7. That where the coal is sold in sacks, a set of scales must be carried on the same vehicle in which delivery is made to the customer.

8. That an official investigation be made into the question of the economical use of coal. This should include information as to the advantages of using mechanical stokers, so that the smaller sizes of fuel can be used where large coal is now required and also as to the possibilities of the utilization of pulverized coal. It is added "In connection with the economical use of coal the matter of saving by-products, such as gas, tar, benzol, from the coal should be considered. It is regrettable to think that such valuable products are being constantly wasted, and every exertion should be made to save them when such can be done economically."

9. That a short ton of 2,000 lbs. and not the long ton should be officially recognized as the standard unit of weight as applied to coal.

General Leckie deals exhaustively with the source of the coal supply of British Columbia, methods of production, treatment, transportation, distribution, geological conditions, and size and character of the coal seam.

Dealing with source of supply, he points out that Vancouver and New Westminster, Victoria, and the large municipalities of the Province get most of their domestic coal from Vancouver Island. For instance, Vancouver, New Westminster and districts are estimated to absorb 23,000 tons per month of Island coal.

He then goes on to describe the various Coast coal fields, dealing first with the Nanaimo area and giving some very interesting particulars of the Wellington, Newcastle, and Douglas seams. The calorific value of the Wellington coal is given as b. t. u. 13,261; of the Newcastle b. t. u. 12,951; of the Douglas b. t. u. 13,200. The Comox area next is dealt with and a typical analysis of washed Comox coal is shown to have a calorific value b. t. u. 13,590.

Taking up the Nicola-Princeton field, it is shown by a typical analysis of the Middlesboro coal, to possess a calorific value of b. t. u. 11,720.

The methods of production are described in detail and in this connection, General Leckie says:—

"In all mines the safety of the men underground was given the greatest consideration. The government regulations in this respect are excellent and are conscientiously carried out. Nearly all the mines use electric lamps underground, and the arrangements for an adequate supply of air throughout the mine workings are first-class. The systematic inspection of the mines for the presence of gas is thorough."

An account is given of methods of transportation and of distribution. With reference to the latter, General Leckie recommends as the most efficient means of unloading, a portable conveyer rested on the scow, and the other was elevated above a screen on the dock. The coal is shovelled on to the conveyer and is carried by it to the screen, over which the coal passes directly into the sack set on the scales. It is emphasized that the consumers should be educated to the economical use of coal and not demand all lump when his purpose could be just as well served by taking a certain percentage of the smaller sizes.

Management of Mines is Excellent.

Under "General Remarks," and dealing with mine operations, General Leckie refers to certain criticisms suggested in the evidence with regard to the Vancouver Island mines. These, he says, were apparently made without knowledge of the actual conditions. He found efficient management; mining methods most suitable to local conditions; the use of coal-cutting machinery, wherever conditions would permit: the use of electric power, wherever economical installation could be effected (the Comox mines are operated exclusively by hydro-electric power), careful handling of the coal, to prevent breakage of lump; and preparation of the coal for the market well carried out. He states that approximately 40 per cent of the product is washed, while in the United States the average is less than 10 per cent. He adds, "Every consideration is shown for the safety of the men encouraged in all the mining localities, and good recreation ground provided."

Reasons for Increased Coal Cost.

Reasons for the high cost of coal as compared to the price per ton in 1914 are given as follows:

1. Increased cost of labour.

2. Exhaustion of the more cheaply-mined section of the coal seams and consequent gradual increase in distance to the working faces, entailing larger haulage-ways, which have to be kept up, and necessitating longer distances for the miners to travel to their work in working hours; in some cases in old mines, almost 20% of the time is taken up in this way.

3. To increase difficulties encountered underground in the way of "faults", "wants", and other irregularities in the formation of the seam.

4. To increased salaries and wages for management and in offices. These fixed expenses, however, vary per ton, approximately in inverse ratio to the coal produced.

5. To increase in price, placed on the coal to permit of a profit being made on the production by the principal operating companies; previously some of the principal companies have been operating at a loss.

6. To the increase in pay to officers and crews concerned in the transportation of the coal.

7. To the increased cost of fuel at the bunkers and of supplies.

8. To the increased cost of labour in handling, screening, sacking and delivering coal.

9. To increased salaries and other office expenses in connection with the dealers, firms. This includes increased rentals.

10. To the increased number of coal dealers engaged in coal business. This necessitates fixed expenses out of proportion to amount of coal handled. There apparently exists among the dealers an agreement to determine the selling price of coal and thus prevent the competition which might eliminate from the business those unable to handle coal cheaply.

11. To the great demand for lump coal exclusively, when a mixed product would serve the purpose equally well.

12. To the desire to have coal delivered in sacks, instead of in bulk. This is chiefly owing to the faulty construction in buildings; no arrangements being made to receive coal in bulk.

Report of the Chartered Accountant.

Interesting statistical information regarding the financial condition of the various collieries of Vancouver Island and the lower mainland, together with statements of the financial affairs of Vancouver and Victoria coal dealers, are given by Mr. A. P. Foster, Chartered Accountant, in his report.

In addition to giving details of the cost of mining coal at the collieries of the Canadian Dunsmuir Co. and the Western Fuel Co. (elsewhere quoted) Mr. Foster deals also with the Nanoose-Wellington Collieries, Ltd., the Granby Consolidated Mining, Smelting, and Power Co., Ltd., and refers to the mainland operators. With respect to the former, as their product does not materially affect the domestic market, it is not of special importance. Regarding the mainland operators, he points out that their output is so small as to be negligible.

In regard to the Canadian Collieries (Dunsmuir), Ltd., it is observed that this company is in a very serious financial condition. The deficit at 30th June, 1920, amounted to $4,934,377, and accrued bond interest at 30th June, 1920, represented a debt of $3,799,888. The printed accounts circulated to its shareholders contain reference to a plan of reorganization. This plan, it is stated, has ben carried into effect. It consists of writing down the ordinary share capital by 70 per cent. and, on the other hand, the capitalization of the interest owing to the bond-holders. The net result is that the capital of the company has been reduced by approximately $9,000,000.

Taking up the affairs of the Western Fuel Company it is pointed out that there are 32,500 shares of $100 each, held by residents of Canada and the United States, and that dividends in all amounting to $9.31 per share have been paid. In the year 1920 there was a net profit of $388,555. Provision has been made for the depletion of mines, at the rate of approximately $10 per ton and depreciation has been provided for, and a provision for contingencies at the rate of $0.05 per ton. This is considered sound accounting and in accordance with common practice. The combined capital and surplus of this company, as at 1st January, 1920, was $3,349,988, therefore the profit of $388,555 represents a return of 11.60 per cent. It has been stated that the company has been selling its product abroad at a less price than the local concerns, and for this reason Mr. Foster gives figures taken from the company's sales register, showing that both in 1920 and in 1921, the sales price outside the province, was the same as that to local dealers.

Particulars are given of the average price received per ton, the average cost and the average net profit of of the firms of Evans, Coleman and Evans; MacDonald, Marpole Company, Kirk and Company; McNeil, Welsh and Wilson and L. M. Deither Coal Company, Ltd., Vancouver, and the firms of J. Kingham and Company,

---

The Canadian Western Fuel Co., of Nanaimo, B.C., has been re-organized as a $5,000,000 corporation to be known as the Western Fuel Corporation of Canada, Ltd. The head office will be in Nanaimo. It formerly was at San Francisco, Cal. but at the time of the last re-organization, in the first years of the War, was transferred to Nanaimo.

A MONTREAL LETTER.

By ALEXANDER GRAY.

What Gold Mines are Giving and Getting.

International amenities do not count for much when it comes to a matter of something other than gold being proferred in liquidation of obligations payable in the yellow metal. Theoretically, of course, the gold standard is fairly well established, and those who have gold are fortunate even if the penalties of adverse exchange are grievous. But it seems as though the American Chiele Company might have displayed a trifle more tact when it started out to compel the Somerville Paper Bag Company of Ontario to pay off a mortgage and interest on the same in gold. The Canadian Company tendered the amount due, $50,000, and $3,098 interest on it, in Canadian money. The Chiele Company adhered to the strict letter of the mortgage. Canadian currency having depreciated, the Chiele Company insisted upon receiving New York Funds. So a suit was instituted.

By and by the American company is within its rights, but the embargo placed upon gold until July 1st, 1922, and the fact that gold no longer is current in Canada, at least raises the question as to how gold mines are going to fare with their bullion, for which they are now getting a premium amounting to the difference in exchange on New York. It would be easy enough for the Somerville people to let the Chiele Company have New York funds, however much they dislike to fork over $5,000 or $6,000 more than the principal and interest. That is a misfortune Canadians doing business with the States have to undergo. At the same time, Canadian companies selling Canadian products to the States are not waiving their right to exact New York funds, thus obtaining a handsome premium.

As to the duration of this situation, authorities in the matter do not expect to see the equilibrium of international exchange restored altogether for some years. A re-arrangement of Great Britain's debt to the United States would favorably affect exchange, no doubt. The premium is rather prejudicial to American trade — and continental fiscal systems are so deranged their readjustment will be more or less evolutionary. Debtor nations have a long way to travel before they reach normal conditions. Great Britain can fund what it owes to the States, but Allied Nations of Europe cannot so easily deal with their debts to Great Britain. Consequently gold is to be in continuous demand, and more especially because continental countries worked their printing presses over-time. This will be a compensating factor for Canadian gold mines, pulp and paper and asbestos producers, who stipulate for New York funds.

The Exchange Premium on New Gold.

South African gold producers are alone in presenting what the premium upon their bullion amounts to by reason of exchange conditions. Possibly the $15,833,178 dollars in gold produced last year in Canada means a million and a half in special revenue. Only $1,642,000 was exported in gold bullion, gold bearing dust nuggets, gold in ore, etc. The remainder of more than ten million was purchased by the Ottawa Mint. Transvaal production continues about steady. The world at large last year accounted for seventy million sterling, taken at the standard value, as compared with ninety-five million sterling a few years ago. In April the premium upon Transvaal gold was 23.6 per cent. equal to £5 5 shillings and a penny per fine ounce. Since the establishment of a free market in gold, in July,

1919, workings costs advanced and offset some of the premium upon gold. While the premium lasts, however, gold producers may submit to excessive working costs. Otherwise many companies would be embarrassed.

How important is the gold premium is evidenced in recent reports from the Union Government Mines Department at South Africa. In January the increased value of Transvaal gold over standard price was £657,-227, or only £90,000 less than the value of the diamond output of the country. The total mineral production of the Union of South Africa in January, with gold at normal, was £4,030,741, and £4,687,968 with gold taken at estimated increased value. In February the excess realized was £522,783. A commentator points out that the premiums of 18s. 9d. per ounce amounts to considerable more than the diamond output, which was £469,749—about £4 per carat—and more than the coal output, valued at £426,951. The March premium on gold was £631,479. As to diamonds, the comparison is rather unfair; for diamond markets are too askew to permit of production to capacity. That the gold industry of South Africa is prospering, and that coal is keeping pace is unquestioned, but diamonds are not so lustrous. Gold is gilt-edged. In the first three months of this year it brought to the Transvaal mines an extra of £1,811,489. This is the tribute to mines that lead all those mineral industries of South Africa which last year paid £14,500,000 in white wages; £8,250,000 in native wages, and £18,000,000 for stores—a combined increase for the year of £5,000,000. In more ways than one gold mining pays, pays, pays.

Possible Re-Investment of South African Gold Revenues in Canadian Mines.

During a recent visit to Canada a noted Mining Engineer made the statement that there is a large amount of South African mining money at New York ready and willing to be invested. The sum specified is incredibly great, and yet South African mining groups, since they were conceded an open market for their bullion may have decided to let some of the proceeds therefrom remain on this side of the Atlantic. The same mining engineer also is alleged to have manifested disappointment over the character of the generality of Canadian proposals submitted to him. Capital is very scrupulous these days. Vendors and promoters have to write down their ideas as to the fitness of things.

THE LATE AMBROSE MONELL.

Canada lost a real patriotic friend by the all-too-early death of Ambrose Monell.

In Canada he had abiding faith; for Canadians he had lasting affection, an affection such as he was capable of cherishing.

His business methods always were constructive. Never did he give thought to a destructive purpose. Ably seconded by Mr. W. A. Bostwick, his successor in the presidency of the International Nickel Corporation of New Jersey, no finer type of scientific executive has devoted his superb judgment to the development of Canadian industry.

With Mr. Bostwick, they planned expansion. During the war he devoted the best that was in him to the furtherance of allied policies. What Messrs. Monell and Bostwick achieved will never be told by the former nor ascertained from the latter—the most reticent and unobtrusive of industrial chiefs.

Downing Street, Washington, Ottawa, the Quai D'Orsay, know—that will have to suffice. Through it all Mr. Monell preserved his characteristic buoyancy, whatever he undertook he never half-heartedly finished. That he was misunderstood at times—by a few Canadians—brought him regret; yet he could not cherish animosity nor resent insularity. That he died in his prime after distinguished service in the American air forces is more deplorable than the generality of those who thought they knew him comprehend.

He had wisdom and wealth beyond his years, but the probity of those years is his finest epitaph.

It was my privilege to have access to Ambrose Monell in thought as well as in deed. I recall that early morning chat in which he enthusiastically produced the personnel of those who followed his lead in subscribing to the capital of the Canadian Exploration Company. His actuating motive was to enlarge Canada's industrial map. Money—multi-millions beyond his initial needs—was available. The central idea was to combine Canadian and American forces, to unite international capital in developing a greater Canada. To my somewhat cynical remark that "if you are seeking to underwrite the Universe—you have the people on that list to do it—but I am afraid it is likely to be misinterpreted," Mr. Monell, who was too open-minded to do otherwise than think straight, demurred.

My off-hand comment rather disconcerted him. "Why," he argued, "should I be misunderstood. Anything is possible in Canada. We may find another Utah or Inspiration copper mine. Your western coal fields will invite large capital. I am going to try to do bigger things for Canadian mining industrialism.

Mr. Monell was true. He was misinterpreted in that instance, but he never deplored having done what was right. Small enterprises and little men he ignored. Chicanery he detested. When he and his assistants realized the Milleret Mine at Miller Lake was good enough for some but not big enough for others, a proposal was entertained. It was submitted by a party wishing to obtain control. Upon consultation, the price was made satisfactory, and the purchasers departed; but not before Mr. Monell had insisted as a pre-requisite, that the minority interest should be given the same terms.

Later, it occurred to Mr. Monell the intending purchasers might induce the minority interest to accept less than the majority was receiving. So, he wired to Elk Lake, had a special messenger sent to the Milleret —and the messenger reached the mine a short while ahead of the would-be purchasers—who intended to do as Mr. Monell surmised.

That was Ambrose Monell's clean-cut style. As a youth he was one of the Carnegie galaxy-steel-makers de luxe, as a man and millionaire he was superfine.

A despatch from Vancouver reporting the export of Vancouver Island coal to South Africa indicates that the excellent position of British Columbia ports as coal-distributing centres is becoming known. A study of the globe, and of the coal-possessing countries that have access to the Pacific Ocean, will show that Vancouver and Prince Rupert must some day become the shipping ports for Alberta and British Columbia mainland coal. The Panama Canal has also completely altered the strategic position of Vancouver with regard to access to countries bordering the Atlantic Ocean.

Northern Ontario Letter

THE SILVER MINES.

The Cobalt District.

The Mining Corporation of Canada will resume general operations on May 25th, Cobalt properties. The mine is in very good condition, particularly the Buffalo side, where a force of men has been engaged for some time on the work of preparing an outlet for the ore from the Buffalo mine to the mill on the adjoining Townsite mine. The mill is also in excellent shape, in fact is officially stated to be in the best condition in its history, the recent alterations and additions having added about fifty per cent to the capacity of the plant.

Recent reports regarding the discovery of a three-foot vein of high-grade ore at depth on the O'Brien mine, have been enquired into, and the "Journal" correspondent learns officially that there is not the slightest foundation for the report. "Unfortunately, the discovery exists only in the imagination of those who have reported it," is a remark which one of the O'Brien officials offered to the writer.

In an interview with F. L. Culver, president of the Beaver Consolidated Mines of Cobalt, it was learned that under present conditions no effort will be made to re-open the Beaver. Mr. Culver stated that the commercial end of the enterprise must be taken into consideration, and that under the present cost of producing silver and the low price which the metal commands on the markets, it would be profitable to undertake general operations at this time. In the meantime, however, the company seems to be in line to likely receive revenue at an early date from the Kirkland Lake mine, of which it controls approximately seven-eighths per cent, in addition to having upwards of $100,000 due in cash to the Beaver Consolidated Treasury from the Kirkland Lake Gold Mines.

The Nipissing mine continues to produce silver at the rate of about $150,000 a month. With the improvement which has taken place in the efficiency of the workers, and the lower cost of material, it is expected this company may reduce its operating costs somewhat further during the balance of the current year. This company has recently held the best record in point of low operating costs per ounce of silver produced, and it is believed the record may be still further added to.

The work of re-opening the Oxford Cobalt and the Victory Silver Mines, situated in the South-eastern Coleman, is proceeding satisfactorily. Concerning the Silver Cliff, nothing definite has so far been ascertained in respect to the reports that the property might be re-opened within a short time. It is learned, however, that the option held by the Colonial Company on that part of the property lying below a depth of 500 feet has been dropped, while the lease on the surface down to a depth of 500 feet which was held by the Northern Customs has also been dropped. These facts lend some weight to the reports that the Silver Cliff Company itself might decide to go ahead with work.

At the Conagas, upwards of 500 tons of ore is being handled daily, and the average recovery is about eight ounces of silver for each ton of ore treated. This would indicate a monthly production of about 120,000 ounces which, at 60 cents an ounce, would be at the rate of about $72,000 or at the rate of about $864,000 a year, not including the premium on United States funds for which the silver is being sold. It is by reason of the treatment of this large tonnage and by paying exceedingly strict attention to economy that the Conagas is is able to treat such low-grade ore as that containing only eight ounces of silver per ton.

The fifteenth annual statement has just been issued by the Peterson Lake Silver Cobalt Mining Company. It contains no surprises, and is quite along the lines as had generally been understood during the year.

W. A. Lamport states "In common with other mining companies we have experienced a very trying year. When the last annual report was sent out we were hopeful that the price of silver would continue around a dollar an ounce in which event we would have had considerable profit to show you on our operations from our low-grade ore, but the rapid fall in the price of silver to under 60 cents per ounce, made it impossible to continue operations and as stated in the manager's report we ceased operations altogether on the 18th December, 1920, and at the present time are not intending to resume the milling of our low grade ore until the price of silver has considerably advanced.

"At the time of the last annual report we had great hopes that our new mill and plant which we had been erecting and installing in conjunction with the Dominion Reduction Company, would be running at capacity before July 1st, 1920. We were, however, doomed to disappointment on account of the deliveries of our machinery being much delayed and when the mill was started on the 9th September, there were to be solved many milling problems referred to in the manager's report, that made it impossible to operate at capacity and necessitated a complete shut-down owing to shortage of power and the low price of silver early in November. We were able, however, to demonstrate that the silver content per ton of our tailings dump was going to run higher than estimates.

"In making our arrangements for the erection of a new mill and the installation of machinery we had received very favorable terms as to credit and have paid off part of our indebtedness, but there will be due a balance on our notes for plant and machinery of some $27,000 to be met in the months of June, July and August. For the purpose not only of discharging our obligations but of carrying forward our development work in very favorable territory, as pronounced by mining engineers, we sent a letter to shareholders on March 7th placing our situation before them and asking them to subscribe to our preference issue. The response has not been very satisfactory. We therefore now urge again upon the shareholders and in their own interests, the absolute necessity of meeting their obligations and for this purpose of taking up this very favorable issue. The directors have done their part and unless subscriptions are forthcoming the company will have to resort to some other method of financing or cease mining altogether although it has assets, actual, tangible and available when the time and opportunity offers, of great value."

In his statement C. V. Filteau, manager of the Peterson Lake summarises the progress made during 1920. Mr. Filteau states that 2,167 tons of low grade ore was shipped during the year, the average grade being a little over 24 ounces per ton, or containing a total of 53,527 ounces of silver. High grade shipments amounted to upwards of five tons containing a total of 13,994 ounces of silver. The total amount of silver taken from the mine during the year was 67,521 ounces.

As of the end of the year the ore reserves were estimated at 13,600 tons containing 126,000 ounces. Of this, 32,000 ounces lie at the 4th and 5th level [illegible]

while 80,000 ounces are contained in 10,000 tons of dumps at Cart Lake adjacent to the mill and 14,000 ounces in the Peterson Lake dump.

Mr. Filteau sums up the question of milling Peterson Lake tailings in these words: "It will necessitate an additional investment of about $4,000 to render the plant adequate to treat the objective of 10,000 tons a month, and resumption of operations on this tonnage basis would only be profitable in the event of a material increase in the price of silver taking into consideration the present reduction in working costs."

Elk Lake and Gowganda Field.

Arrangements are being made to re-open the Paragon-Hitchcock property near Elk Lake, as well as the Triangle Silver Mines in the Township of Auld (formerly known as the Kenabeek.)

It is also understood that the directors of the Regent Silver Mines are planning a trip to the property about the last of May with a view to arranging to resume operations on their Elk Lake property.

Advice has been received by Robert Gamble from Montreal to hold himself in readiness to start work on the Silver Bullion property at Gowganda.

THE GOLD MINES.

The Porcupine District.

It is understood that the Dome Mine is producing upwards of $200,000 a month and may exceed $250,000 a month when the mill is brought up to full capacity within a reasonably short time. Developments at depth continues favorable, and the average grade of the ore is now definitely much higher than early estimates indicated.

At the Hollinger, the weekly production amounts to close to $200,000. This is being achieved by treating about 3,200 tons of ore daily and recovering close to $9 per ton.

The McIntyre-Porcupine continues to produce between $175,000 and $185,000 a month. The mill treats an average of approximately 550 tons of ore daily. The machinery now on order, delivery of which is expected daily, will be installed as quickly as possible and before the end of the current year the mine is expected to be producing close to $9,000 daily from an average of about 900 tons daily. This would indicate that at the beginning of the coming year the mine will be in a position to produce gold at the rate of about $3,250,000 annually.

It is reported that negotiations are under way with a view to merging the properties of the Dome Lake Mining and Milling Company with the West Dome Consolidated. The properties adjoin each other, and on the West Dome there is a considerable tonnage of medium-grade ore in sight, while on the Dome Lake there is a mill which will be able to treat between 75 and 100 tons of ore daily. In some quarters the merger is believed to be assured, while among certain shareholders some doubt is still expressed.

Work on the property of the Goldale Mining Company is to be proceeded with immediately. This was originally in the hands of the Bewick-Moreing interests and is considered to have favorable prospective merit.

The entire entire Porcupine district seems to be alive with industry and the scope of the work exceeds the proportions reached in the previous best days of this field. It would appear as though this increase in activity is to continue for a long time as the work at the big producers increases and while reports keep coming in of new prospective work on outlying properties.

The Kirkland Lake District.

A party of visitors from London, England, accompanied by J. G. Latilla, have just concluded a visit to Tough-Oakes Mine at Kirkland Lake. Arrangements are being made to carry on operations on a big scale, and this mine, together with the adjoining Burnside which is also owned by the Kirkland Lake Proprietary (1919), Ltd., will join the producing list by the end of the present summer.

At the annual meeting of the Argonaut Gold, it was stated that a mine of moderate size is already assured, while the plan of further development work offers good promise of the property developing into one of quite considerable size.

Gold is reported to have been found in the township of Bryce near the Elk Lake branch of the T. & N. O. Railway. About fifty prospectors have gone in and a large number of mining claims have been staked.

Lake Shore Mines, Ltd.

Concerning the Lake Shore Mines, Ltd., of Kirkland Lake, a very great deal has been written unofficially, and comment of various shades and form has been bandied about, so much so that many people have a wrong impression of this mining company and the condition of its property.

The company has never endeavored to get publicity, nor has any effort been made to withold any valuable information from the public. These factors in themselves have tended to make the enterprise a favorite among mining men and that part of the public which speculates in mining shares.

Statements have been printed, pointing out that the orebodies are exceedingly wide, some forty feet in width being mentioned. This impression has been denied as a consequence of discussing the matter with officials, although the authors of the wrong impression proceeded to interpret the denial as an effort on the part of the statement to show that the Lake Shore orebodies are narrow. The fact is that the orebodies are not narrow neither are they forty feet in width.

The facts regarding the size of the orebodies are these, officially. The main stope on vein No. 2 as opened up at the 400 ft. level which is the more highly developed part of the mine is 350 feet in length, has an average width of eleven feet, and contains gold values which average $28.37 to the ton. In this one stope there are 18,702 tons of "broken" ore on which all mining charges have been paid and with no deferred charges entered up against it. This broken tonnage is sufficient to keep the present mill operating at full capacity for a whole year without striking another blow in the mine. Such is not the intention of the management, however, in that further development work is proceeding space and the ore coming from development alone is adequate to keep the mill running at full blast. This means that the ore already broken and that being blocked out is being stored up as a tremendous reserve which will eventually assure the operation of a greatly enlarged milling plant at such time as the company decides the mine has been developed to the desired point.

Indeed, there is no record of a similar achievement in the history of gold mining in Ontario where a property, equipped with a little 60-ton mill has been able to not only finance the expensive work of developing big ore reserves and the construction of a larger mill but to concurrently pay at least a moderate rate of interest on the par value of the shares. "The Lake Shore is only a baby, as yet," said an official to the writer,

"toddling along in its infancy." But, as commented upon by one who had just concluded a trip underground: "It's some baby, though."

Further, as regards the size of the orebodies, it has been learned by the writer from observation that No. 1 vein at the 600-ft. level where recently opened up is equally as wide and equally as rich as found in the main stope on vein No. 2 at the 400-ft. level. Furthermore, a second important stope is being opened up which is intended to be at least 300 feet in length and to be a close rival to the main stope above mentioned.

Regarding the Per Ton Cost.

In connection with the per ton cost of operations at the Lake Shore, considerable discussion is heard and, coupled with street remarks about the great riches of the mine, is to be heard the comment: "—But, take a look at the costs."

To those who are keeping mining operations under close observation, no comment and the meaning it implies could be more unjustified than in the case of the Lake Shore. In this respect, the facts are these: The company is employing a force of from 85 to 100 men and is developing the property on an extensive scale. The number of men employed is entirely out of proportion to the small daily tonnage which the little mill is able to treat and the aggregate cost of work is necessarily great for the reason that only a fraction of the expense incurred is in connection with supplying ore for the mill while the great bulk of work is for the purpose of providing big reserves with which to feed a big mill in the future. In a word, a large amount of energy and expense looking to future great revenue is being incurred, and the whole thing is being carried by the present little mill. It is all being charged against the small tonnage being treated so that no stored-up charges will lie against future production. For these reasons it is a marvel that this total current expenditure does not amount to a great deal more than an average of around $14 or $15 a ton on the ore being treated. Once this daily tonnage is increased, the per ton costs will automatically decline to a very low figure.

The physical condition of the property is exceedingly good, and the ore has an average per-ton gold content greater than any other gold-producing mine in Canada. The management is highly efficient and compares favorably with the best in the country, while the Company's policy is conservative and sound.

PERSONALS

Mr. F. L. Culver, president of Kirkland Gold Mines, is visiting the company's mine at Kirkland Lake.

Mr. H. G. Latilla, of London, is visiting the properties of Kirkland Lake Proprietary, Ltd.

Mr. R. P. Rogers, who was for some years manager of Coniagas Mines, Ltd., is visiting northern mining districts.

Mr. J. M. Dunwoody of the firm of Stroyan Dunwoody Co. of Winnipeg was in Toronto the past week arranging for the opening of a branch office to cover, particularly, the northern mining districts. This firm represents the well known English firm of Craven & Speeding Bros. of Sunderland, who specialize in the manufacture of steel cable particularly adaptable to the mining industry. It is the intention of this company to place in the Toronto office a man of wide experience in steel cable manufacture to take care of the business in the North.

Mr. W. A. Donahue has been appointed mining recorder at South Porcupine, succeeding Mr. G. H. Gauthier.

Mr. R. Enns, manager of McIntyre Porcupine Mines, Ltd., is in Toronto for a few days.

BRITISH COLUMBIA LETTER.

The Metal Mines.

It was to be expected that, with the discovery of oil in the Mackenzie River Basin just outside British Columbia, there would be reports of promising indications in the same or adjacent latitudes in this Province. This observation does not refer to the Peace River Country prospects, for they have been before the Government for some years and exploration was underway before the Fort Norman excitement took place. It does apply, however, to the word of oil found near Burns Lake, on the Grand Trunk Pacific Ry., and to news of important finds both of oil and coal in the Coal River region, which river empties into the Liard River in the far north of British Columbia. Of the two latter nothing official nor definite, is yet known but they are to be investigated. J. D. Galloway, resident Government mining engineer, no doubt will visit the Burns Lake section during the Summer and his findings, together with those of other competent engineers expected to make an inspection, will be awaited with interest. The Coal Creek area probably will be inspected by George Clothier, government mining engineer, before the close of the season.

Prince Rupert, B.C.—While on the surface things may appear to be quiet there is a gradual and steady development of the Portland Canal area, according to D. B. Morkill. The immediate future he explained depended on the price of silver to a large extent and he was confident that it would go to eighty or ninety cents before long. The Premier Mine, he said, would be a bigger proposition that most expected. Last season, he stated, a million dollars worth of ore was shipped by sleigh. This was not a silver mine primarily. Mr. Morkill said but was a gold mine, although the ore contained high silver values. Because of the shortness of the season in the district development necessarily was slow but he thought that it might be confidently anticipated that, in time, other Premier Mines would be proven. This year the Leckie and Tubman and other prospects would be opened up on the Bear River. The Redcliff Mine also had been sold and would be developed. What was wanted, he declared, was not a boom but sonnd and steady development. He urged the people of Prince Rupert to work to that end and commended the forthcoming excursion to the district of businessmen of Victoria and Vancouver as a move likely to redound to the advantage of the Province, as it would tend to the education of the visitors as to the resources, the possibilities and the objects of mining men and other residents of the outlying northern sections of the country.

Alice Arm, B.C.—There is more activity in the Illiance River Valley than in any other section of this district at present. Some development work is being done on the Bellevue Group and the Silver Star. A number of claims also are being opened up by A. J. Bowen, former smelter superintendent at Anyox. In the Kitsault Valley there is no work in progress at present, the Dolly Varden being idle with no information as to what the plans are for the forthcoming season. A. J. T. Taylor, who has returned from the Old Country, has not yet made a statement on this point. He states that much depends on the silver market, which of course is not very enlightening, but it is understood that it is planned opening up on a small scale at any rate and probably doing some development work. The La Rose Group on the Illiance undoubtedly will receive further attention during the summer.

Trail, B.C.—Ore receipts in gross tons at the smelter of the Canadian Consolidated Mining and Smelting for the week, May 1st to 7th, aggregated 9583, bringing the total for the year up to date to 149,399 tons. Of the former figure the mines of the company contributed 9,583 tons and the Sally, of Beaverdell, 33 tons.

Slocan City.—It is predicted that the new concentrator which is being constructed at the Ottawa Mine, Springer Creek above Slocan City, will be turning out its first concentrates in a little over a month's time. The plant was designed by L. H. Biggar, who is superintending the installation. There is enough mill feed on the dump to keep the mill busy for two years and, while this material is being used, development work will be prosecuted.

Fort Steele, B.C.—Hydraulicking operations are being started on Wild Norse Creek by the Gamble Mining Company. At the outset some trouble was experienced with the pipe line but as soon as repairs are made work will be resumed and a successful season is anticipated.

Victoria, B.C.—William Fernie, 84 years old, pioneer prospector, mine operator, and railway promoter, died in Victoria on May 15th last. The City of Fernie, B.C. was named after him and he was the original discoverer of coal in that district. His first work as a mining man was done in the Australian mines of Bendigo and Perdue. Coming to British Columbia in 1860 he located in the Cariboo where he was engaged in mining for many years. In 1873 he was appointed Gold Commissioner for Canada which position he held for four years. On resigning he joined Col. C. Baker and other western Canadians in the effort to obtain a charter for the British Columbia Southern Ry. In this he and his confrères were successful and in 1887 Mr. Fernie located the coal fields of the Crow's Nest Pass. With the opening of these fields there grew up in that locality the now flourishing community of Fernie, which, as stated, was so named in honour of the man primarily responsible for its existenece.

THE COLLIERIES.

What is to be the result of the Coal Inquiry held by Commission on authority of the Provincial Government? Commissioner Henderson and his associates have reported and the chief point of their findings is that a combination of Vancouver City Coal Dealers has existed, that consequently competition has been stifled, and coal maintained at a uniform price among all those engaged in its distribution. Is the report to be followed by a material reduction in retail prices? It is hardly likely and yet the public is looking for such a development.

One outcome is the announcement by the Hon. J. W. de B. Farris, Attorney General, that consideration is being given to the question of those who have been guilty of the offence of joining in a "combine" in restraint of trade. This statement was made shortly after the Commission's Report was made public. Nothing further has happened since except that the Vancouver Coal Dealers' Association has held a meeting at which the organization was formally dissolved. But it is questionable whether this will lead to cheaper coal because, to use the words of W. C. Kirk, one of the members of the

now defunct association, "coal now is being sold for $14.00 and it can't be sold any cheaper unless the collieries reduce their prices."

A suggestion made by Commissioner Henderson that has met with much favourable comment is that a round-table conference be arranged between representatives of the operators, the dealers, and the public at which all questions regarding coal production, coal distribution, and coal consumption should be discussed. The Commissioner's idea is that thus all concerned would be enabled to obtain an intimate knowledge of the problems of the industry and by co-operation and understanding it might be possible to formulate plans that would result in more economical production, less duplication in distribution, more intelligent buying on the part of the public, and, consequently, the introduction of more satisfactory conditions generally, together, perhaps, with somewhat reduced costs all round.

R. R. Wilson, superintendent and resident manager of the Granby Consolidated Mining & Smelting Co's Collieries at Cassidy, Vancouver Island, for the past two and a half years has resigned and on the 1st of June next the duties of his office will be assumed by Charles Campbell, one of the company's well-known officials, he having been for 21 years superintendent and resident manager at Phoenix where operations ceased some time ago. Mr. Wilson is a son of W. R. Wilson, president and general manager of the Crow's Nest Pass Coal Company. He took charge at Cassidy before the industry was on its feet, completed the construction started by the Taylor Engineering Company, built up an efficient and smooth running organization that carried production from 100 tons a day in 1919 to 1200 tons a day in 1920. This was done in a virgin field and without extraction of pillar coal. It is authoritatively reported that it now is possible, should trade conditions warrant it, to increase the daily output to 1500 tons without difficulty.

Coal production for the month of April in British Columbia stands at about the same figure as that of March. In the Vancouver Island fields the output for March was 134,837 tons while for last month it was 135,669 tons, an increase of 832 tons. It will be seen, therefore, that there has been little change in conditions, supply and demand apparently have not materially altered. The most notable increase is in the Nicola Princeton Field, where the production of the Middlesboro Collieries, the Fleming Coal Co., and the Coalmont Coal Company have all risen, the total jump being 2,093 tons. In the Crow's Nest Pass there has been a decline of 8,678 tons, the figures being 68,739 as against 60,061 tons.

Following are the detailed statistics of output for the month of April:

BRITISH COLUMBIA APRIL COAL OUTPUT

Vancouver Island Collieries

Mine	Tons
Canadian Western Fuel Co.	39,773
Canadian Collieries (D) Ltd.	
Comox	40,336
South Wellington	7,756
Extension	17,512
Pacific Coast Coal Mines	Nil
Nanoose Wellington Coal Co., Nanoose	2,792
Granby Colliery, Cassidy	26,584
Old Wellington (King & Foster)	916
Total	135,669

Nicola-Princeton District.

Middlesboro Collieries, Middlesboro	5,133
Fleming Coal Co., Merritt	2,507

Coalmont Collieries, Coalmont	6,278
Total	13,918

Crow's Nest Pass District.

Crow's Nest Pass Co.	
Coal Creek	32,979
Michel	20,818
Corbin Coal & Coke Co., Corbin	6,264
Total	60,961
Total for month	309,648

The exploitation and the safeguarding of foreign markets for Canadian coal, and the preparation of coal produced in Canada for the domestic market, were subjects discussed in an interesting manner by Arthur V. White, consulting engineer of the Commission of Conservation of Canada, in an interview given recently in British Columbia. He said:

"There should be a strict, yet reasonable inspection and grading of coal both for foreign export and for home consumption. The United States gained great advantage in capturing foreign coal markets due to the exigencies of the war. The American coal operators, however later found that some of these captured markets were reverting to British and other coal operators because the European buyer found that he could not, in many cases, rely upon the uniform commercial integrity of the imported coal.

"Consider, for example the case of Denmark. According to official statements, Danish importers of coal have found it necessary to complain regarding breach of contract.

"'It happens too often,' says one authority, 'that shipments have a considerable short weight or that the coal shipped is of a quality inferior to that contracted for, or in case of an upward market, that the coal contracted for is not shipped at all, or only at a price that is higher than the contract price.'

"The United States is now seeking in an increasing measure to hold her export of coal trade by supplying 'inspected' coal definitely and satisfactorily graded with respect to quality.

"The Danish officials expressed the belief that such objectionable commercial features as have just been mentioned were due, in part at least, to the fact that neither the exporter nor the importer had the necessary first hand knowledge of each other, a knowledge which can best be obtained by personal contact and the establishment of mutual understanding and confidence.

Mr. White highly commended the efforts being made on the part of the Alberta Government and operators in now reaching out to secure an increasing portion of the Canadian and other markets, and to have the various coals of the province properly graded so that the purchases might rely upon the commercial integrity of his purchases. "Some coals", said Mr. White, "should not be shipped at all. In the case of South African coal, the government will not permit the poorer grades of coal to be shipped out of the country under any conditions.

"The United States Federal government has just been requested by its bureau of mines to make an ap-

propriation of $725,000 in order to establish a fuel inspection system for the purpose of giving to consumers and to producers of coal accurate information respecting the quality of coal purchased for domestic and industrial uses and for foreign commerce.

"The proposed measure seeks that authority should be granted for the establishment of a fuel inspection system as would provide coal-sampling equipments at such points as may be deemed desirable, procuring by lease, purchase, condemnation or donation the land or equipment necessary therefor; and to utilize those agents or agencies for obtaining representative fuel samples and to make such rules and regulations as may be necessary to accomplish this purpose."

"Shipment of British Columbia coal was recently made to Sweden", concluded Mr. White. "How infinitely better is it to have foreign shipments of our coal in all respects suited for the markets to which they are despatched than it would be to possess the opportunity to enter a foreign market and subsequently have it closed and barred against us because of failure to make the best use of opportunities and resources."

CHANGES IN CONSTRUCTION OF HARDINGE CONICAL MILL.

When the Hardinge Conical Mill was first introduced, it was felt that the very highest point had been reached in the development of a grinding mill. Likewise, down through the ages, it has been thought that some new invention was the last word in improvement. The Hardinge Company engineers, can, therefore, be pardoned for having felt the same way with respect to the Conical Mill.

Mechanically, however, the mill had been improved from year to year until, from the operator's viewpoint, it was mechanically perfect. The main bearings were ball and socket and self-aligning, thereby eliminating friction and reducing power-consumption to a minimum; the lining was built of the very finest material and daily established records for a long life and low consumption per ton of material ground. New types of feeding devices for wet and dry work had been invited and improved until the matter of feeding the mill, under all conditions, was very satisfactorily taken care of. The shape of the mill eliminated all grates and complications, resulting in a simple and fool-proof machine. The mechanical improvements upon the mill brought it to such a development that one man stated: "I worked nine years in that plant before I ever knew they had a Hardinge Mill."

Then there came a development in the method of grinding which revolutionized the field. Engineers found that no grinding machine had ever reached its ultimate capacity; that the capacity was not limited by what it would grind ultimately by rushing the material through and separating out whatever small percentage was finished after the one passage and returning the oversize, or reject, back to the mill for further grinding. This oversize has been termed "circulation load," In other words, the capacity of any mill was limited only by the amount of material which could be rushed through it rapidly enough to build up an enormous circulating load and not by the amount of grinding done in one passage through the machine.

The Hardinge Mill with its conical shape gave a much faster passage to the material going through the mill than any other type of machine, but still it was not fast enough to satisfy the Hardinge Company engineers, nor to answer for the theoretically perfect operation of a ball mill. Consequently, these engineers have re-designed the Hardinge Mill so that a maximum capacity is now attainable. They could not change the shape, because it had proven itself to be the best after long years of experience and grinding in the field under operating conditions. They could not improve the mechanical design which the years of operation had gradually perfected. Therefore, they improved the mill by faciliating the easy flow of material into the mill and out again.

The main bearings were set back upon the feed and discharge cones, shortening the entire length of the mill between centers of bearings, and the diameter of these bearings was greatly increased. The inside diameter of the trunnions was increased to such an extent that unlimited quantities of material could be fed to and discharged from the mill, thereby increasing its capacity to an approximation of the theoretically perfect capacity for a ball or pebble mill. By an ingenious device, arrangement has been made for raising and lowering the ball charge in the mill without affecting in any way the construction of the mill, or causing the grinding mediums to discharge with the ground material.

For dry grinding, where hot materials had to be fed into the mill, provision was made in the bearings for water-cooling them.

The result is that the Hardinge Mill is still the Hardinge Conical Mill, but materially improved in design, construction and operating efficiency and capable of giving much greater capacity for dry or wet grinding.

The many operators of Hardinge Mills, who have long advocated increasing the interior diameter of the feed and discharge trunnions, will appreciate the advantages of these improvements and will realize that the new Hardinge Mill will set new records in the entire field of grinding, even surpassing those formerly set by itself.

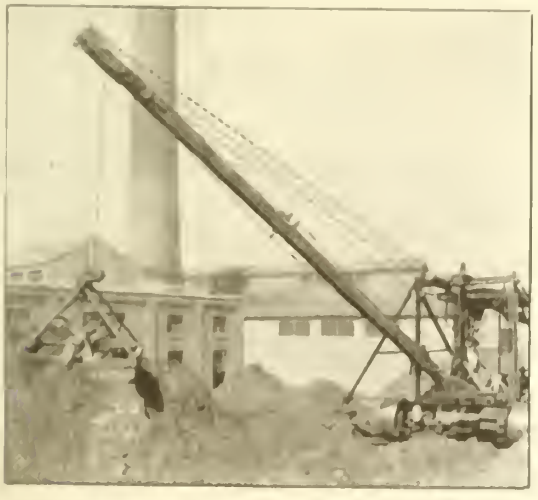
AS OTHERS SEE US.

A Quebec newspaper commenting on the possibility that some of the British coal mines may be ruined by flooding if the pumpmen do not return to their work, has the following remarkable information regarding mines in Pictou County, Nova Scotia.

"Pits where fire had developed in coal mines in Nova Scotia have been flooded to save unmined coal and have taken years to pump out. A still unexplained accident led to a series of most disastrous explosions of fire damp (the marsh gas of mines mixed with air) in the Foord Pit of the Albion Mines in Nova Scotia in 1882, and upwards of a hundred lives were lost. That was then the deepest coal pit in the world. The only way to control a fire of the magnitude of that which became apparent was to flood the mine. Stopping the pumps was insufficient and a channel was cut from the strait of Northumberland to an old pit connecting with the Foord, and the full strength of the Atlantic Ocean turned into the mine, destroying millions of dollars worth of property. Some of the most powerful pumps known to science have been working day and night for nearly forty years and the lower levels have not yet been uncovered nor any of the missing found."

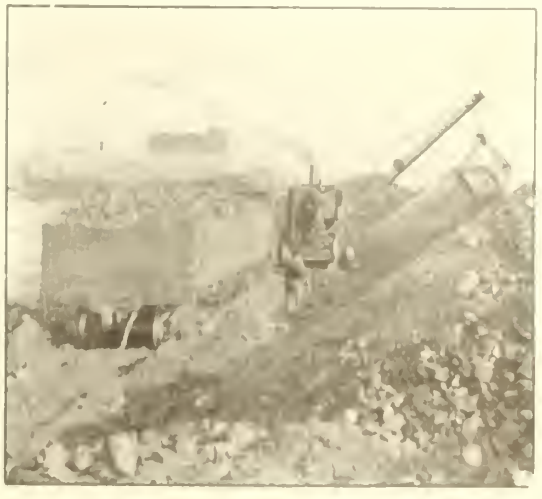
A COAL-HANDLING CRANE.

Steam shovels, with dipping buckets have been extensively used in stripping operations in surface coal-mining, or in reclaiming large storage banks of coal laid down on the ground, but the steam-shovel is a very expensive machine and lacks mobility. It is therefore unsuited to handling coal to and from stockpiles and cars in the manner often required in gas-plants, power companies, factories and works.



Steel crane coal from stockpile to hopper, making own track over piled coal

The auto-crane is a device designed to facilitate coal-handling in operations where expensive permanent coal-handling and transporting bridges are inadmissible, and where steam shovels are unsuited. The auto-crane, as may be seen from the accompanying illustrations is a very adaptable contrivance, possessing maximum mobility, ability to operate in cramped spaces and amid permanent or moving obstacles, and upon uneven ground. While adapted to ordinary contractors' uses, it is particularly useful, and primarily designed for coal-handling, it being virtually a portable unloading tower. The Canadian Sales Agents are Mussens, Limited, of Montreal, who are prepared to



Loading railway cars from stockpile

quote on a varied specification to suit varied uses. For instance, the auto-crane can be fitted for road traffic, to any rail gauge with railroad trucks, or with caterpillar treads, and the boom can be supplied to special lengths

PROVINCE OF QUEBEC

MINES BRANCH

Department of Colonization, Mines and Fisheries

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, etc.

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

MINERS' CERTIFICATES. First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is $10.00, and it is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

WORKING CONDITIONS. During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

SIX MONTHS AFTER STAKING. At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

MINING LICENSE. The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year, and a fee of $10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days labour on each forty acres.

MINING CONCESSION. Notwithstanding the above, a mining concession may be acquired at any time at the rate of $5 an acre for SUPERIOR METALS, and $3 an acre for INFERIOR MINERALS

The attention of prospectors is specially called to the territory in the North-Western part of the Province of Quebec, north of the height of land, where important mineralized belts are known to exist.

PROVINCIAL LABORATORY. Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, MONTREAL, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undounted integrity and reliability.

The Bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

HONOURABLE J. E. PERRAULT,
MINISTER OF COLONIZATION, MINES AND FISHERIES, QUEBEC.

BRITISH COLUMBIA

The Mineral Province of Western Canada

Has produced Minerals valued as follows: Placer Gold, $75,722,603; Lode Gold, $100,272,431; Silver, $50,432,304; Lead, $43,821,106; Copper, $153,680,965; Zinc, $16,818,487; Coal and Coke, $199,123,323. Building Stone, Brick, Cement, etc., $29,991,757; Miscellaneous Minerals, $786,918; making its mineral production to the end of 1919 show an

Aggregate Value of $670,649,894

The substantial progress of the Mining Industry of this Province is strikingly exhibited in the following figures, which show the value of production for successive five-year periods: For all years to 1895, inclusive $94,547,241; for five years, 1896-1900, $57,605,967; for five years, 1901-1905, $96,509,968; for five years, 1906 1910, $125,534,474; for five years, 1911-1915, $142,072,603; for the year 1916, $42,290,462; for the year 1917, $37,010,392; for the year 1918, $41,782,474; for the year 1919, $33,296,313.

Production During last ten years, $322,829,310

Lode-mining has only been in progress for about twenty-five years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those of any other Province in the Dominion, or any Colony in the British Empire.

Mineral locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with Mining Reports and Maps, may be obtained gratis by addressing

THE HON. THE MINISTER OF MINES
VICTORIA, British Columbia

EDITORIAL

The Unfairness of Measuring Canada by the Industrial Standards of the United States

There is a school of thought in Canada which everlastingly measures the industrial achievements of our country against the standards of the United States, more particularly the standard of cost of production. If it should be that industries in Canada prove unable to produce materials at as low a cost or, in as large a quantity as similar materials are produced in the United States, it is argued that the Canadian effort must stand self-confessed as a failure without excuse for existence or efforts toward persistence. It is a doctrine as melancholy as it is fallacious. Its inherent falseness resides in the assumption, usually an unconscious one of course, that, in some occult and unexplained manner, Canada is part of the United States sphere of influence. Any visible basis there may be for this belief has come about as a result of pitting the industrial performance of Canada against those of the United States without admitting that in many respects the United States is strong where Canada is weak, and without admitting the further fact that the strength of the United States and the weakness of Canada is a result of a deliberate choice of the Canadian people.

The attitude of the purchasing departments of the Federal Government, and of the large railways, is to base comparisons of quotations received, for materials required, upon United States bases. Similarly, Canadian manufacturers have learned to make their quotations upon a United States base figure, plus the additional charges accruing to the point of delivery in Canada. Why this everlasting reference to a Pittsburg or New York quotation? One explanation is that Canadian government departments have not yet learned to look to Canada as the only legitimate place to place government orders for articles that Canada can produce, and behind all their actions is the threat (all too often translated into actuality) to buy goods outside Canada, if it should be suspected, or assumed, that the Canadian price is not as low as it should be, measured by United States standards.

This relentless comparison, so far as many tariff created Canadian industries is concerned, is equivalent to raising a boy to delicate ways and then pitting him against a trained pugilist. The exotic flower will not, and what is more, it cannot, by reason of its mode of growth, be expected to live if turned out into the frost of winter.

There are a number of basic Canadian industries which cannot compete on even terms with the corresponding industries in the United States, because they lack the essential raw materials, the market and the availability of labour, conditions which the United States can supply in superabundance. This impossibility of even competition has been seen and acknowledged by our legislators, and they have passed restrictive laws intended to correct the unevenness of competitive ability and enable certain necessary "key" industries to exist in Canada. The reasons for this policy were not originally, and are not now, economic. These reasons were primarily national. The policy was not intended to enrich Canadian individuals, nor has it done so to any remarkable extent, but it was adopted to make possible the existence and persistence of Canadian national self-government and fiscal independence. Viewed from the standpoint of those who see in North America only one territorial unit, the policy was quite possibly one that violates economic laws, but North America is not one territorial unit, but two, and, if it comes to a choice between dearness of materials and abnegation of national independence, we must even put up with the high cost of living.

It is the national habit of comparison with the United States that so inhibits Canadian enterprise as to render this country incapable, to a larger extent that is really necessary, of utilising the things it does possess. If the earthen jug goes too often to the well with the iron vessel the inevitable result is proverbial, but it will be hurried if collision is deliberately sought after, and this seems to be a favorite pastime of our legislators.

The first requisite to a fair viewpoint on the ability of Canada to achieve some measure of industrial power is an admission that our raw materials, in some of their most important instances, are relatively small in extent and expensive to work. This admission does not depreciate Canada's assets, for their extent is not altered by

opinion, but, unless our legislators and the public are given some correction of the exaggerated notions they possess in regard to resources of raw materials in Canada, they will continue to expect the impossible, will continue to damn as incompetency all Canadian failures to reach United States performances, and risk the destruction of Canadian enterprises through sheer misconception of this country's abilities and resources.

One thing a good Canadian citizen will do, if he is a true patriot, is to accept Canadian limitations as a condition urging him to make the best of what we have. He feels it is incumbent upon him to help to make up by personal endeavour for this country's comparative poverty in certain particulars. Such citizens deserve Canada's thanks, but all too often they receive opprobium not because of lack of success, as success should be measured, but because they do not produce as cheaply, or in such prodigality, as is done in the United States. It is dangerous, because of the liability of being misunderstood, for anyone in Canada to maintain that certain things *cannot* be made as cheaply in this country as elsewhere, but it is certainly more honest, and it certainly will lead to greater real progress and permanence in our industries if the public understands the inherent limitations Canada suffers under and is prepared to pay the price that industrial independence under such circumstances calls for.

Canada is more than a place of residence, a place to cash cheques and to receive goods that must be paid for. It is a country that possesses much natural wealth, a little inferior in quality, and a little less in quantity, in some regards, than that of our southern neighbour, but infinitely less developed. The development of our neighbour's estate has been helped by neglect of our own estate, and cheapness is the excuse perpetually given for such disastrous national procedure.

Cheapness is the privilege of a trader, but in some of the most essential things Canada has long since lost her right to be classed as a trader, and has become a suppliant—a beggar. A country that deliberately relinquishes its ability to produce and undertakes to buy instead, puts itself in the position of a man who prefers to rent a house to buying it, although quite able to buy. He takes the risk of being turned out, and scant sympathy he deserves or gets, when the choice is his own.

THE DRAWBACK OF INCOMPLETE MINE-COST DATA.

The April Bulletin of the Institution of Mining & Metallurgy contains a paper by A. E. Petit on "Notes and Records of Mining Costs" together with a transcript of the discussion thereon, that directs attention to a much misunderstood matter. Mine-cost accounting is of course capable of just as accurate and scientific treatment as any other technical department of the mining industry, but it has rarely received it.

Alexander Richardson, in the contributed discussion, remarks: "One grave objection to the publication of incomplete cost data is that the uninformed are led to suppose that the mine is doing far better than it really is, and, therefore is well able to support further heavy financial burdens. Another is that the absence of a standard system of mine accounting precludes the drawing of informative comparisons between mine and mine, and district and district."

This opinion is commended to the members of the parliamentary committee on future fuel supplies now sitting at Ottawa, and it may also be commended to the careful attention of mining executives generally. The use of incomplete and partial cost-sheets is being visited at this time with the inevitable reward of inaccuracy and incompleteness. Much undeserved onus, great financial saving, and more reasonable treatment of the industry would have attended mining had mine-cost accounting been given the attention it deserves, and had mine-cost sheets been what they purported to be, and not merely the addition of out-of-pocket expenses for labour and material expended.

Mr. Richardson points out in his remarks, which refer more particularly to the Rand gold-mining industry, that the sum available for distribution as dividend is usually only sixty-five percent of the working profit. Why should mine executives deceive themselves, and pose to the world as being much richer than they really are, by persisting in a system of cost accounting that is so obviously incorrect?

The Fuel Committee at Ottawa has assumed that if it gets the monthly mine-cost sheets of the coal companies in Canada it will ascertain the cost of coal, but it will not. Probably the most competent witness that has appeared before that Committee is Mr. R. A. Ross, whose professional qualifications do not need enumerating here. Asked as to what he knew about the cost of coal Mr. Ross said he knew nothing, and asked further as to the cost of one horse-power generated from coal. Mr. Ross was unable to determine it, and knew no one who could. For once, the Fuel Committee obtained the precise truth. The Fuel Committee have been extremely anxious to initiate comparisons between the cost of coal in the United States and in Canada, but it will be long before they get that information, because no one either in the United States or in Canada has ever dared to attempt the calculation.

Mr. Britt, General Fuel Agent of the Canadian Pacific Railway, told the Fuel Committee that in 1912 and 1913, his Company bought Nova Scotia coal at $\$2.61\frac{1}{4}$ per net ton on cars at Montreal. If a competent accountant were to endeavour to ascertain what that coal cost the company that sold it he would find that the selling price was less than the real cost, and this is typical of the whole coal-mining industry of North America for many years past, and even today.

No industry knows so little about the cost of the product it sells than the mining industry, and the case of coal is only more obvious because it bulks so largely above all other products of the mine.

Mine-cost accounting has all too often been the province of accountants ignorant of all the factors that determine the profitable duration of production from a mine, or of mine executives ignorant of the principles of accounting, which are not simple. The really expert mine-cost accountant requires to have full knowledge of mining engineering and of accounts, and the combination is a rare one.

The remedy is largely in the hands of the mine executive. Until he reforms his methods of cost-accounting he will continue to be exposed to raids by uninformed tax-gatherers, attacks from self-educated economists representing labour interests, vexatious government investigations and control, and will continue to delude himself that his enterprise is profitable when probably it is not.

LIGHT RAILWAY WOULD HELP DEVELOPMENT

It is reported in Toronto newspapers that the men who propose building a light railway from Swastika, through Matachewan and Gowganda to Shiningtree are endeavoring to get some assistance from the Ontario Government. What measure of support the Government will give the project is as yet unknown; but in view of the nature of the enterprise and the aid it would be in developing three promising mining areas it is reasonable to expect that the Government will assist in some manner. It is to be hoped that substantial encouragement will be given those who undertake to provide the district with the much needed transportation facilities to make possible the beginning of the work of construction this summer. The development of Ontario mineral resources would be given a great impetus by the construction of the railway. At no time has the opportunity for speeding up development been so great as it is now. Gold mining can be made a much greater industry in a short time in Ontario if some definite assurance is given by the Government that it is ready to take some part in providing transportation.

The Ontario Government has been asked to extend the T. & N. O. Railway to mineral areas on either side of its main line. Evidently, however, it is not disposed to undertake such construction at the present time and there seems little chance of the prospectors and mine operators getting transportation facilities of this kind for some years. The next best project is the light railway which private enterprise will build if it gets a reasonable measure of Government assistance. This could be done by the purchase of a portion of the bonds which will be issued by the company. The Province would thus help in the development of the mineral areas without committing itself to large expenditure. Its share in the enterprise would be revenue-producing and secured by the property. The building of the railway would also relieve the Government from the necessity of building waggon roads in places where such roads are costly to build and unsatisfactory when completed.

Gold mining is looming up as one of most promising sources of production at a time when other Ontario business enterprises are experiencing hard times and when larger production of an easily saleable article would have a very marked effect in maintaining the credit of the Province. To encourage whose who would develop gold mines in Northern Ontario would be very wise policy. The results of vigorous development would be felt all over the Province.—R. E. H.

BRADLEY STOUGHTON RESIGNS A. I. M. M. E. SECRETARYSHIP.

Mr. Bradley Stoughton's retirement from the secretaryship of the American Institute of Mining and Mechanical Engineers will be very generally regretted by the members of the sister society in Canada. Mr. Stoughton has attended with great regularity the annual meetings of the Canadian Institute of Mining and Metallurgy, and what he had to say, although never dull and always mirthful, nevertheless conveyed a serious purpose and a stimulating thought. Mr. Stoughton was an ambassador of good fellowship and of international amity, and when he was in Canada he paid Canadians the compliment of one of them, and was always so regarded. The mining men of North America are not a numerous congregation, relatively speaking, but, so far as their influence extends to good understanding between our people and those of the United States, Mr. Stoughton's incumbency of the secretaryship, remarkable as it has been for the progress made by the A. I. M. M. E. itself, will be remembered for its international courtesies, and for Mr. Stoughton's quiet but firm repression of anything that savoured of discord, or of that attitude which William Archer in the "Atlantic" has recently named "The Great Stupidity."

Mr. Stoughton has the good wishes of the mining profession in Canada. His success in professional practice is assured, but nevertheless we wish him luck.

"DEAD MEN ON THE MINER'S CHEST."

The "Mining Journal" of London in regard to the British coal situation states that, speaking roughly, the number of workmen employed at the collieries has increased by 100,000 men, and the output has dropped 50 million tons per year. "It is asserted", says this London paper, "that over 600,000 more men have been employed on the surface since the war, and every mining engineer knows that a growing surface complement and a falling output are the surest signs of inefficiency." The main issue, states the "Mining Journal," is one of output which has fallen from something like 21 cwts per day before the war, to 15 cwts per day in 1920. In Britain as elsewhere, the miner at the face is carrying too many "dead men" on his back. There are too few miners and too many "datallers."

Spectacular Blast at the Trap-Rock Quarry of the Ontario Rock Co., Preveneau.

Specially Contributed to the "Canadian Mining Journal" by Mr. T. F. Sutherland, Chief Inspector of Mines for Ontario.

Mining operations of a spectacular nature and referred to as an "uplifting event" by the "Havelock Standard" were conducted by the Ontario Rock Company on April 29, when 26,000 cubic yards of rock were broken in one blast at their trap-rock quarry at Preveneau. Preveneau is three miles east of Havelock, in Belmont Township, East Peterborough, and on the Toronto-Ottawa branch of the Canadian Pacific Railway. In spite of the day, Friday, the "uplifting event" was a complete success. No damage was done to the plant and an overbreak was obtained. One of the power poles was broken off by a flying rock and the crossing of the high-tension wires added to the general effect and greatly increased the mental agonies of a few important but large gentlemen who had taken the precaution of placing a two-inch birch tree between themselves and the blast.

Officials of the Canadian Pacific Railway, the Dominion and provincial governments, and the city of Toronto, were in attendance, as well as a camera man for the Fox Film Company and a press photographer. When all was in readiness the switch was thrown by John A. Sexsmith, M.P. for East Peterborough. Geo. W. Rayner, vice-president and general manager of the company, had complete charge of the operations.

This quarry is the only trap-rock quarry at present operating in the province of Ontario and was found by geologists of the Ontario Bureau of Mines during their geological survey of this area in 1907 and 1908.* Shortly after the geological survey was completed several enquirers for quarry sites were directed by the Ontario Bureau of Mines to this locality, and work was finally begun by the Ontario Rock Company. The quarry industry here was thus developed directly as a result of the geological mapping of the area.

The rock is a dark-green type, generally too fine-grained to distinguish the constituent minerals without the aid of a microscope. Thin sections examined under the microscope show that the trap rock consists essentially of plagioclase feldspar, hornblende and magnetite. The feldspar is in places comparatively fresh. The chemical composition of the rock is shown by the following analysis:

Silica	45.20%
Ferrous Oxide	9.74
Ferric Oxide	8.37
Alumina	22.30
Calcium Oxide	8.02
Magnesia	1.51
Soda	2.59
Potash	0.46
Water of Crystallization	2.04
	100.25%

The physical properties are as follows:

Specific Gravity	3.05
Hardness	20.00
Toughness (impact test)	20.00
Abrasion	2.5
Cementation	39.00
Crushing Strength.	37,300 lbs. per sq. in.
Weight per cubic foot	181.78
Pore space, per cent	0.44
Ratio of absorption	0.14
Coefficient of Saturation, 1 hour	0.075
Coefficient of Saturation, 2 hours	0.087

The rock is shipped principally to the City of Toronto, the city engineers specifying trap rock for many features of pavement, sidewalk and curb construction. It is also used extensively by the York Highway

General View of Quarry and Crushing Plant of Ontario Rock Co., Preveneau, Ont

Ontario Rock Company's Prevenean Quarry, showing 60 foot face and entrances of Blasting Adits.

Commission and was used in the foundations of the new eighteen-storey addition to the King Edward Hotel. Many architects specify trap rock in all fire-proof buildings. The product is shipped in sizes ¼ in., ½ in., 1 in., 1½ in., 2 in., oversize, rubble and talus to any weight required.

Ten years ago, when the quarry was first operated, one No. 5 gyratory crusher only was in use. Now the primary crushing is done by a 15-inch by 60-inch Superior Jaw type crusher, which delivers the product

Showing some of the blocks (five ft. staff being used).

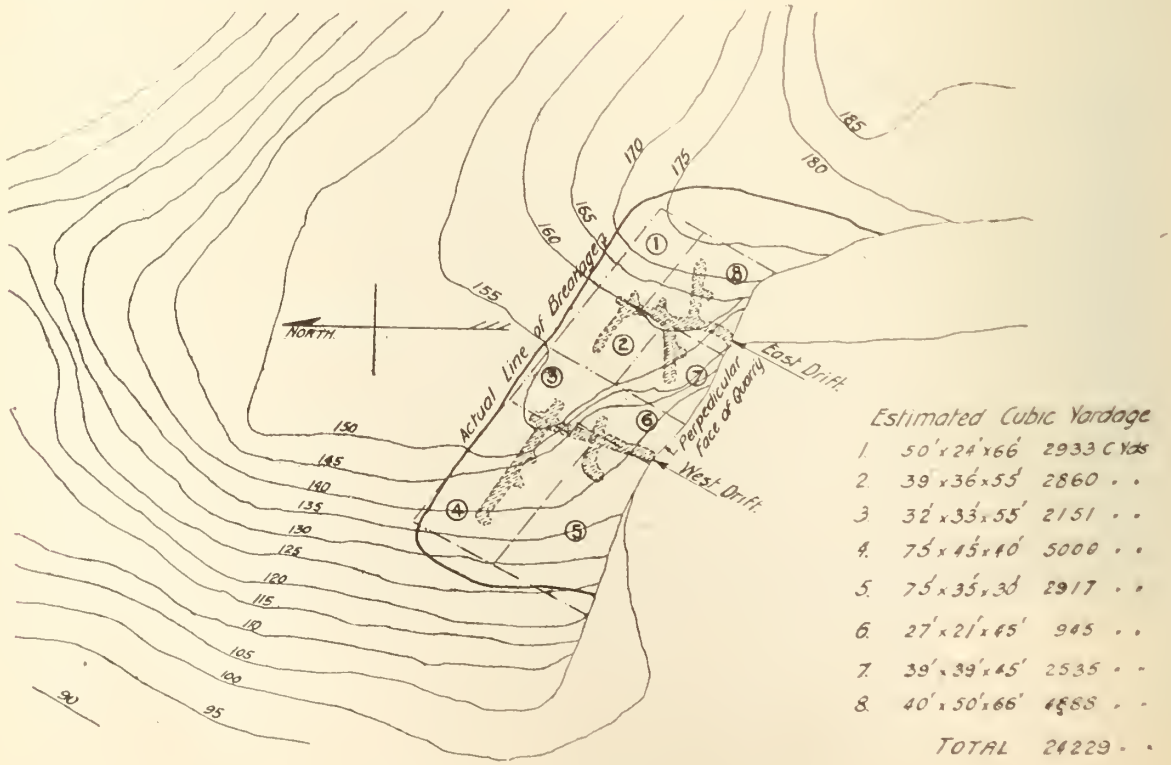
to a No. 8, two No. 6 and three No. 4 crushers which are operated in conjunction with 6-ft. and 4-ft. revolving screens.

One of the principal difficulties in the operation of this quarry has been the excessive cost of drilling and blasting, owing to the hardness and toughness of the trap rock; for example the original method of drilling was by 3¼-inch reciprocating drills; the complete daily footage obtained by these drills being under 20 feet. It was found impossible to drill holes deeper than 18 feet and a great deal of time was consumed in the springing and blasting. To obviate this, drills of the blast-hole well-drill type were introduced. At first an attempt was made to work these drills on a 75-foot face, but it was found that so many drill bits and stems were left in the holes, that there was no advantage in attempting to work a face greater than 30 feet. It was then decided that the quarry would be opened in two benches, so a face was opened up on a bench which at the present time has a face of about 40 feet, and an attempt was made to continue the drilling with blast hole drills. It was found that by drilling with blast-hole drills a good day's drilling would be about 7 feet, while a month's average would not be over 4 feet daily, so it was decided by the management to attempt to increase the output with one large blast.

In December, 1920, two adits were started, the westerly one being under 50 feet of back and the easterly one under 65 feet of back. The manner in which the adits were driven is shown in the accompanying plan. The west, or No. 1, adit was driven 60 feet north and cross-headings 60 feet west and 10 feet east. Three pockets were made in the south side of the west cross-heading as shown in the plan. At 30 feet from the portal, cross-headings were driven 20 feet to the southwest and 10 feet to the east. These headings were loaded with 180 cases of 60 per cent nitroglycerine dynamite, distributed in seven charges, and in each charge two No. 8 electric detonators were used. The detonators were connected in one series of six and one of eight.

Seventy feet easterly the No. 2, or east adit, was driven north 60 feet. Twenty-five feet from the portal a cross-heading was driven east 30 feet, and 30 feet from the portal a cross-heading was driven west 30 feet, and at the face of the adit a cross-heading was driven 30 feet to the west. These headings were loaded with 60 cases of 60 per cent nitro-glycerine dynamite and 120 cases of black powder divided into nine charges with two No. 8 detonators in each charge, connected in two series of nine each.

The charges were covered with oiled paper and then loaded with sand tightly packed. The adits were packed as tightly as possible with rocks, and at 30-foot intervals the face of the rock was covered with a foot of sand.



Plan of Quarry (see letter-press for details).

As the work was carried out, each fuse was tested with a galvanometer, and galvanometer tests were carried out all the way through. Two sets of lead wires were connected in parallel to two wires which carried the current from the Hydro-Electric power lines to the charges.

It will be noted that the method of computing the powder charge to be used was based on an estimate of the ground to be broken as shown in rectangles 1, 2, 3, 4, 5, 6, 7 and 8. In the case of rectangles 1, 2, 3, 4, 6, 8, the amount of powder per yard was estimated at about three-quarters of a pound. In the case of rectangles 5 and 7, less than a half-pound of powder was used to the yard. The reason that the lighter charge was used in these two cases was owing to the fact that in rectangle 5 the rock was pretty well broken and in the case of rectangle 7 there was only about 16 feet of toe on the two pockets.

It was estimated that the shot would break about 24,000 cubic yards and the actual yardage broken was about 26,000.

PERSONALS.

Dr. R. W. Brock, of Vancouver, who was for some years professor of geology at Queens University and later director of the Geological Survey, is visiting in the east. He is at present in Toronto.

Mr. Cyril W. Knight, Assistant Provincial Geologist, is at Cobalt, and will spend the summer there making an underground study of the silver mines.

Mr. J. B. Tyrell has returned to Toronto from Kirkland Lake.

Mr. D. A. Dunlap, vice-president and secretary of Hollinger Consolidated, has joined the board of directors of the Northern Light Railway Company.

Mr. Frank L. Culver, president, and Mr. R. P. Rogers, manager of northern Light Railway Co., have returned to Toronto after making a trip north.

Dr. M. E. Wadsworth, the organizer and for twelve years the president of the Michigan College of Mines, Houghton, died at his home in Pittsburgh on April 21.

Mr. J. R. Finlay has been retained to make an appraisal of the mines of New Mexico.

Mr. A. M. McQueen, of the Imperial Oil Co., is at Edmonton in connection with the company's exploration work in the Mackenzie River district.

Mr. F. L. Culver has returned to Toronto from Kirkland Lakes. Mr. Culver is well known in the north, being to a large extent responsible for the successful development of the Beaver silver mine and the Kirkland Lake gold mine. It is stated that he will be president of the Northern Light Railway Co., which should prove a big factor in developing new mining areas in Northern Ontario.

Lt.-Col. R. P. Rogers, who was for some years resident at Cobalt as manager of Coniagas Mines, Ltd., and who during the war was in charge of construction of light railways in France, is to superintend construction of the Northern Light Railway.

Mr. D. B. Dowling, of the Geological Survey, Department of Mines, is at Edmonton purchasing for an exploration trip down the Mackenzie River. Mr. Dowling has done many years geological field work in western coal and oil areas.

SAFETY OF COAL MINES DURING STRIKE PERIODS.

Bill Introduced into Nova Scotia Assembly Providing for Retention of Maintenance Forces to Prevent Flooding and other Things.

A Bill was recently introduced into the Nova Scotia Legislative Council by Hon. N. J. Gillis, of Glace Bay, intended to prevent damage to coal-mines by flooding and explosions during periods when coal areas are held out of operation by strikes or other reasons. Text of the Bill is as follows:

"Whenever it appears to the governor-in-council necessary for the preservation of the property and interest of the Crown in any mineral in any area or areas held under lease or leases, whether mining operations on said area or areas have ceased or not, that the workmen of any particular class designated or any of such workmen should perform the work they are then or have been performing in or about the mine or mines on such area or areas, the governor-in-council may issue a proclamation that such persons or any of them shall until further order perform or continue to perform the work they are or have been performing, and any person of the class so designated who fails or refuses to obey such proclamation shall be guilty of an offence against this act and shall be liable on summary conviction therefor to imprisonment for a term of not less than one nor more than four months, and any person who by any means whatsoever directly or indirectly persuades or procures or endeavors to persuade, prevail on or procure any such person to disobey such proclamation shall be guilty of an offence against this act, and shall be liable on summary conviction therefor to imprisonment for a term of not less than six nor more than nine months."

In introducing the Bill, Mr. Gillis stated the Dominion Coal Company, for every ton of coal produced from its mines, required to pump ten tons of water. The ownership of the coal areas by the people of Nova Scotia made it necessary to take precautions to prevent damage during periods of cessation of work. In one group of mines, Mr. Gillis stated he was reliably informed, abandonment for four or six weeks would involve an expenditure of a million dollars to recover the mines, and in certain of the mines referred to operations would probably never again be resumed.

The Bill was rejected by the Lower House.

NOTES FROM THE NOVA SCOTIA COLLIERIES.

Coal production during May was slightly speeded up towards the end of the month. The Dominion Coal Company expects to obtain 270,000 tons from the Cape Breton mines and 35,000 tons from the Springhill mines, which will compare with 175,000 tons from Cape Breton and 33,500 tons from Springhill during April.

Coal is moving up the St. Lawrence and between 1 and 1½ million tons should reach St. Lawrence points from Nova Scotia during the season of navigation. A little coal may go to oversea points if, as seems likely, the British coal strike is prolonged. It is, however, unlikely that full time operation of the coal mines will take place until resumption of steel making becomes possible, and this, in its turn is hardly possible until substantial reductions in the mining cost of coal has been found possible.

The Distribution of Coal-Mine Working Force.

(With Especial Reference to Coal Production in Nova Scotia.)

By the EDITOR.

The main economy sought for in coal-mining is increase of the individual unit of production, or, putting the matter in another way, production of a maximum output with a minimum number of workmen. It may be demurred that this is not a problem peculiar to coal mining, but it is especially of importance in coal-mining because only a portion of the working force is actually engaged in coal production. All the other men are engaged in handling the coal produced, so that the task of the colliery manager is primarily concerned with the actual dislodgement of coal from the coal-seam, and, no matter how elaborate the ventilating, pumping, haulage and screening equipment of a colliery may be, the actual success of that colliery as a producer of coal, cannot be greater than the capacity of the workers at the coal face.

Examination of such statistical literature as is available in public prints will disclose that, in all coal districts which have felt the drain of war enlistments, the number of faceworkers has dropped since pre-war times almost precisely in the ratio in which coal production has dropped. This general rule has one notable exception, namely, in the coal districts of the United States, which did not suffer any notable drain by war enlistments.

There is a very general impression abroad that the coal miner (that is the man who actually mines or loads at the working-face) has shown a lowered efficiency. This belief is not confirmed by study of the statistics. It is true that the production of coal per man employed at the collieries has declined, but this is entirely due to the altered ratio of coal miners and loaders to coal-handlers and surfacemen. It is not a question of the inefficiency of the working forces at the coal-mines, but it is a question entirely of the *inefficient arrangement* of the forces employed. The reasons for the existence and perpetuation of this inefficient arrangement it is not proposed to discuss, but it is merely desired here to disclose the fact of its existence.

A comparison of the distribution of the working forces at the collieries in Nova Scotia, based on the Mines Report Statistics for 1920, and the performances of 1915, before reduction of the working forces by enlistments, gives these figures, which are closely approximate, namely:

	1915	1920
Percentage to total employees borne by:		
Surfacemen	13%	20%
Underground Labour	42%	44%
Miners	45%	36%
	100%	100%
Production per man per day employed:		
Surfacemen	19 tons	11 tons
Underground Labour	6½ "	4½ "
Miners	6½ "	6½ "
All classes	2¾ "	2 "

The reduction in coal output, under same conditions of equipment and extraction conditions, has been approximately 30 per cent. The reduction in the total number of men employed has only been 20 per cent, which is the condition that is usually taken to indicate inefficiency among the mineworkers. The decrease in the number of actual miners is very close to forty per cent, which is the true index to conditions, and this condition discloses an *increase* in efficiency among the faceworkers. As an actual fact, the production of faceworkers during the years 1914 to 1920 inclusive, has varied only within the narrowest limits, to be precise, from 6.3 to 6.5 tons per miner per day. That is to say, it has really not varied at all.

In 1915 the Dominion Coal Company employed a maximum of 2,990 miners, who in the maximum month of July of that year produced 462,000 tons. In 1920, this Company, according to the statistics of the Mines Department (corrected) employed only 1,732 miners, a decrease of 1,258 men, or 43 per cent. The decrease in coal production was thirty per cent only, showing that the faceworkers in 1920 worked more efficiently as individuals than at the time of maximum production.

In view of these comparisons, it is difficult to understand why the individual reports of the Deputy Mine Inspectors should state in reference to specific collieries that a sufficient number of men were employed. The cause of the decline in coal production cannot, of course, be separated from a shortage of coal producers, and it is quite evident that until the Dominion Coal Company obtains 1,200 additional miners it cannot bring its output back to where it was in 1915. Precisely the same statement may be made of every other coal company in Nova Scotia, if the matter is viewed from the point of the number of coal producers without reference to the output capacity of the mines themselves.

This is a fact of major importance that the enquiry of the parliamentary fuel committee has not educed, for it is a condition that is not only at the base of decreased coal production but in large measure responsible for increased cost of production.

In 1915, in Nova Scotia, the percentage of non-productive day-paid workers was 55 per cent. In 1920 it was 64 per cent.

The men who mine coal and who make profitable operation of coal-mines possible by that fact, were in 1915 in the proportion of 45 per cent. In 1920 and now they do not exceed 36 per cent. These men are paid on contract rates for what they do.

If two thousand miners could be put to work in Nova Scotia collieries, an additional production of 160,000 tons a month, or say from 1¾ to 2 million tons per year of coal, is possible, and this without adding more than 10 per cent to the non-productive classes of mineworkers. In most cases no additional non-productive workmen would be required to handle the additional coal that would be produced.

The lowered production of coal in Nova Scotia is therefore attributable to shortage of faceworkers, and this shortage is a direct consequence of the war.

J. Austen Bancroft

From "Institute Notabilities" May Bulletin of C. I. M. & M.

DR. J. AUSTEN BANCROFT was born in Upper North Sydney, Cape Breton, N.S. Growing up under the very shadow of the collieries, and in a region of exceptional geological interest, it was only in the natural order of things that, at a very early age, his attention should have been attracted towards mining and geology. It very soon became apparent that his inclinations also turned that way, and this happy conjunction of environment and natural selection has resulted in the development of a very fine type of economic geologist.

Bancroft received his early education at Springhill High School. From there he entered Acadia University in 1899, and after four very successful years he obtained the degree of B.A., graduating with high honours and winning the gold medal for highest standing in his class. In the autumn of the same year (1903) he entered the senior year at Yale University, and obtained the degree of A.B. at the end of the college session. Being then awarded a Fellowship, he continued his studies at Yale for another year, and obtained the degree of A.M. in 1906.

About this time, Bancroft most fortunately began to feel home-sick. At least we find that in 1905 he accepted the position of Demonstrator in the Department of Geology at McGill University, and he has been a member of the staff continuously since that time. Rapid promotion led to his appointment as Dawson Professor of Geology in 1913. At McGill he has won for himself an enviable reputation, not only as a geologist with a thorough knowledge of his subject, but also as a teacher who possesses to an unusual degree the faculty of being able to impart his knowledge to others in a most interesting manner. While to most members of the Institute, Dr. Bancroft is probably best known for his work in the field as an economic geologist, there will be many readers of this BULLETIN, graduates and undergraduates of McGill, who cherish fond memories of their former Professor as a forceful and extremely lucid lecturer, and a most painstaking and patient demonstrator in the laboratory.

Dr. Bancroft has always made good use of his long summer vacations. A change is said to be as good as a rest. Sometimes his change has consisted in a metamorphosis from teacher to pupil, as when he spent the summers of 1908 and 1910 at the universities of Leipzig and Bonn, respectively. Such graduate studies led to his obtaining the degree of Ph.D. at McGill in 1910. For the most part, however, and continuously since 1910, he has devoted his summer vacations to geological investigations in the field, principally in the provinces of Quebec and British Columbia, with the exception of 1917, when he spent several months in British Guiana examining deposits of bauxite. Dr. Bancroft's reports dealing with the several geological investigations he carried out for the Bureau of Mines of the Province of Quebec are well known, and his report on the Copper Deposits of the Eastern Townships (published in 1914), is an especially comprehensive and valuable contribution to our knowledge of the copper resources of that region.

From the first, Dr. Bancroft's leanings have been toward the economic side of geology, and in recent years he has devoted his seasons in the field entirely to that branch of the subject. Two summers (1918-19) were spent in this way examining and reporting upon the copper deposits at Anyox, B.C. for the Granby Consolidated Mining and Smelting Company. That the Company appreciated the high standard and value of his work is evident from the fact that, early in the present year, they offered him the position of Assistant General Manager. This position, Dr Bancroft has accepted, and, for one year at least, McGill will lose his services; for, loath to let him go entirely, the University has granted him one year's leave of absence, in the hope that the prodigal may yet be persuaded to return.

It is almost superfluous, in this brief sketch, to add anything concerning Dr Bancroft's personality; he is so widely known among members of the Institute from coast to coast. For the benefit of the few who have yet to meet him, however, it may be said that he is a big man, both physically and mentally; a man whom it is more easy to follow than to keep pace with, whether it

DR. J. AUSTEN BANCROFT, F.R.S.C.

be in a 'hike' through the bush or the pursuit of life's major objectives. In a word, just as the hypothetical John Bull represents the ideal Englishman so the "J. B." of the present sketch embodies all the best characteristics of the Canadian.

Dr Bancroft was elected a Fellow of the Royal Society of Canada in 1920. He is also a Fellow of the Geological Society of America, and a member of the American Institute of Mining and Metallurgical Engineers. He became a member of the Institute in 1909 and served on the Council during the period 1911-1913. At the recent Annual Meeting he was again elected a Councillor, as one of the representatives for the Province of Quebec.

The Northern Light Railway Company.

A Project to Open up the Silver and Gold Districts lying Between Cobalt and Porcupine in Northern Ontario. Is Backed by Experienced Financiers and Operating Executives.

With practically all the preliminary details completed, including the organization of the company, the granting to it of a charter and the official sanction of the Ontario Government, the Northern Light Railway Company promises to be a tremendous factor in the further development of mining in Northern Ontario. The scheme has been advanced to a stage which permits of actual construction operations being commenced at once and arrangements to this end are being energetically pushed by I. W. C. Solloway, the manager of the company, who is promoting the enterprise.

In the opinion of those in the mining industry the proposed light-railway system, running as it will through the heart of the silver and gold-bearing formations of Northern Ontario, proven by development and production to be of undoubted permanency, will greatly aid development, for in addition to serving the mining operations the railway will assist in establishing other industries. The railway will handle cordwood, pulpwood and coal, in addition to merchandise, and will facilitate the transportation of low-grade ore, which at present will not stand the high cost of transportation. It is estimated that the business to be obtained from the pulp and lumbering industry alone would justify the building of the railway.

In the district of Temiskaming many of the producing camps will be touched including Swastika, Kirkland Lake, Larder Lake and the adjacent districts of Ben Nevis, Skead Township and Boston Creek. The route provided for is as follows: From Swastika on the T. & N. O. Railway, easterly through Kirkland Lake camps in the townships of Teck and Lebel, then southeasterly through Gauthier and McVittie townships, south through Hearst and Skead townships, turning west from Skead, through Catherine and Pecaud Townships, through Boston Creek Mines, and reconnecting with the T. & N. O. at Boston Creek station. Construction offers no greater engineering difficulties and will follow the loop of gold mines and claims that have become established since gold was first discovered in this area.

Kirkland Lake and Boston Creek districts are now supplied with power from Cobalt by the Northern Ontario Light and Power Company, while Larder Lake district is served by the installation of power supply owned by the Associated Goldfields Mining Company, Limited. It is pointed out by the company that besides the established and producing mines in the areas to be served, there are hundreds of other good claims that will be encouraged to develop by the railway, removing the handicap of inaccessibility for transportation. Capital is flowing into the gold belt freely and the value of the vast mineral wealth contained in these areas has been demonstrated. It is stated that by the close of 1921 the yield of gold will surpass any record of the past. The Kirkland Lake area alone has now nearly forty mines, and then there are the Larder Lake mines, and the Boston Creek properties which will be assisted by the new enterprise, together with those in the Fort Matachewan, Gowganda, and West Shining Tree areas. Many mines at present idle are prepared to operate upon receiving railroad transportation.

As an instance of the need that the railway will supply the case of Kirkland Lake area may be mentioned. Information gathered by the company indicates that throughout the area there is urgent need for a railway to take care of the established mines and the extensive developments that are going on. At present thirty cars of railway ties, not counting pulpwood, are being shipped from Timmins each week and the Porcupine branch, 30 miles long, ships out approximately 25,000 cords of pulpwood annually. Most of the tonnage, consisting of railway ties, pulpwood and lumber, hauled over the Porcupine lumber mills which receive their logs by floating them down the river. This terminus can be compared with the proposed terminus of the light railway company at Beaver House Lake. The Mattagami is, of course, longer than the Beaver House, but to date the number of miles that are being lumbered is not as great as is available on the Beaver House, and the spruce for pulpwood and pine for ties and lumber along the Mattagami is no better than that along the Beaver House. From the Argonaut Mines, which for the present would seem to be the company's objective, access would be gained to Victoria Creek, whose waters afford excellent flotation for logs now standing on approximately fifty square miles of timber rather better than the average quality. After touching Victoria Creek it is but 2½ miles east to the Argonaut Mine at Beaver House Lake, on whose property at the outlet of Beaver House Lake the railroad would cross White River. This river will also bring pulpwood, ties and lumber to the railroad. From Kirkland Lake through Lebel Gauthier and McVittie Townships, many mines are being developed on which plants and mills will be installed, necessitating the hauling of large boilers, mill machinery and large tonnages of coal, timbers and lumber.

It is estimated that the Northern Light Railways will serve an area of about 3,000 square miles containing 1,920,000 acres and within this area located about 11,000 mining claims and many producing mines. These areas have gold, silver, barium, asbestos, felspar, copper, waterpowers, pulpwood, timber and farming land, and in this connection it is interesting to note that in Northern Ontario 47 per cent of the freight carried by the T. & N. O. comes from the mining industry, 13 per cent from the agricultural industry, leaving 40 per cent from the lumbering industry. In the United States 60 per cent of all freight comes from the mining industries, therefore forests and mines are considered the most valuable source of revenues to the railways.

The scheme has been developed with the wholehearted support of the Boards of Trade of Northern Ontario and the mining associations, which have failed to obtain government-owned standard railways. The government's policy is understood to include extension of the T. & N. O. Railway to James Bay, by easy

annual stages, and provision of transportation for the outlying districts by light railway feeders, and the Northern Light Railway Company's project is therefore part of the government's railroad policy.

THE TECK-HUGHES GOLD MINES, LTD.

J. A. McRAE, Cobalt.

Among the mines in the Kirkland Lake district which are being placed upon a sound commercial basis is that owned by the Teck-Hughes Gold Mines, Ltd., a company which has paid strict attention to sound methods in the financing and the management of its operations.

This company had just completed its construction program when it found itself in the midst of an extremely adverse economic situation which was brought about by the recent world-war and which no one had been able to foresee. The cost of conducting operations exceeded original calculations, and the company ultimately found its enterprise saddled with a bonded indebtedness of half a million dollars. As against this, is a mine highly developed to a depth of 500 feet, and equipped with a milling plant which can treat 120 tons of ore daily.

In recent years, it was found difficult to make production cover the cost of operation, a fact which caused the company to neglect the payment of interest on its bonds. The situation was not altogether re-assuring to the stockholders, but the fact was never lost sight of that, although carrying a big bonded indebtedness, this was covered by a vast amount of development work which must eventually be of great value to the company.

It would seem that the Teck-Hughes is now about to come into a fair reward for its perseverence. It is learned that the enterprise is now on an operating basis which is moderately profitable, while a further milling addition to a total of about 140 tons daily has been decided upon, and which seems to offer promise of adding still further to the profits which are to materialize.

There has been considerable unofficial discussion of the financial affairs of the company and that a re-organization might be arranged so as to satisfy bondholders and stockholders alike. As to this, there may or may not be some such a possibility. However, that the management is to be given a free hand to proceed with operations is certain, and whether a re-organization is to be arranged, or not, seems to be secondary to the fact that, as stated to the writer by interests closely identified with the project, there will be no interference with the operation of the mine and the outlook is that the earning power of the company promises to be such as will retire a substantial amount of the bonded indebtedness annually and will then permit the enterprise to produce its reward to the stockholders.

Eastern Equipment Co., Ltd., have moved from the McGill Building and taken the entire floor of 231 Beaver Hall Hill, Montreal, where they will have, in addition to their offices, an extensive show room. This firm have recently been appointed Canadian agents for St. Clair Brothers, Galt, Ont., manufacturers of pumps, concrete mixers, hoists, etc. They also handle new and rebuilt contractors' equipment of all kinds as well as locomotives.

WHY THE PRICE OF ANTHRACITE DOES NOT COME DOWN.

(From "Saward's Journal," New York.)

E. W. Parker, director of the Anthracite Bureau of Information, has written a letter to the editor of the New York Herald taking exception to a recent editorial entitled "Coal Prices Must Come Down." The editorial in question is similar to several others which have appeared in the metropolitan papers since then and which were inspired by the "Herald's" comment. In his letter Mr. Parker said:

"It is quite evident that the writer of the editorial is not in full possession of the facts and conditions with which the anthracite industry is faced at the present time. Permit me to say in the first place that no one would be more pleased to welcome a decline in the price of hard coal than the anthracite operators if that could be accomplished without involving serious loss to the industry as a whole.

"The fact is, however, and it is a very important fact, that in the face of the present cost of production no material reduction can be made in the mine price of anthracite without eliminating a substantial portion of the necessary tonnage or compelling its production at serious loss to the higher cost companies. Some mines are now idle for the simple reason that present prices do not permit of their operation at a profit.

Factors Entering Into Costs.

"There are three factors involved in the cost of coal to the consumer, namely, production, transportation, and local distribution. Including the advance in wages granted by the President's Anthracite Coal Commission last year, the aggregate increase in the labor cost of anthracite over the pre-war period has been 138.6 per cent (see "Monthly Labor Review" of U. S. Department of Labor, October, 1920, p. 104) and the award of this commission fixes the rate of wages until March 31, 1922.

"The labor cost in the production of anthracite represents over 70 per cent of the total expense. The cost of supplies, such as timbering, mine rails, explosives, etc., have practically doubled. The wholesale price of domestic anthracite according to the "Monthly Labor Review" (February, 1921, p. 51) has increased 98.5 per cent.

"It is a matter of common knowledge that freight rates have been advanced approximately 100 per cent, and there is no reason to believe that the retailers' expenses have not increased in the same proportion. The anthracite operators, however, have nothing to do with either the cost of transportation or of local distribution.

Wage Agreement Cannot Be Broken.

"It may be claimed that as the increase in wages subsequent to the agreement of 1916, notwithstanding the existence of a four years' contract, and by the President's commission were granted because of the advancing cost of living, the miners should now consent to reductions in wages before the termination of the existing contract, because of the marked decline in the prices of other commodities.

"It goes without saying that any action of that character would almost certainly precipitate a general strike and effectually stop the production of every mine in the anthracite region. The operators are not willing to break their contract. Is it the opinion of the editor of the "Herald" that it would be wise to make the attempt?"

"In conclusion permit me to call your attention to the fact that there are now before the Governor two bills relating to taxes and charges on anthracite coal. If they become laws the total levy in all probability will amount to 3½ per cent on the mine value of the entire commercial production (coal used in the operation of the mines is exempted) and as 30 per cent of the tonnage consists of steam sizes, sold in competition with bituminous coal and at less than the cost of production, the entire tax will have to be carried by the 70 per cent of domestic coal, which by a simple process of arithmetic will be seen to have to carry a tax of 5 per cent. If the bills become laws they will go into effect July 1."

(Editorial Note.—Since this letter was written the Governor has signed one bill imposing a tax of 1½ per cent on anthracite.)

THREE FIVE-MILE THICK AURIFEROUS GEOLOGICAL AGES.

A correspondent of the South African M. & E. Journal, named as the "Rand Stratigraphist," writes:

This country contains three five-mile-thick auriferous geological ages ahead of the rest of the world, as your readers may be tired of hearing from me. Our gold supply is inexhaustible, and the few mines grouped round about Johannesburg, for convenience sake, do not represent a five-thousandth part of the number of holes in the ground that posterity will yet make to help themselves to the precious metal as long as it remains the medium of currency. That's the rub! For if our platinum fields in the Cape Colony prove to be half as rich as reported its supply might in a few years surpass the world's output of gold—and what then?

With regard to the three five-mile-thick geological ages above alluded to, which South Africa has, and the rest of the world has not, I will just give you a rough estimate of their potentialities cut down to half the distances which I am convinced they reach if our coal-measure age, which covers them to a great extent, could be peeled off to expose them. First, The Lydenburg age: Three payable reefs, 300 miles long=900 miles. Second, the Witwatersrand age: Fifteen payable reefs, 300 miles long=4,500 miles. Third, the Black Reef age: 300 miles long, 6 payable reefs=1,800 miles. Total, 7,200 miles of payable reef if joined end to end.

This does not include the auriferous schistose age, of which we have as much as, and probably more than, any other country, but at present is greatly neglected on account of the more easily worked banket beds of the Witwatersrand and Black Reef ages. Home readers would be well advised not to refer to our Geological Survey reports for information re South Africa, as it is absolutely useless from an economic point of view. They must come here and investigate for themselves,

SAMUEL MONTAGU & COMPANY'S CIRCULAR.

The following items on the precious metals are excerpted from Messrs. Montagu's March circulars.

The Directors of the U.S. Mint has reported that gold supplied for the manufacture of jewellery and other industrial uses in 1919 amount to 75½ million dollars, in excess of the U.S. production for that year of 15 million dollars.

Gold is exported from Abyssinia in the form of rings of which the shape varies. The assay is generally 940 milliemes gold and 54½ silver. Such a quality seems to indicate the metal may be derived from gold dust, and suggests that Abyssinia may be a producer, though not figuring as such in official returns.

It is noted that in China currency is replacing unminted metal, and that the silver dollar is replacing lump silver, which, although a few years ago very scarce, are now as much in circulation as the copper cash.

Successive circulars report a continuance of the heavy flow of gold into the United States, particularly from India. "The repeated hammer-blows caused by these shipments of precious metal—not really desired in the United States, where gold is already superabundant—have had, and, if continued, will have the effect of reducing the discount from which the British pound sterling has been suffering in regard to U. S. currency."

The "Journal" suggests a few harder taps from Northern Ontario in aid of the Canadian dollar would not come amiss.

GOLD AND SILVER TRADING IN THE ORIENT.

Messrs. Samuel Montagu's circular of 7th April states that India supplied China last year with silver when it was quoted Rs. 105 the 100 tolas, and has been buying it back at about Rs 85. India bought great quantities of gold under Rs. 23 the tola, and is now selling it at the profitable price of Rs. 30. Exchange operations between gold and silver in the East are of very ancient origin. The Egyptian code of Menes dating perhaps between one and two thousand years before the present era — is thought by some authorities to be connected with the Indian code of Manu, probably of a much earlier date. In it is a reference to a ratio between gold and silver. We need not therefore be surprised if the people of India are adept at the practice of exchanging the two metals.

MORE POWER DEVELOPMENT IN NORTHERN ONTARIO EXPECTED.

The experience of the past winter has made operators in Northern Ontario take a great interest in water-power development. Recently Hollinger Consolidated Mines, Ltd., applied for rights to develop for its uses one of the yet unharnessed water powers. The Company will need a large supply for many years and could well undertake to develop some power of its own. The immediately outlook is not overly bright. The weather has been very dry this Spring as it was last Fall, as numerous bush fires evidence. The streams are not flowing as strongly as might be wished and the operators will be glad to see a spell of real wet weather. If there is not a liberal supply of rain this Summer, there will be power shortage again next Winter. It is to be hoped therefore that no obstacles will be put in the way of those who would increase the power development.

Northern Ontario Letter

THE SILVER MINES.

The Cobalt District.

Silver production from the mines of the Cobalt field amounted to at least 500,000 ounces during the month of May, according to preliminary estimates. On May 25th, the Mining Corporation of Canada resumed production and this will increase the aggregate monthly output to well over 600,000 ounces a month.

The re-opening of the properties and mill of the Mining Corporation has provided employment for from 230 to 250 men, thereby increasing the pay-roll in Cobalt by upwards of 25 per cent. This has greatly improved the industrial outlook here and is pointed to as a clear indication of the general improvement from the economic conditions which were responsible for the company closing down its mines and mill during the early days of March, last.

It is understood the Mining Corporation has been making an examination of property in the eastern part of the Kirkland Lake district, the Lebel Oro being one of the properties investigated. Surface showings on the Lebel Ore are very promising, a vein measuring from two to four feet in width outcropping at surface in which the gold content makes the deposit of a commercial grade. A shaft has been put down to a depth of about 60 feet at the time of writing, and the result of sampling in the shaft and an examination of the surface will decide the question of further negotiations.

The Coniagas has commenced treating its sand pile, and the aggregate tonnage being handled at this mine now amounts to from 600 to 625 tons daily, made up of 350 tons of run-of-mine ore, 110 to 125 tons of slimes and 150 tons of sand. Last year's average mill-heads amounted to well over 10 ounces of silver to the ton, but allowing for a heavy dilution of the average on account of the large amount of sand and slime, it would appear as though the average might now be estimated at about 7 ounces of silver per ton. This would indicate a daily output of approximately 4,200 ounces of silver, or at the rate of 1,533,000 ounces a year during the period which the plant may be operated at the present capacity. At 60 cents an ounce for silver, plus the premium on United States funds, the present rate of production is close to a million dollars a year.

Elk Lake District.

There is a pronounced tendency to regard the newly-discovered iron-deposits in the townships of Morel and Yarrow with reserve. Part of the deposit was reported upon in 1911, but the recent interest has been based on the discovery of higher-grade material than that dealt with at that time. However, until further details may be secured, followed by extensive exploration work by diamond drilling, it will be quite impossible to accurately estimate the merits of the deposit.

The question of installing a mill on the Castle property of the Trethewey Company, at Gowganda, is still under consideration but no definite decision has so far been reached. It is believed a small plant may be installed, adequate to treat about twenty tons of ore daily, and to draw ore which would average about 50 ounces of silver per ton. This is about the average grade as so far determined and, although fair-sized shoots of high grade permit an occasional shipment to the railway, yet the general average of 50 ounces to the ton is not sufficiently rich to pay for the long haul and it is for this reason that a small mill on the property is regarded as a necessity. It is planned to extend the shaft from its present depth of 170 feet to a depth of 270 feet and carry on lateral operations at that point.

The scheme to build light, narrow-gauge railways through the outlying mining districts, including Gowganda, holds out promise of solving the transportation difficulties of this promising silver-bearing area. All property owners appear to be prepared to strongly support the project now that it appears likely to become a reality with experienced men behind it.

Should the plans of the promoters of the scheme materialize, the new line may be in operation from Swastika to Gowganda by the end of this year, in which event it seems reasonable to expect quite a revival in activity to occur throughout the Gowganda district. There are numerous promising prospects in this field, some of which develop successfully were the unsatisfactory and expensive transportation handicap to be overcome.

Quotations for silver remain weak, in spite of the exceedingly small production as compared with normal conditions. Various opinions are expressed as to the cause or cause for the low price of the metal, but these opinions are more or less confusing and conflicting. After studying the opinion being expressed by metal authorities, and not forgetting the varied ideas which take on the aspects of guesses, it is the opinion, or guess, if you will, of the "Journal" correspondent that the weak quotations for commercial bar-silver are due to the impoverishment of the European nations as a result of the war. In a word, the evidence goes to show that the world really requires silver but is too poor to pay for it. Time alone will adjust this situation in the natural working-out of the law of equilibrium.

THE GOLD MINES.

The Porcupine District.

During the fiscal year ended March 31st, the Dome mine produced $1,916,403 in spite of operating under the serious difficulty of a pronounced shortage of hydro-electric energy during the closing five months of the period. The ore contained an average of $7.50 a ton, and recovery amounted to $7.11 a ton, or 94.72 per cent. The total operating cost was $1,239,508. This included mining, development, crushing and conveying, milling, administration taxes, and insurance and left a net balance of $706,891. In addition to this the company received $247,356 made up as follows: $183,081 on exchange, $51,275 interest on bonds, $8,216 bank and miscellaneous interest and miscellaneous income of $1,781. This made a total profit of $954,250 for the year, against which is charged $651,770 for depreciation, depletion, and Dominion Government income war-tax, thereby leaving a net profit for the year amounting to $302,480.

The Hollinger Consolidated is having a preliminary survey made of Kettle Falls with a view to ascertaining the volume of the flow, and other details in connection with harnessing this power. The distance separating the falls from the mine is about sixty miles due north, and the intervening territory presents no serious obstacles in the way of transmitting power provided it should be finally decided to go ahead with the scheme.

A shaft has been sunk to a depth of 150 feet on the property of the Union Mining Corporation, situated in the township of Whitesides, lying about 25 miles south

west from Porcupine. A station is being cut at this depth, where it is planned to carry on lateral work on three veins, one of which is approximately eight feet in width and is said to carry commercial gold-values. Transportation is not very favorable, but the Ontario Government is stated to have expressed its willingness to improve the road. The company is considering the installation of a mill within the next few months, but the plan will probably be held in abeyance pending the improvement of the road.

The work of deepening the main shaft of the McIntyre-Porcupine from its present depth of 1,550 feet is proceeding. The objective is 2,000 feet, with the intention of perhaps carrying the work to a depth of 3,000 feet within the next two years or so. The mine is shaping up in a big way, and by the end of this year will treat about 900 tons of ore daily as compared with a former rate of an average of 550 tons daily.

An endeavor is being made to arrange a resumption of work on the Whelpdale property lying north of the town of Timmins. Former underground work on this property proved the existence of a number of strong veins. Gold values were comparatively low as found in previous work, but prospects are believed to warrant a further extensive plan of exploration work.

A syndicate, in which Toronto interests are identified, has under contemplation a scheme to re-open the Hollinger Reserve property, situated in the township of Deloro a few miles south from the Hollinger mine.

Prospectors are spreading out over the country in various directions and, although the number of men in the field is not large, yet the nature of their activities is such as to offer promise of interesting developments in the outlying districts. These men now have the advantage of comparing their prospects with properties on which real success has been achieved and the element of gamble is thereby reduced considerably.

Kirkland Lake District.

During the month of April, according to the regular monthly statement issued by R. C. Coffey, manager of the Lake Shore Mine, the mine produced $22,214. The mill ran 93.64 per cent. of the possible running-time and treated a total of 1,860 tons of ore. This daily average of 62 tons is the highest so far achieved in the mill, although the average grade of the ore was the lowest for any month since milling commenced.

This low gold-content is due to the fact that it is the policy of the company to treat the material coming from development work and in which there is of necessity considerable waste rock.

At the 400-ft. level, 83 feet of drifting, 72 feet of raising and 51 feet of cross-cutting was done, while at the 600-ft level, a total of 146 feet of cross-cutting and 85 feet of drifting was done. This made a total of 437 feet of work during the month, or at the rate of approximately one mile a year.

In carrying on such extensive development work, an enormous amount of ore is being developed for future milling-requirements, and the tonnage coming from development work alone is adequate to feed the present mill, and does not permit drawing any of the high-grade ore which is being broken in the stopes where the average gold content is well over $20 per ton, and in large sections actually amounts to an average of between $25 and $30 to the ton.

A body of ore seven-feet in width, and containing $21 per ton has been cut by a diamond drill operating from the 900-ft level of the property of the Kirkland Lake Mining Company. In lies in close proximity to the main shaft. It is also officially stated to the "Journal" that a large body of ore is being developed near the shaft at the 700-ft. level, and the general physical condition of the mine is very favorable.

The work of pouring cement for the foundation of the new 100-ton mill on the Ontario-Kirkland mine will commence about the middle of June. In the meantime, the frame-work for the structure itself is being prepared and the work of construction will be speeded up so as to place the property on a producing basis in October.

A. G. Burrows and P. E. Hopkins, Ontario government geologists have completed the field work in the northern part of the township of Skead, and it is expected that the map of the whole district will be printed some time in July.

The work of gravelling the new road from Boston Creek to the centre of activity in Skead is proceeding at a good rate, this government assistance having been given following a demonstration of good faith by claimholders who themselves performed the first work of opening the twelve-mile road for wagon traffic.

These claimholders again formed a "working bee" on May 19th, according to information just sent out by a mining man of that district, and with eighteen prospectors and miners equipped with axes, saws and stumping powder, cleared nearly two miles of road in a single day, thereby putting St. Anthony lake in touch with the main road.

This road work is of especial interest to those pioneering in the newer districts of Northern Ontario, showing as it does a high degree of cooperation between the pioneer and the government.

A GEOLOGIST AS A PROPHET.

United States Geological Survey's Estimates of Natural Gas in Texas Prove Accurate.

An estimate made in 1915 by the United States Geological Survey, Department of the Interior, of the quantity of natural gas available to Dallas, Fort Worth, and other Texas cities has proved to be very nearly correct. Though recognized as a hazardous undertaking, it is evidently possible to make, on a sound scientific basis a fairly close and very useful estimate of the quantity of unrecovered natural gas in any particular region. The estimate made indicated a supply in the Petrolia field—the main source of supply—sufficient for three or four years, though it was noted that there would be shortages in cold weather, if this supply were not supplemented by gas from other sources. E. W. Shaw, the Survey geologist who made the estimate, concluded that the Petrolia field contained 70 billion cubic feet. That field is now nearly exhausted, and the estimate has proved good, the shortage of gas being the occasion for a new examination and report in 1920.

It was also pointed out in 1915 that gas should be brought from Oklahoma, and this was done, lengthening the period of gas burning in these cities from three or four years to five years. Finally the belief was expressed that new oil fields containing both gas and oil would be discovered in Texas, and drilling in the region west of Fort Worth was urged. This region has now been drilled and a large supply of gas has been made available, so that these cities may expect to have gas several years longer—for many years if waste could be eliminated.

TORONTO COAL PRICES

Toronto, June 2.—There have been no changes in the prices of the various grades of coal during the past ten days or two weeks. Slack is quite easy and fairly plentiful. Points on the lower lakes are pretty well filled up with lump coal and it looks as if an embargo against further shipments will have to be put on which would have a tendency to strengthen the slack market. Anthracite is tightening and there is a noticeable difficulty in obtaining good quality stove sized coal. Slack is ranging from $1.10 to $1.90 f.o.b. mines at the mines, lump, from $2.35 to $3.15, smokeless, from $2.35 to $3.15; smokeless, from $2.35 to $3 for mine run. Anthracite is twenty per cent above the circular prices and the independents are charging from fifty to seventy per cent on the advertised prices, which makes chestnut and stove in the neighborhood of $7.85.

A COMPRESSED-AIR BORING-AUGER FOR COAL.

The Westphalian mining weekly "Gluckauf" for 7th May contains a description of a coal-boring auger driven by compressed air which it is stated has been used for some time with good results in a number of Westphalian collieries. The weight of the machine, without the twist-drill or boring-auger is 22 pounds, which can be lessened if aluminium is used for the housing. Test borings in hard coal show that the drill can bore to a depth of 2 metres in two minutes is recorded. The fatiguing effect of the hammer-drill on the operator is said to be avoided. The amount of dust made is also said to be much less than that made by the hammer-drill, and the coal is not reduced to so fine a state by the rotating drill as it is by the blows of a hammerdrill, and the manner in which the auger-drill is withdrawn gives a shot-hole much freer from particles of coal and from fine dust. The comparatively silent working of the drill enables the miner to detect noises indicating movements in coal and roof more easily, conducing to safer working. The rapidity with which the rotating drill works, and its smaller air consumption during a smaller period of operation is said to make much less exacting demands on the air-pressure available.

As an example of the method in which the compressed-air drill is used in a Westphalian colliery, it is stated that one man, specially entrusted with this work, bores all the shot-holes for 100 miners with one machine. The borer carries the machine in a box with necessary accessories. As compared with a hammer-drill type of borer it is said the rotating-drill type enables an increase in coal production of 20 tons per shift of 100 miners.

A special feature of the particular type of drill described is the lubricating mechanism which is based on saturating with oil a small part of the incoming air. The device is said to ensure perfect lubrication with a minimum use of oil.

CHANGES IN STAFF OF DOMINION COAL COMPANY.

The Dominion Coal Company recently reintroduced the system of dividing its collieries into superintendence districts, and a number of changes are announced consequent on the appointment of Alexander McEachern, formerly superintendent of No. 1 District, as chief inspector of mines for the Company.

Alexander MacDonald is appointed in charge of No. 1 district, comprising collieries 1, 2 and 9.

P. T. Prendergast, is promoted from assistant superintendent of No. 1 district, to charge of No. 3 district, including collieries 4, 6, 21 and 22.

A. D. Matheson is prompted to superintendence of No. 2 district, comprising collieries 5, 10, 11 and 24.

No. 4 District, including collieries 12, 14, 15, 16 and 17, remains under superintendence of J. C. Nicholson.

A Jarosite Deposit in Victoria, Australia.

"Chemical Engineering & Mining Review," Melbourne, in the issue of March 5th reports the existence of well-defined seams of jarosite in the cliffs near Anglesea, Victoria. This little-known mineral is described as a basic sulphate of iron and potassium, and in composition corresponds to its better-known sister mineral, alunite, which is a basic sulphite of aluminium and potassium. Jarosite may be described as alunite in which iron has taken the place of aluminium. Economically the mineral can be made to yield sulphuric acid, and pigments, and a company is being formed to develop the deposit for commercial uses Jarosite is a bright yellow mineral, and is sometimes known as yellow iron-ore. The deposits associated with the jarosite seams are carboniferous sands, containing much pyrites and casts of leaves, and in one place a definite seam of low-grade coal is observable. The jarosite seams are thought to have been formed by leaching of the pyrites by water and subsequent concentration of jarosite in jointings of the carboniferous sandstone.

EDITORIAL

The Prescience of Canadian Geologists

One of the most useful publications of the Geological Survey is the descriptive sketch of the geology and economic minerals of Canada by Young and Brock issued in 1909. It is the only publication available to the general public—if indeed it is not the only publication available anywhere—that deals with the economic geology of Canada as a whole in a manner to be understood of the people. Moreover it contains that extremely scarce but often-required reference, a geological map of the Dominion. This excellent publication is, however, very much out of date, and that it should be so obviously so is a testimonial to the rapidity with which certain phases of the mineral industry in Canada have developed. The correctness of Dean Brock's introductory remarks are now revealed as noteworthy. He wrote: "The amount of mineral-bearing territory still awaiting the prospector is prodigious, the greatest in fact that now remains anywhere on the globe. The mining industries of the country may be said to have only just begun".

Some quotations are of present interest. With regard to petroleum, the volume states: "There is evidence of the probable existence of a petroleum field in the north". The authors could not have foreseen Fort Norman and Imperial Oil monoplanes, but their forecast speaks for itself.

With regard to gold in Ontario, it is recorded that "though gold has been found and worked at many points in Ontario, from the Lake of the Woods on the west to the Hastings district in the east, a distance of roughly 650 miles, yet in spite of often highly-promising showings no permanent gold industry has been established. . . . . There is however reason to believe that eventually, as prospecting progresses, the mineral will be found throughout the pre-Cambrian region". Since this prescient opinion was written there has developed Porcupine, Kirkland Lake and other pre-Cambrian occurrences of gold that show daily increasing importance and hope of permanence.

Manitoba is mentioned as containing a pre-Cambrian exposure with similar potentialities to the—at that time—unprospected area of northern Ontario and Quebec. But there is no mention of Manitoba as a mining province in 1909.

Concerning asbestos, the statement is still as true now as in 1909 that the Quebec deposits are the most important in the world. It is regrettable to note, however, that the only monograph on asbestos occurrence and asbestos mining in the whole field of technical literature, that of Fritz Cirkel issued by the Geological Survey in 1910, is out of print, and there is a real need for a new monograph regarding a mineral that is much more important to Canada, as it is much more important to the world, at this date than it was twelve years ago. With the exception of "Chrysotile Asbestos" there is not, so far as can be ascertained, any available manual on the mining, milling and preparation of asbestos.

In the matter of coal, Alberta plays an insignificant role in 1909, less than two million tons being produced. The attention which would require to be given to Alberta coal deposits in 1921, as compared with that given in 1909 is as two million tons is to seven million tons.

In 1909, Ontario was recorded as the only province producing salt. This is by no means the case today. Similar instances might be multiplied. Sufficient has been stated to indicate that the prescience of Canadian government geologists based on partial knowledge and intelligent deduction therefrom, has been abundantly vindicated, and the record is one that justifies every cent of financial expenditure made on the Survey. In some respects the record stands as an indictment of folly against the uninformed parsimony that has shaved down the Geological Survey appropriation to inadequate proportions.

A revision of the 1909 volume of Young and Brock and a new monograph on asbestos are two expenditures that would be fully justified even at a time when our Senate has decided it cannot afford to save money, and for this amazingly inconsistent reason has killed the Research Institute Bill, thereby emulating in unreason the extinction of the Commission of Conser-

vation by the House of Commons. There are yet, as "John A." is said to have remarked, people who are fools enough to believe in these things but the elect are evidently in a minority among our legislators. One can only surmise that their indifference to scientific research arises from lack of knowledge of its value.

THE RESEARCH INSTITUTE BILL.

Many sins have been committed in the name of economy, and the killing of the Research Institute Bill by the Senate is one of them. It would have been better had the senators attributed their action to any motive but that of economy, because the essence and the soul of the Research Institute proposal was that of economy. Not of course that unlovely and foolish imitation of economy known as parsimony, but true economy, the art of making much out of little, or what is ignorantly regarded as little. In all probability the coincidence of the proposal to abolish the Commission of Conservation with the proposal to institute the Research Institute was the main occasion of the action of the Senate, it being an obvious inference that the last-named body would supersede and take over the duties of the first-named. Obvious as such an assumption might seem, it would necessarily be incorrect, as the scope of the work of the Commission of Conservation did not touch, let alone conflict, with that of the proposed Research Institute, and it will later be recognised that the abolition of the Commission of Conservation is an error equal to that made in preventing the creation of the Research Institute.

The members of the Senate who spoke against the bill for a Research Institute referred to the enormous financial deficit of Canada, and the undesirability of adding to it by the creation of another department entailing some cost. The existence of this deficit is, to a considerable extent, a result of lack of utilization of our own natural resources, and Senator McLennan well said it would be a pity if economy were exercised in a quarter and upon a project which would retard national progress.

The action of the Senate is less understandable when it is known that it has been conducting an enquiry into the natural resources of Canada, with particular regard to fuel, oil-shales and iron-ore. Certain members of the Senate are very well aware that Canada is threatened in everything that pertains to the comfort and happiness of her people, and in her very existence as a sovereign state, by the deplorably inadequate state of development of her fuel and iron-ore deposits, by waste of forests and fisheries, and lack of oil-yielding resources under commercial development. Senator Beaubien assessed the action of the Senate accurately by saying that rejection of the bill would place a grave responsibility upon the Senate. It is merely an aggravation of the Senate's action in reversing the decision of the House of Commons, and in assuming responsibility for blocking a policy that is being followed by every enlightened nation, to plead economy. It is not economy for Canada to buy goods abroad that can be mined or produced at home, and it is the finest economy to develop processes that will prevent such a necessity. Senator Dandurand feared the country was entering a field that would involve the expenditure of millions of dollars, "something it could not afford". Those who see how perilous Canada's position really is were hoping the country would have the courage and the wisdom to take precisely the action feared by Senator Dandurand, and believe the short-sighted parsimony that dictates caution in the development of scientific research is also precisely what Canada cannot afford, and the very thing that is making her poor and appallingly dependent. Those who oppose the formation of a Research Institute "purely on financial grounds" as Senator Turiff expressed himself, might find much better fields for economy.

It is only possible to assume that the necessity for a Research Institute is not comprehended by the Senate, as a whole. Possibly the Senate, and other bodies representing the Canadian people, would take a different view of their responsibilities if they realised that unless Canada does very quickly begin to use what raw materials she possesses, the Senate and all other bodies of popular government will disappear because we shall be absorbed by nations who do believe in helping themselves.

CHANGES IN NORTHWEST OIL REGULATIONS.

The Government has amended the Oil and Gas Regulations of the Northwest Territories in two important particulars. In these columns in our issue of 18th March the "Journal" pointed out the propriety and desirability of granting to the holder of a permit to search a location for oil, the first option of a lease of the three-quarter location reserved to the Crown under the regulations as originally issued. This necessary and fair provision has now been made.

The clause requiring the discoverer of oil in paying quantities to use due diligence to maintain production has been amended so as not to require the continuous pumping of oil from the date of discovery. The provision was of course one impossible to comply with until the problem of transporting any oil that may be found to market or railhead, is overcome.

Representations are being made by western newspapers that grouping of locations and common use of a drilling equipment is apparently forbidden by the Regulations, and it seems probable that permission for grouping will have to be given. There seems no good reason why it should be disallowed.

Despite the tenor of the regulations, which are understood to be aimed at preventing the formation of anything approaching a controlling interest or a combine in the exploitation of the putative oil-wells of the Northwest, it is becoming clearer that unified effort in proving and operating the oil formations, and in providing means of transportation, will be a necessary

preliminary to commercial success. While the motives of the government may be good and conceived in what passes for righteousness in popular belief, yet the future will surely prove (should flowing oil-wells be discovered) that the maximum production of oil, at the cheapest cost, over the longest period of yield, will only be obtained from the remote Northwest, when, by commercial evolution, the operation of the oil-wells falls into the hands of very large companies, controlling properties so grouped and of such an area as will practically amount to a concession, in the usual meaning of that term. The course of events between this date and the coming of the Northwest as a great commercial oilfield (always provided the oil is there) will be of a nature that will damage the physical condition of the oilfields, will increase operating expenses, will bring about unjustifiable capitalizations and property valuations, and generally, by unloading individual obligations upon a field that is only suitable for single operation and management, result in increasing the unit cost of whatever oil may be produced when the field settles down to commercial operation and competition against other oilfields more favourably situated.

EN PASSANT.

The reduction of freight rates on coal in the prairie provinces during the Summer, and the news that the Alberta Trade Commissioner has been in Prince Rupert looking into the possibilities of that port as an outlet for Alberta coal, are two signs of the wide-awake and constructive character of the policy of the western coal operators. The Alberta people quite evidently know what they have in the way of coal, know what they want to do with it, and go after business.

The resumption of production at the Nickel Plate gold-mine in British Columbia is cheerful news. By the smallness of Canada's production in coal and iron the premium on New York funds appears likely to be maintained and while to most people the discount on the Canadian dollar is a bugbear and an irritant, it is quite otherwise to miners of gold and silver bullion and asbestos. Gold production bids fair to bulk largely in Canadian mineral returns in 1921.

The policy of the Dominion Steel Corporation in providing a scheme of pensions for the attainment of the retiring age and a specific number of years in the service of the Corporation, or its predecessors, is a good one. The lack of such a provision has in the past placed executives in a position of undesirable and undeserving onus, and experience has abundantly shown that a proper pension provision is necessary in any and every corporation which aspires to corporate importance and has any pretensions to financial strength, or looks forward to the attachment of a capable staff in years that are to come.

The formation of a branch of the Canadian Institute of Mining & Metallurgy at Nanaimo is an interesting result of the Secretary's tour. There ought to be material in such an old-established coal-mining district as Vancouver Island for the making of a branch that will rival the Mining Society of Nova Scotia, which holds up the credit of the coal miner in the extreme East. There is a very considerable similarity between the problems of coal-mining in these two widely separated localities.

In substituting electric miners' lamps for oil-flame safety-lamps in its mines, the Dominion Coal Company is doing excellently well. The electric lamp has many merits, which have been set forth in previous issues of the "Journal", but its chief merit is that of safety. In comparison with the naked light, the gauze-screened, oil-flame safety-lamp had a right to its title, and it has had a long and honoured career; but, in comparison with it, the title "safety-lamp" should now be awarded to the electric lamp.

A correspondent to the S. A. Mining & Engineering Journal, whose ideas on stratigraphy, if unorthodox, have at least the merit of limpid simplicity, advises "home readers" in South Africa not to refer to the publications of the Geological Survey for information, as these "are absolutely useless from an economic point of view". It all depends on the interpretation of the word. From the standpoint of the shady stock promoter's economics we believe the publications of the Canadian Geological Survey will also be found absolutely useless. In fact they are worse than useless, they are an impertinence and an offence and a veritable rock of stumbling.

PERSONALS.

Mr. R. W. Brock, who has been visiting in Ontario and the United States, has returned to British Columbia.

Mr. A. G. Burrows and Mr. P. E. Hopkins have returned to Toronto, and are completing a geological map of Skead township.

Hon. Harry Mills, Minister of Mines of Ontario, is visiting mining districts along the T. & N. O. Railway, including Cobalt, Porcupine and Kirkland Lake.

Mr. A. R. Thomas is in charge of development work at the Tough Oakes Mine for Kirkland Lake Proprietary, Ltd.

Dr. W. G. Miller, Provincial Geologist of Ontario, is visiting gold and silver mines in Northern Ontario.

Mr. H. W. Hardinge of New York is visiting gold mines at Porcupine and Kirkland Lake.

Mr. Robert Bryce of Toronto is examining properties at Kirkland Lake.

A meeting of the directors of Hollinger Consolidated was held at the mine last week.

Mr. H. P. De Pencier, manager of Dome Mines is of Toronto.

Mr. R. J. Innes, manager of McIntyre Porcupine Mines has returned to the mine after a few days in Toronto.

Anglo-Persian Activity in New Brunswick Oil Shales

Eight-ton Testing Plant in Operation, Technical Staffs Being Increased and Larger Plans Being Framed When Results Satisfactory.

By ALEXANDER GRAY.

The Imperial Government, through the Anglo-Persian Oil and D'Arcy Exploration Companies, is making a practical test of the New Brunswick Oil shales.

As the Imperial Government owns a controlling interest in the common stock of the Anglo-Persian company, New Brunswick is in a receptive if somewhat passive mood. In all but its specialties, that has been New Brunswick's habit.

Anyhow, the village of Rosedale on the Albert and Harvey branch of the International Railway, and environs, are a center of scientific and industrial interest —because of the re-birth of shale enterprises.

Rosedale was Baltimore. The old maps show it. Those maps indicate that the shales, in addition to farming and lumbering, provided the incentive for the construction of the aforesaid Albert and Harvey railway. Otherwise Rosedale went into partial eclipse. Apart from the records providing that prospectors and premature promoters acquired and retained areas, there was little to expedite capital expenditure in mineral resources. Certainly there was a Baltimore Railway and Mining Company, Albert Mines, holdings supposed to possess a kind of coal, oil, gypsum, and what not. Seventy years ago was an era of Great Expectations in and about Baltimore. Occasionally in the interim brave men have maintained the section has the elements of wealth in profusion—but not until now have the most optimistic of those felt their hopes are to be realized.

New Brunswick submissively awaits results of the initial operations under the auspices of the Anglo-Persian Company and its subsidiary, the D'Arcy Exploration Company. It is not to be implied that New Brunswick has foresworn allegiance to lumbering, pulpwood and fishing—if we exclude politics. No New Brunswicker worthy his nativity would forego these heritages. First and foremost he is a fighting partisan. Not infrequently rivalry as between Halifax, St. John and Moncton varies the procedure. Self-centered farmers, too, give thought to the probability of cheese going to 15 cents this Summer. Potatoes having been a "bad bet" are likely to "come back." Not unnaturally preferment is cherished for what made New Brunswick self-conscious of its prowess.

The determinations under way at Rosedale evoke only the slightest comment—and are untalked of by all excepting those who are anticipating rewards for years of weary waiting in which their patience and purses were exhausted; those operating the Wallace distilling plant and those engaged in ascertaining the approximate extent of the oil shales.

So complacent is the native New Brunswicker toward the mineral resources of his Province, he is debating whether or not it is advisable to put out his own coal for his own comfortable and efficient National Railway, or to continue to use the Nova Scotian product. In timber, cordwood—saw-logs and slabs—mixed farm-products and fish, New Brunswick revels—not infrequently pausing to take a fling at the millions expended upon dredging, concrete work and breakwaters in and about a certain portion of St. John Harbor.

Moncton's natural gas and what oil assiduous drilling brought to surface, long since ceased to be a novelty, however economical in the household where calories from elsewhere are not mis-spelled choleries. Recurring annual references to the potentialities of New Brunswick's oil shales threatened to become perennial until noted scientists placed their hall mark of approval upon them and enabled Mr. Mathew Lodge and Sir William Mackenzie to enlist, by proxy as it were, the Imperial Government through the Anglo-Persian Company, the latter, at the moment, being the most reticent party to what is happening, while Mr. Somerville, the Scotch shale expert, is making comparative tests.

For all of which there was and is a good and sufficient reason. Matter-of-fact New Brunswickers concentrated their energies upon forests and streams, the more expansive coastal waters; put their money into selected and select securities, one of the consequences being that lessees of oil shale lands and problematical petroleum country—which subsequently yielded gas enough to supply most of Moncton for a while—had to go elsewhere for financial assistance.

Therein New Brunswickers displayed their hard-headedness. Consequently, it required half-a-century for the most expert in modern oil-economics to discern in the oil shales of New Brunswick, Utah, Colorado, Wyoming and other districts what they are now described to be: "The second line of industrial defence." Furthermore, and to begin with, the distinguished service rendered by Dr. James Young in manufacturing paraffin from shale oil, had not influenced other than Scottish shale-owners. Singularly enough, too, Western world scientists and embryotic capitalists confusedly and varyingly designated the New Brunswick deposit as "Coalite," "Albertite," and "Cannel" coal—neither of which it happened to be.

The shales of Albert county are identical with the Scotch shales—only it is claimed in behalf of the former that they are richer in oil and sulphate of ammonia. Anyhow, there was no catastrophe accompanying the discovery of this "Albertite," such as attended the first flowing oil-well on Troublesome Creek, Virginia 103 years ago, when there was a rush of "The Devil's Tar," as the astonished driller characterized it, according to Mr. Victor Ross in his "Evolution of the Oil Industry."

Dr. Young and his Scottish experiments contributed largely to the industrial adaptation of petroleum, which was a revolution of universal moment. It is more than co-incidental that Troublesome Creek product subsequently became one of the ingredients of a medical oil made by a chemist named Kier, who also experimented with the "Tar" as an illuminant.

About forty years elapsed, however, before Kier achieved success and, as Mr. Victor Ross states, evolved a burning fluid which "attained some vogue in rivalry to a kerosene which was being extracted from oil-shales in the Province of New Brunswick." Whatever of groundwork is justly attributable to Dr. Young and Chemist Kier, out of the "Devil's Tar" of Virginia

and the "Coal Oil" later on derived from Albert County, New Brunswick, was devised practical processes for the refining and marketing of crude petroleum. Without those "foundations," as Mr. Ross points out, the decision to test the ground at Titusville, Pennsylvania, in 1859, by means of boring and pumping would not have been so adversely momentous to the New Brunswick shale industry. While Bissell and Drake, encouraged by Professor B. Silliman, of New Haven, were grappling "with the problem of extracting from the crude a safe burning oil end eliminating the offensive odour," it was Dr. Abram Gesner who antedated them by investigating the New Brunswick shales about eight years before Drake's discoveries at Titusville "benefitted mankind, stimulated mechanic arts, enlarged the pharmacopoeias" so that the 2,000 barrels of crude oil produced in Pennsylvania in 1859 rose to 4,215,000 barrels in 1869.

Drake's drilling apparatus and efforts were the joke of the day. Dr. Gesner's distilling plant at Baltimore—now Rosedale—in New Brunswick, evoked ridicule and amusement. Gesner produced and refined "coal oil" at Baltimore, and was the pioneer in this respect. The part he played has been scantily recognized. He lectured throughout New Brunswick on his new lighting-fluid, and it is worthy of emphasis that Gesner's illuminant entered into competition with that recovered from "The Devil's Tar." Nor was the Gesner Baltimore distilling-plant permitted to monopolize the field. "Albertite Coal" was found near Hillsboro, where mining started. A considerable quantity was shipped to the Downer Oil Company, of Boston, for distillation into oil and for use in the manufacture of gas.

Mr. Lodge, five years ago, recited those developments. New Brunswick was a prime factor, therefore, in the initial stages of the oil industry on this continent. Mr. Charles Archibald, of Halifax, Mr. Harding, of St. John, and others, under the guidance of Scotch engineers, also are credited with having operated a retorting plant at Baltimore. The shales and the "Albertite" were appreciated for their unique contents. Americans welcomed "coal oil," paraffin-wax candles, whatever enriched the gas being manufactured in those days.

For the time Baltimore and Hillsboro were to the fore. Albert Mines were an industrial center of some note. Even after natural oil was discovered in Pennsylvania, for a year or two interest in the New Brunswick areas did not wane. The Downer Oil Company, of Boston, headed by Mr. Merrill, Professor Carroll and Louis J. Emery, of Bradford, Pennsylvania, the latter being the scene of important oil developments, busied themselves and undertook to drill St. Joseph, Memramcook and Dover localities. Events in Pennsylvania, the seepages noted in New Brunswick, made adventurers all the keener, but while the upper oil and gas-sands were tapped and were somewhat encouraging they were insufficiently so to withstand the more glamorous Pennsylvanian fields.

Eventually Dr. Gesner and his contemporaries vanished from Baltimore and Hillsboro. Here and there New Brunswickers tried out their country, but New Brunswick's "Albertite," "Coalite" and "Cannel Coal" were "unhonored and unsung," though not "unwept," for nearly forty years thereafter, despite periodic pronouncements that oil would be discovered in commercial quantities. Fluid oil had priority. It was not material that Professor Shaler, of Harvard University, twenty years ago sagely declared with regard to oil that "the sources of supply are waning, and no important new fields have been discovered of late. The search for petroleum has always to be undertaken with a chance of failure."

It took New Brunswick twenty-seven or eight years to think it over. Meanwhile and in the face of Professor Shaler's apprehensions, the United States annual oil production attained to a grand total of nearly 400,000,000 barrels, irrespective of importation. Yet there are those in New Brunswick who accept the estimate of distinguished scientists who represented the Imperial Government in 1914, that there is a possible 4,950,000,000 Imperial gallons of crude oil in one section of the New Brunswick shales. As the shales are said to extend over a longitudinal distance of thirty-six miles, the others than the section quoted by the scientists need not be so strong to put the Albert series upon the oil maps—provided there is adequate profit in the mining, distilling and marketing operations. The 9,000,000,000 lbs. of sulphate of ammonia alloted by the same scientists to this particular section of the shales may constitute a supply that will obviate a shortage.

Since those estimates were recorded further drilling confirmed the confidence of the vendors and the present holders of the shale-bearing areas for which New Brunswick contentedly stipulated a yearly rental of $300, and a royalty of 10 cents a ton after an expenditure of at least $100,000. Desultory years intervened. The province was more prolific in periodic promotions than in production, what money was raised being more on personal account. Lessees in general held areas. Most of those areas were comparatively small and what proof there was as to oil and gas was unimpressive to outside capital. Eventually, however, Mr. Lodge, of Moncton, and associates, decided to seek a concession. They broadened their horizon sufficiently to cover 10,000 square miles and appealed to Premier H. R. Emmerson, who secured expert advice and subsequently was instrumental in putting through an Order-in-Council granting the concession to explore for oil and gas.

The creation of the New Brunswick Petroleum Company in 1899, the identification of the late Hon. B. F. Pearson with the development, the advent of the first drilling rig in 1901 on the farm of Ralph Steeves at Upper Dover, are matters of somewhat forgotten history. Mr. Pearson and Professor Shaler together with Professor Gooderich, lent the weight of their fiscal and professional influence. They urged upon officers of the New Brunswick Petroleum Co that they were "decidedly of the opinion that the field is one eminently fit for exploration, and that the chance for finding oil and gas is extremely good."

The "decided" optimism voiced by Professor Shaler failed of effect other than to promote spasmodic effort. Premier Emmerson, of New Brunswick, enthused. Other countries, including Canada, availed of the Pennsylvania developments. Ontario became a prodneer Roumania led off with "hand dug" wells and at the outbreak of the Great War was yielding 11,000,000 barrels of crude petroleum annually. Russia preceded all countries and in fifty years contributed 1,650,000,000 barrels, the main part, as Mr. Victor Ross states, from an area of about 4000 acres in the Baku district.

Before New Brunswick sought expert counsel in 1893, Russia had drilled nearly 500 wells, and Pennsylvania then ceased to attain to its maximum produc

tion of 35,839,777 barrels in 1891. Emphasis need not be laid upon discoveries of oil throughout the States, Mexico, South America, the West Indies, Europe and Asia. Apart from Ontario, Eastern Canadian areas continued unexploited. Professor Shaler in 1903 advocated a drilling programme to test the deeper sands "west from the Petitcodiac River, elsewhere than at St. Joseph's and Weldon" where, he was confident there was oil and gas, a forecast that was verified somewhat seven years afterward.

Oil shales were not entertained. It is alleged the New Brunswick Petroleum Company, Ltd., which blanketed the country with their concession, to 1905 had expended "some $250,000 in development work." How that much could be distributed without having more to show for it, unless the acquisition of ground and investigations made were costly, it not clear. Oil and gas undoubtedly were located, but it was not until January, 1909, that an arrangement was effected with what became the Maritime Oilfields, Ltd., which took the working option on the concessions, the stipulation being that they had the right to search for fluid-oil and gas.

This company, under the management of Dr. J. A. Leo Henderson, whose father and family were outstanding factors in South Africa, found large quantities of gas, but insufficient oil, so a contract was made with Mr. T. N. Barnsdall, of Pittsburg. The Barnsdall Company organized the Moncton Tramways, Electricity and Gas Company, to serve with gas Moncton and other cities. This Barnsdall Company expended about a million dollars in piping and plant, and supplied Moncton City, its suburbs, and Hillsboro, with gas for lighting and power.

If the million or so expended by the Barnsdall people, the $250,000 spent by a preceding company, and other amounts, be lumped, the return upon capital to the New Brunswick Gas and Oilfields, the successor of the New Brunswick Petroleum Company, and the Maritime Oilfields, Ltd., which were merged, has not been commensurate. Unless the promoters reimbursed themselves, shareholders had no reason to further invest in the exploitation of prospective oil areas or the shales.

This has not deterred the company from persistently endeavoring to maintain the supply of gas, and also to locate oil. Mr. Lodge has chronicled it (in 1917) to be a fact that "several billions of cubic feet of gas have been supplied to the manufacturers and householders for heat, light and power." In the year 1916 there was consumed in the City of Moncton 599,454,000 cu. ft. of gas, at a rate of 25 to 38 cents per thousand cubic feet, a boon to those benefited during the "profiteering" period. Moncton's prosperity coincides with this supply of gas and the advent of railway terminals and factories. For this gas the province receives a royalty of 5 per cent of the value. Speaking for the Canadian Government Railways, in 1913, General Manager Gutelius figured the cost of natural gas used for their engines, at an average cost of $1·17 per horse power per month. With this economy in effect, the impetus and convenience provided throughout by the gas; and the income however small accruing to the province, patient shareholders experienced "the slings and arrows of outrageous fortune." In recent years encouragement was met with in finding a little oil—1920 being the record year in this respect with a production of 714,827 gallons of crude—the daily average of the whole province being given by the Dominion Statistician as slightly over 14 barrels, a somewhat tantalizing quantity. Nevertheless the finding of gas and indications of oil kept on view the larger possibilities, not only in natural oil but in regard to the shales. Owing to non-success in bringing in sufficient additional gas wells the supply is being mainly restricted to households.

The chief actors in those tortuous years saw the curtain rung down upon their performances, in everything other than bulk production of gas and a trifling amount of oil. Scientists did not convince capital New Brunswick shales were opportune. "Production is only kept up by the work of the 'wildcatter.'" Mr. Victor Ross wrote. Natural oil became the vogue; the "wildcatter" became omnipresent; to the end of last year the world had produced nearly as much oil as it is estimated there is remaining in known petroliferous strata—but the extraction of oil and recovery of the other contents of oil-shales continued to be economically out of it. Even now there is a doubt. Authorities declare results from the shales are contingent upon the world's necessities and cheap labor. It is not disputed that the shales will be an industrial refuge. Ultimately not only the oil but the contained sulphate of ammonia are admittedly important — if economically available.

War prices for oils and the rate of consumption of natural oils, finally induced the Washington Government to bestir themselves and determine the quality and extent of the Colorado, Utah, Wyoming and Nevada shales. In this respect, Washington followed the lead of the Imperial Government upon the initiative of Messrs. Lodge and Sir William Mackenzie who sponsored the New Brunswick shales. Concurrently the Hon. W. G. Pugsley and Senator Domville, owning a smaller area known as Albert Mines, or Oil Shales Company, Ltd., made a demonstration in 1918 through a local fuel administrator by shipping free of cost other than a freight charge, 100 tons of their shales, the owners imposing the reservation that the provincial royalty of 10 cents per chaldron of 2,856 lbs. be waived. Of this novel test, the report of the New Brunswick Crown Land Department said:

"It was found to make a hot fire, the oil embedded in the shale forming a brilliant and cheerful flame, and thus rendering it adaptable for use in an open grate. The only drawback was the excessive quantity of residue remaining after the oil was consumed. This drawback was largely overcome by the use of dump grates. Resulting upon this experiment a spur of nearly half a mile in length from the Harvey-Salisbury Branch of the Government Railways has been constructed, and a seam of oil-shale has been opened up in the hillside close to the track, from which several hundred tons have already been mined. The Department is informed that the shale taken from this seam is rich in oil, average samples yielding close to 60 Imperial gallons of oil to the ton, or about double the richness of the oil shales of Scotland, from which the distillation of oil has been carried on successfully for many years. While the use of the oil shale for fuel to help meet the present fuel emergency situation, may in some degree realize the results hoped for, it is also expected that the very general attention which has been called to the richness of the shale in oil — while it is also known to contain a large percentage of nitrogen, useful as fertilizer in the form of sulphate of ammonia — will result in the early establishment of a plant for the distillation of oil, and the production of sulphate of ammonia and other by-products. . . . Already capitalists in the United States are starting in to develop the oil shales; a score of experts are engaged in designing retorts for distillation of oil, which it is claimed will improve upon the retorts in use in Scotland and render the plants better adapted to treating the shales of the United States, which, like the shales of New Brunswick, owing to their greater richness will, it is claimed, require a somewhat different treatment

than the Scotch Shales. . . . It may, as stated above we think safely be said that the time is now nearly at hand when a great and successful shale-oil industry will be esablished in this Province."

That was officially written of the same shales Dr. Gesner had worked in 1851, and ten years after Lodge and his New Brunswick colleagues—subsequently joined by Sir William—concluded that those shales had potential value, their lateral extent of 36 miles in Albert, Kings and Westmoreland Counties promising quantity if quality was persistent.

Governor Pugsley also concluded to have a bulk test made of his shales; so he had 161·5 lbs. shipped from "an opening on seam No. 1, on Frederick Brook, Albert Mines," represented "as a fair sample of the seam," to W. G. Wallace, superintendent of the St. Clair Gas Company, of East St. Louis, Illinois, who had successfully experimented with and patented methods for carbonizing coal and restoring shales. Dr. Haanel, of the Ottawa Mines Department, superintended that test, and he reported:

"The total quantity of shale received at the laboratory of the St. Clair Gas Company, was 151.5 lbs. and this was divided into two lots, 81.5 and 80 lbs. each, which were retorted in two separate tests.

"The recoveries obtained were as follows:

Test One:

Summary of Results.		Per Ton of Shale.	
Shale Charged	Lbs. 81.5		
Oil Recovered	13.6	43	U. S. Gallons
Gas	Cu. Ft. 175	4290	Cu. Ft
Spent Shale	Lbs. 52.15	1297	Lbs.

The oil recovered, viz., 13 lbs 6 ozs., contained a small quantity of water which was not determined. The calorific value of the gas produced also was not determined

Test Two.

Summary of Results	Per Ton of Shale
Shale Charged, 80 lbs.	
Oil Recovered, 11 lbs. 14 ozs.	39.6 U. S. gallons

A leak developed during this run, hence the lower recovery

Those results are quoted because they relate to the solitary shale-bearing acreage of any consequence, so far as I have ascertained, that was not included in the approximately 190 square miles incorporated in the "Albertite, Coalite and Cannel Coal Company, Ltd.," in 1907. Prior to this concession, the broader grant was made covering 10,000 square miles, practically the whole eastern section of New Brunswick, conveying the right to seek natural oil and gas, no reference being made to the shales. Messrs. Lodge and associates obtained a practical monopoly of the shales, upon lenient conditions and terms, for 100 years. The Pugsley Domville smaller area Oil Shales Company of Canada, now, was leased under what is known as the Old Act, and these latter lessees without doing much, and without being called on to do much, simply have to pay a royalty of 10 cents per chaldron, after 6 per cent has been earned on the company's capital. Virtually perpetual the lease brought the holders of it nothing further than occasional effort and non-success in inducing capital to satisfy some of the vendors and take all the risk entailed in attempting to establish an oil shale industry. Early in this year, actually on February 22, one drill hole was completed by the owners of this lease and their friends. It was stopped at a depth of over a thousand feet, without penetrating through the shale series, and this is the log of that hole:

Rock Borehole No. 1.	Color and General Character	Thickness Bored Feet	Total Depth from Surface Feet

Note.—At 700 ft. to 710 ft. [illegible] found on the water.

At 923 ft. to [illegible] [illegible] the water [illegible] half a pint [illegible].

[illegible] stopped [illegible]

Maybe this is the first time a complete [illegible] for this depth has been submitted for publication. The log by no means represents the depth of the Albert Series although it will suffice. The [illegible] concession for fourteen years [illegible] 1907, with the right of renewals, by the "Albertite, Coalite and Cannel Coal" Company [illegible] in view of the [illegible] 190 square miles [illegible]. Messrs. Lodge, [illegible] and [illegible] New Brunswick Gas and Oil [illegible] notwithstanding the 190 square miles [illegible] of their 10,000 square mile grant.

What properly ought to [illegible] the Lodge [illegible] interest [illegible] 800 acres [illegible] heart-breaking [illegible]

tertain the further proposal that $100,000 be expended by them in a stated period, and ultimately to pay 10 cents a ton on shale mined.

Recently it was alleged the concessionaires might not have fully complied with the provisions of the concession. The concessionaires were sustained by the Provincial Government, however. They had been in possession so long, had repeatedly endeavored to impress upon capital the worth of the shales, and if they had not succeeded until recently the Provincial Government felt the holding company was fortified. It has not been for lack of effort that large operations were deferred. Hardly a year elapsed after the concession was obtained before Mr. Lodge made a trial shipment, of which he tells this story:

"In 1908 about 45 tons of the Shales from the property of the company were shipped to Scotland where they were retorted in the regular way under ordinary working conditions, and refined by one of the most successful Scotch Shale Companies, under the supervision of a capable official representing the Government of the Dominion of Canada. An official report of this practical test, which also thoroughly describes the Scotch Shale Industry, was published by the Government.

"It is established by that Government Report:

"(A) That the New Brunswick Shales contained an average of 40 Imperial gallons of crude oil, equal to 48 U.S. gallons, and 77 pounds of sulphate of ammonia per long ton of shale, and that such results were eminently satisfactory, and exceeded the values of the greater part of the Scotch Shales which had been worked for years.

"In his evidence, 1908, before the Committee of the Honorable Senate of Canada, Dr. Ells, the reporting official declared that,

"'In Scotland they are working in oil shales that went from 15 to 25 gallons of oil and 40 to 50 pounds of sulphate of ammonia per ton. Our shale was far ahead of anything we saw there.'

"(B) That the refined products of the crude oil obtained from the New Brunswick Shales worked out, according to two methods of refining, as follows:

Method A.

Products	Gallons per 100 gal. of Crude Oil	Specific Gravity 60 deg. F.	Setting Point Deg. F.	Melting Point Deg. F.
Heavy Naphtha	1.62	0.7670		
Burning Oil	10.04	0.7954		
Gas Oil	14.78	0.8431	25	
Cleaning Oil	2.83	0.8713	25	
Lubricating Oil	9.58	0.8957	30	
Crude Wax	2.26			112.26
" "	0.93			101.00
Residium from blue oil (refined)	0.28			
Residium from treated crude distillate	1.27			
	43.48			

Method B.

Products	Gallons per 100 gal. of Crude Oil	Specific Gravity 60 deg. F.	Setting Point Deg. F.	Melting Point Deg. F.
Heavy Naphtha	1.45	0.7670		
Burning Oil	11.50	0.7955		
Gas Oil	13.04	0.8450	25	
Cleaning Oil	1.56	0.8705	25	
Lubricating Oil	11.03	0.8935	30	
Crude Wax	2.21			113.30

Residium from treated crude distillate	1.95			
	47.07			

(See "Oil Shales" Ells Geological Survey Reports 55 and 1107, published 1909.)

Whatever disparities exist between the test made at East St. Louis in 1918 by the Wallace Process and that of 1908 by the established Scotch Process, the average of about 40 United States gallons per ton of shale is claimed by the promoters. Dr. R. W. Ells, of the Dominion Geological Survey, officially supervised this test in behalf of the Ottawa Government, and Dr. Charles Baskerville, of the New York City University, acted on behalf of the owners of the shale. They also reported a sulphate of ammonia content of 76·94 lbs. to the ton of shale. Nor did the determinations end there. Dr. Ells made others and obtained higher results in oil and sulphate of ammonia. More tests by Dr. Griffiths, of New York, corroborated the Ells-Baskerville data. Mr. W. A. Hamer further tested the shales in the laboratory of the New York University, under the direction of Dr. Baskerville, and reported upon samples selected from seven localities a yield of crude oil varying from 35 to 65 United States gallons, and ammonium-sulphate varying from 75 to 110 pounds per ton of shale.

Presumably the analyses were obtained upon outcropping shales. Had it not been for discoveries of natural oil they might have aroused sympathetic capital. All the eloquence and facts at the command of the promoters, though, could not divert sufficient funds to prove the payability of these shales, or shales anywhere.

Immediately prior to the Great War, Mr. Lodge proceeded to London where, after months of solicitation and negotiation, he induced the Anglo-Persian Oil Company, in which the Imperial Government are said to have a controlling interest, to consider the shales as an all-British proposition. Accordingly Sir Boverton Redwood, then chief adviser in oil matters to the Imperial Government, took up the subject. In 1914 he reported that, under instructions:

"I caused a geological survey to be made by my colleague, John E. Marshall Hall, A.R.S.M., F.G.S., of an oil-shale area of 190 square miles, situated in the counties of Albert Kings, and Westmoreland, New Brunswick.

"It will be seen from the subjoined report that Mr. Marshall Hall, after a prolonged and careful study of the available data, estimated the minimum quantity of readily accessible shale at 145 to 150 million tons, much of which he states, can be mined by the use of the steam shovel.

"The evidence upon which the above estimate is based is set forth so fully in his report that there is no room for doubt as to there being in the area described a deposit of oil-shale of immense magnitude, and as the geographical position of the property is exceptionally favorable in respect to transport facilities it only remains to be shown that the shale is of good quality.

"It will be noted that an unusually large number of representative samples were taken over the whole area traversed. These samples, which I received direct from Mr. Marshall Hall, have all been analyzed in my laboratory . . . "The analytical and practical results collectively demonstrate that the shale is of high quality as a source of the products obtainable from such mineral. On the whole, therefore, I submit that the acquisition and working of this property would furnish an attractive opportunity for the establishment of a lucrative industry of great industrial importance."

Sir Boverton adverted to 21 "representative" samples dealt with by destructive distillation at low temperature. They showed an average oil content of 32·7 Imperial gallons of oil per long ton of shale, equal to 39·24 U.S. gallons. Sir Boverton also gave the chemical results of fractional distillation tests of crude oil, from which it appears that, taking his lowest results obtained, the following percentages of refined and by-

products might be expected per 100 gallons of crude oil:

"Naphtha, 12.5 gals., less 5 per cent for possible wastage in refining.
"Burning oils, 46.5 gals., less 5 per cent for possible wastage in refining.
"Lubricating oil, 10 gals.
"Fuel oil, 10 gals.
Paraffin wax, 4 per cent.
"Coke, 2 per cent."

It was upon the recommendations of Sir Boverton and his staff that the Anglo-Persian Oil Company entered into the agreement which has continued through and since the war, the D'Arcy Exploration Company being in charge of operations. Periodically the semi-official Imperial factors have not seen eye-to-eye with the Canadian promoters. That there was tonnage—and quality insofar as indications and tests disclosed—never has been questioned—but the allied nations, especially the United States, removed the necessity for further Imperial Government operations, particularly when war costs weighed too heavily and war funds had more essential developments to reach for, notwithstanding drilling, left no doubt as to the "immense magnitude" of the deposit. As to the vendor consideration in the transaction, the understanding always has been that it is largely in shares when issued, little cash being forthcoming.

Engineers familiar with such occurrences and with the records of Scottish shale companies, went into the New Brunswick situation thoroughly and slowly. Owing to the war, inevitably the probationary period was tediously prolonged. All told, however, some 17,000 feet of drilling has been done—more holes are going down—and processes for the most economical treatment of the shales have received attention. What are the average contents of the entire cores obtained in drilling has not been divulged. The success of the enterprise depends upon low costs, the quality of the shales with a great tonnage going through the crushers and retorts, and the prices obtaining for the varied products.

The Anglo-Persian Company are alleged to have allocated over $6,000,000 for New Brunswick purposes, all of that much will be needed. Perhaps this newspaper report is wide of the mark. It is said $12,000,000 will be needed. Thus far, to the end of last year, the Anglo-Persian expenditure was $417,000. Since then the technical staff has been enlarged and a testing plant started at Rosedale a month ago, Mr. Wallace being on the work, his process having been adopted.

The daily capacity of the plant is eight tons, and the material as taken from the several surface workings is crushed to egg-size. The viscosity of the shales makes it somewhat difficult to crush finer than this. Naturally there is disinclination to discuss results being obtained. Satisfaction with them is expressed. A 5,000-ton plant is talked of. In that event, should the Red wood average yield of 32.7 Imperial gallons of crude oil per ton of shale be sustained, such a plant working continuously may produce about 60,000,000 gallons per annum. With a paraffin base such oil should command a market. One authority declared there is enough shales assured in the series to supply five plants of 1,500 tons capacity each for fifty years.

An approximate estimate of the per-ton cost of mining, manufacturing and refining with a 1,500 ton plant, put it at $1.7518, and pre-war prices for oils, gasolene and ammonia were taken. That was before the war. So many contingencies enter into such operations that strict injunctions have been given against any and all publicity. Calculating on the pre-War basis, London was petitioned upon the assumption that a 1,500 ton plant dealing with 547,000 tons—working day and night—would provide a gross revenue of $2,198,455, a minor fraction more than $4 per ton. With improved recovery of gasolene from the gases carried over in the distillation of the shales, a further $248,000 was deemed possible. That would bring the gross revenue to about $4.50 per ton.

Obviously, therefore, these shales are not for "fly-by-night" operators. Plants, a railway, marketing facilities, efficient mining and perfect mechanisms, at once preclude small capitalists while increasing the interest in what those who are financing the enterprise are doing. Capital outlay, though, is going to require the utmost economy throughout, and satisfactory markets for the products. That is why the Anglo-Persian-D'Arcy Exploration people made haste slowly. While providing the eight-ton test plant now in operation they laid concrete foundations for a larger installation to follow. A commendable policy adopted is that as much as possible of the plant as and when required will be constructed in the Maritime Provinces.

Should the greater project attain to fruition and huge tonnages of oil-shales become commercially profitable through larger plants deemed possible, similar occurrences in other countries may commend themselves to capital that is willing to take the risk. Some time will elapse before great units can be made and assembled, but the fact that the Robb Engineering works are employed upon retorts suggests a description of the Wallace refining process, as taken from the application for Canadian patent. This process "is applicable to the distillation, carbonization or vapourization of all coals, lignites, woods, oil shales and carbonaceous substances, and while various kinds of apparatus can be used in practising" the process, it is urged that "an apparatus be used which is equipped with a heated distilling-chamber, a perforated take-off duct constructed and arranged inside of the distilling-chamber in such a manner that it eliminates the possibility of the evolved gases, vapours and oils contacting with the hot walls of the chamber in escaping therefrom, and also insures the recovery and immediate removal from the distilling apparatus of all of the oils and liquids evolved in the distilling operation."

PERSONALS.

Directors of Wright Hargreaves were at Kirkland Lake last week when the first clean up was made at the mill.

Mr. E. H. Orser has opened an office at Kirkland Lake. Mr. Orser was for some time geologist for the International Nickel Company.

Directors of Ontario Kirkland Mining Company visited the property last week.

Mr. H. Stevens of the Hollinger staff has a party of twenty men surveying the Company's recently acquired water power—the Long Sault rapids on Mattabi River.

Mr. R. E. Hore has returned to Toronto after visiting the gold mines at Porcupine and Kirkland Lake for the Canadian Mining Journal.

Mr. A. G. Burrows and Mr. P. E. Hopkins of the Department of Mines, Ontario have completed a survey of Skead township.

The Ontario Mining Association meets in Cobalt on June 16.

Ironstone Mining in North Lincolnshire. England

By ROLAND H. BRIGGS, Coulsdon, Surrey.

The ironstone mining of North Lincolnshire is of increasing importance. Sixty years ago the output was only 16,000 tons per annum, by 1870 it had risen to 217,000 tons, by 1910 to 1,800,000 tons, and by 1920 to 2,400,000 tons. The iron content is low, but the ease with which the most modern mechanical methods can be applied to getting it, makes it worthy of the most thorough exploitation, and in addition its chemical constituents make it peculiarly valuable. Frodingham ironstone nearly always contains sufficient lime to enable it to be fluxed without the addition of limestone, and as it also contains about 1 per cent. of manganese, the addition of manganese ore in smelting is also unnecessary.

The first ore was quarried in 1859, and five years later the first of the local furnaces were erected for the smelting of the ore. The replacement system of mining which is carried out calls for careful organisation and operation, and in the early days much of the bottom stone was left where it was, but with modern scientific methods the whole of the bed is everywhere mined and all faces worked to their full depth.

The ironstones of Britain are found in the Jurassic rocks which stretch in a broad band across country from the coast of Yorkshire to the coast of Dorset. The ironstones occur in four different geological horizons. Some ironstone is also found in the Kent coalfield. In 1917 eighty per cent of the total native output of iron ore was found in the Jurassic rocks, the remaining 20 per cent being hematite from Cumberland and Lancashire and elsewhere, and blackband ironstone from the coal-fields.

In pre-war days cheap water-transport made it possible to import high-grade foreign ore, which contained fifty per cent of iron, but during the war it was necessary to fall back very largely on the native ironstone. These ores average about 28 per cent in iron content, and have a high phosphorous and sulphur percentage, and are generally rather siliceous. As the metallurgical treatment of these ores is different, basic-lined steel furnaces had to be substituted as rapidly as possible for the acid type. The magnesite bricks were made from material obtained from Greece and Madras, and new quarries were opened to furnish the dolomite and limestone required. The total production of iron ore in Britain is about fifteen to sixteen million tons per annum.

Mechanical methods of ore-getting in north Lincolnshire were not very quickly introduced, owing to the ease with which the ore could be obtained near the outcrop, but as the workings developed, grab-cranes were brought into action, and these proved a great improvement on hand methods. By 1905, however, the shipping had become deeper, and chain bucket-excavators were then introduced, and proved a great advance on the grab cranes, but later on these were also superseded by costly but most efficient equipment, which has reduced working costs in a remarkable degree.

The long-jib crane type of steam shovel has also become popular in the district, different types being at work which dump at a distance of 60 feet and 75 feet

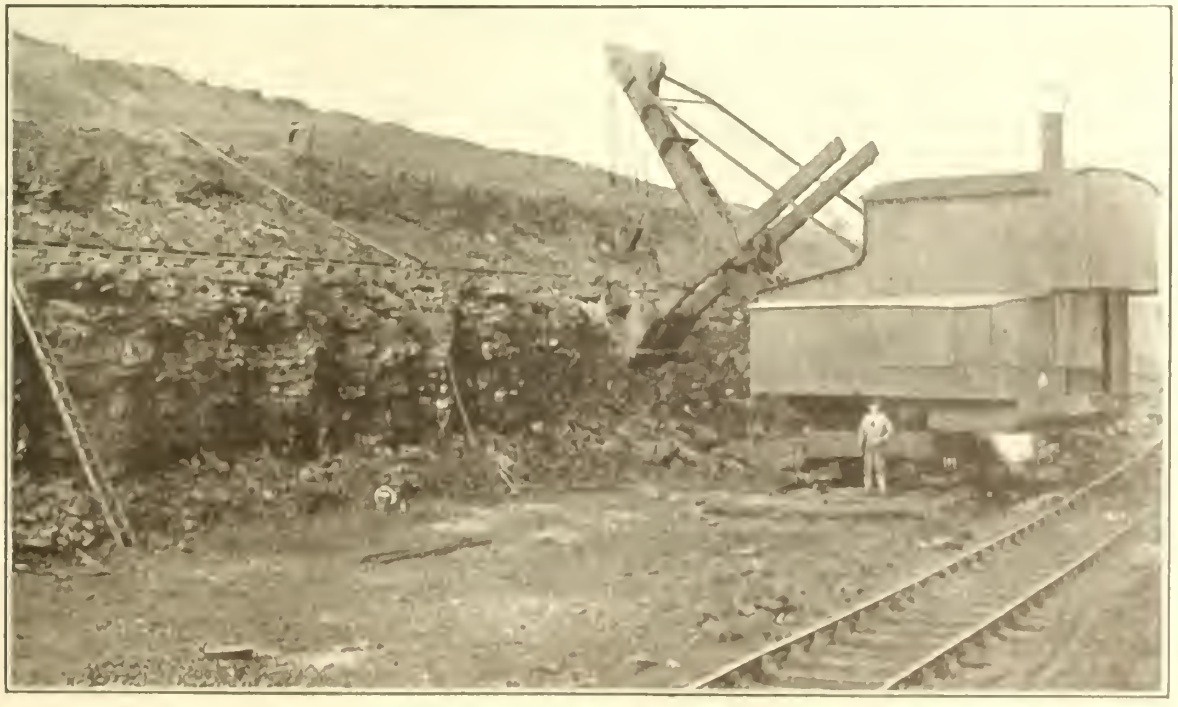
Stripping the Frodingham Iron-Ore Bed.

Stripping Operations—Frodingham Iron-Ore Bed.

respectively, and when a greater distance is required, as for instance when the stripping has reached thirty feet deep, a transporter can be used in conjunction with the 60 foot machine, giving a total dumping distance for the excavated material of 120 feet or even more.

Two types of machines are being used to deal with the Frodingham bed, and the first of these has amply demonstrated its ability to deal with faces up to 16 feet in depth. The second and much larger machine was specially designed to deal with the full thickness of the Frodingham bed, which it does very effectively. Experiments are being made to show whether the smaller machine will work the full depth of stone, by fitting it with a longer jib, and as the smaller machines are much less expensive in first cost, they will probably be the type regularly installed if they will successfully handle the greater thickness.

The actual average filling rates of these machines, taken over a period of several months, are 130 tons per hour for the smaller machine, and 186 tons per hour for the larger machine, but it should be understood that the daily total does not work out on the averages, as



Loading from the Frodingham Iron-Ore Bed

considerable time is lost by stoppages caused by changing cars, coaling, lubricating and minor breakdowns.

The successful use of these mechanical appliances does not depend alone on the efficiency of the machinery or on the care with which it is operated. It also depends very greatly on the skill with which the blasting of the ironstone has been carried out. It was at first considered doubtful whether it was possible for the ironstone to be reduced to such limits as would be satisfactory for the blast furnace, but it has since been shown that if the drilling is carried out judiciously and the explosive used in considerable quantities, the results obtained are to the entire satisfaction of all concerned.

The drilling in most of the faces is carried out by hand machines driven by compressed air. The hole is staged down so as to finish at a diameter of 1 7/8 inch., and these are drilled every 8 or 9 feet, so that sufficient explosive can be used to shatter and distintegrate the ironstone satisfactorily.

In one of the deep faces a machine is used by means of which a hole 6 in. in diameter can be drilled. These holes are spaced at much greater intervals and carry a very powerful charge. The cost of drilling and explosive with this type of machine slightly exceeds the cost of the method in which the smaller holes at shorter intervals are used.

It will be understood that the mechanical equipment of the ironstone mines of North Lincolnshire does not end with the excavating plant for the actual getting of the ore. The mines are complete with up-to-date power-houses, railways, locomotives and rolling stock, air compressors, and other machinery, which enable this area to make so considerable a contribution to the iron-ore supplies of Britain.

In conclusion the writer wishes to express his thanks to Mr. R. E. Westwood, the Manager of the Frodingham Ironstones Mines Ltd., for his valuable assistance in the preparation of this article.

MINING IN MANITOBA.

CHARLES A. BRAMBLE.

Some may say that such a heading as the above recalls the famous chapter on snakes in Ireland, which read "There are no snakes in Ireland." But, with all due respect to those who doubt—there really is in this province that which—without undue exaggeration—may be written of as mining. Indeed the situation looks somewhat more encouraging than it has ever looked. On the Oiseau some remarkable copper and nickel-ores have been uncovered, apparently in bodies capable of yielding a great tonnage. These claims are in strong hands and are being thoroughly tested. Seeing that samples at 20 feet, run 25 percent copper, at one end of the 5,000 feet of outcropping, and five per-cent of nickel at the other end of it, and that the discoveries were made within ten miles of a railway, and of the Point du Bois power plant, it is permissable to predict that sooner or later there will be something doing in this particular locality.

The holders of these locations, have, as has been intimated, plenty of capital, and are going ahead quietly but steadily, the work being done by a reputable contractor, directed by one of the most eminent engineers we have in the Dominion. It is to be expected that within the next few years the moose, caribou and deer, as well as the bear and lesser forest creatures, will have to make room for the locomotive, the smelter, and the townsite.

If these discoveries were "developed" as so many Manitoba properties have been "developed," the daily press would carry many a full-page advertisement, written by some broker, in exuberant language. Happily for Manitoba these latest accessions to our ranks are endeavouring to mine ore, not to mine the public.

Spectacular finds of rich gold-quartz continue to be reported from the Rice Lake field, but the big, promising, bodies of comparatively low-grade quartz are not not being worked—as yet. These are not good stock sellers, so they must await the time when a railway up the east side of Lake Winnipeg shall permit the real mining operator to get a look in. But there are a few quiet, reserved, prospectors developing claims in the neighborhood of Hole River, mostly on the northern side, of which rumour has a lot to say. It is whispered —through a megaphone—that one or two of them have made important discoveries: discoveries that the discoverers have spoken of merely to their backers, and as these bankers dwell south of the boundary line not much can be ascertained by the local amateur detectives. This, of course, furnishes an added motive for decorative details, so that the famous "Lost Cabin" mine yarn seems by comparison poor and insipid. Joking apart, there is much promise in the Hole River district. Here too is situated the Bellevue Group, of which the Luleo is the king pin. This property has had a chequered career, but on July 1st., it is understood things are to begin to happen. The persons who foreclosed on the property a year ago are said to contemplate serious development. As they have a 20-stamp mill on the property, almost in condition to crush, and a certain amount of underground work finished, a year's steady drilling should put the property in shape for producing. It will, possibly, not be a high-grade mine, yet there ought to be a satisfactory margin of profit. Moreover it should give tonnage.

Winnipeg is keeping its head level and its pocket closed as regards oil, frightful tales having been told of the happenings in Calgary some few years ago; also times are hard, and after the butcher, baker and, far worse, the grasping landlord, have been—not of course satisfied, but temporarily appeased and quieted—there is not any vast amount of loose money lying around. Nevertheless, drilling is going on at several spots, and one well, at least, at a depth of 1,000 feet, gives more than a sniff of petroleum. It may well be that we shall not have to go quite to Fort Norman for oil. Those who know the history of the Mid-Continent oil-field will perceive that a short distance west of our outcropping Devonian there should be a good chance of finding oil at depth. Only our folk will have to think in terms of thousands instead of hundreds of feet. If brother Jonathan can go to four and even five thousand feet, why are our holes to be limited to one or two thousand? True we have no Carboniferous strata, such as the Mid-Continent boasts, but though we lack the Pennsylvanian series, which has yielded so richly in the South, our Devonian and Lower Cretaceous may turn out to be worth attention, especially if tested well away from the outcrops.

Northern Ontario Letter

THE SILVER MINES.

Arrangements have been completed to hold the annual meeting of the Ontario Mining Association in Cobalt on June 16, 17 and 18th. The association has a company membership of forty-one, each of which is represented by one member and, in some cases two, in the person or persons of the manager and assistant manager. In addition to the general invitation to these 41 company members, there are 36 specially invited guests on the list as it appears at this date. Of these specially invited guests, twenty are identified as officials of the mine or company belonging to the association, while the remaining sixteen are made up of eight from Toronto three of whom are identified with mining companies operating in the province and five being connected with the Ontario Department of Mines, the other eight guests being invited from Cobalt, Haileybury, New Liskeard and Porcupine. The total attendance will probably be about one hundred.

In addition to general business, a visit will be made to the mines, one feature of which will be a sail on Lake Temiskaming, and a visit to the old Wright Mine lying near the East shore of the Lake in the Province of Quebec. This is the oldest mine in Canada, having been opened by the Jesuit Fathers and worked intermittently for the lead which it contains. Some of this metal figured as bullets in the early skirmishes and wars with the Indians of this country.

The Cobalt District.

The mines of Cobalt are producing silver at a greater rate than since near the beginning of the current year. Revised estimates for the month of May show a yield of considerably over 700,000 ounces during the period. The largest producer during May was the O'Brien mine, which property produced a total of 312,000 fine ounces, thereby leading all other silver producers in Canada for the month. The O'Brien mill treated 6,066 tons according to official information to the "Journal" correspondent and produced an average of a little over 51 ounces of silver from each ton treated. This was the largest tonnage ever treated in the O'Brien mill in a single month.

Silver production during June from Cobalt promises to undergo a substantial increase owing to the camp's four leading mines all being in full operation. These are the Nipissing, Mining Corporation, O'Brien and Coniagas. It is believed the production for this month will reach an aggregate of between 750,000 and 800,000 ounces. It might exceed 800,000 ounces, except for the reason that the mill at the O'Brien lost the first week of the month owing to breakage in its equipment. From present indications, it would appear reasonable to expect an average production of between 750,000 and 900,000 ounces monthly from the mines of Cobalt during the last half of the current year. In addition to the four leading mines mentioned, there are three other substantial producers, these being the La Rose, Chambers Ferland and Bailey Silver Mines.

Reports this week that the Nipissing had been negotiating for the control of the Hollinger Reserve property at Porcupine, now a part of the McEnaney Estate have been flatly denied by Nipissing officials.

During the month of May, according to official advice to the "Journal," the Bailey custom mill treated 5,015 tons of ore. Of this, 1,055 tons came from the Bailey mine itself and the balance of 3,960 tons was made up of ore from the La Rose, Silver Leaf and Ophir. The Customs plant realized a gross profit of $11,838 during the month. The monthly report of development work on the Bailey mine is favorable. Some high-grade ore was encountered in the West drift. Raise 5B at the west end of the stope was driven to determine the extent of the mineralization in the slate formation overlying the conglomerate. The raise encountered the vein in the slates where quite heavy leaf-silver is present, some of the wall-rock being high-grade.

Ore is being shipped from the Chambers-Ferland mine at the rate of about fifty tons daily to the Bailey Custom Mill. The new discovery reported a week ago in the "Journal" is standing up well as work proceeds.

An encouraging find has been made on the property of the Oxford-Cobalt Company. The find was made in a two-foot fracture in which some stringers occur, one of these being about one inch in width made up of smaltite and carrying 600 ounces of silver to the ton. These values occur within six feet of surface and some little distance from the point where sinking operations were carried on last year. J. W. Russell, president of the Oxford-Cobalt told your correspondent that this would result in a modification of the plans of operation. Heretofore, the plan has been to sink to the lower contact in a main shaft which is already down some 200 feet but which is still considerable distance from the contact. The altered plan is to sink at the point where the new find has just been made and where the Keewatin formation is believed to be not more than 80 to 100 feet thick over the underlying diabase. It is recognized that the zone of mineralization in the Keewatin lies, usually, within about 150 feet of the underlying diabase. Therefore, it is believed the new find is full of promise.

The Mining Corporation will hold its annual meeting in Toronto on June 29th. Business will include consideration of the Engineer's report and the financial statement covering 1920, election of directors and general business. The meeting will also be asked to consider approval and ratification of a by-law proposed by the Board authorising the purchase of shares in other companies out of the surplus funds of the Corporation, at the discretion of the directors.

J. Mackintosh Bell, manager of the Keeley Silver Mines declares the physical condition of the property is steadily improving. The tonnage now in sight is understood to contain well over half a million ounces in silver and assures full capacity operations and silver production at a substantial rate just as soon as the mill is set in operation. Fire destroyed the transformer during the past week, but a new one is being installed and the mill will be running by the end of June.

Elk Lake and Gowganda.

Col. R. P. Rogers, manager of construction work on the proposed light railway from Swastika to Gowganda, declares the work of surveying the route is in full swing, but the date for turning the first sod in connection with actual construction has not yet been set.

With the expectation that rail transportation will cause a big demand for property in the Gowganda district, inquiries for options on properties in that field are quite numerous. Companies holding claims are also making arrangements to finance further exploration and development work just as soon as the line reaches the district. A good many claims are being staked along the route likely to be followed. Prospec-

tive settlers are also searching out the more suitable agricultural areas while some of the more optimistic are endeavoring to locate possible townsites.

Ore and Bullion Shipment.

During the week ended June 10th, two Cobalt companies shipped an aggregate of three cars containing 268,717 pounds of ore, this being made up of 2 cars containing 174,898 pounds from the Coniagas and one car with 93,819 pounds from the Bailey Silver Mines.

During the corresponding period, the Nipissing mine sent out two consignments of silver bullion, totalling 77 bars and containing 100,645 ounces of silver.

THE GOLD MINES.

The Porcupine Field.

The directors of the Dome Mines paid a visit to the property over the past week-end, although president Bache was himself not with the party. It has been noted that the visitors to properties in the Porcupine field exceed in number any previous time in the camp's history.

Directors of the Hollinger also paid one of their periodical visits to their mine, and held a meeting on the property. The mill having attained full capacity operations, there is considerable speculation on the street as to the question of whether or not the management will decide upon further increases. It is pretty well demonstrated that an average of 3200 to 3300 tons daily will be achieved with the present plant, and this would appear to assure an output of at least $10,000,000 a year.

Mining interests in Cobalt are reported to be negotiating for the Hollinger Reserve property which is a part of the McEnaney estate. The Nipissing has been mentioned as among the interests inquiring as to the purchase of the property, but this report was denied by an official of the Nipissing. A week ago it was reported that the property was passing into the hands of a Toronto syndicate.

A party of surveyors, accompanied by about 20 men have pitched camp at Kettle Falls on the Abitibi river where a topographical survey is to be made of the falls with a view to harnessing the power. This work is being done by the Hollinger, which company recently secured the right to develop 25,000 h.p., the Ontario Government reserving 10,000 h.p. for its own possible requirements, this reservation being intended to electrify an extension of the T. & N. O. Rly. at some future date.

At the Dome Mines, the work of over-hauling the stamp equipment which has been idle for some years has been completed, and the capacity of the mill is to be brought up to around 1,400 tons daily. Prior to 1916, the Dome employed a battery of 40 stamps which, during 1916 was partly replaced by the installation of Hardinge conical ball-mills, one of which replaced ten stamps of the old 40 stamp-battery. It was then stated, by utilizing all the available equipment, the mill would be able to treat 45,000 tons of ore monthly or at the rate of 1,500 tons daily. These official figures seem to indicate the present estimate of an average of 1,400 tons daily to be conservative.

During the past year, the Dome produced a little over seven dollars from each ton of ore treated, so that in handling an average of 1,400 tons of ore daily, the indicated output at full capacity with its present mill reaches $9,800 daily, or at the rate of about $3,577,000 a year. This would call for the reduction of approximately 511,000 tons of ore. It has been officially stated that although costs were comparatively high during the past year, this was due to a shortage of labor in the early part of the year and a shortage of hydro-electric power during the closing months of the fiscal year ended March 31st, yet since that time with ample power and men, the cost has been reduced to about $3.75 a ton, with good prospects of a further reduction to perhaps $3.50 a ton. As to this, after allowing for all contingencies, it may be conservatively estimated that on $7 ore a net profit of around $3 a ton may be expected. This would indicate a daily profit of around $4,200 or at the rate of $1,533,000 annually. The Dome has an authorised capitalization of $5,000,000 made up of 500,000 shares of the par value of $10 each. Of these, 476,667 have been issued, at par amounting to $4,766,670 on which dividends are being paid. This means that net profits of $1,533,000 as indicated would be equal to a fraction over 32 per cent on the companies issued capital.

As an indication of the growing interest in gold mining in Northern Ontario are the various parties of visitors to mines in these fields. They are coming to this country from distant points, Europe being particularly well represented and the United States perhaps sending more visitors than any other country. Among the parties visiting Porcupine and Kirkland Lake recently may be mentioned the directors of the Dome, chiefly from the United States; the directors of the Hollinger, these being Canadian; a party of stockholders of the March Gold, a mining prospect in the Porcupine district, these shareholders coming largely from Buffalo, N.Y.; a large party of directors and stockholders of the Kirkland Lake Proprietary to Kirkland Lake from England; a visit from directors and interested parties of the King-Kirkland to Kirkland Lake, entirely Canadian; the directors of the Ontario-Kirkland, from the United States, and various other visitors among which Germany among other countries has been represented.

Kirkland Lake Field.

A syndicate of English interests has been making a quiet bid for control of an enormous acreage of mining land in the township of Lebel lying along the easterly strike of the gold-bearing formations of the proven part of the Kirkland Lake district. Various options have been secured on the properties scattered over that territory lying between the Tough-Oakes Gold Mines and McTavish Lake, a distance of about six miles. From the extent of the activities of this syndicate, it is believed a corporation of mammoth size would be necessary to finance the exploration and development of the properties for which a bid for control is being made.

Underground operations have been resumed on the property of the Bidgood Gold Mines in the central part of Lebel township.

The Northern Development Branch of the Ontario Government is calling for tenders on the work of stumping a road through the township of Lebel, beginning at the Tough-Oakes mine and extending over a distance of about seven miles to the east.

Drifting operations have extended 172 feet along the vein at the 100-ft. level of the King-Kirkland Gold Mines, in the central part of the township of Lebel. The assay sheet over the entire distance has not yet been completed, but from the assay results so far received a substantial quantity of the ore will average upwards of $10 per ton. The mining plant on the property is intended only for exploration purposes, and the

directors and management are now considering the question of whether to continue the shaft to a depth of 200 feet or to direct energy toward opening up some of the other veins which contain encouraging mineralization at outcrop. The plans of the company were announced some months ago in this paper, it being noted that the current Summer's work would consist of sinking the present 100-ft. shaft and, after a limited amount of development work, to turn attention to some of the other veins so as to determine the best possible location of a central shaft. As to this, the results in the present shaft have been so satisfactory as to cause some of the interested parties to believe it might be best to concentrate energy at this point. The writer discussed the question with an official of the company and it would appear probable that the original plans of surface work will be followed so that during the coming Winter the company will be in shape to decide upon the installation of a big mining-plant at a point where work may be carried to great depth without interruption and centrally located to the more highly-mineralized veins. Among other things, the entire surface of the King-Kirkland will be prospected this Summer, that is where the over-burden is not too heavy to trench. The exploration of the surface at a point where the "McGee" vein of the Lebel-Or Company is believed to extend onto the Kirk-Kirkland promises to be full of interest. A party of shareholders concluded a visit to the property early this week, among the visitors being W. Fraser, Brantford; Dr. C. C. Fissette, Brantford; Earnest Moule, Brantford; W. T. Stewart, Toronto; Ferguson Pickett, Toronto; and with C. F. Jordan, president of the company having accompanied the party.

Great benefit is expected to be derived in the Kirkland Lake district from the construction of the proposed Northern Light Railway through this area.

TORONTO COAL PRICES.

Toronto, June 14. Prices obtaining in the various grades of coal during the past week are as follows: Slack ranging from $1.00 to $1.75 U.S. funds at the mines; lump from $2.35 to 3.15; smokeless from $2.35 to $3.15. As regards anthracite, the price of pea coal ranges from $5.85 to $6.20; that of chestnut from $7.60 to $7.80; that of stove from $7.60 to $7.80; and that of egg from $7.30 to $7.80. The independents are charging anywhere from 50 cents to a dollar per ton over the prices just quoted for anthracite. The decrease in the price of slack coal is due to the necessity of moving it away to get other shipments out. There has been some little increase in the demand for lump coal owing to the fact that lake shipments are moving pretty freely. Slack is fairly plentiful. Stove coal, however, is quite scarce. It is hard to tell what the condition of stocks is, as people are still only buying from hand to mouth.

TORONTO METAL QUOTATIONS.

Below are the fair average prices for ingot metals (in less than car loads) at Toronto:

	June 8.	June 15

British Columbia Letter

Stewart, B.C.—It would appear that the strike at the Premier Mine, Portland Canal District, is not going to interfere with the working of that property, nor with the progress on the aerial tramway under construction, to a material extent. Dale L. Pitt, the manager, during the closing days of last month announced that the trouble was at an end, and that all tramway workers, teamsters, tractor-men, and part of the mine crew had returned to their jobs. The tramway, it was stated, would be pushed forward. Two new camps had been opened and the Company was sending out fifty men who were to receive $5 a day. The mill is nearly completed, all the tramway right-of-way has been cleared, and the construction towers have been planted.

There are several reports current with respect to the future of the Big Missouri Group of Mineral Claims, Salmon River, Portland Canal District. Pat Daly, who has been in New York for some weeks, is said to have bonded the property and to have received a substantial cash payment in this connection. If this is authoritative work will be started this summer. The Lindenbourg Brothers, Andy and Dan, owners, also are said to have made good progress in the same direction, and it is stated that Dan will have some satisfactory announcement to make shortly regarding financial arrangements necessary for the continuance of development. The Big Missouri was bonded to Sir Donald Mann who, after some work and the securing of a report from Prof. Bancroft, of McGill University, ceased operations. While the effect of this event undoubtedly was felt in the camp it did not discourage the large body of miners and prospectors interested in the district. Their faith remained, not alone in the section, but as well in the particular property in question, and there are many practical and otherwise qualified men who declare that the Big Missouri has a future as a producer. Pat Daly is said to have also succeeded while in New York in bonding the Fraser Group of Mineral Claims, Marmot River, Portland Canal District.

The showings on this property are large and have been proved to some depth. The possibility of establising a hydro-electric plant to provide the residents of the towns of Stewart and Hyder with electric light and with a telephone service is being investigated.

The claims against the Spider Group of Mineral Claims are being settled. This is a property of the Algunican Mining Company, which has done considerable development in the district. It is now reported to be in straightened financial circumstances.

News has been received that the Alaska Gastineau Mine and Mill have been closed down permanently, thus throwing out of employment some 400 men. Possibly a wood-pulp and paper-manufacturing plant will be established in the locality, inasmuch as the necessary power is developed and ready to hand, and considerable of the needed machinery would be immediately available.

Hedley, B.C.—The Hedley Gold Mining Company will reopen the Nickel Plant Mine on the 1st of July. This announcement was made shortly after the return recently of Mr. G. P. Jones, general manager. The mine has not been working for some months, having been closed down because of unsatisfactory conditions relative to gold mining costs as against the fixed value of the precious meal. There having been a material change, the mine is to be put on a producing basis without loss of time. The Nickel Plate is the great gold mine of British Columbia, having paid during the past ten years more than $2,500,000 in dividens.

Trail, B.C.—Ore receipts at the Trail Smelter, of the Canadian Consolidated Mining & Smelting Co., for the week ending May 22 aggregated 9,587 tons, all of which, with the exception of one very small shipment, came from the company's mines. This brings the total for the year up to 167,662 tons.

Vancouver, B.C.—The Bullion Mining Company once again has been the subject of litigation. R. T. Ward, as manager of the Syndicate and trustee of the claims, recently asked for an injunction restraining his partners from operating and developing the property along lines that do not meet with his approval. He asked that the thirty men employed be asked to cease their work. It was argued by the other side that Mr. Ward was nominal trustee of the mine, only for the purpose of registration of title, and that a majority interest was held by those favoring the present development policy, Mr. Ward's interest having been placed, in a previous action, at 3 4-10 per cent. This view was accepted by the Court, and Mr. Ward's application dismissed. At present a 500 foot tunnel is being driven through rock, disused flumes and ditches are being repaired, and the management expects to make a clean-up this fall.

Considerable geological survey work is to be carried out in British Columbia this summer by the Geological Survey Branch, Ottawa. The districts to receive attention are Graham Island, the mainland coast from Burke channel to the head of Royal Island, the Coquahalla Pass, Comox and the Gulf Islands, Alice Arm, Lardeau in the Kootenays, Windermere in the Kootenays, the North Thompson, and in the Yukon Territory, the Mayo District. Dr. W. E. Cockfield already has started for the Yukon to continue his work there. He will cover the Mayo zone of which much has been heard of late, and is accompanied by N. T. Ellis, C. A. Merritt, and T. D. Guernsey, student assistants. Dr. Victor Dolmage, who has just concluded a three year survey of the west coast of Vancouver Island, will work over the field extending from Burke Channel north. He already is on his way in his own boat and with two assistants. Mr. C. E. Cairns is taking a party into the Coquahalla Valley to continue work begun last year. Mr. F. H. McLaren will go to Graham Island, of the Queen Charlotte Islands, to study the geology of that section with particular reference to oil shale and other oil indications which have been attracting attention. J. D. MacKenzie, who is in charge of the Vancouver Station of the Geological Survey, will visit the Comox to report on the coal deposits of that part of Vancouver Island, and also will make the first geological survey of the Gulf Islands. G. Hanson, also of the Vancouver Station, will report on the mineralized zone traversed by the Kitsault River in the Alice Arm District. Dr. S. J. Schofield will gather material for the making of a geological map of the Windermere District to supplement the topographical map now available. Prof. Uglow will go to the North Thompson River; M. F. Bancroft will continue his several years work in the Lardeau, and Mr. William Johnson will carry out researches in the Cariboo. From this outline it is quite evident that the Dominion Geological Branch is perhaps more than usually active in this Province. Such a policy will be appreciated by the mining men, because there is no doubt that there is much geological work to be done in the Canadian West, and it is equally beyond question that the information thus obtained is

of great value to those interested in a practical way in the location and the development of the mineral resources of the country.

Victoria, B.C.—A branch of the Canadian Institute of Mining and Metallurgy has been formed in Nanaimo, B.C., as a result of a recent visit paid to Vancouver Island by Mr. George C. MacKenzie, Secretary of the Institute. Representatives were present from Cumberland, Extension, Ladysmith, Cassidy, East Wellington, as well as from Nanaimo. Officers were elected as follows: Chairman, George O'Brien, Cumberland; Vice-Chairman, F. A. Spruston, Ladysmith; Secretary-Treasurer, W. H. Moore, Nanaimo; Local Council, John John, Nanaimo; C. M. Campbell, Cassidy; C. Graham, Cumberland; and James Strang, Extension. It will be noted that all the centres mentioned are situated in the Island coal fields, so that there is no doubt that the work of the new branch will have to do with coal mining and the advancement of the industry, and the welfare of those identified with it, in co-operation with other branches of the Institute throughout the Dominion.

An expedition of considerable proportions is being organized by Mr. Stuart Henderson and associated mining men to leave for the far northern parts of British Columbia in the course of a few weeks, the object being the location of certain gold and other deposits which have been reported to them. These reports, it is understood, have come from "sourdough" prospectors, and also from the Indians. They are so circumstantial in character, and have been so well supported by samples, etc., that it has been decided to make a systematic investigation. If the expedition is as successful as its sanguine promoters predict there is no doubt that there will be another gold rush into some section of the Cassiar before many months have elapsed.

News of the successful completion of a trip by a party of nine men from Carmacks, a small centre on the Yukon River, to Fort Norman, the hub of the newly discovered northern Canadian oil field, has been received from Atlin, B.C. The distance covered is estimated as being 675 miles. Carmack was left on the 20th March last, Norman was reached on the 18th April. Six days were spent there in staking land. Thirty-five dogs did the hauling of sleighs carrying supplies over the snow. The winter trail is described as having been quite good. Only one divide had to be crossed, there being a gradual ascent to an altitude of 1,500 feet. Game was very plentiful and included moosee, caribou, sheep and ptarmigan. Actual travelling time was: going, 26½ days; returning, 27 days. The party was headed by J. McDonnell, of Vancouver, B.C., and is the only one to make the trip last winter with the exception of the Japanese, Wanda, who went in from Edmonton, Alberta.

The reorganization of the Western Fuel Corporation of Canada, Ltd., until lately known as the Canadian Western Fuel Co., is complete. The change in name will not bring about that reconstruction as to management or as to policy. The directing heads are the same, Mr. C. W. Bowen being the Vice-President and Managing Director, and Mr. John Hunt General Manager. It is hoped, however, that the launching of the new corporation presages the disposition to be ready for an extension of the development of the company's mines and coal lands when the market conditions warrant. At present work of this kind scarcely would be opened up because the domestic trade is at low ebb and lumber business is by no means good. However, an improvement, with the return to stable conditions industrially throughout the world, will come, and the company proposes to be in shape to meet an increase in demand as soon as it becomes apparent.

There is to be a conference of the coal operators, dealers and the consumers of British Columbia to consider the whole question of coal production, transportation, and distribution with a view to deciding whether it is not possible to "cut" expenses and reduce the cost to the user. This is in line with a recommendation made by Mr. A. Henderson, who recently conducted an Inquiry into the matter of coal costs in this Province. Mr. Henderson observed that it was "not too much to hope that there could be devised a delivery of coal by operators to dealers and by dealers to consumers and much cheaper without imposing on operators or dealers undue losses." It also was stated that the operators and dealers were willing to enter into such consultation and that the result might be a reformation of some of the ways, not only of operators and dealers, "but also those of us who are consumers." The consumers would get new ideas on the subject of the best coal to use, the best mode of securing delivery, and also the best methods of using it, particularly in furnaces. Recognizing the force of these arguments, Hon. Wm. Sloan, Minister of Mines, states that the Conference will take place at an early date to be fixed and that all the recommendations made by Commissioner Henderson, and General R. G. E. Leckie, the mining engineer who acted as the former's technical counsel, will be given careful consideration.

Judgment has been given against the Pacific Coast Coal Mines Ltd., Vancouver Island, for $69,500 which amount is made up of wages due and unpaid to miners who had been in their employ. This Company's Mine known as the Morden Mine, has been closed since December 11th. It is considered likely that, as soon as the financial affairs of the concern have been straightened out, such obligations as those indicated will be met and operations will be resumed.

At the present time there is a reserve on the coal lands of British Columbia. This refers, of course, to unalienated crown lands. The government's policy in this respect does not appear to be popular among the prospectors. The Omineca Prospectors Association protests against it, asserting that the reserve is "retarding the development of the natural resources and industries of the Province and is therefore detrimental to progress and prosperity."

Residents of Prince Rupert and other northern provincial coast communities are having some difficulty in getting a supply of cheap domestic and industrial coal. Most of their requirements now are met by supplies taken from Vancouver Island. There are deposits, however on the line of the Grand Trunk Pacific Ry. which if developed, would more than meet the needs. One of these now is receiving attention. It is known as the Aveling coal fields and is situated a few miles up the Telkwa River. It is of high grade quality and there is a fourteen foot seam described as being second to none in the Province. A tunnel has been driven 80 feet and is to be continued. Bunkers are to be constructed at the railroad and it is expected that the output will be augmented this fall that a good part of the coast trade

will be taken care of. The operators, however, have one difficulty and that is in regard to freight rates. These are just 40 cents a ton less in carriage to Prince Rupert than it is from Alberta to the Coast. They argue that, in view of the much greater mileage, the difference in their favor is insufficient and are going after a material reduction.

Robt. Dunn, Victoria, BC.: The coal market in British Columbia during the month of May was decidedly slack in respect of the domestic grades. This is forcibly shown by the fact that the Canadian Western Fuel Co., Nanaimo, B.C., which supplies a large part of the domestic trade, was working short time to a considerable extent. The point is further emphasized by the maintenance of sales by the Canadian Collieries (D) Ltd., speaking comparatively, which concern depends more upon its bunker business than on the domestic consumption of its product. It would appear that the householder is holding back in the belief that the prices are about to decline materially. Those in the habit of filling their bins for the winter at this time of the year do not care to be caught buying on a falling market, hence their hesitation.

An interesting statement appeared recently in one of the Washington State newspapers to the effect that the price of Ladysmith coal would be cut 50 cents a ton on the 1st of July. Although there does not seem to be any aeknowledged authority for the announcement the information may be true. At any rate it is reasonable to suppose that, if at all possible, the British Columbia operators will bring down the retail prices of domestic coal. As conditions now are there is little of their fuel selling in the American market and the sales are likely to remain small until Canadian coal is quoted somewhat under that coming from Utah and other competing American districts.

What will be the developments of the next few months is difficult to predict. Notwithstanding the Washington State strike it is stated that there will be no shortage of domestic fuel this winter. There may be lack of steam coal but that will be met by an abundance of cheaper fuel-oil.

NOVA SCOTIA COLLIERY NOTES.

Coal outputs for May from the Cape Breton collieries of the Dominion Coal Company were 273,445 tons, comparing with 175,324 tons in April. May production exceeded that of May in 1919 and 1920. Fairly steady work at the collieries has been made possible by large movements of coal to St. Lawrence ports, and by some shipments overseas which are a result of the British coal strike. Partial operation of the Steel Plant in Sydney in producing steel rails for the Canadian National Railways is expected, which will provide an outlet for coal that has been greatly missed during the past six months. No definite business for the steel plant is in sight after the conclusion of the rail orders, which is expected about the end of September, and it may be expected that the operation of the collieries during the Summer months will be guided largely by the prospective outlet for coal during the Winter of 1921-1922. Closing down of some of the more expensive mines, and concentration of the faceworkers in other more favorably circumstanced mines, may take place, as unless the balance of productive workers to non-productive employees is redressed, the cost of coal production will become competitively impossible. A production of exceeding 300,000 tons is hoped for from the Dominion Company's Cape Breton mines during June month.

The output of the Nova Scotia Steel Company during May was 43,182 tons, comparing with 34,718 tons in April. The Scotia Colliery (No. 4 Mine) has been permanently abandoned, and partially dismantled. The new mine, No. 7 Colliery, opened on the Lloyd's Cove seam near the seashore betwen Florence Mine and the abandoned Scotia pit, produced 5,747 tons in May, and will increase its production in June. The Florence Colliery and the Princess Colliery, because of the unification of the coal leases under British Empire Steel management, are now permitted to extend their working faces in a manner that will greatly facilitate coal-getting, and immediate advantage is being taken of the removal of prohibitions that had for some years worked real injury to coal production.

An example of the adaptation to circumstances made possible by the consolidation of the coal companies in Nova Scotia is the recent shipping of two cargoes of coal from Pictou Harbour, N.S. to St. Lawrence points. The coal was from the Acadia Coal Company's mines at Stellarton, and was shipped in the "Watuka" and "Volunda" two steel-freighters of about 2,700 tons dw. both built by the Nova Scotia Steel Company at New Glasgow. It is many years since the Pictou loading pier was used for shipment of coal. The British Empire Steel Corporation possesses coal-loading plants at Sydney, North Sydney and Louisburg in Cape Breton Island, and at Pictou, Parrsboro' and Halifax on the Mainland, and it can send coal from mines in Cape Breton, the Pictou County field, or Springhill Mines, as occasion may require, for loading at the several ports to minimise the length of the rail-hauls and to suit the convenience of the available steamers in regard to times of arrival and point of destination. A central despatching office for the freighting fleet will control all ship movements. Wireless telegraphy is proving to be an indispensable aid to work of this kind.

ASK ABOLITION OF ASBESTOS ROYALTY.

By Canadian Press.

Quebec, June 14.—Representatives from leading asbestos companies waited on Hon. L. A. Taschereau, Prime Minister of Quebec, at 11.30 a.m. to-day, the delegation being composed of W. G. Ross, of Montreal, Vice-President of Asbestos Mining Operators, of Quebec; J. B. Waddell, of Montreal, Vice-President, Consolidated Asbestos Company, Limited; D. H. Pennington, of Quebec, Proprietor, Pennington Asbestos Company; Hon. George R. Smith, M.L.C., of Thetford Mines, Vice-President, Bell Asbestos Mines, Inc.; Major Oulster, of the Federated Asbestos Company; J. A. Jacob, of the Black Lake Asbestos and Chrome Company, and E. Stafford, of the Quebec Asbestos Corporation.

A strong plea was presented in favor of provoking the five per cent. royalty on the asbestos output of the Province of Quebec. The delegation stated that South African asbestos concerns are strongly competing with Quebec, and until this tax is removed the asbestos mining industry here will be severely handicapped.

A memorial was presented showing the progress of the South African asbestos industry, and emphasizing that this product is now being sold in great quantities in the United States and Great Britain.

INTERNATIONAL NICKEL CO.

Earned 89 Cents A Share On Common, Against $1.32 In 1919-20.

N. Y.—International Nickel Co. has issued its annual report for year ended March 31, 1921. Surplus after charges and taxes amounted to $2,029,700, equivalent, after deduction of preferred dividends, to 89 cents a share, par $25, earned on the $41,834,600 outstanding common stock. This compares with surplus of $2,745,734 or $1.32 a share in the previous year.

Consolidated general profit and loss statement compares for the year ended March 31, 1921 as follows:

	1921	1920	1919
Earnings	$4,059,647	$6,064,762	$11,186,301
Other inco.	1,106,934	300,710	25,217
Gross inco.	5,166,581	6,365,172	11,211,521
Exp. tx., etc	978,731	1,478,112	2,961,363
Dep. min. exch., etc.	2,158,150	2,111,326	2,324,529
Balance	2,029,700	2,745,731	5,922,629
Pfd. div.	534,756	534,756	534,756
Com. divs.			4,183,460
Surplus	1,491,944	2,210,978	1,204,413

N. Y.—In the International Nickel annual report, President Bostwick states that, while operations in first six months were approximately 60% of capacity, beginning with third quarter were reduced until close of the fiscal year found plants running only 20%.

Foreign business, as well as domestic, was small, due to industrial depression as well as stocks of nickel carried European stocks were only partly liquidated during the year, but "indications of the last two months in the United States are that stocks in many consumers' hands are gradually becoming exhausted, and the result has been increased demand, not as yet large but from an increasingly large number of consumers."

Considerable progress was made in developing markets for Monel Metal and nickel in various rolled forms, with outlook for continued expansion excellent. The company is building a rolling mill near Huntington, W. Va.

Pres. Bostwick says: "No dividends have been declared on the common it having been deemed advisable to maintain financial position of the company and conserve cash resources for such capital expenditures as necessary to complete new rolling mills under construction."

BRITISH EMPIRE STEEL CORPORATION STAFF APPOINTMENTS.

Pursuant to the policy of concentration and unification of management which is to be followed in the staff appointments of the British Empire Steel Corporation, Alexander S. McNeill, since 1919 Superintendent of Mines for the Nova Scotia Steel & Coal Company, and previously for twenty years in official positions with the Dominion Coal Company in Cape Breton, has been appointed General Superintendent of Mines for the Dominion Coal Company's collieries, which gives him, in addition to continued supervision of the Nova Scotia collieries, also charge of all the Dominion collieries in Cape Breton Island and at Springhill Mines on the mainland of Nova Scotia, approximately 25 collieries in complete or partial operation. Further

lars of Mr. McNeill's career were given in our issue of 14th May, 1920, see page 392).

Consolidation of engineering supervision, purchasing and warehousing departments, and upkeep and repair work, will be achieved by further appointments from among the resident staffs of the constituent companies of the Corporation, announcement of which is shortly anticipated. While the staffs are somewhat diminished in number as compared with some years

ALEXANDER S. McNEIL

ago, official changes have taken place largely within the personnel of the constituent companies of the Corporation, which is fortunate in possessing a number of capable officials thoroughly acquainted with the technical history and physical characteristics of the various coal, ore and limestone properties, and the operating of the mines and steel plants. An unusual opportunity therefore exists, and it is understood will be taken advantage of, to reorganize the staff so as to restore former efficiency, and give the Corporation the benefit of technical direction by specialists already trained in and acquainted with the local conditions. While some expert advice on technical matters peculiar to the Corporation's mining properties, such as undersea workings in coal and iron-ore, will doubtless be obtained for strengthening and confirmation of local experience, it is not believed the management of the Corporation contemplates the securing of officials from outside. It is unlikely also, in view of trade conditions, that any large programme of extensions will be entered upon, and a policy of enlargement of output from present openings and plant equipment, combined with strict economy and concentration of working forces, should enable a decrease in unit cost of production.

With Mr. D. H. McDougall as Vice-President in charge of all technical operations, the British Empire Steel Corporation will have at its head an official who was born in Glace Bay, and whose official experience in the service of the constituent companies includes intimate knowledge of coal, iron-ore and limestone mining, railway and plant construction, steel-plant operation and both rail and water transportation: in addition to personal acquaintance with the officials and workmen of the Corporation and thatlocal knowledge of men and things which is as essential in successful management as it is difficult to acquire. Mr. McDougall's unique knowledge of the coal and iron trades in Nova Scotia will enable him to give due importance to the several departments of the Corporation's business, and to preserve a balance in expenditure and development of the varied products it can put out that is most essential to the financial success of a Corporation which, being blessed with two strings to its bow, must know which of them to pull.

NEW OREBODY AT O'BRIEN MINE?

During the past few weeks there have been numerous rumors to the effect that an important discovery had recently been made at depth at the O'Brien silver mine at Cobalt. The owners have not given out any information concerning the discovery, but recent heavy shipments from the mine lend strength to the reports.

EDITORIAL

USE OF OIL DURING BRITISH COAL-STRIKE.

There is a tendency in British newspaper comment to emphasise the coming importance of oil and to dethrone King Coal. One well-informed financial paper sums up general opinion in Britain by stating: "While coal is anything but doomed, the lesson of the coal strike is that it is far less indispensable than was commonly supposed". It is quite true that the country has fared less badly as the result of a three months strike of coal miners than was generally expected, but there are some reasons for this that are not connected with the indispensability of coal, but result from political and trade conditions. It is quite evident that the country was well prepared for the coal-strike. Its occurrence was forecasted by this journal last November upon statements made in the British trade journals, so that there was no element of surprise in the calling of the strike. Since last November the output of British coal-mines was not being fully used by industry, because the state of trade did not permit it, and the country was well provided with stocks of coal when the strike broke out. Also, the metallurgical industries were and are at an almost unparalleled stage of non-productivity, and, in any case, whether there had been a strike or not, the demand for coal for home consumption in Britain would not during the past three months have equalled the supply.

The substitution of oil for coal has been aided by the fall in the price of petroleum and the unloading of stocks in Britain by the United States government, the slump in shipping being both the cause of the overplus of oil and the availability of ships to take it to Britain.

A distinction must be made between the proved excellences of oil as a source of motive power, and the comparative merits of petroleum and coal as a source of motor oils. Unless there is a real fear in the minds of well-posted oil technologists that the supply of petroleum from flowing wells is about to prove insufficient for the world's needs, the political pother about national control of oilfields would appear to amount to much ado about nothing. Yet, it is tolerably certain that there is excellent reason for national solicitude on this score. It cannot be said that the petroleum supplies of the world are assured either as to quantity of annual yield or as to continuance of such yield, because petroleum is essentially elusive, and its reserves cannot be calculated with the definite accuracy that coal tonnages can be. Consideration of the known extent and accessibility of the world's coal reserves will show that, if the technology of the future should acclaim oil as the ideal source of energy, the coal-seams of the world will provide the most dependable source of supply.

So far as Britain is concerned, with the exception of some deposits of oil-shales, there is no domestic source of petroleum, and it is obvious that if Britain were to change from the status of a manufacturing country producing its own source of energy in the form of coal from within its island borders, to a country dependent upon outside countries as a source of energy, the traditional Britain and its strength would become a thing of the past. This is unlikely to happen. What the British people will do is to develop means of extracting all the energy contained in coal that science may make possible, and to use that energy completely and efficiently. It is probably a very good thing for countries whose industrialism is based on coal supply to get an occasional jolt from interruptions of supply and the competitive use of oil. In Britain and in the United States coal has always been too plentiful and too cheap to be properly valued. Had it been less abundant and more costly, men would earlier have devised means to make it go further by getting greater value out of the quantity used.

English papers, however, that indulge in loose talk about the lessened indispensability of coal, and mistake the temporary effects of a miners' strike for a permanent tendency, should first ask themselves whether Britain is prepared to relinquish such portion of national importance as proceeds from her coal seams. We cannot think of anything that would be left worth having if she did, except her population, and she would not long retain that. Fortunately for Britain, while her island coal seams have suffered heavy depletion, and while coal mining must always be carried on at a relatively higher cost per ton than will be the case in North America during contemporary periods of the future, she is still generously supplied with coal, reckoned on European standards. Moreover, it is not with-

out significance that in two districts of England, namely southeastern Yorkshire and north Lincolnshire, and in Kent, there has in recent years taken place two of the most important developments of coal-mining in the whole Empire. No part of the Empire has seen such a definite "boom" in colliery extensions, in new towns and in building and in railway extensions as has taken place in these two districts within the past ten years. These developments were not the result of the war, but of the finding of new coalfields and the normal demand for coal in Britain.

FIREDAMP EXPLOSIONS.

Mr. James Ashworth's communication in this issue is really a continuation of the discussion on the paper read by Dr. Wheeler before the Midland Institute, and it seems necessary to point out that Dr. Wheeler was careful to note that the title of his paper might be misleading, being not written with reference to the conditions attending colliery explosions, but being a record of scientific measurements and observations upon the behavior of explosive mixtures of firedamp and air when ignited under differing conditions. In the discussion upon his paper, Dr. Wheeler remarked: "A very wide subject is opened up by a consideration of what occurs in colliery explosions underground, because in nine cases out of ten, or in ninety-nine out of a hundred, we are not then dealing with firedamp explosions alone, but with the added effects of coal-dust." "I know of only two instances" stated Dr. Wheeler, "where it was possible to regard a colliery explosion as being due to firedamp alone".

It is a sign of the times that so many papers should now be presented to technical gatherings that are records of work in pure science. One of these present when Dr. Wheeler's paper was read remarked that it was an excellent instance of how much science is "measuring", the paper being really "a record of measurements of phenomena that we have hitherto known about only in a general way". It is often difficult for practical men faced with the combatting of physical forces, or the handling of raw materials, to see the application of the detached laboratory investigations of pure scientists, but in recent years we have had most abundant examples of how apparently unrelated scraps of information upon physical phenomena have been pieced together, and eventually proved to have definite and valuable economic applications. It has been appositely remarked that "what the worker in pure science discovers his fellow in applied science utilizes".

There is one feature that remains very clear after perusal of literature relating to coal-mine explosions, especially in the light of Dr. Wheeler's admission that few coal-mine explosions are attributable to the presence of firedamp alone. This is, that the originating cause is always the introduction of naked flame into the myriad physical states of a coal mine that permit of the development of the phenomena of "detonation". The most obvious preventive precaution is suppression of every source of the presence of naked flame in a coal-mine. This precaution is, of course, the most difficult thing of all, but the substitution of the electric-light for all varieties of flame-lights, and the prohibition of the use of explosives of the flaming variety are two precautions that in the light of the present-day knowledge seem almost elementary. Probably we indulge in no over-statement however, in observing that there is more coal being mined today without the taking of these elementary safeguards than is being mined under their enforcement.

PUBLICITY FOR CANADIAN MINING IN LONDON

We reprint in this issue an editorial on "Canada's Minerals" from the "Financier" which refers to the small measure of attention that Canadian mineral enterprises have awakened in Britain, and mentions that the reason for this lack of interest is being remedied by an intelligence service instituted in the City by the Canadian Government, the efficiency of which is praised. This editorial gives point to the suggestion which was pressed upon the Ontario Minister of Mines by the Temiskaming Prospectors' Association recently. Mr. Mills said the Ontario Government had spent a thousand dollars on advertising in Britain, and had sent over rich mineral specimens for exhibit there. The impression we get from reading English exchanges, and particularly those papers that specialise in reporting the financial affairs of mining enterprises, is that the attention which Canada has so far attracted as a place for mining investment is of the most meagre character. The "Financier" rightly says "the mineral potentialities of Canada have not received that measure of attention which is justified by the facts". To read the advertising literature that is so plentifully distributed in Britain by federal and provincial departments and by the transportation companies is to be struck by the superabundant references to agriculture. It would be interesting to compare the amount spent by the Ontario Government on advertising farming possibilities with the thousand dollars spent on advertising mining possibilities. And yet there is a very large portion of Ontario which will always be more important as a source of useful minerals than from an agricultural point of view.

SPECIAL NORTHERN ONTARIO GOLD-MINING ISSUE.

A special issue of the "Journal" dealing with recent developments in the gold-mining industry of Northern Ontario will be published early in July. Mr. R. E. Hore, the Consulting Editor of the "Journal" has recently visited the gold-mining centres of the North, and the information that he has secured will be of a nature to explain the very definite optimism that now exists in the North, and is voiced, according to our Northern Ontario correspondent, by executives not given to over-statement.

SOMEBODY has been good enough to put the Editor on the "sueker list", and he is receiving, with a frequency that portends good times for the printer, literature emanating from Fort Worth, Texas, advertising the Marine Oil Syndicate and the Advance Oil Company of that place. The President of the Advance Oil Company addresses us as "Dear Mr. Gray" and signs himself "Sincerely", and presents what he calls "a real two-sided proposition". We have not been used to such treatment from presidents, and had hitherto regarded the species as being of a distinctly one-sided variety. Mr. Bierkamp (a name wasted in Texas) suggests we take a chance, and mentions that "everything we have on this earth we get by taking a chance". That's right. We got a number of things that way. Mr. Bierkamp suggests the purchase of ten shares of Advance Oil stock at one dollar per, which he says "won't break you, and may go a long way towards making you". "There is nothing that makes big money faster and surer than oil gushers". Except oil-stock "suckers" maybe. One does not need to go to Fort Worth to take a chance. Perfectly reputable Montreal stockbrokers will sell one perfectly good stocks that are chancy enough to suit the most exacting tastes.

Another unknown friend offers "the greatest money-making offer it has ever been my privilege to offer to my friends and clients", led thereto by "chance, good luck, good judgment, unusual foresight, intuitive knowledge, or a guidance that cannot readily be explained". We suggest the Ouija board as a possible explanation. So far as we can gather, Messrs Gilbert Johnson and Company offer us participation in the profits of the "greatest oil-pool in Northern Texas" and in what is probably "the richest oil zone on the American continent" for fifty dollars a share, with a discount for cash down. Mr. Johnson states his belief that he will be quickly able to make these fifty dollar units worth from five hundred to a thousand dollars each, whereupon we see clearly the irksome nature of daily toil and feel like following the advice of Mr. Bierkamp to take a chance.

Both the philanthropists who have discovered the Editor's sylvan retreat quote testimonials as to their wealth and probity from lawyers, printers, hotel proprietors, jewellers, oil-map manufacturers and opticians. The connection is somewhat obvious, all except the optician.

Mr. Bierkamp writes: "May-be you thought my letters to you were just oil circulars, and didn't need a reply—that I just took your name out of a telephone book, or a directory, or sent letters like yours to everybody in town". Funny how these gentlemen read one's thoughts. "Well", says Mr. Bierkamp, "I didn't. I HAD A SPECIAL REQUEST TO WRITE YOU". Mr. Johnson is still more cruel. He writes: "Your name has been suggested to us as one interested in Texas Oil developments". The Editor is wondering who is the suggester.

The oil industry, according to Mr. Bierkamp, is the "safest, surest and most profitable business in the world today". It sure is—for people in Fort Worth, Texas, and for the satellitic jewellers, bankers, hotel proprietors, etc., that attend upon the oil-stock promoter.

The conference of operators, dealers and consumers held at Victoria, B.C., to talk over the retailing of coal seems to have been a very practical and sensible affair. Particularly sensible was the decision of the coal-dealers to push the sale of run-of mine coal and to discourage fancy sizes of coal, re-sereening, forking and other methods of decreasing the general quality and increasing the general price of coal to the consumer. People pay high prices for lump coal, but if they investigated would probably find that the furnace-man smashed it up with a hammer before feeding it to the fire.

British Columbia is not the only place where these traditional and archaic practices survive, and a little conference between operators, coal-dealers and consumers, would be mutually helpful in many urban centres.

Our contemporary in British Columbia, "Mining and Engineering Record" criticises the action of the B. C. Department of Mines in prohibiting the use of naked lights in coal mines throughout the province as unnecessarily restrictive, stating that there are some coal-mines in British Columbia "that are as safe as metal mines so far as open lights are concerned, and which can be more conveniently worked by such lights". We utterly deny the advisability of using open lights in any coal-mine, no matter how reputedly safe it may be. Safety, in a coal-mine, is a matter of degree. Coal-dust alone is a high explosive, brattice cloth and pit timber are inflammable substances, blasting powder is generally used in coal mining, and is not a safe substance to handle in the darkness by the aid of an open light. The absence of "firedamp", over a term of many years in the working of a coal-mine, is—as has been all too-often proved—no guarantee that it will not suddenly make its appearance. Our contemporary criticises the prohibition of naked lights in British Columbia as savouring of "continued tinkering" and as adding to the complexity and cost of coal production. We would emphasise a former opinion, namely that it is a thoroughly well-justified policy, and would add that it has received uniform approval from many distant quarters, both in Canada and abroad.

Firedamp Explosions

By JAMES ASHWORTH, Livingstone, Alberta.

Prof. R. V. Wheeler, D.Sc., having recently contributed a paper on this subject to the Midland Inst. of Mining, Civil and Mechanical Engineers, it will, through its publication in the transactions of the British Inst. of Mining Engineers (Vol. LX, part 2), circulate throughout the whole world and arouse general interest. Its author is well known, and as he has been for many consecutive years engaged in experimental work for the British Government he will therefore be taken with more seriousness than the work of a layman would be. The paper is divided into five sections: No. I, Introduction; II, Firedamp; III, Limits of Inflammability; IV, The Propagation of Flame; V, The Vibratory Movement of Flame. The object of the paper is stated by the author as "not being a disquisition on mining disasters due to firedamp but as describing the conditions necessary for the continued propagation of flame in mixtures of firedamp and air, and details the different characteristics of the flames produced dependent upon the different conditions under which ignition of the mixtures is effected."

One of the first things which draw the attention of the reader who is looking for information on this ever present danger, is that the most important factor in a modern colliery explosion, viz, coal-dust, is not included, nor is another factor named in any form, viz, water vapour; neither is there any information as to why these are omitted. The next notable feature is that the Professor suggests the use of the un-scientific term "firedamp" as meaning methane. This is explained on the second page as being due to the fact that the firedamp of British mines contain as its inflammable constituent methane (CH_4), in predominating quantity.... For all practical purposes, therefore, the firedamp of British coal-mines can be regarded as "methane." In this paper then, the words methane and firedamp will be used as meaning the same thing."

After reading this reasoning, which by the way carries no convincment as to its suitability or usefulness, it is notable that the author only uses the term once or twice in the major balance of his paper and it is not surprising that one of the members present when the paper was read asked the Professor if he would not regard "firedamp" as an unscientific term, to which he replied, "It is a very useful term."

In regard to this the writer has always understood the term firedamp to mean a mixture of any explosive gas found in a coal mine when mixed with air, and that methane was methane, and ethane was ethane. As a practical example it would appear that Prof. Wheeler considers 95% of methane as firedamp (without air admixture), and therefore the natural gas used by the U. S. A. Bureau of Mines to ascertain "The Relative Safety of Brass, Copper and Steel Ganzes in Miners Flame-Safety-Lamps", consisting of 82% methane, 16.4% of ethane and 1.5% of nitrogen would be firedamp also.

Such reasoning seems utterly absurd, and more so when we note that the presence of the higher hydrocarbon gases is now assumed to be acertain indication of an active gob fire; thus if after an examination a colliery official reported only "firedamp", the management wohld be justified in assuming that there might be heating, but no fire.

Now let us see what other advancement Prof. Wheeler has made, take first, the rate of explosion in gases, and compare them with Prof. Harold Dixon's results (N. of E. Inst. of M. & M. E. transactions "The Rate of Explosions in Gases"). The most notable difference between the two is the fact that Prof. Dixon proved the use of five per cent of moisture to be necessary to obtain the maximum explosive force, whereas Prof. Wheeler does not appear to think that moisture is a necessary factor. There was a time and not long ago, when moisture in the air was considered a great safeguard in a dusty coal mine,—and in the U. S. of America it is still considered a great safegnard by some engineers of standing in colliery management. A saturation of five per cent can only be attained by the use of steam.

Then again we have the factor of coal-dust entirely missing, a factor which is never missing in the working life of a coal-mine, and, in the writer's opinion, if missing renders any experiments particularly in large-diameter tubes, of no practical value whatever.

We have, however, the records of experiments made in large-diameter tubes at Altofts and Liévin in France, and it is surprising that Prof Wheeler does not refer to these. Almost at the conclusion of an experiment at each of these testing-galleries, the speed of the explosion flame suddenly increased, and a portion of each gallery was blown to bits, not at the extreme open end but not far from it. In regard to these two experiments Prof. Wheeler says nothing as to what was the explanation of these tremendous exhibitions of force. He however in the concluding paragraph of his paper, says,—"The fastest speed of flame recorded in any experiment was about 60 metres per second, and was a short duration. This is not of the same order of magnitude as the speed of the *Detonating Wave* in gaseous mixtures. It would not be wise to conclude, however, that the detonating wave cannot, in any circumstances, be developed in mixtures of methane and air at normal temperatures and pressure. On the contrary, in several experiments in the steel tube 30.5 centimetres in diameter and 90 metres long, open at both ends, in which restrictions were introduced at two points (consisting of steel rings, $\frac{1}{8}$th inch thick, which reduced the diameter of the tube to 28.6 centremetres at these points), the development of the detonating-wave seemed imminent. These experiments on the effect of restrictions in the tube or gallery are being continued, together with experiments on a larger scale than those described in this paper, on the propagation of flame in currents of methane and air. As a result of these further experiments, it is hoped to fill the *lacuna* in our knowledge that at present exists respecting the extent to which turbulence of the mixture in whatever way it may be imparted, can increase the violence of firedamp explosions".

The above may be considered a very important paragraph in several regards not the least of which is, that the Professor uses the word "firedamp" only once in No. V section.

Personally the writer is trying to find out what is meant by detonation and how it is created, thus he finds Prof. Wheeler stating that "'the speed attained by the flames during the uniform movement are com-

paratively very slow compared with that of the detonating wave, but slow also compared with the speeds during other phases in the propagation of flame in mixtures wherein the detonation wave normally does not develop, such as are mixtures of methane and air.'' In a foot note he adds, ''The detonation wave constitutes a particular phase in the propagation of flame which occurs only with certain mixtures, chiefly those of inflammable gases with pure oxygen. When the wave has been established in such a mixture, it travels with a permanent maximum velocity which appears to be that of sound travelling in the burning gas, which itself is moving forward *en masse*. The velocity of the wave which differs from each inflammable mixture, is of the order of 1,500 metres per second''.

Methane is an inflammable gas, and therefore when mixed with pure air will it *detonate*? The writer well remembers Prof. Dixon stating that such a mixture would *not* detonate,—he has also read of more recent statements by Prof. Dixon in which he speaks of the detonation of such mixtures, and now we find Prof. Wheeler in reply to Prof. Fearnsides and others explaining the word detonation as used in science, as being easily defined thus, ''It is a particular phase in the propagation of flame which occurs only with certain mixtures, chiefly those of inflammable gases with pure oxygen. The detonation wave is a definite physical constant for each mixture of gases, and travels at a permanent maximum velocity, which is the velocity of sound in the burning gases, which are also moving forward *en masse* with the velocity of sound. That is a definition of the term 'detonation wave' in science.''

This explanation does not explain why an explosion flame such as referred to above as occurring in the Altofts and Liévin long testing-galleries and also at Eskmeals in a three-feet-diameter gallery knocked part of the gallery into junk. Why did the flame in these cases suddenly increase its speed and immediately afterwards ''burst'' the testing tubes close to the open end?

The writer many years ago attended a lecture in London by one of the Siemens staff in the course of which it was explained that to detonate say an explosive the detonator *must* produce a vibration corresponding to a certain musical note, and he also showed the effect of musical notes on electrical flame. Possibly some deep student of the mysteries of electrical phenomena can discover its agency in the Altofts and Liévin demonstrations. Why not?

Before concluding, there is one other point brought out in Prof. Wheeler's paper viz, the diffusion of gases, and the writer knows of no explanation for the fact that after many colliery explosions the majority of the killed are not much burned and sometimes not at all, below the waist. In the olden days, before the ventilation of coal mines was modernised, men often came out of the mine only slightly scorched on the back because they laid down on the floor and allowed the flame to pass overhead. Why should this still occur with modern ventilation or do we assume too much when we speak of the diffusion of gases in coal mine ventilation?

From statements made by members when discussing Prof. Wheeler's paper diffusion does not always occur according to rule and therefore we have at times used our coats as a gentle persuader to hasten the diffusion and to bump a whole in a wall of gas which declined to diffuse quickly. Suggestively the saturated dampness of the air might have something to do with the slow diffusion.

The Central Examiners of the British Mines Department when reporting on the recent examination for First and Second Class Certificate of Competency, make the following comment on the First Class answers:—

''The difference between the mechanical mixing and the diffusion of two gases? Very few of the candidates answered this question satisfactorily. Most of them quoted Graham's law, some correctly, others incorrectly. As a rule the answers displayed the most profound ignorance of the process. There was far too much jargon about intermolecular spaces, bombardment of atoms, and similar expressions, which generally finished up with an illustration, such as—that the diffusion of hydrogen and oxygen into each other results in the formation of water, or that of the gases carbon and oxygen in the formation of carbonic-acid gas; carbon and hydrogen in methane and so on. One of the most simple and correct answers was:—We get mechanical mixture in the breathing bag of a resene apparatus when we mix free oxygen with the generated air to form a mixture (air) to breathe. The injector is the artificial mixing-medium in this case. We get diffusion when firedamp in a cavity in the roof or goaf diffuses into the air current without any external aid and in opposition to its density.''

It is evident from the above quotation that the subject of the diffusion of gases deserves much more serious study than it has heretofore received, though at first sight most people are led to assume that it is a fact and there is nothing to study,—and yet we are not too sure that the man who was writing in his examination answers about intermolecular spaces and the bombardment of atoms, had not got some sound theory at the back of his head originating from a study of electron theories. What is more likely to diffuse gases than electrons constantly on the move?

PERSONALS.

Mr. James McEvoy has returned to Toronto from Mexico where he was examining oil properties.

Mr. J. J. Warren president of Consolidated Mining & Smelting Co. of Canada, has left Toronto for the west. He will cross the Pacific in connection with the Oriental trade of his company, whose mining, smelting and refining co-operations are in British Columbia.

Hon. Edgar N. Rhodes has been appointed president and managing director of British America Nickel Corporation. Mr. Rhodes is Speaker of the House of Commons.

Mr. F. H. Stover of Chatham is at Edmonton en route to Fort Norman where he will have charge of drilling operations for two oil companies.

Mr. Morton F. Stern and Mr. Frederick G. Corning of New York have been appointed directors of Dome Mines Ltd. succeeding Mr. A. H. Curtis and Mr. C. D. Kaeding. Mr. Kaeding was for one time general manager.

Mr. J. S. Bache president of Dome Mines Ltd., is in Toronto for the annual meeting of the company.

Peat Production in Ireland

ROLAND H. BRIGGS, Coulsdon, England.

The very important work carried out by the Canadian Government at the Alfred Bog in Ontario, and the comprehensive schemes for electricity generation and high-tension distribution from the peat areas to industrial centres with which it is hoped to partly meet the fuel shortage in Germany, make the British Government report which has just been published on the winning, preparation and use of peat in Ireland of special interest in the peat-producing countries of the World.

The use of peat fuel in Ireland is not by any means one of the recent activities of the country. For a very long time an average production and consumption probably exceeding 6 million tons of air-dried peat per annum has taken place. Over great portions of the country peat is the only source of fuel supply, and it is considered that the available peat reserves will produce 4000 million tons of air-dried peat. What steps can be taken to make this peat supply serve to the fullest extent the domestic and industrial needs of the country is the problem which the committee of experts which have been considering the matter has endeavoured to solve.

More than a century ago the peat bogs of Ireland were the subject of Government and scientific investigation, but the Treasury was drained by the effects of the Napoleonic Wars, the Irish landlords were themselves too poor to attempt systematic exploitation of the peat areas, and the value of the land if reclaimed for agricultural purposes was reduced by the general low value of agricultural land in the British Isles, caused by the importation of cheap foreign foodstuffs.

The peat supplies of Ireland are, nevertheless, of unusual commercial value owing to the shortage of native coal-supplies, the thickness of the peat deposits, their proximity to industrial areas, and their suitability for draining and land reclamation. The peat areas cover more than 3,000,000 acres, of which a considerable percentage consists of flat deep bogs, estimated to average at least 17 feet in depth. It is considered that the native peat supplies would last for at least 250 years at the present rate of consumption of the whole fuel and power requirements of the country, even if all imported coal was replaced by peat. The pre-war coal production of Ireland was about 88,000 tons, and the imported coal about 4,650,000 tons per annum.

It should be understood that the most important use of peat in Ireland is as a cheap domestic fuel. Whatever steps may be taken to use peat industrially in Ireland, the domestic needs must always come first. The mechanical winning and preparation of peat may, however, in all countries be advantageous for the production of peat for domestic purposes.

Peat is usually cut in Ireland from the end of April to the beginningg of July, and carried home in August and September. The work is carried out at periods which both suit the farm work and the weather. The maximum cutting-period could probably not generally exceed 120 days. Most of the 6 million tons of fuel now used is cut with a wing slane by men, and saved and clamped by the women and children. Wing-slane fuel is cut from the bog with the long axis in a vertical direction, but where the breast slane is used the sod has its long axis horizontal. The latter sods are larger and more regular, and will stand transport with less damage. A small amount of "hand turf" or "mud turf" is produced, this being well-humified peat raised from a bog-hole, mixed with water and spread on the surface of the bog, mixed and puddled by the feet of men and horses, and levelled and parted by hand.

The winning of peat-moss litter is unimportant in Ireland compared with that of peat fuel, but it represents the best example of modern methods in the hand winning of peat as practised in Ireland. A narrow slice 2 ft. wide and 2 ft. deep is cut from the face of the cutting-bank, this being cut in sods 18 in. by 6 in., which when air-dried produces one cwt. of moss litter per lineal yard of face. The cutter can place this amount of raw peat on the surface of the bog without moving from his position and without other help, and an output of 3 tons per day is thus obtained from one man.

The bog is divided by a main road in the centre, with collecting banks 12 yards wide on both sides at 112 yard intervals. Between the banks the bog is divided up by drains 2 ft. wide and 3 ft. deep, and 11 yards from centre to centre, forming cutting banks 100 yards long and 10 yards wide. The narrow slice described above is cut from these faces. The season for cutting moss-litter peat extends through the winter from October until June and the saving and stacking are completed by September.

The various types of peat machines available are described and illustrated in the Report referred to above. The earlier models used in Germany are unsuitable for Ireland owing to the large amount of labour which is necessary to operate them, but it is often necessary to use hand-fed elevators in Europe instead of dredgers because of the number of logs and branches which are met with. In the Irish bogs the peat is singularly free from logs, except at the edges.

In the most modern electrically-driven machines the raw peat is excavated and elevated from the bog, is macerated and mixed by means of rotating and fixed knives and a single or double-screw conveyor, which forces the peat through a nozzle or nozzles in a stream, which is cut into lengths for sods, these sods being carried away by a conveyor and deposited on the bog. This only leaves one operation still to be done in the peat producing, that is, the collection and stacking of the air-dried peat.

Most of the machines used in Germany and Austria have excavators of the ladder-dredger type and work on an inclined face, so that the face when cut at a proper slope is in equilibrium. Continuously-rotating excavating-buckets fixed on a chain are used. The sods produced are about 10 x 10 x 40 cms., and the conveyor usually consists of a number of plates resting on rollers, each plate receiving one sod. The conveyor may extend at right angles to the cutting face for a distance of 60 to 120 metres. This system is considered more suitable for Ireland than the Canadian method of transferring the macerated peat to a spreading machine by means of buckets on an overhead telpher, as the difficulty in Ireland is to provide sufficient suitable labour at any particular point, and the latter system is thought to require more operative labour, although it has the great advantage of giving a much larger drying-ground.

While economy in the labour required appears to be given by the automatic machines described, one of these requiring only 3 to 5 men for the excavating and spreading of 76 tons of air-dried peat per day, they have the drawback that the width of the drying ground is limited

by the length of the conveyor, which as mentioned above may be from 60 to 120 metres. A narrow width of drying ground means that a greater length of cutting-face must be developed for a given output per season, and a larger area of bog must be laid out for working in consequence. The narrow drying-ground also limits the amount which can be cut off per lineal foot of the working-face per annum, and this results in a higher capital expenditure on the light railway required.

It is suggested that another labour-saving appliance which should be used with the automatic peat machine is the belt conveyor and stacking machine for collecting the air-dried peat into stacks adjoining the drying ground.

Automatic machines for peat-winning in Ireland are advocated because sufficient labour for hand-winning is not available, and a longer season can probably be worked when machines are used; because the work may proceed by night as well as by day, cheap electric-light being available; because machine peat dries more rapidly and is less affected by rain than slane-cut peat; because machine-cut peat shrinks more than slane-cut peat and has thus a higher calorific value per cubic foot, a very important item for transport and grate areas; because machine-cut peat will stand handling better; and because peat machines can cut for the whole depth of a deep bog, so that a more uniform product is obtained, an important matter for steam-raising and gas-producing.

It has been argued that the surface of the bog will not support the weight of the machines, and that their heavy initial cost and the difficulties caused by stumps and tree roots make them unsatisfactory, but the consolidating effect of proper drainage makes the bog surface suitable for supporting the weight of either rails or caterpillar tractors, capital costs are balanced by savings in labour, and the Irish bogs except at the margin are very free from obstructions.

From a number of figures which have been collected it has been shown that to win mechanically 100,000 tons of air-dried peat per annum for 100 years would require a total area of 5000 acres, 20 feet deep, which area includes the necessary drying-ground, transport, stacking and working areas, and for this output 13 to 14 automatic machines would be required and about 130 men and 400 women and children from February to the end of September, with 35 men only for the remainder of the year. It is considered that .77 tons of air-dried peat will equal in value 1 ton of coal as delivered in Dublin, that is, with an average calorific value of 11,000 to 12,000 B.th. U. per lb. The by-products of peat place it in a more favorable ratio to coal if both fuels are gasified in a gas producer.

As the area of the peat bogs of Ireland is one-seventh of the whole land-area of the country, their drainage for peat production has an important bearing on the agricultural resources of the island. The lime required after the bogs have been drained and stripped of the peat is present, close to the bogs, in ample quantity, and good crops of potatoes, barley, mangolds, parsnips and carrots can be seen growing in Ireland on reclaimed peat-stripped bog-land. It is obvious that the increase in the value of the land for agricultural purposes can be subtracted from the cost of winning the peat supply.

The recommendations of the Committee include the suggestion that the State should purchase a large peat-bog capable of producing at least 100,000 tons of air-dried peat per annum, that the bog should be drained both for peat-winnings and agriculture, that the various electric-driven plants should be tested under working conditions, that an electric power-station should be set up, the generators being driven by gas-engines operated by peat producer-gas, and that the recovery of the by-products should be practised in the most efficient manner, that an electro-chemical industry depending on cheap electricity should be started to prove the economy of the power system, and that the necessary dwellings for the employees should be erected. While no such comprehensive scheme as the above has yet been put into operation, experiments with peat machines are being continued and the results eagerly watched.

ONTARIO MINING ASSOCIATION MEETS AT COBALT.

The annual meeting of the Ontario Mining Association was held at Cobalt from June 16th to 18th. At the end of two years the Association reports a membership of 41 companies, representing a gross capitalization of $175,000,000. The business meetings at Cobalt were interspersed by local motor-drives and visits to the mines. On Saturday the visitors, as guests of the Temiskaming Mine Managers' Association visited the ancient Wright Mine on the Quebec shore of Lake Temiskaming.

The proceedings of the Association were not made public. The mining companies represented by their officers included the following. Algoma Steel Corporation, Bailey Silver Mines, Beaver Consolidated Mines, Cobalt Reduction Company, Coniagas Mines, Coniagas Reduction Company, Crown Reserve Mining Company, Dome Mines Company, Dominion Reduction Company, Edwards & Wright, Limited, Geo. H. Gillespie & Co., Henderson Mines, Ld., Hudson Bay Mines, International Nickel Company, Keeley Silver Mines, Kerr Lake Mining Company, Kirkland Lake Gold Mining Company, Haileybury Frontier Mine, Lake Shore Mines, La Rose Mines, Lightning River Gold Mines, McIntyre Porcupine Mines, McKinley Darragh-Savage Mines, Miller Independence Mines, Mining Corporation of Canada, Mond Nickel Company, Nipissing Mining Company, Northerown Porcupine Mines, O'Brien Mine, Ontario-Kirkland Gold Mines, Petersen Lake Mining Company, Teck-Hughes Gold Mine, Temiskaming Mining Co., Trethewey Mining Co., Wright-Hargreaves Mine, Aladin-Cobalt Co., British America Nickel Corporation, Dominion Improvement & Development Company, Kirk Gold Mines and Lakeview Gold Mines.

Invited guests included the Minister of Mines and his Deputy, the Mining Commissioner, the Provincial Geologist and Chief Inspector of Mines, and a number of prominent mining engineers from Toronto and Northern Ontario.

The officers elected for the ensuing year are as follows. R. B. Watson, General Manager of the Nipissing Mining Company, president; C. V. Corless, General Manager of the Mond Nickel Company, first vice president; J. P. Watson, second vice-president. The Directors include E. Hibbert, A. D. Miles, George Cowie, H. P. Depencier, J. P. Bickell, A. Fasken, J. G. Dickenson, F. L. Culver, R. C. Coffey, G. C. Bateman and George H. Gillepsie. Mr. Balmer Neilly was reappointed Secretary. Messrs. Miles, Culver, Watson, Bickell, and Fasken, with the Secretary, form the Executive Committee of the Association.

Oil Prospecting in the Great Plains and the Northwest

New Geological Survey Reports on Oil and Coal.

Part B. of the Summary Report of the Geological Survey for 1920 contains a number of reports of progress on the geological study of possible oil-bearing formations in the Great Plains and in the Mackenzie drainage area. These will be of general public interest, as will also be some papers on coal horizons in Saskatchewan and further west. A list of the reports is as follows:

Mesozoic of Upper Peace River, British Columbia.

F. C. McLearn reports that the lower member of the Bullhead Mountain formation in the district covered by his reconnaissance is not promising as a coal producer, some seams noted being too thin and of too poor a quality to be of commercial importance. The upper member requires to be prospected, and it is suggested has important possibilities as a coal-bearing formation.

While the district was too large to be covered adequately in one season, the evidence gathered is not favourable to oil possibilities, and geological evidence so far as collected does not indicate any place where drilling for oil would be justified. The structure is unfavourable, there has been much faulting and the rocks have undergone much metamorphism, as indicated by the high carbon content of the coal, where it is exposed.

Placer gold found on bars on the river flats is not thought to have a local origin, and enrichment at bedrock is not to be expected. A very small amount of platinum has been found with the placer gold.

The writer points out in the reason for the frequency of landslides in this district,—and directs the attention of railway engineers to the comparative stability of the Pleistocene sands, as opposed to the mobility of surface layers of sliding boulder-clays.

Upper Elk River, British Columbia.

J. R. Marshall reports on the coal-bearing formations of the Upper Elk River, British Columbia. Lower Cretaceous rocks in the area examined contained important seams of bituminous and semi-bituminous coal, particularly in the Kootenay Formation. As many as 22 distinct seams, yielding a thickness of 175 feet of coal are reported. Seams from 10 to 15 feet thick, and some as thick as 20 ft. are present, and one section showed 89 ft. of coal in 3,386 ft. of measures. Another section, measured by Dr. Dowling, gives 175 feet of coal in 1,169 ft. of measures. A sample from a 12 ft. seam gave upon analysis 1.2 moisture, 8.2 ash, 26.6 volatile and 64.4 percent of fixed carbon. The seams pitch from 35 degrees to 50 degrees, the coal measures occurring in a synclinal trough. Two main sections, the Elk River and the Fording River are mentioned. The mining of the coal is said to be possible without serious difficulty, and the valleys of the Elk and Fording rivers afford practical routes for a railway.

Review of Prospecting for Oil on the Great Plains.

D. B. Dowling reviews prospecting operations for oil in Alberta in five distinct structural provinces. The work is being done by companies with sufficient capital to complete individual undertakings and to retain a staff of expert geologists. The results of drilling, may therefore, states Dr. Dowling "be looked forward to with more confidence than the sporadic work of 1913." A very small percentage of the 1913 holes reached horizons in which there would be some chance of finding oil, and many of the failures were made on unfavorable structures.

Mr. Dowling comments on the presence of oil in rocks of Lower Cambrian age at Waterton Lake and Cameron Brook, and quotes from Dawson in the Summary Report of 1898, suggesting a possible overriding of Cretaceous rocks by very ancient rocks "probably of Lower Cambrian age". A later opinion of Daly suggesting an overthrust of 40 miles is quoted, and the oil is suggested to have originated in the Cretaceous through the action of heat. Mr. Dowling states the petroliferous character of the lower part of the Cretaceous in the foothills is proven by actual discovery further north, and he suggests the oil that is found in the Lower Cambrian was introduced as a vapour.

Mr. Dowling's report deals in detail with each drilling operation, and it is not possible to usefully condense it.

Underlying Seams of the Souris Coal Field, S.E. Saskatchewan.

Mr. Dowling reports on underlying seams in lignite area of Saskatchewan known to exist below the seams naturally exposed and worked at Estevan, Bienfait and Taylorton. These seams are covered by a mantle of drift, and the coal-seams, where reached by wells, have shown a continuity in horizon but a great variation in thickness.

Great Slave Lake Area.

G. S. Hume reports on study of the north shore of Great Slave Lake during the season of 1920, continuing the work of A. E. Cameron in the seasons of 1916 and 1917. Material collected by Cameron and others included the whole Devonian as found in this region, and it was desired to discover what might be available between the base of the Devonian and the top of the pre-Cambrian, for which purpose the north Arm of Great Slave lake seemed to be most favourably situated.

Raised beaches, indicating successive lowerings of the lake level were noticed. The Silurian exposures on the North Arm are described, together with some of the fossils obtained.

In regard to oil possibilities, at Windy Point a number of oil seepages occur from the Presquile formation of Middle Devonian age. The Presquile formation is a porous dolomite containing caverns lined with dolomite crystals and partly filled with a heavy thick oil. Films of oil are found on the water of the lake, and, on hot days, oil oozes from the rock and stains the face of the exposure. "There is no doubt," states the Report, "that this horizon contains oil in quantity, but the outcrop of an oil horizon cannot be expected to be a very favorable location from which to obtain commercial quantities of oil by drilling." The possibilities of finding oil at some distance inland from Windy Point are as yet unknown, but from what is known of the regional structure, the Windy Point anticline is a local fold on a much larger structure dipping southwestwards. "If favorable structures can be located in this region with a cover of Simpson shale, the possibilities of finding oil would seem to be very good."

The presence of sulphur springs near the outcrop of the Presquile dolomite is discussed, and is regarded by

the writer of the report as an unfavorable indication of the presence of oil of light specific gravity.

Oil-bearing Rocks of Lower Mackenzie River Valley.

This is a full and well-illustrated report by E. M. Kindle and T. O. Bosworth, from which extended extracts will be given in a later issue of this journal. A sketch map, showing approximate geological structure of the Norman-Good Hope area, and a sketch map showing the geology along the Mackenzie between the Ramparts and the Delta, are included, and some interesting photographs. A table of the formations, with thicknesses, and a correlation with Great Slave Lake and Upper Mackenzie formations, is also given. Formations which may contain oil are numerous. The oil-sands are stated to contain an oil that is light and colourless, with an odour indicating a paraffin base and high gasolene content. Numerous oil-seepages are mentioned, and gas is being given off from all places where oil seepages were noticed. In addition to the oil-sands there is a large area of the Devonian that contains highly bituminous limestone. "At depth, under favourable structural conditions, it is possible that some of the beds in this series (Beavertail limestone) may be found to hold accumulations of fluid oil." Enormous areas of bituminous shales are mentioned. One outcrop, between Bear Mountain and Carcajou, is a hundred miles long, and in a number of places the bituminous shales are undergoing slow combustion at their outcroppings.

In regard to structures favourable for oil accumulations, the Report states, "the conditions conducive to the formation of oilfields are here very favourably fulfilled."

> "Extending over a large area we have 1,000 feet or more of highly bituminous limestones and shales, from which an immense quantity of petroleum might readily be generated. And overlying these beds, there are 2,000 or 3,000 feet of clay-shales and sandstones from which numerous seepages of oil arise. Finally, this mass of petroliferous deposits is traversed by large, bold, anticlinal folds.
>
> The high parts of the anticlinal hills are not now territory favourable for oil, since denudation has removed the oil-bearing formations from them. But these main anticlines pitch up and down, and probably in some parts of the low flat land, on the west side of the river, perhaps along the prolongation of these axes of folding, similar great arches of the petroliferous formations may be present underground. Such would be ideal situations for the accumulation of pools of oil.
>
> Away from the crests, the dip slopes of the main anticlines present considerable possibilities; for changes in dip or porosity, faults, and minor flexures, may result in the accumulation of many oil pools at quite a distance from the main anticlinal axes.
>
> Apart from the large folds, the minor undulations also may prove important. In such deposits as these it is probable in any case that oil accumulations will be formed. If large structures are not available the oil will find the small ones. These smaller structures, similar in dimensions, for instance, to the anticlines of the Oklahoma and Texas oil fields, probably occur throughout the territory, both on the dip-slopes and also at a distance from the axes of the main folds."

The Discovery Well at Norman was put down on a location chosen in 1914 "not as a spot where great production was hoped for, but as a site where a hole of moderate depth could not fail to penetrate the petroliferous formations which had been discovered." Whether this well will yield a steady production or not is not certain, but the Report makes the most important statement that "it has already demonstrated the prospect of important oilfields in the region." The oil from the well is of light colour, low specific gravity, high gasolene content, and low cold test.

The sum of the geological evidence, together with the result of the test well, "indicates an extensive oil region in which a number of oilfields may occur." "The capacity of the wells and the productivity of the fields are matters beyond present calculations. *But they are likely to be comparable to those of other Paleozoic oil-fields.*"

This preliminary report, which will probably be followed at a later date by a new memoir on the oilfields of the Mackenzie District, is one of the most important reports of progress that the Canadian Geological Survey has issued in many years. Copies can be obtained by application to the Department of Mines at Ottawa.

"Mining & Engineering Record" of Vancouver for May contains a compilation of information regarding oil in the Canadian northwest by the Editor, Mr. E. A. Haggen, and maps of the Athabaska river and Mackenzie river Basin that contain a great deal of local detail. Mr. Haggen is to be congratulated on this number.

Richard Lewis Lloyd, vice-President of the Dwight & Lloyd Sintering Company, and also of the Dwight & Lloyd Metallurgical Company, was recently honoured by the degree of Master of Science from Washington University at St. Louis, Miss. In conferring the degree, the Chancellor referred to Mr. Lloyd as having been trained at the Washington University and as associated with many improvements in metallurgy, particularly in the smelting of copper. Mr. Loyd has also shared in the development of the Dwight & Lloyd sintering apparatus, which because of its possible application to the beneficiation of Canadian iron-ores has attracted much attention in Canada.

HAMILTON'S GEAR BOOK.

The Hamilton Gear & Machine Company of 62-100 Van Horne St. Toronto has issued a useful book on cut gears, complied by Chester B. Hamilton, Jr. containing formulae, tables and interesting data on gears, and showing the equipment of this up-to-date house. The book is not a catalogue, but is really a modern handbook on gears, their construction and materials used in their manufacture, and heat-treating. The treatment is so technically excellent and so complete as to indicate that this Canadian firm knows its business thoroughly, and is equipped to give accurate and dependable service. The company was first organized in 1911, and the growth of the business has necessitated successive enlargements of the plant. An organization which did good work in munitions manufacture from 1914 throughout the war has been retained intact. The book is one that should prove useful to any mechanical engineer having to do with gears, or interested in a choice of gear materials.

"CANADA'S MINERALS."

(From the "Financier", London.)

With interest on this side restricted to only a few companies it is not surprising that the mineral potentialities of Canada have not received that measure of attention which is justified by the facts. The explanation is, perhaps, largely due to unavoidable delay in the compilation of statistics sufficiently up to date to command the attention of the speculative investor, in conjunction, as we have said, with the fact that the facilities for exploiting capital in Canadian mining enterprises are so extremely limited. This state of affairs, however, is being remedied by the progressive policy of the Canadian Government through the valuable intelligence service which has now been instituted in the City, and which may aptly be described as a veritable bureau of information regarding all matters pertaining to Canadian trade and industry.

As there are tangible grounds for the belief that British capital will be attracted more and more by the mineral possibilities of Canada, special interest atttaches to the preliminary report now available on the mineral production of the Dominion for the year 1920. This document is based upon direct returns received from the mines and smelters, and although these are not complete, sufficient data are available on which to base a fairly accurate record.

Lower Outputs with Enhanced Values.

In reviewing the industry as a whole, the custom is adhered to of expressing the mineral production in terms of dollars or total values. There has been a wide range in the prices of many metals during recent years, and the continuation of high prices for many products has, of course, resulted in greatly increasing the total value of the mineral production, even though the actual quantities of minerals obtained show a decline. As an instance, the average price of coal at the mine has increased from 2.49 dollars in 1913 to 4.65 dollars in 1920, so that the same tonnage of coal as was produced in 1913, viz., 15,012,178 tons, would have a value in 1920 greater by over 32,000,000 dollars.

The rapid strides which have been made since the war is shown by the fact that the total estimated value of the mineral production in 1920 of 217,775,080 dollars constitutes a record, being an increase of 41,077,690 dollars over the 1919 production, or 23 per cent, while compared with 1918, the previous maximum year, the increase was 6,473,183 dollars or 3 per cent. This interesting fact has thus far been somewhat obscured by the economic depression, falling prices and restriction or complete cessation of operations which characterized the closing stages of the year.

Gold Recovery Maintained.

The outstanding features of the period under review are the quick recovery in the production of copper, nickel and zinc among the base metals and in the output of coal and other non-metallic products. Only a very modest increase is shown in the total gold production, which amounted to 766,912 ozs., valued at 15,853,478 dollars, but the point is made that Canada occupies the almost unique position in being perhaps the only gold-producing country which has not shown a serious falling off in the production of the precious metal. To the aforesaid total Ontario, needless to say, was by far the largest contributor with 564,959 ozs., or over 73 per cent of the total production of the Colony. Now the active operations have been resumed in the Kirkland Lake district the assumption is that this province will easily maintain its pre-eminence.

As already indicated in the production of the base metals and coal, the period under review established a record. The total output of copper amounted to 40,577 tons, against 37,527 tons previously, which, at the average price in New York of 17.456 cents, would be worth 14,166,479 dollars. With the exception of silver it has to be remembered that metal prices were well maintained throughout the first nine months of the year copper standing slightly above the average, lead at about 50 per cent and zinc at 30 per cent in excess of the previousyear's average. Since then, of course, there has been a serious crash in metal prices, and as in other parts of the world these industries have been faced with a corresponding curtailment and suspension of operations pending an exhaustion of accumulated stocks and a market demand to restore higher prices, or alternatively until the vexed problem is solved by reducing the costs of production to the point of successfully meeting the prevailing prices.

Great Latent Possibilities.

While the report does not disguise the fact that present conditions foreshadow a considerable shrinkage in mineral production for the current year, the hope is expressed that it will rapidly be followed by an industrial activity based upon more healthy conditions of price and profit. While Canada has her domestic problems in respect of supplies of iron and petroleum and distribution of coal, it is pointed out that the great basic factors of her enormous mineralized areas, her great known resources in coal, nickel, copper, gold, zinc, asbestos and other metals too numerous to specify, and her infinitely greater latent possibilities should never be lost sight of. It need scarcely be added that there is evidence that the British investor is becoming more alive to the fact.

ONTARIO'S MINERAL OUTPUT.

The report of the Department of Mines of Ontario covering the first three months of 1921 shows a great falling off in production of metals as compared with the previous year. Nickel, copper, silver and iron were produced in relatively small quantities owing to market conditions. Gold production was down owing to shortage of power during the period. The present output of gold is however very much larger and the report for the three months ending June 30th will show a big increase. There has recently also been some revival of activity at Cobalt mines though the price of silver is still low.

STEEL FIRM OPENS AT COBALT.

The well-known English steel firm of Samuel Osborn (Canada) Ltd., has just opened a branch office and warehouse at Cobalt, to take care of the Northern Ontario mining business. Mr. Hubert S Southworth is the manager at Cobalt. This firm, which has its headquarters in Montreal, has just removed its Toronto office and warehouse to 126 Wellington Street, West, Toronto. The Toronto manager is Mr. H L. Usborne

THE LATE GEORGE BLAKE WALKER—COAL MINER AND SCIENTIST.

By the death of George Blake Walker, at the age of 67, British coal-mining loses one who was a leader in all improvements in the methods of coal extraction and utilization. His grandfather, father and himself were successively in charge of the Wharncliffe Silkstone Colliery from 1853 until within a few years ago. In connection with this colliery undertaking many of the now approved modern practices in coal-mining were first tried. The first by-product coke-ovens in the Midlands Coalfield (if not the first in Britain) were erected by the Simon-Carves Company at Wharncliffe Silkstone Colliery about 1890, and at this colliery, coke-oven gases, after extraction of the benzol and other by-products, were used to drive gas-engines, and to provide motive-power for the air-compressors and electric-lighting. Coal-cutting machinery was installed at a very early date in these collieries, and at a neighbouring colliery, Mr. Walker was instrumental in introducing the use of the first electrically-operated coal-cutter to undercut a seam under two feet in thickness.

Mr. Walker was responsible for the introduction of the first oxygen-breathing apparatus into British coal-mines, and the Tankersley Rescue Station, for which he was also chiefly responsible, was the first in Britain. He was also a pioneer in the introduction of pit-head wash-houses, and took a lively interest in all housing schemes for coal-miners.

His labours for the scientific advancement of coal mining covered a long period. He was a Fellow of the Geological Society, and was the first lecturer in coal-mining at Firth College, Sheffield. His exertions in the formation of the University of Sheffield, and particularly in its coal-mining activities were recognised in 1918 by the honorary degree of Master of Engineering from that University. He was one of the original members and an ardent supporter of the Midland Institute of Mining & Mechanical Engineers, being President from 1896 to 1898, and Honorary Secretary until 1918. He was the first recipient of the Peake Medal for conspicuous service to the mining industry. In 1918, his great services were recognised by his election as President of the Institution of Mining Engineers, and he also received the Telford Medal and premium from the Institution of Civil Engineers, of which he was a member. He was a member and President of the Sheffield Society of Engineers and Metallurgists.

THE LATE GEO. BLAKE WALKER.

Mr. Walker lived and worked among his employees from a boy, and in 1916, after 42 years continuous residence and service with the Wharncliffe Silkstone Collieries, his workmen presented him with a portrait in oils as a token of their esteem. The Wharncliffe Silkstone Colliery is historical in that it had the first checkweighman appointed under the Coal Mines Regulation Act, and it was the first colliery to have a miners' union.

As a consulting mining-engineer, Mr. Walker visited Australia and Canada on numerous occasions, and his health was impaired by hardships experienced in a blizzard while examining coal properties in the Rocky Mountains in 1909. He made two reports on the properties of the Dominion Coal Company in 1904 and 1907. He visited Canada in 1919 again.

As a pupil of Mr. Walker's, and as one of many who received many personal kindnesses, and wise direction, encouragement and help in mining studies, from a man who always regarded mining education as a life mission, the Editor desires to express his gratitude for the example of a good man, of great scientific attainments, actuated by the highest ideals, whose probity was never challenged. In addition to his eminence as a mining engineer, Mr. Walker was a musician and composer, and published several volumes of verse. It was a privilege and an honour to be intimately acquainted with such a man, whose comparatively early passing will cause regrets in the many quarters of the world where his former employees and pupils are scattered.

NORTHERN ONTARIO ORES DISPLAYED IN TORONTO.

A remarkable and attractive display of gold and silver ores representative of the mineral wealth of Northern Ontario, is on exhibition in the G. T. Railway ticket office window King and Yonge streets, Toronto. This unique display is arranged by Mr. E. R. Fairey in an endeavor to bring more forcibly before the people resident in, and visitors to Toronto, the tremendous activity now taking place in the gold mining districts of the Province. Mr. Price Green, Commissioner of Canadian National Railways, secured for this display the very spectacular ores from the Creo us Mine showing the gold as it is found in the quartz. This ore assays two hundred and fifty thousand dollars to the ton, and is well worth seeing. Other ores are from the McIntyre Porcupine Mine, Atlas Mine of West Shining Tree district, and Silver ores from Cobalt and Gowganda.

METHODS ADOPTED TO OVERCOME COAL SHORTAGE DURING THE BRITISH COAL STRIKE.

(By our English Correspondent.)

On March 31st. last the coal mines of Britain closed down for the usual Easter holiday, at the time of writing, ten weeks later, they have not yet reopened. The miners call it a lock-out, the owners say it is a strike, and the wise man calls it a stoppage. It has been conducted with remarkable forbearance on all sides, and is the result of economic circumstances rather than of unreasonableness on the part of anybody.

Very briefly it may be explained that at the end of Government Control the coal industry in Britain found itself in a state of complete bankruptcy, instead of the most profitable concern which it had been before the War. In 1913 the production of the country was over 287 million tons, of which nearly 98 million tons was exported or used for foreign bunkers. In 1921 the annual rate of production before the stoppage had fallen by at least 70 million tons, and the coal export to one-third of the 1913 figure.

The price of coal had increased by so large an amount that it was throttling the very existence of the iron and steel-producing trades, and other industries where large quantities of coal were required. The coal owners therefore determined to bring costs down to an economic level. This was a simple matter in those areas where coal is reasonably easy to procure, but an almost unanswerable one where the difficulty of getting the coal is so great that that much of the available money is swallowed up in non-productive wages and materials.

Geological difficulties and differences have made the coal stoppage, and the difference of opinion between the owners and miners only relates to the method with which those difficulties should be met. The miners say a national pool of profits and wages, by means of which the earning power of the various coalfields would be levelled up, would solve the question, but the owners, with the effect of Government war control of most industries still fresh in their memories, say such a solution is economically unsound as it would result in certain waste and inefficiency.

The natural differences in the coalfields are very marked. In some areas it is fairly easy to get the coal by mechanical methods, the seams are of fair average thickness, and the mines not unduly wet. In other districts on the contrary great difficulties are met with. Excessive squeezing of the strata has resulted in the formation of lateral cracks in the coal full of very fine dust which is discharged into the atmosphere when the coal is obtained and forms a highly explosive mixture. The coal cannot be undercut easily by machinery as it usually falls and jams the machine, and the quantity of timber and steel required for supporting the roads and the number of men needed for placing it is many times as great as in other collieries. Gob fires are particularly prevalent, or water is present in such large quantities that very heavy pumping-charges are incurred. These and other difficulties make coal getting a very expensive matter, yet the price obtainable for the coal is the same as that for coal which can be mined almost as easily as in an outcrop. Hence the differences in wages proposed by the owners, and the very natural resentment of those miners who are required to accept a heavy reduction as compared with their fellows in the better paying mines.

For twelve weeks the three thousand collieries of Britain have been idle, although it has been through its coal supplies that the industrial prosperity of the country has been largely built up. And how, it may be asked, has a manufacturing nation been able to exist for so long a period without this most essential commodity? How has it been possible to continue its ordinary business, its football and international cricket and golf? How could a record "Derby" on June 1st draw together so vast a concourse of the horse-racing public?

The answer may be given in half a dozen words. Organization, trade, slump, oil and foreign coal, given in that order of importance. The coal stoppage had been threatened for a long time, and as far as it was possible industrial concerns and public utility companies had been building up stocks. The nation had become drilled during the War to put up with almost anything and to do without almost everything, and a mild form of war control, was immediately put into force.

The railway train service was cut down with a most drastic hand, and the tramway services in a similar manner. All late trams and trains were cancelled, and only a meagre service run during the rest of the day. All excursions, cheap fares, special trains and the like were abolished. Outside illuminated signs were stopped, and street lighting drastically curtailed. Coal was strictly rationed and issued out to householders with a most sparing hand, and severe penalties against hoarding were put into force. Bakeries and similar businesses were requested to undertake the cooking of meals for private families, so that fuel should be conserved, and a general appeal was addressed by the Government to the public to save coal, gas, oil and electricity in every possible way.

This action, throughout the length and breadth of the land, had a marked effect on the national coal consumption, and merely inconvenienced, without in any way hurting, the public. Another factor which has greatly helped people to get through the difficult time has been the remarkably dry and warm weather which has lasted practically the whole time, and which has made domestic needs very much less than they generally are in the early springtime.

The second reason for reduced coal consumption is the trade slump, which seems to have affected all countries about equally. The tin mines of Cornwall have been closed for months, and only two or three are pumping, some iron mines are only working three days a fortnight, many engineering and textile works are only running three days a week. All are obviously using far less coal for light and power than usual. The "daylight saving" arrangement also greatly helps in reducing lighting requirements.

Oil has also been a factor in neutralizing the effect of the coal stoppage, the very large number of oil-driven or oil-fired ships having been running as usual, and on land, much of the freight and passenger traffic normally carried by the railways having been diverted to the highways. A certain number of railway locomotives have been converted to use oil-fuel, and help to augment the coal-fired trains, and various power stations, which generate the power for electric railways and tramways have been rapidly fitted up with oil-burning apparatus.

Public and vital services, such as the railways, hospitals, food-preserving industries, and certain other necessary organizations were supplied by the government with imported foreign coal, which is understood to have been received from both America and Europe. No figures are available with regard to the total amount of foreign coal so far imported, although it was stated in Parliament last week that the amount of "reparations" coal received to that date was 94,000 tons.

While these are the means which have enabled the nation to carry on for so long a period, it is not for a moment suggested that the coal stoppage has been anything less than a disaster of the first magnitude. There is no blast furnace working in Britain today, most of the steelworks are closed, and other trades are on short time or are nearing the end of their resources. Industry is now almost at a standstill and unemployment increasing by leaps and bounds.

Nevertheless there is an undercurrent of optimism in the minds of most far-seeing people. It has been felt that something was necessary to bring the nation back to realities from the false position it had drifted into during the War, and the subsequent trade boom of 1920. Some industrial upheaval seemed necessary to carry us back to a firm economic foundation from which it would be possible to compete successfully in the markets of the World. Firms that had written up their capital, have, in some cases, had to write it down again, and unskilled workers or inefficient executives who had risen to lucrative positions through war-luck rather than ability are having to find their level again during this searching time.

Thinking people therefore hope that when the coal stoppage and other industrial differences are settled, it may again be possible to see life and industry from a sane viewpoint, to remember that the burden Adam left us has not yet been removed, that the printing of paper money does not create wealth, and that the test of a nation's industrial capacity is the position it can hold in open competition with the other great manufacturing nations of the World.

MONTREAL METAL QUOTATIONS.

Following are the fair average prices for ingot metals (in less than car-loads) at Montreal:

	June 16	June 22
Copper, Electric	18	17¾
Copper, Casting	17¾	17½
Tin	37	36
Lead	6¾	6½
Zinc	7¼	7¼
Aluminum	31	31
Antimony	7½	7¼

TORONTO METAL QUOTATIONS.

Below are the fair average prices for ingot metals (in less than car-loads) at Toronto:

	June 22
Copper, Electric	17
Copper, Casting	16¾
Tin	39
Lead	7
Zinc	7½
Aluminum	30

(Unchanged from previous week.)

CROW'S NEST PASS COAL COMPANY'S REPORT FOR 1920.

The Crow's Nest Pass Coal Company held its annual meeting at Fernie recently, and the improved standing of the Company may be gnaged from the following comparisons:

	1920.	1919.
Coal Production (tons)	779,942	536,543
Coke "	75,928	63,915
Current assets	$1,303,673	$936,595
Current liabilities	412,987	328,473
Inventories	222,131	240,604
Cash	541,128	281,294

A decrease in inventories and increase in working capital are unusual features in annual reports at this time, and the report should please the shareholders.

W. R. Wilson was re-elected President and General Manager, and several changes were made in the directorate.

Northern Ontario Letter

THE SILVER MINES.

The Cobalt Field.

During the third week of June, 16, 17, and 18, the annual meeting of the Ontario Mining Association was held in Cobalt. More particular mention is made elsewhere in this issue.

Although some of the mines are still closed, yet the silver-mining industry of Cobalt seems to be re-entering another period of prosperity. The four larger mines are producing at full capacity, while a number of smaller mines are also producing at a steady rate. Of the medium-sized mines which still remain closed, it is impossible to tell when they will be re-opened. It is evident, however, that a continued decline in the cost of operation is steadily bringing the date closer when all these mines may again join the producing list.

The Nipissing Mining Company will disburse a dividend of 3 per cent on July 20th to stockholders of record June 30. This will call for the distribution of $90,000. As regards production, an average of close to $150,000 monthly is being maintained. The output in May amounted to $142,036, as compared with $142,610 in April. The new headframe is now in use at shaft 73, replacing that destroyed by fire some weeks ago.

In spite of the curtailment of work at the silver mines during recent months, the figures of the Ontario Bureau of Mines shrow an output of 2,106,045 ounces during the first quarter of 1921, as compared with 2,280,665 ounces during the first quarter of 1920. Ten mines contributed to the output, these being the Nipissing, Mining Corporation, O'Brien, Coniagas, La Rose, Miller Lake O'Brien, McKinley-Darragh, Beaver, Trethewey (Castle) and Bailey. During the quarter, the Beaver closed down and has not re-opened, while the Mining Corporation also closed down early in March, but has resumed production at full capacity and is treating a larger daily tonnage than ever before in its history.

W. R. Sweeny, secretary of the Bailey Silver Mines, was in Cobalt during the past few days and expressed himself as being very optimistic about achievements in the Bailey mine as well as the Company's customs mill. Under the management of G. C. Bateman, expenses at the mill are stated to have been reduced nearly $3,000 monthly.

A break in one of the parts in the mill on the O'Brien Mine caused a loss of nearly a week in milling time and promises to reduce the figures of production as for month of June, but production is now under way at normal rate.

Negotiations are under way between one of the producing companies and the controlling interests of the Silver Leaf Property with the object in view of buying the Silver Leaf. Details are withheld for the time being, but it has been intimated to the Journal that further information might be available within the course of another week or two.

A small force of men are at work on the old Colonial property, which adjoins the O'Brien Mine. Some patches of high-grade ore are being encountered, and the general outlook for the property is said to be favorable. The geological conditions on the Colonial are somwhat similar to the O'Brien, while a number of veins are in evidence in which silver occurs in encouraging quantities. The Colonial control is closely held and the property has lain in idleness for quite a number of years. Last year, a little work was done but the necessary financial arrangements had not been made to keep the enterprise going. It is regarded as being a property of more than ordinary merit.

Work is being speeded up at the Keeley Silver Mines for the purpose of getting milling operations under way some time in July. This will be the first time for a mill to operate in South Lorrain, with the exception of the plant on the old Wettlaufer Mine. This mine, now considered to have been worked out, produced something like 2,000,000 ounces of silver in a comparatively short time and paid $637,465 in dividends.

Elk Lake and Gowganda.

Work in the Gowganda district is not extensive, there being a tendency on the part of claimholders to bide their time pending the outcome of the scheme to build a light railway through the field.

Some road work between Elk Lake and Gowganda has been under way for some time, but Hon. H. Mills, Minister of Mines for Ontario, visited Elk Lake on June 18, and in an interview with the representative of the Journal made the statement that this road work would probably be stopped because the light railway is to be built to Gowganda from Swastika. This may indicate that the Ontario Government has decided to lend financial assistance to the Northern Light Railway Company, which concern recently appealed to the Government for support to the extent of purchasing $3,500 in bonds in the new company for each mile of line built. The proposed line, which is intended to serve Kirkland Lake, Fort Matachewan, Gowganda and West Shining Tree is about 100 miles in length, and assistance from the Government would approximate $350,000, while the Northern Light Railway itself is disposing of an additional bond issue of $1,500,000 for construction and equipment.

The Collins property at Leroy Lake will not be re-opened for some weeks, although it had been reported not long ago that operations would be resumed by early Summer.

Work in Gowganda consists chiefly of the operations on the Miller Lake O'Brien, Trethewey (Castle) and the Saunderson property near Wigwam Lake. A few men are working at Babs Lake, while arrangements are being made to open the Powerful property within the next six weeks.

THE GOLD MINES.

The Porcupine District.

Optimism among the gold miners in Northern Ontario was never so marked as now. This optimism has developed among mine managers who during the past few years have repeatedly cautioned against over estimates of probable achievements. Time has shown the wisdom of this cautious attitude.

Now, however, the economic conditions are improving, and the outlook justifies the optimism of conservative and well-informed mining men.

H. P. De Pencier, general manager of the Dome Mines, and referred to by the company's president J. S. Bache as formerly being almost pessimistic, made the official statement: "I have not been so well pleased as I am now since the discovery of the large ore-bodies in 1914."

A talk with A. F. Brigham of the Hollinger Consolidated is all that is required to convince anyone of the physical status of that mine being the best so

far in its history. The same is true of R. J. Ennis, general manager of the McIntyre-Porcupine.

Indeed, the producing gold mines of Northern Ontario, located at Porcupine and Kirkland Lake, without a single exception have been adding to their proven ore-reserves at a rate which presages achievements far greater than anything in the past history of gold mining in Canada. That is a statement which may be verified time after time by a visit to each of the producing gold mines.

Good headway is reported in connection with the negotiations between the Dome Lake and the West Dome Consolidated. It is intimated in usually well-informed circles that the consolidation of these two properties has every appearance of becoming a reality. It is believed a re-organization will take place in which there will be a substantial amount of stock placed in the treasury for financing work.

The announcement recently made in the Journal that the E. J. Longyear interests were contemplating a drilling campaign in that area lying west of Porcupine and which is covered by an extensive sand-plain has caused a good deal of interest in the Porcupine district. These interests are known to have discovered many millions of dollars worth of nickel by carrying on a similar exploration effort at Sudbury and have also been responsible for development of coal-mining at Longyear City in Spitzbergen.

Owing to difficulties said to have developed in connection with the failure of the Thompson-Krist interests to meet their obligations in connection with financing the Northerown Mines, the operations of that property have been temporarily suspended. In the meantime, the underground workings are being kept de-watered.

Details pertaining to the Allied Porcupine Gold Mines, Ltd., which was incorporated a few months ago for the purpose of taking over a number of properties in the eastern part of the township of Whitney in the Porcupine district, have been secured, the salient features of which are these:

The company is incorporated under the laws of Ontario, having an authorized capital of $5,000,000 made up of 5,000,000 shares of the par value of $1 each, and of which 2,500,000 shares are in the treasury.

The following properties have been acquired by the new company:—

A group of eight mining claims comprising 309 acres which formerly belonged to the Three Nations Gold Mining Company, Ltd.

Also a group of four claims comprising about 160 acres which formerly belonged to La Palme Porcupine Mines, Ltd.

Also two claims comprising 80 acres which were formerly known as the North Whitney Gold Mines as well as the Cavana Veteran claim comprising 160 acres, thereby giving the company control of a total of approximately 720 acres all situated in one block.

In addition to the exchange of shares in the Allied Porcupine for the issued stock of the former companies, the Allied Porcupine is taking over the mining plant and mill which was erected some years ago on the Three Nations property. The mill has a battery of ten stamps and is estimated to be able to treat about 40 tons of ore daily, and for this mill and the mining plant, the Allied Porcupine is paying $75,000.

The management contemplates testing the property by much underground cross-cutting, and will diamond drill the whole vein-system to a depth of a thousand feet.

"Improvements will be made in the 10-stamp mill, by the addition of concentrators and cyaniding plant, to bring the mill up to a daily capacity of 40 tons daily. The mill will be used for testing ore from development work."

The officers of the amalgamation are as follows: Col. W. A. McConnell, president; Rufus S. Hudson, vice-president and treasurer; A. J. Young, secretary; P. Kirkegaard, consulting engineer. W. D. Robb, vice-president of the Grand Trunk Railway, is a director of the new company.

Kirkland Lake Field.

Lateral work is proceeding along the new ore-body recently found at the 900 ft. level of the Kirkland Lake Gold Mines. The gold content of the ore across a width of about seven feet has so far been found to average a little over $20 to the ton.

Milling operations in the new plant on the Wright-Hargreaves mine have been exceedingly satisfactory. The mill is treating about 140 tons of ore daily and it is evident that the grade of the ore will not be far below the high average established on the Lake Shore.

Further new gold finds have been reported during the past week. One such report comes from the township of Rattray, south of Larder Lake, and a considerable amount of claim-staking is being done. A new find of tellurides of gold is reported on claims at Sesekinika which belong to the Lightning River Gold Mines.

TEMISKAMING PROSPECTORS WANT MINING ACT AMENDMENTS.

The special general meeting held in the Court House at Haileybury, June 15, under the auspices of the Temiskaming Prospectors' Association was well attended. The meeting had for its object the presentation of the views of the prospectors on questions having a vital bearing on their profession. There were several who spoke in the interests of the prospectors, at the conclusion of which Hon. H. Mills, Minister of Mines replied in a general way to the majority of the suggestions put forward. The "Journal" covered the meeting by special representative.

J. Hill, president of the Association dealt briefly with the work of the Department during the past year and expressed approval particularly of the reduction in the amount of assessment work required to be performed on mining claims, as well as giving his approval to the holding of Prospectors' classes in the mining districts.

Mayor N. J. McAuley extended a welcome to the Minister of Mines, and pointed to the large gathering of prospectors as evidence of a general desire to encourage the Minister to co-operate with the prospecting fraternity which was so essential to the mining industry and the general welfare of Northern Ontario.

The Discovery Clause.

Peter Graham, speaking as a prospector on behalf of the Association in connection with the Mining Act and the necessity of making a valuable discovery of mineral in place, stated that: "The discovery clause is regarded by most prospectors as a farce." Mr. Graham stated that there are very few mines in Northern Ontario the staking of which was based upon such a discovery. In Kirkland Lake, he said there was only one

such mine. He cited a case of where one prospector makes a promising discovery on the edge of a swamp or sand plain. There may be no way of determining whether or not the vein runs beneath the swamp or sand, although it probably does. The prospector "takes the bull by the horns, stakes out a claim and proceeds to take a false affidavit," that he has discovered valuable mineral in place. He suggested that the discovery clause should be struck out and application should be required "for mining land only."

The views of Mr. Graham were supported by remarks from Mr. Pinelle, who stated that the existence of the discovery clause and the lack of its enforcement made the law unstable.

Timber Ownership on Claims.

Mr. McLeod spoke for the Association on the question of denying the prospector the right to the timber upon mining claims. He believed the prospector, after patenting his claim, should become the owner of the timber. He emphasized the point that the prospector would thereby take an interest in protecting the country from disastrous forest fires. As matters now stand, it is not in the interests of prospectors to protect the timber.

Assessment Work.

Mr. L. Howey, spoke for the Association in connection with assessment work on mining claims. He suggested that work performed by prospectors between the date of staking out a claim and the date of recording such claim should be extended from 15 to 30 days, as this would relieve the prospector from the necessity of coming out to record a claim and then return again to do the assessment work. Nothing was said as to the present unsatisfactory and jumbled form of the Act which permits prospectors to hold a mining claim for two years by the performance of only 30 days' assessment work.

Passenger and Freight Rates.

Mr. M. B. Grover advanced an excellent plea for a greater degree of cooperation on the part of the railways toward the prospectors of Northern Ontario. He asked the Minister to use his influence to secure a more reasonable rate in connection with the shipment of small lots of dynamite and also asked for special passenger rates for the prospectors. He stated that the mining industry made the T. & N. O. Railway and that it is up to the T. & N. O. to help the prospector.

Roads and Trails.

Thos. Montgomery dealt with the question of roads and trails and stated that although he had packed over nearly every trail in the North, yet in no case had he travelled over one which had been cut by the Government. The prospectors, he said, are obliged to cut their own trails and the mining law gives no credit for it in computing the amount of assessment work required to be done. He cited the case of Lebel township where the Government is having a road stumped and urged "more speed" in connection with the work. It was pointed out that fire rangers do little or nothing in the way of opening trails.

Mr. Paul, speaking for the prospectors, asked that in cases of where more than one abstract may be required that the Recorders should provide the original for the usual fee of 25 cents each, but that duplicate copies should be provided for 10 cents each. He also urged the Ontario Government to be more aggressive in connection with advertising the mining industry in the province abroad.

Professional Engineers' Bill.

Mr. Stevenson, for the Association, made a pointed attack upon the proposed Engineers' Bill. "We, as prospectors, strongly object to this Bill which dictates who or whom we shall employ to work our property. We believe it is presumptuous on the part of the Government to legislate in such a manner as to cause us to either stop work or employ a "walking certificate"." Mr. Stevenson pointed out that the prospectors were not in any way opposed to the activities and good work of engineers, and expressed the opinion that the real engineer who has practical experience as well as technical knowledge is in very great demand and able to command his own price without the protection of a bill which would tend to protect the incompetents.

Proposed Light-Railway.

Mr. Pinelle dealt with the question of the proposed light railway which is to run east and west from Swastika. The Government, he said, has been asked to contribute $3,500 for each mile constructed, but although favorably disposed to do so, is holding the final decision in abeyance. He urged speedy action.

Replies from the Minister of Mines.

Hon. Mr. Mills replied to the suggestions pretty much in the order of their presentation. He stated that late this Fall, probably about Nov. 15, the holding of prospectors classes would be resumed, and the field would be extended.

About the "discovery clause", the Minister declared that such a clause is necessary in cases where title is given to the holder. The matter of eliminating the discovery clause had been considered at the last session, but a decision was reached to leave the matter in abeyance pending its further consideration. He stated: "I am rather sympathetically inclined to remove the discovery clause," said the Minister, and it was also intimated that the question was under consideration of finding a way to assure continual work on claims rather than let them fall into a state of idleness after patent was under consideration. "I don't believe work should stop when a man digs a hole and then sits down." He intimated some method of continuous work should be decided upon.

In regard to trails, Hon. Mr. Mills stated that in the recent reduction in the amount of assessment work on mining claims, it is made easier for the prospector to find time to cut trails to his claims. The Minister also stated that last year the sum of $10,000 had been placed in the estimates to cover this requirement, but that not a dollar had been asked for. This year, he said, the estimate was reduced to $5,000. He believed that in mentioning this, a hint would be sufficient to the wise.

About the question of timber, the Minister blamed the abuse of the privileges formerly bestowed as the reason for the present stringent regulations. He stated, however that he believes the present law is too hard on the prospector, and that claimholders should be allowed to use timber required for buildings and for mining purposes.

The Minister stated that the suggestion concerning assessment work as presented in a resolution by the Association could be adjusted satisfactorily

In the matter of passenger and freight rates, the matter is one which rests with the T. & N. O. Railway Commission and the Railway Board. Mr. Mills told the prospectors but that he would do what he could to have their case considered.

Mr. Mills stated that arrangements would be made

to provide duplicate abstracts for 10 cents each where more than one were required.

As regards advertising, the Government had spent $1,000 recently in advertising in England, and had sent some of its richest speciments to the Old Country for exhibition purposes. The Minister did not appear to be very enthusiastic about this question of advertising abroad.

In connection with the Engineers' Bill, Hon. Mr. Mills stated that it had been only referred to a special committee, and that no one need entertain any fear that it would pass in its present form.

At the conclusion of the Minister's statements, Mr. W. E. Simpson suggested that if a scheme of continual work on claims were to be considered, some scheme for the claimholders to turn this work to more profitable account should be considered and that the Government should be prepared to consider the question of erecting small custom plants where the prospector could have ore treated and in that way produce at least a moderate amount of new wealth for the country as well as having a means of getting something in return for his energies rather than the mere routine of performing assessment work. In this way he believed the Government could help the prospectors to become owners of mines rather than devoting their time in searching for a possible buyer at the purchasers' own terms.

British Columbia Letter

Alice Arm B.C.: The Dolly Varden Mine still is idle although Major North, the manager for the Taylor Mining Co., is busy on a general survey of the property, as well as of the Wolf Claims, with a view to the opening of development work at an early date—The McPhee, "Mother-in-Law," "Black Diamond," Toric, and the Independent properties are receiving attention, in most cases the owners taking advantage of the season's opening to start assessment work. On the Independent a tunnel is being driven.

Trail B.C.: Ore receipts at the Consolidated Mining Smelting Co's plant, Trail B.C., for the week ending 29th May totalled 7918 tons. For the following week, the first in June, there were received 7,137 tons. The aggregate now is over 180,000 tons for the year and it would seem that the 200,000 tons mark will be exceeded by the end of the half years. In addition to company properties the Paradise Mine, Windermere District, and the Knob Hill, a Washington State Mine, appeared on the list of shippers for the first week of this month.

Nelson B.C.: Ore taken from the Gold Reef Mining Company's property, Lemon Creek, is being subjected to a mill test in Vancouver which, if necessary, will to a mill test in Vancouver which, if satisfactory, will ore is practically all free milling. Harold Lakes, superintendent of the Nugget Gold Mines Ltd., Sheep Creek, states that 100 tons a day now is being put through the mill with 97 per cent recoveries. Lack of experienced miners, he says, makes it impossible for the stoping to keep pace with the mill requirements, so that it is necessary to draw to some extent on the 4,000-ton reserve. There are 35 men employed underground and at least 15 more exeprienced miners are needed. No trouble is met with in finding muckers but the classof skilled labor desired is not easy to find. The mill has been tuned up since it began running on April 29 and is giving every satisfaction. More bunkhouse accommodation has been provided and working conditions in the mine have been improved. Stoping is being done on the main vein which was struck at a depth of 650 feet last year by a long cross cut from the Motherlode. For a length of about 180 feet, with both ends of the stope in ore, the ore-shoot has been stoped out for a height of some 200 feet according to Mr. Lakes. Fourteen drills are being operated in this section of the mine and four in the Motherlode.

Duncan, B.C.: The manganese deposits of Hill 60, Cowichan District, Vancouver Island, were inspected recently by George C. Mackenzie, formerly of the Canadian Geological Survey and now general secretary of the Canadian Institute of Mining & Metallurgy. It is likely that, as a result, the property will the thoroughly prospected by means of diamond drill. George C. Aylard, of the Standard Silver-Lead Mining Company, who now is in control of the manganese property, is expected to provide the financial backing necessary to make the proposed exploration as complete as possible.

Merritt B.C.: What is said to be a new mineral has been found in the district adjacent to Merritt by William McNeill and, as a compliment to Mr. Charles Camsell, deputy Minister of Mines for the Dominion, and who has done much for the western country in geological research, has been named Camsellite. The Canadian Mineralogical Department writes Mr. McNeill that a paper describing the occurrence of a boron mineral from a serpentine mass near Douglas Lake has been presented to Section IV of the Royal Society of Canada. The new mineral is said to take the form of fine fibres being distingnishable with diffienlty from the chrysotile with which it often is very intimately mixed. In addition to the camsellite and the chrysotile in the specimen examined there is more or less dolomite. The three minerals do not occur in the same proportion throughout the material; in fact there are wide variations in this respect. It was not found practicable to separate the camsellite in an ideally pure state, but three analysis were obtained—one of the camsellite mixed with small quantities of chrysolite and dolomite, one of the pure chrysolite and one of the pure dolomite—from which the normal composition of tthe new mineral was calculated as follows:

Magnesia	47.87
Boron trioxide	41.44
Water	10.69
	100.00

It is further stated that the possibility of a commercial use being found for this mineral would be kept in mind and the discoverer informed of any developments.

Cranbrook B.C.: Sluicing has been commenced by the Gamble Mining Co. on Wild Horse Creek, Cranbrook District. The first clean-up of the season is reported to have been satisfactory. From one sluice box only, gold values aggregating $800 were taken and the management is optimistic over the prospects. Water has been diverted from Boulder and Fisher Fisher Creeks and the force is strong enough to move most of the boulders encountered although in a few instances it is necessary to use powder.

Vancouver B.C.: Reports of the annual meeting of the Granby Consolidated Mining, Smelting & Power Co. indicate that all the old directors were re-elected with the exception of the replacement of S. H. Steel, deceased, by J. T. Cabbe. The annual report is expected to be issued in about ten days. Meanwhile it is stated that the 1920 operations will show a deficit. At present it costs the company slightly over 12 cents a pound to produce copper. During the past few months economies had been effected reducing costs to 14 cents Canadian or 12.4 American currency, said to be four cents a pound better than during the six-month period prior to the changes. Reserves of high-grade copper were reduced 200,000 tons, being reported December 31 as 10,986, 420 tons. Copper production in 1920 amounted to 27,000,000 pounds of blister copper of which 25,000,000 had been refined. Unsold copper at the end of the year came to approximately 20,000,000 pounds of which 3,000,000 pounds represented metal in process. Sales of copper for the year totalled 19,464,000 pounds. Decrease in the ore reserves was due to the confining of running operations entirely to ore production during the present period of relatively high costs. As soon as the 150-foot level at the Hidden Creek Mines had been opened sufficiently, permitting development without interference with ore production, prospecting to extend the ore boundaries will be resumed. Labor conditions are described as good.

Victoria B.C.: The Standard Silver-Lead Mining Co. is reported to have sold its mines at Silverton for $75,000, subject to the ratification of the deal by the shareholders. A meeting for this purpose is to be held on June 20 and as shares are controlled by the directors there is no doubt of the result if there is no change of the situation in the interval. The Standard has yielded to its shareholders some $2,700,000 in dividends, having been one of the big producers of the Slocan District.

Edmonton, Alberta: Gold is reported to have been discovered on Cadotte river, about 70 miles northeast of Peace River town. News of a rich find spread through the district on wings and when the original locator woke one morning he found many gold seekers on the ground. There is doubt as to the importance of the camp but those first on the scene are satisfied. One of the latter explains that "I secured several pans of gravel and in each one I washed a tail flower of gold about three inches long and about the width of my little finger and, I should judge, containing about 300 colors."

From the Pas, Manitoba, comes a report that a rich gold strike has been made at Elbow Lake in the Athapapuskow mining area and east of the Gordon dyke discovered last summer. Some of those who have returned give details of a vein sixty feet wide containing free gold plainly visible to the naked eye.

Two prospectors, Dick Inkster and T. E. Hankin, have returned from the Liard River District, northern British Columbia, where they were engaged in a search for oil. They have brought back samples, which are attracting much interest. Mr. Hankin tells of his, and his companion's experiences, entertainingly. He says:

"The place where we got our samples is at the foot of a river. There is a ridge of sandstone along the river which the Indians told us had been burning for years. There is plenty of evidence that this ridge of rock had been subjected to great heat, as it is baked red, but the fire has died out. A heavy slide of clay and gravel occurred behind this burning rock, which apparently interfered with the fuel supply that kept the fire going in the rocks and it went out. It is now burning behind this ridge in the clay and gravel, but in a much less degree. There is also a very strong smell of gas at this place, and when the air is still, the whole atmosphere is impregnated with it for some distance around, in fact it made us sick when we stayed in it too long. We took samples from different spots for a distance of about half a mile. No doubt if we were there in the Summer time we would have had a better opportunity to get samples. As it was, we had to get them where the snow was off."

"On our return trip we came across a white man who lives in that far-northern wilderness with his young daughter. They were on their way up to the Hudson's Bay post for supplies and expected to return by canoe when the river opened. The man informed us that if he had known that any one was in the country he would have brought samples of oil from his place, 30 miles farther down the river. He said that oil could be seen floating on the surface of the water during the Summer, and that gas bubbles were continually forming on the water. There are also hot springs there, and he grows potatoes and other vegetables with great success."

"We also came across some Indians, or rather they came across us. They saw our tracks and followed us, telling us later that they knew our tracks were not made by Indians. They stayed with us, and more turned up later, till we had a regular caravan of dog teams with many bells and gaily-decorated harness, and sleighs in all colors of the rainbow. They carried very little camp equipment and very scanty rations of dried moose-meat. They put up with all the discomforts attendant upon such a life with a cheerfulness that was surprising. We found them very friendly and anxious to assist us in any way they could. We had to hold school every night, as they were very anxious to learn how to read and write."

One day the Indians happened to overhear me singing. (I was singing a little song that I had learned in the trenches in France). One of them asked me what kind of song it was. I told him it was a soldier's song. After that, nothing would do, but I must sing 'soldier's sing.' I put them off till we got back to Liard post, when the whole tribe descended on us and begged me to sing 'soldier song.' My fame had evidently spread among them, so there was nothing to do but start in, which I did, after apologizing for the racket I was about to start. The natives evidently seemed delighted with my performance, as I was applauded and encored at every turn. No grand-opera star ever had such an appreciative audience as I had in that tightly-packed log-hut in the lonely northern wilds. I sang them anything that happened to come into my mind, from 'My Home in Tennessee' to 'Rule Britannia'."

"The tea drinking tendencies of the Indians are enormous, drinking it as they do, at any time they can get it. They made sad inroads into our sugar-sack and tea supply. However we were able to get more at the post, where there is a large stock of everything necessary for the grub-box on such a trip. The prices are necessarily high at such a place, and, plus the high cost of living, comes rather high. Sugar is 50 cents per pound, flour three pounds for a dollar."

"We met with courtesy and kindness from all those with whom we came in contact on our journey. We averaged about 30 miles a day with our dog-team. It was one of the best dog-teams I have ever owned, and I have had many."

"The country is comparatively flat after passing down the Dease River, and mountains can only be seen in the far distance. Game is plentiful and we had no trouble in keeping ourselves supplied with moose meat, but there is such a thing as knowing how, and it takes a lifetime to learn about the wilds and how to get the best of it."

"I must mention that in getting our samples, we could not help getting clay and other foreign matter mixed with it. When I washed the shovel that I had been digging with, the surface of the water became immediately covered with an oily substance resembling the colors of the rainbow. In places the gravel appears to be soaked with oil, but not enough to get it up without taking up the dirt as well."

"The colors and consisteney of the oil varies at different spots, some being thin and light-colored, and in other places dark and heavy, that is very thick from a greenish-black to a dark-brown. It seeps out along the foot of the bank at short distances apart as far as we could see where the snow is off. The rock formation is of a shaley character, from a gray to a blue-gray color."

"We did not prospect for gold, and there were many places I should have liked to try, but our time and supplies were limited, and it was hardly the season for that kind of work, as everything was still frozen up, but with proper exploration there is no doubt that this great Northland will yet reveal wealth that will be a surprise to the world. It is not too difficult of access, there being a down-stream water-way from Dease Lake into the very heart of the Liard country with a few short portages. Dease Lake is reached from Telegraph Creek by a first-class four-foot trail, and Telegraph Creek is reached by river gas-boat from Wrangell, Alaska. The distance from Telegraph Creek to Dease Lake is 72 miles."

Coal production in British Columbia for the month of May shows a decline in comparison with that of April of 17,599 tons, the totals being: April, 209,152; May, 191,553. Whether the cause of this evident slackening of trade is the easing of the situation as to fuel-oil supplies and the consequent reversion of users to the foreign liquid-fuel or whether it is to be found in the natural falling off in demand with the advent of the Summer are questions difficult to answer. Likely the true explanation lies in about equal proportions between the two circumstances. Fuel oil certainly is more plentiful and cheaper and more of it is being consumed. That every gallon imported displaces home-produced coal is an incontrovertible fact.

On Vancouver Island the two large collieries, Canadian Western Fuel Co. and Canadian Collilieries (D) Ltd., produced in May a total of 103,548 tons. It is significant that the Western Fuel Co.'s output for May, 37,398 tons, was 2,385 tons less than that for April. As this Company's trade is in the domestic market to a very large extent it is clear that this business is not as brisk. On the other hand the Canadian Collieries made a small increase of 556 tons in May over April. As 90 per cent of its trade is found in supplying mercantile traffic and in other sources outside the purely British Columbia requirements it would appear that the outside requirements have not declined in any marked degree.

The Granby Collieries, Cassidy, Vancouver Island, which were placed under new management on the 1st of June, fell off in production in May some 2,223 tons in comparison with the April total.

In the Nicola-Princeton Field, the Middlesboro and Fleming Collieries show an improvement of 421 and 565 tons respectively, while the Coalmont Collieries, where new plant is being installed and over work of a development character is under way, produced about 4,783 tons less than during the previous month.

The Crow's Nest Pass Coal Company at Coal Creek produced 5,289 tons less in May than in April; at Michel the decline amounted to 3,744 tons, while the Corbin Coal & Coke Company's output fell 782 tons. The explanation, no doubt, lies in the fact that unusually mild weather has been experienced on the prairies. It is likely that these collieries will be put under a serious handicap during the next few months if the recent 10 per cent reduction in freight rates, extended by the Railway Board to the prairie provinces, is not extended to include them.

Following are the details of the coal production in British Columbia for the month of May:

Output of Coal for May, 1921.

Mine	Tons	
Vancouver Island District.		
Canadian Western Fuel Co., Nanaimo	37,398	
Canadian Collieries (D) Ltd.,		
Comox	41,210	
South Wellington	7,812	
Extension	17,138	
Nanoose Wellington Collieries	2,852	
Granby Consolidated MS & P Co.,		
Cassidy	24,361	
Old Wellington, (King & Foster)	435	
Total	131,196	131,196
Nicola-Princeton District.		
Middlesboro Collieries, Middlesboro	5,554	
Fleming Coal Co., Merritt	3,072	
Coalmont Collieries, Coalmont	1,485	
Total	10,111	10,111
Crow's Nest Pass District.		
Crow's Nest Pass Co.,		
Coal Creek	27,690	
Michel	17,074	
Corbin Coal & Coke Co., Corbin	5,482	
Total	50,246	50,246
		191,553

TORONTO COAL PRICES.

Toronto, June 22.—The prices of anthracite coal remain absolutely unchanged since last week. In the slack market the prices range from $1.00 to $1.75, depending on grade. Mine run is $1.75 to $2.70 and lump coal $2.35 to $3.25. The difference in price, between the range named, depends on quality. Business is about the same—at least, there is no sign of improvement. Bituminous production has decreased, approximately, 1,000,000 tons in a week. This decrease faithfully reflects business conditions. Of course, so far as the coal dealers are concerned, less production now will mean larger profits for them later on.

BRITISH COLUMBIA

The Mineral Province of Western Canada

Has produced Minerals valued as follows: Placer Gold, $75,944,203; Lode Gold, $102,753,823; Silver, $53,668,284; Lead, $46,637,221; Copper, $161,513,864; Zinc, $19,896,466; Coal and Coke, $212,573,492; Building Stone, Brick, Cement, etc., $32,168,217; Miscellaneous Minerals, $1,037,408; , making its mineral production to the end of 1919 show an

Aggregate Value of $706,192,978

The substantial progress of the Mining Industry of this Province is strikingly exhibited in the following figures, which show the value of production for successive five-year periods : For all years to 1895, inclusive, $94,547,241; for five years, 1896-1900, $57,605,967; for five years, 1901-1905, $96,509,968; for five years, 1906-1910, $125,534,474; for five years, 1911-1915, $142,072,603; for the year 1916, $42,290,462; for the year 1917, $37,010,392; for the year 1918, $41,782,474; for the year 1919, $33,296,313; 1920, $35,543,084.

Production During last ten years, $331,995,328

Lode-mining has only been in progress for about twenty-five years, and not 20 per cent. of the Province has been even prospected ; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those of any other Province in the Dominion, or any Colony in the British Empire.

Mineral locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with Mining Reports and Maps, may be obtained gratis by addressing

THE HON. THE MINISTER OF MINES
VICTORIA. British Columbia

PROVINCE OF QUEBEC

MINES BRANCH

Department of Colonization, Mines and Fisheries

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, etc.

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

MINERS' CERTIFICATES. First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is $10.00, and it is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

WORKING CONDITIONS. During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

SIX MONTHS AFTER STAKING. At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

MINING LICENSE. The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year, and a fee of $10.00 on issue. It is valid for one year and is renewable on the same terms on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days labour on each forty acres.

MINING CONCESSION. Notwithstanding the above, a mining concession may be acquired at any time at the rate of $5 an acre for SUPERIOR METALS, and $3 an acre for INFERIOR MINERALS

The attention of prospectors is specially called to the territory in the North-Western part of the Province of Quebec, north of the height of land, where important mineralized beltsare known to exist.

PROVINCIAL LABORATORY. Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, MONTREAL, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The Bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

HONOURABLE J. E. PERRAULT,
MINISTER OF COLONIZATION, MINES AND FISHERIES, QUEBEC.

EDITORIAL

AN OIL PROSPECTUS FROM THE PAS, MAN.

The Manitoba "Free Press' publishes the prospectus of the Pas Oil Development & Exploration Co., Ltd. The Company is incorporated under the Manitoba Companies Act, and the directorate contains the names of leading citizens of the Pas. The Company is incorporated for the purpose of testing a property for the presence of oil. The land to be prospected is near the village of Turnbury, Man., about thirty-three miles south from The Pas, near the Manitoba-Saskatchewan boundary, in the Pasquia Hills district. The property is presumably worth testing, but specific reference to this district in regard to oil possibilities in the Geological Survey reports is confined to mention of the oil-shales in Mr. McInnes's report on the basins of the Nelson and Churchill rivers. (See C.G.S. Memoir No. 30). Under the conditions the presence of fluid oil would seem to be a possibility only. The enterprise of the citizens of The Pas is to be commended, but the advertising literature of the Company contains inaccurate statements, and has some of the ear-marks of the worst kind of oil "puff." For example, under date of 18th June, the advertisement states the price of mid-Continent crude oil as being $3.50 per barrel, with additional 50 cents as a premium, and "is going much higher." The price, as given in the Boston News Bureau of the 22nd June, is actually $1.00 per barrel, and is expected to go lower. The quality of the appeal of the advertisement may be gauged by the statement that Victory Bonds "are taken at face value," and there is the usual list of oil projects showing how one hundred dollars made many thousands. Given certain suppositious happenings, it is also stated: "One share of this stock, then, would be worth $600 per share on a ten percent basis." Under the heading of "Facts" we are told "It is an established fact that more so-called investors, men and women who were able to invest only in amounts of from fifty to one thousand dollars made fortunes in oil during the past year than were ever before recorded." Names of the fortune-makers, their residences, investment and extent of the "fortune" made would be more convincing.

It is not good to see the names of members of parliament, physicians and Board of Trade members, heading a prospectus that contains such nauseating stuff, and it is far from encouraging that the initial prospecting in this newly-opened territory should have to be financed by money obtained through the creation of hopes of a nature unlikely to be fulfilled. Even if oil were to be obtained in very profitable quantities, the ultimate success of an enterprise will not justify reputable men in descending to the level of the thoroughly unscrupulous promoter by copying his style of "approach."

NATURAL GAS SUPPLY IN KENT FIELD, ONT.

The report of Samuel S. Wyer to the Minister of Mines of Ontario on the natural gas situation in the Kent Field of Western Ontario is a candid hard-hitting document, and is so simply written and so free from technicalities as evidently to have been prepared by a man who knows his subject. The supply of natural gas is declining at a rate which promises to reduce the rock pressure from its present figure of about 250 pounds to less than 50 pounds in fifteen years time. The pressure was 570 pounds in 1910. Under such conditions, the "criminal waste" in distribution of gas which Mr. Wyer reports as the result of percentage contracts and a leaky system, warrant him in stating that those who "recklessly, defiantly, persistently and continuously waste natural gas, and boldly declare their purpose to continue to do so, ought not to complain of being branded as enemies of mankind." There is apparently no system of metering the natural gas. Percentage contracts "actually stimulate a wanton waste of a limited natural resource." Distribution pressures are too high, a very aggravated condition with a leaky pipe and valve system, and the average domestic consumer is stated to "waste much more gas than he consumes."

Evidently it was high time some one examined into this natural-gas situation and told the truth, and the duty of the Ontario Government has been very plainly put before them. Every citizen of Ontario who desires to see a failing natural resource, of very great value, conserved as it is possible to conserve it, and made to last for a generation longer than it will otherwise last, should stand behind whatever legislation the Govern-

ment of Ontario enforces with this end in view. Mr. Wyer very properly remarks that contracts which encourage waste of natural gas are against public policy and should be abrogated, and that the community interest is paramount. Conservation of natural gas in Ontario, and its preservation for the use of domestic consumers, is only possible by raising the price to consumers. There is no choice in the matter. It is a case of continuing to use gas wastefully by perpetuation of existing contracts, and exhausting the supply in five years; or of paying the price for conservation methods that will prolong the gas supply maybe for twenty-five years.

THE ELBOW LAKE GOLD DISCOVERY.

In view of the very wide publicity given to the spectacular gold discovery at Elbow Lake, Manitoba, the Editor is obliged to Mr. J. P. Gordon of the Pas for the note of observations made on the ground which is elsewhere included in this issue. Mr. Gordon was himself the fortunate discoverer of a very rich local concentration of virgin gold at Copper Lake Manitoba,* and his knowledge of the mineral belt of Northern Manitoba is unexcelled. It is a country of alluring possibilities, and one that has already been proven to contain large mineral deposits of substantial value. When this season's prospecting closes the Commissioner should be able to publish another chapter in the series of mineral revelations that Northern Manitoba has so far yielded in a brief span of years.

*Note.—"The Gold Discovery at Copper Lake." R. C. Wallace, see page 731, C. M. Journal, 1st Oct., 1919.

THE SPECTACULAR GOLD FIND AT ELBOW LAKE, MAN

By J. P. GORDON, The Pas, Man.

Considering the publicity given to the spectacular gold find at Elbow lake, by the daily papers the following observations made on the ground may be of interest..

Location.

The Murray gold discovery is located at the outlet of Elbow lake about one mile south of the extreme end of the peninsula that separates the inlet from the outlet of the lake.

Spectacular Showing.

About 200 feet north of the No. 2 post and covered by 2 feet of water a spectacular showing of gold can be seen. Here the porphry sheets are separated or parted about one inch in width and this space is filled with virgin gold for that width and a length of one foot.

Other Showings.

Three hundred feet north-east of the spectacular showing of gold the prospectors have cross-channelled the dykes and at different points from the Elbow lake or north-west side of the dyke some free gold can be seen in quartz stringers over a width of 60 feet. These stringers are about 10 feet apart and vary in width up to an extreme width of 4 inches.

Formation.

The gold occurs in quartz stringers in a quartz-porphry dyke which is genetically connected with the granite. On the south-east side the porphry is in contact with the granite, that is on the discovery claim. The prospectors were of the opinion that a basic rock of the district was of a more recent occurrence than the porphry and referred to it as having "pressed over the dyke" in places. This impression is readily proven erroneous by examination of the formation on a small island to the north-east of the Murray claims, where the porphry dyke intrudes the basic rock for the entire length of the island.

Probabilities of the Prospect Developing into a Mine.

In my opinion the problem to be solved is: Are there a sufficient number of these enriched quartz stringers throughout the massive porphry or any part of it that will give a working width of commercial ore and I think this can be best determined by fairly deep trenching across the lode. The porphry is well mineralized in places with iron pyrites and may carry low gold-values that would help up the average per ton assay. Unless the porphry does carry values the usual sampling would not give satisfactory results not be a fair test to the prospect.

Island Lake Float.

It has been claimed that the spectacular float found by Ottawa and Woosey on Island lake was float from Murray find, but anyone that has seen the Island lake float and has examined the Murray claim can readily disclaim this supposition, as the float ore showed spectacular gold in a dull-grey quartz and chlorite schist, while the gold in the latter occurs in a more crystalline glassy quartz. The lode or vein from which the Island lake float was detached by some force of nature is yet a hidden treasure to be discovered by the prospector.

THE KENT NATURAL-GAS FIELD OF ONTARIO.

A report made to the Minister of Mines of Ontario, under date of 31st May, 1921, by Samuel S. Wyer of Columbus, Ohio, upon the natural-gas situation in the Kent Field of Western Ontario, submits the following recommendations:

1—Since 1910, average rock pressure has declined from 570 to 256 pounds.

2—There is no justification whatever for making open flow volume test of wells, because of needless gas waste.

3—The transmission and distribution leakage is excessive and should be curtailed.

4—The percentage contracts for sale of gas are against public policy, and should be abrogated at once.

5—Meters should be installed to measure gas into and out of all transmission lines.

6—Domestic consumers waste enormous quantities of gas through improper appliances.

7—All gas using appliances should be inspected at once by gas companies.

8—The use of wasteful appliances should be prohibited.

9—All extensions to merely maintain service should be paid for out of operating expense and not capitalized.

10—A just retail price can be fixed only by paying an adequate return on the present fair value of natural gas properties.

11—The immediate carrying out of these recommendations is imperative in order to cope with the cold weather conditions of next winter.

Memorandum on Howry Creek Gold Arsenic Area

A Report To The Ontario Department Of Mines.

By JOS. BARTLETT, Mining Inspector, Sudbury, Ont.

There are three groups of claims in the Howry Creek area on which work was in progress on April 21, 1921, when inspection was made; these are the Bousquet, the Howry Creek, and the Craig-Pollard claims. The Bousquet and Howry Creek are six and a half or seven miles east of Willisville station (revised railway mileage 65.6 miles from Sudbury) on the Algoma Eastern railway. In summer the trip to these two properties is made by a good water route, consisting of Charlton lake and Howry creek; in the winter the ice is used to the east end of Charlton lake, from which point a road has been built to the working properties. The Craig-Pollard claims are near West River station, which is at railway mileage 63.4, and are some eight and a half miles west of the claims mentioned on Howry creek proper.

The predominant rock in the area is a quartzite or arkose series; with this quartzite is associated some greywacke and conglomerate. There is also a diorite, which was seen on both the Bousquet and Howry Creek properties and along the railway between Willisville and west River.

Bousquet Gold Mines, Limited.

This company has an authorized capitalization of $2,000,000, and the shares are of $1.00 par value. Its head office is at 6 King Street West, Toronto, and the officers are: president Harold Tough, Willisville, Ontario; vice-president, Robert R. Tough, Willisville, Ontario; secretary-treasurer, Wm. B. McPherson, Toronto; directors: Thomas Baird Tough, Niagara Falls, Ontario; James A. Bousquet, Willisville, Ontario.

The holdings of this company consist of ten mining claims S. 2272, S. 2277, S. 2481, S. 3180, S. 3181, S. 3182, S. 4382, S. 4599, S. 4600, and S. 4601, in Timber Berth No. 11, in the Sudbury Mining Division.

Gold occurs on claims S. 3180 and S. 3181 in a belt of gray schist, striking approximately east and west and containing some pebbles. The rock looks like a schistose greywacke. Mr. C. W. Knight, on examining a specimen of the schist under the microscope, found it exceedingly fine-grained and composed of micaceous minerals and quartz grains; in this fine-grained matrix are quartz grains of larger size. The width of this band of schist was not ascertained, but at one point it is exposed for a horizontal width of 24 feet with no contacts visible. A slope sunk in this schist is said to be 44 feet deep, but, as it was nearly full of water, only the upper portion could be examined; this showed the schist to contain very narrow veins of quartz and ankerite and to have a dip at the surface of 55 degrees to the north. A 2-compartment vertical shaft, measuring 6 feet by 10 feet outside, is now being sunk, and on the day inspection was made had reached a depth of 20 feet.

Clean and comfortable buildings, consisting of a sleeping camp, a cook house and an office, have been completed on the claims; these are of lumber covered with "paroid." Near the shaft and incline, which are not far apart, is a combined power-house and blacksmith shop; this building contains a locomotive-type boiler, an Ingersoll-Sergeant-Cooper compressor, and an 8 by 10-inch James Cooper hoisting engine.

The Howry Creek Mining Corporation, Limited.

This company owns four claims south of the Bousquet Gold Mines' property namely S. 2279, S. 2782, S. 2783, and S. 3673.

The main vein is about half a mile south of that on the Bousquet; but is of a different type. It occupies an irregular fracture, having a general direction of east and west, and consists of altered quartzite, quartz, ankerite, arsenopyrite, pyrite, and a little chalcopyrite. At one point the combined width of the vein matter and schistose quartzite is nearly six feet, but this was the widest place seen. On the whole the vein is narrow.

The vein occurs in quartzite, or arkose, North of the vein and at one point within a hundred feet of it diorite occurs; the contact between the quartzite and diorite is covered by drift, but judging from the topography, it is probably roughly parallel to the vein. This diorite extends through to the Bousquet claims. Mr. Knight made a microscopic examination of a specimen of this rock from the Howry Creek property, and says regarding it: "It is a diorite consisting largely of plagioclase and hornblende: the plagioclase is much altered to secondary minerals. There are a few micrographic intergrowths of quartz and feldspar."

It is interesting to note that the Long lake gold mine, now abandoned, lies 25 miles to the northeast of the Bousquet and Howry Creek groups, that the ore body was an arkose carrying gold and arsenopyrite and that it was associated with diorite.

The Howry Creek Mining Corporation have sunk several test pits on the vein, the deepest of which is said to be 18 feet. An adit is now being driven N. 20 degrees W. magnetic from the south slope of the ridge on the top of which this vein outcrops. It was 90 feet long on April 21, and a few feet south of the face a vein 18 inches wide had been cut.

Near the portal of the adit a boiler house has been built which also serves as a blacksmith shop. In this building are an Ingersoll Rock Drill Company compressor, 12 inches by 16 inches, and a Nagle 50-h.p. locomotive-type boiler.

Seventeen men are being employed by this company. They are being temporarily housed on the shore of Howry Creek in some log camps that were built by a lumber company.

The capitalization of the company is $1,000,000 and the head office is at 77 Victoria Street, Toronto. The officers are: president and treasurer, Glenn C. Bull, Chicago; vice-president and manager, A. L. Kemp, Willisville, Ont.; directors: Sid. A. Erwin, Detroit, Mich.; William Benziger, Chicago; W. A. Werrett, Toronto. The company began mining late in 1920.

It is the intention of the company to produce refined arsenic, as well as gold; with this end in view a second-hand arsenic kiln that went through the ice on Charlton lake in March, 1921, this machinery is now on the property, but is not set up.

Majestic Gold Mines, Limited.

The company was incorporated on January 24, 1921, with a capitalization of $1,000,000 in $1.00 shares. The head office is at 213 Carlton Street, Toronto, and the directors are: president M. A. Attalah, Toronto; Saad

Lattief, Toroto; secretary, Charles Gregory, Parry Sound, Ont. This company owns patented mining claims in lot 4, concession 11, Beatty township, and has a five-year option on six claims in Coulson township, viz., L. 6417, L. 6418, L. 6419, L. 6420, L. 6421, and L. 6422; both these groups are reached from Matheson on the T. and N. O. railway. In April the company began to prospect under option four claims beside the Algoma Eastern railway on the north shore of Miles lake and about half a mile west of West River station; this station is at railway mileage 63.4. Three of these claims are S. 4706, recorded in the name of J. G. Pollard, and S. 4730 and 4731, recorded in the name of George Craig; the number of the fourth claim was not ascertained.

The vein being tested is in quartzite, or arkose, and has a strike of S. 46 degrees E. for 3 chains and N. 68 degrees E. For 8 chains. The vein consists of quartz, white, gray and in places almost black. The average width of the vein for this 11 chains is approximately 8 feet; at one point it is 16 feet wide. Not much mineralization is visible on the surface, but in a test pit which was recently started, occasional bunches of pyrite occur.

Seven men were working on these claims under the direction of Peter Greco. A very small boiler was being used to supply steam to a plugger drill.

The Howry Creek area is also described in the Summary Report of the Geological Survey of Canada for 1917, Part E.*

* See our issue 25 March 1921, p. 226.

WORLD'S COAL INDUSTRY IN 1920.

An interesting report has been issued by the United States Geological Survey giving a review of the world's coal industry during the year 1920. It points out that the prices reached were the highet of modern times, and, as usually happens at such a time, the quality of the output deteriorated. In the last two years of the war the world's outpnt had risen close to the pre-war level. After the Armistice, however, the cessation of munitions manufacture and the delay in resumption of normal business curtailed the demand for coal. Industrial disputes, both in Europe and America, closed many mines late in 1919 and further reduced the supply. Thus, when in 1920 the world set his face to work again and industrial activity was resumed where resumption was possible, consumers' reserves of fuel proved insufficient, and an almost universal feeling of apprehension over the coal supply swept around the world. The reasons for this alarm — lately a thing of the past — become clear when the world's production in 1920 is cast up.

The World's Production of Coal, 1910-1920.

Year	Production (in part estimated) Met. tons	Per cent produced by U. S.
1910	1,160,000,000	39.2
1911	1,189,000,000	37.9
1912	1,249,000,000	38.8
1913	1,342,000,000	38.5
1914	1,205,000,000	38.6
1915	1,196,000,000	40.4
1916	1,296,000,000	41.4
1917	1,345,000,000	44.0
1918	1,331,000,000	46.2
1919	1,158,000,000	42.9
1920	1,300,000,000	45.1

The fluctuations in world coal supply become somewhat clearer if expressed as index numbers, taking the output in the year 1913 as equal to 100. The production in the other years then becomes as follows:

1910 .. 86	1914 .. 90	1918 .. 99
1911 .. 89	1915 .. 89	1919 .. 86
1912 .. 93	1916 .. 97	1920 .. 97
1913 ..100	1917 ..100	

These figures are necessarily in part estimated, for official statistics are slow in coming in, but the margin of error in the total probably does not exceed 1 or 2 per cent.

In comparing the 1920 output with that of the years before the war, it must be remembered that the world's consumption normally increases by leaps and bounds. The average yearly rate of increase in the 20-year period preceding August, 1914, was 38,000,000 tons.

The decrease in output centring in Europe may be likened to a condition of vacuum. The stimulus of demand was felt not only in neutral countries of Europe — Spain and Holland — which developed their scanty resources to the utmost, but extended to the Americas, Africa, and Asia. Japanese, Chinese, and East Indian mines took over the bunkering business relinquished by the British in the Far East. In the bitterness of Europe's need American coal was shipped through Trieste and Fiume to Austria, or carried up the Rhine to Switzerland, passing within gun-shot of the great Ruhr field of Germany. Considerable tonnages were brought from South Africa. Even the East Indies and far-away Spitzbergen felt the stimulus.

The manner in which the outlying countries came to the assistance of Europe is shown in the following table, which gives production, by continents, before and after the war:—

Production of Coal, by Continents, 1913 *and* 1920.

Continent	1913	1920	Per cent of change
North America	531,600,000	601,300,000	+13.1
South America	1,600,000	1,700,000	+ 6.2
Europe	730,000,000	597,500,000	—18.1
Asia	55,800,000	75,800,000	+35.9
Africa	8,300,000	11,800,000	+42.2
Oceania	15,000,000	11,900,000	—20.7
World	1,342,300,000	1,300,000,000	— 3.2

PERSONALS.

Col. John I. McLaren, of Hamilton, and Lieut.-Col. Lawrence Martin, of Ottawa, have been appointed members of the Temiskaming and Northern Ontario Railway Commission.

Hon Edgar N. Rhodes, president-elect, and Captain D. Vogt, retiring president of British America Nickel Corporation, Ltd., are visiting the properties of the corporation at Nickelton. Captain Vogt is returning shortly to Norway, and will be in charge of the European end of the corporation's affairs. Mr. Rhodes is Speaker in the House of Commons, and it is said that he will retain that position after taking over the management of the Nickel Corporation's affairs.

Mr. Frank G. Stevens, of Toronto, is at the Rex Gold Mine in the Herb Lake district, Northern Manitoba.

Mr. Robert Bryce, who has been examining gold properties in Northern Ontario, has returned to Toronto.

NOTES FROM THE PAS.

Gold, Copper and Oil-Shale Prospects.

REECE H. HAGUE, The Pas, Man.

Interest in Northern Manitoba at present is divided between a new gold discovery at Elbow Lake, a copper find at Lake Athapapuskow and the oil situation.

Two brothers named Murray recently made a rich find at Elbow Lake, eight miles from the sensational discovery made by J. P. Gordon at Copper Lake two years ago. Samples of the ore brought into The Pas are the best yet seen in the district, the gold content running around $100,000 a ton. The discoverers are busy stripping the vein and many prospectors have visited Elbow Lake to get in on the new find.

The discovery was made on the edge of Elbow Creek, where the gold was very plentiful. Three hundred feet away the vein was again picked up and further free gold was discovered. The vein is said to have a width of 50 feet without uncovering the walls and the gold is fairly well disseminated.

The ore body lies in a greenstone formation, and is made up of porphry and quartz stringers. The overburden is not particularly heavy, it is reported.

Several prospecting parties had previously visited Elbow Lake, but only one discovery of any note had previously been made there. This was a gold find made by Thomas Webb in the fall of 1919, about miles from the Murray strike.

A large copper-sulphide body has been located by two prospectors named Baker and Patton, on Lake Athapapuskow. Samples brought into The Pas appear to be almost as rich as the Mandy ore and the body is said to be an immense one. Baker and Patton discovered a big sulphide body last year some distance from the scene of their present find and running parallel with it. The new body is situated near the mouth of the Pine Root River and extends down a bank eighty feet in height. It has been traced for a length of 200 feet and a width of 20 feet without finding the walls.

One Star Oil rig has already arrived at The Pas and will be transported 90 miles by barge and 12 miles by team into the Pasquai Hills, where boring for oil will be commenced at an early date. The rig has been purchased by a syndicate comprising a number of Saskatchewan men headed by George McMillan and J. Norton.

A very large territory has been staked for oil and several syndicates have been formed. It seems probable that other drills will soon be on their way into the country.

Mr. McMillan recently received an analysis return for samples of shale sent to R. Homrighous, Wichita, Kansas which showed a petroleum content of 17 imperial gals of oil per ton and 26 pounds of ammonium sulphate. The sample was taken from weathered surface shale, and the assayor stated that the oil was free in the paper shale and easy of treatment.

Professor R. C. Wallace, Commissioner for Northern Manitoba, has returned from a trip to the Pasquai Hills where he spent a fortnight investigating the shales. In the course of his report the doctor deals with the topography and geology of the country, devoting space to the various shales encountered. Dealing with the distillation of bituminous shales he says:—"Samples of shales of the various horizons of the Niobrara and of the top of the Benton were taken for analysis in order to determine which horizon carries more hydrocarbon. From rough tests in the field it would appear that the beds immediately below the hard limestone ledge, as they appear down the Man River, carry the highest value. The results of the analysis, which are not yet to hand, will settle this point. There has previously been an official analysis made of a sample which was taken by William McInnes of the Department of Mines, Ottawa. This analysis was:

Crude oil 7 Imp-gals per ton.
Sulphate of Ammonia 22.5 lbs per ton.

"The sample was taken from the shales underlying the limestone bed on the Man river, and from the scarp which would in all probability have lost some of the bituminous contents to be found, for instance, in drilling through the same horizon some distance back from the exposure. As is well known, the oil distillation industry has thriven in Scotland for many years, the average content of the shales being 16.35 Gals per ton in petroleum and 30.75 lbs per ton in ammonium sulphate. The shales are mined in Scotland from considerable depth, thereby adding much to the cost of mining above what would be necessary in surface operations such as are possible in the Pasquai Hills.

"The question of distillation of oil shales has become an important one on this continent in recent years, owing to the ever increasing price of gasoline, and the now well known oil-shale resources of Utah and Colorado. Many plants have been erected in the western States, some after the Scottish practise, but mainly with retorts built to suit the new conditions. Owing to the fact that, for some years at least, the market for ammonium sulphate will be limited on this content, while it commands a good price as a fertiliser in the British Isles, it is necessary to build up the industry on shales with a considerably higher oil-content than is mined in Scotland. Eventually there will be a large market for ammonium sulphate fertiliser, when the soils of the western plains reach exhaustion.

"The day of the oil-shale distillation industry on this continent is being hastened by the fact that demand now exceeds the production from the present oil-fields. It will probably be necessary to be assured of considerable sections of oil-shale with an average content of at least 40 gallons to the ton, exposed under conditions which will admit of steam-shovel methods of excavating before it will be advisable to consider operations. When the industry is established on a commercial basis in the western States, the most successful methods of operation there will serve as a guide in the Canadian fields. Dr. S. C. Ells of the Geological Survey Department will carry a full investigation of the shales during the summer."

Work is proceeding on the drill hole at Mafeking, some 70 miles from the Pasquai Hills, where good indications are said to have been secured and sands containing a large amount of bituminous matter encountered. The Manitoba Government drilling plant is operating at Winnipegosis, but up-to-the present many difficulties have been encountered and slow headway made with the work.

NO REDUCTION OF COAL RATES.

Mr. Edgar E. Clarke, chairman of the Interstate Commerce Commission, recently issued a statement in which he said that there were no proceedings pending before the Commission in respect of a general reduction of coal rates.

Outbursts of Firedamp in Coal Mines, and Control of Atmospheric Conditions in Hot and and Deep Mines

Digest of Papers Read Before the Institution of Mining Engineers, London, at the June Meeting.

(Reported by our English Correspondent.)

An important meeting of the Institute of Mining Engineers was held on the 9th. of June 1921 in London, at which two papers of great interest were read and other papers which had previously appeared in the proceeding of the Institute were discussed. Professor Henry Briggs, D.Sc., dealt with the "Characteristics of Outburst of Gas in Mines", first taking a general review of the gas outbursts which had occurred in various parts of the World and the lessons which may be learnt from them, and secondly, describing some special investigations and experiments which were carried out to determine as far as possible the reasons for the gas outburst at Ponthenry in Wales.

Firedamp is not so commonly met with in Britain as in Belgium, France and Silesia, but it occurs from time to time, and the case at Ponthenry would be classified as an outburst from solid coal, and is therefore of special interest. The outburst was not so serious as the gas disaster in France in 1907, when 4,000 tons of coal were moved, or the one at the Morrissey Colliery in British Columbia which displaced 3500 tons of coal, but it had nevertheless many features of interest and importanec.

The outburst occurred at a time when a "nip-out" had been reached in a seam of anthracite, normally consisting of an upper six-inch portion and a lower 32 inch portion. The depth of the seam was 900 feet. A slant of 7 inches per yard had been driven through the nip-out, and the face had reached 22 yards from the slant, when the outburst occurred.

The top coal was continuous and unaffected, but the lower coal was absent in the slant. The heading was turned off to explore the extent of the "want", and the bottom coal which was in a most friable state was immediately met with. The outburst occurred with great violence, so that in addition to the discharge of a very large quantity of gas 280 tons of coal was displaced, of which 170 tons was shot into the heading and slant. A large cavity was left in the place of the coal and subsequently another outburst occurred in the same part of the mine. There is no doubt that the coal was broken up and squeezed into its fresh position under very great lateral pressure, and one of the most remarkable features of the occurrence was that the upper coal had not suffered from this cause.

It has been the almost invariable case that outbursts of gas of this type from the solid coal have occurred during the driving of winning headings, or when "working in the whole" in bord-and-pillar mines. There seems to be no doubt that the best way to avoid danger from this cause is by working advancing longwall and by the avoidance of pushing forward the faces with too great rapidity. The slow advance of a wide straight face should enable the gas to drain quietly out of the coal.

In Europe it has sometimes been found advisable to prohibit the use of machine cutters in mines subject to these gas outbursts, as hand-cutting gives the gas a better chance to escape. It is also a good plan to carry out advance boring. A regular discharge of gas from the face is a sign of safety, and the stoppage of such a discharge should be regarded as a danger signal.

It has been shown by chemical analysis that the outburst coals from the Ponthenry seam contained a greater proportion of incombustible matter than the normal, and it seemed evident that the additional substances had become mixed with the ash by mechanical action rather than that they were present in solution. The invading substances was very high in acid insoluble and in silica and low in iron, and were doubtless caused by the churning up of the coal and soft rashing which usually separates the upper and lower coals, with the addition of some of the fireclay floor of the seam.

The action of South Wales anthracite most closely corresponding to the material of the outburst has been studied under experimental conditions, and it has been possible to come to some conclusions with regard to the gas given off and the reasons for the outburst. If the gas pressure was from 4 to 8 atmospheres, the fire-damp released would probably amount to from 49,000 to 53,000 cubic feet at 15 degrees C., calculated from the fact that about 7,200 cubic feet of coal were blown out or disturbed. One point which it is of importance to notice is that the coal ejected by these outbursts from the solid is dry, as the absorptive power of coal is greatly reduced when moist, so that outbursts of this type are not likely to occur in seams from which water exudes with gas at the faces.

If, however, water should enter for the first time into a virgin seam of coal which contains gas absorbed under pressure, an evolution of gas would take place, and, in the absence of outlets, the pressure might be increased. It is possible that this fact may have some bearing upon the problem of sudden outbursts from the floor and roof. It seems evident therefore that sudden outbursts of gas and coal from the solid are due to the co-existence of four factors, namely, the presence of gas under considerable pressure; the presence of a mass of disintegrated coal which is loose enough to move under a sudden relief of pressure and to set free almost instantaneously the greater part of the gas absorbed in it; the absence of water in the soft coal; and the employment of a method of working which affords little opportunity for the gas to drain quietly from the soft coal; or alternatively, the presence in the seam and surrounding a soft zone, of ribs of low permeability which prevent or interfere with that drainage.

The investigations carried out further showed that in the case of the Ponthenry outburst the phenomenon of activation played a part in increasing the volume of the gas absorbed by the loose coal. Activation is however not an essential factor, as normal coal can

absorb sufficient gas to cause outbursts if the necessary conditions exist.

Another paper of great interest was read by Mr. J. P. Rees. It was the third report of the committee on "The control of atmospheric conditions in hot and deep mines". This report gives data and statistics which have been collected from investigations carried out in a number of English collieries where temperature control is of unusual difficulty owing to the depth of the workings or other adverse conditions existing in the mine. The deductions drawn from the observations made are intended to show how the causes leading to high underground temperatures and high wet-bulb temperatures usually operate.

The instrument used in the test was a whirling hygrometer especially designed for underground work. It is constructed from two mercury thermometers of great accuracy held in cork pads by means of seccotine and set up in a wooden frame and guarded by metal bars. A slit enables the thermometers to be read when held against the light and an oval hole is cut in the frame for the bulb of the dry thermometer. The bulb of the wet thermometer is moistened by means of a strip of muslin which dips into a glass water reservoir at the base of the frame.

A handle for whirling the frame is provided and by rotating the frame at about 200 r.p.m. an air rate passing over the bulbs of about 600 feet per minute is produced.

The chief reasons for a rise in temperature in underground workings are three in number, heating due to the compression of the air as it descends the shafts and inclines, conduction of heat from the surrounding strata, and the formation of heat in the oxidation of coal, timber and other substances. The amount of heat and moisture given off by men, horses and lamps is a negligible quantity in coal mines. The increase in the moisture contained in the air of the mines is due to the evaporation of the water which percolates through the walls of the shafts and roads, or which may be present in freshly-exposed coal or other minerals.

It is only possible to reduce heating by compression at the expense of evaporation, but as the walls and shafts give off heat partly in accordance with the temperature of the external air on the surface, the underground temperature from this cause becomes more or less averaged throughout the year. Heating by conduction from the surrounding strata may be reduced to a very low figure by the passage of a sufficiently large volume of air as when once a zone of cooled rock has been created around a shaft or airway, the passage of heat through this rock is comparatively slow.

The different conditions which have to be faced in different parts of the world is strikingly brought out by the increase in the natural rock temperatures with increase in depth, in Britain and elsewhere. In the Witwatersrand area in Africa the rock temperature increase is about 1 deg. Fah. or every 250 feet increase in depth, whereas in the English collieries investigated in the research being described the increase is about 1 deg. Fah. for every 60 to 70 feet. The air temperature increase from compression in these collieries is about 1 deg. Fah. in 182 feet.

It therefore follows that the abundant ventilation of a dry deep mine in the Witwatersrand would warm the temperature, whereas in Britain it cools it. The investigations have further demonstrated that heating by oxidation can also be controlled by abundant ventilation.

An ample ventilating-air supply will also tend to keep the temperature of wet roads low owing to the evaporation which takes place and this again indirectly controls the amount of moisture in the air and the wet-bulb temperature. One of the points brought out by the investigation was the particularly rapid rise in moisture content of the air when passing along a working face over fresh and relatively moist coal.

CHANGES IN BRITISH EMPIRE COLLIERY STAFFS.

Alex. S. McNeill, General Superintendent of Mines announces a number of promotions in the superintendence staffs of the Dominion and Scotia collieries, namely:

D. H. McLean, Manager of Princess Colliery becomes assistant to the General Superintendent of the Dominion Coal Company. John Murphy, hitherto manager of the Jubilee Colliery, becomes manager of the Princess Colliery, and is succeeded at Jubilee by Thomas Merrit. Daniel Brown is appointed manager of the Florence Colliery, succeeding J. R. McNeill, who is appointed District Superintendent at Sydney Mines. The appointment become effective 1st July. The collieries formerly operated by the Nova Scotia Steel Company and separately managed from the head office of that company, are, by this announcement, constituted a superintendence district of the consolidated collieries of the Corporation, and will be managed from the office of the General Superintendent of Mines.

Shipments of coal to Britain and European ports from the Cape Breton collieries have steadily continued during the past few weeks. Although it is now probable that the 1st of July will see the end of the strike, stocks in Britain have been sufficient to prevent any acute physical suffering from the lack of coal, but after three months total idleness of the British collieries, the public is beginning to be painfully affected, and the shortage is by this time so pronounced that importations of coal will be needed for some time, as it will not be possible to obtain anything like full production from the collieries before the late Summer. The tonnage of coal which the Montreal market can take from Nova Scotia during the present season is not large enough to give an outlet for the full production of the Nova Scotia collieries, so long as the steel industry is not working full time, so that the European outlet which has been developed as a result of the British coal-strike has proven very welcome to the Nova Scotia coal companies. But for this, the collieries could only have worked part time during the Summer. The winter of 1920-1921 was a very hard one at the collieries, and the coming winter may be even a harder one, as business prospects are far from bright. The mine workers will therefore be wise to earn all that is possible during the remainder of the Summer, and to accumulate as large a reserve as they may find possible.

The Harbor Commissioners of the City of Vancouver are considering the purchase of a hulk for the bunkering of coal. The fleet of wooden war-built hulls on Lake Washington, near Seattle, which the United States Shipping Board is said to be anxious to dispose of, may be inspected with this in mind.

METAL PRODUCTION OF ONTARIO DURING FIRST QUARTER 1921.

Returns received by the Ontario Department of Mines from the metalliferous mines, smelters and refining works of the Province for the three months ending March 31st, 1921, are tabulated below. For purposes of comparison the quantities and values are given for the corresponding period in 1920. Tons throughout are net tons of 2,000 pounds.

		Quantity		Value $	
		1921	1920	1921	1920
Gold	ounces	111,096	142,840	2,296,522	2,953,036
Silver	ounces	2,106,045	2,280,665	1,226,551	2,954,695
Platinum metals	ounces	445	100	19,179	7,172
Copper metals	lbs	1,562,150	1,508,014	206,064	242,630
Copper in matte exported*	tons	222	1,976	35,520	553,280
Nickel in matte exported*	tons	519	4,571	259,500	2,285,500
Iron ore exported	tons	22	44	99	322
Iron, pig**	tons	16,208	13,428	467,538	344,241
Cobalt, metallic	lbs	81	46,479	365	108,430
Cobalt oxide	lbs	27,242	213,024	79,075	340,232
Nickel oxide	lbs	5,133	1,788,183	2,105	413,944
Nickel, metallic	lbs	2,855,698	2,159,316	1,000,240	753,163
Other Nickel compounds	lbs	2,364	159,183	189	15,308
Other Cobalt compounds	lbs	.....	1,417	.....	1,417
Lead, pig	lbs	809,440	509,075	42,832	48,278
Total				5,626,779	11,021,654

* Copper in matte was valued at 14 cents per pound in 1920 and 8 cents in 1921, while nickel was valued at 25 cents per pound for both years.

** Total output of pig iron was 147,345 tons worth $4,250,347. Figurees in the table represent proportional product from Ontario ore.

General Remarks.

The mineral industry with the exception of gold mining has suffered depression and a general lowering of values in common with most other industries. The nickel-copper and silver producers in particular have been affected—the former owing to lack of a market and the latter because of the prevailing low price of silver. Hydro-electric power shortage, as a result of unusually low water during the Fall and Winter months, had the effect of seriously curtailing the output of gold and also, to some extent, of silver. The iron and steel trade was very quiet during the early part of the year. More recently, however, there has been a decided improvement. The price of lead shows a marked decline, although the output is considerably in excess of the first quarter of 1920. Further details are given under the separate headings.

Gold.

Although the figures in the table show a decline in gold production as compared with the first quarter of 1920 this situation will undoubtedly be reversed for the first half of the year, the falling-off as explained above being due to hydro-electric power shortage. Since early in April an ample supply of power has been available and the Hollinger mine is treating 3300 tons of ore daily. The following table shows the output:

Source	Ore milled tons	Gold Recovery ounces	Gold Recovery Value $	Silver Recovery ounces	Silver Recovery Value $
Porcupine	241,353	100,477	2,077,048	17,935	10,568
Kirkland Lake	23,719	10,576	218,612	1,168	675
Total	265,072	111,053	2,295,660	19,103	11,243

In addition 43 ounces of gold worth $862 were recovered from nickel-copper refining operation. Gold mining companies received further a total of $331,356 by way of exchange premium, or as earnings on credit balances in the United States. Gold shipments go to the Canadian mint and are paid for by cheque on New York. Three mines at Porcupine—Hollinger, Dome and McIntyre were producing, and at Kirkland Lake—Lake Shore, Teck-Hughes and Tough-Oakes. In May the Wright-Hargreaves at Kirkland Lake commenced milling operations.

Silver.

Considering the combined disadvantages of power shortage, a decline in the price of silver and the fact that several properties are closed down, the output for the quarter is creditable. The average New York price of silver was 60.5 cents per fine ounce for the period as compared with $1.30 for the first quarter of 1920. The following ten mines made shipments: Nipissing, Mining Corporation, Coniagas, O'Brien, La Rose, Miller Lake O'Brien, McKinley-Darrage-Savage, Beaver Trethewey (Castle) and Bailey. In addition to 2,089,989 ounces shipped by the silver mines, there was a recovery of 19,103 ounces by gold mines and 2,953 from nickel-copper refining operations. The mines also received payment of $4,809 for 32,531 pounds of cobalt.

During the period southern Ontario refineries located at Thorold, Deloro, and Welland recovered 1,073,202 ounces of silver in addition to arsenic, nickel and cobalt in various forms. The market for all these products was poor and in consequence stocks have accumulated. The figures in the table refer to products sold.

Nickel-Copper.

Both the International Nickel Company of Canada and the Mond Nickel Company are operating on a greatly reduced scale from that of the war period. No shipments of nickel-copper matte were made during the period by the Mond Company to its refinery in Wales. Surplus stocks of nickel are gradually being absorbed. The British America Nickel Corporation shut down its smelter on Feb. 26th. A reorganization of the company is probable before work will be resumed. Meantime a small force has being doing some underground development work at the Murray mine. During the period 153,387 tons of ore were smelted and 7,568 tons of Bessemer matte produced. The latter contained 3,861 tons of nickel and 2,315 tons of copper. Of the total matte product 3,367 tons were shipped to Canadian refineries at Port Colborne and Deschenes, and 896 tons to the United States. The two refineries treated 2,554 tons of matte for a recovery of 2,853,512 pounds of nickel and 1,562,150 pounds of blister and ingot copper. The average New York price for electrolytic copper was 12.66 cents per pound for the first quarter of 1921 as compared with 18.93 cents in 1920.

Iron Ore and Pig Iron.

With the exception of a small sample shipment of hematite from the Wallbridge mine near Madoc, not a ton was shipped from Ontario mines. At the Magpie 42,198 tons of siderite ore were raised. Both the Magpie mine of the Algoma Steel Corporation and the mine at Sellwood owned by Moose Mountain, Limited, are idle at the present time.

During the quarter the Algoma Steel Corporation (Sault Ste. Marie) operated three blast furnaces for the production of pig iron, the Steel Company of Canada (Hamilton) two, the Canadian Furnace Company (Port Colborne) and Midland Iron and Steel Company one each. Of a total of 287,769 short tons of ore charged to the furnaces, only 31,597 tons or 11 per cent was of Ontario origin. Of the total output of pig iron 71,862 tons were used, along with scrap, in the production of 117,824 tons of steel worth $4,593,520.

Northern Ontario Letter

THE SILVER MINES.

The Cobalt Field.

Uniform quotation for silver is enabling the companies in the Cobalt field to take stock of their assets and to estimate with reasonable accuracy just what may or may not be done in the way of operating their mines. The leading mines are all realizing a substantial margin of net profit, and the trend of prices for supplies is still downward. The coming reduction in freight rates offers further promise of a continued decline, all of which contributes to improved economic situation and encourages the hope that some of the smaller mines which are still closed may be re-opened within a reasonably short time.

It is learned on good authority that a further cut in price of blasting powder may be expected at an early date. Competition will be keener within the next month or so than ever before in the history of mining in Cobalt. This is due to two or three new concerns preparing to make a bid for a part of the business of supplying the mines of Northern Ontario with dynamite. A substantial reduction in the price of this mining necessity would automatically cause a big drop in the cost of producing metal and would thereby widen the margin as between the cost of operation and the value of the metal produced.

High-grade ore has been opened up in a two-inch vein at the first level of the Buffalo Mine of the Mining Corporation of Canada. Very little work has so far been done on the new vein, and officials are unwilling to offer any estimate of its importance. The indications appear to be that it may "sweeten" the grade of the ore, however, which has been estimated to contain an average of 20 to 21 ounces of silver.

On July 15th the Kerr Lake Mines, Ltd., will pay a dividend of 12½ cents a share to stockholders of record July 1st. This will call for the disbursement of $225,000 and make a total of $9,085,000 paid so far to the stockholders of this company. The Kerr Lake is not producing anything from its Cobalt property, the work here consisting of exploration and development work. As regards the silver property acquired over a year ago in Utah as well as a gold dredging property in New Zealand, there is very little information available in Cobalt.

The find reported recently on the O'Brien Mine had no basis in fact, according to official information to the correspondent of the "Journal."

Work has been suspended on the Ophir property, following the shipment of one carload of ore. The property was being worked under lease, the royalty being ing subject to an increase on June 1st and a second increase July 1st. The leaseholders found the silver content of the ore too low to bear the cost of shipping.

Good results are reported officially on the Keeley Silver Mines. The mill is turning out about one and a half tons of concentrates daily, while at times it is possible to cob out some of the higher-grade ore which is being bagged preparatory to making a high-grade shipment in due course.

No new developments have been reported in connection with the negotiations in which one of the producing companies in Cobalt is negotiating for the purchase of the Silver Leaf property.

Niccolite has been discovered in a vein on block 45 in the Gillies Limit. The samples brought in have been taken to the assayer for analysis. The vein occurs in diabase formation and is about three inches in width. The owners of the property state they have also discovered galena in the vein and they believe it will show an encouraging silver content when sampled and assayed.

In a general way, there is more optimistic feeling among silver mine operators than has been apparent for several months in the Cobalt district. There are various schemes under way for opening idle properties which on one or the other might reasonably be attended with good results.

Elk Lake and Gowganda.

Reports are current in Elk Lake that another outcrop of hematite has been found not far from the Hartley-Wescott property. Details are lacking, and confirmation of the report could not be secured before the despatch of this letter to the "Journal." In the meantime, Messrs Hartley and Wescott are busily engaged in examining their property and securing an estimate of the extent of the high-grade iron ore occurrence.

Arrangements have been made to resume work on Downey property, situated between Elk Lake and Silver Lake. J. Darroch has been in Elk Lake making preliminary arrangements and plans an aggressive scheme of exploration work. Some years ago, the owners of the property took out about $10,000 in high-grade ore from the surface of the Downey claim, but nothing was done toward developing the property underground. It is now proposed to go ahead with an underground exploration and development scheme. Among other things, the death of Larry Downey, the original owner, caused the prolonged suspension of work on the property.

In the Gowganda district, the tendency to await the building of the proposed Northern Light Railway continues, and the indications appear to be that there may be a general revival of activity should the laying of rails become a reality. The railway project in the meantime depends upon the ability of its promoters to dispose of bonds which it has received authority to sell, these amounting to $15,000 a mile for a total for each mile of line constructed, up to as much as 100 miles. In addition to this, the Ontario Government is considering the question of itself subscribing $3,500 per mile, this is to be done through the Northern Development Branch instead of through the T. & N. O. Railway.

THE GOLD MINES.

The Porcupine Field.

During the month of May, the gold mines of the Porcupine and Kirkland Lake fields produced upwards of $1,300,000. The output for June will be known during the coming week and may show a still further increase. This would tend to show that during the last eight months of the current year, as from May 1st, the output of gold from these districts will reach close to $11,000,000. Added to this is a little over $3,000,000 produced during the first four months of the year when the mines were restricted in their operations on account of a shortage of hydro-electric power. An estimate of $14,000,000 for the current year, therefore, seems to be quite conservative, and compares with a former high record in Ontario of $11,381,000. There is also the fact that further milling additions are being made, and that by the end of the year or the beginning of the

next year the mines may be turning out gold at the rate of $1,500,000 monthly, or equal to $18,000,000 a year.

In regard to the harnessing of Kettle Falls on the Abitibi, it has just been learned that the Abitibi Power and Paper Company desires to control the Falls, claiming "prior right." In the meantime, it is understood the Ontario Government had authorized the Hollinger Consolidated Gold Mines to go ahead and develop the power, toward which end the Hollinger recently sent in a party of men to make a topographical survey. The Abitibi Company has created a big storage basin at the head of the Abitibi River, and the desire of this company to control possible hydro-electric development down river seems logical. At the same time, however, the Abitibi has already harnessed Iroquois Falls, as well as just completing the harnessing of Twin Falls, which two plants provide between 50,000 and 60,000 h.p., thereby providing an abundant supply of energy for the requirements of the Abitibi itself. It is generally believed that any difference of opinion that may exist in regard to Kettle Falls will be satisfactorily adjusted and that the Hollinger will be permitted to go ahead with its scheme to utilize this energy for the benefit of the gold mining industry, at the same time, keeping in mind the expense incurred by the Abitibi in providing and maintaining water-storage facilities which directly benefit all power developments down the river.

At the Dome Mines, the low-grade product of the American Cyanimid Company is being used instead of high-grade cyanide from the Cassel Cyanide Company of Glasgow. Details in regard to the results achieved have not been secured.

A part of the grinding equipment which is intended to add about fifty per cent to the capacity of the McIntyre-Porcupine Mines has arrived at the property but the work of installation has not yet commenced.

A small force of men is at work on the property of the Big Dyke Gold Mines. This company controls what was formerly the McRae-Porcupine, as well as having taken over the Pike Lake property and two other mining claims situated in the township of Ogden. The company's engineer, Lieut. F. G. Huycke, is in favor of sinking on a vein which occurs in a contact between Keewatin and a small strip of porphry, instead of carrying on diamond drilling operations. The officials are now bending their energies to the task of raising money with which to finance the work planned.

A road is being cut through the township of Shaw for the purpose of putting the Triplex property in touch with South Porcupine. The Triplex was formerly known as the Tommy Burns, and a force of men are already engaged in doing exploration work.

Kirkland Lake Field.

Although the deposits of ore are not so large in Kirkland Lake as in the Porcupine district, yet it is already apparent that the Kirkland Lake district will have as many producing mines as Porcupine. There are four now producing, with two more to be added by the end of the current year, while many outlying properties offer promise of developing successfully.

During recent weeks, engineers and representatives of men with money have been scouring the Kirkland Lake field for proven or prospective gold-mines and during the next few months there will probably be a lot of new capital employed in opening up one or another of the promising new properties.

The White-Kirkland is the name of a new company with an authorized capital of $500,000 which has just been formed for the purpose of taking over and operating property in the Kirkland Lake District.

During the month of May, the Lake Shore mine produced $29,637.18. The mill ran 93.55 p.c. of the possible running time and treated 1,865 tons of ore. This was an increase over the April output, but is still below normal in point of value produced. As to this, your correspondent interviewed Harry Oakes, president of the Lake Shore, and was informed that from this date forward the grade of the ore would be more uniform. Mr. Oakes explained that during the past few months the ore has been coming from development work and that a stope which was being driven entered a lean streak all of which was sent through the mill without stopping to draw any of the large tonnage of high-grade which is broken and lying in the stopes. Now that the shaft has been completed to the 600-ft. level, and with lateral work already under way at that depth it will be possible to regulate mill heads. Mr. Oakes stated that no effort would be made to enlarge the mill at present. He stated that the tank and other equipment was adequate to deal with an output of about $500,000 annually and this amount can be produced with the present 60-ton equipment. At a later date, when development has reached a point where the management feels justified in going ahead with further construction, the question of adding aquipment about three times the size of the present plant will be taken into consideration.

Boston Creek District.

The financing campaign, set for the month of May, to dispose of a bond issue of $50,000 amongst existing stock-holders of the Miller Independence is proceeding slowly but satisfactorily with some $10,000 or $12,000 yet to be subscribed.

As soon as the full $50,000 issue is subscribed, the diamond drilling program will be put into active operation, the starting of the new work being conditional and co-incident with the completion of the financing campaign. In the meantime preparatory work is in progress and the laboratory sampling and concentrating outfit is being installed ready to go into commission when required.

Miller Independence is at present the centre of considerable road-construction activities, the highway from Boston Creek to the Skead goldfield running east and west through the property while a government contract has just been let for clearing a two mile section from the mine south towards Krugerdorf. This piece of work when completed, will put the mine in direct road communication with Cobalt via Englehart and the Company is rendering all co-operative assistance in its power to have the work expedited.

CURTAILMENT ASBESTOS PRODUCTION.

A New York letter to asbestos users states that half the producing asbestos properties in Canada are closed down, and that the remainder of the mines are working on one shift for five days weekly, with the intention of suiting the supply to the reduced demand. It is expected, according to this New York advice, that the idle mines will not reopen for production until next Spring. No reduction in prevailing asbestos prices is expected, and consumers are advised to stock sufficient supplies to fill their requirements until next Spring.

TORONTO MINING QUOTATIONS.

Quotations on Active Stocks on Standard Stock Exchange for Week ending 25th June 1921:

	High	Low	Last

	June 29.
Copper, Electric	17
Copper, Casting	16¾
Tin	39
Lead	7
Zinc	7½
Aluminum	30
Antimony	9

(Unchanged from previous week.)

Dr. G. A. Young, of the Geological Survey, is on his way to the Belcher Islands, Hudson Bay. Important iron ore deposits have been found there in recent years.

TORONTO COAL PRICES.

Toronto, 29th June.—To say that there are market conditions, but no market, about sums up the coal situation in Toronto. There is really no market. Throughout the entire Province, retailers are pretty heavily stocked up with coal, but consumers will not buy. In fact, so heavily stocked are some retailers, that a number of them have had to cut off shipments altogether because of the physical impossibility of handling coal by reason of lack of space. Present Toronto prices are: Slack coal, $1.00 to $1.75; lump coal, $2.10 to $3.00; smokeless mine run, $2.10 to $3.35. Anthracite prices, as given last week, will all be advanced 10c. on the 1st July. In addition, on the 1st July, there will also become effective a Pennsylvania State tax of 1½ per cent. on the price of the coal at the mines. This State tax is meeting with opposition on the ground of unconstitutionality, and the legality of its imposition will be tested in the courts. In the Pocohantas market, slack is a little easy, but the lump market is very stiff, prices being as follows: Slack, $1.25 to $1.90; lump, $5.50 to $6.00; Pocohantas mine run, $3.50.

BRITISH-AMERICA NICKEL CORPORATION ANNOUNCES RE-FINANCING.

A despatch from Ottawa under date of June 20th announces that the British America Nickel Corporation, Ltd., has definitely carried through its re-financing scheme and the corporation's capital is now arranged for as follows: $6,000,000 first income bonds; $18,500,000 second bonds; $20,000,000 common stock.

The corporation which has temporarily shut down its plants, is only waiting for the right time to resume operations.

Captain D. Vogt, president of the Norwegian Nickel Works, has, during the financing period, been in charge of corporation's affairs. From the first of July, however, Hon. Edgar N. Rhodes, Speaker of the House of Commons, will take charge of British America Nickel Corporation, Ltd., having been appointed president and managing director of the corporation. On the same date, Capt. D. Vogt resigns as president, having been elected vice-president of the corporation and managing director for its European office.

A. Gronningsater, who up to the present, has acted as chief consulting engineer, has been appointed technical director and S. M. Brown, secretary-treasurer, has been elected a member of the board. Some other members of the board of directors of the corporation are: J. Fred Booth, Ottawa; F. W. Field, Toronto. Sir Eric Hambro, London, England; E. R. Wood, Toronto; Sir U. J. R. Borresen, Christiania, Norway.

The corporation's mine and smelter plants at Sudbury and its refinery at Deschenes, Quebec, are of most modern and adequate construction, and have a capacity of up to 10,000 tons of nickel per year. The plant managers are respectively: E. Hibbert, E. J. Carlyle and R. L. Peck.

The mine property itself as well as the plants and the smelting and refining processes, have recently been very favorably reported upon by independent mining and metallurgical experts, and the company can, no doubt, look forward to a successful future as soon as general trade conditions improve.

British Columbia Notes

Stewart, B.C.—It is said that the Guggenheims have acquired the Forty Nine Group of Mineral Claims, Salmon River, which was located in 1910. The Woodbine Group, situated on Cascade Creek and close to the Premier Mine, is reported to have been sold through the efforts of Pat Daly, the prospector and operator whose recent New York activities received considerable publicity.—No active mining operations are being carried on at the Premier Mine at present. The management is concentrating on the work of the completing the Mill, putting the tramway in shape for the handling of the output, 100 men being engaged on this alone, and in general construction and development in and around the property. Over 1,000 tons of ore has been sacked and awaits shipments.—R. L. Clothier, superintendent of the Red Cliff, has taken in a gang of men to establishment camp preparatory to the initiation of systematic development.—In explanation of the closing down of the Spider Group of Mineral Claims, as well as of the failure of the Algunican Company to continue development plans on other properties in the Portland Canal District, it is said that the rate of exchange against Belgian capital finally forced investors of that country to close down on advances. F. C. Drumm, a legal gentleman of Orange, California, and N. V. D. Brock, of the same town, are quoted as saying that American interests may assist in financing the company's enterprises. If the money is forthcoming development on the Spider Group will continue. It is considered a promising mining property. The Red Top Group, of the Bear River District, is to be developed further this summer. G. Sieffert is reported to have obtained necessary financial backing in New York. The property is on the north side of the Bear River about 21 miles from Stewart and discussing it in his 1919 report George Clothier, resident mining engineer, said: "The lowest showing, at an elevation of 2,550 feet, consists of an open cut, 15 feet deep at the face, exposing a slightly mineralized, broken-up oxidized, slaty-looking rock about 15 feet in width. The hanging-wall of a coarse-grained igneous rock, probably andesite, is well defined striking east and west into the hill and dipping 60 degrees to the north. Sufficient depth has not been gained to get any idea of what the solid vein matter may be. Above this cut, about 15 feet, another cut has been excavated and the overburden stripped from the vein for a further distance of 50 feet, showing the same decomposed and shattered slaty material as below, slightly mineralized with chalcopyrite. Seemingly the shattered slates have absorbed the surface iron-oxides until the whole is a soft earthy mass. At 2,600 feet elevation the vein has been stripped for a length of 100 feet or more along the side hill, exposing in places ribs of fairly good chalcopyrite ore. There does not appear to be any definite strike or dip to the vein at this point, or to the hanging wall, which was so well defined below. It seems to be a mixture of bunches of sulphides in quartz, country-rock, and oxides, all blending into the country-rock above. About 15 feet is the greatest depth obtained anywhere and it will necessitate extensive exploratory work to define the vein and prove the ore-bodies. "The work planned consists of the driving of three crosscut tunnels, two of which were started last year. The lower one is expected to cut both leads in about 160 feet and the upper will cut the upper vein at about 125 feet. A new tunnel will be opened up some 800 feet west of the present workings to cut the upper vein. The intention is that each of these tunnels shall cut the leads from wall to wall, thus permitting drifting on them both ways.

Alice Arm, B.C.: While there is not much, if any, prospect of actual shipping from this district at present the explanation is not to be found in any lack of mining opportunity but in the metal markets and general financial conditions. The Dolly Varden Mine is to be further developed and work, it is understood, is to be carried out on the Wolf Group, situated adjacent to the Dolly Varden Claims. Meanwhile the community is optimistic, some road work is being done by the government, progress is being made in the improvement of wharf accommodation, and the prospectors are hitting the trail for the hills of the Kitsault and the Illiance rivers.—On the Bellevue property, it is reported, a promising lead of first-class ore was struck at a depth of something over 100 feet. The striking of ore at depth is considered of first importance in the upper Illiance country indicating that the ore bodies are not confined to the surface, or to the near surface. It adds to the possibilities of the many rich surface indications of the district.

Anyox, B.C.: Col J. T. Crabb, New York, executive vice-president of the Granby Consolidated Mining, Smelting & Power Co. Ltd., was most optimistic in a statement made while on a recent visit to northern British Columbia. He is quoted as follows: "Copper is not the only mineral in British Columbia. Though it is rich in that mineral it is quite rich in gold and silver and many other valuable minerals, including iron. If much has been taken out of the province, it is nothing to what remains. Why, the country has not been scratched. It is very rich in minerals."

Hartley Bay, B.C.—The Drum Lummon Mines Ltd henceforth will be known as the Douglas Channel Mines Ltd., this change having been decided upon at a recent meeting of the shareholders held in Vancouver. Officers were elected as follows :President, John Broatch; secretary, J. F. Meads; directors, Dr. T. D. Turner, Penticton; Theed Pearce, Courtenay; W. Patterson, J. Tomand, J. T. McGregor, of Vancouver Operations are to resume at the mine shortly on a considerable scale. It is probable that the plant will be overhauled and altered and that new development will be undertaken.

Trail, B.C.—The smelter of the Canadian Consolidated Mining & Smelting Co. continues busy with the product of the company mines. Between the 10th and the 17th of June some 7,540 tons of ore from this source were treated. A shipment of 93 tons was received from the Florence Silver Mining Co., Princess Creek, near Ainsworth, and the Knob Hill, of the Republic Camp, is credited with 162 tons.

Nelson, B.C.—Development work is to be resumed at the McAllister Mine, Three Forks, after July 1st, it being the intention to bring the property up to the point of being able to produce on a milling scale. The installation of a concentrator next Spring is contemplated.

Victoria, B.C.—Much interest is manifested in a report issued by the Imperial Mineral Resources

Bureau showing that the output of zinc from Canadian mines has more than quadrupled since 1916. Previous to that time the production was negligible and the Bureau did not keep a record of it. In 1916 it was 2,655 and in 1919 it had jumped to 11,005 tons. Discussing the output within the Empire the Report attached special significance to the zinc-lead silver ores of this Province and to the development of facilities for their treatment at the Trail Smelter. "Much still remains to be done" it is stated "before the British Empire can be considered to be self supporting in the matter of spelter production." A hopeful indication was the construction of a successful plant at Trail, B.C., with a capacity of 15,000 tons of smelter a year.

The Imperial Oil Company's drilling crew has left Edmonton for Fort Norman, A. W. Harris being in charge as superintendent of the company's field work in this district. Bear Island, opposite the site of the present well, has been selected as the season's headquarters. T. A. Link, the company's geologist, will have chosen sites for further drilling before the arrival of the main expedition. — Wm. Nicholson, of Banff, Alta., states that he is planning active operations on his claims at Fort Norman, and the Stewart Oil Company, promoted by a group of Calgary, Alta., investors, is reported to have arranged with drilling contractors for drilling at Fort Norman and Windy Point.

The oil shale deposits of Graham Island, Queen Charlotte Islands, are being thoroughly tested, a small plant having been installed for the purpose. While the results are not yet known those responsible for the work are confident of success. It is thought that it can be demonstrated that shale running 20 gallons to the ton can be profitably handled. Surface shale is reported to show an oil content of from 7 to 10 gallons to the ton but much work must yet be done in prospecting and determining the limits of the belt of oil-bearing shales. The deposits are on the west slope of the Island.

Preparations for the exploratory work of the Imperial Oil Company in the Ponce Conpé District of Eastern British Columbia, practically on the border of this Province and the Province of Alberta, are well underway. Wet weather at the beginning of May interfered with the work of transporting plant and supplies but since then conditions have improved. All the equipment and the casing necessary for the first well, however, is on the ground. An unusually heavy outfit is being used for the first well. It drills a 21-inch hole and is capable of going to a depth of 4,000 feet. The hole is being sunk in close proximity to one of the seepages. The most promising of these is at the junction of Tepee Creek and the Ponce Conpé River. Oil, it is stated by geologists, is most likely to be found either at a depth of 700 or of 3,300 feet. Negotiations are said to be in progress for the purchase of 200 sections of land in the district by New York capitalists and it is probable that between fifteen and twenty drills will be operating in the field within the next two or three months.

The Kitsumgallum Basin Petroleum Co. Ltd. has been incorporated in British Columbia with a capitalization of $300,000, head office Terrace, B.C., the objects of which are to prospect for and develop oil properties on the Kitsumgallum Lake. A number of promising indications are said to have been found and several claims in the neighborhood of Beaver and Cedar Rivers have been recorded.

Coal operators, dealers and consumers were represented at a conference with Hon. Mr. Sloan, Minister of Mines for British Columbia, held on the 9th of June for the purpose of considering the possibility of producing coal that will retail at a cheaper rate than at present.

The discussion was based on the recommendations of Mr. Alex Henderson, K.C., who recently conducted an inquiry into the coal industry of the Province, and of General R. G. E. Leckie, B.Sc., who was Mr. Henderson's technical counseller.

Taking the recommendations seriatim the Conference's sentiment generally speaking was as follows:

That there would be no practical purpose in changing from the long to the short ton in all sales. The Canadian Collieries (D) Ltd. explained that only about 9 per cent of their sales were for the domestic market and that all deliveries by bunker to mercantile trade were computed in long tons.

That there was no objection by the operators to furnishing the Government with reports of operating costs and sales realisations of their several mines providing the same were kept confidential. The companies, however, had competitors outside the Province and it was not right that they should be kept informed of the business of the provincial collieries.

That no power existed in the Province to license retail dealers. It would be quite as reasonable for the legislature to attempt to restrict the number of meat merchants as to undertake to regulate the number of coal dealers in any particular area or district.

That the suggestion that all larger users should lay in their coal during the summer was a good one and that such a practice should be encouraged in every possible way.

That there was no objection to the publication of the analyses and characteristics of the coals of the several mines of the Province while it was doubted whether any good purpose would be served inasmuch as the coals of Vancouver Island and most of those of the lower provincial mainland were very similar—a high-class bituminous coal.

That lists already were available setting out the different grades of coal the several uses to which the different coals may best be applied and the prices.

That it would be a useless duplication of machinery for the Province to appoint a Fair-Weights Officer because the municipal officials of Victoria, Vancouver and New Westminster already were efficiently taking care of this work. The coal dealers scored here when the Fair-Weights Officer of Victoria in person reported that in 1919 and 1920 the loads which went over his scales for the most part were slightly over-weight, some were exact, and very rarely was one found any short. At this point the dealers took occasion to show their resentment of the suggestion of Commissioner Henderson that the public had been short-weighted. They declared that the coal dealers were an honorable body of businessmen who protested against such an aspersion inasmuch as there was no evidence in its support. No doubt there were some instances of short weight because of the dishonesty of carters who held back an occasional sack and sold to peddlers. One dealer told of a specific instance of this and an alderman representative of Vancouver said that the practice would be stopped. The latter added that the cor-

poration's equipment for coping with this question had been improved recently and that the public would be assured of full weight not only in coal but in all other commodities. The dealers re-asserted that they were not responsible but if anything, lost in quantity in the redistribution of coal from their bunkers to the consumers.

That residences in the west should be constructed hereafter with provision for delivery in bulk of coal, wood, and other fuels was a suggestion receiving unanimous endorsation.

That combines formed to keep up prices should be dissolved was not disputed although the dealers said that their organization since declared *non est*, was not for that purpose but was designed to promote efficiently in distribution by the interchange of ideas and general co-operation.

That operators should be compelled to supply coal to any person demanding a quantity not less than 40 tons was stoutly opposed. This, it was said, would lead to a crop of "snow-birds"—irresponsible dealers peddling from hand to mouth only in the winter, would discourage the storing of quantities of coal by regular dealers, and might result in a dangerous shortage of fuel at a time when it would be essential to householders.

That recommendations 11, 12, and 13 were not controversial. There was no doubt that there should be less waste of coal by-products and if study would have that effect it was desirable. It was equally true that the greater use of pulverized coal would be an advantage but there were problems, at present apparently insuperable, connected with its general use for domestic and industrial purposes. Too expensive a plant was required for its use under ordinary average conditions. However the time might come when it would be more commonly utilized. The B. C. Sugar Refinery Co. Vancouver, now used it as a fuel, but it was exceptional, the plant being a large one and the facilities for burning complete. As for the reduction of freight rates, both by rail and water, from Nanaimo and other coal centres it was felt that anything that might be done to that end would be beneficial, but little hope was held out of accomplishment.

That standard sizes of coal should be established officially was a suggestion that did not receive support. The concensus of opinion was that any further segregation and sorting of the coal mined for the purpose of marketing would but have the effect of increasing retail quotations. Thomas Graham, general superintendent of the Canadian Collieries, explained that to make another size of domestic coal would cost his Company at one mine $50,000, which amount would have to be added to the cost. He told of screens having been installed at the Western Fuel Co., Nanaimo, for the production of an "egg" coal which coal never became popular. Hon. Wm. Sloan, the Minister, declared himself as opposed to the proposal. In Nanaimo he received for years ordinary "run-of-mine" coal and always found it satisfactory. He advocated the "pushing" by the dealers of "run-of-scow" coal, which was a high-class lump, in every respect suitable for domestic purposes. This, it was agreed, could be sold for $1 a ton cheaper than the "lump" coal now retailed, which is put over the screens by the dealers after it is taken from the scows. The dealers undertook to undertake an organized advertising campaign with a view to persuading the public to give this coal a trial.

That a set of scales should be placed on every delivery wagon or truck was ridiculed and passed over as being impracticable.

Announcement was made shortly that the Board of Railway Commissioners of Canada had issued an order providing for a 10 per cent reduction on coal shipments within the three prairie provinces, Alberta, Saskatchewan and Manitoba. This concession is to obtain only for the summer months—June 1st to August 31st.

Hon. Wm. Sloan, Minister of Mines, has entered a vigorous protest on behalf of the eastern British Columbia Collieries who thus are placed at a disadvantage in shipping to the Canadian prairie market. He pointed out that the Crow's Nest Pass Coal Co. and the Corbin Coal & Coke Co. are situated in District 18, U.M.W. of A., which comprises the eastern provincial coal fields and those of Alberta, that they are under the jurisdiction of W. H. Armstrong, Dominion Director of Coal Operations; and that they depend practically upon the same markets as do the collieries of the immediately adjacent coal fields of the Province of Alberta. It also was explained that in 1920 they shipped into the Winnipeg market 26,000 tons of coal and 2500 tons of coke.

In his reply F. B. Carvell, Chief Commission of the Railway Board, said that only a small amount of coal went into the prairies from British Columbia, that most of it was used largely for steam purposes and would not be stored in great quantities, and that the Board's object was to force the storing of coal during the summer months, thus releasing railway equipment for the moving of crops in the Autumn.

This was answered by Mr. Sloan by the statement that over 40,000 tons of eastern British Columbia coal went into the middle Canadian provinces in 1920 from the collieries of the Crow's Nest Pass Coal Co. alone and that this year's shipments, given favorable freight rates, would amount to over 75,000 tons; that the larger producers of the Province of Alberta operate steam-coal mines while the British Columbia Collieries are the only other mines shipping into the market covered by the Board's Order; and that it was clear that the stated object of the Order would not be realized "unless the source of the coal that is likely to be stored is given the advantage of the summer freight-rates." Mr. Sloan added that there did not appear to be much fear of the creation of a dangerous precedent "inasmuch as the British Columbia coal fields referred to are very little further west than those in Alberta that will be benefitted, and also for the reason that the more westerly collieries already are paying the higher freight-rates imposed because of their greater distance from the market."

The Board has again been asked to enlarge its Order to take in eastern British Columbia coal fields but as yet nothing further has been heard as to its attitude.

There has been considerable activity in connection with the development of coal measures along the line of the Grand Trunk Pacific Railway, anticipating, no doubt, the growth of a considerable domestic market, as well as bunkering trade, in the Port of Prince Rupert. The Telkwa Collieries, which have been working on a small scale, have not been producing for some months but are expected to re-open before the end of the summer. J. M. Gillespie is opening some measures on what is known as the Aveling

Property in the same locality. A road and bridge has been constructed to permit access to the railway and there is no doubt that coal will be shipped in some quantity to the Coast from this source. The Fraser Lake Collieries, Ltd., also are sinking a shaft on a coal seam situated on the shore of Fraser Lake. They have a good-quality bituminous coal. The Company has not yet obtained title to the land because of the present provincial reserve on coal but have complied with all the legal requirements, ordinarily called for, and expect that the reserve will be lifted.

OCCASIONAL NOTES

By Our TORONTO CORRESPONDENT.

At present the mining industry of Ontario looks to its gold properties in the North as its backbone. Most of its other mining properties are not paying and hence are for the time being, liabilities. At any rate, they are on the liability side. However, it is necessary to keep them in shape in order that they may produce revenue in the future. But there is no revenue to be got from them immediately.

One had hoped that the Ontario Government would have done something to encourage the mining industry. But it has done practically nothing. Everything is being done to encourage the farmers. They get help from the State in the shape of special railway rates to agricultural laborers. Prospectors and others interested in the mining industry need, at the moment, as much encouragement as anybody else—but no special rates for them! This is all wrong. Those concerned in the mining industry need to be cheered on as much as possible by both the Dominion and the Ontario Governments, and nothing to that end should be left undone by either.

The spokesmen for the present Ontario Government are never tired of expatiating on the beauty of life on the farm. But judged by any and by every standard, the worker in the mine has a far better time than the average hired man on the farm. The latter's time is not always a bed of roses; if one has to judge of it from a verse of a poem which the present writer has received from a hired man on an Ontario farm, and which professes to be descriptive of the life of the aveage farm help. The verse runs:

"Buck up when the clock strike five,
And yon wake on your small, hard bed;
One half of you just alive,
And the other half nearly dead.
Thirty minutes your "dinner hour,"
And but half of that time to sup;
Oh! in scorching sun or in drenching shower,
'Tis buck up for your life, buck up!"

The worker in a mine has better wages, and much shorter hours, he is better housed, better fed, has more facilities for recreation, better schooling for his children, and is better cared for generally than any hired man on a farm. But this is a side of mining that is quite insufficiently considered, and quite inadequately appreciated, by the general public. In fact, the general public knows very little of the exceedingly comfortable and pleasant conditions under which mining operations are carried on at the present day—at all events, in Ontario. There seems to be a prejudice against the occupation of the miner — a prejudice which probably survives from centuries long past when mining was the work of slaves.

This prejudice is totally unwarrantable today. The shaft that takes men down into and up from a mine is as comfortable and convenient as an office elevator. The work is steady and easy. The worker sets up a drill and then sits down and watches it do the work. If it goes out of repair, he must be able to make a simple repair. The shovelling is not as hard as shovelling on a street or farm. The machinery work is easy and pleasant and is performed under comfortable conditions. For all laborious work is done by machinery. Plenty of fresh air is supplied. The temperature is never too hot or too cold.

In fact, conditions for labor in Ontario mines are altogether ideal. There is no more danger to be found in working in them than is to be encountered from the traffic at the corner of King and Yonge streets, Toronto. In ninety-nine cases out of a hundred, the man who gets killed in a mine, gets killed by reason of his own carelessness or default. There is very little danger in the work so long as a man exercises proper care.

OLD-TIME COAL WORKINGS.

In the course of coal-getting at a number of pits which "strike" miners have sunk to work an outcrop coal seam on the Wrightington Estate, Shevington Vale, near Wigan, some old-time colliery workings, which penetrate long distances underground, have been discovered. The workings date back further than living memory, but the Liverpool Daily Post says that an aged native of Wrightington, the grandfather of the present agent of the Wrightington estate, who died fifteen years ago at the age of ninety years, had recollections of the seam being worked in his childhood days over a hundred years ago. This is borne out by an interesting relic, in the shape of a "Liverpool halfpenny," which has been found by the men in the long-abandoned workings. The coin which bears the date of 1791, would seem to indicate that this early Lancashire colliery was working 130 years ago, and it is recalled that before the days of railways, a wagon road, traces of which were formerly to be seen, ran from the site of the forgotten coal mine to the Leeds and Liverpool Canal, which is not far distant, and the coal could thus, prior to the railway era, be transported by water to Liverpool, Manchester, Leeds, and other towns by the canal. The "Liverpool halfpenny," discovered in the underground, after the lapse of over a century bears the representation of a sailing ship in full sail, and is in a good state of preservation. The miners on entering the old workings found plenty of coal awaiting to be got in the coal pillars which their predecessors of more than a hundred years ago had left to support the upper strata of surface soil. Thousands of tons of coal of excellent quality have been cut from the seam, which is about five feet thick, being the Arley Mine outcrop. Workings were started in the hillside and in the woods and a two-acre field was honeycombed with miniature pits from which the fuel was obtained. In one place the men excavated the seam from underneath a clump of beech trees to such an extent that one of the trees tilted over.

"Science and Art of Mining."

BOOK REVIEW.

FIELD MAPPING FOR THE OIL GEOLOGIST. G. A. Warner. 4¼ by 7 ins. 143 pp. Fabrikoid binding, pocket size. Price $2.50. John Wiley & Sons, New York. 15 shillings, London, Chapman & Gall.

The author of this little handbook is field geologist for the Empire Gas & Fuel Company of Bartlesville, Oklahoma. While the geological conditions under which petroleum may be expected to occur are reviewed in a brief but very effective manner, the book is really a strictly limited treatise on field surveying and topographical mapping as developed in practice to suit the requirements of oil mining, and is evidently compiled from personal experience in the field. A number of surveying tables are appended, and typical rock sections of the better-known oilfields in the United States are given. To those who have to undertake mapping of an undrilled oilfield the treatise contains many valuable practical hints.

FIELD METHODS IN PETROLEUM GEOLOGY. Cox, Dake and Muilenburg. 5 by 7½ inches 305 pp. with tables and Index. Fabrikoid Binding. Mc.Graw-Hill Book Co., New York and London.

This work discusses the minutiae of field procedure, as applied to the highly specialised work of oil geology, and is written for those who have at least moderate familiarity with the fundamental principles of geology, surveying and mathematics, including at least trigonometry. The introduction summarises what is known of petroleum occurrence. Following chapters describe field instruments and their uses, field procedure, and the geological criteria used in correlating beds and identifying structure. The authors are or have been all connected with the Department of Geology in the Missouri School of Mines & Metallurgy, at Rolla, Mo. A glossary is appended, and a number of surveying tables.

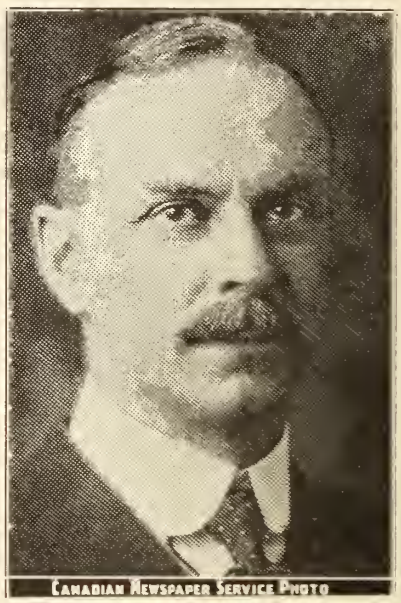
OIL LAND DEVELOPMENT & VALUATION. R. P. Mc. Laughlin, formerly State Oil and Gas Supervisor of California. 200 pp. by 5 by 7½ ins. Fabrikoid binding, $3.00. Mc. Graw-Hill Book Co., New York & London.

The author writes from experience in California, which leads him to believe that the necessity for careful and systematic development and conservation of oil deposits has not been generally recognised. Well-drilling, and questions of repairing, deepening and abandoning wells are dealt with. The extent and character of the information that should be assembled and recorded in oil production is indicated. The factors determining the value of oil lands are fully gone into in the concluding chapter. The book is well illustrated and contains many graphic charts and maps. The book seems to have real practical value. It does not discuss oil geology, but is confined to consideration of the steps necessary for the full and proper development of lands which have been determined to be oil-bearing.

ENGINEERING EQUIPMENT COMPANY OF MONTREAL.

The Engineering Equipment Company, Limited, Sales Engineers, Montreal, have recently moved from 263 St. James Street to more commodious quarters in the New Birks Building, Phillips Square.

This firm is composed of men well known in the engineering industry and is specializing in mining, contracting and industrial machinery. They have been fortunate in securing selling rights in Canada from some of the leading manufacturers of mining equipment in Great Britain and the United States. They are specially handling air-compressors, rock-drills, pneumatic tools, hoists and pumps.



Mr. Norman M. Campbell.

The officials of the Company include:

Norman M. Campbell, Managing Director of the General Combustion Company, Limited, and for many years General Sales Manager of the Canadian Ingersoll-Rand Company. Mr. Campbell is well known to both the Mining and Industrial Community.

Mr. Samuel Seaver, formerly Canadian Sales Manager for Sullivan Machinery Company and Canadian Rock Drill Co., equally well known to the Canadian Mining Industry.

Mr. F. H. McKechnie, formerly associated with McKechnie and McLaren, Sales Engineers, Montreal.

Mr. Samuel Seaver.

Mr. Percival J. Woolf, late Manager of the Duluth, Minn., office of the General Electric Company and for some time associated with the Chicago Pneumatic Tool Company.

The Company has recently opened a Pacific Coast Office at 60 Credit Foncier Building, Vancouver, B.C., in charge of Mr. J. N. Bell, for many years in charge of Canadian Ingersoll-Rand Company's work on the Coast. They have also concluded arrangements for the opening of a branch office in Winnipeg to handle the middle-West territory.

COPPER IN NOTRE DAME BAY, NEWFOUNDLAND.

The purchasers of copper areas in Little Bay, Notre Dame Bay, Newfoundland, formerly owned by W. A. Mackay, of North Sydney, N.S., have engaged the Sudbury Diamond Drill Company to drill the property, and S. J. Fitzgerald, president of the Sudbury Company, recently passed through North Sydney on his way to Newfoundland. The present shaft on the mine is down 1,200 feet, following a vein of high-grade ore which is stated to have run from seven to fifteen per cent. copper. There is said to be a large quantity of low-grade ore available, some of which is piled in a surface dump, and is amenable to modern treatment methods at a profit.

The Ontario Government railway, Temiskaming and Northern Ontario, carries four times as much mine products as farm products. The railroad was built chiefly to open up farming lands; but it has derived most of its revenue from the mining industry which resulted from its construction.

Owing to the increased activities and extension into a fully equipped engineering works manufacturing all classes of steel plate work and handling mechanical repairs of every description and also boiler repairs, the St. Lawrence Welding Company have, in order to make their name more representative of the field they are covering, changed their name to St. Lawrence Welding & Engineering Works, Ltd. No change will take place in the personnel of the firm. A. M. Barry, Vice-President and General Manager, remains in active charge. The head office and works are located at 138-140 Inspector St., Montreal.

The "Journal" for April 1st last contained photographs illustrating progressive destruction of a portion of the Carboniferous strata near Glace Bay, Cape Breton Island, being an addition to the series of views shown in the issue of 28th May 1920. By courtesy of Mr. B. A. L. Huntsman we are enabled to show a near view of the only remaining portion of the sandstone spur.

LIGHT RAILWAYS IN THE NORTH.

Relative Merits of Narrow-Gauge vs. Standard-Gauge Lines.

By J. A. McRAE, Cobalt.

The proposed construction of light railways to the outstanding mining areas of Northern Ontario is meeting with general support in all the districts which it is proposed to serve. Mining, lumbering and agricultural industries promise to receive added impetus as a result of being given much-needed rail transportation facilities.

There has recently been more or less discussion relative to the question as to whether narrow-gauge or standard-gauge would be the more suitable. The promoters of the project appear to have set their minds upon narrow-gauge lines such as were used in France for transportation of troops, munitions and supplies behind the fighting lines. Col. R. P. Rogers who is in charge of construction is a strong advocate of the narrow-gauge system.

Without any attempt to criticise, the writer has secured what information possible to gather hastily in support of a standard light railway, and submits the following as a suggestion which might receive the attention of the promoters of the Northern Light Railway Company.

Some Objections to Narrow Gauge.

In the first place, the construction of narrow-gauge lines will necessitate the transhipment of all freight and passengers at the point or points of junction with the standard railways. Secondly, the equipment used on narrow-gauge lines will be entirely useless on the standard mainlines and none of the standard equipment will be of use on the narrow-gauge lines. So much for the objectionable features of building a railway of a different gauge to those already in operation through this country. It presents the entire absence of desirable flexibility.

A Standard-Gauge Light Line.

There are many factors which appear to be in favor of the construction of a standard-gauge light line. The writer has enquired quite extensively into the subject, and some of the favorable features are these: The construction of a standard-gauge light line would entail very little more expenditure than the narrow-gauge line, perhaps even less for the reason that a good deal of the lighter rolling stock along the line of construction without the necessity of transhipment. The huge standard locomotives would, of course, be entirely too heavy to travel over the 56-pound rail which it is proposed to use. Further, the light road-bed which the estimated cost of around $15,000 a mile will provide would not allow these big locomotives to travel over the line. It is apparently for this reason that the 8 or 10-ton oil-burning locomotive has been selected, as best suited to haul the trains over the light line.

Therefore, to build light lines at the moderate cost estimated and keep to the standard-gauge, without using the heavy steam-locomotive, is the problem. The oil-burning locomotive would be employed at the sacrifice of the uniform gauge which is so desirable, and the one solution seems to be the employment of railroad motor-cars which have already been operated successfully on standard gauge lines, and which are cheaper than the oil-burning engine.

Case in Point.

According to T. J. Lee, vice-president and general manager of the Palatine, Lake Zurich and Wauconda Railroad Company, at Palatine, Illinois, where a railroad motor-car of the suggested type is in operation, it would appear as though the results achieved would commend the method to the promoters of this light line through Northern Ontario.

Costs Only 18 Cents Per Running Mile.

The cost of operating this railway motor-car is approximately eighteen cents per mile. This is made up of 2 cents for depreciation, 2 cents for repairs, insurance and so on, 7 cents for gasoline and oil, and 6½ cents for motorman's pay. Mr. Lee declares such a railroad motor-car in the passenger service will easily handle two trailers which will seat 40 passengers each

and accommodate a maximum of 100 people during rush hours. One of these cars in use on the line mentioned has handled 44 gross tons and pulled the load over a seven percent grade. It has also been found that the car has been useful in handling cars at terminals where a great deal of shunting is required and where as high as four loaded standard freight-cars have been moved about in switching. Were such a car to operate on a route say Elk Lake to Gowganda at 18 cents per mile, the round trip of 54 miles would cost just $9.72, which would be distributed over anything from 35 to 45 tons of freight. There would, of course, be the added cost of receiving and clearing the freight as well as the cost of administration and depreciation of the line itself. But all this appears small when compared with the expense heretofore of about $30 for each ton handled by teams. At this rate the cost of hauling 45 tons to Gowganda with teams amounts to $1,350, which tonnage could be handled in a single trip by the cheaply-operated railway motor-car.

Had such a line been operated during the past ten years to the centre of activity in the Gowganda district, the mining industry of that field would probably have attained much greater proportions. Such a line could have been built with the money which the Ontario Government has spent on the poor wagon-road which now serves the field, and this rail transportation would have saved many hundreds of thousands of dollars for exploration and development work which has gone into great waste incurred as a result of having to employ the inefficient wagon with a mere handful of material each trip.

EDITORIAL

OIL POSSIBILITIES IN THE PASQUIA HILLS, MAN.

Dr. Wallace has been good enough to forward a copy of his preliminary report on the search for oil in the Pasquia Hills district of Manitoba, which bears upon criticisms made in these columns in last week's issue of the statements and implications contained in the prospectus of the Pas Oil Development & Exploration Company. "While the possibility of the presence of oil pools cannot be excluded in any formation where the rocks contain oil, as in the Pasquia Hills, the evidences on the field would indicate that such a possibility is somewhat remote in the Pasquia Hills district". This is Dr. Wallace's conclusion regarding the country which includes the Turnberry areas, and emphasises the exaggerated character of the promises held out to those who invest money with the hope of vast returns from the drilling of these areas. Men who put their money into a drilling project of this kind, with the deliberate desire to test a territory for oil, are, if they can afford it, men whose enterprise is to be commended as adding to general knowledge, and holding out some hopes of personal profit. It is doubtful, however, if the average reader of the Manitoba "Free Press", guided by such an advertisement as that we have mentioned, would invest his money on any such understanding. This is of course an excellent explanation of the oil-promoter's deliberately misleading method of advertising, but it is certainly no justification of the method, and it is, moreover, one that should not be employed by men who desire to keep their reputations unclouded.

THE SULLIVAN MINE.

The chequered history of the Sullivan Mine at Kimberley, B. C., is described in this issue by Mr. Alexander Gray, from its inauspicious beginnings to the present time, when with the treatment processes developed by unremitting research, the undoubted presence of a very large ore-body makes it possible to class the Sullivan Mine in the first rank.

In view of the tonnages of ore and their metal content, Mr. Gray's statement that the public viewpoint of the Sullivan mine has been out of focus seems warranted. Temporary depression of metal markets does not, in the long run, impair the value of so vast a reserve of metals as the Sullivan property is believed to contain.

The importance of the metallurgical chemist is the most striking lesson of the Sullivan Mine. Insofar as the chemist has made the Sullivan ore available for merchandising, he has made the mine. It is such definite incidents as this that arouses the sardonic mirth of mining men when they read of the Senate killing a proposed research institute for reasons of economy. Many of Canada's metal occurrences are today in similar position to that of the Sullivan orebody before its profitable treatment had been worked out. The solution of such problems does not come by luck or fortuitously. They have to be worked out, and there is no royal road to the desired goal. It is fortunate that Canada has some large and enterprising corporations that can to some extent make up for the deficiencies of our parliamentary leaders, by ability to tackle national problems with almost as wide a grasp of national needs as that which should imbue the ideal statesmen.

A report by a competent geologist upon the probable origin and extent of the orebody at the Sullivan Mine would be of much scientific interest, and would seem a good thing for the Consolidated Mining & Smelting Company to have in any case.

SIR ROBERT HADFIELD, FRITZ MEDALLIST.

It was a happy thought of the federated engineering societies of the United States to send the Fritz Medal to London by the hands of a representative group of American engineers for presentation to Sir Robert Hadfield; and in thus signally honouring this eminent metallurgist, and, as is specifically stated, honouring the engineers of Great Britain for their engineering achievments during the war, our neighbours have given Canadian engineers reason for reflected pleasure over this altogether happily conceived incident.

Sir Robert Hadfield is not only the directing head of a steel company with an enviable reputation for business acumen and probity, but he is a scientist whose

work has profoundly affected all the economic uses of steel. Manganese steel, low hysteresis steel for electrical uses and researches into the nature of sound steel-ingots, are some of the better-known instances of his research work. In his relations with workmen Sir Robert has been in advance of the views of other employers, and Hadfield's was always a good shop to work in.

The technical education of workers in the iron and steel industries has been more than a hobby of Sir Robert, and it is fitting that the most coveted honour in the gift of American technologists should be given to the English engineer who has done probably more than any other living Briton to energise the commerce of iron and steel, and to apply science to steel-making in Britain.

TERMS OF SETTLEMENT OF BRITISH COAL STRIKE.

The British coal-strike, as forecasted, has followed the precedent of 1893 and lasted three months, which appears to be about as long as Britain can go without coal without general breakdown of civilized amenities. The country must have been vastly relieved by the compromise which permits the miners to go back to work, although when the terms of settlement are soberly examined, it will be seen that the social revolution in Britain, while proceeding in a constitutional and peaceful manner, is nevertheless proceeding apace.

The British coal-miner, through the mistaken policies of his chosen leaders, innocently enough on his part no doubt, attempted to bell the cat at the bidding of the International Miners Congress held at Geneva in 1920. This congress definitely agreed upon a policy of enforcing "nationalization" of the coal-mines of the world, and the British leaders undertook to lead the vanguard of attack upon private ownership, expecting, there can be little doubt, to receive the backing of the American and European unions that awarded this dubious honour to the British Miners' Federation. Of course they did not get it, nor did they receive the support in their "direct action" policy from other trades-unions which was definitely asked, and as definitely expected. British labour looked over the precipice to which the miners' leaders had led them, and decided not to jump. The miners themselves have been fearfully misled, and unfair advantage has been taken of their traditional loyalty and tenacity. The very qualities which made the British miner the best of all possible soldiers during the War, and endeared him to all that knew him as a fighting man, except the enemy, caused him to follow the course decided upon by his union leaders, although their aims were nebulous and revolutionary in their very essence. The abstention of many miners from voting at the ballot which shortly preceded the settlement was really an expression of pique because the executive of the Federation did not indicate its own views, or advise the men how they should vote in their own best interest. The men's feeling was that the leaders, having got the union into a bad mess, should get them out; and while the attempt of the leaders to shift responsibility for the strike was resented, nevertheless the miners did not break away from what they felt was faulty guidance. The general abstention of the miners from violence was expected by those who knew them intimately. Another feature which had a good deal to do with prolongation of the strike was the fact that the British miner has had an uninterrupted opportunity to work for seven years and he really did not mind a holiday in the fine weather.

The major significance of the failure of the miners' leaders to enforce their proposal of nationalization of the industry and a national wage pool, is that the Cabinet resisted, and the public supported it against an attempt to force such preferential treatment of a section of workers as would have inflicted definite injury upon the community at large. This preferential treatment was demanded, not as a right, but because the coal-miner thought he could get it. The apathy of the other trades-unions arose from a knowledge that the high cost of coal, associated with the favourable and partial treatment accorded the miner, was killing industry and taking the bread out of the mouths of the other workers. There was also a subconscious jealousy of the comparatively higher remuneration and the shorter hours of labour that the miner has been able to obtain which was aggravated in the other workers by the personal inconvenience of the coal shortage. The miners' leaders have met well-merited defeat of their dangerous policies, and they will probably be made to realise that fact, as on them personally, more than on the miners individually, is the public placing the onus of calling and unnecessarily continuing a strike that never had the slightest justification.

At the same time, examination of the terms of settlement will show that they are merely temporary, being terminable at three months notice; and that they also contain features quite novel to British procedure, inasmuch as they include a subsidy from the government, and a national authority for the division of any profits accruing over and above the standard percentage of profits allowed by existing legislation to the mine owners. That is to say, the settlement approves the principle that capital should not earn more than a specified return, and that anything above that shall go in major portion (in this case to the extent of 83 per cent) to the workers.

The British Government has also been empowered to acquire for the State all the coal deposits in Britain, and to this extent the ownership of the coal-seams is already "nationalised". Now private profits have, by mutual agreement of employers and workers, been confiscated for the benefit of the workers. The fly in the ointment is that the trade outlook does not promise

any profits in the mining of coal in the near future, but surely the miners can claim that they have enforced in Britain several entirely new social laws, and have gained acceptance of some principles affecting private ownership of natural resources and division of the profits accruing from their exploitation that are not yet included in the written or unwritten constitutions of North America?

The whole arrangement is predicated on a continuance of large profits in the coal-mining business, and yet it is very generally agreed that a revival of industry in Britain is only possible through a drastic reduction in the price of coal. The two things are not compatible, and it will be interesting to note how the national coal authority will take care of financial losses in coal-mine operation. In view of these uncertainties of the future it is understandable why the arrangement is terminable at short notice, and why Mr. Lloyd George should call the terms of settlement "a great and promising experiment". The greatness of the experiment is not hidden, but the character of its promise only the future may disclose.

A CARBON-MONOXIDE MASK.

The development of a carbon-monoxide mask is announced from the United States and if this device should prove capable of protecting a wearer against deadly percentages of this insidious gas, it will find many industrial uses, particularly in blast-furnace works, and in connection with various forms of coal-gas distillation. Such a mask will of course be of no value where the atmosphere to be respired, in addition to containing an actively poisonous gas like monoxide, is deficient in oxygen. The possession of a mask protecting men against comparatively small percentages of monoxide would in many cases have enabled men to escape from "after-damp" poisoning after coal-mine explosions, as in some cases the atmosphere that killed the victims of such explosions did not put out the light of oil-lamps. The wave of monoxide-carrying air in many instances, is of short duration, and only a short distance of poisonous air would in these instances have had to be traversed to reach good air. There would seem to be possibilities of a self-rescue apparatus in the carbon-monoxide mask that one may hope will be further developed.

Monoxide, in addition to being a quick and sure poison in percentages exceeding half of one per cent in respired air, is in smaller quantities a cumulative poison, and if men are constantly exposed thereto, deterioration of the blood constituents supervenes and becomes incapable of remedy. Where there is likelihood of the presence of small quantities of escaping monoxide, as around blast furnaces and gas producers, the use of the protective mask now available seem indicated.

GAS MASK FOR CARBON MONOXIDE PERFECTED.

The first public demonstration of the gas mask for protection against carbon monoxide, manufactured by the Mine Safety Appliances Company, Pittsburgh, Pa., and in which is utilized the special mixture called Hopcalite, developed by the U. S. Bureau of Mines and Chemical Warfare Service, U. S. Army, was given the afternoon of May 26th in the special smoke room of the United States Bureau of Mines, Pittsburg, Pa. The U. S. Bureau of Mines, in its research of various types of gas masks, including the carbon monoxide mask, has a very large smoke roof especially adapted for testing purposes and the courtesy of the use of this smoke room was extended for this demonstration. In addition the first public demonstration was also given of the U. S. Bureau of Mines gas mask for city firemen, also containing Hopcalite, for carbon monoxide protection.

In this test two men entered the smoke room which contained 1 per cent carbon monoxide gas in the air. of the atmosphere. The canary bird collapsed in to indicate to the observers the poisonous nature One of the men carried a canary bird into the room 45 seconds, and it was immediately removed to fresh air where it was revived with oxygen.

Tests were also frequently made with the M-S-A Carbon Monoxide Detector to show the observers the strength of the gas. The wearers of the mask remained in the atmosphere for 30 minutes doing vigorous work part of the time, and experienced no ill effects whatever from the poisonous carbon monoxide gas. The gas masks gave perfect protection through the entire period of the test.

The carbon monoxide gas mask is of special interest to iron and steel industries, fire departments, industries using gas producers, illuminating gas plants, coal and metal mines and to all other persons who are apt to encounter carbon monoxide gas in their work.

Carbon monoxide occurs frequently in dangerous quantities around blast furnaces, gas producers, etc., and is a constant hazard because of its poisonous nature. A simple protective device, light in weight, devoid of all complicated mechanisms has long been needed for the protection of men engaged in such work.

While the gas mask used will give protection in higher percentages of carbon monoxide, 1 per cent of carbon monoxide will kill a man in a few minutes time. The percentage found in working places where there is ventilation usually amounts to considerably less than 1 per cent.

One-tenth of one per cent of carbon monoxide, however, will seriously affect a man who is working and therefore breathing hard in about one half hour's time, while two-tenths will affect him seriously in about 10 minutes' time.

The carbon monoxide gas mask is therefore of great importance to the country's industries and it is important to note that a splendid accomplishment of the U. S. Bureau of Mines and Chemical Warfare Service in their work on poisonous gases during the War has been adapted to a most important industrial use.

The Sullivan Mine

Canada's Greatest Zinc-Lead Mine.
Study of the Valuable Property of the Consolidated Mining & Smelting Company, where Millions of Tons of High-grade Ore have been Developed With a Minimum of Publicity.

ALEXANDER GRAY, Montreal.

An opportunity was availed of to visit the Sullivan Mine at Kimberley, British Columbia, to ascertain the historical significance of the announcement made eleven years ago by the Managing Director of the Consolidated Mining & Smelting Company of Canada, to his colleagues of the Board—

> "A lease has been taken upon the Sullivan Mine, near Kimberley. A royalty is paid upon all ore shipments, and the Consolidated Company has undertaken to perform $10,000 worth of development work. The mine is producing about 2,500 tons monthly of ore containing approximately, lead 18 per cent., silver 6.0 ounces per ton."

That modestly-stated fact entailed the risk of an inconsiderable amount upon properties unheard of outside the vicinity of the apostolic Mark Creek. Consolidated directors had no wilful intent to soft-pedal the transaction. They offered not a word in self-defense. About all anyone other than the trail-birds of those mineral-laden mountains knew of the Sullivan was that it was located upon Sullivan Hill, not far from Cranbrook on the Crow's Nest division of the Canadian Pacific Railway, was skirted by Sullivan Creek; that a specialist in townsites had duly incorporated Kimberley—for what reason never has been explained.

Sullivan suggested the "Big Fellow"—that superman—the Boston blacksmith who knocked out Ryan—who possessed the punch. Appropriately, also, in due course, a Tipperary claim was included in the Sullivan areas—perhaps Sullivan was a "fighting Tip"—or maybe a certain Baron who reveres Tipperary had something to do with it. At any rate, there was a Milesian flavor about the Sullivan—and it was in order to have a Galore claim—another named Kathleen—and for a Sweeney subsequently to make sheep's eyes at the properties without realizing he was borrowing trouble.

Sure enough the layout was Irish—and there were "bulls" in it, as events disclosed. Naturally Sullivan subordinated Smith, one of his partners in the staking. Both were eliminated by processes familiar to prospectors who are ahead of their time. When nobody possessed of more money and patience than existed thereabouts in those days could continue flirtations with fortune, it devolved upon the Consolidated Mining & Smelting Company to hesitatingly take the lease and bond on the Sullivan—and to begrudgingly assume the obligation to expend $10,000. That the Consolidated directors and management lived up to their contract, goes without saying. They did 375 feet of new development work in the year ending June 30, 1910—bringing the total development to 4,575 feet. A trifle more than a foot a day was the extent of the confidence displayed in the properties, which in that eventful year yielded:

Tons of Ore	6,704
Ozs. Silver	46,196
Pds. Lead	2,451,758
Value	$110,790

That was not a bad start. To June 1910, therefore, reckoning back to 1894, two years after Sullivan, Smith, and their mate drove in their stakes, the Sullivan Mine had produced 92,110 tons of ore: 781,993 ounces of silver; 38,653,397 lbs of lead—the gross value of the whole being $1,931,226.

Probably that was why the Directors discreetly refrained from recording a plea in justification of their "undertaking to perform $10,000 worth of development work," and to pay a royalty on what was shipped. They could have exculpated themselves by referring to the outputting records of the mine—but Messrs. Matthews, two of the inevitable Oslers, Charles R. Hosmer, F. P. Buck and Managing Director Aldridge—five of whom have lived to appreciate the wisdom of their action—felt it was incumbent upon them to make haste slowly. A minor fraction of over a foot a day exclusive of 534 feet of diamond drilling—was all they could afford to do, in the circumstances. The managing director perfunctorily reported progress at the end of the year, although he did not apologize for having exceeded the speed limit of $10,000 as prescribed. Actually, the management spent $18,774.73 for mining, smelting and general expense on account of the Sullivan; $7,057.51 going toward development. Nor were the lessors faring so badly. They took their royalty of the 6,704 tons of lead-silver ore reported — and they did not demur to it with silver at 51.948 cents and lead bobbing around £13 a-ton. Evidently Consolidated directors were reassured and saw a little light on the situation, for they sanctioned 1,798 feet of further development and 8,798 feet of diamond-driling in 1910-11 — which had something to do with what happened to the output of the Sullivan in that year:

Ore	Tons	34,065
Silver	Ounces	258,376
Lead	Lbs.	14,187,354
Gross Value	$	635,223

Even then the management was not overconfident. Taking the 1910-11 output, general manager R. H. Stewart solemnly wrote that "the loss of the St. Eugene tonnage has been serious, but will be partly overcome by the operation of the Sullivan, in which the mineral-bearing area has not been thoroughly prospected". Apparently it would take more than that year to "thoroughly prospect" the Sullivan section. It will take several years yet to reach that objective. Consequently Consolidated directors indulged in no jubilatings when they briefly made this allusion in 1910-11 to Mr. Stewart's report:

> "During the year the company has acquired a majority of the stock of the Fort Steele Mining and Smelting Company, Ltd., owner of the Sullivan Mine. The lease to the Consolidated Company expired on June 30th., and the Fort Steele Company is now operating the property and shipping ore to Trail. The mine is producing between 2,500 and 3,000 tons of ore

containing approximately, lead 20 per cent, silver, 6.6 ounces."

Concurrently and incidentally the Consolidated directors casually announced the expenditure of $217,613.90 — most of it "in purchasing stock and bonds of the Fort Steele Mining and Smelting Company, and the Sullivan Mining Company, owning the Sullivan Mine at Kimberley".

So, a decade ago, the Consolidated Company wished the Sullivan onto itself — salvaged it, rather — and promptly disinherited the makeshift Fort Steele Smelter Company. Then the Sullivan had contributed 126,175 tons of ore containing 1,040,369 ounces of silver; 52,840,751 lbs. of lead — the gross value of it all being $2,566,449 — zinc being unmentionable. Besides, the Sullivan Mine had 2.87 miles of workings. Consolidated sponsors must have been relieved when they had a clearer title and a better chance of procuring tonnage for the railway and treatment charges for Trail. They hardly gave a thought to the historic fact that the Sullivan was only getting its stride — nineteen years after it was staked, Sullivan having been killed, Smith being ruefully resident somewhere in the southland — and the third party to the staking being lost sight of.

During those strenuously unprofitable years, pioneers operating in that sector had invoked the benedictions of the saints by creating a Maryville — where the Fort Steele Smelter was — a St. Eugene; St. Mark, St. John and St. Matthew Creeks — not forgetting the resort to astrology by incorporating the North and Center Star. Devotees at those shrines in this manner strove to propitiate the saints. However, it takes more than fervency to make mines and money out of them. Excepting the Sullivan, the "good" things around Kimberley "died young". Across the creek dedicated to Mark, a streak of rusted rails attests that there was a tramway to North Star Mine. Near by Donald Mann cavorted with the fickle jade. Undoubtedly the district was completely canonized by pioneers. Somehow the wires got crossed. What interest was displayed by outsiders resulted adversely to Smith, who discovered that a vendor consideration paid in assessable shares was a liability he could not meet.

Never was it disputed that the Sullivan Mine was an outstanding feature. It induced the Turner, of Spokane, following to incorporate a company — the Fort Steele Mining and Smelting Company — to operate at Maryville. Charles Sweeney, and his associates, profaned or praised the saintly situation. They came to understand that while Sullivan ores were appraised in public for their silver and lead contents, recoveries were relatively ruinous. It is not material, now, that 150,000 tons of ore carrying 35 per cent lead and running well in silver, was taken from the uppermost workings of the mine. Percentages were running against complex ores in those days — and are yet for that matter, in most instances — "glory holeing", "gophering", getting after the "high spots" — and defective treatment — eventually brought the Sullivan into the lap of the Consolidated Mining and Smelting Company, where it is likely to remain. Electrochemical metallurgical processes — minerals separation by oil flotation — efficient concentration — were not far enough along to extract contained metals without discouraging losses.

Zinc-lead sulphide ores always have met with extreme penalties. Zinc in the estimation of metallurgists pertain to Gehenna and as such is as welcome to them as was "Old Nick" to German chemists when they encountered nickel. Turner and Sweeney with the Maryville smelter and Sullivan complex ores were as unhappy as were the Nichols people and Col. R. M. Thompson when they struck the nickel snag in the Sudbury nickel-copper orees — from which they could not recover clean copper. Zinc was the Nemesis of metallurgists. Hand-to-mouth miners succumbed under the burden of fines and low recoveries. The more experienced, where there was zinc to contend with, urbanely remarked: "Après vous, Alphonse", to those who fancied such complicated ores.

The average of Sullivan ores, excepting where lead predominates, always has had just sufficient silver to warrant its recovery by modern practice. Turner and Sweeney had to confess themselves disconcerted — Sullivan mineralogy was as perplexing to them as nickel was to expert copper-refiners — consequently, the only thing to do was to forego the saints and see if the Guggenheim technical staff would not take over the Sullivan Mine and its appurtenances. But Turner and Sweeney might have known that gift-bearing Greeks are given the third degree by Guggenheim scientists. Upon investigation the Guggenheims, though greatly appreciating the privilege accorded to them — and the generosity of the proponents — were unimpressed. Something of the simplicissimus kind was preferable to the representatives of the metal-market masters.

Here we have a glimpse of the psychic moment, after the 1907 financial upset, when the Consol' Company needed ore, had a more or less inefficient plant at Trail, and the Canadian Pacific would make more freight business. The St. Eugene was petering out. It is customary to rail at the Canadian Pacific now-a-days for sponsoring the Sullivan and the Consolidated Mining and Smelting Company — somewhat to the exclusion of smaller producers. To a certainty the Sullivan Mine, if pressed, is capable of exceeding existing metal-markets. The effect is obvious — but without the Sullivan the incentive to enlarge and perfect the Trail metallurgical works would be less in evidence.

Admittedly, until recently, Trail metallurgy was deficient. Between unsatisfactory recoveries, freights, and treatment charges, as well as the vagaries of metal markets — Trail all these years has had troubles it could not disclose to a policeman. In the beginning, really the Sullivan was a doubtful risk. When the mine was taken over, Manager Stewart thought it had not been "prospected", although it had produced metals to the gross value of $2,566,449. Five years later the Consolidated annual report contained these items:

	Year 1915-16	1894 to Date
Sullivan, Lead Ore	60,266 tons	
Sullivan, Zinc-Lead Ore	30,863 tons	355,537 tons

Having practically trebled the tonnage mined, the primary five-year period of Consolidated control probably increased in corresponding ratio the Sullivan credit. From $42,646,025 the Trail plant production in 1916 had mounted to $81,294,627 — to which advance the Sullivan handsomely contributed. Meanwhile, of course, the Rossland section was re-awakening; copper was in urgent demand. The necessity which knows no law and disdains scientific preconceits led to capital expenditure, research, electrolytic prac-

tice, the adoption of oil-flotation and improved concentration. That was how the Sullivan properties had to be developed and directed toward their true if troublesome destiny. Leaving out the Sullivan, and notwithstanding the revival in precious-metal mines at Rossland, where the War Eagle is yielding excellent results, the Consolidated plans for Trail works would not be so ambitious.

Once the Sullivan asserted its magnitude, the exigencies of the Great War, and urgings from Downing Street, impelled the Consolidated directors to enter upon a capital outlay which makes humorous the $10,000 risked upon the Sullivan. After deducting $278,386 for the year 1915-16, the Consolidated balance sheet showed a net increase on plant account, of $2,047,634. Improvements and extensions were made to the lead-smelter, the laboratory and the assay offices; additions were built to the mechanical department; the lead-sampling mill, crushing-plant with conveyor bins, etc; also a tube-mill for fine grinding, were provided. Details of extensions need not be elaborated. War metals were wanted. Sullivan ores were ready; their metallurgy — bothersome metallurgy — was improving. It is not denied that Trail metallurgy in this respect called for what it obtained — concentration, flotation — and the "White Coal".

On October 12, 1915, work began on the new zinc plant — which now covers an area of about nearly 200,000 square feet — notwithstanding the fears expressed as to the effect of the exhaustion of the St. Eugene. Another new departure was the sulphuric-acid plant, with lead chambers, much of the pyrite coming from the Sullivan. A hydrofluosilicic acid plant accompanied this construction. But it had to be acknowledged that —

> "The process for the production of electrolytic zinc from Sullivan and other ores has been developed under the difficulties of new plant, new process, and limited time".

Concededly, after twenty-four years had elapsed, the Consolidated Company continued to struggle with vital economies, while the copper refinery was approaching fruition, without having sufficient copper ore within the control of the company, or easily accessible. Those paroxysmal years have been misunderstood by outsiders. Not until the Fall of 1918 could the supporters of the Consolidated assert the Trail works "are now working satisfactorily and can be extended indefinitely, producing zinc of great purity. The process will be eventually reduced to a cost lower than the furnace process."

"Eventually" meant that Sullivan ores were busying the staff. Construction work had not ended. To the contrary, the zinc plant was aptly described by Mr. Warren as "the original". Electrolytic-zinc production hardly had begun in March, 1916, when the Imperial Munitions Board placed further contracts for zinc, and large additions had to be made. A great deal had been accomplished. Director Warren, though, impliedly conveyed his hope for betterments when he wrote: "Doubtless improvements in methods will be made as the operations proceed". Sullivan Mine ore in 1916 accounted for all or most of the 3,088,199 lbs. of zinc — and not a little of the 39,974,411 lbs. of lead. That was the initial zinc production — at least in quantity and purity. Blister and refined copper, acids, manganese dioxide, were forthcoming — and metallurgical manager Hamilton went further than Mr. Warren by asserting of Trail:

> "The plant now places Canada in a position to declare her independence of the world for her supply of lead, copper and zinc, all of the highest commercial purity."

To meet that horoscopic view, the Sullivan Mine was placed in the forefront. Of it, manager of mines, Archibald, in 1916 said:

> "The new lower tunnel was advanced. Development work was carried on at the old tunnel level and on the level below. Ore reserves of high-grade lead have not been maintained, but some promising zinc stopes have been opened up and considerable tonnages of low-grade lead-zinc ore developed. Additional development work is being carried on to increase the reserves of high-grade lead."

Mr. Archibald has a reputation for not over-stating. The Sullivan Mine is too comprehensive for other than measured judgment. At that writing there was a total development of 6.26 miles and in the nature of things, with varying values and widths, he was properly conservative. In point of development expense, though, the Sullivan remained secondary to the Le Roi and the Center Star. Mr. Warren was more affirmative than Mr. Archibald; for he informed the Board that:—

> "The completion of the copper refinery marks an epoch in the metallurgical history of Canada. During the War both refined copper and zinc are readily saleable for munitions purposes; after it is over, there is no reason why the entire output of these metals should not be absorbed by the Canadian metal-trades and fabricated by Canadian workmen—a condition possible only because these metals will then be available in a refined state."

Heroic and hopeful as that utterance was, commendable as Consolidated Mining & Smelting Company achievements have been, the wartime remarks of the manager director as quoted, contrast with this paragraph in his latest report of March 1921:

> "While the developments in the mines are very satisfactory, the plants and equipment in a high state of efficiency—and the improvements in metallurgical practice many—and most important—the sudden and precipitous fall in metal — prices which took place in the early Fall and continued over the end of the year has had a very serious effect on profits."

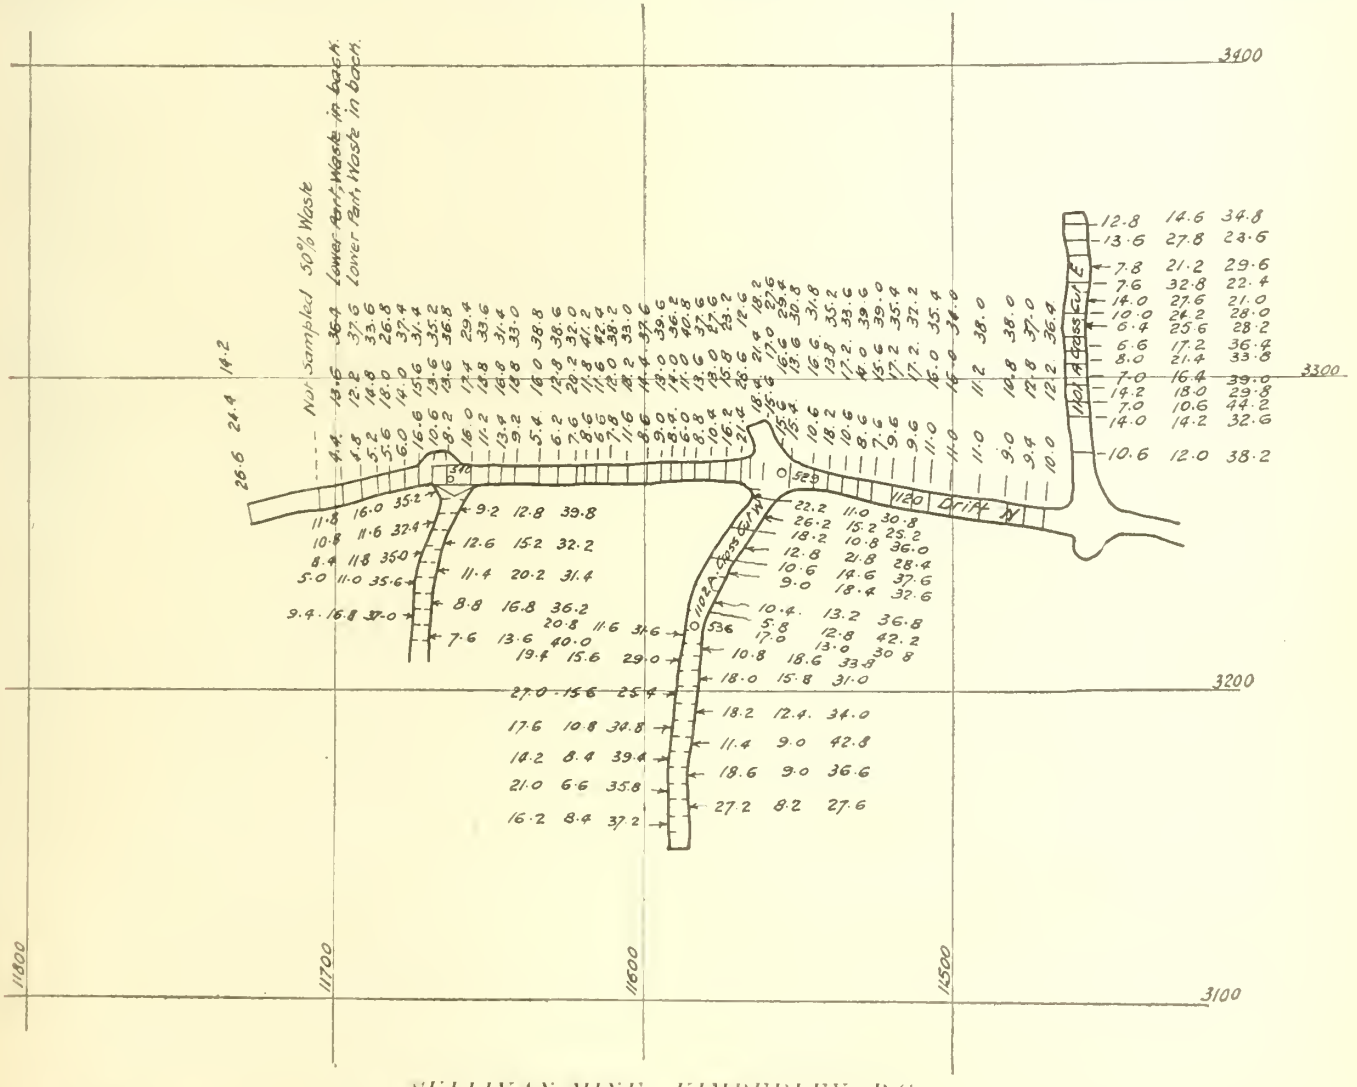
Trail shared the universal experience, plus the tribulations of special-metal producers, who had to contend with minimum demand and urgent competition, inventories and what not. The experience acquired in adversity will be beneficial when Sullivan zinc and lead in assured quantities have to command markets. Wealth stored in Sullivan ores is for circulation—not for cold storage. In December last 5,000,000 lbs of refined zinc was produced at Trail without increasing the working force. What the Sullivan Mine is disclosing was in part outlined by Mr. Warren, who said:

> "In addition to the favorable developments in the mines during 1920, since the beginning of the New Year, further important discoveries have been made in the Sullivan Mine; an extension of the workings on the 11th level has en-

countered a large orebody carrying high-grade zinc and fair lead values; but what is most significant is that diamond drilling on the bottom level of the mine has cut the high-grade lead orebody which was so profitable in the upper levels. This downward extension was located 8,700 feet from the portal of the lower tunnel."

An assay plan of the 11th level extension—where the orebody furnished a very agreeable surprise beyond a diorite or gabbro intrusive dyke—makes cheerful reading. Seemingly the orebody swung more to the north at this point. After drifting on the vein, it was crosscut, and I submit a section which the management courteously permitted me to have for the information of those who are unfamiliar with underground conditions at this extraordinary mine. In combined metals and magnitude this will bear comparison with other great mines of the kind—and with the unique Creighton Mine at Copper Cliff. Confirmation of this development on the lower level fifteen hundred feet on the incline below the upper level upon which it is being blocked out, would give the Sullivan a still larger place and enable the Consolidated Company to meet markets which might be disconcerting otherwise. Basic ores in widths necessitating pillars—and the low angle of dip of the orebody—22 degrees—are causing the management to devise ways and means whereby mucking will be done most economically. Mechanical muckers are useful. At present a drag arrangement is being tested. It takes the broken ore from the working-faces, drags it to chutes, appears to be an effective solution of the mucking problem, and a saving in handling cost that may assume importance in the disposal of a large tonnage. Every economy put into effect makes possible the utilization of lower-grade ore when the Sullivan has its own concentrator on the site selected on the premises.

With the funds and plant available Sullivan operations are all that can be reasonably expected. Whatever of banter, or jollity has entered into this review of a unique mine and its antecedents, my visit to the properties, access to the assay plans and first-hand knowledge of what has been and is happening, leaves little to conjecture. Trail metallurgy, through scientific persistence, is recording about 65 per cent. zinc product and around seventy per cent. of a lead product with a good grade of ore and the small silver content give the Consolidated a "Consolidated" status. At the moment nearly 800 tons is the daily shipment. The mine provides the heaviest traffic of the section to the Canadian Pacific. Last year it supplied 242,294 tons of zinc-lead ore, 13,214 tons of lead and 4,306 tons of



SULLIVAN MINE, KIMBERLEY, B.C.

Assay Plan showing 1120 *ft. Drift North. Figures indicate lead, zinc and iron percentages in order given. Analyses were made from average sample across face every* 5 *ft. in the drift and along the crosscut on alternate sides.*

pyrite—a grand total of 259,814 tons, as compared with 60,266 tons of lead ore and 30,863 tons of zinc-lead ore—a total of 91,129 tons in 1916. Better than a seventy per cent. product from one thousand tons per day—and more if the market requires it—will bring more than encomiums to those who are entitled to the credit for having sustained the managing director and general manager S. C. Blaylock throughout years of unremitting effort.

The relationship of the Sullivan in the matter of the total treated at Trail in 1920 is shown in the figures as given and the aggregate receipts of 592,763 tons. This comparison applies to the ores from every source treated at Trail. As affecting the Sullivan status, it needs only to be urged that 67,838 tons of that ore came from the other various properties of the Consolidated company. And that was a year of miscalculations—of depressed metal workers and high costs of freight and coal. In reality, as Mr. Warren has pointed out, the cost of producing zinc in 1920 was reduced by 40 per cent.—in which result the mining and metallurgical departments divided the honors. Flotation and concentration, hydrolytic accessories, enabled the Trail plant to handle 900 tons per day of Sullivan ore—and we have the acknowledgement of the management that "results were very much ahead of anything thought possible last year, and with the certainty of still further improvement." To the end of 1920, the Sullivan had produced 1,032,359 tons—and the mine had about nine miles of underground development.

Considering everything, the metallurgical unpreparedness, antiquity of a great deal of the surface equipment, extent of the wartime development, expansion of the mine, slump in metals and attempts of the O.B.U. to dictate to the management, it is astonishing to have the degree of efficiency in evidence. The strictest economy—not always the wisest policy where such a mine should have the most modern equipment—has been observed. Mining and tramming costs, the ore being hauled to tipples by electric motors and aerial gear, are about all that could be expected until outputting is increased. Little timbering is required, for the quartzite walls are strong and no difficulty is looked for in having the country rock stand up.

It would be interesting—and it is something the directors might think about—to have the mine and its environs carefully geologized in view of the extensions noted and changes in the character of the ore from time to time. Undoubtedly the directors have had other things in mind, but the Sullivan is one of those realities which warrant action and optimism.

The limit of the available power facilities has been reached. As an exhibit some of the machinery is informative. Pelton wheels when the weather permits, and costly coal in winter, a collection of compressors, the evidences everywhere at surface of enforced economy—excepting in the food supplied to the men at reasonable cost—form a chapter in the history of this remarkable mine.

Since the Sullivan has become one of the greatest factors in the zinc-lead markets of the world, capital expenditure upon a concentrator on the spot, the provision of all-the-year around electric power, and on plant and dwellings, is imperative in order to effect savings and promote social conditions during larger operations. Sites for the concentrator, offices and more surface works await construction. A new townsite and a number of residences are ready. Places for fraternizings and amusement are lacking, although *esprit de corps* exists throughout. Supt. Montgomery being in close touch with his staff and his men. Sullivan equipment has served its purpose. The mine and its mission have outgrown it.

Of this aspect of things, however, it is to be said that it is flattering to the board and the management that they gave precedence to the mine and the metallurgy of its ores. The upper workings at the 1,000 and 1,100-ft levels are being drawn on. The area above the 1,000-ft level is about exhausted. At 1,100 elevation an upper tunnel has been driven into Sullivan Hill for a distance of over two miles—and only two faults have been noted. Neither has had adverse effect upon the ore-body, which has been proved for about 3,300 feet in lateral extent, of varying grade and width, carrying an average of about 2 ounces of silver, and offering a zinc and lead content which the management endeavours to maintain at a shipping average of 10 per cent. lead and 18 per cent. zinc. This, of course, excludes second class ore. To make the grade some sorting is done. Where there is so much ore it is easy to ship almost any average desired. For example, a recent train of cars, the ore in which came from both the upper and lower tunnel levels, went 2.6 ozs. silver, 10.6 of lead and 18.2 zinc. It is not claimed the ore carries more than about 2 ounces of silver. Here and there, where there is a larger lead-content, the silver values are higher, but those enrichments are localized. However, the management wants more of them and expects more of them, as indicated by the statement of Mr. Warren that the high-grade lead recovered from the uppermost workings had been cut by a diamond drill at a depth considerably below the lower tunnel where there is ore 1,500 feet on the incline from what is designated as the upper tunnel.

It was in this upper tunnel, too, and at the north end, beyond a diorite or gabbro dyke, that the mine furnished a gratifying surprise. Close check is kept wherever lead predominates, for the grade improves. On what is called the sill of the Montreal stope, there is a recurrence of this richer lead and higher silver. This, and the disclosure in the diamond-drill hole, removed the necessity for conjecture as to what the ore-section proved and represents in tonnage and dollars and cents.

The Sullivan Mine has so many millions in its lead and zinc that optimistic estimates would be hazardous. To a certainty, the two tunnels, crossents, raises, stopes and exploratory drill-holes, have removed doubt—if doubt existed—regarding the tonnage in a block of first-class ore, say 1,500 ft. by 2,000 ft. by 6 ft. Conservatism does not belittle the Sullivan. There are stopes as big as those at the Creighton nickel-mine—and those are big enough for the most exacting. Clambering through several of those stopes with the quietly enthusiastic Superintendent, with their sections from 100 to 150 ft. wide and massive ore, similar in this respect to the Creighton, leaves no room for doubt as to Sullivan certainties. Not all of the tunnel-level ore-sections are in shipping ore, by any means. The mineralization in the nature of such occurrence varies. Every test thus far applied reveals exceptional quality and tonnage. I quote the results of two exploratory drill holes put up from a long raise from the lower to the upper tunnel, each hole cutting a section 40 ft. in width:

Percent Lead.	Zinc.	Percent Lead.	Zinc.
23.1	18.1	13.6	14.6
7.8	15.3	6.8	13.0
4.5	8.4	10.4	11.4
15.2	3.8	16.0	15.0
16.6	18.7	23.4	12.2
28.2	1.8	11.6	14.2
16.6	0.7	8.0	16.8
15.2	5.7	28.0	5.2

To meet any contingency the Sullivan block of ore between the tunnel levels is to be systematically opened up by raises and intermediate levels, for which latter stations will be cut in long raises. Meanwhile, the interseeting of the ore body a considerable distance to the northeast and a further thousand feet or so on the incline, fortifies the mining position. A glance at a blue-print surface-plan, new red pencillings on claims lately Crown-granted; the location of the drill-hole referred to by Mr. Warren, and of another to tap the ore-body at still greater depth, attest the expanding views of the management. Naturally, therefore, those in charge are chary about venturesome estimates as to the actual or probable ore-reserves. They count on 5,000,000 tons of high-grade or 10,000,000 tons that are equal to any emergency—and those would not be the last words, by any means, if the deep drill-hole does not furnish a disappointment.

For the moment, the management is bent upon keeping the lower tunnel in the footwall, about 4 or 45 feet from the ore-body where it can be tapped by a series of crosscuts and raises and drawn on. Mr. Montgomery rests his case upon the brief statement that he thinks "the biggest part of the Sullivan is below"—and it may be so. Manager of mines Archibald who has a reputation for far-sighted thoroughness, has ventured no projections. A mine that is prepared to supply a thousand tons a day for a good many years, and that has every indication of prolonging that life, is removed from special pleading. Undoubtedly the Sullivan properties—and the ores—have raised difficulties. Those difficulties have been met. Success could not have been attained—so soon at least—were it not for the influential backing of the Canadian Pacific.

How to dispose of Sullivan products when markets are "baffling", as Mr. Warren put it, and competition is keen, brings to the fore the necessity for centralization that will reduce freight charges and bring down mining and power costs. Consolidated directors are indebted to Canadian Pacific chiefs for what has been achieved at Trail, and for what the Sullivan mine is. That is the long and short of it. The Sullivan Mine when equipped could swamp its metal markets—and that is all there is to that—were it the part of wisdom to indiscriminatingly force markets. Stoping widths of 140-150 feet in places, the lateral and vertical continuity of the ore body, the grade established in a large tonnage, and the solution of the metallurgy will compel metal masters to reckon with the Sullivan.

Greatness is inseparable from liabilities. Sullivan metallic fixed quantities are worth the commitments of the Consolidated Mining and Smelting Company-stocks, bonds, special loans and overdrafts—several times over. Since the Sullivan was gingerly taken on in 1910, the liabilities of Consolidated Smelting have nearly trebled—but the asset position is infinitely stronger. In place, proved and indicated, there is anywhere between half-a-million and three quarters of a million tons of lead. Zinc contained in the ore-reserves will almost double that in quantity. So the Sullivan is in a class by itself, and the average Canadian view of Trail doings—which are predicated in no small degree upon Sullivan developments and the solution of the metallurgy of Sullivan ores—has been out of focus. That there is more to do at Kimberley, is obvious. A Board consisting of president Warren, vice-president George Sumner, Sir Edmund Osler, Charles R. Hosmer, H. S. Osler, W. L. Mathews, J. G. Hodgson, Henry Joseph and J. K. L. Ross, and the management, will not deny to the Sullivan all it requires. Last year, Consolidated Mining and Smelting showed its appreciation of the broadening situation by making these expenditures:

Advance to West Kootenay Power & Light Co., for Extension of Power lines ..	$698,000.00
Construction, Rossland Ore Concentrator, being used for treatment of Sullivan ore	269,561.14
Enlargement of Copper Refinery	208,912.09
Construction of Rod Mill	127,440.28
Construction, Copper Anode Refining Furnace	29,229.94
Construction, 3 additional Dwight & Lloyd Sintering Machines	158,760.56
Kimberley Housing	59,941.63
Additional Zinc Smelting Furnace	21,802.46
Thaw House	33,631.26
Advances & Expenditures, Account Sunloch Copper Mines, Ltd	72,963.27
Advances to Coast Copper Company, Ltd	130,704.03
	$1,802,066.66

The Trail works now can deal with raw ores to the refining of the metals—and provide finished products.

PERSONALS.

Mr. J. P. Bickell, president of McIntyre Porcupine Mines, has returned to Toronto after visiting the company's coal mine in Alberta, which is now operating successfully. The McIntyre and Temiskaming companies are jointly interested in the coal mining enterprise.

Hon. E. N. Rhodes, president and general manager of British America Nickel Corporation, announces that he will retire from public life upon dissolution of the present Parliament. Mr. Rhodes is Speaker of the Canadian House of Commons. He recently took up the task of supervising the reorganization of the nickel company's affairs.

Mr. A. G. Burrows, of the Ontario Department of Mines, has returned to Toronto after examining a gold discovery recently made at Gondrean, Ont.

Mr. P. E. Hopkins has returned to Northern Ontario gold districts on field work for the Department of Mines.

Mr. E. P. Mathewson has returned to New York after spending several weeks in England and on the Continent.

Hon. Harry Mills, Minister of Mines, has returned to Toronto after a visit to Northern Ontario mining districts.

Mr. Peter Kirkgaarde is at South Porcupine in connection with the development of the properties of Allied Gold Mines.

Mr. R. W. Brock, who was recently visiting in Ontario and Eastern States, is now on his way to England, having made a trip back to British Columbia to get his family.

The Search for Oil in the Pasquia Hills

A Preliminary Report by Dr. R. C. WALLACE, Commissioner for Northern Manitoba.

Topography.

The Pasquia Hills form a part of that escarpment of Cretaceous shales resting on Palaeozic limestones which is generally known as the Manitoba escarpment. In Manitoba the escarpment is represented by the Pombina Hills, The Riding, Duck and Porcupine Mountains, while in Saskatchewan the escarpment continues as the Pasquia Hills and Wapawokka Hills. The elevation of The Pan, at the base of the hills and over forty miles distant from the nearest scarp is 880 feet. The elevation of the summit has not been accurately determined, but is less than 2500 feet above the sea level. The general direction of the hills is determined by the Carrot river which flows in a northeasterly direction into the Saskatchewan river, and has dissected a wide valley in the western plains. Between this valley and the valley of the Red Deer river at the south side of the hills, carved by that river on its eastern course to Lake Winnipegosis, there has been left a triangular block of shales forming the Pasquia Hills, the base resting against the Red Deer river to the south, and the acute-angled vortex elongated toward the northeast along the Carrot river valley. This northeast corner of the hills is being somewhat rapidly eroded by the headwaters of the Pasquia river, which almost parallels the Carrot river in its northeasterly course to the Saskatchewan river, which it enters at the forks where stands the Town of The Pas.

Geology.

The general geological features were worked out by McInnes in 1907, and correlated with the work done by Tyrrell on the Porcupine, Duck and Riding Mountains. The hills are made up entirely of Cretaceous shales resting on a base of sandstone, the whole in turn lying on the Palaeozic limestones. The general section of the Cretaceous is as follows from top to bottom:

(4) Pierre Shales
(3) Niobrara Shales
(2) Benton Shales
(1) Dakota Sandstone

(1) Dakota sandstone is soft, friable, gritty and usually carries saltwater. In our recent investigations the Dakota sandstone at the rapids on the Carrot river, 10 miles above Red Earth Indian Reserve gave the following section, from top to bottom:

(c) Coarse grit with small pieces lignite	2½ ft.	
(b) Soft sand, ferruginous and diagonally bedded	10	ft.
(a) Hard sandstone with Calcareous cement	3	ft. exposed
	15½	ft.

There is no doubt that this does not represent the total thickness of the Dakota sandstone in this area. No data was obtained, however, to give a satisfactory estimate of thickness. Elsewhere in Manitoba the thickness of this formation is very variable, ranging from 19 to 200 feet.

The importance of this sandstone in the present connection lies in the fact that what oil might be collected from the overlying bituminous shale would collect and be held in the Dakota sandstone. The indications and structures in this sandstone are therefore significant of the presence or absence of oil.

Benton Shales.

(2) Normally the Benton shales are dark, soft, readily breaking down into clay, and not apt to show good exposures. In the present investigation the lowest outcrops on the Man river, at the log jam (elevation 1225 feet) and the lowest scarps on the Pasquia river south of Mountain cabin (elevation 1185 feet) are attributed to the Benton formation. In both cases the shales carry no fossils, are apparently only slightly bituminous, and disintegrate readily. As the elevation of the upper exposures of the Dakota sandstone at the Carrot river rapids of 1070 feet, the Benton shales cannot exceed 115 feet in thickness, and may be much less. Elsewhere this horizon has been found to be 178 feet thick.

Niobrara Shales.

(3) The Niobrara shales are the important oil-bearing shales both in the Pasquia Hills and elsewhere in the Manitoba escarpment. They are light grey, carry numerous fossils, are highly calcareous, fairly hard, and contain in the section on the Man river a bed of limestone 8 in.-10 in. thich, which serves as an excellent marker throughout the exposures. The section taken as Niobrara in our investigations on the Man river is as follows from top to bottom:

100 feet	fissile oilbearing shales characterised by occasional bands of yellowish bentonite
8 inches	limestone, highly fossiliferous
18 feet	fairly hard shale, bluish grey, with four bands of bentonite the lowest 5 in. thick
40 feet	very light grey shale, breaking into small pieces
159 feet	

On the Pasquia river the base of the Niobrara shales is taken to the top of the second scarp above the log chute, or 35 feet above the river bottom at the log chute. The section is obtained, though imperfectly, on the sharp ascent on the north and south timber line immediately south of the hill on which the log chute was made. The highest elevation reached on this hill was 1385 feet, while the elevation of what is considered to be the top beds of the Niobrara on the Man river is 1390 feet.

The total thickness of the Niobrara shales in the Pasquia Hills may therefore be taken as 150-175 feet approximately. Elsewhere they have been found to vary in thickness from 130 to 250 feet or possibly considerably more.

Pierre Shales.

(4) Overlying the Niobrara shales, and probably extending to the summit of the Pasquia Hills, are found the Pierre shales, which are dark, soft, with a tendency to break into rectangular blocks, the joint planes often showing a rusty surface. They contain nodules of clay ironstone, apparently in bands, and commonly carry small crystals of the transparent variety of gypsum solinite. From the point of view of the present investigations they are not of importance, as they are not as a rule bituminous. A very good section of the Pierre shales is exposed on the Man river giving a total scarp

of 110 feet, the lower 35 feet of which is partially covered by slides, but the upper 75 feet is exposed in a vertical section.

Economic Possibilities.

The fact that the Niobrara shales are in part bituminous has led to the leasing of certain areas on the hills with the intention of drilling for oil pools. Activity has been confined mainly to the scarps on the Cracking river, Man river, headwaters of Pasquia river, and on the plain at the foot of the hills in the vicinity of Turnberry. The shales and the possibilities of oil reservoirs will be considered independently.

(a) **Distillation of bituminous shales.**—Samples of the shales of the various horizons of the Niobrara and of the top of the Benton were taken for analysis in order to determine which horizon carries most hydrocarbon. From rough tests in the field it would appear that the beds immediately below the hard limestone-ledge, as they appear down the Man river from the point where the Fir River Cabin trail crosses the river, carry the highest value. The results of the analysis, which are not yet to hand, will settle this point. There has previously been an official analysis made of a sample which was taken by McInnes for the Department of Mines at Ottawa. This analysis was

Crude oil 7.00 Imp. Gal. per ton.
Sulphate of Ammonia 22.5 lbs per ton.

The sample was taken from the shales underlying the limestone bed on the Man river, and from the scarp which would in all probability have lost some of the bituminous contents to be found, for instance, in drilling through the same horizon some distance back from the exposure. As is well known, the oil shale distillation industry has thriven in Scotland for many years, the average content of the shales being 16-35 gallons per ton, and of the ammonium sulphate 30-75 lbs per ton. The shales are mined in Scotland from considerable depth, thereby adding much to the cost of mining above what would be necessary in surface operations such as are possible in the Pasquia Hills.

The question of distillation of oil shales has become an important one on this continent in recent years, owing to the ever increasing price of gasoline, and the how well known oil shale resources of Utah and Colorado. Many plants have been erected in the Western States, some after the Scottish practice, but mainly with retorts built to suit the new conditions. Owing to the fact that, for some years at least, the market for ammonium-sulphate will be limited on this continent, while it commands a good price as a fertiliser in the British Isles, it is necessary to build up the industry on shales with a considerably higher oil content than is mined in Scotland. Eventually there will be a large market for ammonium-sulphate fertiliser, when the soils of the western plains reach exhaustion.

The day of the oil-shale distillation industry on this continent is being hastened by the fact that demand now exceeds the production from the present oil fields. It will probably be necessary to be assured of considerable sections of oil shale with an average content of at least 40 gallons to the ton, exposed under conditions which will admit of steam-shovel methods of excavating before it will be advisable to consider operations. When the industry is established on a commercial basis in the Western States, the most successful methods of operation there will serve as a guide in the Canadian field.

In case the Niobrara horizon already described prove to contain a sufficiently deep section of shales averaging 40 gallons to the ton, the section on the Man river at the crossing of the Fir River Cabin trail, that on the Pasquia river above the log chute, and, perhaps even better placed for transportation, a section on the headquarters of the Papikwan river, would be well worth holding for future operations.

Dr. S. C. Ellis of the Geological Survey will carry out a full investigation on the shales during the summer.

(b) Oil Reservoirs.—The main interest is centred in the chances of obtaining oil by drilling. Some staking took place at the base of the hills on the eastern side last year, and very considerable staking has taken place on the hills this year. While a possibility of the presence of oil pools cannot be excluded in any formation where the rocks contain oil, as in the Pasquia Hills, the evidences on the field would indicate that such a possibility is somewhat remote in the Pasquia Hills district. The reasons for this conclusion are the following:

The carrying rock for oil expressed from the Niobrara shale would be the Dakota sandstone at the base of the shales. There are no beds of sand in the shales of sufficient thickness to act as accumulators of oil. In the vicinity of the hills the Dakota sandstone is exposed at the Carrot river rapids, and on the Red Deer river. Further afield the same sandstone is seen at Wapawekka hills, on Swan river, and at Kettle hill at the south end of Swan Lake. While there are thin beds of lignite in this sandstone, nowhere is there evidence of bituminous material, as would undoubtedly be found if the sandstone contained oil reservoirs.

The hills form an isolated eminence sharply cut off on every side except the southwest. The distance to an outcrop of any shale horizon is very short, and any oil that may have been expressed has had an unobstructed path horizontally to an outlet at some scarp. For this reason better opportunities for oil should occur south-westwards towards the western boundary of Saskatchewan, particularly where the Dakota sandstone, which is 1045 feet above the sea level in the Carrot river, reaches with its southwesterly dip an elevation of say 500 feet or less above sea level:

There are minor foldings both in the Dakota sandstone at the rapids and in the Niograra shale on the Man river. No major folds have yet been determined such as would be of significance for retaining oil. The exposure at the rapids is too limited to determine whether the local flexing of the sandstone represents part of a major anticline in the Dakota sandstone with a northwest and southwest trend.

The oil shales of the Niobrara series and the underlying formations have been drilled at Neepawa, Riding Mountain, Vermillion River, Deloraine, Manitou, Snowflake and Rathwell without oil being obtained, and drilling is now being carried on near Mafeking on the Porcupine Mountains. The underlying Devonian limestone in which remarkably perfect domes are found in the exposures on the west side of Lake Winnipegosis, is now being tested by the Provincial Government by drilling on one of the most pronounced domes yet mapped, southeast of the village of Winnipegosis.

A final test can however be made only with the drill. A Star drill outfit is now at The Pas, which will be shipped to the Man river to drill the shales in that district. Apart from testing the possibilities of all pools, the drill record will be of value in determining the oil contents of the shales of the difference horizons from

specimens which have not by any chance been affected by weathering, as have all the shales from the river scarps. It will also establish thickness of horizons as a guide to future exploration in a much more satisfactory way than from surface exposures. It would seem advisable to establish the drill hoe some two miles east of the already described scarps on the Man river, on the jackpine ridge at an elevation above sea level of not less than 1500 feet, if a suitable point with this elevation can be satisfactorily established.

Agricultural Lands.

While not directly connected with the matter of this report, the agricultural value of the lands on the slopes of the Pasquia Hills are of such importance as to demand notice. The writer had previously been aware of the importance of the bottom lands of the Carrot river valley and the so called triangle, all of which will afford soil which can hardly be excelled in the West when a reclamation scheme is completed. On the higher lands of the Pasquia Hills, however, at an elevation 200-500 feet above the valley of the river, and probably to considerably greater elevations, there is land, now fairly heavily timbered with spruce, jackpine, and poplar, which will soon maintain agricultural communities of great importance. Tradition has it that the timber on the hills is of recent growth. To the Indians they are the "Pasquia" or Prairie Hills; and the character of the country would seem to bear this out. The Canadian National Railway line from Melford northeastwards will presumably cross the Carrot river at or above the rapids and skirt the northern slopes of the Pasquia Hills in order to connect with The Pas. Agricultural settlers will immediately press in on the heels of the railway over the whole of the Pasquia Hills section, with great advantage to this wonderfully fertile section of Northeastern Saskatchewan and to the Town of The Pas as well.

PEAT DEPOSITS OF PORT ARTHUR DISTRICT TO BE INVESTIGATED.

J. J. O'Connor, Port Arthur.

The peat resources of the Port Arthur district are about to be investigated by the Geological Survey, under the direction of Mr. A. Anrep, who is now on the ground.

The party will go into camp at Roslyn, on the outskirts of Fort William, and will direct their operations covering the extensive peat beds in this vicinity, from that point.

Mr. Anrep is a son of the famous Dr. A. Anrep, a Swedish scientist and inventor, of Stockholm, Sweden, whom the Russian government induced to remove to Moscow, in 1880, for the purpose of research work in peat fuel, and the application of the scientific methods in use by him, on the immense peat resources of Russia.

In 1883, his inventions solely controlled the peat industries of that country. In 1910, something over four million tons of peat was produced through his machines. The product is in the form of bricks, air and sun dried, but without briquetting.

Mr. A. Anrep, in charge of this party, was born in Moscow, and followed in the footsteps of his father, devoting all his active business life to the scientific production of peat fuel. He was invited by the Dominion Government to come to Canada fourteen years ago, and designed the first scientific peat-plant in Canada, at Alfred, Ontario, for the Federal Government, in 1908.

This plant was operated jointly by the Federal and Ontario governments, on an experimental basis in 1919-20, during which period between six and eight thousand tons were produced. An improved type of spreading conveyor to be tried out this summer is expected to effect further saving in labor costs. Peat can be manufactured at Alfred, for $4.00 per ton, f.o.b. cars.

The economic importance of a plentiful supply of peat fuel at the Head of the Lakes, cannot be overestimated by residents of this coalless region. If the beds that are to be investigated prove to be of satisfactory composition, the transportation charges will be within figures that will ensure a moderately-cheap domestic fuel.

LE ROI No. 2 TO ADOPT FLOTATION CONCENTRATION.

At the twentieth annual meeting of the Le Roi No. 2 Ltd., held in London on June 23rd, Lord Ernest Hamilton, Chairman of the Company, said the period of fifteen months covered by the financial statement had not been a profitable one. The margin of profit over expenses, never very large, had been wiped out by a general increase in costs of labor and material, and there had been no returns from the smelter for over a third of the period, owing to the Trial Smelter having been closed down. Prospects, however, were more hopeful, as costs were being reduced, and the Manager, Mr. Lay, had advised them from Rossland, that "no reasonable doubt can exist as to the successful application of flotation to our ores." The process would enable re-working of the dumps, which it was estimated, could produce $55,000, more than enough to cover the cost of the flotation plant. The consulting engineers reported that plans had been made for the alteration of the existing mill, and economies had been found possible, first by adoption of the simplest form of the Minerals Separation machine, and secondly by having the plant built in Canada. It was hoped to have the new plant in operation in July. The consulting engineers stated that the amenability of the Rossland ores to treatment by the Minerals Separation plant had been amply demonstrated by the Consolidated Mining and Smelting Company.

DEATH OF W. D. HANNAH.

A well-known figure in the coal trade of eastern Canada has been removed by the death of Mr. W. D. Hannah, who was for many years General Fuel Inspector for the Grand Trunk Railway. Mr. Hannah was born in Scotland and was 77 years old at the time of his death. He was in the service of the Grand Trunk Railway from the time he arrived in Canada as a young married man. Mr. Hannah's genial personality was not allowed to interfere with his native shrewdness in his duties as fuel inspector, and he insisted on a square deal for his road. Mr. Hannah had a wide acquaintance with coal producers in the Maritime Provinces and in the Eastern coalfields of the United States. Although for some years retired from active work, the news of Mr. Hannah's death will be heard with regret among those who remember him as fuel inspector.

Northern Ontario Letter

THE SILVER MINES.

Now that work has settled down into a steady groove, there is a tendency to regard the silver-mining industry of Cobalt with renewed confidence. The leading companies are showing a determination to realize satisfactory net profits and are considering ways and means of still further reducing their operating costs.

Cyril Knight, Ontario Government geologist, is making satisfactory progress in connection with a resurvey of the Cobalt field, and expects to complete the work early during the coming Fall. Mr. Knight expressed the opinion to the "Journal" correspondent that although the richer deposits have probably been discovered, yet in various of the operating mines as well as some of the old properties which have never been extensively worked, there are good prospects of further important developments. Ore-shoots may occur with decreasing frequency, yet there are excellent chances of intelligent effort being well-rewarded, in the opinion of Mr. Knight.

The Mining Corporation is now realizing a profit on its operations. This fact is made clear in the following statement which was made at the company's annual meeting by J. P. Watson, president of the company:—

"Since the first of the year, we have refrained from selling silver in quantities, owing to the continuing low price, and we are carrying about 650,000 ounces. To offset the loss of interest we would otherwise make, we have been selling spot silver in London at a premium over forward purchases of the same quantity which, without any risk to the corporation, enables us to earn interest on the value of the silver sold and a small profit besides.

"As to the condition of our Cobalt properties. In the first place, I am very glad to say that we have been amply justified in the purchase of the Buffalo mine. You will have noted from the annual report that the reserves in the Buffalo alone are estimated at 1,350,060 ounces; and recently we have been fortunate in the discovery of two new veins on this property, which will make a valuable addition to these reserves. In addition to this, we are continually finding on our different properties new stringers or small veins which add to our milling ore, and finding unexpected extensions to existing high-grade veins.

"I would like to point out to you that at the end of 1917 our ore reserves were estimated at 1,545,370 ounces. Since that date, we have produced 4,602,923 ounces and our total reserves at the end of 1920 are estimated at 2,181,000 ounces.

"For some time, we have been aware that certain alterations could be made in our Cobalt Reduction mill which would increase its efficiency and consequently, reduce costs. But, while silver was at its high point, we did not think it advisable to close down for the necessary two or three months to make the alterations. However, this spring, we concluded that the time had come, and our mill was closed from March 7th to May 25th, during which time the alterations were made, increasing our capacity from 180 tons per day to 200 tons. This increase of tonnage, together with improved methods of treatment and lessened cost of labor with its increased efficiency will, we hope, so reduce the cost of production that even the present price of silver will give us a fair net profit.

"Our intention is to go ahead full speed, but in this connection I would ask the shareholders not to be alarmed should we again close down during the coming year, as it will not be done because of any lack of ore but for other reasons, to safeguard the interests of our shareholders, your directors being determined that they will not operate and sell silver at a sacrifice price, nor submit to inefficient labor at an excessive wage.

"The policy of our corporation for years has been the acquisition of new properties to prolong its life as a mining company. By the acquisition of the Buffalo property, we have undoubtedly added both to the value and length of life of your company; but our recent acquisition of a majority interest in a large copper, gold and silver property in Manitoba is the most important step we have taken. A short, conservative description of this property has been given in our engineers's report. Briefly there are 16,000,000 tons of assured ore, and additional possible and probable ore of another 9,000,000 tons in the ore-body on which we have worked. In the property there are 1,303 acres, which have unknown possibilites, but it is in the centre of a well-mineralized country. The values given for the ore in our report are based on assays of the diamond-drill cores; but, in the sinking and driving which took place last year, careful moil-sampling was done, and I am pleased to tell you that the copper contents showed an average of about 32 p.c. in excess of those given in our report; the gold and silver remaining as shown by the drill cores. Many difficulties and problems will be encountered in the development of this ore-body, but the values already proven are so stupendous, and there being no metallurgical difficulties, we are encouraged to hope that we have reached our goal in providing for an indefinite life for the Mining Corporation of Canada."

On July 20, the Nipissing Mining Company will disburse a regular quarterly dividend of 3 p.c. This will call for the distribution of $180,000.

The Kerr Lake dividend of 12½ cents a share, payable July 15, will call for the disbursement of $75,000, and not $225,000 as reported last week.

Arrangements have been completed to commence shaft-sinking on the Oxford-Cobalt property at the point where rich ore was found some weeks ago. A hoist has been set up, and the shaft will be put down to contact, about 60 or 70 feet.

The carload of ore reported in May as having been taken from the Ophir mine, came from the dumps of the Peoples Silver Mines, Messrs. Chitty and Johns having had a lease on the dump.

Fire destroyed surface equipment at the Trethewey property in Gowganda, and the property is now idle. It is understood the directors may make an endeavor to raise additional finances with which to re equip the property as well as erect a small mill.

The annual statements of the Beaver Consolidated Mines, Ltd., and the Kirkland Lake Mining Company, Ltd., have just been issued. That of the Beaver Consolidated covers the fiscal year ending February 28th, while the report on the Kirkland Lake Company covers the fiscal year ended May 31st.

Features of the Beaver Consolidated statement for the year are these:—

Total income	$189,902
Total expenditure	193,520

This shows that without making provisions for de-

preciation, the loss for the period amounted to $3,617. Factors contributing to this loss were the shortage of labor in the first half of the year, a power shortage during the last half of the year, together with a sharp decline in the price of silver.

The Beaver Statement shows a balance to credit of $953,255 an analysis of which shows the balance to be made up largely of money advanced and stock purchased in other companies. It is noted that the Beaver paid $371,519 for the stock of the Kirkland Lake Gold Mining Company, in addition to which the Beaver has advanced $421,881 in cash with which to develop and equip the Kirkland Lake enterprise. This proposition, therefore, represents an investment of $793,401. There is a further important item which is classified as balance to credit, this being $143,250 in the Beaver Auxiliary Mines, a prospect venture which the Beaver entered into several years ago in the Elk Lake district and which has not been worked in recent years.

For the year ended May 31st, the Kirkland Lake Mining Company made a profit of $34,990. This was reduced, however, to a loss of $11,082 by writing off $13,493, for depreciation and providing for interest on notes amounting to $32,580. This loss, added to the deficit as of the beginning of the year, leaves the Kirkland Lake with an adverse balance of $28,958.

Production for the year amounted to $277,007, the mill having treated 45,479 tons of which all but 2,657 tons came from below surface, the latter coming from the surface dump. Features of the Kirkland Lake operation are these:—

Daily tonnage	124
Tons treated	45,479
Value produced	$277,007
Per ton value	$6.09
Cost, less interest	$291,704
Per ton cost	6.41
Loss per ton, about	.32

The company realized $36,106 on exchange. Weighing against this is $32,580 which the company had to provide as interest accrued on notes.

The physical condition of the property is stated to be strong, and the prospects of realizing substantial net profit during the current fiscal year is good.

Ore and Bullion Shipments.

Following is a statement of ore shipments over the T. & N. O. Ry. for the month ending May 31st., in tons of 2,000 lbs.

Cobalt Proper.	Tons.	
1. Coniagas	81.20	
2. LaRose	42.03	
3. O'Brien	133.61	
		256.84

The above shipments were made to the following Companies:

Canada.

Delora Smelting & Refining Co.	Delora	133.61
Coniagas Reduction Co.	Thorold	79.46

United States.

American Smelting and Refining Co.	Perth Amboy	43.77
		256.84

Price of Silver.

Note.

May 7th.	Highest	62.500
May 31st.	Lowest	57.500
	Average	59.810

THE GOLD MINES.

The Porcupine Field.

The turn of the last half of the current year finds the gold mines of Northern Ontario in a strong physical condition and enjoying very satisfactory prosperity. In the increasing tonnage being handled for each man on the pay-rolls of the leading mines lies the secret of the increasing margin of net profit now being realized. In the case of the Hollinger, an average of around 2¼ tons of ore are being handled daily per man, as compared with the low average of under 1½ tons per man when efficiency was at its worst during the past few years.

It is believed that the gold mines of Porcupine and Kirkland Lake from this date forward, will realize an aggregate net profit of over $8,000,000 a year. This may be still further increased within the next year or so. Those in close touch with the mining situation as found in these high-grade goldfields believe the stockholders of the producing companies stand in line to cash in cheques amounting to at least $8,000,000 a year as a reward for their patience during the adverse conditions of the past few years.

The McIntyre-Porcupine, on June 30, closed one of the most favorable fiscal years in its history. It will probably be two months before the annual statement can be prepared, but among other favorable features, a substantial increase in ore reserves is expected to be shown. The company is now in a position to proceed at once with the work of enlarging its plant, with a view to treating about 900 tons of ore daily by the end of the current year.

A promising discovery has been made on surface on the Three Nations property of the Allied Porcupine Mines. P. Kirkegaard, consulting engineer for the company is at the property this week. The surface work now under way is in charge of L. K. Fletcher, and a shear zone has been opened up in which mineralization is encouraging, some favorable assays having been taken.

Kirkland Lake and Boston Creek.

The annual statement of the Kirkland Lake Mining Company is presented under the "Silver Mines" in this letter.

Drifting operations at the 300-ft level of the Bidgood property continue to be favorable. The vein has a greater width than the drift, and, in places, visible gold occurs. Considerable lateral work will be done before the shaft is continued to deeper levels.

Word has just been received at the mine in Boston Creek from the head office of the Miller Independence Mines, Limited in Ohio that the $50,000 bond issue, under offer to existing stock-holders, has been fully subscribed, a matter which, in these days of financial depression, can be accepted as indicative, in the most practical fashion, of the enthusiasm and feeling of satisfaction permeating all those associated with the enterprise.

The recent period of slackness at the property has been well utilized for work of a preparatory nature and diamond drilling, which has been under discussion for some time past, will be commenced at the earliest moment. It is planned to carry out most of the operations in the "A" shaft at the 500 ft. level but the neighborhood of the "D" shaft, with its spectacular showings of telluride ore, will also probably receive its share of exploratory attention.

TORONTO MINING QUOTATIONS.

Quotations on Active Stocks on Standard Stock Exchange for Week Ending 2nd July, 1921.

TRETHEWEY.

The plant of the Trethewey mine at Gowganda was seriously damaged in the recent fire and development work has necessarily been temporarily discontinued. The shaft had reached a depth of about 270 ft. when work was stopped by the fire.

BIDGOOD.

Development of the Bidgood property in Lebel township is reported to be giving good results. Drifting at the 300 ft. level is in progress.

SILVER SHIPMENT FROM MAYO.

"Dawson Weekly News" reports under date of 17th June the arrival of barges containing 54 tons of silver ore from Keno Hill. This shipment, together with a previous one of 500 tons, will be sent to the smelter via St. Michael. It is the largest single shipment of silver ore as yet made from the Yukon Territory, and is part of 2,350 tons which so far have been selected from Keno Hill.

TORONTO COAL PRICES.

Toronto, th July. — Toronto coal prices are absolutely identical with those of a week ago. The attitude of the public, too, shows no change. They are still delaying their purchases of coal in the hope that prices will drop — a hope which is not likely, having regard to the logic of present conditions, to be realized. There is one aspect of the coal situation which deserves notice, and that is the marked decrease in Lake shipments of lump coal. These shipments are falling off very rapidly. At present, indications are that there will be a considerable stiffening in the price of slack coal pretty soon.

TORONTO METAL QUOTATIONS.

Below are the fair average prices for ingot metals (in less than car-loads) at Toronto:

	Cents per lb.	
	June 29th	July 6th
Copper, electric	17	17
Copper, casting	16¾	16¾
Tin	39	38
Lead	7	7
Zinc	7½	7½
Aluminum	30	30
Antimony	9	9

MONTREAL METAL QUOTATIONS.

Following are the fair average prices for ingot metals (in less than car-loads) at Montreal:

	Cents per lb.	
	June 29th	July 6th
Copper, electric	17¾	17¾
Copper, casting	17½	17½
Tin	36	36½
Lead	6¾	6½

Aluminum	31	31
Antimony	7¼	7¼

BOOK REVIEW.

Longwall Coal cutting Machinery. G. F. F. Eagar. 109 pages with index. Sir Isaac Pitman and Sons, Toronto. Price one dollar.

This addition to Pitman's Technical Primer Series is recommended to all who are connected with the use of coal-cutting machinery in longwall faces, or who contemplate adopting a practice that is likely to develop in Canadian coal mines. The economic aspect of coal-cutting by machinery, types of machines, namely, disc, chain and bar machines are admirably summarised. The choice of type of cutter to suit local conditions, the position and depth of the cut are discussed and illustrated by examples of undercutting, overcutting and cutting in bands in the seam. The comparative advantages and disadvantages of available motive powers are clearly contrasted, and there is an interesting description of the new development of the compressed air turbine as adapted to coal-cutters. Taking into consideration the small size and low cost of this primer, the writer has succeeded in condensing much practical information, dealing chiefly with English practice, that mining students, in particular, will find quite helpful.

British Columbia Letter

Metal Mines.

The first application under the "Radium Act" of 1914 has been received by the Provincial Department of Mines. A prospector claims that he has discovered the exceedingly valuable mineral in place on Vancouver Island and he wants the reward which is offered by the terms of the Act in question. No particulars of the deposits, their location, character, etc. are given, the bald statement being made that the discovery has been made and that the staker is prepared to have the fullest investigation made to establish the truth of his assertion. The Act referred to describes radium as "all deposits of carnotite, pitchblendes or other ores containing radium in sufficient quantity for commercial extraction." The Lieut.-Governor in Council is empowered to place a reserve on all radium within the public lands of the Province and at pleasure to remove such reserve. It also is set out that "to the first person proving to the satisfaction of the Lieut.-Governor in Council that he has discovered radium within the Province the Lieut.-Governor in Council may pay a reward not exceeding five thousand dollars." The Executive in addition is authorized to make rules and regulations for the exploration, occupation and purchase of radium-bearing ore lands and "to make such other rules and regulations for conserving and developing radium within the lands of the Province as may seem proper; and to make provision for the retention by the Crown of an interest, not exceeding fifty per cent, in all radium produced from the radium-bearing lands of the Province, or for levying and collecting a royalty on such production of radium." The application having been made by one who is convinced that he has found the precious ore "in paying quantities" it remains for the technical officers of the Department to undertake the inspection and investigation required either to prove or disprove the claim. If the mining man proves important developments in connection with the mining industry of the Province in recent years. The practical value of the mineral to humanity, its scarcity in comparison with the growing demand, make the prospect of British Columbia proving a source of supply exceedingly attractive from whatever point of view is considered.

Stewart B.C.: The Lindenbourg Brothers intend doing considerable development on the Seven Mile Property, which is situated on the main road to the Premier Mile, seven miles from Hyder. A tunnel already has been driven 340 feet. The ore carries gold, silver and lead and, while assays have been obtained as high as $200 to the ton, the owners do not consider it a shipper. They are of the opinion that a sufficient tonnage of concentrating ore will be proven to warrant the construction of a Mill. Further work is to be done this year on the Fish Creek Mining Co's Claims, the intention being to put a crew of from five to seven men on the job. A 240-foot tunnel already has been driven and last year some fifty tons of high-grade ore was sacked but was not shipped owing to lack of transportation facilities.

Alice Arm B.C.:—A meeting of the North Coast Branch of the Canadian Institute of Mining & Metallurgy was held recently at Alice Arm, Major C. B. North, of the Dolly Varden Mine, occupying the chair. Among the speakers were Bert Kergin, M.L.A., G. P. Riel, G. C. Mackenzie the secretary, H. Fowler, M. Peterson, H. M. Roscoe, and John Stark. The members afterwards were the guests of the citizens of Alice Arm at dinner. George Clothier, government mining engineer, has been spending a week examining various properties in the Illiance and Kitsault valleys.

Victoria B.C.: The announcement that the Great Northern Ry. Co. proposes to close down its branch railway from Rossland to Northport Wn. on the 30th of June next is made the subject of a vigorous protest by the Rossland Board of Trade to the Premier and the Minister of Mines of British Columbia. The members of the organization in question take the stand that the withdrawal of this service will seriously interfere with future mining operations in the Rossland Camp. In particular it will prevent shipments from the Velvet Mine, which has been operating steadily for the past year. Rossland's gold production, it is stated, will be $1,500,000 this year and that a better showing is promised for the future. Any move calculated to remove railway or smelting competition, it is argued, may discourage outside capital. The granting of the right to abandon branch lines also would mean the establishment of a dangerous precedent. Both Premier Oliver and Minister of Mines Sloan took up the matter with the Chairman of the Board of Railway Commissioners, Ottawa, urging that the views of the people of Rossland should have every consideration, declaring that the withdrawal of this railway would have a serious effect on the mining in that section of the Province, and asking that the Board exercise whatever powers may be vested in it in the interests of the affected part of the Province. There seems to b a doubt, however, as to the authority of the Board to prevent the railway company carrying out the policy its announcement appears to forecast.

Prince George B.C.: The placers of the Goat River, about 120 miles east of Prince George, are bringing good returns. Seven Chinamen brought $1400 worth of gold dust to the town recently, reporting that they had cleaned it up in the course of two weeks. Several white miners also are working on the river bars.

The British Columbia Department of Mines has received an invitation from the United States Bureau of Mines to be represented at a series of conferences to be held on September 1 to 3 inclusive, 1921, at St. Louis, Missouri for the purpose of "standardizing the use of mine-rescue breathing-apparatus and to consider the possibilities of standardization in the apparatus itself." It is added that "since the mining departments of a number of foreign governments are also actively engaged in similar work it is proposed to make these conferences international in character and if possible to have present official representatives from the several countries." Hon. Wm. Sloan, Minister of Mines, has accepted the invitation on behalf of the Province. As a matter of fact it was he who is responsible for the initiation of the movement. Shortly after the disaster in the "Black Diamond" Mine, Pacific Coast Coal Co., Wn., which occurred July 10th, 1920, and in which three men wearing mine-rescue apparatus lost their lives, he took up with the U.S. Bureau of Mines the question of standardizing the apparatus and its use, with a view to simplifying the training of men, it being felt that the adoption of a common method would eliminate present possibilities of confusion in emergency and give greater assurance of the safety of those going underground under dangerous conditions for

purposes of rescuing human life. The suggestion was taken up promptly at Washington and the conferences referred to are the result.

Trail B.C.: J. J. Warren, president of the Consolidated Mining & Smelting Co. of Canada, in addressing the Board of Trail of Trail recently stated that, if the Dominion Government had placed an aqeduate tariff on copper rods and flourspar, the provincial pay rolls in this particular branch of the mining and smelting industry would have been very substantially increased; one 700 additional men now would be employed in the work. He criticised the Government for not taking action, notwithstanding that the difficulties in the way of the maintenance of the industry in the West without protection were pointed out to the Ministers in time to permit the necessary amendments to the Act at the last session of Parliament. He pointed to the large sums invested by his Company in their copper-rod mill at Trail and their Fluorspar plant near Grand Forks and added that, not only would these have been benefitted, but the Copper Mountain Mine, of the Canada Copper Company, probably now would be operating and furnishing work for many.

COLLIERIES.

The Coalmont Coal Company has undertaken the thorough development of its coalfield, situated in the Nicola-Princeton District. Operations have been closed down for some days but work if not already resumed, will be in a short time. The new carrying-cable, which will replace the present inadequate transportation system, is practically in place and will be ready for operation shortly. It is a lock coil, 1-⅝ inch cable, made up of 61 three-sixteenth-inch wires, arranged in four concentric layers, the weight being 18 lbs per yard. Therefore it should be able to stand whatever load may have to be put on it. A number of the towers had to be re-built and this time special cars has been taken to maintain suitable deflection angles, wherever a change of grade proved necessary. Coalmont is situated 2,400 feet above sea level and the mine at 4,000 feet. This gives a total drop of 1600 feet in a distance of about 3 miles.

The Coalmont powerplant contains as a.c. generator 480 mp. 600 v. at 150 revs., direct connected to a John Inglis cross-compound, Corliss condensing steam-engine. Steam is raised by two B. & W. marine boilers, originally designed for use in American torpedo boats. At the mine there are two boilers and an air-compressor. Edison miners' lamps are used, and a small d.c. generator will be installed for charging purposes. The machine shop is adequately equipped for colliery purposes.

The mine is reached from Coalmont by a waggon road, four and one half miles long, skirting Granite Creek Gulch. "To anyone unaccustomed to the dare-devil modes of travelling still in vogue in the more remote parte of the Province" declares one who recently made the trip" a trip on one of the five-ton motor-trucks, carrying supplies up to the mine, would seem quite an exciting experience. At times one side of the truck grazes a rock wall while the other hangs over a sheer drop of 1,000 feet."

The Coalmont coal measures, although somewhat limited in area, constitute a rather rich field. This may be described as a number of seams, or rather one seam, about 140 feet thick, with a number of intervening rock bands varying from 10 to 15 feet in thickness. The field is intersected by at least three dykes and the associated sandstones and conglomerate are partly capped by a flow of olivine basalt. All the present workings are in the upper benches of the seam. The quality of the coal is good and the demand in excess of the capacity of the present workings. Mine timber of excellent quality is cut on the hill-side and loaded on the waggon road at a distance of about one mile from the mine.

An amendment to the "Coal Mines Regulation Act" was passed at the last Session of the British Columbia Legislature providing that "no lamp or light other than a locked safety-lamp of a pattern approved by the Minister of Mines shall be allowed or used underground in any mine." It further was provided that this change should become effective on the 1st of July, 1921. Formal notificationhas been given the various collieries of the Province that the new rule will be rigidly enforced, the Hon. Wm. Sloan, Minister of Mines, being determined that no coal mine within his jurisdiction shall, after the date set, use anything but approved safety-lamps underground. By his instructions each of the operators have been provided with a list of "approved" safety-lamps. There are included in this the electric lamp manufactured by the Edison Storage Battery Co.: the Concordia portable electric-lamp, manufactured by the Concordia Electric Co., Pittsburg; the Wico portable electric mine-lamp, manufactured by the Witherbee Igniter Co., Springfield Mass.; the Pioneer Electric Mine Lamp Co., Philadelpria Pa.: the Wheat portable electric mine-lamp, manufactured by the Hoehler Manufacturing Co., Malboro, Mass.; and five types of flame safety-lamps. It is specially noted, however, that "while the use of flame safety-lamps is permitted it is the policy of the Department of Mines to encourage the use of approved electric safety-lamps for all persons underground in the coal-mines, except such flame-lamps as may be required by the officials of the mines in the carrying-out of their duty." The day of the naked lamp in British Columbia coal-mines under any conditions, therefore, is at an end. The Minister takes the stand that a mine that may be found safe today may develop dangerous conditions tomorrow and he had firmly adopted the principle of "safety first" where the lives of miners are concerned. It means that all collieries operating on any scale will adopt some form of electric lamp, if not immediately, certainly in the course of a few months. As a matter of fact the majority of the mines already are so equipped or have been preparing for the installation of these lamps.

The Minister of Mines has authorized the prosecution of the Pacific Coast Coal Mines Ltd., South Wellington B.C., "Mordon Mines," for infractions of the "Semi-Monthly Payment of Wages Act." This colliery closed down some months ago, having failed to meet the wage payments of their employers for a considerable period. Since then the men have secured judgment under the Mechanic's Lien Act against the Company for wages in arrears approximating $52,000. No action was taken under the "Semi-Monthly Payment of Wages Act" until this litigation was disposed of but now it is intended taking the necessary steps of the measure which provide for a severe monetary penalty on conviction.

EDITORIAL

Gold Mining in Northern Ontario

In this issue will be found a series of articles, prepared by the Consulting Editor of the "Journal," Mr. R. E. Hore, dealing with the present status of gold-mining in Northern Ontario. Mr. Hore reviews the growth of gold-mining at Porcupine and Kirkland Lake, describes the treatment of the gold-ores in these two main centres, and discusses the significance of the persistence of gold at depth at Porcupine and Kirkland lake, as so far proven. The information contained in these articles has been obtained by personal enquiry within the past few weeks.

Apparently gold-mining at Porcupine, which, notwithstanding its respectable proportions at this time, has only a boy's age, never until quite recently worked at anything like the capacity of the mines and mills. The hindrances which gold-mining at Porcupine has met with have been unrelated to the physical capacity of the camp to produce gold. The only serious drawback to capacity production from existing developed properties at Porcupine at this time appears to be an insufficiency and some seasonal uncertainty in the quantity of electric current, generated by water-powers, that is available. Provision of an adequate supply of water would seem to be the matter chiefly requiring outlay and effort in the Porcupine District.

Kirkland Lake daily assumes greater importance as a producer of gold. There are several other districts of Northern Ontario where gold occurs, but where gold-mining has not yet become so established as is the case at Porcupine and Kirkland Lake. It is fair to state that some of them are quite as promising as Porcupine was a little over a decade ago, and as Kirkland Lake was at a much more recent date.

Eminent students of currencies believe that the demand for gold is about to become more pronounced. The "Financier and Bullionist" of London quotes Mr. Samuel Evans, chairman and managing director of the Crown Mines, and a South African expert of acknowledged rank, as believing the pendulum has swung very far in a direction adverse to gold-mining, but that it is swinging back. Judging by precedent, Mr. Evans suggests the pendulum should in time go equally far in the other direction, which is likely to cause "a rise in the value of gold greater than anything that has ever been experienced since gold has been the enemy of civilized nations." The "Financier" states: "It is a point to remember that the annual production of gold in the world has diminished by 27 per cent. since 1915, while the probabilities are that in the course of the next few years the demand for the metal will be greater than it was since the adoption of the gold standard by England . . . . . History shows that the appetite for gold is intensified amongst populations which have for long experienced the extreme discomfort and harrassing uncertainty of a constantly depreciating paper currency."

In Canada we have our own good reason for increasing by every possible ounce the production of new gold. The renewal of the Order-in-Council banning gold exports for another year is an indication of our fiscal position. Every ounce of gold that can be won from the rocks of Canada lessens the strain upon our government and those who have to finance Canada's adverse trade balances. Gold-mining in Canada is good business, and a necessary one. It is encouraging to know that it is likely to prove profitable to those who have invested their money in Canadian gold-mines, because only a profitable undertaking can survive, and it is necessary for our fiscal well-being in Canada that gold-mining should be profitably undertaken on the largest scale possible.

The ability of the gold-mining companies of Northern Ontario to make headway when economic conditions were adverse, indicates that when conditions are favorable the industry should do very well indeed. In view of such a real possibility, it may not be amiss to suggest that taxation authorities and governments should recognize that the increase of gold production is a thing to be encouraged. The more profitable gold-mining is, the more people will become gold-miners, and the more new gold that is produced in Canada, the easier will our economic condition become.

ASSESSMENT WORK.

In the many discussions as to what should be done to encourage prospecting for mineral deposits it has been noteworthy that there has been little said by the prospectors themselves. Some of those interested in the subject have called attention to the need of more expression of opinion by prospectors in order that their view be better known by others who are interested in the mining industry. Recently there was formed a prospector's organization in Temiskaming and it is worth noting that this organization has shown that prospectors favor the lightening of the assessment work burden. The recent change in the Mining Act which makes the holding of claims comparatively easy seems to meet with the approval of the prospectors.

This development shows that the prospectors' desires were not well understood in the past. It was generally believed that the more stringent regulations which have been in force since the early days of intensive prospecting at Cobalt were regarded favorably by prospectors. In some cases the necessity of doing 240 days work in three years was a hardship; but in the main it was fortunate for the prospectors that the assessment work was required. Those who took over claims did so with the knowledge that they must do a certain amount of work and in many cases prospectors were employed at times when the work would not have been undertaken but for the fact that is was necessary to keep the title to claims clear. Thus the prospector had opportunities for working for wages in dull periods, earning a grubstake for his next venture. The general impression was that the regulations favored the prospector and it is more or less of a revelation that prospectors are in favor of the regulations which have recently come into force. Obviously it gives the prospector a better opportunity for disposing of his claim as he is not obligated to do much work on it for a long period. What he gains in ability to hold a claim in idleness however will in most cases be lost by failure to properly open up discoveries. From the examining engineer's point of view the assessment work is very desirable, for stripping and trenching is often neglected if not absolutely required of the prospector.

It will take some time to determine whether the new regulations have enough good features to offset the bad ones. The prospector's views have been asked for, however, and he should know as well as anyone else what is good for him. If the regulations prove satisfactory to the prospectors and result in more activity in prospecting many will be surprised but all will be pleased.—R. E. H.

THE LIGHT RAILWAY.

It is announced that the Ontario Government is not in favor of granting financial assistance to the company which plans to build a light railway to serve mining areas on either side of the Ontario Government railway. Reported statements of the Minister of Mines indicated that the Government was favorably disposed towards the project and would give assistance to the builders of the railway. It is a pioneering enterprise and many believe that the Government should take part in it; but evidently it will have to be done wholly by private enterprise. This puts a new light on the undertaking as these seemed reasonable ground for believing that the Government would give financial assistance to a company that help to supply transportation facilities in Northern Ontario.

Whether the promoters of the light railway will proceed with construction without aid from the Government is not yet known.—R. E. H.

COST OF STAPLE FOODS BY PROVINCES.

The assortment of staple foods used by the "Labour Gazette" to calculate the weekly cost of an average family budget, shows the cost by provinces, and there are some things in the statistics it is hard to understand. In the period before the war, running from 1900 to 1913, the cost of foodstuffs in the four western provinces was uniformly higher than in the remaining provinces in the East. Since the war the cost of foodstuffs in the West has declined until the latest figures show that they are cheaper in Manitoba, Alberta and Saskatchewan than in the Maritime Provinces. Another feature of the statistics is that the increase in the cost of foodstuffs since 1913 has, in the East, varied from 72 to 80 percent, whereas, in the West, it has reached only 44 to 54 percent. Comparing Alberta with Nova Scotia, as an example, the budget of foodstuffs now costs $12.53 in Nova Scotia against $12.02 in Alberta, and while the increase over pre-war figures is 72 per cent in Nova Scotia it has been only 44 percent in Alberta.

The inference is that the West is now more self-supporting, and less dependent upon imported foodstuffs than was formerly the case, and that in the East an exactly opposite development has taken place. With the negligible exception of Prince Edward Island, the cost of foodstuffs 20 years ago was lower in Ontario than in any part of Canada, but today the Ontario prices are higher than the average of the three prairie provinces. The growth of industrialism cannot be to blame, for the progress in industries other than agriculture has been very marked in the West, whereas in New Brunswick, for example, manufacturing has made very small progress, and foodstuffs have increased there by 77 percent since the war. Viewed as a whole, the figures vary within surprisingly small limits, considering the extent of Canada, and the great variation in living conditions. They seem to indicate more than anything else the influence of railway freights on imported foodstuffs, and suggest, as before stated, that the East is becoming more dependent on imported foodstuffs, and the West less so. The disadvantages which will accrue to the East if this tendency remains unchecked are sufficiently obvious.

WHEN WILL COAL BE A "BUY?"

The weekly report of the United States Geological Survey on bituminous coal production forecasts that the production of 1921 will be less than 400 million tons, and mentions that the last year the United States was able to manage with so small a quantity was 1909. Indications seem to be that bituminous coal production in the United States will be in 1921 about 100 million tons less than the average annual production during the seven years preceding.

The British coal strike has caused a loss of probably not less than 75 million tons of coal. Although there have been notable recoveries in coal production in Europe, particularly in Westphalia and Belgium, the output does not yet total anything like pre-war figures. What Russia is doing the rest of the world does not learn, but the territory indicated by that geographical expression is certainly not producing much coal.

While Canada's coal output is relatively unimportant — except to Canada — it will be less in 1921 than it was last year.

It is fairly evident that the world is doing its best to avoid purchase and storage of coal, actuated by a general and world-wide hope that the price will come down, and that coal-miners will accept smaller wages and work longer hours. It is also fairly evident that coal production at the reduced rate of recent months cannot continue much longer.

The increase in the selling price of coal has cumulatively increased every serial operation of manufacture in which coal is required, but the process of "reconstruction" (to use a euphemism for wage reduction) has proceeded in the reverse direction, so as to have created the anomaly that in the two branches of industry which are most basic in character, namely coal production and rail transportation, wage reductions have come last, or not at all.

It is of course certain that the drastic reductions in the prices of steel products recently announced mean equally drastic reductions in underlying wages. The wages of steel workers have been very substantially reduced, and as probably 70 percent of the cost of steel represents the use of bituminous coal, it seems fairly evident that steel manufacture cannot proceed until the labour cost of coal production is lessened. It is also equally apparent that the lack of demand for bituminous coal is a result of the cessation of the use of coal in steel manufacture, and that this slackness of coal demand will continue until such time as the selling price of coal will permit its use in steel manufacture.

The post-war cost of coal is one on which most diverse opinions exist, but on its determination there waits all the long train of transportation, manufactures and agriculture. There will be very little progress restoration of general business conditions until the public has made up its mind that coal is "a buy". And in this regard, the domestic consumer is not of decisive importance.

DISTRESS AT CORNISH MINES.

The South African Mining Journal for May 28th contains a letter to the Editor from the Chairman of the Central Relief Committee at Camborne, Cornwall, appealing for financial help from Cornishmen and their descendants abroad for the Cornish people at home, where every "Bal" is idle. The letter is one which seems to indicate that mining in Cornwall is for all practical purposes finished, and that further emigration of Cornish miners will be forced by the decay of the industry of mining in the County. There are, however, a number of old miners and their dependents who will be unable to find work of any kind so long as mining in Cornwall is dead, and, as stated the industry seems depressed beyond hope of revival. There are a number of Cornishmen in Canada, and many more in the United States. Contributions would be gratefully received by Joseph Cock at Camborne, who writes: "If you can help, help soon."

WATER POWER DEVELOPMENT AT PORCUPINE.

The increasing demands for power of the mines at Porcupine are expected soon to result in the development of additional water powers. The unusally light rainfall of last summer and fall resulted in a severe shortage of power during the winter, and uneasiness is felt as to requirements being met with in future. The present demands of the mining companies may be satisfied if the rainfall is normal this Summer and Fall; but the plans for increased output as well as assurance of power for present output are dependent upon more power being developed. On this account both the Hollinger and McIntyre companies have taken up water-power rights with a view to development. It is considered probable, however, that the power company itself will make arrangements for meeting the demand. The McIntyre Company has surveyed its water-power at Sturgeon Falls, on the Mattagami River, and the Hollinger Company has surveyors at work on its power at Long Sault Rapids and Kettle Falls, on the Abitibi river. The development of this water power will be a very big undertaking, and it will take many months to make the additional power available. As an insurance against shortage, and to fill additional requirements, however, power development on a big scale will undobtedly be begun soon by either the mining companies or the power company.

Timmins, the chief town in Ontario's premier gold mining area has a population of 6,000. Freight receipts for the year 1920 were $725,000; payroll for the year totalled $4,500,000; assessment was $2,225,000; revenue from taxes, royalties and rates was $170,000; bank clearings for the year amounted to $7,000,000. Twelve years ago there was no town at or near Timmins and the nearest railroad was thirty miles away.

Gold Mining in Northern Ontario

A Review of the History of Gold Mining in the Porcu pine and Kirkland Lake Districts, the Milling Practice, and the Significance of the Persistence of Gold at Proven Depth. With some Reference to the Outlying Properties.

By REGINALD E. HORE, Consulting Editor.

GOLD MINING AT PORCUPINE.

The development of gold deposits at Porcupine has resulted in the establishment in Ontario of a gold mining industry which seems destined to become one of the mainstays of the Province. Already the industry has assumed large proportions, employing several thousand men, purchasing annually supplies that amount to several million dollars in value and producing now over $1,000,000 per month in gold. What has been accomplished during the past twelve years is best appreciated by those who know the history of the industry, for many difficulties have been encountered and overcome successfully by the men who are chiefly responsible for the results that have been achieved. The war period and the subsequent period of high prices might easily have killed a less robust infant. But before the war there were times when the men who put their money and energy to the task of making gold mines had even more serious difficulties to face. They were venturers in a new and unproven field in a Province that had not previously given a good account of itself as a gold producer. They had good reason to be doubtful as to the results of their enterprise, even if fortune favored them. Then when development had given more confidence, fires and strikes were added to the mine operators' troubles. In spite of delays and losses occasioned by fire, strike and war the industry has nevertheless grown in twelve years, since the discovery in 1909, until it has put Ontario prominently before the world as a gold producer, and given the Province the distinction of having one of the best gold mines. But greater even than the progress made at Porcupine is the new aspect it has given to the gold possibilities of large areas in Northern Ontario. It will take many years to mine the ore at the mines now producing at Porcupine and Kirkland Lake and it will be strange indeed if many new producers are not added to the list during the lives of the present producers.

To appreciate the present situation at Porcupine it is well to recall that twelve years ago the present Hollinger, McIntyre and Dome Mines were but minute patches of the forest, thirty miles from the railroad. The prospectors in 1909 made little clearings around their discoveries; but the area was still practically virgin forest and travel was by trail, river and lake. Then came the men who developed the properties, who risked their money at a time when the difficulties were obvious and the extent and value of the deposits very doubtful. To transport light machinery and supplies rough roads were cut through the forest. In Summer, supplies were dragged part way through the muddy roads and trails and carried on small boats on river and lake. Then the windlasses and head frames appeared on the outcrops and the clearings widened and more log-cabins rose. The quartz veins were stripped and carefully sampled. Shafts were sunk and ore of doubtful value hoisted. Then at the Dome and Hollinger results of exploration led to heavier expenditures on development. At the Hollinger a little Tremaine mill was installed and proved to be a big factor in the history of the mine. At the end of the year 1910 the Dome and Hollinger were being vigorously developed. The McIntyre was still an interesting prospect. Around Porcupine Lake settlements were springing up. The winter road was crowded with teams hauling supplies from the railroad. The operators were asking for the construction of a branch line to Porcupine. During the following year construction of a railway to the Dome mine was begun and later, after much urging, the railway was extended to the Hollinger. Towns sprang up rapidly at Porcupine Lake and Pearl Lake. Of those at Porcupine Lake, South Porcupine, nearest to the Dome mine, grew largest. The Pearl Lake settlements gave rise to the present town of Schumacher. The town of Timmins, laid out later across the lake from the Hollinger, has become the leading town of the district, having a population of about seven thousand. During 1910 and 1911 a little gold was produced amounting in all to $50,976. Then in 1912 production on a large scale began and Porcupine has since that time produced about ninety per cent of the total gold output of Ontario. The output rose from $1,730,628 in 1912 to $9,397,536, in 1916 and then fell off slightly, when under normal conditions it would have continued to increase. It is only within the past few months that Porcupine mines have been making the production that was planned for some years ago. War conditions, and then labor and power shortage, have kept production down. Now deeper development is being planned and capacity production being a reality increased capacity is being talked of.

The Hollinger mine is Porcupine's prize exhibit. There was a time, some few years ago, when a less familiar name threatened to become more prominent; but with the organization of the Hollinger Consolidated Mines the Acme mine has become part of the Hollinger. Had it not been for the consolidation the Acme mine would itself be one of Porcupine's best mines. Much of the best ore at the Hollinger comes from the Acme claims. The main veins on the Hollinger strike north-easterly across the property, bending southerly at the west and east from the course at the original Hollinger claim. The easterly extension of the deposits or series of deposits crosses into the McIntyre property. The western and southern extension has not been proven beyond the boundaries of the property. The best part appears to be the Acme claim between the original Hollinger and the McIntyre. Good ore extends across the Hollinger, but development has apparently been more successful towards the east than towards the west. The vein system which sweeps across the Miller-Middle, Hollinger and Acme claims and extends into McIntyre ground is now yielding over $30,000 in gold per day and may be confidently expected to yield some such amount daily for many years. The men who developed the deposit have good reason to be well satisfied that they know an ore deposit when they see one. The deposit, if we use the word to embrace the system of veins, contains a number of ore bodies which can be profitably mined under present conditions and also a very large tonnage

of somewhat lower grade which under better conditions may be worked profitably. The reports of the Hollinger and McIntyre companies show that ore reserves of very substantial size and values are proven and that exploration indicates the presence of a large quantity of ore yet undeveloped. In the recently issued annual report of Hollinger Consolidated Mines, Mr. A. F. Brigham, the general manager, gives an estnmate of the ore that will average over $6 per ton. The figures will be found on another page in this number of the "Journal." Refercnee to these figures will give a fair idea of the gold content of the developed ore.

In developing the Hollinger and McIntyre mines a number of shafts were sunk on the veins and it was found that they are nearly vertical and that the main orebodies hold well with depth. Drifts were run along the veins and the several shafts connected. As development proceeded at the Hollinger the work was centralized more and more at one shaft and main haulage-ways established at the 425 and 800 ft. levels. At the lower levels development is carried on from a long tunnel south of the vein system which is used as a main haulage way. From this tunnel crosscuts are run through the veins. These crosscuts serve as haulage ways from the

3050

Hollinger Mine ten years ago.

drifts to the cross cuts and then hauled by electric locomotive to the main tunnel and hence to the hoisting shaft. Below the 800 ft. level development has been carried on by winzes. A level has been established at 1250 ft. and from this level raises are being cut at the two operating shafts. Most of the ore that has been taken from the Hollinger mine up to date has come from above 550 ft. Stopes are now being opened up on two veins at the 675 ft. level.

At the McIntyre, development near surface was not very satisfactory. The deposits there were irregular and the ore relatively low-grade. In the first few years of operation the management found it difficult to locate any great quantity of ore and very difficult to make any profit on the ore that was developed. The production up to March 15, 1915 was 127,349 tons which yielded $1,020,250, Prior to 1914 operations gave no profit. As development proceeded, however, and greater depth was reached, ore more like that at the Hollinger was encountered and mining on a profitable basis became possible. Then with greater depth the McIntyre began to loom up as a big mine and now the probabilities are that McIntyre will develop into a big mine with depth. It is already a large producer; but apparently will be much larger. In the early days the strong point in McIntyre's favor was that it seemed likely to carry the extension eastward of the Acme veins. Thanks largely to the skillful management of Mr. R. J. Ennis the mine lived through some very trying times until eventually the better orebodies were discovered at greater depth.

At the Dome mine a big body of ore was found near surface and about one million tons was mined from above the 100 ft. level. This was taken from open pits at a relatively low cost. As development proceeded, however, it was found that there was much poor ground at lower levels. Then another big orebody was opened up below the first ore. Again this second one became poor. Further development has opened up a third big orebody at the tenth level, the present lowest level. The Dome orebodies are not tabular like those at the Hollinger and it is not easy to estimate quantities or values between levels. Such information as can be gleaned from the company's recent report indicates that the new orebody is higher grade than those nearer surface and that it is of good size.

Dome Mine and Mill.

The history of the three mines has thus been quite different. Hollinger has advanced on a fairly steady course. McIntyre started weak and has grown strong. Dome has been in and out with a fairly good average and a strong present bottom. The story of progress reflects very well the nature of the ore deposits at the three mines.

The development of the mines has resulted in quick settlement of the district. The millions of dollars disbursed by the companies for labor have given the community a considerable buying power and many merchants have established good business enterprises. The railroad has found in the mining industry its chief source of revenue and the Porcupine branch of the Ontario Government railway is one of its busiest sections. Along the line, lumbering and pulpwood enterprises have sprung up. Farmers settling in the district have found a good market for their farm products and work when they needed it at the mines and lumbering camps. In the towns good schools have been erected and recently the Hollinger company finished construction of a splendid hospital. Where a few years ago the forest

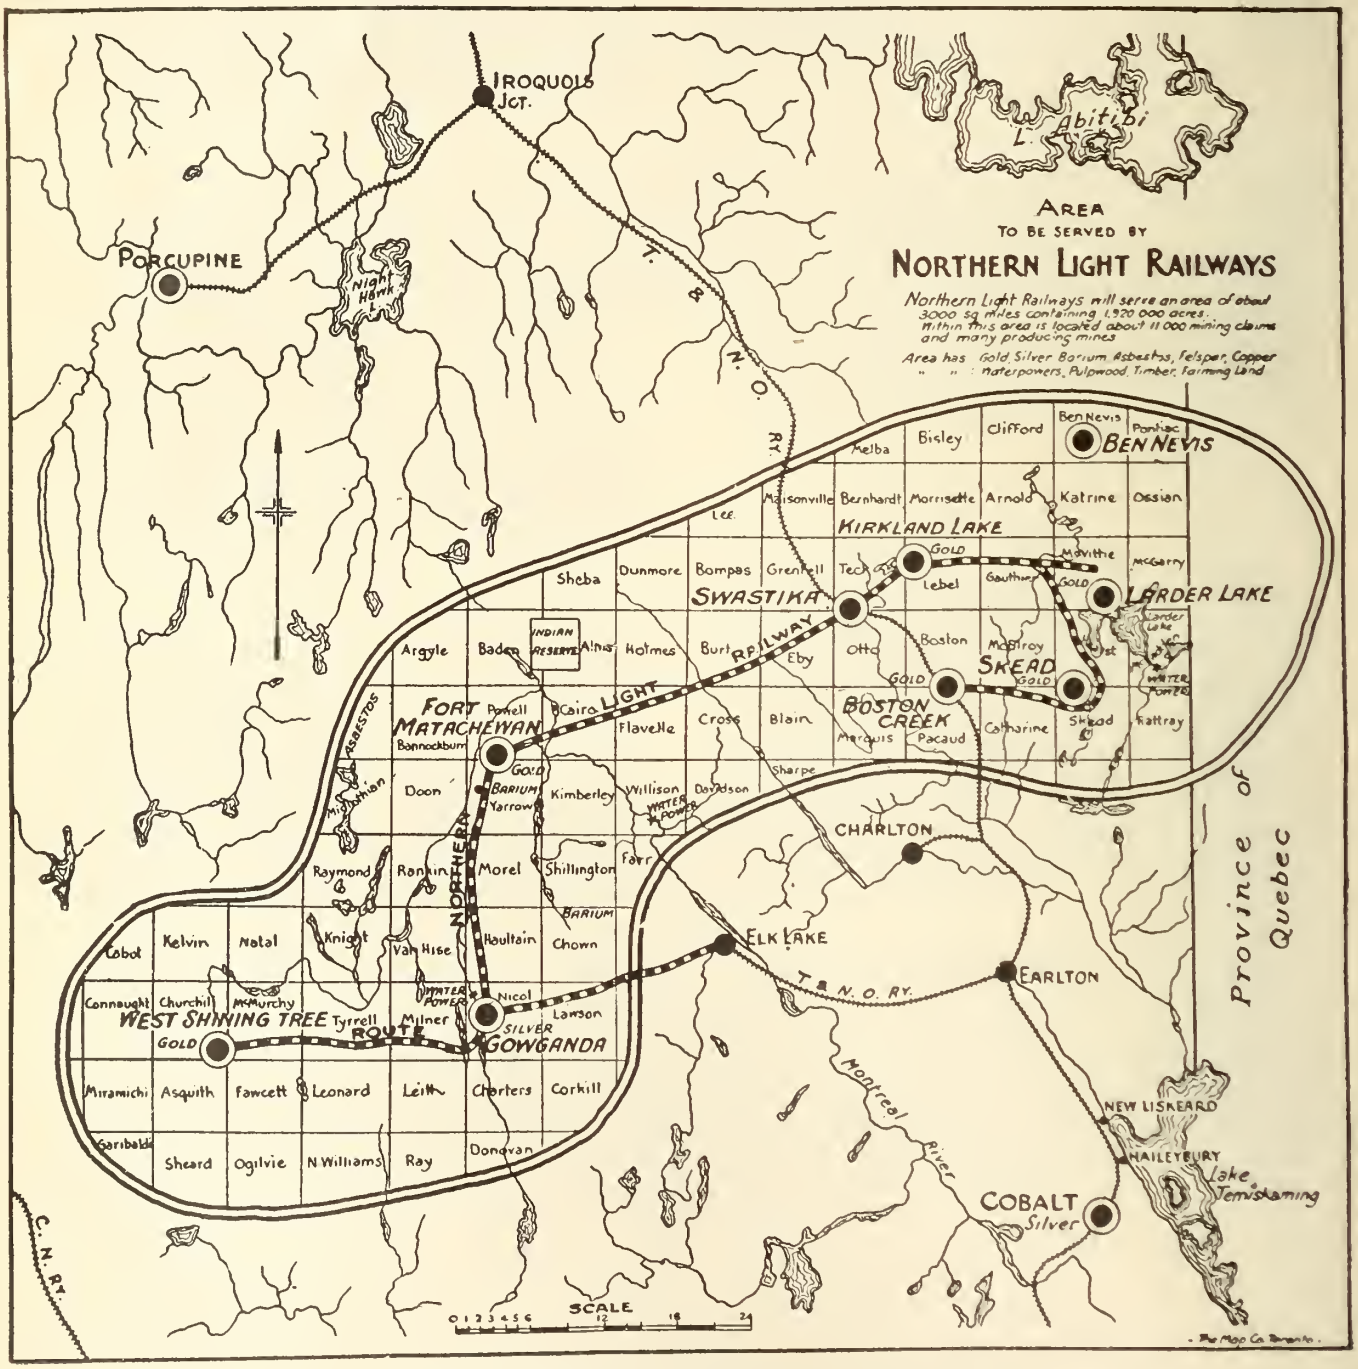
was unbroken there is a skating arena and a golf course. Along the course of the old trail from Mattagami River to Miller Lake there is now a road along which motor cars run. Here between Timmins and the river a clearing has been made for 150 houses that are to be built for Hollinger workmen this summer. Crossing the old trail is the power transmission-line from the plants on the Mattagami which make the river run the machinery at the mines and mills and provide light for mines, shops and houses.

The business done in Timmins is shown by a report by the Board of Trade on conditions in 1920, when activity was not as great as it is now. During the year freight receipts totalled $725,000, bank clearings amounted to $7,000,000, the assessment totalled $2,225,000. The population at the end of 1920 was about 7,000 and it has grown rapidly during the past few months. Pay-rolls totalled $4,500,000 in 1920 and will be much larger this year.

During 1920 there was a great shortage of labor at the gold mines; but conditions changed rapidly during the winter and there is now a plentiful supply of workmen. There is a surplus of unskilled labor, but experienced miners will still find opportunities for employment at the gold mines. During the past winter there was a shortage of power and the Hollinger and McIntyre have both acquired water rights. The Hollinger alone could have used all the power available last winter and proposes to develop the Long Sault rapids on the Abitibi river. The McIntyre is making plans for development of Sturgeon Falls on the Mattagami river. It is possible that the mining companies and the power companies will in some way combine forces to meet the situation. Unless there is a plentiful supply of rain this

Summer and Fall the mines will probably be handicapped again by shortage of power before the year is over. Arranging for more water power is therefore one of the most important tasks of the Porcupine gold-mine operators this year. The production of gold during the coming year should far surpass that of previous years if the necessary power is provided.

The mines of Porcupine are at present supplying the mills with about 4,800 tons ore per day. The three companies employ about 2,600 men. At the present rate of production the output for 1921 will be much larger than in any previous year. In 1920 there was treated at Porcupine mines 1,162,065 tons ore yielding $10,597,572 gold and 93,872 oz. silver. Hollinger treated 650,205 tons yielding $6,164,264 in gold; McIntyre 191,032 tons yielding $2,202,100 and Dome 295,220 tons yielding $2,005,640 in gold. This output was made in a period in which labor was scarce followed by a period when there was a shortage of power. It does not therefore show capacity output by any means.



Proposed Scheme of the Northern Light Railway.

It is understood the Ontario Cabinet will not extend financial aid to this project. The map shows how necessary such a railway is for the gold prospects east of Kirkland Lake, and how useful a railway would be for the area indicated.

Gold Mining at Kirkland Lake

General View, Kirkland Lake.

Kirkland Lake now has four producing gold mines and next to Porcupine is Ontario's leading gold district. The ore mined is relatively high grade, being the richer parts of a single mineralized zone which extends east and west from the lake which gives its name to the district. This deposit was developed at the Lake Shore mine, where it is known as No. 2 vein, and has made that company's operations very profitable. To the west it has been developed at the Teck-Hughes and Kirkland Lake Gold company's mine. To the east it is being developed at the Wright-Hargreaves. Further east and not yet definitely connected with this deposit similar ore was mined at the Tough-Oakes mine.

The first producer at Kirkland Lake was the Tough-Oakes mine. Here very rich ore was mined for a few years, much of it averaging $20 to $25 per ton. About $2,000,000 in gold was produced at this property while it was being operated. An attempt is now being made to find extensions of the orebody which was cut off by faults laterally and at depth. This work is being carried on by Kirkland Lake Proprietary Ltd, which corporation controls also the neighboring Burnside property and is understood to have an option on the Sylvanite. The Tough-Oakes orebody was an exceptionally rich one and it is reasonable to expect that considerable money will be spent in an endeavor to find more such ore on this and neighboring properties.

During 1912 and 1913 when development work was being carried on at the Tough-Oakes some of the ore was hand sorted and shipped out for smelter treatment; 101 tons of such ore yielding $46,221 or about $457 per ton. In 1914 the company shipped 212 tons ore averaging $350 per ton and milled 3,492 tons ore averaging $22.33 per ton.

At the Lake Shore milling operations were begun in March 1918 and during the first nine months there was treated 14,498 tons ore which yielded $24.76 per ton. In 1919 there was treated 11,907 tons which gave an average recovery of $24.67 per ton.

The mines at Kirkland lake producing in 1920, treated 91,237 tons ore which averaged $11.38. Lake Shore Mines Ltd., treated 19,779 tons yielding $502,113, Kirkland Lake Mines Ltd. treated 40,812 tons yielding $285,170 and Teck Hughes Gold Mines Ltd. treated 30,646 tons yielding $246,194. The average yield will probably be higher in 1921 owing to operations at the Wright Hargreaves mine.

The Lake Shore mine has been the making of Kirkland Lake as a mining district. The operations at the Tough-Oakes brought the district prominently before the mining public and led to much prospecting and development on neighboring claims; but it remained for the Lake Shore to demonstrate the fact that the main ore deposit crosses several claims and that it can be profitably worked at many places. To Mr. Harry Oakes belongs most of the credit for making the Lake Shore mine and incidentally its neighbors. By persistent effort he carried on development of the property and proved the presence of much high-grade ore in No. 1 vein. Then his company exploring under the lake developed the No. 2 vein which has been since found to be the main vein. The Lake Shore company installed a 60 ton mill and is turning out a steady stream of gold while continuing development on an extensive scale.

West of the Lake Shore, the Teck-Hughes company carried on development for some time without obtaining good results. Lately, however, the company has been more successful and is now reported to be operating profitably.

Adjoining the Teck-Hughes the Kirkland Lake Gold Mines Ltd., which is controlled by a Cobalt company, Beaver Consolidated, has succeeded in developing good ore and is a steady producer. Quite recently production has been begun at the Wright-Hargreaves where excellent ore is reported to have been developd. The mill has just been in operation about two months and no statement of character of ore being treated is as yet available. It is understood that the grade is about the same as that of the ore treated at the Lake Shore mill.

The gold production of Kirkland Lake district in 1920 was $1,033,478. Production this year is expected to show a very considerable increase as labor conditions are better and another important addition has been made to the ranks of producers.

The nature of the operations being carried on makes it appear probable that the grade of ore treated will be relatively high for some time. To break low-grade ore at present is not considered good policy. The present conditions favor the treatment only of the better parts of the known deposits. At some later date larger scale operations will doubtless be used for treatment of the lower grade ore.

Kirkland Lake is four miles from the Ontario Government railroad. For years it had very poor transpor

tation facilities. There is now, however, a very good stone road serving the mines and motor trucks are busily engaged in freighting supplies. As at Porcupine electric power is used at all the mines. It is expected that the area east of the mines will be opened up in the near future and construction of a light railway is being planned to serve this area.

As compared with Porcupine, costs are relatively high at Kirkland Lake. This is partly due to the nature of the ore deposits and partly to the nature and size of the operations being carried on. For some time it will be impossible to compare costs in the two districts fairly.

Some account of the nature of the deposits and of the methods of treating the ore at Kirkland Lake will be found on another page in this number of the "Journal." It will be evident that the discovery of such deposits and the development of them necessitates a great deal of careful and in many cases unproductive work and that the mining and crushing of the ore necessitates the expenditure of more work than is entailed in operations at Porcupine.

Wright-Hargreaves Mine and Mill.

The weathered surface of Kirkland Lake ore deposits is not of a nature to attract much attention. In many places ore and rock show few distinguishing features. Where there is considerable quartz the deposits are not so likely to be overlooked; but, the inconspicuous nature of much of the ore necessitates careful stripping, breaking and sampling. The removal of the overburden and the thorough examination of the stripped ground make prospecting slow and arduous. The difficulty of recognizing ore at the surface without systematic stripping and sampling has led to a desire to get underground where the troublesome overburden is avoided and a continuous horizontal section of the deposit can be sampled. Such prospecting is neeessarily costly and slow. The chances are that the surface will give a fair average of the character of a deposit and wherever possible it should be stripped and rigidly examined there. The surface section is as likely to prove an average section as that at any other level. There seems to be a belief that the deposits are better at depth than at surface and there are doubtless cases where this is true. To no small degree, however, the difficulty of recognizing the deposits at surface is responsible for the belief that the oreshoots do not run to surface. The two mines that have earned dividends had high-grade ore at surface. The best known vein lies for the most part under Kirkland lake. Much of the area is drift covered. The chances of finding more high-grade veins at surface still remain very good and further intensive surface prospecting will have to be done before the possibilities of the district are known. Much careful work has been done; but the difficulties presented to the prospector have made the work very trying. It is to be hoped that there will be a revival of the search for high-grade ore at surface, more use of pick and shovel in stripping leads, more liberal use of dynamite and more searching examination of the uncovered rock and particularly more sampling and panning. Such ore as has been mined at the Tough-Oakes and Lake Shore mines need not be in large quantity to make profits for the operators and such deposits are well worth looking for, even though much careful work has already been done and the chances of discovery to that extent made smaller.

The development work at the mines has given confidence in the persistence of ore in depth and in some cases has given results more satisfactory than the surface showings indicated. The finding of better-grade ore at the lower levels in some of the mines gives reason for hope that other deposits which are not very high-grade at surface may be found to be high grade at a depth of a few hundred feet. It is a fair speculation for those who can afford to stand the cost of shaft sinking and underground prospecting. There seems,

however to have been too easily assumed an idea that the high-grade deposits do not reach the surface and that therefore further surface prospecting in the neighborhood of the mines is not likely to give good results. This idea discourages those who might spend a relatively small amount of money at surface in searching for ore. It is well to remember that the present surface bears no known genetical connection with the ore deposits and that the difficulty of recognizing them may have easily resulted in the overlooking of deposits that are high grade at surface.

The producing mines will be able this year to make a good output, considerably larger than in previous years. A prosperous and busy year is anticipated.

The Lake Shore Mine and Mill.

TREATMENT OF GOLD ORES AT PORCUPINE AND KIRKLAND LAKE.

At all Porcupine and Kirkland Lake gold mines the cyanidation process of recovering gold is used. Crushing at the Hollinger is by stamps; but in all the other plants by ball-mills. The Dome has sixty stamps; but does nearly all its crushing in ball-mills, feeding only some of the larger-size crusher product to the stamps. At the Hollinger, where there are 200 stamps in operation, one ball-mill is in use. At the McIntyre, Lake Shore, Kirkland Lake, Teck-Hughes and Wright-Hargreaves, ball mills are used exclusively.

Primary crushing by gyratories or jaw crushers followed by rolls or small crushers prepares the ore for stamps or ball-mills. Tube mills are universally used to regrind the ball-mill or stamp-mill product. Pebbles are used in the tube mills; but recent experiments at the McIntyre and Dome mines have given results that are likely to lead to the use of balls instead of pebbles in the tube mills.

At the Dome, the tube-mill product goes to classifiers for separation of sands and slime which until recently were treated separately. At present all the product is slimed. Before treatment by cyanide the pulp is passed over amalgamating plates and a blanket. About two thirds of the gold recovery at the Dome is made by amalgamation. The pulp passes on for cyanide treatment.

At the Hollinger, concentration plays an important part. At the McIntyre cyanidation is depended upon entirely, the fine grinding being done in solution and the slimes passing direct to the tanks. Agitation and filtering decantation methods at the three mines have been described in technical articles and have not changed much since those articles were published. One notable improvement has been made by removing the air from the solutions before precipitation, as is now being done at the McIntyre and Dome mills. This effects a large saving in zinc. A noteworthy change in practice will be made when treating ore high in carbon content. The ore carrying much of this substance will be treated chemically before being cyanided, in order to reduce the precipitating activity of the carbon.

At Kirkland Lake the method of treatment is much the same as at Porcupine, the plants being designed for fine grinding followed by cyanidation. The most recently constructed mill at Kirkland Lake is quite similar to that at the McIntyre.

The Kirkland Lake ore however is much more difficult to crush than that at Porcupine and the crushing department of these mills is necessarily more prominent. A high recovery is made at both Porcupine and Kirkland Lake and the mill practise is given a high rating by metallurgists who are familiar with results obtained in many districts. The nature of the ore is responsible for the relatively low capacity of the grinding equipment at Kirkland Lake mills.

Descriptions of methods of treatment at the various mills are to be found in the publications of the Canadian Mining Institute, Ontario Bureau of Mines reports and in the reports of the Mining Engineer of the T. & N. O. Ry. Commission, and those who are interested will find that the literature is quite extensive and that many leading metallurgists have contributed to the development of the practise. Improvements and changes to meet new conditions are always being made and Northern Ontario is assuming a leading place in development of methods of treating gold ore as it has in the case of silver ore.

The plans for the new mill to be built this year at the McIntyre will be of considerable interest to metallurgists, as provision will be made for treating some ore that has been left unmined because of its carbon content. We hope in a later number of the "Journal" to give an account of the process devised to treat such ore.

PERSISTENCE OF THE ORE WITH DEPTH AT PORCUPINE AND KIRKLAND LAKE.

That the gold deposits at Porcupine and Kirkland Lake will be worked to very considerable depths is becoming more obvious year by year. There is good reason to believe that development during the next few years will result in very large quantities of good ore being opened up below 1,000 ft. Lower workings are giving encouraging results and deepening of shafts at Hollinger, Dome and McIntyre will be under way this year if plans are carried out as expected.

The Hollinger-McIntyre series of orebodies are enclosed in carbonated grey rocks that appear to be for the most part altered volcanic rocks. The orebodies fringe masses of quartz porphyry and extend roughly in the direction of the axis of the porphyry mass. The main mass widens towards the east and near surface crowded the McIntyre to its southern boundary. Then orebodies were found north of the porphyry and the chief source of McIntyre ore latterly has been across the lake from the early workings. At the Hollinger the porphyry influence was not so noticeable in the early workings; but as development proceeded eastward the wedge of porphyry from the McIntyre began to influence the course of the openings. For some time therefore the determining of the shape of the porphyry mass has been recognized as one of the important structural problems, particularly at the McIntyre. The results of development during the past few years indicate that the porphyry is not such a serious obstacle as it seemed likely to be.

At the Dome mine the orebodies are for the most part enclosed in sedimentary rocks bordered by porphyry. Exploration has extended into dark colored igneous rocks and one orebody in these rocks has yielded a good tonnage of ore, but workings in the porphyry have resulted in that mass being considered the boundary of the ore deposits.

At both Hollinger and Dome the individual orebodies continue downwards nearly vertically. In the orebodies that have been opened up at the Hollinger a remarkable similarity has been found at the several levels. It is noteworthy because in many districts the oreshoots show pronounced pitch or rake along the veins. At the Dome also the orebodies showed no pronounced pitch and the second orebody was found below the first large one. The orebody now being opened up is to the east of the first two, but is apparently a distinctly separate one. The two areas are similar in that development has resulted in discovery of orebodies at depth further east than the orebodies which outcropped and also similar in that the orebodies which were worked from the outcrop had a vertical or nearly vertical pitch.

Most of the ore that has been mined at the Hollinger up to date has come from above the 425 ft. level and nearly all the remainder from above the 675 ft. The deepening of the shafts to the 1,250 ft. level is now underway. The manager estimates ore reserves at 4,087,083 tons carrying $41,719,670 or an average of $10.20 per ton. Of this 1,394,453 tons averages $14.02 and 1,748,456 tons averages $9.09. Ore reserves above the 425 ft. level amount to 1,433,409 tons and above the 825 ft. level there is an additional 1,629,753 tons. It is difficult without maps and assay plans to tell how individual orebodies are behaving, but the information given in the company's last annual report indicates that those that were good near surface have continued so for several hundred feet down and that some of the new orebodies are proving up well. The following tabulation of Hollinger ore reserves tells much of what is de-

A Stope in the Hollinger Mine.

finitely known about the orebodies. Taken in connection with developments at greater depth at Hollinger and McIntyre these figures are very impressive. Without careful study of the results of deeper exploration at the two mines it would be idle to make predictions as to the probable downward extension of the individual orebodies; but those who are interested in gold deposits will find in the Hollinger and McIntyre reports information that will strengthen their confidence in the belief that deposits of this character have no genetic connection with the present surface. The downward extension of any one orebody is likely to terminate just as does the lateral extension; but the downward extension of the ore deposit as a whole has no known limitations.

At the Dome mine development has proven that while the orebody first mined did not extend to any considerable depth, there are other orebodies below it. The first orebody yielded about one million tons of ore above the 150 ft. level, but did not behave well with depth. Then another large orebody was found a little deeper than the first. This also was of no great vertical extent. Now a third orebody is being opened up at the 10th level or 1145 ft. below surface and the mine is looking well at the bottom and the manager is planning on deepening the shaft in the immediate future.

At Kirkland Lake also good ore is being found at the lower levels of the mines. At the Tough-Oakes, which is at present without ore, there is a reasonable possibility that exploration will result in more good ore being found beyond the faults which cut off the orebodies. At the other mines work at the lower levels has given ex-

cellent results. At the Lake Shore the 600 ft. level is now being opened up. At the Kirkland Lake mine the 900 ft. level is said to be in good ore. None of the mines in this district are as yet explored at very great depth; but so far as development has proceeded it has increased confidence in the results that will be obtained in deeper workings. Some of the orebodies are evidently better than work at or near surface indicated. Increase, like decrease, in values with depth, however, is evidently not genetically connected with the present surface.

Developments at Porcupine and Kirkland Lake give reason for confidence that gold mining in these districts will continue to great depths. The present surface is apparently best regarded as a mere incident in the life-history of the ore deposits, being non-existent when the deposits were formed and having very little influence on them since. Structural problems will doubtless continue to arise with development; but the chances that values are better at depth are at least as good as the chances that they are poorer. The depth to which mining will continue will depend on the exploration policies of the operating companies as well as on the cost of mining. It is hardly to be expected that individual orebodies will extend downwards for several thousand feet; but there is good reason to expect that exploration will result in the discovery of a series of orebodies that will make mining profitable to great depths.

Developing Mines

Associated Goldfields.

Development work is being steadily carried on at the Associated Goldfields property at Larder Lake. Transportation has been made more economical by use of a tractor which hauls heavy loads over the roads with comparative ease. The company has its own water power plant. It is understood that sinking of the three compartment shaft and opening up of the ore deposit at several levels will be the company's chief activity for some months. Considerable development work has, however, also been done at the Harris-Maxwell mine.

Argonaut.

The Argonaut Mining Co. has been handicapped for some weeks as a result of a fire which destroyed part of the plant. The company operates a stamp mill and has been recovering considerable gold while carrying on development work. The tailings from the temporary treatment plant will be treated later when a cyanide plant is installed. The recovery in the present plant is said to be about $7 from $10 ore.

Triflex.

During the past few weeks a number of men have been employed at the property of the Triplex Mining Co. in Shaw Township, Porcupine district. Major Harrison is manager of the company, whose property consists of a large number of claims including those of the Tommy Burns Mining Co.

McIvor.

It is understood that further development of the McIvor gold property will be carried on this summer. The property is near Swastika and about three miles from Kirkland Lake. It is proposed to do some development at the 100-ft. level which has already been reached in the shaft.

Lebel township.

A number of discoveries have been made during the past two years in Lebel township east of Kirkland lake. Recently a new discovery has been reported from the Moffatt-Hall property. During the past year considerable development work was done at the Bidgood property near Mud lake. The operating company, Bidgood Gold Mines Ltd., having installed plant for underground work and sunk a shaft and opened up veins at depth. The King Kirkland Gold Mines has several claims in this township. The discovery on the Moffat-Hall and discoveries on other claims now being prospected is giving considerable confidence to those who are developing claims in Lebel. Transportation facilities are much needed. It is expected that a waggon road will be constructed this year and there is a possibility that the township will soon be served by a light railway.

Skead township.

During the past few years a number of gold discoveries have been made in Skead township. Geologists of the Ontario Department of Mines examined the area recently and are now preparing a report on it.

Shiningtree.

A number of important gold discoveries have been made in the Shiningtree area and the development work done has shown that this area will be a productive one. Most of the work done was accomplished at a time when conditions were very unfavorable. Transportation has however been considerably improved by the construction of a waggon road from Westree. With the return to conditions favorable to gold mining renewed activity in the Shiningtree area is expected this summer. Several companies are planning to resume development work soon. At the White Rock a small mill has been installed to treat ore as development proceeds. The Wasapika company proposes to construct a mill which will be enlarged later when the mine is further developed. The Atlas company is planning to instal plant for development work. It is expected that the Churchill Mining Co. will resume development of its large property soon.

War conditions and the subsequent period of high prices have handicapped operators at Shiningtree and the lack of a good waggon road was a serious obstacle. Better progress may be expected now that these obstacles have been removed. The Wasapika orebody has proven to be a large one and rich ore is known to occur on several properties in the area.

Comfort-Kirkland Mines Ltd.

The Comfort-Kirkland Mines Ltd. has been incorporated to develop claims in the Kirkland Lake district. The property is situate between the Ontario-Kirkland and Minaker properties in Teck township. The directors are Dr. C. V. C. Comfort of Rochester, Andrew M. Stobie of St. Catharines, Malcolm Stobie, Archibald McVey Little and Henry M. V. Weller of Toronto. The capital is $1,500,000 in shares of $1 each.

Ontario Kirkland.

At the Ontario Kirkland mine underground development is proceeding and some high-grade ore being opened up. Progress is being made with construction of a mill. The site has been made ready and materials for the building are being assembled.

Goldale.

Exploration of the properties of the Goldale Mining Company at Porcupine is underway. This company has several claims east of the McIntyre and the work now being done may result in important discoveries. Mr. H. Poirier is in charge of operations.

Other Gold Areas.

Gold has been found in many parts of Northern Ontario and in several areas there are properties which are likely to add considerably to the Province's gold output. These properties are in various stages of development and have been handicapped by adverse conditions which are gradually disappearing. War and the period of high prices for supplies and labor made development of gold properties unattractive. Now the increasing purchasing power of gold is increasing the possibilities of the, as yet, unproductive mines. A further impetus to gold-mine development is the prospect of the provision of better transportation facilities for several of the promising areas. Conditions having changed for the better, it is probable that the search for gold will result in important developments during the coming year in several areas in Northern Ontario.

Porcupine Crown.

Search for new orebodies is proceeding at the Porcupine Crown. This mine was profitably operated for some time, but is not at present productive. It is planned to do more underground exploration before resuming mill operations.

NORTHERN ONTARIO AS SOURCE OF PLACER GOLD IN INDIANA.

Indiania State Geologist in 1902 Forecasted Northern Gold Occurrences.

By C. HAFER (From "Engineering and Mining Journal").

Some months ago, at a meeting of the Canadian Mining Institute, the question arose as to the whereabouts of the placers from erosion of the Ontario gold veins.* Without knowing anything of Ontario gold deposits, either in place or fragmental, I am inclined to believe that they may have been removed during the glacial period, scattered over the drift-covered area of the interior northern states, and, in some places concentrated, forming placers of sufficient richness to suggest near-by gold veins and affording a field of effort to the inexperienced.

Among numerous localities where gold has been found in the drift-covered region, the most important is probably Indiana. Little known to miners throughout the world, this field has awakened considerable interest in the Middle West, and has been the scene of activity, at intervals, with little profitable result, as far as I know. In 1901-02 I spent part of the two summers there panning and testing the deposits with a sluice box. The counties of Brown and Morgan, lying forty to sixty miles southwest of Indianapolis, are the ones most prospected for gold, though there are a number of others from which gold has been reported.

In Morgan County, the surface features are typical of the Middle West, in general flat, with valleys carved by streams. No igneous or metamorphic rocks are known to exist here, and certainly none are visible in place. The placers have been satisfactorily determined to be of glacial origin, as a result of the investigation of a number of geologists, among them glacial specialists in the Government employ.

It is evident to the miner that the debris he finds below his boxes is not all of local origin, as there are fragments of granite, gneiss, amygdaloid, greenstone and iron ore, and in the riffles one finds pieces of corundum, garnets, and, in addition, an abundance of black sand.

According to the state geologist of Indiana, Blatchley, in his report of 1902, gold was discovered in Morgan County by returned Californian miners in 1850, who observed the characteristic black sand in the ravines and began prospecting. They found gold in the tributaries of Sycamore and Lambs creeks, and some were able to recover two to three dollars per day for several weeks. Numerous fortune hunters were attracted, and the pay dirt was washed out in a short time, when the boom subsided. Since that time washing has been carried on by a few workers, with pan and rocker, in Brown and Morgan counties, with a total production, estimated in 1874, at $10,000 and since then probably doubled. The largest nugget recorded is of 132 grains, valued at $5.50. The silver content is small, a mint report of July 12, 1901, making return of 61c. for silver in 14.05 oz., $250.07 being the total amount of the return.

In 1902 we washed only ten yards of dirt, with a recovery of $2.50 in the boxes, when the water supply gave out, and with the gold pan we tested the little valley in which the work was carried on, finding nothing more to attract us. The gravel stratum above bed rock here was largely of the country rock, with little of the foreign wash. On Gold Creek, to the northeast, there were more foreign boulders, and apparently better and heavier values. All of the gold found was flat and well polished, indicating the long journey to its present resting place.

It is interesting to note that several diamonds of value have been found in this gold field. Mr. Blatchley mentions having seen eight, ranging in weight from one eighth of a carat to four and seven-eighths carats.

The conclusion of Mr. Blatchley, in his 1902 report, was that the original home of the gold and diamonds was in the neighborhood of James Bay, in Canada, and he ends with the following, suggestive of prophecy: "It is not improbable that within the next quarter century, a new Eldorado will be discovered among the igneous rocks of this Far Northern region, which will be as rich in gold and precious stones as any heretofore known to man." The discoveries made in Ontario since that report was made seem in a measure a fulfillment of that forecast.

*Note.—"Lost Placers of Ontario, Dr. A. P. Coleman, Toronto meeting C.I.M. & M., 1920. See C. M. Journal, page 221, issue 19th March, 1920."

PERSONALS.

The President of the Algoma Steel Corporation announces that Mr. S. V. McLeod is appointed Purchasing Agent of the Algoma Steel Corporation, Limited, with headquarters at Sault Ste. Marie, Ontario, vice Mr. L. L. Jacobs, resigned, effective 1st July.

Mr. Frederick F. Sharpless has been selected to succeed Mr. Bradley Stoughton as secretary of the American Institute of Mining and Metallurgical Engineers. Mr. Sharpless is at present secretary of the Mining and Metallurgical Society of America. He is a gradnate of the University of Michigan and was for five years Professor of Metallurgy at the Michigan College of Mines.

Mr. C. F. Rand of New York has been elected an honorary member of the Iron and Steel Institute, London. Mr. Rand, who is prominent in the Cuban iron industry, is a past president of the A.I.M.M.E.

Dr. J. J. O'Neill, who is at present in the Mackenzie River oilfield, has been appointed to fill Dr. J. A. Bancroft's place on the geological staff of McGill, during the latter's absence on leave.

Mr. N. F. Dye, manager of Northcliff mine, is in Toronto, on his way to Buffalo. The Northcliff mining company is developing a silver property at Gowganda.

Mr. A. J. Daimpre is in charge of development work at the Murphy gold property, Goudreau, Ont., recently acquired by Toronto interests.

Mr. Kirby Thomas of New York is in Toronto on his way south after a visit to the Gowganda silver district.

Mr. George Carson has opened a customs assay office at Porcupine. Mr. Carson was formerly on the staff of Northerown Mines.

Mr. S. Evans, Chairman of the Crown Mines, Ltd., of South Africa, predicting a coming demand for gold, recently said: "That means it is within the bounds of possibility that the time may yet come when the Crown mines will find it profitable to start again at the outcrop, and mine three penny weight reef".

Northern Ontario Letter

THE SILVER MINES.

The Cobalt Field.

News that the coinage of silver is to be resumed in Russia on September 1st is an indication that sooner or later there may be a general tendency in this direction among the leading nations. Currency without metallic backing has received widespread condemnation, and precious-metal coins promise to find increasing favor from this date forward. Any new demand added to the silver requirements through regular channels seems almost certain to increase the quotations for commercial bar-silver. With this belief in mind, some of the leading operators in the Cobalt district are holding a large reserve of silver bullion in their vaults. This is particularly true of the Nipissing and the Mining Corporation of Canada. The latter company has not shipped any silver in quantity since the beginning of the year, the president J. P. Watson, explaining the situation thus:

"Since the first of the year, we have refrained from selling silver in quantity, owing to the continuing low price, and we are carrying about 650,000 ounces. To offset the loss of interest we would otherwise make, we have been selling spot silver in London at a premium over forward purchases of the same quantity which, without any risk to the corporation, enables us to earn interest on the value of the silver sold and a small profit besides."

For the fiscal year ended Feb. 28, the Beaver Consolidated Mines, Ltd., showed a deficit of $3,617.38. This was attributed to a shortage of labor during the first half of the year, together with a power shortage during the last half of the period, as well as a rapid decline in the price of silver which caused the mine to close on Dec. 31. In his annual statement to the shareholders, F. L. Culver, president of the Beaver, makes the following comment, a summary of the report itself having been presented to the readers of the Journal last week:—

"No new ore bodies were developed during the year on the upper levels, but on the 1400-foot level, driving on the vein which had previousy been encountered at this depth and on into the Prince Davis property, of which we hold a lease, the formation is very strong and well mineralized.

The shortage of power and labor were serious factors in the year's operations, not only enrtailing production and development, but in conjunction with the drop in the price of silver forcing us to finally close the property on December 31, 1920, as we cannot profitably mine the product at present low prices. The mine is being kept pumped out ready for a resumption of operations when conditions become normal.

We would direct your attention to the report of the Kirkland Lake Gold Mining Company, Limited. With the large stock of holdings of Beaver Consolidate Mines, Limited, in the Kirkland Lake Gold Mining Company, Limited, together with the notes held for advances made by it to the latter company for the development of its property and the erection of a mill thereon, Beaver's interest is transferred temporarily to the production of gold. Your directorate, however, are confident in the belief that the throes of world reconstruction are already fast passing, and that with the return of normal conditions, general business will experience an unprecedented revival, bringing an important and enduring demand for silver for use both in coinage and in the arts."

A feature of the affairs of the Beaver is that the company paid $371,519.66 for the stock of the Kirkland Lake Mining Company and has advanced an additional $421,881.34 to develop and equip the mine, thus representing an investment of $793,401.00.

The Coniagas mine is treating upwards of 600 tons daily, made up of run-of-mine ore, slimes and sand tailings. The average grade is understood to be under eight ounces per ton, and the company is realizing a satisfactory profit. This represents one of the most efficient operations in the district.

Advice from South Lorrain tends to indicate that good results are obtaining on the Keeley and the Haileybury Frontier. The Keeley is produeing not far under $1,000 a day, while on the Haileybury Frontier an encouraging amount of high-grade ore is being encountered. It is also learned that the Lang-Caswell property in Lorrain is being de-watered with a view to having it thoroughly sampled. This is one of the properties which became forfeited last Fall, following the general cancellation of claims on which certain provincial taxes had not been paid.

Elk Lake and Gowganda.

Considerable interest is centering about the proposed construction of a light narrow-gauge railway, the details about which have been presented from time to time in this letter. As to the present situation, there seems to be some doubt. The "Globe," Toronto, carried the following note a few days ago:—"The proposed light railway from Swastika into the mining districts of the Montreal River and Larder Lake was taken under consideration by the Government-in-Council. It is understood that the project is not favored by the Drury Cabinet and that it is improbable that the line will be backed by the Government."

The plan of the promoters of the Northern Light Railway Company was to sell $1,850,000 worth of bonds, $1,500,000 to be sold privately and $350,000 to be taken up by the Government. It has been noted that a good many owners of property along the proposed route of the line have not shown much enthusiasm in connection with the scheme. The chief objection heard is in connection with the line being narrow gauge and thereby necessitating the trans-shipment of freight at junction points.

In view of the report that the Ontario Government may refuse to back the project, it would be difficult at this time to hazard an opinion as to what the promoters will do. This, presumably, will depend largely upon the measure of success being met with in connection with the private sale of bonds. One thing is certain, and that is that F. L. Culver, president, and Col. R. P. Rogers, construction manager, were both very optimistic recently with respect to the outlook.

THE GOLD MINES.

The Porcupine Disrict.

Current gold output from the gold mines of Porcupine and Kirkland Lake is at the rate of $1,350,000, amounting to a rate of $4,050,000 quarterly. This compares with a production of $2,953,036 for the first quarter of the year according to figures issued by the Ontario Bureau of Mines, and compares with a preliminary estimate of $3,734,345 for the second quarter

of the year by the correspondent of the Journal.

The increase in tonnage planned at the mines would encourage the belief that production may increase to a rate of close to $1,500,000 a month by the end of the current year, and may approach $2,000,000 a month during the Summer of 1922.

J. P. Bickell, president of the McIntyre-Porcupine is quoted in the press stating that the McIntyre-Porcupine and the Temiskaming Mining Company have lost a total of around $100,000 as a result of their first year in the coal business in Alberta. These companies took over the Blue Diamond coal mine about a year ago, at which time, very glowing remarks were made by officials. In the meantime, the Temiskaming mine is itself not producing any revenue, while the loss on the Blue Diamond coal-mine, together with the salary of $35,000 a year which the McIntyre and the Temiskaming are paying J. P. Bickell, is equal to nearly two month's net profit on the McIntyre in spite of that company producing $2,000,000 a year in gold.

Mill heads continue to run high at the Dome Mines, the ore from the lower levels being about fifty per cent richer than was the average in the upper levels. This is placing the Dome in a strong physical condition, and the treasury is steadily increasing. Provided no unforeseen difficulties arise in connection with labor or hydro-electric power during the coming fall and winter, it is believed the Dome directors will be favorably disposed and in a position to commence making a capital reduction about the end of this year, or early in the new year.

Work is proceeding on the North Davidson property, situated in the north-eastern part of the township of Tisdale. The work is being done under contract, and very encouraging results are reported, although there are no details available.

Kirkland Lake Field.

Interest does not appear to be very keen in Kirkland Lake over the question of building a light, narrow-gauge railway through his field.

The Ontario-Kirkland is proceeding with work in connection with construction of its mill. This company hopes to join the producers some time during the last quarter of the current year. Underground work has placed a substantial quantity of ore in sight, some of which runs about $18 to the ton, and with likelihood of mill heads averaging upwards of $12 a ton.

The new mill on the Wright-Hargreaves is giving extremely high efficiency, and mill heads are high, the average so far being not far under the Lake Shore. For the time being, the ore is coming largely from development work, and heads tend to fluctuate. This policy will be followed for a number of months, during the time stopes are being opened and work advanced far enough to regulate the grade of the ore going to the mill.

Fire destroyed one-and-a-half-miles of power-transmission line at the Associated Goldfields during the past week. This caused a few days' delay in work on the Argonaut property which draws power from Larder Lake. It is officially announced however, that work is again in full swing at the Argonaut, and is being centered at the 350-ft. level. The downward continuation of the main ore-body has been encountered at this horizon, and the values are such as makes the ore of commercial grade.

Shareholders of the Goldfields, Ltd., of Larder Lake, have become so aroused over the schme of the Associated Goldfields to merge various properties into one 30,000,000 share concern on terms not favorable to Goldfields, Limited, that a Protective Committee has been appointed for the purpose of taking legal proceedings to prevent the scheme going through.

The Protective Committee consists of John Keating and Hugh I. McNiel, of Oakville, together with P. Kirkegaard, of Toronto, which committee has just addressed the following letter to the shareholders of the Goldfields, Limited:—

"At a recent meeting of a number of shareholders of Goldfields, Limited, we were appointed a committee for the protection of shareholders' interests.

"For many years the shareholders of the company were not informed of the affairs of the company—no meetings of the shareholders were held and even the annual returns to the Government were not made.

"The properties in which the company was interested were operated, but no return was made to the shareholders.

"Another company, under the name of the Associated Goldfields, Ltd., was promoted by the persons in charge of the affairs of your company, and apparently was operated in close connection with Goldfields, Ltd. The shareholders have never been advised of the relations that existed between these companies or as to the manner in which your affairs were carried on.

"Recently, a third company has been promoted by the same interests, under the name of Canadian Associated Goldfields, with an authorized capital of $30,000,000.

"It is the intention of the persons who have been in charge throughout to transfer the assets of Goldfields, Ltd., to this new company on a basis that will give the stockholders of Goldfields, Ltd., only one share in the capital stock of the new $30,000,000 company in exchange for four shares of Goldfields, Ltd. At the same time the shareholders of Associated Goldfields, Ltd., are to be taken in on a basis of share for share in the new company.

It is the belief of a number of shareholders of Goldfields, Ltd., that the only properties of real value that the new company will control will be those heretofore controlled by your company, Goldfields, Ltd., and that the present transaction is of the same character as the transactions of past years and that the properties of your company are to be exploited to the advantage of Associated Goldfields and Canadian Associated Goldfields.

"It is the opinion of a number of shareholders that the transaction practically amounts to a confiscation of your interests.

"Under these circumstances a committee has been appointed, and propose to take such steps as may seem advisable for obtaining full information as to the past dealings with the properties of the Goldfields, Ltd., and to secure adequate return to the shareholders or in the alternative to have the proposed transaction set aside. Legal proceedings will be necessary for this purpose.

"In order to provide necessary funds we propose that any shareholder who approves of the proposed steps to be taken should contribute one cent for each share held by him, or at the rate of $10.00 for every 1000 shares of Goldfields, Ltd. Cheques may be made payable to the order of Goldfields, Limited, Protective Committee.

"We also request that you sign and return the enclosed authority.

TORONTO COAL PRICES.

Toronto, 13th July. — Last week it was intimated, in this column, that a stiffening in the price of slack coal was liable to take place pretty soon. It has already occurred. Slack coal has now advanced from ten to twenty-five cents a ton. The consumer does not yet realize that there has been a stiffening in price and that there is a possibility that this will go further. Anthracite prices are unchanged. The 1½ per cent Pennsylvania State tax on the price of the coal at the mines, which became effective on the 1st of this month, was not applied to the price of the coal to the consumer — that is to say, the producing companies absorbed the tax.

The public are still holding off from purchasing anthracite, with the result that, all through the Province of Ontario, dealers are very heavily stocked with anthracite. The householder is not buying his winter coal. In many cases he cannot. For example, in Toronto, with large numbers unemployed, and with still larger numbers working only part time, money is not too plentiful with very many householders. Then, again, the housing situation is operating detrimentally on the ordering of anthracite by householders. Many of them are uncertain whether they will be in their present abodes over the winter. If rents fall, as there is some tentative indications that they may, well and good. But, if they do not fall, then large numbers of householders will have to get out of their present dwellings, and join with others in the expedient known as "doubling up". Finally, back of the minds of very many who are refraining from getting in their winter coal, is the idea that prices will be lower in consequence of reduced freight rates. This idea will, most probably, prove fallacious. But, whatever the reason for the public's attitude in holding off from buying anthracite, it is creating a serious situation for many of the retailers in the Province. Many of them are very heavily burdened with the amount of coal they are being forced to carry. They cannot afford to carry it, either from a financial standpoint or from that of the physical space at their disposal. Speaking generally, unless the Ontario retailer has something like a tolerably equal distribution throughout the year, he is "up against it".

With regard to bituminous coal, here, again, the depressed conditions of industry are adversely affecting the situation. Industrial concerns are purchasing only in small quantities — and this though they had been warned that every day's delay, from now on, in purchasing in bulk, is likely to add to the price they will have to pay when they do make up their mind to purchase. Had the demand, which was expected, occurred on or about the 1st June, production could have been speeded up to meet all requirements. But now there are likely to be grave difficulties in doing so. There is need for the railroads and other utilities, both public and private, to purchase in larger quantities than they are doing. In this connection, it is noteworthy that Mr. Edgar E. Clarke, chairman of the Interstate Commerce Commission in the United States, has written to public utilities operating in that country, urging them to start all the coal they can now. The effects of this letter are already noticeable in the resumption of shipments to the New England States.

METAL QUOTATIONS.

(Unchanged since last week.)

Bidgood Gold Mines Ltd.

According to the "Northern Miner" operations at the Bidgood mine in Label township have been very successful and since operations were resumed a few weeks ago even greater success has been enjoyed.

Temiskaming Testing Laboratories.

On July 1st the Ontario Department of Mines took over the Temiskaming Testing Laboratories from the T. & N. O. Railway Commission. Test runs of ore can be carried on at this plant at very moderate cost.

American Matatchewan Gold Mines.

The American Matatchewan company is developing its claims in the Matatchewan gold area. Mr. J. H. Dixon who recently visited the property is interested also in the Lake Matatchewan property on which work is to commence soon.

Gowganda.

Recent travelers over the Gowganda road report that a number of men and teams are at work and that the road is in better shape than usual. Improvement of the road would greatly benefit those who are developing properties in Gowganda district.

Kirkland Lake Gold Mines.

During the past year Kirkland Lake Gold Mines Ltd. treated 45,478 tons of ore. Shortage of labor and power retarded development.

Of developments at the 900-ft. level President F. L. Culver says: "After cutting to the ore zone at the 900-ft. level we have done 409-ft. of drifting encounting several bodies of rich ore." The drift at the 900-ft. level will soon be under the Central shaft. It is proposed to raise to the 700-ft. level with the intention of having this shaft open from surface too 900-ft. as soon as possible. This shaft is now 520-ft. deep.

Earnings for the year were $313,210 and charges $278,211 leaving a profit on operations of $34,900 which provided for interest on notes $32,579. Profit and Loss account shows an adverse balance of $11,081 for the year.

The largest single item in mine operation costs is labor. It is probable that the $750,000,000 spent iby Ontario metal mines at least $250,000,000 was paid for labor employed in Ontario. While some part of the remaining $500,000,000 went out of Ontario for equipment and supplies the greater part was spent for supplies purchased in Ontario.

British Columbia Notes

Stewart, B.C.

A considerable body of gold-silver-copper ore is reported to have been opened up on the Fitzgerald Group of Mineral Claims, Bear River Valley. An assay return of $32 to the ton has been secured from a sample taken from near the surface. The vein has been uncovered for a width of 100 feet.

Anyox, B.C.

The slump in the market quotations on copper has affected Canadian production less than it has that of the United States. Today the Canadian production is 52 per cent that of the 1920 total at the same time while the output of the United States is figured at 20 per cent that of 1920. In 1920 the United States produced 36,000,000 lbs. of copper monthly while Canada produced 4,600,000 lbs. Practically the whole of the Canadian production came from British Columbia, the output of Ontario being confined to that obtained as a by-product to nickel. The Granby Consolidated Mining & Smelting Co. is reported to have had the biggest month of its history in point of production in May. The output ran to 91,000 lbs. The recent fall in the market, following signs of a rally, has again started speculation as to the immediate future of the Industry in this province. It is possible that a further decline of a point or two would mean the closing down of the Anyox Plant although it is explained by the Company management that this would be done as a last resort. There are 1,150 men employed at the smelter centre at present and a considerable number at the Cassidy (Vancouver Island) Collieries which are operated by the same company and from which coal is secured for industrial uses at Anyox.

Smithers, B.C.

Development work is to be resumed on the Babine Bonanza Group, Babine Mountains, by James Cronin, the well-known British Columbian mining man. Last year he ran a long tunnel that tapped the vein some 350 feet below his former workings and over 1,000 feet below the apex of the hill. He did some development work on the vein but the advent of snow, and general weather conditions, forced the closing down of the work. It is his intention to carry on until a shipping proposition of considerable proportions is proven or otherwise. He is confident of success.

Trail, B.C.

Ore shipments in gross tons at the Trail Smelter of the Consolidated Mining & Smelting Co. for the week ending June 21st totalled 6,476 tons. The bulk of this, some 6,237 tons came from the company's mines. The Florence Mine, Princess Ck., contributed 102 tons; the Knob Hill, Republic, Wn., 50 tons; and the Surprise, Republic, 87 tons.

Trout Lake, B.C.

The snow is leaving the mountains a month earlier this year than is usual and a number of engineers are expected in the district to inspect various properties on behalf of outside interests. Among those to be examined are several belonging to Mrs. A. Jowett, who brought out some fine gold-bearing samples a few months ago. It is possible that there will be a revival of interest in placer mining. Dan Savoy, a veteran prospector, who has returned after an absence of twenty-five years in the Klondike and Alaska, is making tests along the Lardeau. If the results are as good as is expected a company will be formed to exploit the placers of the Lardeau and its tributaries.

Kitchener, B.C.

The Leadville Group of silver-lead claims, situated at the junction of Goat River and Leadville Creek, is being thoroughly explored. Iron ore claims, located on Iron Mountain, and owned by C. P. Hill, of Montreal and associates, are to be prospected this summer. The crew already has left to do the work. A tunnel is being driven on the Sullivan-Larsen Copper Claims with a view to striking the vein at depth.

Nelson, B.C.

The difficulty of identifying mineral ground held by Crown Grant and otherwise in some of the districts of British Columbia was discussed recently by the B. C. Prospectors' Association. Considerable areas, it was contended, should be re-surveyed, permanent location posts planted, and maps prepared on a scale of 1,500 feet to the inch showing all important rivers, creeks and other topographic features mentioned in the original field notes. It is argued that forest fires, and the natural destructive agencies of nature, have obliterated signs and notices of original prospectors and mining men to such an extent that the present prospectors is totally at a loss in efforts to obtain his bearings. Therefore it is said to be in the interests of mining that the provincial government take the steps necessary to improve field conditions in mineral bearing zones. Representations to this effect are to be made to the proper authorities.

Prince George, B.C.

The North Point Mining Co. is developing a promising silver-lead-gold property situated near Hudson Spur on the Fraser River and near the Grand Trunk Pacific Ry. Recent tunnel work is reported to have cut an 8-foot lead showing good assays. The main tunnel now in 350 feet is expected to strike the principal vein at about 600 feet.

Greenwood, B.C.

The Providence Mine has made its first shipment of the year to the Trail Smelter and is expected to continue such shipments regularly.

Grand Forks, B.C.

The Horn Silver Mine, Similkameen, has been acquired by Herbert Powell. Shipments have been made this year to the Trail Smelter. It is probable that Mr. Powell will endeavor to interest capital with a view to the installation of a small plant.

Edmonton, Alberta.

The gold rush into the Peace River District, to which reference has been previously made, has proved to be a "false alarm." The stampeders did not obtain results warranting any special enthusiasm.

Victoria, B.C.

Four parties have been outfitted by the Geological Branch of the Dominion Department of Mines to investigate the oil and other resources of the Mackenzie River region. Dr. D. B. Dowling, Dr. G. S. Hume, Dr. M. Y. Williams and Mr. E. J. Whittaker are in charge of the parties.

Forty-nine sections of tar sand lands along the banks of the Athabaska River have been withdrawn from location by the Dominion Government. Theses comprise all the known occurrences of tar sand not already alienated.

EDITORIAL

ELBOW LAKE PLACER STAKING.

Mr. J. P. Gordon's letter in this issue gives information on a curious complication that has arisen at Elbow Lake, Man., subsequent to the recent discoveries of gold at this point, regarding which Mr. Gordon gave interesting particulars in the last issue of the "Journal".

Regulations covering the staking and mining of placer-gold deposits could not have had in mind such adventitious and local accumulations of displaced lode-gold as could take form in a recently glaciated lake of the "Rocky lake" type, typical of the pre-Cambrian rock exposures of Northern Manitoba. It must lead to grave complications if grants of placer claims are given in such localities, as they can serve no useful purpose to those who take out the claims, and will operate only to hinder the extraction of such gold as is present in the rocks. It is to be expected that any important yield of gold from this district will be taken from deposits of lode type, and the local conditions are so little adapted to the formation of important placers that their occurrence would be a surprising discovery.

THE COMING INSTITUTE MEETING AT EDMONTON.

We are informed by Mr. T. B. Williams, the Convention Secretary of the Annual Western Meeting of the Canadian Institute of Mining & Metallurgy, which is to be held at Edmonton from the 14th to the 16th of September, that it is proposed to make this meeting one of the best in the history of the Institute. A tentative programme of the proceedings is published in this issue. The Secretary of the Institute, who is soon to return to headquarters from his going to and fro in the land, has, if we may judge by his advocacy of the use of western coal in Northern Ontario, come back impressed by the coal industry of the West and the hospitality of the brethren, and will doubtless do his best to enlarge the attendance of eastern members at the Edmonton gathering. As the coal-bucket, the oil well and the granary of the Dominion, Alberta is destined to bulk more and more in importance in industry, and as recent events have indicated, in political influence. Alberta has that combination of circumstances which Jevons postulates as causative of great industrial eminence and density of population, namely, an agricultural community with capital accumulations and widespread education possessed of great accumulations of bituminous coal.

Alberta has also distinguished itself by selecting scientific men to advise and direct its mineral development, and it has put university training in the forefront of industry. If it continues this wise course, and at this early stage of the coal industry will make provision for the small statutory impost on coal production that would be required to permanently endow coal-mining education and research in the Province, Alberta can and will become the pillar and base of Canada's industrial future.

ASBESTOS FABRICATION IN CANADA.

Our well-informed contemporary, "Asbestos" of Philadelphia, expresses itself as "utterly confounded" at the opinion expressed in this column in our issue of 27th May that "the spectacle of one of the largest and "most experienced asbestos companies in Britain build-"ing a factory to utilise Canadian asbestos in the "United States is not one that the Province of Quebec "can be expected to view with equanimity". The further remarks of our contemporary are quoted elsewhere in this issue in full, and it will be noted it is assumed that, if British fabricators of asbestos fibre were forced by high import tariff imposed by the United States to erect manufactories in the United States, they would utilise South African asbestos, and would consume "as little Canadian raw asbestos as would be absolutely necessary." The likelihood that South African asbestos would be used by British manufacturers in the United States in competition against Canadian asbestos seems rather remote, but it is not of course impossible. Our objection, however, was based on the assumption that such a British manufacturer would use Canadian asbestos—as is most likely—and it would be distinctly distasteful to Canadians to hear that British capital was being invested in the fabrication of Canadian mined asbestos fibre in a new factory in the United States, seeing that for many years there has been a very clearly defined desire in the Province of Quebec that some portion, at least sufficient to sup-

ply the Canadian market, of the profitable business of fabricating this unique domestic product should be located within the Dominion. Any proposal of a British manufacturer to erect a factory in Canada to utilise asbestos mined outside of this country would probably be dealt with here as such matters are now being dealt with in the United States, namely by the imposition of a protective tariff sufficient to make its importation unprofitable.

To put the matter baldly, the people of Quebec know that they mine 80 percent of the commercial asbestos of the world, and they know that Canadian asbestos is of first class quality and will always be in good demand. They also know that while the total revenue from asbestos sales is approximately ten million dollars annually the business of fabrication will run into ten times that annual turnover. It is recognised that asbestos fabrication is largely a matter of assembly of asbestos with other raw materials, and that the market available in the United States has made possible the present development of the asbestos-mining industry in Canada. Admitting all this, however, it has always been felt as somewhat of a reproach upon Canadian business enterprise that almost all Canadian asbestos should be shipped out of the country merely as prepared fibre, by virtually as a mine concentrate, and should undergo all further elaboration by labour and capital expended in other countries.

It may be quite correct, such is the unfortunate complexity of our Canadian situation, that a high import tariff in the United States is necessary to protect industry in that country from European competition under existing exchange rates, but when such an industry is based on a supply of raw material mined in Canada, and the import tariff is directed chiefly at Britain, it is seen that Canada, like Agag, has need to walk delicately.

Notwithstanding this complex situation, however, there is good reason to believe that Canada's anomalous — not to say subordinate position—in regard to asbestos fabrication will gradually right itself, and that Canadian asbestos miners, as their financial abilities will allow, will little by little develop fabrication plants and the utilisation of the by-products of asbestos mining, and will not be always content to be miners only.

Perhaps we might also explain, in response to the courteous comment of our Philadelphia friends, that the views of the "Canadian Mining Journal" are possibly a little in advance of the quickly-passing, present-day phase of Canadian status, and have in mind that in regard to many things, and particularly in regard to mineral policies, Canadian business is only nascent. We have attempted to indicate tendencies of the future rather than to find fault with the things that are accomplished.

THAT "SIXTY MILLION DOLLAR" YARN.

A Canadian Press despatch from Ottawa, under date of June 13th, quoted Dr. Ami, as Acting Governor of the Imperial Mineral Resources Bureau and Technical Adviser to the Canadian High Commissioner as stating "that probably $60,000,000 worth of platinum metals had been lost to Canada annually for 25 years past." This statement, which on its face was erroneous, gained wide circulation and credence, as was to be expected from its credited origin and its publication by the Canadian Press. No definite correction of the report has come to our notice, although the newspapers that printed the original statement later modified it to the extent of stating that the loss of sixty million dollars mentioned was not an annual occurrence, but was the estimated cumulative loss since the beginning of extraction and treatment of the Sudbury nickel-copper ores. Lies die hard, however, and the Montreal "Gazette" for July 18th states: "Canada has during the past 25 years lost sixty million dollars annually through failure to segregate properly platinum and other precious metals found in Northern Ontario." This false and damaging report will circulate in the British and foreign press for years, until by dint of repetition it will become an article of popular belief, as other equally inaccurate and unfair stories about Northern Ontario have already become.

The value of the precious metals in the Sudbury ores are estimated as being from 75 cents to a dollar per ton in value, the last-named figure being an ideal maximum content. The total ore reserves in the Sudbury district are estimated at roughly sixty million tons, so that it would have been necessary, had the first-published statement been correct, to mine all the ore in the district, and totally recover all its precious metals, in one year.

It is a rare thing in economic metallurgy to recover all the valuable metals that laboratory analysis of an ore indicates that it contains. It may be emphatically stated that the chemist-metallurgist made possible the recovery of precious metals from the Sudbury ores, and not the precious metals only, but the copper and the nickel for which the ore deposits are primarily and chiefly exploited, and by doing so made the mining of the ore a commercial success. The recovery of gold and silver from the Sudbury ores was not a difficult metallurgical feat, and such recovery has been virtually complete, but the recovery of the platinum group of metals has been a problem that has been slowly solved. Moreover the theoretical value of the contents of an ore does not represent the recoverable value, as it has often occurred that the cost of recovery would amount to more than the sale value of the products recovered. For example, a certain well-known iron-ore, of which many millions of tons have been used in Canada, contains an appreciable percentage of rare metals, but no one has yet suggested a feasible plan of recovery. It would be just as fair to state that the companies using this iron-ore were annually throwing away on the slag dumps a substantial sum of money, which could be accurately and

impressively calculated in dollars and cents—if the practical questions of recovery were ignored.

The nickel companies have been accused of many sins, most of which were as airily conceived and had as little real basis in fact as the throwing away of sixty million dollars annually. One newspaper that was in the habit of going for the nickel companies every little while accused them of omitting to recover polonium from the Sudbury ores. There is no limit to the imaginary contents and values of a complex ore, as perusal of prospectuses will show, but there is a very distinct limit to their economic recovery. But while those who are conversant with these matters are able to assess the value of a "news" item and pass it by with faint amusement, the general reading public is unable to detect what is false. The C.I.M. & M. Bulletin pertinently remarks in this connection: "Here was a colossal waste, " and since the metals of the platinum group 'might' " have been recovered, the obvious inference to be " drawn was that those in charge of the mining and " metallurgical operations have been negligent, either " wilfully, for some unexplained reason, or through " ignorance and stupidity. In either case, the profes- " sion is brought into contempt, or worse, and mining " gets the reputation of being either a swindle or a " gamble. . .the power of the Press to do harm is not " one iota less than its power to do good."

We do not believe Dr. Ami authorised for publication the unqualified statement that was credited to him.

THE NEW U. S. TARIFF.

The tariff bill reported by the Ways and Means Committee at Washington on June 30th contains many items of interest to those producing minerals. The Washington correspondent of the "Engineering and Mining Journal" predicts that it will pass easily through the House, but that it will arouse considerable discussion in the Senate. The "Mining and Scientific Press" says: that the Bill will be vigorously debated in the House, and it is expected that it will come to a vote within two weeks; it is not expected that there will be any changes in the Bill on the floor of the House.

The Fordney bill contains provisions for duties on a large number of minerals and metals including 75 cents per pound on molybdenum ore or concentrates; five cents per pound on nickel in pigs or ingots and 30 per cent ad valorem on nickel in rods, bars, etc.; five cents per pound on aluminum in crude form and nine cents for aluminum in plates, sheets, etc., ten per cent ad valorem on graphite; $5 per ton on fluorspar for one year and then $4 per ton; six cents per pound on mica plus 17 per cent ad valorem. Imports on lead and zinc ores and products vary according to composition.

The proposed impost of 35 cents per barrel of 42 gallons on crude petroleum has been deleted from the schedule in the House on representations from the President that a protective tariff against imported crude petroleum was inconsistent with the policy of the government of the United States, which he stated in his letter "is doing every consistent thing to encourage the participation of American citizens in the development of the oil resources in many foreign lands."

ANOTHER NICKEL STORY.

The "*Financial Post*" of Toronto reports that Hugo Stinnes is coming to Canada, and "is believed to be definitely after a share of control of the Canadian nickel industry". It is suggested that Stinnes is behind the Norwegian financial people who recently interested themselves in the reorganization of the capitalization of British-American Nickel Corporation. It is further commented: "The position of the British Government in the nickel corporation is the one point that casts doubt upon the theory that Stinnes is in the Company". As a conclusion of these ingenuous surmises, the "*Financial Post*" says: "But it is an open secret that the British Government is anxious to get money out of the company now that the war is over."

To suggest that the British Government would allow a German industrialist to obtain a share in control of a Canadian nickel enterprise to retrieve some paltry millions of war expenditure is equivalent to suggesting that the British Cabinet is composed of idiots with a leaning to high treason, with Canadian ministers as complaisant accomplices.

C. W. BARRON, the publisher of the *Boston News Bureau* and an outstanding publicist in the United States, who was distinguished during the war by his clear understanding of the causes then at issue, is contributing to his Boston paper from European points a series of articles on conditions existing in the several countries of Europe. A late comment, written from London, discusses the coal production conditions in England under the title of "Coal Power Beneath an Empire". In stating that the rate of wages paid to the British coal-miner had gradually receded from 1873 "until in 1914 the British miner ranked with the lowest-paid hand labour in the world", Mr. Barron is very much in error. In the matters of working hours and in wages in 1914 the British coal-miner held a preferred status among British workers, and, politically the unionised miners were the strongest working-class unit in the United Kingdom. In stating that "the best miners went to the front and went down" Mr. Barron has put his finger on the main cause of the decrease and apparent inefficiency in coal production in Britain, and he has singled out a dominant fact in British affairs regarding which there is much inexplicable reticence in the British newspapers and reviews, namely, that the British population has during the war lost its fittest members. A new generation must grow up before Britain can restore her industrial efficiency, because, alas, the efficient ones are dead or maimed. Mr. Barron's concluding statement refers to his own country, and is

the soberest kind of truth. He writes: "In the United States is the supreme power; not because its national debt is less; not because of its wheat fields, its cotton or its pork production; but because it has an equipped capacity to output for many generations 600,000,000 tons of coal per annum, and because more than two-thirds of the world's oil output is now American-owned."

Mr. Barron might have added another 400 million tons to the United States' capacity for coal production without undue exaggeration. He might also have added that the feverish anxiety of the world regarding flowing petroleum at this time is a passing phase, and that as the future generations go by it will more and more be recognised that the stable basis of material power resides in the national possession of bituminous coalfields. There is much public misunderstanding of two entirely separate things, namely the ideal method of fuel combustion and the source of the fuel. Admitted that consumption of oil and gas is technically correct, it will be found, after due consideration, that the most dependable and infinitely the greatest reserve of fuel-oil and gas is the coal that remains ungotten in the earth's crust.

THE position of the United States would seem, under the circumstances, to be fairly comfortable. Commenting in a similar connection, "Mining & Scientific Press" remarks: "Our people control eighty percent of "the oil production of the world, and we ought to be "able to meet others in competition without getting "hot about it...The English-speaking peoples cannot "afford to quarrel over such matters, when issues so "much bigger are at stake. We have been comrades in "arms recently in defence of our civilisation, we have a "common purpose in striving for world peace; our "peoples desire intensely that general disarmament "may be brought about by conference between our "leaders and those of other nations; most of us are "sick of the petty jealousies and mean recriminations "that have followed the successful conclusion of our "war with Germany and her dupes; is all the fine "emotion to be lost in petty spites and commercial ri-"valries? Can we not recapture the vision of the heroic "years but lately past, and once more rise above all "meaner things to a plane of manly goodwill and "friendly competition?"

Thanks, Mr. Rickard, there are a good many millions on both sides the line and across the seven seas among the English-speaking peoples who think just about the way you put it. Unfortunately, however, many, so very many, of those who had that fine vision in the heroic years died because they saw early and clearly, and as a consequence the percentage of malicious malcontents is today much greater and rather less restrained in their utterances.

In national relations, as in industrial efficiency we miss those that died in battle.

CORRESPONDENCE.

The Pas, July 4th, 1921.

The Editor, Mining Journal.

Staking Placer Claims Over Ground Staked Under the Quartz Mining Regulations at Elbow Lake.

Dear Sir,—Since my visit to Elbow lake an unique condition has arisen, caused by "Placer claims" being staked over "Quartz mineral holdings."

The idea of staking claims for placer on Elbow river is ridiculous and the only significance of colors obtained by panning, on the bars, or even coarse gold being found by panning, is to convey the information to the intelligent prospector that a quartz lode, carrying free gold, exists in the district, and that by means of the pan he may follow this displaced gold to its source.

The spectacular gold showing on the "Murray find" is in the river and the striae of the glaciers are well marked on the enclosing rock, so that there has been very little change in the surface since glacial times either from erosion or other causes and it therefore follows that to expect to find an alluvial deposot where the gold is concentrated in commercial qualities is absurd.

Under the present mining regulations the holder of a "lode claim" has no surface rights and it would seem that there is no clause in either the Quartz Mining Act or the Placer Act to hinder a prospector from staking a placer claim on ground that is covered under the lode mine regulations.

Now, the definition of "placers" is. "Placers are deposits resulting from the decomposition and erosion of metal-bearing rocks and the concentration of the metallic fragments in beds where they have been carried by water." This definition would have to be changed to justify the Elbow Lake placer staking, to read as follows: "Placers are deposits that have in any way become displaced from the dyke or vein in which they originated."

With this interpretation a placer prospector would be within his rights in so placing his stakes as to cover the oxidized zone of a mineral lode thereby forcing the lode-holder off the earth, until he, the placerman, had sluiced off the surface concentration.

The staking of placer claims might be looked upon as a joke, but it has its serious side. If the rights of the placer prospectors are acknowledged by the Government and recorded, the double ownership, or rights being vested in separate parties between whom no partnership or business arrangements exists, would certainly tend to keep prospective purchasers away. This staking will probably not occasion any serious phase and should go a long way towards emphasizing the fact that holders of "Lode claims" should be entitled to surface rights. In fact a concentrated effort of all mining interests in Manitoba should be made to get the Dominion Government to re-establish the Crown Grant.

My only excuse for this letter is that the mining game has been kept particularly clean and free from wild-catting in this district and with proper mining legislation may be so kept.

Yours truly,

J. P. GORDON.

PERSONALS.

Mr. A. M. Bateman is at the Alaska properties of the Kennecott Copper Corporation.

Notes on Allanite Deposit at Lac a Baude Champlain Co., Que.

By ROBERT HARVIE.

Published by permission of the Director, Geological Survey, Ottawa.

In October 1919 the writer visited the locality at Lac a Baude which, although noted in various reports as being rich in allanite, had not been examined since the first material determined in the laboratory to be allanite was collected. The chief purpose of the writer's visit was to obtain a supply of the mineral for examination by the Mineralogical Division of the Geological Survey but in view of the possible commercial importance of the deposit the following notes on the means of access and general physical conditions may be of interest.

Lac a Baude is in Normand Township one of the projected but unsurveyed townships in the northwest part of Champlain County, Quebec, in latitude 47° 04′ N. and longitude 73° 19′ W. The mineral locality lies 44 miles due northwest of Grand Mere and at the middle of the top edge of the Three Rivers Map sheet of the Geological Survey. The best available general map of this district is published by the Department of Colonisation, Mines and Fisheries of the Province of Quebec, entitled "Carte d'une Partie de la Vallee du St Maurice," scale 2 miles to 1 inch.

The locality is best reached by way of Grand Piles, the terminus on the St Maurice River of a branch line of the Canadian Pacific Railway. From Grand Piles the trip of 32 miles upstream to Grand Anse may be made by steamboat during the summer season. At Grand Anse wagons are available to cross the 9 mile portage to lake Wessonneau where the Laurentian Club which has under lease the fishing and hunting rights of almost the whole district, maintains a clubhouse. From this point the remainder of the journey at the present time must be made by canoe, the steps being as follows,—lake Wessonneau 5 miles; seven portages in 1¾ miles to Steamboat Rock lake; lake 1½ miles; 9 portages in 2 miles to lake Wakanmekonke; lake 3 miles; portage to occurrence about 2 miles. In view, however, of the number of lumber roads that have been built under similar conditions in nearby districts it seems probable that a wagon road of about 12 miles could be readily built from the clubhouse direct to the deposit, thereby completing connection with the steamer service above mentioned.

An alternative but poorer canoe route starts from Creek des Prairies, a flagstop on the Canadian National Railway 23 miles west of La Tuque, and ascends the Vermillion river and its branch the Pabelognang which is the discharge of Lac a Baude. This route, however, is about 60 miles long and entails 2 portages of 3 and 5 miles each as well as seven others of ½ mile and less, in addition to difficulties due to a heavy current.

The occurrence of allanite was first noted by N. J. Giroux in 1893 while engaged as assistant to R. W. Ellis in the preparation of the Three Rivers map sheet for the Geological Survey.[1]

[1] Geological Survey, Vol. XI, p. 36 J., see also VII, pp. 12 13 R. for brief mineral description.

The writer found for his purpose an abundance of the allanite in a small cliff situated 200 yards east of the end of the portage leading to lake Wakanmekonke and about 50 yards south of the actual trail. Other exposures were not examined. This cliff is about 70 feet long, 20 feet high at one end and 20 at the other Below the cliff huge blocks derived therefrom form a talus about 50 feet high. The actual face is composed of a coarse reddish granite but at one end it may be seen that this granite runs back into the cliff for only about 20 feet, while at the other it is limited top and bottom by a brownish-black hornblend gneiss. It seems evident that the granite has intrusive relations to the adjoining hornblend gneiss with the cliff occurring close to the irregular contact.

Scattered through the granite of the cliff face are tabular crystals of allanite which attain a maximum size of about 6 inches by 4 by 1¼ thick, individuals 3 inches long being quite common. The larger crystals are the centres of very prominent radiating fractures presumably caused by some great difference between the cooling conditions of the mineral and of the parent rock. This feature both assists in identifying the allanite and serves in separating the crytals from the rock. The first specimen collected by Giroux contains 57 per cent of allanite in crystals of 1½ to 2 inches long. The present writer found that although most of the larger crystals occurred singly, there was a tendency for the smaller one to occur in clusters or bunches thus giving rise to the very rich material of the discovery.

The actual proportion of allanite in the granite was not calculated, but is probably not more than 1 percent. and as a mining proposition this proportion might be considered rather small. However, in the space of four hours with the geographical hammer it was found possible to obtain from the more easily reached portions of the cliff alone over 90 pounds of nearly pure allanite. The radiating cracks were found to be of immense service in separating the mineral. In addition to the allanite there are also found occasional large crystals of hornblend which on account of their general resemblance in size and color might prove confusing. However, when bruised with a hammer the hornblend has a greenish color in distinction from the dead black or grey of the allanite.

Note: Allanite is of economic interest as a possible source of cerium, and related metals didymium and lanthanum. Some samples of allanite have been found to carry a little thorium. The most important use of cerium is in the manufacture of pyrophoric alloy, which because of its property of emitting sparks when scratched has been largely used for ignition purposes, as in pocket-lighters. During the war the United States Army was supplied with such lighters which created an unusual demand for cerium. Ferrocerium is an active deoxidizer, and papers read before the American Electrochemical Society have suggested its use as a "scavenger" in iron and steel mixtures.

Asbestos Manufacture in Canada

The Action Of The Canadian Johns-Manville Company, Ltd. In Erecting A Manufacturing Plant In This Country Is A Departure Fraught With Great Possibilities.

By A. R. R. JONES.

The Canadian Johns-Manville Company, Ltd., which, some while ago, placed contracts for a large manufacturing plant to be located at Asbestos, in the Province of Quebec, is making very satisfactory progress with the carrying-out of this work. The grading has been done, and the steel for construction work has just about arrived by this time. It is hoped that the plant, where all classes of asbestos products, including asbestos paper, asbestos roofing, asbestos shingles, packings, pipe coverings, asbestos textiles, brake band lining, and so forth, will be manufactured, will be completed by next October. On its completion, manufacturing operations will be at once commenced. At least 100 persons will be employed in the plant, to begin with.

Pioneer On A Big Scale.

Attention has frequently been drawn to the anomaly involved in the fact that in Canada, which supplies something like eighty-five per cent. of the world's production of asbestos, so little is done in the way of undertaking the manufacture of asbestos into finished articles. Why Canada, and, in particular the Province of Quebec—of the total value of the mineral production of which Province asbestos is accountable for half—should not derive some of the benefits that would naturally accrue from a proportion of the various forms of manufactures of asbestos being carried on in this country—and especially in Quebec in contiguity to the asbestos mines—has not seemed altogether clear to many of us. Hitherto the only manufacture of asbestos carried on in Canada—at any rate, in the Province of Quebec— has been that of asbestos boards which are manufactured at Lachine, near Montreal.

There is certainly a very general feeling in Canada that the fabrication of asbestos production in this country is eminently desirable. Last year, the exports of asbestos from this country were of the value of approximately $12,000,000. They probably represented, in manufactured form, something like seven times that amount in value. The action of the Canadian Johns-Manville Company, Ltd., in locating a plant in the Province of Quebec, for the manufacture of asbestos products will do much to right this state of things and to preserve for Canada and for Canadians something of the profit that accrues from the transformation of this valuable non-metallic mineral into the finished article.

Something About the Factory.

The factory in course of erection at Asbestos, Que., will thus be really a pioneer in the manufacture of asbestos products on any considerable scale in Canada. This week I had the advantage of a talk with Mr. W. M. Hiller, vice-president of the Canadian Johns-Manville Company, Ltd., and its general manager for Canada, with regard to the factory. It will be, as all the Company's factories are, standard to its purposes. It will be the last word in up-to-dateness alike of design and of construction; it will be a modern plant in every particular; and it will take advantage of all the latest scientific and other devices of use for the manufacture of asbestos products.

It need scarcely be said that for such products there will be awaiting them, at the outset, a large market in this country where previously we have been in the habit of using asbestos products of all classes imported from the United States. In addition, a demand from Australia and other parts of the British Empire for Canadian-made asbestos products can confidently be reckoned on. In fact, when conditions generally right themselves to a larger extent than at present, the opportunity for the profitable expansion and development of the manufacture of asbestos products in this country should be almost without limit. As regards the Canadian purchaser, it is obvious that, in lower freightage, in the absence of duties, and in the home manufacture of articles of every-day use, he will be getting advantages which must inevitably result in a substantial decrease in purchasing prices and in a consequent benefit to the Canadian public at large.

Company's Mines And Other Factories.

The machinery for the factory at Asbestos, Que., will come, much of it, from some of the Company's other factories. These other factories are seven in number, and are located at Manville, N.J., Milwaukee, Wisc., West Milwaukee, Wisc., Lockport, N. Y., New Rochelle, N. Y., Riverdale, Ill., and Nashua, N.H. Much of the machinery used in an asbestos factory is of a very expensive kind.

It should be added that, in addition to Toronto, the Company has offices in Montreal, Winnipeg and Vancouver, as well as in some fifty-six cities and towns in various parts of the United States. Mr. T. F. Manville is president of the Company; Messrs. J. R. Pearson (who is the Company's treasurer), C. H. Shoemaker and W. M. Hiller are vice-presidents; and Mr. H. E. Manville is secretary. The Company's products comprise over fifty lines, which include automotive equipment, building materials, insulating materials, power plant products, electrical products and specialties. There is a construction department for applying the Company's materials.

The Company's mines are situated at Asbestos, Que., about five miles from Danville, which itself is some eighty-four miles south of Quebec City on the Grand Trunk Railway. They represent an asbestos property as large as, if not larger than, any other in Canada which is another way of saying in the world. These mines give employment to between 700 and 1,200 persons, and are at present working to something like capacity. It is certainly a matter for congratulation that the first factory for the manufacture of asbestos products on any considerable scale to be erected in Canada will be owned and operated by a concern of such reputation and responsibility as the Canadian Johns-Manville Company, Ltd.

Geological Investigations in the Maritime Provinces

Part E of the Summary Report of the Canadian Geological Survey for 1920 consists of three reports on New Brunswick and Nova Scotia map areas, namely:

Coal Seams of Gloucester Co., New Brunswick.

G. A. Young reports on thin coal occurrences, of no economic importance, in the northeastern part of New Brunswick. The coal occurs in strata of an age not definitely determined, but which is thought to be of early Carboniferous date. The country is covered by drift, and rock exposures are few. No definite conclusion is possible as to the thickness of the sediments or the number of coal-bearing horizons, except as the result of systematic diamond-drilling, and without much further study and mapping, the expense of drilling is not warranted. The writer of the report enlarges on the accepted theory of coal deposition to combat a local belief that coal seams which are thin at their outcroppings are likely to gain in thickness under deeper cover. There has always been much dubiety about the age of the coal-bearing strata of New Brunswick, and in view of the general haziness of the stratigraphy and the little paleontological knowledge that has been gathered since Dawson's time, much more extended study leading to more exact understanding of the New Brunswick and Bay of Fundy strata generally, could be profitably arranged for, if the appropriations of the Survey could stand it.

Carboniferous of Sydney District, Cape Breton.

A similar impression of incomplete knowledge is conveyed by W. A. Bell's brief communication reporting progress in study of the paleontology of the Sydney District. Mr. Bell properly points out the looseness of the lithological terminology that has been used in describing the Coal Measures of Nova Scotia, originally based on the nomenclature used in Britain, and unfortunately implying correlation which is not determined to exist.

"For example", Mr. Bell states, "it has generally been tacitly assumed that the productive coals of the various coal district of Nova Scotia, that is, the Stellarton-Thorburn, the Springhill and the Sydney-Glace Bay, belong to the same epoch of sedimentation. On the contrary, the productive portions of these fields may represent several individual epochs."

As an actual matter of fact, there is so far nothing but intelligent assumption regarding the correlation of even the subordinate basins of the major synclinal structure of the Sydney coalfield, and the exact relationship of the seams on either side of Sydney Harbour, separated by only a mile of water, and with workings little over half a mile apart, is unknown. There has been no systematic paleontological work on the Nova Scotia coalfields since Dawson's time and, generally speaking, the coal geology of the Maritime Provinces is imperfectly understood and only partially mapped. The result of Mr. Bell's work will be looked forward to with long-deferred hope. Something of later date than the controversies of Prof. Lyman and Sir William Dawson, and the patient local investigations of Richard Brown would be very welcome.

Berwick and Lakeview Map Areas, Kings and Annapolis Counties, Nova Scotia.

E. B. Faribault communicates an eleven page report on the mapping of Kings and Annapolis counties in Nova Scotia, which was interrupted by the untimely death of Hugh Fletcher from pneumonia in the course of his field duties in 1909, and on which notaing has been done in the meantime with the exception of some work in the vicinity by A. O. Hayes in 1916.

The Paleozoic sediments in the areas examined are contorted and fossils are scarce and of obscure character, "referable to any age from Cambrian to Devonian". Mapping is therefore difficult and it was necessary, for example, to make a large scale map of certain well-defined quartzite bands in order to elucidate the structure.

The economic minerals of the district are given in detail. Metallic occurrences are numerous and varied, including gold, copper, manganese, and iron, but the quantities so far known are small and the deposits discontinuous. Of non-metallic minerals it is suggested that infusorial earth, white quartzite for silica, white and red clays and peat for leiter and fuel, should receive special attention in view of the well-settled character of the countryside and the nearness of railways to the deposits.

The structural geology of the vicinity of the iron-ore beds in the Torbrook-Nictaux district was examined, and the conclusion was come to that "the north and south beds of iron ore that outcrop about a mile apart and dip steeply towards one another are probably the same beds, repeated on the opposite limbs of a complex synclinal fold, composed of at least two minor synclines and one intervening anticline." It is regarded as possible that the iron ore beds of the Nictaux mines are brought up near the surface on this fold, and may be increased along the apex to form ore-shoots. In the Wheelock shaft, the shell-ore bed was found to increase in thickness from six to twelve feet on a fold, and a knowledge of the structure of the ore-beds may therefore be of great assistance in their development.

These ore deposits are not now being worked.

G. W. V. A. DRILLING COMPETITION AT COBALT.

The drilling competition at Cobalt on July 4th under the direction of the Great War Veterans' Association was a great success, and from all accounts would have been very fittingly accompanied by the C. I. M. & M. particularly its declamatory chorus.

Teams from the Kerr Lake mine took both first and second places. Contestants had to set up their tripods, which were laid out on the ground with all joints and extensions loose, and make all their own water and air connections. Fifteen minutes was given to set up and drill as much as possible.

Miller Bros. from Kerr Lake, took 1 min. 13 sec. to set up and connect, and drilled nine feet and five-eighths inches in 13 min. 47 sec. Williams and Horne, Kerr Lake, took 1 min. 8 sec. for the set-up and drilled 8 ft. 6¾ inches. Third place was taken by McGillivary and Brdyges, of Kirkland Lake Gold Mine (the only entry from points outside of Cobalt) who took 1 min. 49 sec. for set-up and drilled 7 ft. 7 3/8ths inches. Eleven teams in all drilled.

The competing drills included seven Cleo No. 88 "jackdrifters" made in Sherbrooke by the Canadian Ingersoll-Rand Co. and six other drills of United States manufacture. The Sherbrooke drill took all the prizes, getting the first six places and ninth place.

Why a Tariff on Asbestos?

An Authoritative U.S. Opinion.

Last month we referred briefly to an article appearing in the India Rubber Journal of May 21st, in which, under the head "Export or Branch Factories," Mr. J. Alfred Fisher, Chairman of the Board of Bell's United Asbestos Company, Limited, London, England, severely criticised the suggested tariff schedule on Asbestos goods now under consideration by the United States Congress.

Mr. Fisher intimated that the imposition of high import duties by the United States would probably result in English manufacturers establishing plants in the United States.

Since the India Rubber Journal is printed in England, we were not particularly surprised at its point of view. When, however, the Canadian Mining Journal, of issue May 27th, reprints the India Rubber Journal article, and then goes further to say editorially that Canada would welcome the establishment of English-owned plants in Canada, and that Canada should oppose the establishment of English owned plants in the United States, then we are not only surprised, but utterly confounded.

The Canadian Mining Journal is looked upon as a dependable authority concerning Canadian Mining matters, hence it is the more difficult to understand how its editors could have overlooked the real point in this whole situation.

The principal producing Asbestos area in the world is in the Province of Quebec; the major part of the Asbestos producing properties is owned by Canadians. Eighty-five to ninety per cent. of Canada's production is shiped to United States manufacturers. Does the Canadian Mining Journal realize that English manufacturers, even in pre war times, took a relatively small percentage of the Canadian output and that, during and since the war, that percentage has been steadily decreasing, owing to the fact that several of the leading English manufacturers have purchased and are operating large Asbestos producing properties in Rhodesia and South Africa?

We can think of nothing more inimical to the interests of Canadian producers of raw Asbestos than the encouragement of low tariffs on imports of Asbestos manufactures into the United States, because it is a well known and readily understood fact that most of the merchandise which would be offered by European manufacturers would be made from raw Asbestos obtained from sources other than Canada.

To be sure the rates which have been asked of Congress will discourage the imports of manufactured goods; but from the point of view of the American manufacturer, the American financier, or the Canadian producer, all the evidence at hand indicates a necessity for adequate tariff protection.

Under the title "Wages in the United States for Foreign Countries," a 103 page book has been issued by the U.S. Government Printing Office, and prepared for the use of the Committee on Ways and Means of the House of Representatives. In this most carefully prepared survey of the subject appear some very interesting comparisons of wage rates paid in different countries to different classes of workers. For instance, weavers in the United States receive $39.00 per week, in Germany, $4.35, Japan $6.00, England $17.70, Belgium $9.63. The same ratio maintains throughout other classes of labor. Just how the American Manufacturer is to remain in business and meet in competition merchandise manufactured by labor securing anywhere from fifty down to about 10 per cent as much as is paid in the United States is rather hard to understand.

Added to this great labor advantage, the European Manufacturer has obtained control of the second largest raw Asbestos deposits, (in Rhodesia and South Africa) and since the raw Asbestos in these fields is produced by kaffir labor, working at an average wage of 25c a day, just how the Canadian producer of raw Asbestos, paying an average daily wage of $4.00 is to meet this competition is not quite clear.

It is obvious that English manufacturers would utilize in American or Canadian plants controlled by them, Asbestos from their own mines. Their own mines are not in Canada, hence the establishment of English operated plants in either United States or Canada clearly means that these plants would consume as little Canadian raw Asbestos as would be absolutely necessary.

We would be interested to know whether the Canadian Mining Journal in writing its editorial, discussed with any Canadian producer of Asbestos the question at issue, and particularly the probable effect upon the Canadian Asbestos business in case finished Asbestos merchandise from European plants is admitted to the United States on the present ruling scale of duty.

Then, too, in considering this question of tariff it is most interesting to study the attitude of our international competitors toward it.

Canada has a protective tariff much higher than ours, and it can, under the law, be increased at will by a so-called Order of Council.

England has a tariff which runs as high as 66 per cent.

Austria maintains a wall of protection eighty times higher than her pre-war schedule.

Chile has put up heavy barriers to protect her agricultural interests.

The nations of the world are not operating on an altruistic basis and it cannot logically be expected that they will so operate.

Just why America is supposed to play a lone hand in this game of blind man's buff is not clear.

ASBESTOS FIBRE USED IN PAVING.

"Canadian Engineer" contains a note by H. Caldwell, Warren Bituminous Paving Company, regarding laying down on Woodbine Ave., Toronto of 600 sq. yds. of a bitulithic pavement containing finely divided asbestos fibre as part of the aggregate. A test area of pavement of similar composition was laid down in New Bedford, Mass., on a heavy traffic street, and as a last resort in the search for a pavement material that would stand up against the heavy loads from the cotton mills. It is said to have given desired results. The asbestos fibre is said to add qualities of toughness and indestructibility by wear that more than compensate for the additional cost of the asbestos fibre. As presumably the qualities of flexibility and suitability for spinning and textile uses would not be so important in pavement uses, there would seem to be an opening in this novel departure for use of asbestos that are not now highly regarded for textile purposes.

NEWS FROM THE QUEBEC ASBESTOS DISTRICT.

From the July Bulletin of the C. I. M. & M.

THE asbestos industry is passing through a period of quietness. The majority of the mines are working one shift only, five days a week, and with reduced forces at that. The present condition at the mines is attributed to the state of the asbestos market, which is said to be absolutely inactive. Reasons for this are the inability of British manufacturers to resume operations on account of the coal strike, and the difficulties experienced by American manufacturers in disposing of their output—due no doubt to some extent to the rates of exchange between European countries and the United States, and partly also to the sluggish revival of the building trade, notwithstanding the dearth of dwellings in populated centres.

Shipments are at a very low ebb compared with those for the first three months of the year, which are always small months for production. According to the monthly report of the Department of Trade and Commerce, shipments last March exceeded (in tonnage) those for the corresponding month in 1920 by 33 per cent. This no doubt represents the balance of contracts signed during 1920.

During May, wages were reduced, and common labour is paid now at the rate of 32½ cents an hour; a reduction of ten cents on last year's wages.

Until this year, there was only one firm in the Province of Quebec manufacturing asbestos goods—the Asbestos Manufacture Company, Ltd., who supply the building trade with well known grades of asbestos paper, shingles, pipe covering, etc. Since April a second factory has opened in the province at East Broughton. Here Mr. Jos. Poulin has a well equipped plant to thread, spool, and weave, asbestos fibre, and he is making brake linings. The goods are sold under the trade name of *Asbestonos,* and the first shipments have been to automobile supply dealers. It is also reported that the Canadian John's-Manville Company, Ltd., which operates a mine at Asbestos, near Danville, has let out contracts for the construction of a large plant for the manufacture of all classes of asbestos products formerly imported from the United States. These products include asbestos paper, roofings, shingles, packings, pipe coverings, textiles, brake linings, etc.

At East Broughton the only actual producer is the Quebec Asbestos Corporation. This company has been seriously inconvenienced since the compressor plant on the mine was burned down on the 25th of May. The company is now getting air from the compressor plant of the Asbestos Fibre Mining Company, located on the adjoining lot, which property is now owned by the Quebec Asbestos Corporation.

The Asbestos Mines, Limited, previously known as the Boston mine, and which was purchased last year by Mr. J. A. Jacobs of Montreal, has remodelled the mill near the main line of the Quebec Central Railway. As the mine is on lot 13 of range IV, a distance of a little over a mile by team road from the mill, a cheaper method of transportation had to be resorted to. An aerial cableway was constructed, and completed on the 1st of June of this year. The installation consists of two ore-bins, one at each end of the line. The one at the pit end has a capacity of 500 tons, the other at the mill end can hold twice that amount. The distance between the bins, from centre to centre, is 4,250 feet. The difference in elevation between the charging floor at the pit and the receiving floor at the mill-head is such as to permit the aerial line to be run practically by gravity.

At the end of 1920 the property of the Asbestos Fibre Mining Company was purchased by the Quebec Asbestos Corporation. The mine of the first named company is shut down.

All work has been stopped at the Fraser mine; and only a few men are to be seen around the plant of the General Asbestos Company.

At Robertson, the Federal Asbestos Company is working one shift five days a week. The old inclined tunnel and the crushing plant at the bottom of the open-cast pit have been abandoned. The rock is now hoisted by a new incline following the edge of the pit.

The mine of the Pennington Asbestos Company is one of the few working day and night. They have been steady shippers during all this spring.

Mr. Donat Guilmette has re-opened an old prospect on lot 13 of range IV of Thetford township. He has just completed a mill of very small capacity to test the rock on this property.

At Thetford, there is little activity. On June 1st only one mine, the Bell, had men working at night. The Johnson's mine is completely shut down, and the Bennett-Martin has only a few pickers of crude at work. The other mines are working on day shift only.

The Consolidated Asbestos, Limited, apart from carrying on operations on a reduced scale at their Thetford mine, are remodelling the mill of the Berlin mine on lot 2, range V of Thetford township. The property had previously been worked during the years 1910 to 1912 by the Berlin Asbestos Company, Limited. The Consolidated Asbestos, Limited, also acquired mining rights last fall on lots 23 and 24 of range II of Wolfestown township. During the winter the mill on one of their other properties was taken down and rebuilt on these lots, near the old Smith mine. A number of other houses have been put up which are to be used in connection with the mining operations here.

The Maple Leaf Asbestos Corporation, which has a long term lease on the Reed lot, range A of Coleraine township, has had a well equipped mill built near the open east pit worked previously by Messrs. Blais & Fillion. The mill has now been in operation for a few weeks.

At Black Lake, the conditions at the British Canadian mine are similar to those of the Thetford mines. At the property of the Black Lake Asbestos and Chrome Company, Limited, improvements are under construction in the track lay-out around the mine and the mill. This will permit easier train manoeuvres.

Back of the Black Lake hill, on lot 23, range B (known as the Ward-Ross lot), the Asbestos Crude and Fibre Mining Corporation, Ltd., has a mill in course of erection. This lot was prospected last summer by Mr. W. Jacobsen.

Near Coleraine, the Vimy Ridge mine has resumed operations under the management of Mr. C. H. MacNutt. Alterations have been made to the flow-sheet of the mill during the winter season. The Canada Asbestos and Chrome Company, Ltd., has started to operate its mill, recently built on Block B of Coleraine township, one and a half miles north of Coleraine station.

The Windsor Asbestos Company, Ltd., is also operating.

The Weedon mine was the last of the cupriferous pyrites mines to close. The state of the sulphur market and the low price of copper have to share the responsibility for the shut-down of the Eustis and the Weedon mines.

Only one chrome mine is now operating: that of the J. V. Belanger Mining Company. Some twenty tons of chrome concentrates are produced daily. The Mutual Chemical Company of Canada disbanded its staff last January, and the mine is now flooded. The headframe over the mine shaft of the Caribou mine of the Black Lake Asbestos & Chrome Company, Ltd., has been dismantled.—D.

SUDBURY NOTES.

By D. E. CUSHING.

Another cycle of mining prosperity seems due in Northern Ontario, especially in gold camps, and strong efforts are being put forth to develop production somewhere in this area that years ago boasted of many mines.

Today there are four distinct operations, or group of operations in this vicinity, attempting to turn out a producing mine.

The most unusual enterprise is that nearest to Sudbury. With a desire to place Sudbury area on the map as a gold as well as nickel-copper producer, 100 of Sudbury's leading merchants and business men have put up $100 each and incorporated the Mines Service Corporation. It is a movement to find out whether or not there is gold in the Sudbury District. They placed an experienced prospector in the field, and already he has located a promising prospect. It is located east of here near Whanipatae Lake. A vein about fifteen feet wide has been traced for a half mile. It is on a contact of quartzite and conglomerate and is intersected by quartz stringers. Free gold has been generously found in the outcrop. It is the intention to do some trenching and stripping and sink a few test pits to find out the values.

The next camp of importance is the Howery Creek, where three companies are operating. The trio believe that they have what will prove to be good mines and their assay sheets so far lend every encouragement. The Howery Creek Co. plans to treat the ore for arsenic as well as gold and platinum. All three properties are now engaged in shaft sinking.

Farther on to the west comes the Goudreau as the scene of renewed activity. Some rich samples, studded with free gold, have been brought out of that camp, and just lately the Porter interests of Toronto have taken an option on the newly discovered Murphy Claims. J. G. Daimpre, former manager of the Associated Gold Fields of Larder Lake, has taken charge of the development. The Goudreau camp cannot be said to be anything but a prospect as yet, but a certain amount of sinking has been done and as far as the work has progressed, it has shown results warranting most of the enthusiasm displayed over the camp.

Half a mile east of Schrieber is the Jackson and other mines and here is the prospect of another good camp. This is far from a new camp. The Jackson mine, owned by W. S. Jackson, Fort William had a certain amount of work done on it 40 years ago, but it was never patented and reverted to the Crown. Jackson staked it and has been working on it for the past six years.

Eleven veins on surface have been traced over the property, running over a large hill, 500-ft. high at its loftiest point. The veins are parallel, and test-pits sunk indicate that they run true to their position on surface, this making it possible to cut all by means of a tunnel from the hill side. It is understood that a ton of ore taken from these veins and shipped to Kingston produced gold to the value of $118.21. Other assays show even higher values, but all are practically surface. Work on cutting a tunnel in 100 feet which will cut 265 feet below the top of the hill is now being started. A small mill to handle some 15 tons daily is to be installed.

Another interesting fact about this property, is that tests of sands in the valley of this large hill, pan gold in sufficient quantities to make placer mining a paying proposition. There are 6 to 8 inches of this sand, while beneath it and in the centre of the basin a vein was found and one shot showed that it had a width of ten feet. It appeared to be equal in richness to the other veins, but as these two discoveries are but recent ones, the assay reports have not been received as yet.

It is understood that John Caldwell, Winnipeg, owner of the old Sultana Mine, is negotiating for the purchase of some of the Jackson claims, and if a deal is made will move the machinery of the latter mine to the new property.

The Missabe Iron Mining Company is interested in this area also, through one of its officials, John Lee who has staked claims to the east of the Jackson holdings. Samples from these claims show 46.74 magnetic iron. Two miles to the west, Lee also made what is believed to be an important discovery. Not much work has been done but assays from samples picked near the surface give $18 in gold. Not far from this latest discovery are two claims reported to contain nickel ore of Sudbury type.

It would be most interesting to see this old abandoned area come through with a big producing gold-mine. There are today many abandoned mines along the North Shore of Lake Superior, which for the most part were operated from about 1853 to 1886, but abandoned usually because lack of transportation facilities, made mining too difficult.

PERSONAL—MR. J. F. K. BROWN.

Mr. J. F. Kelloch Brown has been appointed Assistant General Manager of the Hudson Coal Company, Scranton, in charge of all engineering. The Hudson Coal Company is a progressive anthracite mining concern. It had a record month's output in June of 840,000 tons, and a production of 9,000,000 tons is probable in 1921. Mr. Brown was with the Dominion Coal Company about 1912, and was afterwards for a short time with the A. D. Little Company and the Honorary Advisory Council for Industrial & Scientific Research. He has made a special study of the mining of thin coalseams, and prepared a bulletin on this subject which was published by the Mines Branch at Ottawa a few years ago. The Hudson Coal Company is mining anthracite under unique conditions. Seams under two feet in thickness are being extracted from beneath the broken waste and pillars of previous workings. In several instances, surface streams have been diverted or flumed to permit the working of anthracite seams lying below at short distances. Very large expenditures have been made by the Hudson Company on new wet-breakers and on a comprehensive scheme of electrification of all operations. Mr. Brown's friends will be glad to hear of his promotion, and to hear of the successful application of ideas that must soon find much more general application than they have yet attained. The principle of working superimposed coalseams with a view to the most economical admixture of the costs of thin and thick coalseams, and with definite planning and forethought as to the effect of workings in a lower seam upon a higher seam in the series, or vice-versa, is one that the Hudson Coal Company has comprehensively adopted.

BRITISH WHITE PAPER ON THE EXPLOSIVES COMBINE RECOMMEND CONTINUOUS STATE SURVEILLANCE.

A White Paper (Cmd. 1,347) was issued last week containing a report on the explosives industry, prepared by a sub-committee appointed by the Standing Committee on Trusts. The terms of reference were: "To inquire into the existence of any trade combinations of makers of explosives and ammunition, and the effect of any such combination or combinations, if found, upon supplies and prices."

The Committee's conclusions may be summarised as follows:—

(1) There are in the explosives industry four combinations, viz.:—(i.) The High Explosives Trade Association, (ii) the Safety Explosives Trade Association, (iii.) the Electric Detonator Fuse Trade Association, (iv) the Fig. Signal Association.

(2) These Associations fix the manufacturers' and retail minimum prices of practically all the explosives, detonators, and fog signals manufactured and sold in this country. Moreover, by reason of supplementary agreements with foreign manufacturers, these prices become the standard prices of practically all imported explosives; there is virtually no price competition.

(3) Foreign competition may be said to be negligible except in the case of sporting and rifle ammunition, and there seems to be little prospect of it becoming severe in the near future, in view of the agreements held by the Nobel Combine and the principal Associations with foreign manufacturers, which have for their purpose, amongst other things, the standardisation of prices and territorial restrictions of markets.

(4) All the explosives companies in this country, with the exception of three relatively small concerns, constitute one group—the Nobel Combine—under the control of Nobel Industries, Limited.

(5) This Combine at the present time practically controls the policy of the various trade Associations, and is thus able to determine substantially the prices at which explosives and detonators are sold in this country. The power of the Combine is not affected by the competition of the independent manufacturers, and there is nothing to prevent the Nobel Combine from maintaining prices at a higher level that they would have been had their constituent occupation remained unassociated.

(6) For reasons stated in the Report, the agreement of the Board of Trade and the Treasury with the Nobel Combine does not appear to afford a workable scheme of control or supervision, and the Committee recommend, therefore, that the powers of the Board of Trade should be supplemented by statutory authority to require from the Combine any information which may be necessary to enable review to be made of its operations and prices, and to enable the Board to make recommendations for the adequate protection of the consumer.

(7) The formation of the Combine opens up the possibility of economies in management costs and overhead charges, and of increased efficiency in production, and points to the probability of general advantages resulting from centralised research and from the institution of central buying and selling organisations. The effect of it should be to reduce the prices charged to the consumer, but there is no guarantee that this will be the result other than the powers given by the agreement to the Board of Trade, the inadequacy of which is pointed out in the Report.

The Committee regret that it has been found impossible, owing to the early expiration of their powers, to conclude an investigation into the costs of production and profits, or to make a complete survey and review of the financial operations and results of the Combine, with which some 78 companies are associated more or less closely.

The question of the effect of combinations on prices is touched on only briefly in the Report, but a statement is given of the prices of the principal explosives during the years 1913 to 1921. They represent the highest prices reached during these years. The following are some of the figures extracted from the table:—

	Gelignite per ton.			Blasting gelatine per ton.			Electric detonators No. 3, per 1,000		
	£	s.	d.	£	s.	d.	£	s.	d.
1913	85	0	0	115	0	0	4	12	0
1916	115	0	0	145	0	0	7	1	0
1918	160	0	0	190	0	0	8	11	0
1920	170	0	0	215	0	0	8	11	0
1921	170	0	0	215	9	0	8	11	0

The Committee have been furnished with a statement of the cost of raw materials, ingredients, and labour during the years in question, and these undoubtedly show a considerable increase. Without a costings investigation or an exhaustive study of these figures, however, they are unable to express an opinion as to whether the increases in the selling prices as given in the above table have been reasonable or otherwise.

In view of the monopolistic control exercised by the Nobel Combine over the explosives industry, the Committee strongly urge that its operations should be brought under the continuous and effective surveillance of the Board of Trade or some other Department of State, on the lines of the recommendations contained in the Report dated April 24, 1919, of the Committee on Trusts. The present authorised capital of Nobel Industries, Limited, is £21,000,000, and they now hold practically all the share capital of the 33 firms embraced in the merger. Of these 28 manufacture explosives, ammunitions, or accessories, but 6 are either liquidated or in course of liquidation. Of the 14 firms in which a controlling share interest is held, 7 produce explosives; of the 24 businesses where the holding is between 33 1/3 and 75 per cent., only 8 produce explosives, and of these 5 are in other countries; all the companies in which relatively minor interests are held manufacture explosives, but with one exception they are situated abroad.—"Colliery Guardian."

DEVELOPING ASBESTOS PROPERTY, MATACHEWAN AREA.

Development work is being carried on at the Sinclair asbestos property in Bannockburn township, Matachewan district. Samples of first class asbestos have been brought out from the property and arrangements have been made to bring out a sample carload of 'crude'. Mr. Wm. Judge is in charge of operations. Owing to transportation difficulties only the better grade of fibre is being considered at present. As No. 1 crude brings over $1,500 per ton, transportation on this class of material is not prohibitive. The lower grade product will however be of no value until better facilities are available. The proposed new light railway would help the development of the asbestos area.

ACCIDENT PREVENTION IN CAPE BRETON.

M. L. Fraser, Field Officer of Nova Scotia Accident Prevention Association.

Two hundred and seventeen employees of the Dominion Coal Company have successfully passed examinations on "First Aid to the Injured" and in the course of a few days will receive diplomas from the St. John Ambulance Association. During the past winter this company organized and carried on among its employees sixteen classes in "First Aid." The total enrollment in these classes would be approximately 450, but on account of the unstability of circumstances only the 217 referred to were able to attend all the lectures and therefore qualify for the examinations. The net result of the Company's initial effort is 450 men instructed in first aid measures, 217 of this number fully qualified certificate holders. This is a most commendable performance worthy of being emulated by the other large industrial concerns of the Province. The value of trained first-aid men in any community is most obvious and particularly is this so in regard to mining and industrial communities.

First-aid equipment has been going into Glace Bay in practically carload lots. This is actually so in one instance, as recently the Company received a carload of the latest type of stretchers. These stretchers are kept in convenient places on the surface and underground, and are so situated that no matter where a man is injured there is always one near at hand on which to take him to the "First Aid Station." Those underground are protected from dampness and dirt by galvanized containers. At every bankhead there is a "First Aid Station" which is in charge of one of the recent first aid graduates. These stations are splendidly equipped with approved appliances, comfortable beds, necessary medicines, etc. are always warm, and absolutely clean and tidy. In those stations which are not in close proximity to a regular hospital there are also standard hospital operating tables.

Accident prevention measures, as well as first-aid instruction and equipment, are receiving the serious attention of the Coal Company's management and officials. The "Safety First" campaign began with a general clean up of scrap material and rubbish around the various collieries. In this general clean-up something like eighty-seven carloads of material were gathered up and properly disposed of. As a consequence the different bankheads, yards, machine shops, etc. now present a tidy and well kept appearance, and the accident hazard in them is correspondingly lessened. In conjunction with the cleaning-up process, attractive signboards have been freely displayed calling attention to places where danger exists and soliciting the co-operation of everyone in the campaign of "Safety First."

The safety organization of this Company functions similarly to that of the United States Steel Corporation and other large American industrial concerns which have had remarkable success in this work. There are in all twelve Safety Committees, eight are mining bodies from the different districts, two are from the two shipping-piers, one represents the Mechanical, Electrical and Railway Departments, while the twelfth is the General Executive Committee.

All Committees meet regularly once in every two weeks. The duties of the eleven district and department committees are as follows:

(1) To make a general inspection of the whole plant at least twice a month, and make a written report of the safety and sanitary conditions in and about the plant on forms furnished for that purpose.

(2) To make a record of all safety problems that come up in their respective departments from day to day, and to submit these reports to the committee at the regular meetings for discussion.

(3) To investigate all accidents and consider in each case methods of preventing a repetition. The result of this investigation to be made in writing to the Safety Department.

(4) To caution and warn fellow-workmen against unsafe practices, and to report to the foreman any cases where a fellow-workman does not heed the warning given.

(5) To help enforce all Safety rules and regulations.

They finally dispose of all minor matters brought up, while matters of major consequence and involving the expenditure of more than a stated amount of money are referred by them, with recommendations, to the General Executive Committee. This Committee is made up of twenty-one of the Company's officials, the Assistant General Manager being Chairman and the Superintendent of Industrial Relations, Secretary. At its fortnightly meeting all recommendations from other committees are discussed and acted on, as well as all other matters pertaining to safety and first-aid. Acting in conjunction wth these committees there is a capable and experienced Safety Engineer and an equally capable Safety Inspector.

The Company is a member of the National Safety Council of Chicago, and from it receives sixty Safety Bulletins a week. These are displayed on attractive-looking bulletin boards situated in most suitable places all over the Company's properties. In addition to these purchased bulletins, some home-made ones are displayed having a local application, as well as circulars covering various phases of the safety work, such as one calling attention to the necessity of having small cuts and scratches properly cared for in order to avoid blood-poisoning.

Although the safety organizations has only been functioning for a few months, yet considerable good has been done. In four months $26,000 has been expended in the purchase of safety and first-aid equipment. Guards have been placed on dangerous machinery parts, safety railings and fencing built where necessary, safety electric switches installed on high-voltage currents, dangerous practices on the Company's railroad stopped, and in many other ways the activity of the organization is displayed.

THE EDMONTON MEETING OF THE C. I. M. & M.

The Annual Western Meeting of the Canadian Institute of Mining & Metallurgy will be held in Edmonton on the 14th, 15th and 16th of September. Mr. T. B. Williams is the Secretary in charge of arrangements, and will be glad to make hotel reservations for visitors. The provisional programme includes an address by the Albertan minister in charge of mines, an address by the President, Mr. C. V. Corless, luncheons and the annual dinner, visit and entertainment at the University of Alberta and a special train in connection with a visit to the Oliphant-Munson and Cadomin and other representative collieries.

Mineral Production of British Columbia in 1921

(From Our Victoria Correspondent.)

The official report of the value of the mineral production of the Province of British Columbia for the year 1920 places it at $35,543,084 in comparison with $33,296,313 for 1919 and $41,782,474 for 1918. The estimated output value for 1920 was $35,580,625, the difference being so inconsiderable as to warrant special comment and a word of congratulation to those officials of the Department of Mines responsible. The mineral production of the province from 1852 to the present now is placed at $706,192,978. This figure, however, must not be accepted as incontestably correct as the statistics for ten or fifteen years following 1852 are open to some question, there being no doubt that much of the gold production of the Cariboos, for instance, was taken out of the country without official record.

It now is possible to make the definite statement that the gold production of the province in 1920 dropped $734,153 in value. This is a considerable decline, perhaps not altogether accounted for by the stock explanation of increases costs of labor and supplies. However, it is likely to climb soon, if not this year the next should show an improvement. There is a marked increase in interest in placers by the individual miner, the hydraulic operator, and the dredge operator. The changes in the Placer Act also is having its effect. Large sections of river beds that are promising but have been held by lease holders in arrears in respect of their rentals are being thrown open and as quickly taken up by individuals and companies meaning business. Of the $221,600 taken from the placers of British Columbia last year the greater part came from the Cassiar and the Cariboo Districts. Not only is there much room for greater production in those sections but there are other parts that should figure prominently in the reports of the future. There was a decline of 21 per cent in the lode-gold production, $2,481,392 for 1920 and $3,150,645 in 1919, the Granby Company having closed its mine and smelter in the Boundary District, the Nickel Plate Mine having been closed down in the month of September, and the Rossland Mines having failed to contribute their usual quota.

Of silver there was a production of 25,270 oz. less than in 1919, the decline amounting to 10 per cent. Decline in the market accounts in a substantial degree for this unsatisfactory showing. Copper output increased in volume, being 44,887,676 lb., or 2,428,337 lb. greater than in 1919, but in value there was a decrease, again owing to market conditions. Lead statistics tell a different story—an increase in quantity of 9,855,250 lb. and in value of $1,289,260 or about 84 per cent. The smelter of the Canadian Consolidated Mining and Smelting Co., Trail, must be given credit for the greater part of this and the fact that lead was the only metal to increase in value over 1919 accounts for the gratifying comparison with the previous year's results. Zinc fell in output from 56,737,651 lb. in 1919 to 47,208,268 lb. in 1920, the production being valued at $3,077,979, a decrease of $462, 450 or about 17 per cent.

Under the heading "Other Minerals" some interesting information is given. Comments made in this connection follow:

Iron.

So far there has been no metallic iron produced in British Columbia, but it has been strongly advocated in many quarters that the conditions are favourable for the establishment of an iron-smelting plant somewhere on the British Columbia coast. So far nothing definite has materialized, although there is apparently a prospect of such a plant being established. As is well known, there is on the Coast, in the aggregate, an adequate supply of magnetite-iron ore, quite sufficiently free from impurities as to be within the "Bessemer limit" to supply ore for such a plant.

Further investigation of the Taseko limonite-deposits was made during 1920 by a party sent out by the Department of Mines. The deposits were also examined in detail by Dr. J. D. MacKenzie, of the Geological Survey of Canada.

The only shipment of iron ore made this past year was for 220 tons from the Iron King at Alta Lake to Vancouver.

Platinum.

The well-known fact of the wide occurrence of platinum throughout the Province in connection with our placer-gold deposits gives reasonable hope that such may be found in payable quantities and justifies further investigations. As far as reports received indicate, the only output this year is about $400 worth from the Similkameen District.

Molybdenite.

Since the Armistice the market is dormant, like other metal prices, but nominal quotations vary from 75 cents to $1 a pound. No advice has been received of any shipment this year.

In 1918 about 800 tons of chromite ore, carrying from 30 to 45 per cent chromic oxide, was shipped from the Mastodon claim, Grand Forks Division; and a deposit on Scottie Creek, near Clinton, but no shipments were made. With the end of the war the market for chromite temporarily collapsed ,as large stocks were available, with no purchasers in sight. It is believed that no ore was shipped in 1919 or 1920.

Manganese.

Nearly 600 tons of manganese ore, running over 50 per cent manganese and less than 20 per cent silica, was shipped from the Hill 60 property on Cowichan lake before the roads became impassible through winter rains. The company has installed an aerial tramway, which should prevent, in the future, interruption to sustained shipments. During the latter part of the year shipments ceased and development work only was carried on.

Non-metallic Minerals.

About 7,500 tons of fluorspar concentrates was shipped from the Rock Candy group, in the Grand Forks Division. This property is owned by the Consolidated Mining and Smelting Company and is equipped to make steady shipments in the future. The growth of this property has been very interesting during the last two or three years. The property is now equipped with an efficient concentrating mill, in which about 20,000 tons of ore was traced, producing nearly 7,500 tons of concentrates, carrying about 87 per cent calcium fluoride and 6 per cent silica, and having a total value of about $175,000. The mineral is shipped to the Trail smelter and is used for making hydrofluoric acid, which is used in the lead-refinery, and to other points in Canada and to the United States.

Shipments of magnesium sulphate (Epsom salt) were made from Spotted lake, Osoyoos Division, but figures

have not been obtained. About 1,100 tons of magnesium sulphate was said to have been shipped from deposits of this material near Clinton.

Deposits of hydromagnesite in the Clinton Division, which are reported to be large and of great purity, have attracted considerable attention during the past year. No shipments have been recorded.

A production of arsenic valued at $22,000 was made by the Nickel Plate mine in 1920.

Talc.—Some 100 tons of talc was mined and ground in the Victoria Mining Division, for which product there appears to be a large demand.

Some 100 tons of talc was mined and ground in the Victoria Mining Division, for which product there appears to be a large demand.

Iron Pyrites.—At the Sullivan mine in East Kootenay some 4,300 tons of iron pyrites was mined and shipped to Trail.

The Coal Mines.

Coal figures show an increase over 1919 of 287,826 tons gross and of 327,584 tons net. The 1920 gross production of coal was 2,696,774 long tons of which 101,649 tons was made into coke leaving the net production of 2,595,125 tons. The quantity of coke made was 67,792 tons, which is a decrease of 23,346 tons as compared with 1919. The greater part of the gross Provincial coal coal production still is being mined by three companies—the Crow's Nest Pass Coal Company of East Kootenay, the Canadian Collieries (D) Ltd., and the Canadian Western Fuel Company of Vancouver Island, which mined, collectively, 77 per cent of the output. There are no new developments of special note in the Vancouver Island, the Nicola-Princeton and the Eastern British Columbia coal fields but reference is made to "a new coalfields opened up in the Omineca (northern B.C.) where a small colliery is being developed on the Telkwa river that last year shipped 1,400 tons of coal." Of the gross production for 1920 there was sold for consumption in Canada 1,384,005 tons; in the United States, 792,293 tons; and in other countries, 7,647 tons. All the coke produced came from the Crow's Nest Pass Coal Co's. ovens; those of Cumberland, V.I., were not operated, and the by-product ovens of the Granby produced for the use of the Anyox Smelter only.

ANGLO-PERSIAN COMPANY TO PROSPECT NEWFOUNDLAND FOR OIL.

It is announced that the Newfoundland Government and the Anglo-Persian Oil Company, through its subsidiary, the D'Arcy Exploration Company, have concluded an agreement which gives the oil company exclusive rights during a period of two years to prospect all unoccupied Crown lands in Newfoundland for oil, bitumen, natural gas, and clays or shales capable of yielding oil. The "Financier" of London states that the oil company has despatched three staff geologists to commence the survey, and gives detailed particulars of the agreement entered into, as follows:

"The company is entitled during the prospecting period to enter upon every part of the unoccupied Crown lands, and make geological and topographical surveys thereof. The surface of the land may be turned up to depth not exceeding 20 feet and the company shall from time to time furnish to the Government full reports of all surveys, together with all necessary copies of maps and plans relating thereto.

"There may be removed samples in reasonable quantities. Payment must be made by the company to any third party in reasonable compensation for injury or damage, and at all times the Government must be kept indemnified against all liability.

"If the company shall at any time during the prospecting period give notice to the Government that it desires to test any part of the unoccupied Crown Lands, not exceeding a total area of 3,600 square miles, it shall be entitled during the remainder of the prospecting period and for a further period of three years after the first two years to test the lands comprised by sinking therein such test wells as it thinks fit without payment. The company may retain or dispose for its own account and benefit any substances of the natures that have already been enumerated which it may discover or obtain during the period. This is providing, however, that the company shall, within six months after the expiration of the prospecting period — two years — have commenced to sink at least one test well in respect of each area, and thereafter vigorously prosecute the sinking. Unless this is done it shall forfeit all further rights to test an area.

"Any lease that the Government shall grant to the D'Arcy Exploration Company prior to the expiration of the latter three years shall be for a term of ninety-nine years from the date of determining an area to which a lease relates, but power is given to the Government to determine the lease in the event of failure continuously to work and develop the property.

"It is provided that the consideration by the company shall be the payment in cash to the Government of one-eighth — 12½ per cent — of the value at the easing head of all oil won during the term of a lease.

"Whenever the company shall be desirous of acquiring a right of way for tramroads, or roads or sites for wharves and piers, or an increased quantity of surface land for purposes connected with the working of petroleum oil or other substances already named, it shall be entitled to a grant of unoccupied Crown lands at the price of 30 cents an acre.

"The company may then construct, maintain and operate suitable pipelines, telegraph and telephone lines, railways, tramways, aerial ropeways, roads and bridges from any parts of the lands comprised in leases, to any points on the seaboard which it may select. Workmen's houses and business offices and refineries may be erected.

"The company shall not be required at any time during the currency of a lease directly or indirectly to pay to the Government any tax, assessment, levy or other payment in excess of the rate paid by any other person, firm or corporation in the Colony.

"There may be imported all material and plant required for the purposes of the agreement with the Government free of import duty for a period of twenty years from the date of the agreement. This applies to both original installation and any further extension, but does not include the substitution of old material and plant.

"Within one month from the expiration of each year for the term of every lease returns must be made to the Government, verified on oath by the lessee, of the total quantity of oil won by the company during each year and the value of such oil at the easing head."

NOVA SCOTIA COLLIERY NOTES.

Production from the Glace Bay collieries of the Dominion Coal Company in June was 295,097 tons, comparing with 282,520 in June 1920. Work at the mines was not continuous throughout June, but the output is the largest since last November. For the half year, the Glace Bay mines produced 1,422,796 tons, which is 192,477 tons below the production of the first half of 1920. Having regard to the capacity of the mines and the trade outlook it is not to be expected that production for the remaining six months of the year will increase, and indications are that 1921 output will reach about 3,100,000 tons, comparing with 3,260,000 tons for the year 1920.

Outputs from the Springhill Mines continue practically unchanged around 30,000 tons monthly. For the six months of 1920, outputs total 210,000 tons, approximately equal to those of the first half of 1920.

The output from the collieries of the Nova Scotia Steel and Coal Company for June was unusually large, amounting to 61,300 tons, comparing with 43,182 tons in May. For the first half of the year, outputs total 283,825 tons, comparing with 315,329 tons in the corresponding period of 1920. Scotia's coal production in 1920 totalled 633,845 tons, but the outputs for 1921, under probable trade conditions, will scarcely exceed 575,000 tons.

The production of coal in the province has distinctly slowed up in recent weeks. The extra demand arising from the British coal strike helped the Nova Scotia collieries and avoided idle time during the early Summer, because the St. Lawrence has not, and does not promise to take all the coal that the collieries can provide. Large purchasers of coal, from lack of cash and reduced scale of coal consumption, are holding back from commitments, and it appears likely that broken time will be the rule at the collieries during the remainder of the year. The mainland collieries will experience a little better demand as Winter approaches, but no immediate thorough recovery of buying ability is looked for.

The Dominion Coal Company has closed down its No. 17 Colliery, a partially developed mine in submarine territory which has been carried on as a prospecting operation in recent months, and will put the miners into other collieries. The information gained as to the quality and extent of the submarine coal in the Waterford district is stated to be most encouraging, and it is probable that a new opening in this vicinity will develop the series of coal-seams by means of a deep shaft and a rising cross-measure drift, in the manner that is now recognized as being the most practical and economical way to develop the submarine fields. In the Waterford district, also the consolidation of coal areas achieved by the British Empire amalgamation gives to one company the entire control of all the seaward coal to the extremest limit of mining operations as this may be determined by the physical conditions encountered. Under the previously existing arrangement of coal leases the Dominion Co. had lease of only the first two miles of seaward coal fringing the shores. This was a decided technical weakness, as it did not permit of such capital expenditures in preparation for coal extraction during the projected life of the leases as becomes both necessary and justifiable when all the seaward coal is available. In the Waterford district, the coal seams are present to the full extent of the series so far as they are known, and, presumably because of the conditions of original deposition of the coal-seams in the centre and least disturbed area of the Sydney coalfield, the seams are thicker and of better quality than in those areas which approach the shore of the Carboniferous sea and the source of the Coal Measure sediments. The Waterford district will eventually become the most important productive area of the Sydney Coalfield. The workable coal-seams are probably not less than five in number. The inclination of the seams seawards becomes much slighter at about a mile to sea, which means that the superincumbent land and water cover will not hamper mining by its weight to an insuperable extent, and the sea frontage between the subordinate folds in the main field ensures an uninterrupted territory probably eight miles wide, with an indefinite seaward extension of the seams.

PORT ARTHUR NOTES.

By J. J. O'CONNOR.

Voting on the By-law to confirm the sale of two hundred acres of water-front property, to the Palatine Mining and Development Company, by the City of Port Arthur, will take place on the 27th. instant. This sale was made for the sum of ten thousand dollars, subject to the votes of the qualified ratepayers. It is confidently believed that the By-law will be carried by a handsome majority.

This tract of land has a frontage of 1650 feet on the shore of Thunder Bay, and includes a water lot containing 83 acres, situate immediately north of Bare Point, within the city limits. It is expressly understood and agreed that the lands and premises are to be used for industrial and manufacturing purposes only, and that no dwelling houses shall be erected thereon. The purpose of the company in acquiring these lands, is to locate an iron steel plant together with associated industries, requiring large waterfront facilities, and a large land acreage for the erection of buildings to accommodate their scheme of development.

The Palatine Mining & Development Company now control about 2,500 acres of iron-ore lands in Cook county, Minnesota, which includes the Paulson nontitaniferous deposits. The company is now securing estimates on ten thousand feet of diamond drilling, to be done on these lands, other than the Paulson, where the company plans to begin mining soon as practicable.

It is the intention of the company to use the Paulson ore in the furnace at Port Arthur, which is now under its control, and is being rapidly modernized preparatory to being put in blast. The company has acquired the furnace under a four year rental option to purchase. The purchase price has not been given out, but is generally understood to be about $800,000. The improvements to the furnace call for a considerable initial expenditure, to place it in condition for production.

It is understood that the company are now making arrangements for an ore supply, to be used in conjunction with the Paulson ore for a furnace mix.

Actual development work has been started by the Islet Exploration Company, on the famous old Silver Islet Mine. Drifting was begun on July 1st. at a depth of two hundred feet, from what is known as the old fourth level, good progress is being made. This drift is headed west, in the direction of Shangoinah Island.

A shaft is being put down on a vein containing massive arsenical silver, on Edwards Island, nine miles east of Silver Islet.

Northern Ontario Letter

THE SILVER MINES.

The Cobalt District.

Economic conditions are steadily moving toward a solution of the difficulties which forced a curtailment of operations at many of the world's silver mines during the past year. The price of the metal having fallen almost precipitately during the past eighteen months, the operators found themselves in an exceedingly difficult position, especially because the price of supplies used in mining as well as the cost of labor did not decline to any very marked extent.

While the cost of material commenced to decline soon after the slump in silver quotations, yet the decline was not very pronounced. This resulted in the wiping out of what otherwise would have been a reasonable margin of net profit. The end was that a number of mines in a comparatively weak physical and financial position were compelled to close.

During the past few weeks, the decline in the price of material used at the mines has been going down more rapidly than any time on record. Dynamite has declined $4 per hundred pounds since December last, the price now being $17 per hundred for 40 per cent material as compared with $22 last Fall. Machinery, chemicals, lumber and all building material is declining rapidly in price, some of the machinery going down more than 25 per cent during the past two months.

Features in the silver mining situation are these: The price of the metal came down in "waves", so to speak, and settled at around 60 cents an ounce. Some time later, after considerable hardship had been experienced by the mining companies, the price of supplies commenced to also come down in waves, at first small reductions but now reaching proportions which promise to strike a more reasonable balance as between the cost of producing silver and the price which the metal commands on the open markets. All of these re-adjustments carry favorable tidings to the stockholders of mining companies owning property in the silver fields.

The Kerr Lake is encountering good ore at the 9th level, at a point about 125 feet beneath the lower contact. The silver occurs in small stringers about half an inch in width, assaying about 300 ounces of silver per ton. The company shipped a carload of ore during the past week containing 45,184 pounds and carrying approximately 350 ounces of silver to the ton.

During the first half of 1921, the Bailey mine shipped approximately 6,451 tons of ore, in addition to which was a large tonnage of customs ore, all of which resulted in the Bailey Customs Mill realizing a gross earning of $68,936.77 for the half year. An official of the company declares that the known ore bodies are being developed and shipments of ore are being made daily from the mine. The underground work is referred to as being "most encouraging". For the month of June, the custom mill treated 4,150 tons of ore, of which 1,060 tons came from the Bailey mine itself. This resulted in gross earnings of $12,451.98 for the month for the Bailey mill.

In regard to the report circulated recently, stating that Malcom Lang, M.P.P. for the Cochrane district, had been approached by the Ontario Government with the offer of the portfolio of Minister of Mines in the Drury Administration, to succeed Hon. H. Mills, the correspondent of the Journal has received the following statement from Premier Drury: "There is absolutely no foundation in the rumor you mention, and Mr. Lang's name has never been thought of or suggested for an appointment under this Government."

At the annual meeting of the Beaver Consolidated Mines, Ltd., the former board of directors were re-elected. Frank L. Culver, president and general manager, told the stockholders that the mine is being kept in shape to re-open at short notice at such time as conditions warrant such a step. In the meantime, Mr. Culver stated that he would not draw any salary during the period which the mine lies idle.

Production from the Nipissing Mine underwent a substantial increase during June when the output amounted to $162,824, as compared with $142,036 in May. A feature of the report is that $25,560 in cobalt was produced as a by-product.

In his regular monthly report to the president and directors, Hugh Park, manager, says:— "During the month of June the company mined ore of an estimated net value of $162,824 (including $25,560 of cobalt metal) and shipped bullion from Nipissing and customs, ore of an estimated net value of $208,536. The value of the silver production was estimated at 59¾ cents per ounce.

"Underground developments continued to be about the same as they have been for the past few months. Most of the tonnage treated was obtained from the stopes, development work contributing a small amount.

"The low grade mill treated 6,580 tons of ore. The high grade plant treated 174 tons. The refinery shipped 352,749 fine ounces of silver.

A meeting of the Cobalt branch of the Canadian Institute of Mining and Metallurgy was held in Cobalt July 15th, on the occasion of the visit of Mr. Mackenzie, secretary. Among the subjects discussed were "Slime Reclamation" by Fraser D. Reid; "Present Status of Gold Coinage", by H. G. Mathewson; "Pottery Clay in Temiskaming", by Arthur A. Cole.

Elk Lake and Gowganda.

The proposed narrow-gauge railway through the Gowganda district is still hanging fire. The Ontario Government seems to have definitely decided not to lend financial assistance to the project. In the meantime, the promoters are still engaged in the endeavor to finance the scheme entirely through the private sale of bonds. It is intimated that the Drury Cabinet, having in mind the commission to be made on the sale of bonds, etc., feared among other things that Government assistance might be capitalized as government endorsement of the scheme as an investment from the point of view of individuals. Property owners along the proposed route are not coming forward with any assistance.

Ore and Bullion Shipments.

During the week ended July 15, two cobalt companies shipped an aggregate of three cars containing approximately 226,500 pounds of ore. This was made up of two cars containing 140,504 pounds from the Coniagas and one car with 85,996 pounds from the La Rose.

During the corresponding period, the Nipissing mine made two shipments of bullion, making up an aggregate of 113 bars containing 151,722 ozs.

THE GOLD MINES.

The Porcupine Field.

It is estimated that approximately 2,500 men are engaged in the mining industry of the Porcupine field, and that the total pay-roll is about $4,000,000 a year. It is estimated that the Kirkland Lake field employes about 800 men, with a pay-roll of over $1,000,000 annually. Of this total of $5,500,000 the producing mines pay perhaps $4,000,000. A shipment of five tons of ore will be made shortly to the Temiskaming Ore testing Laboratory, Cobalt, from the Triplex property situated in the township of Shaw, in the Porcupine district. This shipment is for experimental purposes in determining the process best suit to treat the ore should it be found in the commercial quantities.

Officials of the Porcupine V. N. T. Mines are engaged in an endeavor to raise some $200,000 for the purpose of reopening the mine and remodelling the mill. The company has 475,000 shares in its treasury which may be sold, either that, or a loan may be secured. The property is in a strong physical condition, the blocked out ore amounting to about $1,000,000.

Work has been commenced on the Big Dyke property, in Deloro township. At present, only a small force of men are employed in driving a tunnel, but arrangements are being made to carry on aggressive exploration. This company controls the McRae-Porcupine as well as the Pike Lake properties.

What is an "ill wind" to Canada in a general way in the form of adverse exchange of upwards of 14 per cent as between Canadian and American currency, is proving to be a boon to the producers of gold throughout the Dominion. The fact is that at this time, each ounce of gold which is produced in Canada continues to command the full standard value of $20.67 an ounce in the United States. This, in terms of Canadian dollars and cents, is equal to approximately $23.57 an ounce. In a word, the gold mining companies in Canada are receiving a premium of approximately $2.90 an ounce for the gold which they produce.

Without careful analysis, the full significance of such a situation is difficult to measure in its bearing upon the gold mining industry as a whole. The added revenue is something which is adding to the incentive to mine gold ore. It is one of the laws of industry that profit and loss regulates its velocity. It is necessary that profit must be obtainable. Furthermore, the greater the margin of profit, the greater the effort put forward.

Then, to analyze the favorable influence which the present adverse exchange rate is having upon the gold mining industry of Canada: In the first place, the mines of the Porcupine and Kirkland Lake districts, in Northern Ontario, are producing gold at the rate of approximately 67,500 ounces monthly, or a "standard" value of between $1,350,00 and $1,400,000 a month. This standard value is received in full in the terms of American funds, which, in turn, when converted into Canadian currency, is increased by upwards of 14 per cent. That is to say, the mines of Northern Ontario in producing 67,500 ounces of gold per month, are actually receiving a premium at this time of $195,750 monthly, or at the rate of $2,349,000 a year. This sum, in addition to the standard value of $20.67 an ounce on which operations at the gold mines are based, is adding in an important degree to the incentive to produce gold bricks at maximum capacity.

To go still further, it may be well to note that in so much as the mines in the districts of Porcupine and Kirkland Lake contain an average of approximately one-half an ounce of gold per ton of ore, it follows that this premium of $2.90 an ounce on gold is adding to the value of the ore at the rate of approximately $1.45 per ton.

To grasp the significance of this still further, it is only necessary to keep in mind that the total cost of mining and milling a ton of ore in these districts ranges from $3.50 to $6 a ton. Indeed, there was a time in the history of one mine, that being the Dome, when the total cost was reduced to approximately $2.50 a ton. Keeping these facts in mind, it may readily be seen just now important is a premium of $1.45 a ton which is all net profit entailing no additional effort.

It is a fact that the pay-roll in the gold-mining industry of this district as a whole amounts to around $5,000,000 a year. The producing mines pay over $4,000,000 of this total, so that it may be seen that the current premium is actually at the rate of well over fifty per cent of the total pay-roll at the producing mines.

Having this fact in mind, Mr. Mackenzie, secretary of the Canadian Institute of Mining and Metallurgy, made the statement that the gold mining companies of the Porcupine district are not very keenly disposed to co-operate with a view toward reducing the rate of exchange. Mr. Mackenzie received this impression as a result of having approached the Porcupine miners with a view toward encouraging them to secure their coal from Alberta instead of going to the United States for it. "They seem to feel that they have the bull by the tail up there", said Mr. Mackenzie, "and take the attitude that this premium is only a fair reward for the adversities which the gold mines were obliged to pass through during recent years."

Kirkland Lake Field.

During the month of June, the Kirkland Lake Mining Company treated upwards of 4,000 tons of ore. Details are lacking as to the average gold content, but the average at this property may be figured at around $8 per ton, although for the past fiscal year, the gold content ranged between $6 and $7 per ton. Total costs, including mining, milling and administration amount to approximately $6 per ton.

At the Teck-Hughes mine, the mill has recently been treating an average of between 115 and 120 tons of ore daily, or at the rate of around 3,500 tons a month. The ore on this mine has recently averaged approximately $10 per ton, thus indicating an output of approximately $35,000 a month. This would tend to show net profits at the rate of not far under $500 daily.

During the month of June, the Wright Hargreaves mine produced approximately $51,000. About 25 per cent of the possible running time was lost, 16 per cent of which was due to power shut off and the balance to various causes. This enterprise appears to be shaping up definitely as the fourth largest gold mine in Canada, and an output of at least $2,000 daily seems to be assured. The mill has recently been treating an average of 150 tons of ore daily, and will probably reach an average of 160 tons a day. The ore contains from $15 to $16 a ton in gold, which would indicate a production of $2,400 daily when

running full capacity. The mine now enjoys the distinction of treating over a ton and a half of ore and producing approximately $25 every twenty-four hours for each man on the pay-roll. This is the highest production per man in gold-mining in Canada. Another fact of great importance which reflects favorably upon the judgment and efficiency of the management of the Wright-Hargreaves, is that during the first ten months following the completion of the mill, the mine will produce a greater gross value than the total cost incurred in connection with developing the mine and equipping it with the present big mining plant and one of the finest mills ever constructed.

During the month of June, the Lake Shore Mine produced more gold than during any previous month in its history, in spite of the fact that the mill was operated only 75.9 per cent of the possible running time. Production for June amounted to $52,539.92, this amount having been recovered from 1,656 tons of ore treated. These figures show that an average of $31.64 was recovered from each ton of ore treated. Features of the report are that this is the first time the mill heads ever exceeded the $30 per ton mark, the previous highest grade having been $29.98 per ton. It is also noted that the output for a single month exceeded the $50,000 mark only once before in the mine's history when $52,425.45 was produced in July, 1920. In an interview with R. C. Coffey, manager of the Lake Shore, Mr. Coffey stated that the No. 2 ore body at the 600-ft. level is looking exceedingly good, and stated that the loss of about seven days in the operations of the mill during June was the only thing whoch prevented a production of around $60,000 during the month. This loss of time was largely beyond the control of the management in that 16.1 per cent of the total running time was lost due to power shut-off on the part of the company which supplies the electric energy and the excessive fluctuations of the voltage burning out motors.

It is noted that the greater part of the work was done at the 600-ft level during the period, the report showing 99 feet of drifting and 29 feet of raising at the 400-ft level, while at the 600-ft level some 261 feet of drifting was done.

Heretofore it has been a quite general impression that the Lake Shore equipment could take care of the production of about $500,000 annually but, in the light of the June achievement, it would appear as though an output of between $600,000 and $700,000 could be taken care of.

Mr. Coffey stated that no milling additions will be made for the present other than perhaps speeding the present plant up to an average of about 65 tons daily as compared with a former capacity of about 60 tons.

MEETING OF COBALT BRANCH OF C.I.M.M.

A meeting of the Cobalt branch of the Canadian Institute of Mining and Metallurgy was held in the Board Rooms of the Temiskaming Mine Managers' Association, Cobalt, July 15. The meeting was the first to be held by the local branch since 1914, about 50 members and their friends being present.

Mr. Mackenzie, secretary of the Institute, reviewed briefly the status of the organization in all parts of the Dominion. Mr. Mackenzie has just completed a tour as far west as the Pacific coast, and declares that the Institute is in a decidedly healthy condition. He urged, among other things, that the local branches should be more aggressive. In this connection, the secretary had some suggestions to offer, based upon a survey of the entire field.

Reclamation of Slimes.

During the course of the evening, Fraser D. Reid, manager of the Coniagas mine, gave a ten minute talk on the "Reclamation of Slimes." Mr. Reid stated that his company had approximately 40,000 tons of the material to deal with, and took the matter with consideration at a time when silver was quoted at $1.30 an ounce. At that price, a substantial margin of profit appeared to be assured. The flotation process was tried, but gave only about 50 p.c. recovery. The price of silver began to decline, thereby necessitating improved methods. It was then decided, after careful experiments, to adopt the cyanide process, from which a high efficiency has been obtained, it now being possible to recover 5 ounces per ton as compared with the total content of 6 ounces. The total cost of re-treating the slimes approximates $1.50 per ton. The cyanide consumption amounts to about 2.8 pounds.

Status of Gold Coinage.

Mr. H. G. Mathewson, manager of the Cobalt branch of the Canadian Bank of Commerce, was requested to give a ten minute talk on the "Status of Gold Coinage."

Mr. Mathewson recounted the condition which had compelled the Canadian government to empower banks to issue bank bills as legal payment in discharge of promises to pay in gold, and stated that the government's action had avoided declaration of a moratorium. He enlarged upon the curious situations that the gold embargo had created in international banking exchanges, instancing that presentation respectively on a Canadian bank of a cheque for a hundred dollars on New York, of the same amount in U.S. bills, and U.S. gold coin to the value of one hundred dollars, would give the recipient $114 in the case of the cheque, $112 in exchange for the bills, and $100 in the case of the gold coin, all in Canadian paper currency.

Pottery Clay in Temiskaming.

Arthur A. Cole, Chairman of the meeting, and a former president of the Institute, spoke on "Pottery Clay in Temiskaming." Mr. Cole showed samples of clay taken from the Matagami River district, north of the Transcontinental Railway, which is rated as being the best grade so far discovered in Canada. The speaker illustrated his remarks with a piece of china manufactured from this clay. Other samples of inferior quality were shown, these coming from the Missinabi River, as well as near New Liskeard. Mr. Cole stated that the high grade clay of the Mattagami River district is without economic value until such time as transportation facilities may be provided, but referred with considerable optimism to the possibilities of this resource at some future date.

Following is the executive of the local branch of the Canadian Institute of Mining and Metallurgy, elected at this meeting:—

Arthur A. Cole, president; Angus Campbell, secretary; with H. A. Kee, M. F. Fairlie and G. C. Bateman on the council.

TORONTO MINING QUOTATIONS.

Quotations on Active Stocks on Standard Stock Exchange on July 20th, 1921.

Toronto, July 6th, 1921.

Canadian Mining Journal,

Dear Mr. Gray:—

I would like to draw your attention to the fact that the American Association for the Advancement of Science, the largest scientific and technical association in America, holds its annual meeting in Toronto in December next. Among its several sections is one on engineering, including mining and all other branches of engineering. It is to be hoped that our engineers will turn out in full strength at this meeting and make it a splendid success.

J. B. TYRRELL,

SILVERTON MINE SOLD.

The Standard mine at Silverton has been sold to New Yorkers for $75,000. The operating company has paid $2,700,000 in dividends and has a substantial cash surplus which will enable it to purchase and develop another mine.

IMPROVING SHININGTREE ROAD.

The waggon road from Westree to the Shiningtree gold area is being improved this summer. The greater part is in first class condition and a gang of forty men are now at work on the unfinished part. There will soon be a good gravel road from rail to mines.

EDITORIAL

The Search for Oil in the West

Mr. Alexander Gray, in this issue, reviews the search for oil in the Great Plains, the Alberta Foothills, and the drainage area of the Mackenzie, from the standpoint of the oil prospector. The review discloses how very wide has been the rake of the Imperial Oil Company, how thoroughly it has tested a continental area for the presence of oil in commercial quantity, and how large the capital expenditures incurred have been, especially in view of the slightness of the reward to date. The meagre appropriations of the Geological Survey have been handsomely supplemented by the operations of the Imperial Oil Company. Our geologists now have actual bore sections to work on, and a store of precise knowledge that never could have been gained with the staff and money at the disposal of the Survey. It is intimated that the precise knowledge gained by a series of borings designed to prove the position of the rock formations will necessitate some revision of the geological maps, so far as horizontal extension of the named formations is concerned, a fact that is not in the least surprising. As to the existence of structural features favorable to oil accumulation, it is difficult to see how even the most accomplished geologists, given ample time and funds for intensive study, could map these, without the aid of borings, in a country with prairie topography. So far as we have been able to glean from the reports of those officers of the Survey that have been detailed to work on the oil geology of the Great Plains, they have never held out any other hope than that this great area of undisturbed sediments was worth a systematic testing for the presence of petroleum, and there has been very evident on several occasions a tendency to criticise the officers of the Survey as lacking in optimism. Whatever may be misconceptions and shortcomings of the non-technical administrative departments of the Government, it will be generally admitted by those who have followed the reports of the Survey that these have been remarkably correct, and such forecasts as have been made have been strikingly confirmed by the precise knowledge that can only come from boring.

It may also be inferred that if the administrative departments at Ottawa had asked its scientific officers to tell them honestly, on purely technical reasoning, how best to utilise the oil that may be found in the Mackenzie Basin, the existing regulations would not have been framed. The statutory lease area, not being related in any way to geological structure or to the peculiarities of a fluid accumulation, is entirely illogical. As it is evident that oil can only be won from the Far North by rich and experienced corporations, the encouragement of small operators by provision of small lease units and the prohibition of grouping of claims (now modified) is also illogical. If the Government desired to hold fast to its possession of the oil-lands, it should have let out their exploitation to the most competent contractor putting in a bid. If, on the other hand, it desired more than anything, speedy production of oil in quantity, it should have given to some large and established oil company a concession sufficient in area to justify the very onerous capital expenditures that oil prospecting in northern Canada entails. If oil is found in the Upper Foothills, and in the Mackenzie area, the regulations as they stand will result in creating individual possessory titles to tracts of oil-bearing country. In the course of transference of these claims to the large oil companies that will eventually control the oil production of the North (should it materialise) some individuals may gain wealth by dealing in oil-mining rights, but this pernicious evolution will not help oil production. On the contrary it will defer the opening-up of productive areas and will increase the price of oil to the ultimate consumer, who will someday pay, not for the cost of producing oil as a physical operation, but for the over-capitalization of the industry by the creation and disposal for profitable prices of a host of possessory titles that will quite unnecessarily have been created.

WE had always supposed that the traditional incompatability of opinion between the East and the West was a Canadian idiosyncrasy, but the debate in the House in the United States upon the Fordney tariff bill discloses that this custom, like high tariffs and the class consciousness of the agriculturist, comes from the South. The "Boston News Bureau" refers in rather unBostonian heat to "the Western oligarchy in the House" and regards the tariff bill as "very pettish prejudice", which possibly its proponents feel "is a piece of revenge—retribution by the West upon the East."

It is a peculiarity of the development of North America, that, proceeding as it did from the settlement of white men on the Atlantic Coast, the East should have become urban and industrially developed before the West. From the standpoint of natural resources, however, when settlement shall have been completed in North America, the West is much better provided with the basis for the textile, shoe, iron and other industries that have played so prominent a part in the East, and it is a commentary on the times that the cry of the West for protection against the supposed tyranny of the East should have now changed to pleas from the East against western dominance. We believe there is no conflict between the East and the West, but only just a little discrepancy in date of development, and that future generations will laugh at a mentality which presupposed some necessary hostility between them. In the meantime, the great business of North American politicians, on both sides of the line, is to preach the essential solidarity of East and West, because they not only meet, but their interests commingle and are inextricably blended.

PEOPLE in Johannesburg seem to be greatly worked up over the declining condition of the gold mines working the Main Reef series, and there seems to be a very widespread disbelief in the State geologists, whose conclusions the "S. A. Mining & Engineering Journal" refers to as the "futilities of academic geology". This South African journal gives space in a recent issue to the opinions of pioneers and prospectors who urge investigation of reefs that are situated above and below the Main Reef, stating "the sober facts are that the majority of the mines of the Central Rand are well-nigh exhausted". Reduction of costs and improvements of operating methods so as to bring the large tonnages of low-grade ore within the possibility of profitable mining are urged, as well as thorough proving of the various auriferous zones of the Witwatersrand "which have hitherto been disregarded simply be- " cause the predominance of the Main Reef series has " cast the various reefs of the auriferous tract into in- " significance."

It is unfortunate when the mining circles of a district that is wholly dependent upon mining lose faith in the opinions and researches of government geologists, and it is a fairly sure sign that there is something requiring to be remedied when this takes place. The geologist and the prospector must work together, and each is seriously handicapped if they do not. The geologist may possess great knowledge and much scientific intuition proceeding from that knowledge, but when he attempts to dogmatise on what may be found in the earth's crust without the aid of a drill-core, he is after all only an intelligent guesser. The diamond drill is the finest assistant that was ever given to geologist and prospector alike, and the three combined are usually required to give that knowledge which perfects opinion.

Instances have been known of scientific men persisting in an opinion long after that opinion had become untenable, which is one of the proofs that a scientist is human. Prospectors and amateur geologists often hold opinions that convince the scientist of the truth of the dogma of original sin, but it has often happened that the academic geologist would have benefitted and he impartially examined these unorthodox opinions.

It is a fortunate circumstance that in Canada we have come to look upon our Geological Survey officers as the safest of guides, and it is one of our national traditions that the geologists of the Survey should see the unprospected areas of Canada first and suggest to the prospector where he should look for mineral wealth. Unfortunately, the appropriations of the Survey have not allowed it to revise some of the maps of mining territory where industrial development has been large and rapid, but when any new mineral discovery is reported in Canada our friends at Ottawa can usually turn up a Survey reference of respectable antiquity.

PERSONALS.

Mr. Charles A. Richardson, manager of the Chambers-Ferland mine, Cobalt, is on his way to England. He will be in London for a few weeks.

Dr. G. A. Young of the Geological Survey is at Moose Factory on his way to the Belcher Islands. According to reports reaching Toronto, Dr. Young has been delayed by loss of his equipment when a sailing vessel on which he was a passenger struck a reef on its way from Albany to Moose Factory. Eighteen persons on the boat all reached shore safely; but instruments and supplies suffered and will have to be replaced before the expedition leaves for the Belcher Islands. Dr. Young and his party will make an examination of the iron deposits, which have been reported on by Toronto and American mining engineers very favorably.

Col. David Carnegie, who was a member of the Munitions Board in Canada during the war, has recommenced private practice as a consulting engineer in London. Col. Carnegie, in addition to his experience as an ordnance and metallurgical engineer, has always taken a deep interest in industrial arbitration having, it will be remembered, read a paper on the Whitley Scheme before the Canadian Mining Institute during the war and he is prepared to give advice and personal services in arbitration work.

What Canada's New Oil Fields Have Disclosed

Millions Being Expended To Prove Their Worth But Results Thus Far Are Not Arousing Enthusiasm, Although Much Remains To Be Done.

ALEXANDER GRAY, Montreal.

How much oil in commercial quantities is going to come out of the Canadian Northwest—anywhere and everywhere in that Great Last West—between the Cypress Hills and Milk River areas near the Montana boundary and the place where Dr. Cook said he was?

Quite a few would give a good deal to be able to intelligently respond to that poser. Millions have been spent by the enterprising scientific field forces of the Imperial Oil Company. Smaller sums have been forthcoming from other companies. More millions are being devoted by the Imperial Oil Company to determine the merits and demerits of possible or impossible oil horizons, from Coutts to Fort Norman, and from the Peace Coupé across into Saskatchewan.

It was these expenditures, the presence of a fine organization, the participation of numerous syndicates and scientists—the manifest purpose of the Imperial Company to develop a Canadian oil supply — as a matter of patriotic duty as well as to serve their own chain of refineries—that prompted a trip to the centers of exploration. To have an oil field, or series of fields, would be an achievement of such great moment —the solitary Fort Norman well having provided a measure of confidence—a suggestion that a visit to the Northwest might be informative, was availed of.

Interior Department bureau chiefs have maps, reports—and a bewildering series of Regulations—each in seriatim disorder being designedly helpful from the Government viewpoint, and effectually confusing from the public standpoint, if not disconcerting to those who wished to ascertain where oil is likely to be found—and to go after it. Admonitory bulletins embraced the statement of fact that there is so many square miles—hundreds of thousands of square miles—of probably oil-bearing country in the Mackenzie River basin and elsewhere. The archives held the reasons for that generalization. Nothing could be more roseate, in perspective. Land there is a'plenty. As abundant as Orders-in-Council simultaneously imposing rentals, restrictions, royalties—and revocations — singularly unmindful of the difficulties and 60 degree below temperatures and the brevity of working seasons. Having summarily concluded that the Northwest Territory and Prairie Provinces are a vast Oildorado—no doubt with laudable intent—the department of the Ottawa Government having jurisdiction inferentially conferred a halo upon so much country that a journey over the prairies from east to west, and then cross-sectioning them, causes one to ponder upon the frailty of human foresight—even though it be official.

It is not the fault of Canada's transportation systems that such a swing around the great circle in mid-Summer is not a rest cure. The roadbed and club-car accommodations of the berated Transcontinental—the luxuries of the Grand Trunk Pacific, made all the more enjoyable by observation of bumper crops in the making throughout Alberta and Saskatchewan—the excellence of the Canadian Pacific service—the buoyancy of the West in the prospect of a bountiful harvest—all should be tonical to the wayfarer in quest of oleaginous inspiration—but the crop of inspiration was short of requirements. Volubility about growths, speculation as what those crops will bring—15c eggs and 20c butter at Medicine Hat—were on the conversational menu. Oil developments are little thought of outside of a limited circle in Edmonton and Calgary. The man who came by the Macdonald hotel, at 7 A.M., with a handful of young wheat tenderly wrapped, who stopped me and remarked: "There's no use in talking. That is wheat soil" was unconcerned with oil. He said the plant had grown two inches over Sunday—it was Monday morning. If I mistake not, with perfect sincerity, he had seen a growth of four inches over a week-end.

So Ottawa need not have feared there would be a *furore*—that the Fort Norman event would precipitate another orgie. Likewise the precautionary Alberta legislators who prevented the passage of pipe-line legislation lest it foster an imaginary monopoly, could not extend their range of vision beyond the long grass. Instead of overtime on printing presses, to meet the demand for script, there is industrial lassitude—the few who can afford to exploit remote areas on the off-chance of producing oil, mostly reside in the eastern urban places which supposedly crave continuous control of western provincial mineral resources.

Apart from the crops, and the optimism which the Westerner breathes, moves and has his being in; beyond the activities of the Imperial Oil Company, some others, and Col. J. K. Cornwall, D.S.O., there is very little that is enervating to the opportunist and adventurous. Collections are slow. The break in commodity markets put a crimp in the agriculturist. Pat. Burns frankly admits he thought he was a race horse but finds he is a draft horse. Sleek cattle and well-bred horses are pasturing in a wealth of grass. There is a market for bonds. Coal mines are working three and four days a-week. If there was money for speculation in oil acreage, the Calgary "boom" cured many of the oil habit. Incontinental real-estating and the frantic rush for oil shares during the Calgary episode, obviated the necessity of Ottawa guarding against a plethora of lithographed paper—even if the isolated Fort Norman Well be all it was and is represented to be by those who have least to do with it.

Col. Cornwall At The Front

Leases are plentiful, however, Calgarians, though, are disposed to be "Missourians"—and are not throwing bouquets at whatever may redound to the glory of Edmonton. Optioneers at Calgary have a preference for Southern Alberta and more convenient sections in Eastern Alberta and Western Saskatchewan. Edmonton brokers, as a consequence, have combed American and Eastern Canadian cities for funds—Vancouver and Seattle not being overlooked—and the display of photographs of the Fort Norman "gusher", array of derricks at Burkburnett, samples of Devonian rocks, tar sands, etc., bear testimony to the local interest—slight as it is. What action there is in the oil movement, undoubtedly emanates from Imperial Oil Com-

pany offices, "Jim" Cornwall, W. Ross Alger, and the "pussy-footing" representatives of other large oil-operators and promoters whose purpose it is to tag on to areas acquired by those who have drilling outfits on their locations. And, by the way, what Col. Cornwall has not to do about keeping open the line of communication to the Mackenzie Basin, or anywhere else below or above the Peace River, has yet to be learned. Whether in command of a pioneer battalion in a dangerous sector, packing whatever has to be portaged *en route* to the sub-Arctic oil fields, boosting real estate or transporting all that is essential to far-northern operations, "Jim" Cornwall is ubiquitously efficient. Originally from Brantford, he became a handy man on the rivers and especially in the white waters of the region now being adventured. Manipulating the wheel, steering clear of lurking rocks and getting there, he made a reputation for intrepidity as a riverman and a mail carrier, a duty which involved mushing it when the thermometer was bumping on bottom.

With his dogs it was the same. He broke trails ahead of the dog teams, or followed them with the gait of an Indian. From cooking and making camp at temperatures that would break the nerve force of the bravest, "J.K.", graduated in fur trading and freighting, eventually becoming a political leader and a capitalist. As a matter of course, men of his temperament are impulsive and optimistic, consequently when he was not opulent he was the opposite. But "J. K." always has been an essential element in the boosting of the Northwest—and what he made in the Calgary excitement he put into other things—which frequently has left him more time than anything else on which to ruminate. Just now he is sharing the transportation business from the end of steel to the end of creation, as it were—and incidentally he has promoted several companies whose purpose it is to explore areas for oil. One of these companies is the Northwest, with which W. W. Butler, Senator Curry, railroad officials, and a number of other Montrealers are identified. Possibly Col. Cornwall is more of an enthusiast than an expert in oil country—and it is said some of his equipment is unsuited to immediate results at the sections where he is seeking oil. That, though, will not dampen his ardor. He plays the game like a true gamester, has his friends and does not care a whoop for the next fellow—all of which has made "Jim" Cornwall an Edmontonian when he is not north of where game laws are inapplicable. His Northwestern Oil company has pre-empted areas in the Mackenzie Basin and around Slave Lake—but that does not exclude him from his other enterprises, including the Great North Services Ltd., which contemplates the aerial transportation of passengers, dispatches, light freight and express packages to Fort Norman, Great Slave Lake, Ponce Compé and Peace River districts.

Col. Cornwall is an omnipresent individual and is doing his bit to further developments. Without the Imperial Oil Company, Col. Cornwall, the Hudson's Bay Company, the railways to the Peace and Fort McMurray, the generality of those who have the wherewithal to finance expeditions, would be on a fool's errand; for the restricted operating period is accentuated by the difficulties and hazards of transport. Besides rapids there is a sixteen-mile portage obstructing the all-water route. Rivalry exists as to which route has most advantages. If you go from Edmonton via the Dunvegan and British Columbia railroad for 312 miles to Peace River, you may appreciate not having to hike it, but the tortoise is a pace-maker compared with the speed at which the weekly or tri-weekly trains travel, on hurriedly-laid tracks, on which Pullmans and buffet cars afford relief. Down the Peace from the town of Peace River, it is a distance of 300 miles to Vermillion Chutes, which can be flanked by a four-mile trip by wagon. Further down the river is the town of Fitzgerald—a matter of 275 miles, from which point it is sixteen miles overland to Fort Smith on the Slave River. The uninitiated are admonished that there are dangerous rapids between Forth Smith and Fitzgerald, but from the former it is all down-stream, a fact which lends an element of fatigue to the return journey, whether by Hudson's Bay, Northern Trading, Alberta and Arctic Trading or Lawson & Hubbard steamboats. Another route via Fort McMurray and the Alberta Great Waterways Railway, means a distance of 290 miles by rail, thence 285 miles to Fitzgerald. Either way is the "highway to wealth" at the moment—and neither is open long enough for the tourist to linger. Navigation on the Peace, Athabasca and Slave Rivers begins in the middle of May and continues until the middle of October—but there is very little open water in the Great Lake before the first of July—and that limits communication to less than four months. Under the most favorable circumstances the trip to Fort Norman can be made in six weeks or two months.

How the Oil Movement Started.

Since 1870, if not before, the likelihood of finding oil on this portion of the practically uninhabited end of the globe has been discussed. At that time Sir George B. Dawson told the Senate at Ottawa there was oil up there. Dominion geologists emphasized the significance of the Athabasca tar-sands and seepages; a "gasser" or two added confirmation of a kind. Prior to the War attempts were made at drilling. The Calgary experience, however, took the edge off such explorations, notwithstanding Calgary had natural gas and a small production of oil was and is being obtained. Von Hammerstein got gas at Pelican Portage before the War. The Shell Transport and Trading Company sought a comprehensive concession that would give them the right of selection. It was fully realized Canada needed an oilfield, because importations of crude and the high adverse rate of exchange against Canada were becoming so formidable that President Stillman of the Imperial Oil Company announced to his shareholders they must leave nothing undone to provide a Canadian source of crude. Bringing in from 250,000,000 to 300,000,000 gallons of crude, and petroleum and petroleum products to the value of from $40,000,000 to $50,000,000 had its disillusionments.

Right there is where the whole thing started—culminating in the bringing in of the Fort Norman Well—something like 1900 miles from Edmonton by the round-about route. How much that well is going to yield when the gauge is on it, as yet is a matter of guesswork. The net result of two years of aggressive effort and an outlay of more than has been made public, was one reputed "gusher" in August 1920. And Dr. Bosworth is to praise or to blame for it. Whichever it is, shortly will be known. Dr T. O. Bosworth happens to be a pole-to-pole person. As a geologist he became interested in the Athabaska Sands—the "Tar" Sands—which have been the object and subject of concessions until the solitary certainty concerning

them is that not a thing can be done with them, even though the superficial area over which they have been noted might be tempting to capital—when a feasible process has been devised. Dr. Bosworth impressed upon the Imperial Oil Company the advisability of paying heed to the indications prevailing throughout the Northwest Territory, and in Alberta where a little oil and considerable gas had been found. Dr. Bosworth also favored drilling the "tar"-sand sections. Consequently, Vice President A. M. McQueen, accompanied by Dr. Bosworth, went up and down to the frigid haunts of the Yellow Knife Indians, and philosophically enabled the full-grown mosquitoes and bulldog flies to transfuse considerable of his rich, red blood. Contemporaneously Mr. McQueen ran short of gasoline a time or two—and the trader who helped him out of his difficulties chuckles to this day at what Mr. McQueen remarked about the price per gallon for what he needed for his own launch. Mr. McQueen told the trader there would be cheaper gasoline in that bailiwick, one of these days. He meant every word of it—and of what he did not express.

Mr. McQueen neither has kept his word to that Bolshevik, nor made good his implied threat to cheapen gasoline in that neck of the woods. If potato spirits would do duty either in aeroplanes, launches, or the flat-bottomed floating palaces which correspondents are describing, there is a portion of the Peace River country where they raise as much as 400 bushels to the acre. Unfortunately there is a limited local market for potatoes—for any purpose—and in this connection it may as well be admitted that the Alberta Government was somewhat ahead of the age in which the Peace River will be within range of markets. In 1907 assisted passage was given by the Alberta Government to a number of what looked like desirable settlers. Land was taken up by those agricultural scouts. This land and quite an acreage besides, has the finest sort of soil, a rapidly-growing season and all the attributes of prosperity—excepting an accessible audience of consumers. Rod Mackenzie is the most active spirit at the moment—unless it be "Jim" Cornwall and the others who are bossing the rivermen and pushing scows to their destinations.

Peace River is splendidly Arcadian—for a fraction of the year—when sixty-day grain is growing throughout a twenty-four growing day. There the analogy ends. The man last year who took 8,000 bushels of grain to market—at a cost of 28 cents a bushel—and got less than cost a bushel for it—learned more about economics than is discerned by the average adventurer whose perspective is blurred by adjectival descriptions of the "wonderful" Peace River section. Conceding to Peace River its wealth of soil and ability to raise crops on the double-quick—it is not an impertinence to assert that "it is all dolled up and no place to go." Settlers exist. Should the oil fields fulfil the glowing prospectuses, all the more credit to those who went there and stuck it—and many of them are Americans.

Where Geologists Went Wrong.

That discursive paragraph was interjected because Mr. McQueen and Dr. Bosworth, along with their Imperial Oil principals, have a good deal to answer for. Dr. Bosworth was *connaissant* as to oil. Mr. McQueen, acting for his people was willing to be shown. Up and down the serrated fringes of the Arctic, across fish-laden lakes, Mr. McQueen and Dr. Bosworth, in their launches, or mushing it, may have felt Cleopatra in her barge had a shade the best of it—but they were in quest of the barrel of oil at the rainbow's tip—and realities.

That was in 1917—Dr. Bosworth also was a landed estate proprietor, holding areas at Great Slave Lake and other auspicious points. So impressive was the rock doctor, he and his associates disposed of his holdings to the Imperial Oil people. Having paid this admission fee there was nothing to it but for the Imperial Company to take the title to other areas. Rival undomesticated great oil-corporations would have made a globular preserve of the northwest—and were prepared to expend half-a-million or so on explorations. When the Imperial executives, however, propelled themselves into the situation they could hardly have foreseen what it has cost their company to get what they have territorally, although the Fort Norman Well, let it be understood, is an altogether inadequate compensation.

Drilling around Fort McMurray and elsewhere was unprofitable, in 1917. Eugene Coste had a hold on the Government Reserve in the Viking Field in Eastern Alberta. Co-operation with his was attempted. The Coste Natural-Gas Company was proferred what gas was found—the Imperial Company was to have all the oil that might be tapped. Nine wells in all brought in gas—but somebody cast monkey wrenches into the machinery of this arrangement—and the gas-wells available for Edmonton remain capped. For this, various explanations are offered—the most probable being that the owners of privileges in the Reservation preferred to leave well-enough alone—they had gas—they might not get oil—and they might get salt water that would be decidedly detrimental to the gas wells. Then the section around Czar was spotted, after things had slowed up.

That was the introductory to a chapter that promised to be a romance. It has developed into a tragedy. For ever so many years the Department of the Interior has preserved sacred reports and cherished a "base map from engraved plates of the Department of the Interior. Geology compiled from published and unpublished maps of the Geological Survey." Nothing in the archives was more sacred than this map. It covered the territory between Chipewyan at or about 58 degrees north latitude, to the Montana boundary, and from the Rockies to Lake Winnipeg. Dawson, his contemporaries, and some of their successors, accepted as their geological gospel the mapping of the Edmonton Series, the Pierre—without identifying lower Pierre in places—the Belly River formation, the Benton shales, the Dakota and Kootenay sections, Devonian, Ordovician, Athabaska sandstone—and whatever could be defined. A great splotch of green from the Beaver Hills to Oban, thence south to Saskatchewan Landing, southwest to Medicine Hat, and then curving around past Lake Pawkoki to the international line, was plotted as Belly River formation. East and West of this Belly River area was placed the Pierre and Foxhill, and the La Biche and Foxhill. Cross-sectioning this area and running northeast through Hardisty, is the Battle River. Thereabouts is a series of "domes"—construed to be structural—generally extending from the Beaver Hills, on through the "Tit" Hills to the Misty Hills.

Authorities—not all of them—seemingly assented to the deduction that those hills were structural, therefore possible oil horizons. The Viking and Irma gas fields rather sustained this view, in recent years. Nothing, therefore, was more natural than that Im-

perial Oil geologists should lay in a supply of this "Battle River Anticline," as it came to be known.

Right on the anticline the Imperial company squatted —and Ralph Arnold of California—with a reputation for alertly picking land with a chance—hitched on the Imperial star, not proposing to be lonesome. If anything, Arnold had a shade the best of it for squatting capacity. He began at Birch Lake, kept spreading out until he got to Coste's reservation—and then stuck closer than the proverbial brother to the Imperial acquisitions around Czar and Monitor—all the way to the Misty Hills.

Anyhow the Imperial, Calgary Gas (Coste), Arnold, and a few wise ones, rode that anticline for all it was

worth. Mr. Arnold organized as many syndicates as he has fingers, almost. The members, or subscribers, knew him to be prudent and scientific in making selections. That "Battle River Anticline" had a larger liability against it right then than Dawson or his heirs in the Dominion Survey ever thought of. To all appearances, reckoning from the gas wells to the northwest, the hills contained treasured oils—over half a million acres was ripe for "spudding." Mr. Arnold was only one of many who thought as he wrote in behalf of one of his organizations, on September 20, 1920:

"The lands . . . . embrace something over 160,000 acres, and have been selected by me after a personal examination of every locality, with one exception. I might say that the holdings of the company include acreage on fifteen different structures, seven of which are now being tested by wells already in operation, and on two or three more of these structures wells will be put down shortly by responsible companies. The land is held in compact areas—the most desirable type of holdings for development purposes. I, therefore, consider the holdings ideal from a strategic standpoint."

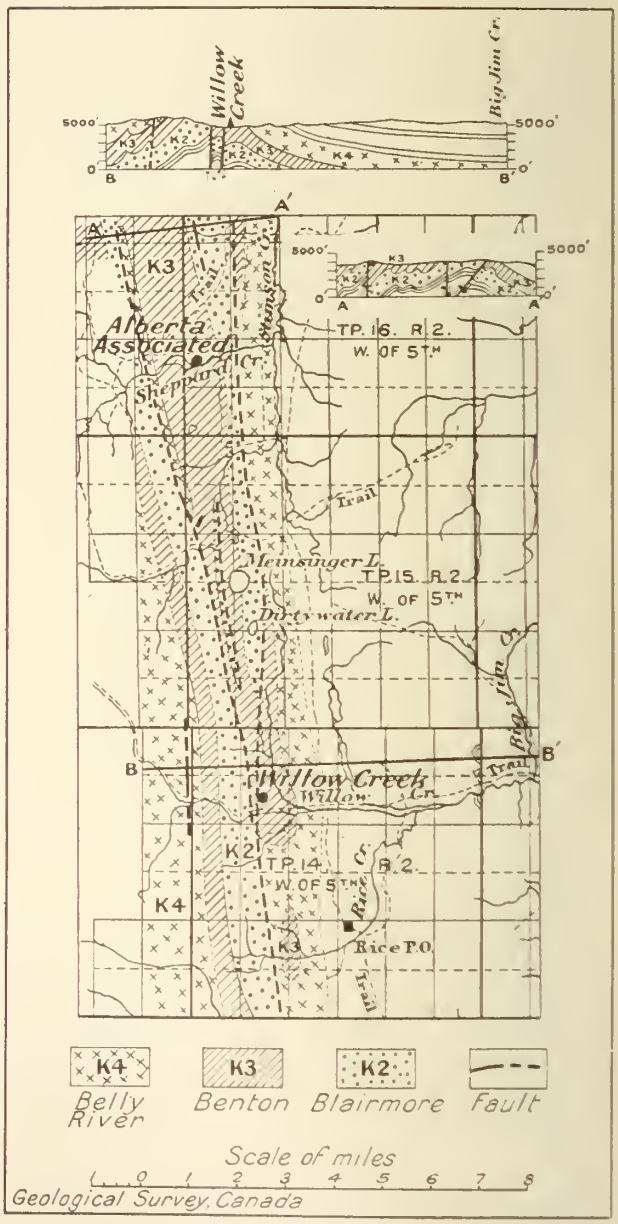

Diagram and sections of Sheppard and Willow Creeks, Alberta.

"I will not go into an extended discussion of the evidence which leads me to believe that the particular regions in which we are operating are destined to become commercially productive. I will state, however, that my examinations of the great tar sand regions of Athabasca, Clearwater and Christina Rivers are indisputable evidence of the presence of an adequate source of oil. The structure in general consists of a south-dipping and west-dipping mono-

3069

Misinterpreted as Structural Indications.

cline which swings around from the region of Lesser Slave Lake into the regions of Birch Lake, Muddy Lake and Sounding Lake, and thence southward to the international boundary. Along a certain belt on this monocline are a number of minor folds which offer ideal conditions for the accumulation of oil in the underlying strata. Wells have been drilled to the gas sands at several points in this belt, and all have encountered commercial quantities of gas and some have yielded traces of high-grade oil. At Viking, where nine gas wells have been drilled, there is a potential capped-in supply of about 50,000,000 cu. feet per day. The owners of this company have a franchise in Edmonton, and the gas will be piped to that city as soon as pipe can be secured for the purpose. Small quantities of high-grade oil were encountered in three of these wells. None of the wells in this belt has yet penetrated the zone corresponding to the tar-sands of the Athabasca region to the north. I look for commercial quantities of oil in the oil-sand zone under these favorable structures just mentioned. The lands held under lease by the Northwest Oil Exploration Company of Canada, Ltd. cover favorable locations on most of the known structures of this belt and, as previously mentioned, development operations which will soon prove much of this territory are already under way."

"Recent developments in Montana in the southward continuation of the prospective oil-belt just described have shown the presence of commercial quantities of high-grade oil. Some of the wells in this Montana district are reported as yielding over 1,000 barrels per day. The results obtained in Montana certainly strengthen the belief that commercial quantities of oil can be found in the region under discussion."

Czar Hole Discouraging.

With an honesty of intent which no one who knows him personally and professionally, will call into ques-

3070

CHOCOLATE BUTTE

(Misty Hills South)
Illustrating one of the deceptive structures.

tion. Mr. Arnold further committed himself when he wrote:—

"A hole testing all horizons to the base line of Cretaceous will be not over 2,000 feet in depth, and should not cost more than $30,000."

"One hole, if sunk to the lowest probable horizon will prove or disprove a very considerable area of the dome."

This is "truth, strong as Holy Writ." One hole—the Czar hole—has wrecked data and official intelligence maps upon which the army of capitalists and their geologists entered the field. Salt water and no oil was encountered in the Czar hole, of which the log was:

Surface to 1,050—Belly River formation underlain by Lower Pierre;
1,050 to 2,900—Benton Shales;
2,900 to 3,250—Lower - Cretaceous Sands (probably Dakota);
3,250 to 3,500—Limestone.

Thus was the epitaph inscribed upon "a very considerable area," to quote Mr. Arnold's projection. The

TWIN BUTTE WELL
No. 2 of the Imperial Oil Co.

Czar hole penetrated below sea-level. Czar is at elevation of 2,234 feet above sea-level. The other points in this vicinity at which drilling is proceeding, are Monitor and Irma, which are situated 2,219 feet and 2,000 feet respectively above sea-level. Ranfurley, to the northwest, is at elevation of 2,150 feet. There another of Mr. Arnold's organization is drilling. But the Czar hole, and what thus far has been noted in three holes near Monitor, relegates to the scrap-heap the hopes of those who shared the view of Mr. Arnold, to this effect.

"Tit Hills district is underlain by two and probably four probable oil-horizons, all of which are believed to be within reach of the drill."

As there are no horizons, and as the Czar hole demonstrated that the "domes," or "structures" are mere "erosion remnants," one of the most revered traditions entertained by non-technical departments at Ottawa has gone a'glimmering.

The Czar Well has given eastern Alberta a casualty list which conveys more than a moral—but the Government hardly will return the money received as acreage taxes. A slender hope remains that the hole now going down in Imperial Oil Company ground at Irma will strike it— but the hope is an almost forlorn one. Rather than abandon its entire acreage on this Ranfurley-Monitor line, the Imperial field parties will give this Irma area a final try out.

It was in this area what is known as the Grattan Well brought in a "gasser" at a depth of 1,900 feet. The intention is to put down a new hole below the gas vein, and to the base of the Cretaceous Sands. Upon the result rests the fate of the whole legendary "Battle River Anticline"—and a huge section of the Alberta prairies—too huge to be at all agreeable.

The experience gained at the expense of the Imperial-Arnold-Dumm forces will be profitable as an object lesson. Victims of deceptive contours—of what looked like foldings—are entitled to a measure of sympathy rather than censure from those who subscribed money upon the assurance that characteristic structures existed. How widespread will be the application of this development has yet to be determined. Certainly the prairie section is to be liberally discounted—and that is why the Imperial Company crews are concentrating to the south of Calgary, near to the Montana line: at Ponce Coupé away to the northwest, beyond Grande Prairie, and on the Mackenzie, at Fort Norman—a solitary test being made in the Rush Lake area in Saskatchewan, on the Canadian Pacific line. What little is being done at Great Slave and Muddy Lakes in Saskatchewan is more a matter of duty than of design, notwithstanding the broad policy of the Imperial Oil Company to give Canada its greatest chance to become self-sustaining in oil.

Imperial Company Universally Helpful.

Not unnaturally Imperial officials are non-committal concerning these Czar happenings and their effects. It took two years to prove the Czar to be the center of a "lemon" patch, hence a reticence that is perfectly plain. Money has been spent in a sporting spirit sustained by capable technical staffs and equipment beyond the ken of those who appreciate what is involved in the exploitation of real or imaginary oil-fields. An army of drill crews: all the paraphernalia inseparable from such operations: a yard-full of piping and casing, derricks, "strings of tools" so as to be prepared for any and all emergencies—a thousand-and-one things—not including the commissariat and clothing outfits— have displayed the avidity of the Imperial Oil Company. A warehouse at Calgary is on the wire. A large machine shop and foundry manned by trusted employes who are as keen as their chiefs, supplies drill-crews on the hop with whatever is needed.

Nor are these facilities restricted to Imperial operations. Above all things the company wants production —and nothing to that end is left undone. Whoever needs piping or drilling materials in a hurry can have it. Without the Imperial forces those engaged in drilling would be handicapped. When deliveries by rail are too slow, automobiles are employed. What the Imperial does not possess, the Hudson's Bay or one of the other trading companies sends along. The fellowship is admirable. Undoubtedly the burden has been borne by the Imperial Company, thus far, notwithstanding glowing expectations emanating from the Fort Norman Well. Just what other interests, have, excepting the Whitehall Company, conferred watching commissions

upon representatives in the Northwest, has not been divulged to any extent. Royal Dutch engineers or geologists have given the country the once over. The Whitehall Company are supposed to be acting for another British corporation. Major Preston is supposed to be doing things for the Pforzheimer people. Turner and Talpey have dealt with a combination that can provide capital—W. B. Thompson, Jules Baehe, Seeley Mudd, Jackling, and others.

Yet there is no *furore*. The Imperial Oil Company are the greatest "wildeatters" the Northwest has entertained. Far from being reprehensible "wildcatters," they are noteworthily eonstruetive. Despite official geologieal date, nearly every well attempted has been of the "wildcat" speeies—and inevitably so—until the various areas are tested. Without "wildeatting"—not necessarily by means of money indiseriminately raised—oilfields everywhere would be much slower in reaching the producing stage.

Where Drilling is Proceeding.

Preeedence has been given to the *dénouement* at the Eastern Alberta-Ranfurley-Monitor section beeause it was intersected by three trunk-line railways, and the presenee of gas hastened its testing. If there was oil there, it would be commercially useful. Imperial Oil Production Department did not confine its efforts to that acreage, however. It disproved the Fort McMurray country. In 1919 it had 22 geologists in the fields, and all their investigations required. The Fall of 1919 notified the spotting of the Czar Well—and drilling started there. The Big Muddy area in the Porcupine Hills of Saskatchewan was located. An expedition was sent to Fort Norman, and another to Windy Point on Great Slave Lake. It took all of the Summer of 1919 for the outfits to get there. A crew was left all winter at Fort Norman. The Windy Point hole got down 300 feet, without indications. Incidentally arrangements were made with the Coste interests, as outlined, and the Great West Natural Gas Company,, holding ground on the bank of the Saskatchewan, 23 miles northwest of Rush Lake where a blank was drawn.

Drilling began in the Monitor section. Imperial ubiquity was in evidence. Uniform disappointment was recorded. When I was on the fields, the Rush Lake hole was down 1,670 feet, and in blue shale; the Muddy Lake hole was down 1,157 feet, and in shale, and the Monitor or Misty Hill hole, 940 feet.

Far Northern Areas to Be Proved.

The one bright spot in the Imperial drilling campaign was the Fort Norman Well, whieh was brought in at the elose of the 1920 season. At 783 feet the structure selected by the geologists qualifiedly proved its worth. In this eonneetion, it is no disparagement of the Imperial Company or the staff, to assert that the estimated produetion of the well may not attain to expectations, or representations. At the moment, a erew is *en route* to clean out the well and test it. Should its flush production eonfirm the estimate made by those who were present when the well was brought in, there will be fewer heartburnings. On the other hand, if the flow is not such as to arouse enthusiasm—considering the remoteness of the field—a revision of plans must ensue. Anyhow, the Imperial Company gathered a momentum that cannot be stopped short. Three standard rigs have been alloeated for further testing of the Fort Norman field—and other companies will supplement these. This season and next, it is officially stated, the Imperial will spend $400,000 to determine beyoun question whether Fort Norman is a whale or a sprat, as it were. Simultaneously, Windy Point, at Great Slave Lake will be attended to, the hole there having been left uncompleted last year.

IMPERIAL OIL COMPANY'S CHRISTIE WELL, S. W. ALTA. Showing structure west of Nanton.

To illustrate what these far northern expedition entail, it may be stated that 40 men will be at Fort Norman, fully provisioned and otherwise equipped for a stay of sixteen months, every reasonable comfort and safeguard, libraries, gramophones, and a doctor being taken along. While this is being said and done, it is to be borne in mind that the one big or little well at Fort Norman is economically useless—until produetion is increased sufficiently to suggest transportation facilities. The hope is that this season's work, to be participated in by Montreal, Toronto, Vancouver, and other companies, will settle all disputes as to the potentialities of Fort Norman. No one sincerely desirous of success is decrying the locality—and yet Fort Norman is responsible for between two and three million acres being leased. Aerial intercourse has been established between Peace River and way stations northward.

Nothing in this summary of the situation is deliber-

ately prejudicial to any district, interest or factor engaged in furthering development. Events have been too disconcerting to be at all agreeable. That there will be more oil found—somewhere—confidently is expected. It will not be underneath the great stretch of Edmonton Series. Between the Kootenay section at Banff and the assumed uplift which really does not exist from Medicine Hat along the ill-fated "Belly River Anticline," the chance of reaching oil in the central section on a commercial basis is slender once you leave the Kootenay Shales. The one prospect appears to have been eliminated by the Czar hole.

Really, therefore, the expansive explorations of the Imperial Oil Company have been in the nature of a process of elimination. The horizontal academic idea that oil is likely to be as plentiful as the lignites and real coals of the prairies—that the oil horizons were widespread—has been discarded. It never obtained in well-informed quarters.

Even the Imperial Oil Company with all the data and book and map lore at their command has had to unlearn a great deal of what was stored away in their brain cavities—and that without weakening the purpose to continue its present policy until success—or failure— is assured. Which is admirable, if expensive. Should the Mackenzie River area prove up in quantity, there will be a consolation prize. As for Great Slave Lake and the Peace River, very little is being forecasted, lest more banks be registered. More testing will be done along the Peace River—not by the Imperial parties. They have other engagements—more propitious.

The Fort Norman Position.

According to Dominion and Alberta Provincial horoscopes there are "upwards of 300,000 square miles in Alberta, the lower Mackenzie basin, and Western Saskatchewan underlain by formations suitable for the accumulation of petroleum." This is accepted as a basis for optimism, even though "the problem of working out the structures in this area is extremely difficult on account of the scarcity of outcrops, the thick veneer of glacial debris, and the extensive muskegs." Naturally development of production can proceed only so fast. The belief has been that the possible fields are: Southwestern Alberta, Southeastern Albert, Okotoks, Central Eastern (Czar, Monitor Viking), Central Western (between North Saskatchewan and Athabaska rivers within the foothills), Peace River (lower), Peace River (upper), Great Slave Lake, and the Lower Mackenzie (Fort Norman). Leaving out the Czar, Viking, Monitor area, for reasons already stated, and setting aside the lower Peace River section which has been tested; pending further proof of the existence of oil; while awaiting something more tangible than is forthcoming from the western end of Great Slave lake—there remains more than sufficient territory to occupy the attention of capitalists and scientists for some years to come. Nothing like a final judgment as to the Great Slave Lake region will be put on record until the Imperial and Northwestern Oil Company test holes are completed —and more is known from other sources. Of the Lower Mackenzie, where folded Devonian rocks were noted, Dr. T. O. Bosworth, who spotted the Fort Norman hole as far back as 1914, says:—

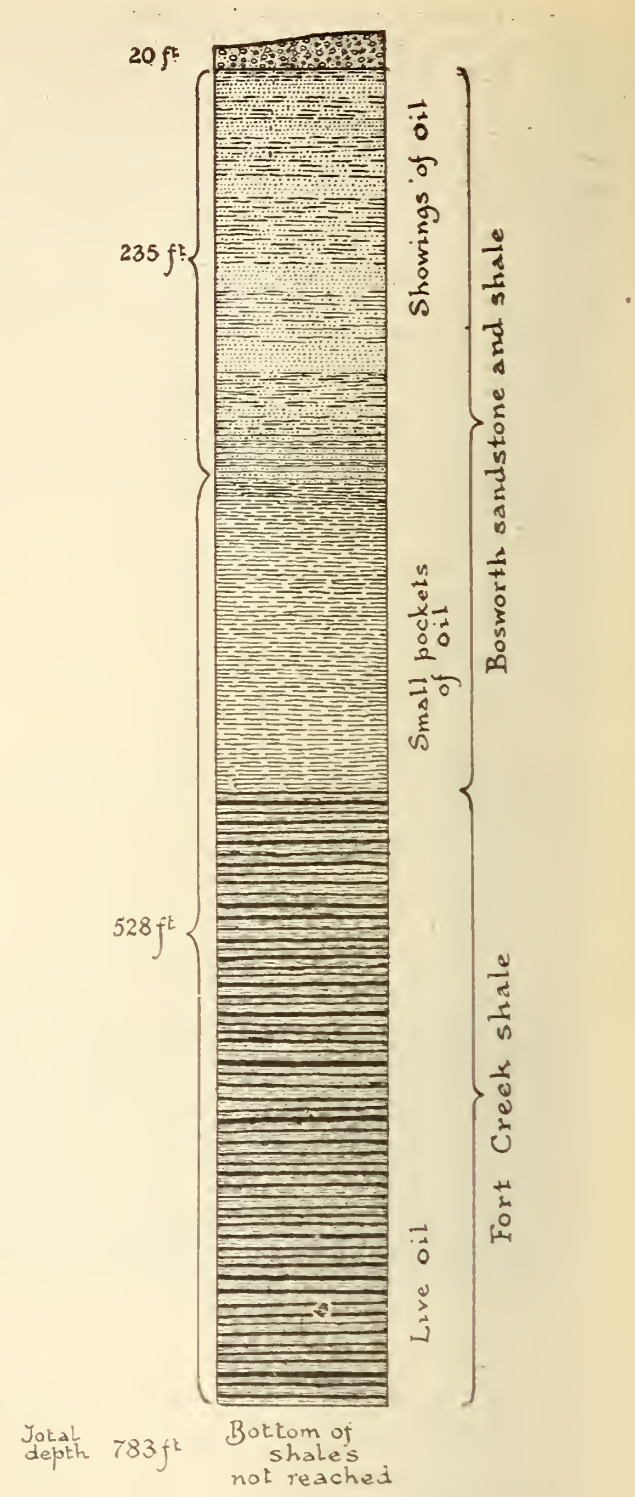
"At Fort Wrigley, Rock-by-the-River-Side, etc., the river is in contact with outlying parts of the Mackenzie Mountains, and here again folded Devonian rocks are visible.

"From Fort Wrigley to Fort Norman the river proceeds on a N. N. W course for some 130 miles, gradually drawing out of sight of the Franklin range.

"After passing Fort Norman the river comes in contact with another mountain system—referred to as the Limestone Mountains.

"These mountains, which consist of anticlinal folds of Devonian rocks, are encountered by the river for a distance of a hundred miles.

"It is in this territory that the favorable indications and structural condition were found which have led to the recent strike of oil. This is the site of the new oil field."



SECTION OF DISCOVERY WELL, FORT NORMAN
(Cut loaned by Geological Survey).

Dr. Bosworth places the "Discovery Oil Well' on the right bank of the Mackenzie river, some 45 miles beyond the little trading post known as Fort Norman, and within 90 miles of the Arctic Circle. Again quoting Dr. Bosworth:—

"The location of this first test well was chosen in 1914, as the site where a hole of moderate depth could not fail to penetrate the several petroliferous formations which had been found.

"The well is on the river bank about half-way down the Long Reach, near the mouth of Camp Creek, where there are copious seepages of oil.

"The well was drilled during the summer of 1921. Almost from the start oil was coming into the hole, and before a depth of 100 feet was reached a yield of five or ten barrels a day could be obtained."

At 783 feet "a strong flow of oil was encountered which spouted to a height of 70 ft. After about ten min. the well was capped. Some hundreds of barrels of oil issued from the well before it was finally shut in, but no dependable estimate of its capacity can yet be made. It is thought that the initial output will be at least 500 barrels a day."

This is the language employed by Dr. Bosworth. He estimates the flush production at 500 barrels. Other reports made it all the way from 1,200 to 1,500 barrels. That it was an important development, President Stillman of the Imperial Oil Company admitted—but mature deliberation does not concede the "initial output" at so large a total as Dr. Bosworth presents. No estimate has been "dependable." Analysis of the oil is satisfactory. The Imperial company has extensive locations for some miles along both banks of the river—and the map indicates they are not lonesome. Recently the Imperial Co. has taken over additional areas.

The Imperial company will drill on the north bank, further east—and will put down three more holes at points already selected on the north and south bank. Other holes are planned by Toronto and Vancouver companies so Fort Norman may have a series of wells at the end of this season. In a few weeks the "discovery" well is going to state the facts as determined by the gauge. That should clear the atmosphere. Most of the holdings are large enough if they are good enough. Dr. Bosworth has committed himself irrevocably in regard to the vicinity, as follows:

"The principal seepages occur on the shores of the Long Reach, where the river flows for 75 miles along the outcrop of the Camp Creek Series.

"Near the mouth of Camp Creek (which at first we called Oil Creek) the seepages are conspicuous for a distance of two and a-half miles. On digging in the river gravel the outcrops of the green oil-sands are exposed, and the oil could be collected in considerable amount. Further out in the river much oil rises up to the surface of the water, and in winter it collects, forming pools in the ice.

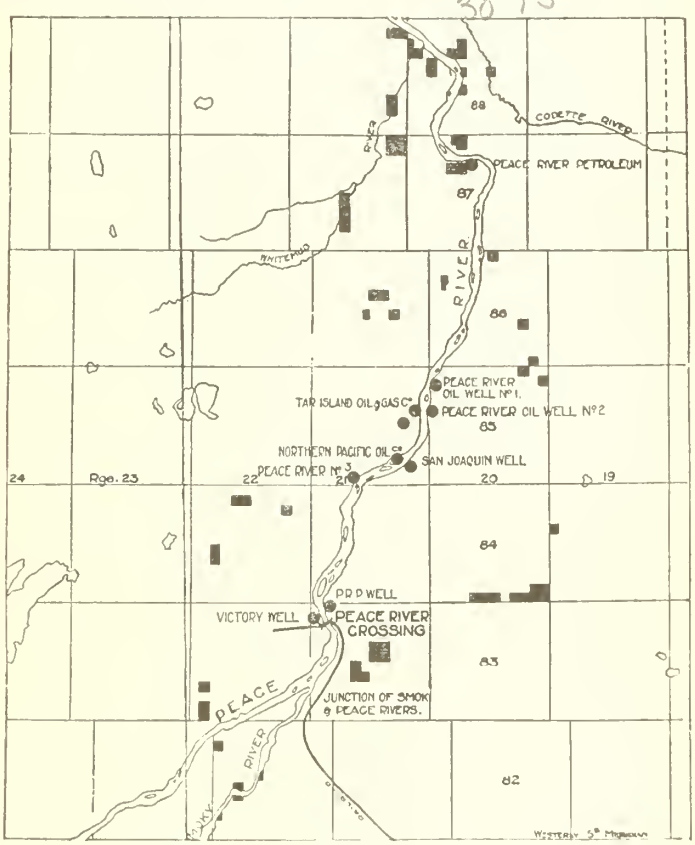
"Extending over many thousands of square miles, we have 1,000 ft. or more of richly bituminous beds And overlying these rocks there are 2,000 ft. of shale and sandstones, from which seepages of oil arise Further, this mass of petroliferous deposits is traversed by large anticlinal folds.

"The high parts of the anticlinal hills are not now favourable territory, for there the oil-bearing beds have been denuded away. But on the flanks of the folds and on certain low parts of the crests, and also on the minor structures, the petroliferous beds are more or less intact.

"Thus there are many places where satisfactory structural conditions occur and pools of oil are likely to be found."

Pouce Coupé Outlook.

It is a moot question whether the forms of the announcements concerning the Fort Norman Well were altogether judicious, without having established its flush production. As a consequence, between two and three million acres are held throughout Northwest Territory, Alberta, Saskatchewan—and in the Pouce Coupé country where 3,500,000 acres were ceded by British Columbia to the Dominion Government. While applying the "acid test" to the Fort Norman District, the Imperial company and others keenly alive to the situa-



Location of Drill-holes in the Lower Peace River area, which have yielded Gas in places, but no Oil as yet.

tion as disclosed there have taken up large areas in the Pouce Coupé section. There results are being eagerly sought; because the Edmonton & Dunvegan Railway is handy and can be utilized if production is obtained. In all approximately 800,000 acres are under lease in the Pouce Coupé—mostly it is alleged by the Imperial, Whitehall, Ptorzheimer, and other interests. Two weeks ago the Imperial crew started for there. The rig and camp is ready for this No. 1 Well. Cost of freighting was so high, the company built a road that will be useful to settlers desirous of reaching Grande Prairie 125 miles away. Freight has been $60 per ton. To Fort Norman it is 9½c a lb. There are seepages in the Pouce Coupé which promise well—and No. 1 Well equipment provides for going down as far as may be necessary, sufficient casing being on the ground. This hole is now being put down some distance from the heaviest seepage, but on the same anticline and at a depth of 100 feet there was a small showing of gas and the colour of oil. A local chronicler states that "anywhere in the vicinity holes dug varying from a foot to greater depths will seep full of oil in a short time. A few days ago Mr.

J. H. Sissons LL.B., acting for a Toronto concern took options on a considerable area. A local brokerage concern is busy securing options. If is in the latter township that the U. S. Canadian Oil Co. has announced early operations. A large Detroit firm of bankers has also, in the past week, secured holdings. Capt. Preston of the Ardua Syndicate, is returning from New York where he has been successful in interesting capital in the development of the holdings of the Ardua Co.

If the Pouce Coupé seepages are not disillusioning, explorations ought to be rewarded. Owing to its accessibility, the locality is favored. Further south there is another bright spot—a new location in the Coalspur Forest Reservation, about 125 miles west of Edmonton, where experts declare there is "the finest structure we have seen in the West, thus far." That was sufficient inducement for the Imperial Field forces to move upon the district, and drilling will proceed. Should indications become a remunerative certanty, it is obvious the last word cannot be spoken regarding our Western oil areas. Meanwhile the Pouce Coupé will bear watching. Grande Prairie is optimistic concerning that "bay in the Rockies," and hopes to have other Midwest New Yorkers share this view. Over the border in British Columbia, too, Mr. Dresser did some careful geologizing for the Provincial Government, which may start an official well or two.

Southern Alberta Prospects.

Officials who feared "the wildest kind of stampede" to the Northland were off in their calculations. Acquisition of millions of acres has proceeded without excitement. While the Pouce Coupé, Fort Norman and Great Slave Lake areas have been thoroughly leased — and the Government at Ottawa wisely concluded not to insist upon full rentals — there is an impression that Southern Alberta may derive more immediate benefit from developments in Montana. Taking outfits to the Mackenzie tries out manhood and treasuries. We have rather positive statements the Fort Norman site was chosen for its certainties—which leaves it for further drilling to provide production adequate to justify transportation facilities. Great Slave Lake calls for extensive exploration before it can be condemned. It is 133 years since Mackenzie noted the probabilities of oil and gas up there—and if it takes a few years more to create an oilfield, or a number of oilfields—at least the country can be patient and Ottawa lenient toward those who have the money to make the pace.

At this writing the Imperial Oil people are operating in what may generally be described as the foothill and boundary country, in Southern Alberta. Holes at Twin Butte, Willow Creek, closer in Saskatchewan to the bounday of Montana, and elsewhere, are at depths of from 1,000 to 2,500 feet. The Record Well at Okotoks is down over 4,000 feet. Several "fishing jobs" were being done when I was in the neighborhood, and the Imperial Company were pushing the reconstruction of their Absorption plant, under an arrangement with the Calgary Petroleum Products Company. Two holes at Twin Butte; two at Willow Creek, West of Nanton —and one at the Black Diamond property west of Okotoks, ought to give that section a fixed status, when wells are finished. The sixth hole in this southern area is within a mile of Montana, in Saskatchewan, and is down over 1,000 feet.

Whether in the Cypress or Sweet Grass Hills, around Lake Pakowki, at Etziko Coulee—close to Montana where wells are being brought in—speculative interests are on the qui vive. The Imperial Company propose to utilize what excellent oil there is—it is not much—coming from the Turner Valley, west of Okotoks, thirty-five miles southwest of Calgary. This oil was found in 1914, and signalized the Calgary "boom," during which some 500 companies were organized, but only a few ever got to the drilling stage. Were it not for the efforts of the Imperial and Whitehall companies, even some of the survivors of that Calgary episode would have nothing left of a profitable character but the experience gained. The purity of the light oil and willingness of the Imperial company to co-operate with any and all having something that might be put to profitable account, is what led to the deal with the Calgary Products, Black Diamond and one or two other companies, by which Alberta in any event will have a gasoline production small as it may be.

Lately, it is understood, Producers & Refiners people have entered the Milk River section. The Record Well on Sheep River had not been stopped at 4,400 feet, according to the last information. Further East, near Cardston, the Boston and Alberta Oil Company have areas. Lethbridge hopes the Montana horizons to be proven to extend over the border—and yet it remains to be seen whether there is another of those vagaries which kept great bodies of iron-ores in the ranges of Wisconsin, Michigan and Minnesota without givin Canada more than it has of them—in quality and quantity.

Transactions in lands along the International boundary, on the Canadian side, and recent visits of Americans, reflects the view that Montana may have pointed the way to accomplish something. Louis Hill has blocks of ground in the Blackfeet Reservation in Montana, not far from the boundary: consequently a drilling campaign is contemplated. If oil is located in this Canadian section it is apt to be deep-seated and not every promotion can carry the cost—unless production is greater than it has been from those wells which the Imperial took over.

The Conflicting Regulations.

Apart from the Fort Norman Well, those interested in oil developments think they know where oil is—and certainly know now where it ain't. The "Consin Jack" maxim is: "Where it is; there it is." More might have been achieved—or could have been accomplished during this drilling season, had the Government regulations been fixedly helpful. Heretofore, as Mr. Dowling of the Geological Survey has pointed out, explorations have been "sporadic." Important interests have earnestly undertaken the onerous work of proving fields—and have little to show for it—at present. They are not through, by any manner of means. In the very nature of things, they cannot stop—and write off all they are not sure of. Vice President McQueen has intimated that 1921 results should be completely determinative. It might have been more constructive had the Government refrained from confusing regulations, however, admirable was the purpose to conserve territory for National purposes and to prevent over-speculation. A large acreage throughout was secured under former, and more liberal regulations. Then when the Fort Norman Well came in, it was thought there would be oceans of oil. It was presumed vast areas were the containers of huge reservoirs of oil—and, in that event, Canada and the Empire must reserve a supply against all contingencies. So existing regulations were suspended, more regulations and still others were issued by Orders-in-Council. Sir James Lougheed—and his bureau chiefs oscillated between doubts and devised what they thought would suffice to hasten explorations while insuring to the Government their proportion—and more.

In some instances there was the possibility of virtual confiscation of leasehold titles. This was rectified where locations antedated the stringent regulations. Again revisions were necessitated by the rigours of the northern latitudes and impossibility of doing the impossible in a stated time. Experienced oil-operators wanted statutory provisions instead of having their holdings subjected to periodic impulses. It was too optional for the Government to impose elastic royalties or percentages. Lessees were compelled to raise capital, select four square miles—prove them—and then hand over three of them to the Government—unless they put up the price on themselves. Anything so unworkable, considering the difficulties and uncertainties, alienated those with working capital, and certainly put the quietus upon the catch-penny cult.

The story of developments to date, plain and unvarnished, is neither prejudicial nor personal. Obviously there has been over-estimation and needless hesitancy about trusting those alone who can hasten conclusions, Imperial and Whitehall companies, of all the large corporations, alone are heartily displaying their enterprise.

Even the Whitehall people are "watchfully waiting." There is little demur to the inhibition of alien ownership—and yet the fear that somebody might find something that some one else should have, has been positively deterring, all unmindful of the inexorable fact that very little oil has been secured notwithstanding great expenditure.

That the Ottawa Government now is more responsive, is an admission that the risks to be assumed were out of keeping with the remuneration capital has to have. Where companies have shown a disposition to develop areas, a nominal acreage—tax has been accepted—payment of the remainder being deferred. The effect of this is to leave more initial capital for proving. The uncertainty due to variations, however, recently was remedied by more Amendments-in-Council, by which each applicant may file application for 2,560 acres or four square miles, for which he will be given a permit for four years, during which time he must discover oil, or his lease lapses. He has two of those four years in which to get his rig on the ground. Besides, up to five of those groups of four square miles, or in other words 20 square miles, may be held as far as development is concerned, by grouping them and drilling one well. If this well is completed within four years, and if oil is obtained, a reasonable extension will be granted within which to drill wells on the other groups of four sections contained in the larger group.

Should oil be obtained on any group of four sections, the permittee shall be allowed to choose one square mile out of the four for which he shall obtain a lease for 21 years, permitting him to proceed to develop the property and produce oil therefrom, paying to the Government a royalty of 5 per cent to April 1926, and 10 per cent thereafter. The title to the other three square miles will remain in the Government, which may dispose of them as it sees fit, except that the lessee of the one square mile shall be given opportunity to meet all *bona fide* offers either on a royalty basis or a basis of purchase, as the Government may decide. His offer being equal to the highest offer submitted, each of these sections shall either be leased or sold to him as the case may be.

This is decidedly tolerant, if academic, owing to the possibility of collusion in bidding, or for mischief-making. The change indicates a greater degree of sanity. Nor is it the only new departure. The Regulations again by Order-in-Council dated 11th February 1921, contained stringent cancellation clauses in the event of default of the lessee. The latest Order-in-Council just passed has ameliorated these clauses to a very substantial extent, and generally speaking the lessee is now to have a notice giving sixty days within which he may remedy his default before cancellation.

It would almost seem as though the Government policy is being stabilized. Retroactive features have been obliterated. Mandatory provisions afford safety and security of title. The grouping privilege will be welcomed, for by it the operator can hold twenty square miles with one rig. Such an area in remote sections makes a rational business proposition. If oil is found, on his groups, he will have a quarter of his area at a not un-reasonable royalty. That he will have to meet competition should the Government exact a higher price or royalty on the other sections, so as to obtain from the field what they regard to be the fair share of profit to which the people of Canada are entitled, may not nor work out satisfactorily in practice. It may meet with the approval of the speculative promoter rather than the pioneer. At any rate, Ottawa —better late than never—has relieved the strain, notwithstanding it raised the rental to 50c per acre for the first year, and $1.00 an acre for each year thereafter. Provided drilling equipment is installed within the first year, no rental is to be charged for the second year. If drilling operations are commenced prior to the beginning of the third year, payment of rental will not be required for the third year.

Should these regulations be final—and if they are made statutory—the assistance they contain will allay much of the unrest attributable to vacillations and academic attempts which retard developments.

For Sands Mix-Up.

As a finale in this narrative—the sole design of which is to present the position as it is—confusion worse confounded exists with regard to the much-exploited tar sands. With these, officials are said to be doing a hesitation waltz—which was supposed to be taboo in the very best circles. More deproclamations in June—the notifications that those who have tar-sand areas cannot do this, that and the other thing with them—and that those wo have supposedly natural-oil areas cannot do this, that and the other thing with the tar-sands—has been perplexing. Holders of leases, who thought they had certain rights now are impressed with the vacuity of those rights. No doubt those tar sands—dealt with as a whole—may attract government enterprise—when government railways finances and lignite plants are perfected and economically satisfactory. But concessions were granted within tar-sand territory. Leases were given, abandoned and held—until, as the Washington Congressman who had been interrupted, incoherently remarked: "Where am I at", is a refrain.

Prior to 1911, several parcels of McMurray tar-sands were granted in fee simple to applicants. According to Ex-Governor Bulyea, there was 4,000 acres so held. Others contend that 12,000 acres were granted. On August 16, 1911, "Tar Sand" Regulations were issued, permitting the tar-sands to be worked and "carried away", at the pleasure of the lessee. The tenure under those regulations was for twenty-one years, with option of extension for twenty-one years—and no royalty was to be imposed until 1931.

Now, at all times, the ordinary Petroleum and Nat-

ural Gas Regulations of 1914—and those Petroleum and Gas Regulations which preceded 1914 — were applicable to the Fort McMurray areas. So applicants began to apply for the tar-sands under these Regulations, the assumption being that the Petroleum and Natural Gas Regulations conveyed the right to oil from the tar-sands. Moreover, the leases granted unto these areas read in part as follows:

"His Majesty doth grant and demise unto the lessee for sole and only purpose of mining and operating for petroleum and natural gas . . . .".

Within the lease as granted, reference was also made (clauses 4, 7, 8 and 9) to the manner in which "mining operations" should be carried on, and for the protection of "mine excavations, mine debris", etc.

In Mareh, 1920, all remaining areas in the McMurray District known to contain tar-sands, were withdrawn from disposal. On Mareh 21, 1921, an Order-in-Council was passed providing that all "oil shales" and all "oil from the oil-shales" should not belong to holders of petroleum and natural-gas leases—but only oil obtained "in a free state by boring".

More recently, in June, other tar-sands sections were withdrawn—those who retain leases cannot touch the sands—and there is "nobody home" in the whole matter. I quote the Ottawa letter which an Edmonton journal in opposition to the government prints as "Ottawa's Latest Oil Joke", and which it avers, "Stands In a Class By Itself, Effeetually Hinders Work:

"Ottawa, June 8th, 1921—I beg to refer you to Petroleum and Natural Gas lease number..... acquired by you, and comprising..... The regulations under which this lease was issued while conveying the right to the oil and gas only, contemplate the recovery of sueh oil and gas by the ordinary process of boring, and do not authorize the extraction of the oil from the tar sands, which may be upon the location, by any other process of recovery. I am directed to inform you, therefore, that while the lease gives to the lessee the right to recover the oil and gas from the location by the method provided in the regulations, namely by drilling or boring. This lease does not anthorize the extraction of oil from tar-sands which may be npon the location by any other process."

This makes uncomfortable those who have tar-sands and no "free oil." It is a ease of

"Mother, may I go in to swim?"

"Yes, my charming daughter.

"Hang your clothes on a hickory limb—

"But don't go near the water!"

Nothing written about the whole sitnation is designedly prejudicial. At Fort Norman and thereabouts; in the Ponce Coupé country; in the Coalspur Reservation around Okotoks and throughout the Southern Alberta areas, the intention is to find oil. It is fully realized that more than the ordinary oil risk is presented. That risk, however great, has been assumed—in largest part by Canada's leading oil corporation—and whatever be the disappointments to date, they are not irredeemable—if the fullest co-operation is maintained. Samples of oil will not suffice. Seepages are inconclusive—if suggestive. Owing to disconcerting regulations this season's results may not be comprehensively encouraging—but we have the statement of vice-president MeQueen of the Imperial Oil Company, that this year will go a long way toward settling many of the points at issue.

Northern Ontario Letter

THE SILVER MINES.

Dividends paid by the mines of the Cobalt district during the first half of 1921 amounted to $1,030,000. The Nipissing was the leader among the silver-mining companies, this concern disbursing $780,000 in the half year. The Kerr Lake came second with $150,000 while the Coniagas paid $100,000.

The silver mines of Cobalt have now paid a grand total of $83,531,066 from the date of discovery in 1903 to June 30, 1921. In addition to this, closed corporations have paid upwards of $4,000,000.

The Nipissing mine has been the largest dividend payer, this company disbursing $23,863,297. The Coniagas holds second place, with a distribution to date of $10,940,000. The Kerr Lake is third with $8,935,000, with La Rose having paid $6,300,546 and the Crown reserve occupying fifth place with $6,190,849. The McKinley-Darragh holds sixth place with $5,955,391, while the Mining Corporation is next in line with $5,530,768.

In paying over a million dollars in dividends during the first half of 1921, the silver mines of Cobalt stood in a class by themselves among silver mines. It is well known that the decline in the price of silver absorbed the greater part of profit which might have otherwise accrued to the silver miners, and, in the case of the majority of the world's silver mines, it has been largely a question of making ends meet.

Conditions, as stated last week in the "Journal," have undergone a marked improvement recently, and the cost of material as well as all economie factors assume aspects which give rise to the belief that industry in Cobalt will soon steady down to almost normal. Wages are still high, but with the cost of living offieially declared to be 40 p.c. below June, 1920, there is promise of further adjustment in the wage schedules. The supply of labor is abundant.

Chas. A. Richardson, manager of the Chambers-Ferland mine, owned by the Aladdin-Cobalt which is now a part of the Kirkland Lake Proprietary (1919) Limited, sailed from Quebec during the past week on his way to London where he will be engaged for about six weeks on company business.

A continuation of the present trend of commodity prices, all of which indicates greatly reduced operating costs at the mines, would soon enable a number of silver mines in the Cobalt field to re-open. Among these are the Beaver Consolidated, Temiskaming and McKinley-Darragh. This is also true of the Kerr Lake where some work is being done, but where production is only being maintained at a minimum rate at present. These four mines could now produce silver at an average cost of perhaps a little under 70 cents an ounce. As against this, the price of silver continues to hover around 60 cents an ounce plus the exchange on New York funds, making a total return of around 66 or 67 cents an ounce to Canadian silver producers. It may be gathered from these facts that either a strengthening in the quotations for silver, or a continued decline in the cost of producing the metal is bound to result in these four mines resuming work in due course. Such a development would stabilize industry in Cobalt, the following mines being even now under operation at normal capacity: Nipissing, Mining Corporation, Coniagas, O'Brien, Chambers-Ferland, Bailey Silver Mines, while the La Rose and the Kerr Lake are producing from certain parts of their properties.

Elk Lake and Gowganda.

The Ontario Government is extending reasonable help to the Gowganda district by continuing the work of improving the road from the railhead at Elk Lake. Those interested in the district are anxious to have this road work continued for the reason that the proposed ligh railway is not a certainty. It is noted that a motor road from Swastika to Kirkland Lake is giving good satisfaction and that although the Gowganda road is about five times as long as that running to Kirkland Lake, yet it should meet the requirements of the field in a reasonably satisfactory manner.

As regards the proposed light railway itself, the promoters of the enterprise are understood to have engaged bond salesmen, and are now endeavouring to sell the bonds privately. It will be recalled that the announcement was reeently made in the "Journal" that the Ontario Government had decided to not lend financial help to the scheme by purchasing a part of the bonds. The scheme of the promoters was to sell the Ontario Government $350,000 worth of bonds, this being at the rate of $3,500 a mile. In addition to this, the promoters secured authority to sell $1,500,000 in bonds privately, this being $15,000 per mile. This would mean a total of $18,000 per mile (less commissions) with which to build the proposed light, narrow-gauge railway. However, the government having refused to take up the $350,000 purchase as requested, leaves the promoters in a position where they were endeavouring to sell the $1,500,000 issue and to make this cover the entire cost. As to the prospects of success, there is a tendency at this time in the mining districts to hazard even a guess.

Exploration work is being done on the Hartley-Wescott iron property, lying some 14 miles north-west from Elk Lake. The owners are reticent as to the result of the work, this attitude having been adopted following unfavorable comment by a section of the press which became confused as to the location of the property, and had no information in regard to the real discovery.

An exceedingly high-grade discovery of asbestos has been made in the Mt. Sinclair district, lying about half way between Elk Lake and Porcupine. The ore is the richest of the kind so far discovered in this field. Together with other asbestos deposits in this district, it is believed to be important.

THE GOLD MINES.

The Porcupine District.

Dividends paid by gold mining companies operating in the Porcupine district amounted to $2,175,361 during the first half of 1921, thereby being more than double the profits distributed by the silver mining companies. The total dividends paid since discovery in 1909 up to June 30, 1921, amounts to $20,282,017 from the Porcupine mines.

During the first half of 1921, the Kirkland Lake field accounted for $40,000 in dividends, this bringing the total up to $718,625 from this field to date. It is noted, however, that a number of other mines were realizing profits and, in the case of Wright-Hargreaves in particular, the dividends from the Kirkland Lake area will shortly be increased.

Another important discovery has been made at the 1,350-ft. level of the McIntyre-Porcupine mine where another ore-body has been opened up. This is believed to be the continuation of one of the important ore-bodies which runs in a north-easterly direction from the Acme side of the adjoining Hollinger Consolidated. In regard to the proposed increase in milling facilities at the McIntyre, the ball mill is already on the ground, but nothing has been done toward installing it.

The Porcupine V. N. T. is still awaiting the outcome of the effect to raise money with which to resume operations. It is understood that certain New York interests are anxious to proceed with this financing and it is thought suitable arrangements may be made. The details have not been announced officially, but a general outline may be available within the next week or so.

The Northerown Mines are lying in total idleness, and very little information is available as to the prospects of adjusting the affairs in such a manner as to assure continuous operation. This is understood to be due to the Thompson-Krist faction being unable to meet its financial responsibilities.

A working station is being cut at the 300-ft. level of the Beaumont Gold Mines, formerly known as the North Davidson. A considerable amount of lateral work is planned for this horizon. Values are said to be encouraging.

Work on the Paymaster property in the township of Deloro is being attended with encouraging results. Work is being carried on largely at the 200-ft. level.

It is unoffieially stated that the ten tons of ore shipped from the Triplex property contained upward of $300 a ton in gold. Work has not advanced far enough to determine whether this ore occurs in a pocket, or not. The Triplex lies in the township of Shaw, and was formerly known as the Tommy Burns.

The Porcupine Peninsula Mines is the name of a new company which has been incorporated for the purpose of taking over property on the shore of Night Hawk Lake. A shaft is down 85 feet, at which point some lateral work was formerly done. It is planned to carry this shaft to a depth of 400 feet provided the required finances can be obtained.

An extremely spectacular discovery of gold has been made on a property lying about 2½ miles east of Bourke's Siding. The find is on a patented property of 160 acres owned by A. O. Anderson. Pieces of gold as big around as a twentyfive cent piece occur in the vein in leaves. The mineralized body is about eight feet in width, with a number of stringers occurring at intervals, these stringers being from two to three inches in width. The gold occurs in one of these stringers in a somewhat similar manner as the silver occurs in the high-grade ore at Cobalt. The discovery is being examined this week by an engineer representing a leading Cobalt company.

The Kirkland Lake Field.

Activity in the Kirkland Lake District is steadily increasing. The latest property upon which arrangements have been completed to carry on extensive mining operations is the Sylvanite. This property lies directly between the Tough-Oakes and the Wright-Hargreaves and is regarded as a mine of importance. The ore bodies which occur on the east and the west of the Sylvanite will probably extend across the property as the main break along which the ore occurs in this district cuts right through the Sylvanite. It had formerly been believed that the Sylvanite would be included in the merger with the Tough-Oakes and would thus be controlled by the Kirkland Lake Proprietary, 1919, Limited. This has not been the case. It is now learned that parties in England who are heavily interested have joined hands with interests in Buffalo and the required money to carry on operations has been

assured. The work will be directed by Albert Wende, manager of the Wright-Hargreaves mine.

A new vein has been opened up at outcrop on the property of the King-Kirkland Gold Mines. The vein is about seven feet in width, and is well defined. A feature is the fact that it runs under a small lake on the property at such an angle as to lead to the belief that it may prove to be the main break from which all the other veins on the King-Kirkland radiate. Further work is being done in opening up the new discovery.

The drift at the 300-ft. level of the Bidgood has been in ore for more than 100 feet, and this property offers promise of developing into a real mine. Work will be centered largely at the 300-ft. level for some months, after which the shaft will probably be continued to a depth of 500 feet. The plant now operating on the property is adequate to carry operations to that depth.

Favorable information is coming from all parts of the Kirkland Lake district, and further substantial growth appears to be assured.

C. A. Foster, at one time identified with the Foster-Cobalt mine, the West Dome and the Tough-Oakes, is understood to have become interested in an option for the Berry group of claims which lie to the east of the Ontario-Kirkland and south of the Burnside Mines.

Arrangements are being made to let an extensive diamond-drilling contract on the Miller Independence Mines at Boston Greek. It is planned to get this work under way early in August. The plan is to carry on drilling from the 500-ft. level, as well as a limited amount from surface.

TORONTO COAL PRICES.

Toronto, 27th July.

The price of slack coal has advanced, and is now anywhere from $1.65 to $2.00 a ton. It is strong and firm at that price and seems likely to advance further still. The demand for coal is unbalanced, that is to say, there is not enough demand for lump coal to ensure the production of sufficient slack to cope with the demand for the latter. Despite the rising market, however, there is no great increase, at present, in the demand for slack, because the public have not yet realized that it is advancing. But when they do, they will come into the market. Opinion seems to be that there will be no more cheap slack this year.

The anthracite situation is getting worse from the retailers' point of view. The number of retailers who are refusing shipments, because they cannot sell the stocks they have on hand, is increasing every day. There seems to be a slight weakening in the prices charged by the "independent" companies.

METAL QUOTATIONS.

Following are the fair average prices for ingot metals (in less than car-loads).

LEBEL TOWNSHIP GOLD.

According to the "Northern Miner" ten properties in Lebel township are being worked. At the Bidgood mine drifting in one at the 300 ft. level is proceeding. At the King-Kirkland a drift is being run at 100 ft. level and the company has been successful in making new discoveries by surface work. At the Wood-Kirkland a shaft has been sunk 100 ft and the vein cut at the 50 ft. and 100 ft. levels. On the Queen-Lebel claims camps are being erected. At the Lebel-Ore good values were found. At the Moffat-Hall an important discovery was made a few weeks ago and exploration is being carried on.

SHININGTREE.

Mining engineers recently returned to Toronto from Shiningtree report that the work of finishing the last section of the waggon road is proceeding at a good pace. At the White Rock mine shaft sinking is under way. Reports that new machinery is being hauled in to the Wasapika mine are denied by the president of the company.

British Columbia Letter

Anchorage, Alaska.

There has been a stampede to a reported strike of rich gold quartz in a district 39 miles south of Anchorage.

Stewart, B.C.

The management of the Premier Mine, Salmon River, Portland Canal District, is reported to have its cyanide mill in operation. Gold-silver bullion probably will be shipped to the Selby Smelter at San Francisco, Cal. for refining. Low-grade ore will be shipped over the new aerial tramway, which this is completed, to the Anyox smelter of the Granby Consolidated Mining & Smelting Co.

On the Silver Leaf Claim, of the Patricia Group, Marmot River, a tunnel, now in 20 feet, has opened up a showing of four feet of ore, assays of which are reported to run $22 in all value, $12 of which is in gold.

Camps are being established on the M. C. Group, situated on the east side of Bear River, preparatory to the prosecution of development work. The property carries promising gold and silver values.

Anyox, B.C.

An important ore body is reported to have been uncovered by Wm. Hanna on his mineral claims near the Hidden Creek Mine of the Granby Consolidated Mining & Smelting Co.

Gratifying results are said to have been achieved by the Granby Company in reducing the smelter charges in connection with the treatment of the Hidden Creek Mines ores.

Alice Arm, B.C.

The announcement that the provincial government intended discontinuing work on the Illiance River trail caused much disappointment which since has been removed by the statement that the project is to be carried through. The road to the Kitsault Glacier, near which the Homestake Mine is situated, is to be constructed to that point by the Homestake Company in order to permit the shipment of machinery to the property.

With the resumption of operations, though on a somewhat reduced scale, at the Dolly Varden Mine the spirit of pessimism, rather in evidence lately in the Alice Arm Camp, has given place to a feeling of renewed confidence. The railroad is being re-opened and trains will make regular runs over the eighteen miles of track between tidewater and the mine. The Northern (B.C.) Press contains the following, no doubt authorized statement, in this connection:

"This season's operations at the Dolly Varden will be along different lines to past years. More attention will be paid to development work and not so much to shipping. In the past the efforts of the Company have been more towards heavy shipping at the expense of proper development. This policy will be changed in the future, but shipping will not cease although it will not be on such a large scale as previously. Just enough ore will be shipped to the smelters to cover the payroll for the development. Major C. B. North, who has been on the ground for some time, will remain in charge."

Nelson, B. C.

The Nelson Branch of the B. C. Prospectors' Association has asked the Dominion Government to arrange for the advance to shippers to the Trail Smelter of a certain proportion of the value of ore so shipped. With money available as soon as shipments are certified to it would be possible, it is argued, to continue without interruption the development of properties which, at present, can only be worked intermittently.

E. W. Widdowson, a provincial assayer and mining man, reports that thirteen sacks of high-grade ore from the new discovery at Elbow Lake in the Pas country, northern Manitoba are expected for treatment. A sample pound, he says, was received a short time ago with a gold content of $20,000 to the ton. Many of the samples received contain hundreds of dollars to the ton and not a few have little or no value, as is the case with samples from a new field. There has been more activity in the Kootenays, Mr. Widdowson reports. A carload each has been shipped to the Trail smelter by the Bell and Beaverdell Mines, which ore is expected to run about 200 ounces of silver to the ton. Operations on the Queen Mine have been resumed after a suspension of six years and the Le Roi No. 2, Rossland, again is working.

Judgment has been handed down in Insinger vs Cunningham, in which the plaintiff is a banker of Spokane Wn. and the defendant a mining operator of Slocan District, B.C. The dispute arose over the alleged non-fulfilment by Cunningham of certain contractural obligations entered into by him when he took over, under option, the Hewitt Mine at Silverton, B.C. Robert Insinger is successful in recovering a sum equal to the value of the development work which Mr. Cunningham apparently agreed to do, but did not complete, while he was working on the property in 1918 and 1919. On all other counts, however, the defendant succeeds. He is not required to make an option payment that Mr. Insinger claimed was due nor is Mr. Insinger allowed damages on account of being prevented from operating the property. On the latter point the judgment says: "As plaintiff (Mr. Insinger) took no steps to enforce his claims for possession, and as, I think, he must be taken to have known that defendant was continuing to operate the mine, and as plaintiff continued to accept payment of royalties or ore mined, I do not think he has any right of action against defendant for retaining possession. Plaintiff is entitled to an accounting of ore mined, as was conceded at the trial."

Trail, B. C.

Receipts at the Trail Smelter, Canadian Consolidated Mining & Smelting Co., for the week ending July 7 were 6,969 tons of ore and concentrates. Of this 6,912 tons came from the company's mines and the contribution of 57 tons by the Surprise Mine, of the Republic Camp, completed the total. The independent shippers to Trail thus far this year follow: Nelson-Arrow Lakes, Gold Hill and Millie Mack; Boundary-Similkameen, Bell, Horn Silver, Providence, Sally, and Sutherland and Thompson; Slocan-Ainsworth-Lardeau, Black Prince, Blue Bell, Florence, Gem, Krao, Nettie L., Last Chance, L.T., Nip and Tuck, No. 1, Ainsworth, and Ruth; East Kootenay, North Star and Paradise; Washington State, Chatterboy, Knob Hill, San Poil, and Surprise. The Blue Bell, of Riondel, with 1,111 tons is the biggest of these shippers. The Knob Hill and Surprise have shipped 395 and 236 tons respectively and the Horn Silver, of Chopaka, Similkameen, has contributed 260 tons. The others have lesser amounts to their credit.

Revelstoke, B. C.

That asbestos exists in the serpentine rocks near Arrowhead has been known for a number of years, reports A. G. Langley, resident government engineer. Nothing was done to exploit it until recently when

some surface stripping and opencut work was done. He observes, however, that development has not advanced sufficiently to determine its economic possibilities.

Cranbrook, B.C.

The Columbia Section of the American Institute of Mining and Metallurgy has been invited to visit the East Kootenay District of British Columbia and to visit some of the mining properties and prospects of the country. A similar invitation has been extended members of the western branch of the Canadian Institute of Mining & Metallurgy. The arrangements for the proposed gathering and field excursions are in the hands of the East Kootenay Branch of the Prospectors' Assn., headquarters, Cranbrook. The rendezvous will be Cranbrook and the time, the week beginning August 21st next. While the programme has not been definitely prepared it certainly will include a visit to the Sullivan Mine, Canadian Consolidated Mining & Smelting Co., the largest operating property of western Canada.

Vancouver B.C.

The threatened dissolution of the British Columbia Chamber of Mines, Vancouver B.C. has been avoided. A substantial grant has been promised by the government and the members have responded to an appeal to advance the additional funds necessary to permit the continuance of the work of the organization.

Glenville A. Collins, who is supervising the development of the Drum Lummon Mine, Hartley Bay, leaves shortly for the property.

A fairly good general grasp of mining conditions throughout British Columbia during 1920 may be obtained by a glance through the reports of the mining engineers in charge of the six mineral survey districts into which the province has been divided.

George Clothier, of No. 1, North-Western District, points out that his terriory may be divided into three belts or zones—"The Coast Range granites, the Western Contact Belt, and the Eastern Contact Belt—the last mentioned has had the greatest amount of prospecting and development this year (1920), though the increase in the number of prospectors throughout the district has been very evident. With the exception of in and around the two centres of activity, Stewart and Alice Arm, there is room for hundreds of prospectors. When the comparatively small areas at the head of Portland Canal and of Observatory Inlet are compared with the remaining absolutely unexplored portion of the Belt, from the head of Salmon river north to Atlin, a distance of 250 miles, some idea of the enormity of the mineralized country and its wonderful probabilities can be gained. The discovery and development of a few more properties such as the Granby mine at Anyox, the Dolly Varden at Alice Arm, the Premier at Stewart, and the Engineer in Atlin would make it the greatest mineral producing Belt in the Province. While there is a great deal of it that is inaccessible, very appreciable portions can be opened up from the Unuk River, the Stikine and Iskut rivers and the Taku river, which empties into Taku arm just below Juneau." He adds that the Coast granites and the Western Contact Belt should not be overlooked, that they are particularly favorable for the occurrence of economic minerals.

The mining industry made satisfactory progress in the northeastern during the first half of the year, according to John D. Galloway, mining engineer, but later "a gradual decline set in." The change he attributes to financial depression and lowered market prices. Production, however, was slightly greater than in the previous year. The Silver Standard, the principal shipper, doubled its output. Practically no copper was mined in the district but "when an improvement in the copper market takes place some of the copper properties on Rocher Deboule mountain and in other parts should again make a production." The placer-gold production, coming chiefly from the Cariboo and Quesnel Divisions, was about the same. Mr. Galloway is of the opinion that the Placer Act amendments will be beneficial and "the impending era of lower prices, which automatically effects a higher relative price for gold, will undoubtedly stimulate the search for yellow metal."

A. G. Langley, engineer in the eastern district of the Province, reports that the industry suffered through lack of labor and that the difficulty was accentuated by strikes called by the O.B.U. He goes on: "The outstanding feature governing this year's production of Lead and Zinc has been the continuous operation of the great Sullivan Mine by the Consolidated Mining & Smelting Co. Under adverse conditions this mine has greatly exceeded last year's output and has been able to supply the smelter with a steady stream of ore thus offsetting the decrease in tonnage from other sources." The season, he says, was an exceedingly busy one in the hills for the small operator, leaser and prospector. To my knowledge many results obtained among the prospects have been very encouraging and it is fully anticipated that next season will see a number of new names on the shipping list, providing market conditions are favorable."

The situation in regard to the Canada Copper Corporation is touched upon by Philip E. Freeland, of the southern mineral survey district. "It seemed probable" he says "that the output from the Canada Copper Corporation's mines on Copper mountain, near Princeton, would offset the loss of the Phoenix tonnage (the Granby Mines at Phoenix were closed down and the plant there dismantled) but, owing to unforeseen difficulties, operations did not commence until late in the Autumn and about the same time the price of copper dropped to 13.5 cents a pound, making impossible profitable mining for the company in its early stages. The mine was closed down pending a rise in copper prices or a decreased cost in supplies and wages. Satisfactory results were obtained in the mine, the ore breaking easily and in comparatively small pieces. It was found that the 42—by 36-inch Farrel-Bacon jaw-crusher in the primary crushing plant had very little work to do, whilst the No. 6 McCully gyratory crushers were overworked. In the mill the rolls did not crush the small siliceous pieces of rock satisfactorily and it seems probable that some type of crusher giving a hard blow will have to be used."

Dealing with the Western District Wm. M. Brewer, mining engineer, tells of the grub-staking by the government of twenty-five parties, of two returned men in each, and describes the manner in which he supervised the work of those who were assigned to his territory. His comment is that "the results, so far as locating mineral claims are concerned may be considered as being only fairly satisfactory, although the results, from the standpoint of valuable information brought back relative to the fields in which prospecting was done, are considered as being quite sufficient to justify the policy pursued by the Government." He

asserts that nothing outstanding has occurred during the year but "very considerable progress has been made in development work, especially on mineral claims on Vancouver Island, where a total amount approximating $500,000 has been spent with satisfactory results." It is to be regretted, it is stated, that the Britannia Mining & Smelting Co. was obliged to discontinue production temporarily because of the fall in copper prices but "it is gratifying to record that the Tidewater Copper Co. Ltd., operating on Sidney Inlet, west coast of Vancouver Island, made the first shipment of concentrates in December, 1920, from the Indian Chief copper mine since the completion of the construction of the concentrating mill and the replacement of steam by electric power."

Nothing is added by R. W. Thomson, of the Central District, to his preliminary report for the reason that he was seriously ill for some months.

THE COAL MINES.

The coal production for the Province of British Columbia for the month of June follows:

Vancouver Island Field.

	Tons.
Canadian Western Fuel Co., Nanaimo	36,221
Canadian Collieries (D) Ltd., Comox	34,993
" South Wellington	6,945
" Extension	16,003
Nanoose-Wellington, Lantzville	1,786
Granby Consolidated Ming., Smltg. Co., Cassidy	23,015
Old Wellington Coal Co.	230
	119,193

Nicola-Princeton Field.

Middlesboro Collieries, Merritt	6,770
Fleming Coal Co., Merritt	3,187
Coalmont Coal Co., Coalmont	
	9,957

Crow's Nest Pass Field.

Crow's Nest Pass Coal Co., Coal Creek	31,989
Crow's Nest Pass Coal Co., Michel	17,298
Corbin Coal & Coke Co.	4,390
	53,677

Grand Total for Month . . 182,827.

The total for the month of May was 192,061, so that there has been a decline in the output in comparison with the previous month of 9,234 tons. The Crow's Nest Pass Coal Co., both at Coal Creek and at Michel, has slightly increased its production while at Corbin there has been a decrease. On Vancouver Island there has been a drop in the production of every colliery. In the Nicola-Princeton section there is little difference except in the case of the Coalmont Coal Co. which has not been producing, having been engaged in completing the installation of plant. Coal now is being taken out on this property, however, and the mine may be expected to figure as a shipper during the present month.

POSSIBLE APPLICATION OF THE "MYSTERY GUN" TO MINING.

A correspondent of the "Manchester Guardian" couples the name of Sir Edgar Jones, M.P., with the noiseless gun, said to have been invented by an Englishman who was a member of the British Inventions Board during the war. In reply to the questioning of the correspondent, Sir Edgar stated:

"I have seen it and took a lot of interest in it when I was in New York. But I am not interested in it as a gun, but in its application to industry, particularly to coal-mining and quarrying. It is a very small instrument, that will make blasting with powder unnecessary. These developments are proceeding, and one of these days I think we shall have a very considerable and remarkable development.

"It is true that as a gun it will revolutionize gunnery, because it has no recoil and makes no noise. The inventor is not keen at all in applying his discoveries to destruction but in making them applicable to production. And it is from that point of view I am interested.

"Who is the inventor? He lives just outside London, and is working away to apply the invention to industrial purposes. But as a gun, I think our own people were getting ready to use it before the war ended. The inventor is a very clever man. He was a member of the Inventions Board, and has several important inventions all over the world. The arrangements for the trials of which the cables speak now were made when I was in New York.

"What of its applicability to mining?"

"Well, here is the instrument" (measuring a space of about a foot). "The man with it goes up against the face of coal. He works the instrument, and 'biff,' splits the whole face of the coal. Then all he has to do is to get the coal out. It is not a blasting operation. It is just the delivery of a blow at a terrific velocity on a small patch which cracks the whole piece. It will crack granite or slate or any hard rock. It is very small but very complicated and very effective. There is no contact with the air, and therefore no sound and no recoil. It is based on new mechanical principles absolutely."

OIL PROSPECTING.

The "oil fever" has spread to British Columbia. There have been a number of parties leave this Province for the Fort Norman, Northwest Territories, during the past few months. For the most part they have been composed of former Yukoners, men accustomed to the northern trails, who have treked from Dawson over the snows to the scene of the late notable Canadian strike. Those who made this trip, for the most part have been in, staked their land and are out again. One such expedition staked 10,000 acres of land in three sections, one close to Fort Norman and the others close to the river but further away. Meanwhile the rush from Alberta over the now open waters continues. In the Province of British Columbia the government continues the prospecting of the Peace River Block and the Imperial Oil Company is at work in the Pouce Coupé Country. From Rolla, B. C. comes the reports that "a fairly strong flow of gas with a slight mixture of oil has been encountered by drillers for the Imperial Oil Limited at the company's well, twelve miles northwest of here, after less than a week of operation. The well is situated practically in the bed of Pouce Coupé River, 650 feet below the prairie level. The formation is sandstone. The drillers are continuing with their heavy rig on a twenty-inch hole, making now about fifty feet to the shift. The well is just on the Alberta side of the inter-provincial boundary." In the region of the lower Fraser River drilling still is in progress at various points and from Quatsino Sound, northern Vancouver Island, comes the news of the finding of oil shale.

COAL OUTPUTS, B. E. STEEL CORPORATION, FIRST HALF 1921.

The coal production of the constituent companies of the British Empire Steel Corporation for the first half of 1921 compares with the two previous years as follows:

	(Long Tons)		
	1919	1920	1921
Dominion Coal Co.	1,727,018	1,825,439	1,634,903
Nova Scotia Coal ..	243,576	315,329	280,824
Acadia Coal	190,558	249,463	197,960
Total	2,161,152	2,390,231	2,113,687

From present market indications the production of the combined companies for 1921 may reach 4,250,000 tons, which will compare with 4,839,402 tons in 1920 and 4,439,360 tons in 1919. The combined production of the three companies in 1913 was 6,473,581 tons, and the 35 per cent reduction in coal output which recent years have shown from the 1913 figures is chiefly attributable to the drain of the war upon the man power at the collieries, and to the fact that this drain was concentrated upon the producing class of mineworkers.

In neglecting to ensure the continued output of coal and gold from Canadian sources during the war period, and since, the political leaders of Canada were ill-advised.

SUBMARINE COAL EXPERT IN CANADA.

The Chief Mineral Inspector of the Department of Woods and Forests in Britain, Mr. Westgarth Forster Brown, is visiting the mines of the British Empire Steel Corporation in a professional capacity as an advisor on submarine coal mining. The coal lying beyond the foreshore in Britain—with one exception—is the property of the Crown, and its administration and leasing for operation comes under the direction of the Department of Woods and Forests. Mr. Brown will consult with the mining staff of the Corporation as to submarine mining practice in Cape Breton, and will probably visit the ore mines at Wabana. The British Empire Steel Corporation is now operating twelve mines in the Sydney district which are wholly submarine operations, and its existing land mines will, by a course of natural extension eventually become submarine operations also. Additional openings from the shore on submarine territory will also be made in the future. As miners of the submarine iron ore body at Wabana, Newfoundland, in addition to its coal mines under the sea, the British Empire Steel Corporation directs the most extensive undersea mining operations in the world, and its submarine workings are likely to become much more extensive both as to area and as to distance of penetration of the submarine tracts from high-water mark.

THE DIABASE MASSES AT GOWGANDA.

By R. E. HORE.

Mr. Kirby Thomas who has just returned from a trip to examine mining property at Gowganda calls attention to the nature of the masses of diabase in the silver district. He states that his observations lead him to conclude that geological structure at Gowganda is more like that at Cobalt than is generally supposed. While there are some undoubted dyke like diabase masses, much of the diabase is in the form of a thick sill. Most of the work done has been near the upper edge of the sill. Mr. Thomas argues that more general recognition of the sill form of the diabase should result in more exploratory work along its lower contest.

At Gowganda as at Cobalt the silver deposits are associated with diabase masses and are believed to be genetically connected with them. At Cobalt most of the silver mined has come from sedimentary rock intruded by a diabase sill. The silver deposits are seldom far distant from diabase. Some of the silver is in veins in the diabase itself, but most of it in the rocks immediately below or above the sill or its former extension. Most of the silver at Cobalt was below the diabase sill.

The sill character of the diabase masses at Gowganda was noted by the Bureau of Mines geologist, Mr. A. G. Burrows and sketches showing the supposed relationships of the rocks in the vicinity of Miller Lake are included in his report on the area. He states that the diabase sills, here and there exposed by erosion, are in large volume. They not only intrude the Cobalt series, but in places cut below the contact of this series with the older rock. In the vicinity of Miller Lake an area of Keewatin overclaim by conglomerate, and about two miles in width, lies on the diabase sill.

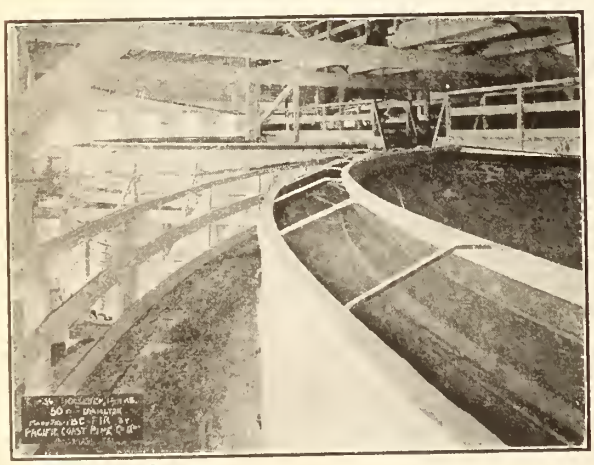
It was remarked by Mr. G. M. Colvocoresses, who was for some time manager of the Millerct mine, that while Dr. W. G. Miller reported that 85 to 90 per cent of the silver production at Cobalt came from the footwall of the diabase sill, yet nothing has been found in the footwalls of the several diabase intrusions which carry silver in the Gowganda district. Mr. Thomas makes the same observation and suggests that possibly more searching investigation of the footwall rocks would be rewarded by discoveries.

ANNOUNCEMENT OF MALCOLMSON CONSOLIDATION.

Announcement is made that the Malcolmson Briquet Engineering Company has consolidated with the St. Louis Briquette Machine Company under the corporate name of the Malcolmson Engineering and Machine Corporation. The Corporation will continue to act as engineers and contractors for the building of complete plants for fuel briquetting, peat harvesting, low temperature distillation of fuels, preparation of phosphate rock, and for the drying, crushing and screening of coal and rock products. It will also maintain an engineering department devoted to the generation and use of steam, special furnace design and other heat problems. In addition, it will manufacture Rutledge, Komarek and improved roll-type briquetting presses, fluxers and other special machinery and machine parts, direct and indirect heat-dryers, and vibrating screens.

NIPISSING COMPANY INTERESTED IN PORCUPINE DISTRICT.

It is reported that the Nipissing Mining Company of Cobalt is examining claims in the Porcupine District with a view to operation. It is stated that the Rochester-Veteran Claim at Porcupine will be drilled by the Nipissing interests with a view to deciding its desirability as a purchase.



EDITORIAL

Northwest Oil Regulations --- Further Criticisms

The Montreal "Star" shows commendable enterprise in sending its special correspondent to Fort Norman. The public is tremendously interested in the oil possibilities of the Northwest, and its imagination has been stirred by the remoteness of the places where drilling for oil is now being carried on; by the use of airplanes, by information regarding the great rivers and forests and the comparative habitability of territories which only a few geologists, the Hudson Bay Company and the Indians knew about; and by the vaguely menacing scramble of the nations of the world for petroleum, made more avid by the proved usefulness of petroleum in war. There are indications that those who are searching for oil may, as has been the case in other countries, of the advance guard of those who shall discover other deposits of economic value, and, whether the Northwest proves to be a producing oil country or not, the general knowledge of conditions in the largely uncharted North appears certain to be enlarged, and the boundaries of settlement will be permanently extended northwards in Canada.

The most recent news sent by the "Star" correspondent confirms our previously expressed belief that the opening of the Northwest for oil staking under the recent Regulations is about to lead to confusion in titles, to wholesale peddling of staked claims, and to retardation of the efficient commercial development of the field. Mr. Chester Bloom writes: "The oil locators aboard the "Northern Trader" (the first steamship to arrive at Fort Norman this year) "learned with astonishment that more than 700 miles of territory have been staked out for oil claims in the vicinity of Fort Norman gusher since last Winter. . . Practically every half-breed in all the northern posts has been busy at this work during the Winter and Spring, and then making over their holdings to syndicates or companies." As is to be expected, the claims have been inaccurately staked, and much overlapping will result. "They are laid out," writes Mr. Bloom, "by all points of the compass, and already there are murmurs of storms to come over prior rights of filing." As soon as a claim is staked, the stakers "beat it" out of the district to get to some recording office "and then return home." This kind of thing is not the way to develop an oilfield, nor to reduce the cost of such oil as may eventually come out of it. Neither will it, in the long run, help the revenues of the Canadian Government, as it must inevitably lead to unskilful operation of oil properties, to creation of fictitious values recorded on paper, to endless litigation and endless legal costs. The traditional method of opening up hard-rock mining areas for staking in this way is no reason why it should have been applied to oil deposits held by the Crown in a remote region. The whole proceeding has been based on false premises, and is fundamentally illogical. No economic, and most certainly, no geological reasoning could have led to the framing of the amended and re-issued North West Oil Regulations. The Government should have been guided by one set of considerations only, namely, how to get the most oil out of the North Country, at the earliest date and over the longest period of yield, at the lowest producing cost and with the greatest possible monetary return to the Government. If these primary conditions had been studied, and the regulations framed to achieve them, it would have been seen that a concentration of capital and effort and not a wilful dissipation, was required, and the present lamentable mix-up, which will bring tragedies and bankruptcy in its train, could have been avoided. The Government has desired to have its cake and eat it too. It will end by achieving neither aim.

CERAMICS IN CANADA.

At a teachers' gathering in Toronto there were recently exhibited specimens of artistic pottery made from clay mined in the vicinity of Bowmanville. This clay is stated to be peculiarly suited for pottery uses in its natural state, and does not shrink on being fired, but undergoes a slight expansion.

In a bulletin on the resources of Saskatchewan issued by the Natural Resources Intelligence Branch there is shown a remarkable range of clay products made from Saskatchewan clays, including glazed and modelled vases, bowls, plaques and specimens of the ceramic art that are of much beauty and excellence.

Mr. A. A. Cole, at a recent meeting of the Cobalt Branch of the C. I. M. & M. spoke of the pottery clay that is found in a remote part of the James Bay slope, from which the finest porcelain can be made.

There are a number of clays in the Maritime Provinces suitable for earthenware, and as those who are familiar with the local potteries of the United Kingdom and Europe are well aware, it is not necessary to have a china clay to make pottery in which craftmanship can be acceptably displayed.

The Prairie Provinces, as may be ascertained from perusal of the literature of the Ceramic Branch of the Mines Department at Ottawa, are rich in suitable clays for ceramic uses.

It is therefore most pleasing to read that teachers' associations are interesting themselves in pottery, even if it be only for the sake of inculcating love of craftmanship and the pleasure of handiwork into their pupils. All great pottery industries have commenced in this way, and the art has always been one in which the individual craftsman could make his mark and found a local industry.

The provincial departments of education, and the federal department of technical education, should encourage the plastic arts, and particularly any attempt made by local artists to utilise clay occurrences that have especial merit as ceramic materials, because by this means not only would much pleasure be given and obtained by those who engage in a fascinating pursuit, but substantial local industries could be established and an avenue of cultural improvement would be opened up that so far has been much neglected in Canada.

There is of course a much wider opening for utilisation of Canadian clays in the manufacture of terra cotta, fireproof building-materials, refractory bricks and the more usual clay products, but these are matters requiring much capital outlay and market demand.

There is a school of Canadian art today, well-established and possessing much genius, as a visit to the art galleries and exhibitions will disclose, but it is largely pictorial and monumental art. Ceramics and plastic arts generally should be given more attention, and if this were done, there is no doubt that Canadian craftsmen could turn out articles that would be more beautiful than some of the imported abominations that are offered for sale.

MINERAL PRODUCTION OF THE UNITED STATES.

The preliminary summary of the mineral production of the United States for 1920 is a unique document, and its appearance at a date which is little past the half year of 1921 is a considerable achievement, because the scope of the compilation includes not only estimates of production, but also statistics of imports and exports and the mineral production of foreign countries.

The estimated value of the minerals produced in the United States during 1920 totals the really stupendous figure of $6,707,000,000, exceeding any previous annual value, and comparing with the previous record value of $5,540,496,000 in the year 1918. Coal, iron-ore, petroleum, copper and clay products stand out by their magnitude, and coal alone accounts for about 35 percent of the total.

Some modern tendencies are discernible from study of the statistics. Aluminium showed a growth both in domestic production and in imports, and the value of sulphur production nearly doubled over 1919. Titanium ore, uranium and vanadium minerals show remarkable increases, in quantity and in value. Production of the precious metals used in currencies amounted to a little over one hundred million dollars in value, a comparatively insignificant amount in comparison with the value of the raw materials of industry.

Of a total apparent consumption of unmanufactured asbestos valued at $10,133,182, the value of imported mineral was $9,120,253, noted as being "mainly from Canada." The recorded figures of asbestos production in other countries, including South Africa, do not indicate that either Canadian or United States miners of asbestos need fear very urgent competition, even if quantity is considered and quality disregarded. The nickel imported into the States during 1920 was valued at $10,857,657, ninety-one percent being of Canadian origin.

The story of the mineral production of the United States is shown by the total value of mineral production by five-year periods over the quarter-century ending 1920, as under:

Five yrs. ending	Value of Mineral Production
1900	$4,138,729,000
1905	6,961,356,000
1910	9,437,174,000
1915	11,101,236,000
1920	25,361,431,000

This is a record without parallel in history, alike as to the rate of growth and the magnitude of the tonnages. While to some extent the spectacular rise of the aggregate value of the mineral production of the United States is due to the decreased purchasing value of paper currencies causing an apparent rise in monetary value, yet the actual performance on a basis of tonnage production has no precedent, and, to an extent that is not determinable, the increased value of mineral products is a real one, inasmuch as it represents enhanced intrinsic value arising from depletion of mineral reserves

If the United States can produce at this rate in a lean year like 1920, what may she not produce when the lassitude of the war fever has been cured, and the whole world bends its energies to production from the soil in agriculture and mining combined?

It is not without interest to Canadian readers, in view of certain changes in the duties of the Division of Mineral Resources at Ottawa to observe in the prefatory note to the Washington Mineral Summary the following remarks: "Many of the figures for both 1919 and 1920 are preliminary, and some are estimates. This incomplete condition of the figures for 1919 is due to the plan of co-operation with the Bureau of Census, by which producers' reports for 1919 to the Geological Survey are received through the Census."

THE NORTHERN LIGHT RAILWAY PROJECT.

We are glad to note that the Toronto "Globe" stresses the desirability of a railway to serve the area included in the project of the Northern Light Railways, and particularly agree with the statement that wagon roads are a costly and unsatisfactory compromise in comparison with rail service. The proposal to extend the T. & N. O. railway to James Bay, and even the more modest proposal which was recently made to extend a short distance north of Cochrane, was, we believe premature and not required by any real economic needs of Northern Ontario, and its abandonment at this time is a wise action. But the district lying between the T. & N. O. and the C. N. railways, in the potentially important and comparatively accessible area between Porcupine and Cobalt offers very definite promise of profitable production, and anything that will increase the output of new gold in Canada at this time is worth the most urgent and serious consideration of governments. Any economy that retards gold production at this date is actually not an economy at all, but the reverse.

MR. R. E. HORE, in this issue stoutly defends the gold miners of Northern Ontario for making the best of the depreciated value of Canadian paper money by disposing of new-mined gold, by way of the Canadian Mint, and receiving for it United States paper money, which, because of the inflation of our own paper issues and the comparative non-inflation of United States paper issues, commands a premium when exchanged into Canadian paper currency. He states "the lowering of the exchange rate is not the business of the gold producer." Possibly not, but there is no one in Canada that is doing more at this time than the gold miner to bring about a condition which the general public desires more than our political leaders and our financiers desire it, namely, restoration of Canadian paper money to parity at New York. The corrective of exchange is a good, though bitter, medicine. The gold-producer in Canada at this time is a person attended by singular felicity, because he profits by the New York premium, and at the same time knows that he is helping Canada's credit. The assistance in correcting exchange in Canada's favour that the Canadian gold producer can give by purchasing Canadian-mined coal and mine materials is not so great as the assistance that he can give by producing gold in continuous and ever-increasing quantity. We are suffering from a shortage of the gold backing to our currency, and, so long as we buy more than we sell in commercial exchanges of materials, the mine is the only place from which we can get new gold. The gold miner should be encouraged by every possible means available to Canadian statesmanship. It may be further remarked that as a user of raw materials, such as coal, the gold-mining industry is not remarkable. When gold-mining is successful, it produces large monetary returns with a comparatively small expenditure of materials and a small number of workers. It is an industry that at this time should be worked insistently and intensively, and it has always been a source for wonder that Canadian statesmen have never realised the possibilities for maintaining our national credit that the country's gold mines have presented during the period since 11th November 1918 and this date.

The Ontario Government has decided not to erect a provincial cement plant. The Minister of Public Works states that the many calls on the finances of the Province have led to the decision. It is a wise one. There are no reasons why a provincial cement plant could operate more cheaply than a privately-owned plant, and there are many reasons to expect the operation to be more costly. The only excuse that a provincial government could legitimately give for erecting a cement plant would be that of inability to obtain cement because of shortage of cement-making plants, and this condition does not exist. Even where there is reason to believe that unreasonable profits are being made by a manufacturer, the duplication, unnecessarily, of manufacturing capacity, is a waste of public monies, and it has not been proved that cement prices are unreasonable.

Applications are asked by the Publishers of the "Canadian Mining Journal" for the position of Editor, which will become vacant shortly through the resignation of Mr. F. W. Gray, who is joining the staff of the British Empire Steel Corporation in Montreal.

DR. STANLEY SMITH GOES TO QUEEN'S.

Dr. Stanley Smith is appointed assistant in the department of mineralogy and geology at Queen's University, Kingston. Dr. Smith is an M.A. of Cambridge, and a D.Sc. of Durham University. Before the war he was lecturer on fossil corals at the British Museum and Wales in Aberstwyth. He served two years during the war, being recalled at the end of 1917 to take over the department of geology at the Welsh University. The announcement is made by the Principal, Dr. Taylor, who has returned to Kingston from an overseas visit.

CORRESPONDENCE.

Winnipeg, 27 July, 1921.

The Editor, Canadian Mining Journal.

Dear Sir,—Mr. J. P. Gordon hits the nail on the head, in your impression of July 22, in urging a return to Crown Grants under Dominion mining regulations. It was a long step backward when the Crown granting regulations was repealed and these infernal leases substituted. (Infernal is a French word as all scholars will recognize). I have written much on this subject, and have done all I could to awaken the mining community to the utter idiocy of the substitution of a lease for a Crown Grant, but there is so little actual mining in Manitoba, as yet, that my appeals fell on deaf ears. To the wild-catter leases and grants look "allee samee."

The Flin Flon people had to protect their claims by taking out placer leases, and Mr. Gordon would have been wise to do as much—but it should not be possible for any one to record placer claims in Ontario, Manitoba, Saskatchewan, or Alberta. There was a certain cold spell occurring as some deeply scientific men tell us, about 20,000 years ago, and which other equally scientific men assure us took place not less than 250,000 years before Winnipeg was founded, which effectually did all the cleaning up any respectable placer could demand. All that was left is a little "Chinaman's gold," a light, floatable, leaflet form, in meagre quantities in some of our river bars. If any poor devil wishes to scrape up this stuff, let him do it without license or fear of the law, but don't let placer leases conflict with legitimate attempts at hard-rock mining.

Yours faithfully,
CHARLES A. BRAMBLE.

DEATH OF A. C. ROSS.

The late A. C. Ross, whose death is reported in Montreal on the 30th July, was intimately connected with the development of coal mining in Cape Breton. His father, Rev. Hugh Ross, in 1867, opened the first workings into undersea coal under Sydney Harbour. In his book on "Minerals and Mining" Hon. Robert Drummond writes: "It is claimed for A. C. Ross, ex-M.P., that to him belongs the honour of having been the first to drive a pick into the seam at Victoria Mines. Though the starting of a colliery to run under the sea was, in those days, a momentous occurrence, there was no formal, no elaborate, ceremonial at the opening, otherwise Mr. Ross would be the possessor, not of a silver trowel, but of that rarer implement, a silver pick."

Mr. Ross was prominent in the negotiations for consolidation of the companies and areas that preceded the incorporation of the Dominion Coal Company in 1893, and was associated with the late B. F. Pearson of Halifax in his nmmerous mining and transportation promotions.

In newspaper circles and politics Mr. Ross was well-known in Nova Scotia, he having owned and published several of the Cape Breton newspapers, and having been member of parliament for a Cape Breton riding in the Liberal interest. He was a leader in the promotion of a large number of mining and transportation companies that are now in operation in Nova Scotia, many of them being now included within the properties of the British Empire Steel Corporation. He was born at Margaree, Cape Breton, in 1847.

Mr. Ross was a true type of the *entrepreneur*, and had a native genius for marshalling information on local natural resources in a manner that attracted and interested capital in their development. His lively interest in such matters continued through a long and active life, and up to the time that his health failed.

COLLOIDAL PITCH THE LATEST FLOTATION REAGENT.

For two or three years metallurgists interested in flotation have heard reports of a mysterious new flotation reagent which was said to be giving remarkable results in an experimental way. A few knew that the discoverer was a Mr. Luckenbach whose headquarters were in Brooklyn, N. Y., and a still smaller number were permitted to visit his laboratory and see demonstrations. The actual composition of the reagent used has been carefully concealed until recently, however, until the publishing of the British patent specifications (Engineering and Mining Journal, June 25, 121).

Mr. Luckenbach has named his discovery "Rex"—meaning "king" of course. It is common pine pitch added to a solution of caustic soda. This is to be sold as a plastic mass, it is understood, which is to be mixed with water at the mill and added to the flotation circuit. The pitch does not go into solution, but forms a colloidal suspension, and is said to have remarkable properties as a frother and collector. It has not yet been used on a commercial scale, but has been thoroughly tested out in the Luckenbach laboratories, and also by some of the Cobalt mining companies and by the Canadian Department of Mines at Ottawa. Comparative tests at Ottawa on 1,200-lb. samples crushed to 80 mesh are said to have given the following results:

	Luckenbach Reagent Per Cent Cu			Callow "XY" Reagent Per Cent Cu		Oil Per
	Test 1	Test 2	Test 3	Test 1	Test 2	Cent Cu
Feed. . . .	1.65	1.55	1.60	1.72	1.49	1.35
Concentrates	10.63	13.95	13.95	6.70	8.50	10.70
Tailings . .	0.19	0.26	0.19	0.20	0.28	0.62
Recovery. .	90.1	89.8	89.9	90.8	84.3	57.6

The ore on which these tests were run was from Anyox, B. C., and the mineral was chiefly chalcopyrite. Excellent results are also claimed on carbonate ores, without sulphidization.

Just what success this reagent will have on a large scale remains to be demonstrated as it has never been nsed as regular practice in a commercial mill. It is said to retain practically all of its virtnes in the return water, undergoing scarcely any decomposition with nse. We are reliably informed that pitch in all of its various aspects was thoroughly tested ont in the many experiments which were conducted at the Mellon Institute and was fonnd not as desirable as some other reagents, bnt the experiments of Mr. Luckenbach have no doubt been much more exhanstive.—Engineering & Mining Jonrnal.

LOW-TEMPERATURE DISTILLATION OF ALBERTA COALS.

A despatch from Edmonton states that an English syndicate, in which Lord Morrison, formerly Prime Minister of Newfoundland is interested, proposes to acquire coal property in Alberta to demonstrate the snitability of Alberta coals for low-temperature distillation, yielding by-products and residnal fnel.

Mineral Production in Quebec During 1920

In contributing a forecast of the mineral production of the Province of Quebec during 1920 to New Year issue of the "Canadian Mining Journal," Mr. Theo. C. Denis stated that "whether or not the total figures of 1920 would be found to exceed those of 1919 or not would depend on the value of the building materials," and it is therefore interesting to note that the 1920 value of these materials totalled $12,054,857, compared with $8,090,651 in 1919, an increase of fifty per cent. The Quebec report for 1918 commented on the serious effect that the war had upon the output of building materials in the Province, the value of these having declined from 8 million dollars in 1913 to 5½ million dollars in 1917 and 1918. The 1920 achievement not only shows a remarkable recovery from the depression of the war years, but it exceeds the best of the pre-war years.

The value of the annual production of Quebec continues its unique ascension, reaching $28,392,939 in 1920, which compares with $13,119,811 in 1913, itself the record year to that date. Asbestos continues to be the dominating product of the Quebec mines, and is elsewhere referred to in detail in this issue.

The mining industry of the Province employs 8,806 persons (or 7,428 persons working 300 days per year), earning $9,820,431 in wages, being at the rate of $1,322 per person per year, the highest yearly average yet recorded, comparing with $1,025 in 1919, and only $593 in 1915. The rate of common labor has risen from $1.75 per day in 1915 to $4.25 in 1920.

The fatal accident rate in 1920 was high, being 3.52 per thousand persons employed, which compares with 0.6, 4.5 and 1.67 in 1917, 1918 and 1919 respectively. It is significant that out of 25 fatal accidents, 17 took place in open pits and quarries, and were chiefly associated with rock-falls and slides. The Superintendent points out that some of the open pits are 300 feet deep, and suggests special precautions to remove all loose rock after blasting. The remarks of the Superintendet on preventable causes of accident are well worth the attention of the miners of Quebec, as the accident rate is altogether higher than it should be, or could be. The full statistical information given in regard to accidents is a very commendable feature of the Mines Report.

Copper and Sulphur Ores.

Production in 1920 was 15,186 tons, comparing with 53,965 tons in 1919 and 125,446 tons in 1918. The competition of sulphur from the Southern States, and its reduced market price, combined with low price and lack of demand for copper are chiefly responsible for the small production of pyritons ores in 1920. Production was almost entirely from the Weedon mine.

Chromite.

The production in 1920 was 10,585 tons compared with 8,184 tons in 1919, and 23,000 tons in 1918. In view of the market conditions the slight recovery in output in 1920 is satisfactory, but competition from Rhodesia and New Caledonia has resumed much importance.

Gold and Silver.

As gold production in Quebec has so far been confined to a by-product of copper and zinc-lead ores, and as the output of these ores has been reduced by market conditions, gold recovery shows a decline, being 935ozs. gold and 57,714ozs. silver, compared with 1,446ozs. gold and 127,223ozs. silver in 1919. Development in the Lake de Montigny district has not proceeded beyond assessment work.

Molybdenite

No production of molybdenite was recorded in 1920, for which market conditions were entirely responsible. Preparations for output have been proceeded with during 1920 at several points.

Magnesite.

Production increased from 9,940 tons in 1919 to 17,941 tons in 1920. The Scottish Canadian Magnesite Co. and the North American Magnesite Co., of Grenville, and the International Magnesite Co. of Harrington Township, are the three producers reporting. The Grenville magnesite contains more lime than is considered desirable, and experiments carried on at the ore-testing laboratories of the Mines Branch at Ottawa indicate the possibility off "producing caustic magnesia, low in lime, from the high-lime magnesites at the same time obtaining a by-product, dolomite lime paste suitable for structural purposes or for utilization in the manufacture of sulphite pulp." Experiments on a larger scale are being proceeded with in Ottawa. It seems likely that the production of magnesite in Quebec is a permanent industry.

Graphite.

There was no production of graphite in Quebec in 1919, but 466,420 pounds was produced in 1920. The Quebec Graphite Co., after a prolonged shut-down, commenced in the concluding part of 1919 to install the Callow process of flotation, and resumed miling at Buckingham in May, 1920, with satisfactory recoveries. This company has gone into the manufacture of finished products, and are now marketing lubricants and pastes, and intend to make electrodes, greases and stove-polish. While the flotation process of graphite recovery as applied at the plant of the Quebec Graphite Co. and also by the Consolidated Graphite Co., both in Buckingham Township, the selling price of graphite is depressed by competition of accumulated stocks in Ceylon and elsewhere.

Mica.

Value of mica produced was $281,729 in 1920, compared with a value of $224,988 in 1919. Mica statistics are stated by the Report to be indefinite, because of the difficulty of grading mica into statistical divisions. 1919 production, which brought a smaller yield in money than 1920 production, was estimated at 3,853,265 pounds, whereas 1920 production is estimated at only 1,496,399 pounds. Quebec produced 77 per cent. of the Canadian output of mica in 1920, comparing with 82 per cent. in 1919.

Miscellaneous Products.

Silica rock shows increased production with 24,865 tons. Feldspar amounted to 849 tons, some of it being shipped to France as "dental spar" for the manufacture of artificial teeth. A company is being formed to exploit a deposit of marl earth at Millette Lake for the manufacture of whiting, and the Report lists a number of occurrences of deposits of fresh-water marl in the Province.

Building Materials.

Quebec is rich in building materials, particularly deposits of building stone from which dimension pieces of any desired size can be obtained. Ornamental marbles are found in many places and largely worked, marble to the value of $250,000 having been produced in 1920.

A deposit of red slate, associated with ornamental marble in the seignory of St. Joseph de Beauce, is being crushed by the British Canadian Marble Co. for surfacing roofing shingles. Cement and brick production account for 30 per cent. of the value of building materials in Quebec during 1920, and show an increase of 55 per cent. over the values of 1919.

The Mines Report, as is usual, is notable not only for the extent and accuracy of its information, but for its generally helpful character.

While Quebec is not a large mineral producer, yet her minerals and their exploitation are associated with certain specialized requirements of high development of civilization and the mechanical arts. Other phases of Quebec mining, such as the use of building materials, reflect urban growth and increase of population, and, in recent years, Quebec has not been remarkable for prospecting expeditions or new finds of mineral, although the Province has a northern hinterland which is less known than any part of Canada today. It seems altogether likely that Quebec will continue to record annually increasing extent and value of mineral production.

ASBESTOS MINING IN QUEBEC.

The Annual Report of the Superintendent of Mines of Quebec for 1920 puts the value of asbestos and asbestic at about 53 percent of the total value of the mineral production of the province in both 1919 and 1920.

The relation of the value of asbestos production to the total mineral value of Quebec for the past ten years is shown by the following table.

Year.	Value of Asbestos. $	Percent of Total Mineral Production Value. %	Average Value of Fibre per ton. $
1911	3,026,306	35	29.60
1912	3,059,084	26	27.52
1913	3,830,504	29	28.04
1914	2,895,935	25	26.96
1915	3,544,362	31	31.33
1916	5,182,905	39	38.87
1917	7,198,558	44	52.45
1918	9,019,899	48	63.35
1919	10,932,289	53	80.47
1920	14,749,048	52	81.89

The asbestos content of the rock mined has varied during this ten year period within quite narrow limits, the highest value being a content of 117.3 pounds per ton of rock in 1918, and the lowest 96.9 pounds in 1915. The average of the period is 108 pounds of asbestos recovered per ton of rock mined, the figure for 1920 being 109.1 pounds per ton.

The average annual production over ten years has been roughly 130,000 tons of fibre, so that the production of 179,891 tons of fibre in 1920 is 38 percent above the ten-year average. The annual figures are shown below.

Annual Shipments of Asbestos Fibre, Net Tons.

1911	102,224	1916	133,339
1912	111,175	1917	137,242
1913	136,609	1918	142,375
1914	107,401	1919	135,862
1915	113,115	1920	179,891

Inspection of the foregoing figures will disclose that asbestos production in Quebec has borne a very exact relation to the price of fibre, and 1920 was a year of high prices and heavy demand. The Superintendent of Mines states that up to September the supply could hardly keep up with the demand, and that the mine sheds were bare of stocks. Towards the end of the year the market reflected the decrease in business in the United States, and during the first months of 1921 curtailment of production became general.

Exports of crude and mill stock during 1920 showed the following distribution, condensed from the Report:

Destination.	Tons.	Percent.
United States	115,283	75.6
United Kingdom	11,881	7.8
Europe	18,057	11.8
Other countries	7,519	4.8
	152,740	100.0

Virtually all the asbestos sand and waste, to the extent of 36,218 tons out of 36,303 tons, was exported to the United States.

Modernisation of the Asbestos Mines.

A significant feature of the Superintendent of Mines Report is the progression of asbestos extraction from open-pit mining to regular underground workings, and the general modernisation of the mining equipment. Derrick-hoisting is being superseded by inclined tramways and shafts. An interesting example is the mine of the Canadian Johns-Manville Company at Asbestos. Here the quarry is laid out in wide benches, the rock being loaded into cars of standard gauge by steam-shovels and hauled in trains to the mill by steam locomotives on a maximum grade of three percent. The layout is similar to the approved method of mining iron-ore in the Lake Superior ranges, although of course the material is a different one, and the magnitude of operations not so impressive.

Another mine, the British-Canadian mine at Black Lake is in a transition stage between the quarry and the mine, the Report stating that the previous method of hoisting by cable-derrick will soon be entirely superseded by the glory-hole and underground haulage.

In this mine as also in the other mines of the Asbestos Corporation of Canada at Thetford, there has been a further utilisation of electric power, all the steam locomotives at the King Mine having been superseded by electric locomotives, which, apart from the considerations of uncertainty of coal supply that have led to this change, is in line with approved mining practice. At the British-Canadian mine it is proposed to use electric-trolley locomotives for underground haulage through the tunnels. At the Consolidated Asbestos Limited mine at Thetford (formerly the Jacob's Mine) underground haulage is done by storage-battery locomotives, with charging installation underground.

At the Pennington Asbestos Company's mine, Robertson, an electric hoist and an inclined tramway is replacing the steam locomotives formerly used for haulage.

There seems no reason why the completest electrification of the asbestos mines should not be generally adopted; and a good many reasons why it should.

The use of modern drilling tools is also noted. The Canadian Johns-Manville Co. are using turbo-rotator drills, made by the Denver Rock-Drill Mfg. Co., drilling 2 inch holes up to 40 ft. in depth and the Quebec Asbestos Corporation at East Broughton is using a Sullivan submarine drill that can drill a 3-inch hole to a depth of 75 feet.

The report does not mention the quantity of explosives used in blasting, but as these deep holes are heavily charged, the total quantity must be quite large.

While the war stimulated the demand for asbestos to a noteworthy extent, the experience of 1920 indicates that the uses of asbestos are now so various and established that there is no likelihood of any serious decline in the demand for Canadian asbestos. Indeed the uses of asbestos are growing, and the quantity so far ascertained to exist in other countries is not sufficient, nor is the quality of sufficient excellence, to warrant any serious fears for the future of the market for Canadian asbestos.

ASBESTOS DEMAND.

A market letter from New York advises that asbestos companies having selling agencies in New York are now absorbing the five percent tax of asbestos exports which is imposed by the Quebec government, from which it is evident that this tax must have been separately billed to American customers during the period that it has been in force. The change seems a not undesirable one. Enquiries for asbestos are stated to be fifty percent greater than last month, and no material decrease in the selling prices of crudes or fibre is looked for, as the mines are running on very curtailed production, or are entirely shut down, and no exceeding of demand by production is looked for.

B. E. STEEL STAFF APPOINTMENTS.

D. H. McDougall, Vice-President of British Empire Steel Corporation, announced under date of July 15th, appointment of George D. Macdougall, latterly General Superintendent of the Nova Scotia Steel & Coal Company, as Chief Engineer of the Corporation, and of A. McColl, for many years Secretary of the Nova Scotia Steel Company and Assistant to the President, as General Manager of the Nova Scotia Company, including the consolidated properties of the Corporation centred around New Glasgow.

Mr. Macdougall's experience has been of a nature to fit him exceptionally well for the wide and onerous duties that he will have to undertake as Chief Engineer of the Corporation, as these will extend over an area and will include a variety of engineering problems unique in Canadian corporate industrialism.

Mr. Macdougall, who was born in 1873 at St. Peter's, Cape Breton, graduated from McGill in 1895 with the degree of B.A.Sc. (with honours) in mechanical engineering, and the following account of his career following graduation is taken from "Institute Notabilities" series in the Bulletin of the C. I. M. & M. of June 1920.

"Beginning with the Robb Engineering Company of Amherst, N.S. Mr. Macdougall went across the line, and was engaged in shop and engineering work for the G. F. Blake Manufacturing Company, of East Cambridge, until 1898. For the next year he was chief draughtsman on marine engineering for the Fore River Ship & Engine Company, Weymouth, and later was in charge of power-house design and erection with the Edison Illuminating Company of Boston. In 1900 he went with the Dominion Iron & Steel Company as master mechanic and assistant manager of the ore-mines at Wabana, Newfoundland, but returned to the United States at the end of 1901 to become assistant chief engineer of the Lackawanna Steel Company, Buffalo, and later mechanical superintendent. From 1904 to 1909 he was with the Steel Company at Sydney, two years as mechanical superintendent and three as chief engineer, following which he was superintendent of construction for the Canada Iron Corporation at Midland, Ont. At the beginning of 1911 he returned to the Dominion Company as mechanical superintendent, and in 1916 became assistant general superintendent, retaining this position until in 1918 he became general superintendent of the Nova Scotia Steel Company."

Mr. Macdougall is President of the Mining Society of Nova Scotia, a vice-president of the Canadian Institute of Mining & Metallurgy, and a member of the Engineering Institute of Canada. He was also the first president of the Nova Scotia Accident Prevention Association, and is Grand Master of the Freemasons in Nova Scotia.

Mr. A. McColl's appointment comes naturally after a term of service with the Nova Scotia Steel Company, and its predecessors, that extends from his graduation from Dalhousie and Boston Tech. to the present date. He has seen the Scotia Company grow from the humblest beginnings, and has taken an active part in that development. The official statement in connection with Mr. McColl's appointment announces that he will have his headquarters in New Glasgow, and will direct the operations of the Steel Plant at Trenton, the Eastern Car Company and the Acadia Coal Company, and that, at a later date, the Springhill collieries, now managed from Glace Bay as a district of the Dominion Coal Company, will be attached to the New Glasgow management, thus consolidating all the mainland operations of the Corporation, which are not far apart and are physically very similar.

These appointments are in continuation of the policy of utilising the best executive material in the staffs of the consolidated companies, so as to restore former efficiency and give the Corporation the benefit of technical direction by specialists already trained in and acquainted with local conditions.

CHANGE IN ACADIA COAL COMPANY MANAGEMENT.

Mr. J. J. McDougall has been appointed Assistant General Manager of the Acadia Coal Company, succeeding M. F. E. Notebaert in the operating management of the Acadia collieries, who is returning to Belgium. Mr. McDougall was for a number of years the Resident Manager of the Wabana Mines of the Dominion Iron and Steel Company in Newfoundland, and has for the past two years been assistant to Mr. Notebaert at Stellarton.

Mr. Notebaert, during his technical management of the very difficult property of the Acadia Coal Company at Stellarton, has established his professional competency, and leaves the mines in better order, from an engineering standpoint, than they have ever been in. A succession of fires and explosions has been the record of the Acadia mines throughout their history, and during Mr. Notebaert's term of office, one disastrous explosion and a number of fires have occurred, the fighting of which has called for the most expert knowledge and skilful handling, and much personal courage, in all of which Mr. Notebaert distinguished himself. A series of borings, carried out under Mr. Notebaert's direction, fixed with accuracy the number and position of some nine coal-seams underlying the lowest worked seam in the Acadia areas, and corroborated the report of Hartley and Logan published by the Geological Survey in 1869. Previous failure to confirm this report

had led to the belief that the Acadia property was much less valuable than is actually the case. The demonstrated extent of good-quality coal in this property, and the better control over the fiery nature of the coal and associated shales in a remarkable concentration of burnable deposits which systematic fighting and control of the fires has made possible, have put the Acadia Coal Company's mines in very much improved position as producers of coal. The strata column in the Stellarton field includes 16 coal-seams, aggregating 189 feet in thickness in a depth of 2,780 feet, mostly composed of shales that are approximating to oil-shales and are in many instances highly carbonaceous and gaseous. The troubles with mine fires in this district in the past have largely arisen from failure to extingush fires in the coal-seams that have, because of the curious nature of the strata, not remained confined to the seam in which they originally started.

BELGIAN-AMERICAN COKE OVENS CORPORATION.

A corporation has been organized in New York, headed by Thomas F. Ryan, to introduce and operate in the United States the Piette by-product coke oven. Hector Prud'homme of Brussels is vice-president. Mr. Prud'homme was for several years General Manager of the Acadia Coal Company, at Stellarton, Nova Scotia. The technical part of the organization will be composed of Belgian engineers, and this will be added to by appointment of American engineers and executives.

EXPLOSIVES MANUFACTURE IN CANADA.

The report of the Dominion Bureau of Statistics on the explosive industry in Canada for the year 1918 is interesting as a record of a phase of munitions activity, and the figures of that last year of the war, while impressive as showing what the country can do under the compulsion of war necessity, are not representative of normal business in the explosives industry in Canada.

The value of explosives made in Canadian factories in 1918 is placed at $1,477,828, and the value of exports of cartridges, explosives and detonators from Canada in that year is placed at $272,913,776. There is therefore a very wide spread between the two sets of figures, representing, presumably, costs of making explosives into shells of various types, and taking in probably the product of the previous year's output.

The report states that over five million dollars was spent in Canada during 1918 in the construction of new buildings and the repair of those already constructed. The investment in plant and equipment in the explosive industry in 1918 was nineteen million dollars. No doubt, by this time, much contraction in the scope of the explosive industry has taken place, but it is evident that there should be no difficulty in supplying Canadian industries with explosives in ample quantity in ordinary times.

The Bureau of Statistics is co-operating with the Explosives Division of the Mines Branch in the obtaining of statistical data, and a joint form for collection of such information is being used. Of interest to the coal-mining industry in Canada is the use of over five million pounds of toluol in 1918.

BITUMINOUS COAL PRODUCTION IN THE UNITED STATES.

The weekly bulletin of the United States Geological Survey on coal production in the United States contains the following comparison of the production of bituminous coal during the first half of 1921 against corresponding production in nine years preceding.

Year	June production	Cumulative production to June 30
1913	37,405,000	226,000,000
1914	31,412,000	205,000,000
1915	33,957,000	193,000,000
1916	37,742,000	246,000,000
1917	46,834,000	273,000,000
1918	51,138,000	282,000,000
1919	37,034,000	214,000,000
1920	45,114,000	258,000,000
1921	33,852,000	196,000,000

If the second half of the year 1921 shows no greater output than the first half, the total for the year will be less than 400,000,000 tons. The last year in which the country required less than 400,000,000 tons was 1909.

Examination of the table shows that up to the end of June, the year 1921 was:

9 million tons behind 1914
18 million tons behind 1919
30 million tons behind 1913
50 million tons behind 1916
62 million tons behind 1920
77 million tons behind 1917
86 million tons behind 1918
3 million tons ahead of 1915

Compared with the average of the eight years preceding, 1921 is 41 million tons behind. Before concluding that this subnormal production indicates a future shortage, the greatly decreased consumption of coal caused by the depressed condition of industry in general should be considered. Cumulative production is but little less than that in 1914, which also was a year of general business depression. In that year no shortage of soft coal occurred. It is even slightly ahead of the first half of 1915 when the allied war orders had not begun to stimulate the demand for coal. On the other hand our national requirements normally increase at the rate of from 10 to 20 million tons a year, so that what was sufficient in 1914 would ordinarily be far from sufficient now.

PORT ARTHUR NOTES.

By J. J. O'CONNOR.

Two by-laws were submitted to the ratepayers of Port Arthur on the 27th July. One confirming the sale of two hundred acres of water-front property by the City of Port Arthur, to the Palatine Mining & Development Company, for the purpose of erecting thereon ore-docks, and an iron and steel industry, together with allied industries, the other confirming a tentative agreement made by the City Council, with the above company, placing a fixed assessment on its blast furnace for a period of ten years.

Both by-laws were carried by practically a unanimous vote, being the largest vote of the kind ever registered here, showing the confidence the local people have in the iron-ore resources of this district, and the possibilities of an iron and steel industry at this point.

Memorandum on Part of the Goudreau Gold Area

By A. G. BURROWS, Ontario Dept. of Mines.

In accordance with my instructions of June 22nd I proceeded to Goudreau station, on the Algoma Central railway, to examine the recent gold find on the Murphy claims which are located in township 28, range 26 of the Michipicoten area. This township is included in the lands grant of the Algoma Central railway and claims staked in it are recorded at the company's office at Sault Ste. Marie.

Means of Access.

The area is most conveniently reached from Franz, a station at the crossing of the C. P. and A. C. railways. Goudreau, which is the nearest railway station to the gold discovery, is 17 miles southward from Franz; the Murphy claims are about 3½ miles southwestward from Goudreau. The camp is reached by a good canoe route which starts one-half mile south of the station. The route, which requires about two hours' travelling, is by way of Jackson, Long, Doherty, Aitken and Murphy lakes. The longest portage is about one mile. The find is located near the north shore of Murphy lake on mining claims 407 and 408.

Discovery.

The discovery was made by Thos. Murphy of Goudreau while engaged in fur trapping in the month of April. A. V. J. Selkirk, merchant of Franz, and Jas. Perry, Goudreau, were early partners with Mr. Murphy; later, several others were given interests in the claims. Twelve claims in the vicinity of Murphy lake were staked by these gentlemen. At the time of my visit the claims were being examined by C. G. Daimpré for A. R. Porter, of Toronto. Mr. Porter was on the ground and before leaving procured an option on that part of the property on which the gold-bearing veins are located.

Geology.

The rocks in the area to the southwest of Goudreau are dominantly basic volcanics of Keewatin age. Rocks of this character were observed from Goudreau all along the portage route to Murphy lake. The ellipsoidal structure, along with amygdules so characteristic of much of the Keewatin, is frequently seen. In places the basic lava contains considerable carbonate and is lighter-colored than the normal dark-colored rock. Most of the lavas are altered to schist which has a general strike nearly east and west. With the lavas there is a small amount of banded iron formation, magnetite and silica, seen on claims 408 and 412. In the vicinity of Goudreau the main iron formation zone is prominent. Two of the large iron pyrites properties, the Goudreau mine of the Nichols Chemical Company and the Rand Consolidated Mines, are near Goudreau; neither of these is in operation at the present time.

With the basic volcanics in the vicinity of Murphy lake there are several intrusions of quartz-porphyry or quartz-feldspar-porphyry; these acid rocks are generally schistose like the darker lavas. Some of the quartz-porphyry occurs as dikes crosscutting the strike of the lavas flows. One small mass of porphyry intrusive into the basic rock can be observed on the north line of claim 407.

A mass of grey granite, gneissic in places, occurs on several claims to the west of the gold discovery.

Several narrow dikes of diabase with a N-S strike cut the older formations. One of these, along the east line of claim 459, is an olivine diabase. The rock relationships are illustrated in the attached geological sketch map.

Veins.

The first discovery of gold was made in a quartz vein in the southeasterly part of claim 408 where, for a distance of about 20 feet along the hanging-wall side of the vein, there are a number of showings of quite coarse gold in the quartz. The quartz vein has been traced by trenching and outcrops for about 800 feet on claim 408. It strikes approximately N. 30 deg. W. and the dip, where observable is from 60 deg. to 80 deg. S. It varies in width from seven inches to three feet. Along the quarts vein the wall rock has been altered in places to rusty schist containing ankerite and sericite and carrying quartz veinlets together with sulphides at different points. The width of the altered rock appears to vary greatly, but, owing to the small amount of cross-trenching, the width of the possible mineralized wall rock could not be determined. The hanging-wall contact of the quartz and schist is more definite than the footwall. At the location of the gold showings, the vein, including the wall rock, is about 3 feet in width, while 15 feet to the north is a subsidiary quartz vein a foot in width, to the north of which is a band of ankerite. Twenty feet to the west this smaller vein is only 3 feet from the main vein. The quartz vein in places is well mineralized with the sulphides, pyrites, copper pyrites and pyrrhotite; 150 feet southeasterly from the above showing the quartz vein is about 7 inches in width and, in a thin band of sugary quartz and schist on the hanging-wall, visible gold was seen.

Work has also been done on claim 407 to the east. At the west line, 200 feet north of Murphy lake, a narrow quartz vein about a foot in width has been traced 65 feet; it strikes S.80° E. The wall rock for a few inches is quite rusty and carries sulphides. Visible gold was observed at two points along the vein. About 200 feet easterly from the west line work has been done on a wide ankerite-schist band up to 20 feet in width which carries quartz veins roughly parallel with the ankerite band. It has been traced for 170 feet in a direction S.70° E. No visible gold was observed in this vein, but at one point an assay of $6.00 in gold was obtained over a width of 2 ft. 9 in. of quartz and $4.00 in gold over a width of 5½ ft. of the schist and carbonate, carrying quartz, lying to the north. Owing to the highly altered character of the schist by oxidation, the latter assay is only indicative of the presence of gold which may be concentrated. The quartz vein carries pyrite, copper pyrites, pyrrhotite, and a little zinc blende. It is possible that this easterly vein is the faulted part of the vein exposed on claim 408.

A geological sketch map showing the approximate location of the veins on claims 407 and 408 accompanies this memorandum. A number of assays of samples obtained at points along the veins showed gold values ranging from a few cents to $28.00 per ton. In addition, two assays were made of specimens of quartz carrying a high percentage of sulphides, from a pit a few feet west of the rich gold showings, which gave $31.20 and $48.80 in gold.

The property, however, was not in condition for any

thorough sampling since few cross trenches had been made exposing the walls of the vein and none below the superficial oxidation. The main vein shows high-grade ore for at least 40 feet near the discovery, but extensive work will be required to determine the possible ore shoots along the veins, since large portions of the vein are concealed by drift. C. G. Daimpre is at present examining the property for A. R. Porter of Toronto. Cross trenches and blasting to the unoxidized vein, preparatory to sampling, will be carried on, and it is expected that a shaft will be sunk on or near the rich section of the main vein.

Townships 48 and 49.

A short trip under the guidance of Jas. Cline, a prospector, was made northeastward from Goudreau in townships 49 and 48, range 27. Gold has been discovered on a number of claims between Goudreau station and Goden lake, which lies in the southeast part of township 48.

McCarthy-Webb.—The McCarthy-Webb group of claims 2049, 2050, etc. near Iron lake, has been described by W. H. Collins in his report on the Magpie-Hawk area. Briefly, the rock is a schistose porphyry which, in places, is a quartz-porphyry with a strike N.84° E. mag. Shear zones occur in the porphyry and these are indicated by a rusty surface containing vague quartz veinlets, which is in marked contrast to the white porphyry. The rusty streaks are very irregular in length and breadth, being from a few inches to a few feet in width, containing fine-grained iron pyrites. Gold in a very fine state has been found in the rusty zones. In addition, there are widely separated transverse veinlets of quartz carrying much tourmaline in which coarse gold has been discovered. These veins are more definite than those running with the schist. The property has been sampled several times, particularly in one place, for a length of 100 feet where the rusty condition is most pronounced.

Morrison.—The Morrison claim, 2075, on the north shore of Goudreau lake, is similar to the McCarthy in structure. However, the rusty zones running with the schist are less pronounced, while there are more of the transverse quartz-tourmaline veins. Visible gold has been found in a number of the narrow veins which are parallel to the schist and also in the transverse veins. The main shears strike from N.66° to N.86° E., whereas the cross veinlets strike N. 6° E. The latter vary from a fraction of one inch to 4 inches in width and are too far apart to mine together.

Cline.—A number of claims about 1½ miles northeast east of Pine lake were also visited. Visible gold was seen on claims 2186 and 2189. The rocks are Keewatin schist in which narrow quartz veins have been formed. A shaft was sunk 25 feet on claim 2189 in a quartz vein from 1½ inches to six inches in width in which there is a high percentage of sulphides, and visible gold. The extension of the vein to the west where it was cut by a diabase dike, has not been found.

On claim 2186 there is one narrow rich quartz vein about 5 inches wide in which gold has been found over a length of 20 feet. A second vein from 8 inches to 3 feet wide occurs on the claim. It consists of quartz and schist on which a 5-foot pit has been sunk. Material from this vein showed much gold on panning. Owing to the heavy drift covering it is difficult to trace the veins any distance.

Some rusty shear zones were also observed on claims 2183 and 2184. On claim 2184 in one trench the rusty zone is 15 feet in width, which diminishes rapidly to the west. Some visible gold is reported near the north wall. Sufficient work has not been done on any of these claims to determine their value.

Literature.

The geological reports on the Michipicoten area for the greater part refer to the iron ranges. These reports include those by W. H. Collins, J. M. Bell, A.P. Coleman, and A. L. Parsons. W. H. Collins in his report on the Ore Deposits of Goudreau and Magpie-Hawk Areas in Michipicoten District, Geological Survey of Canada, Part E., 1918, refers to the gold area to the northeast of Goudreau. His geological map of the Goudreau Pyrite Area extends westward to within a mile and a quarter of the Murphy claims.

Ellis Thomson is at present in the field for the Geological Survey continuing the mapping of the area begun by W. H. Collins. His work will include an examination of the area southwest of Goudreau in which the Murphy claims are located and the area near Pine lake.

THE McINTYRE MILL.

When the treatment of ore was begun at the McIntyre, the chief source of ore was from deposits near the southern boundary of the property. The present mill and cyanide plant grew up close to the shafts on the south shore of the lake. Then as development proceeded, the source of ore became to a larger and larger extent the deposits north of the lake. For some time consequently it has been necessary to bring the ore across the lake from the mine. Now that additional milling facilities are being arranged for, the management has had seriously to consider whether to build a complete plant near the main hoisting shaft or to make an addition to the present mill and continue to bring ore across the lake. It appears that a compromise plan has been decided upon and that the procedure will be to install working machines on the mine side of the lake and utilize the present cyanide treatment plant, with necessary additions. The pulp from the grinding mills will be brought across the lake for cyaniding.

At present the ore at the McIntyre mill is crushed in cyanide solution. In the proposed new method of treatment, however, the ore will be crushed in water and treated chemically before cyanide is added. This breaking of the operation into two stages will therefore confine the cyanide treatment to the pulp and makes a division in process that will fit in well with the proposed division in plant.—R. E. H.

LAKESHORE.

Treating less ore than in April or May the Lakeshore produced more gold in the month of June than in the two previous months together. In June 1,656 tons was treated which yielded $52,539 an average of $31.73 per ton. As the ore treated during the early part of the year was considerably lower grade than that previously treated, the June record is of particular interest. Drifting during June, was carried on at the 400 ft. and 600 ft. levels.

The comparatively low-grade block of ore which has been responsible for the lower average recovery for some time has evidently been worked out. As much of the ore treated comes from drifts or drift stopes it would appear that good results are being obtained in development at both the 600 and 400 ft. levels as well as in stoping.

Flat Screens

A Discussion of Screening Capacity.

JOHN S. WATTS, New Glasgow.

The question is often raised as to what area of screening surface is required to screen a given tonnage of a given material, the idea being that for any given material, a certain number of tons can be screened per square foot per hour, and that if this tonnage can be found by reference to a technical text-book, all that remains is to divide the maximum tonnage per hour, to be screened, by the tons that can be screened per square foot of screening surface per hour, as given in the text book, and the answer will be the area of screen required.

For reasons that will appear later on in this article, it is impossible to state the capacity per square foot of any screen on any material until all of the varying factors, many of which are not controlled by the screen at all, are known and their effect on the screening capacity rightly determined. It is therefore not possible to give an empirical formula for screens, and for that reason nothing but the vaguest, if any information, is given in the reference books, and the subject is one that has had very little attention by technical writers.

On the other hand, the action of any particular type of screen can be subjected to analysis, and from a study of the laws governing it, a close approximation to the actual capacity can be calculated, especially so if we have data available of the capacity of a similar screen. Great care must however be taken in basing calculations for a proposed screen on the performance of an existing screen, to make due allowances for all the conditions which effect the capacity of a screen, as it is easily possible for a slight change in one or other of the factors to reduce or increase the screening capacity by one hundred per cent or more.

The first point in deciding the capacity of a proposed screen is to take into account only that area of the screen which is actually covered by the stream of material. That is, if a belt conveyor two feet wide, is delivering onto a screen six feet wide, there will be two feet of screen at each side which is not covered by the material, and is therefore of no value, for that length which the material travels along the screen until it spreads or thins out to the full width of the screen, if indeed it ever does.

On the other hand, it is absolutely essential for the efficient removal of the fines, that the screen be sufficiently wide and long so that the stream of material will, before leaving the screen, be reduced in thickness to that of the size of particle that will pass through the screen. This because every particle of the material must come into actual contact with the screen, it being obvious that if the stream is any thicker than one individual piece, some material that should pass through the perforations may ride across the screen on top of the larger particles.

At the same time it is obviously useless to make a screen wider than the width to which the stream will spread itself out, and owing to the perforations in the screen, particularly in wire-cloth screens, tending to prevent any sideways travel of the material, it is useless to make the screen much wider than the width of the stream as delivered to it, unless some measures are taken to compel the stream to spread out. The methods used to ensure the stream being spread out to cover the full width of the screen will be taken up later in their proper place.

Presuming then that we having determined the maximum effective width that we can give the screen, the thickness of the stream will be determined by calculating the sectional area of the stream by dividing the maximum cubic feet of material passing over the screen per minute, by its velocity in feet per minute. This area divided by the width of the stream will be its initial thickness, assuming that the feed to the screen is in a stream of equal thickness throughout its width. If, as often happens, the stream is deeper in its centre than at its sides, the side portions of the screen will not get their proper proportion of the material, and the screen will require to be made long enough for the central portion to screen the thickest part of the stream.

To determine the length of screen to handle a stream of a given thickness as calculated above, it is necessary to study just what happens while the stream is traversing the length of the screen. In a general way as the stream advances, the fines in the strata next to the screen will fall through the perforations, and the fines above gradually percolate down through the stream, until they ultimately reach the screen and also fall through it, thus reducing the thickness of the stream by the removal of that percentage which will pass through the screen holes.

The minimum length of the screen then, must be that length through which the stream will travel along the screen in the time which it will take the particles of fines on top of the stream to travel down through the stream, and reach to and fall through the perforations. It is clearly impossible to determine the time it will take the fines to pass through the stream, except by measurement on some existing screen working on similar material, or by experiment. Where it is possible to do so, the best method is to observe the length of screen required to effectively remove the fines from a given thickness of stream, choosing the screen for observation that is nearest in type to the proposed one, and on material as near as may be the same as that to be screened. This length being once accurately determined for a given material, in a given mixture as to sizes of particles, on a given type of screen, with given perforations, we can calculate the screen required for any output of the same material with absolute certainty, if the other factors remain the same.

That is the width of the stream of material as delivered to the screen will fix the width of the screen, and calculation will give us the thickness of the stream as explained above. The length of screen required will be in direct proportion to this thickness, being in the same proportion as that determined by the test suggested above, so long as the other conditions outside of the thickness of stream remain as before. As the condition will very rarely be the same precisely it will be necessary to observe what the effect of any variation of these conditions will be upon the capacity of the screen.

A mixture containing a high percentage of large particles will allow the fines to pass through the stream

much more quickly than one which consists of particles nearly uniform in size.

The larger the perforations in the screen the more rapidly will the screening be done. The nature of the material itself also varies the length required to screen, as a sticky material, especially if wet, will take much longer than a dry hard material will.

The thickness of stream which can be screened on a certain length of screen, varies practically in direct ratio with the size of perforations in the screen, that is if we have two screens of the same length but one having perforations four times as large as the other, the screen with the large perforations will screen a stream four times as thick as the other, the other condition being equal.

The greater the percentage of material which will pass through the screen, the more rapidly will the screening be performed, or in other words, the shorter will be the length of screen required for a given quantity, the length of screen being about in inverse proportion to the percentage of fines.

The capacity of the screen may be reduced by the choking of the perforations; the more vibration a screen is subjected to, the less choking will occur, and a perforated plate is more liable to choke than a wire-cloth screen, or a fixed bar-screen. For a wire-cloth screen it is almost always essential to have some kind of vibration to prevent choking, and for material that is at all wet or sticky, a knocking screen is best, as the jarring of the screen shakes the fines loose from the screen, which would otherwise soon fill up and become useless.

The delivery to the screen is an important factor, as if it is at all intermittent in character, the screen must be calculated to take care of the maximum feed, and not of the average, otherwise when a sudden increase in the feed occurs, the screen will allow some of the fines to pass over into the coarse. This condition may be alleviated somewhat, and the stream also widened and thinned at the same time, if it is possible to have the delivery made by a chute fitted with a gate, the chute being widened out at the bottom to the full width of the screen, and the gate set to leave an opening under it, just sufficient to allow a steady stream to pass through of an even thickness.

If the velocity of the material over the screen can be made greater than that of the feed, the stream will in increasing its speed, thin out and so accelerate the screening, and it is therefore the speed of the material over the screen that must be used in calculating the thickness of the stream, and not the speed of the feed. At the same time the velocity of the material over the screen must not be so great that the fines will acquire sufficient momentum to jump over the perforations. This velocity must never exceed 300 feet per minute, and is better kept below 200 feet per minute. To make sure of preventing this jumping over the holes, they are in perforated plates usually slot-shaped, being three or four times longer measured along the chute than they are wide measured across the chute.

To summarize, the procedure is to determine by calculation the speed of the stream over the screen, and from that the thickness of the stream that will give the required output, the width being already fixed by the feeding arrangements to the screen. From the best data available or by test on the screen nearest like the under consideration, decide on what length of screen will handle this thickness.

In the absence of any more exact information, it may be taken that under fair average conditions, screening rock that is dry and not sticky, a screen 9 feet long with ¼ inch perforations will screen a stream 12 inches thick. As stated above, the thickness of stream that can be screened varies as the size of the perforations.

UNITED STATES PRODUCTION OF FLUORSPAR IN 1920.

The total quantity of fluorspar reported as shipped from domestic mines in 1920 according to figures compiled by Hubert W. Davis, of the United States Geological Survey, was 18,778 short tons, valued at $4,718,547, which shows an increase of 35 per cent in value as compared with the figures for 1919. The general average price per ton f.o.b. mines or shipping points for all grades of spar in 1920 was $25.26; in 1919 it was $25.49.

The total quantity of merchantable spar recovered in 1920 was 201,372 short tons, an increase of 31 per cent over 1919.

Stocks of spar at mines or shipping points, mainly in Illinois and Kentucky, amounted to 41,784 short tons, an increase of 31 per cent over 1919.

Imports and Exports.

The imports of fluorspar into the United States in 1920 were 24,612 short tons, valued at $265,630, an increase over 1919 of 254 per cent in quantity and of 147 per cent in quantity and of 147 per cent in value. Of the imports England supplied 69 per cent, Canada 29 per cent, Germany 1.6 per cent, and Australia and British South Africa supplied small quantities.

The exports of fluorspar from the United States Geological Survey by the producers, amounted to 2,764 short tons, valued at $65,475. All the fluorspar exported was sent to Canada.

The imports of fluorspar during the first four months of 1921, the greater part of which was brought from Canada, amounted to 4,049 short tons, valued at 339,990. The figures showing the imports were compiled from the records of the Bureau of Foreign and Domestic Commerce, of the Department of Commerce.

Consumption and Stocks.

Figures furnished by steel manufacturers who produce about 75 per cent of the output of basic open-hearth steel show that the steel industry consumed about 117,000 short tons of fluorspar in 1920 and that the stocks of spar on hand January 1, 1921, at all steel plants were about 66,600 short tons. From January 1 to April 30, 1921, about 22,600 tons of spar was consumed by basic open-hearth steel plants. Figures showing the shipments of domestic fluorspar to steel plants during this four months period are not available, but the total was evidently small, and of the 4,000 tons imported practically all has been taken by steel manufacturers.

ENORMOUS RESERVES OF LIGNITE IN ALASKA.

The reserves of lignite in the Nenana region, Alaska, are estimated by the United States Geological Survey to be nearly 10,000,000,000 tons, which exceeds by nearly 3,000,000,000 tons the estimate made a few years ago, on the information then available, of the total quantity of lignite coal in the Territory. The new estimates, which are very moderate, indicate that the quantity of coal available in the Nenana coal field is greater than that in all the other surveyed fields of the Territory.

British Columbia Notes

Stewart, B. C.: Work on the tramway to the Premier Mine is being hastened at all high-level points in order that a possible early snowfall will not retard progress. This finished what is to be done at lower points along the line will receive attention. Some 70 of the ore buckets to be used on the line have arrived. About 46 miles of cable will be used on this aerial transportation system. Much of it is on hand and has been distributed along this line. — The Lake View Group, Glacier Creek, Bear River Section, is being re-opened. The old workings are being cleared out and it is possible that a shipment of high grade silver bearing ore will be made shortly. — On the Silverado, of the same District, a 40 foot tunnel has been driven and from two to three tons of high-grade ore is being sacked per week. — A tunnel has been commenced on the Montrose and Waterloo Claims of the Red Cliff.

Alice Arm, B. C.: Shipments have commenced from the Dolly Varden Mine. There are about 3,000 tons to be brought to tidewater and thence shipped to the smelter. Development, meanwhile, is to be pushed.

Nelson, B. C.: The Rampolla Group on Lightning Peak, Arrow Lakes District, is being quite extensively developed. Since July 3rd of last year 450 feet of a crossent tunnel has been driven and is expected to cut the vein at depth in a few weeks. In the tunnel 100 feet above for drift is in the ore shoot for 150 feet. The vein there is six feet wide and contains stringers up to 12 inches in width. The Lompy Group adjoins the Rompolla and on it there is a first-class showing, the vein containing values in lead, copper and gold. The property of the Lightning Peak Mining Company, now under lease, is being opened up further by the lessees. The Waterloo has not been worked this year but a start is to be made soon. The Silver Shoot, which is adjacent, also is to be developed. Some work will be done as well on the Detector Group of the same Camp.

Trail, B.C.: Ore receipts of the Smelter of the Canadian Consolidated Mining and Smelting Co. for the week from July 8 to 14 aggregated 6,929 tons. Of this 6,170 tons came from company properties. Other shippers included the Highland, Ainsworth, 28 tons; No. 1, Ainsworth, 38; Surprise Republic, 225 tons; and the Velvet, of the Rossland Camp, 53 tons.

Slocan City, B.C.: The New "Ottawa" Mill, at the Ottawa Mine, Springer Creek, a few miles above Slocan City, has been completed and already is engaged in the treatment of ore. It is specially designed for the economic handling of the dry-silver ore of the Slocan section, the flotation process being employed to a greater extent than probably by any other plant in the country. L. H. Biggar, who designed and under whose supervision the mill was constructed, and L. McPhee are partners in the enterprise. The installation of the plant was started last Fall and the plan is to first treat ore from the "dump" and eventually to develop the mine. This they have under lease and bond from the Consolidated Mining and Smelting Co. — The Black Prince, 6,000 feet above sea level at the junction of Lemon and Springer Creeks, is being opened up and a few cars of ore, already blocked out, are to be shipped. — The V and M, Barnett and German Groups, Lemon Creek, now owned by the McLeod-Slocan Mining Syndicate, of Vancouver, are being developed this Summer, a crew of fifteen men having been put to work some weeks ago. In work done heretofore good showings of ore high in silver and with substantial gold values have been disclosed.

Asheroft, B.C.: Gold is reported to have been taken from placer ground situated on the Douglas Lake Indian Reserve. As Indian lands now are open to location on the securing of a permit from the Indian Agent, and as gold and silver may be taken from such locations, considerable local interest is being taken in the recently staked diggings.

Interesting experimental work is in progress in connection with the Bentonites occurring in the Nicola and Merritt Districts of British Columbia and those found in the Province of Alberta. Samples tested so far indicate that the product of British Columbia does not compare as favorably with the well-known deposits of the State of Wyoming as does that of Alberta. It should be borne in mind that the investigation has only started, that a considerable shipment of the Bentonite of this Province probably will be made to permit further research, and that, as the matter now stands, it seems to be established that Western Canada contains Bentonite, in quantity and of the requisite quality, to hold its own in the market with the output of any other section of America.

The Chemical Industries Committee of the Imperial Mining Resources Bureau speaks favorably of the hydro-magnesite of British Columbia. The Committee will recommend the utilization of this material. The impression, however, seems to be that there is not sufficient of the material available for the manufacture of bricks for lining furnaces etc. as refractories and that, therefore, its quality being exceptional, it must be used for the manufacture of magnesia for chemical pharmaceutical purposes. There is no doubt that the hydro-magnesite of Atlin District (B.C.) would be desirable for the latter purposes because it is unusually pure and it is possible that there are other similar deposits. Then there are the deposits of the Clinton (B.C.) District. Mr. Reinecke, of the Canadian Geological Survey, referring to these, places the total visible amount of first class magnesite at about 173,000 tons. These deposits are shallow lake-bed deposits of 2 to 3 feet in thickness. They have been taken up by different companies and the development being done eventually will accurately disclose the tonnage. The quantity of the Atlin material is given as about 180,000 tons.

Alice Arm B.C.

That 3,000 tons of ore is to be shipped from the Dolly Varden Mine is the effect of a statement recently made authoritatively. The railroad also is to resume operations. No definite announcement, however, has been made regarding the resumption of continuous work at the mine.

The Copper Group of Mineral Claims, Upper Kitsoult River, is to be developed by the Homestake Mining & Development Co. G. H. Gerhardi is in charge. He proposes completing the trail, installing a compressor and driving a tunnel that is expected to strike the surface lead at 200 feet depth. The surface indications are good and George Clothier, government engineer, in his 1918 report spoke favorably of it as a prospect.

Trail work is underway by the provincial government along the Illiance river. This is a promising mineral district hitherto handicapped because of transportation difficulty and the trail will be a boon to prospectors and operators. To the Alice Arm Holdings Ltd., owners of the Bellevue, and to others interested in promising properties in an early stage of development, it will be welcome.

Greenwood B.C.

The Tam O'Shanter Property, situated in Deadwood Camp about four miles from Greenwood, is reported to be looking up, a lead having been struck running high in grey copper and native silver.

Hope B.C.

S. A. Parnall is opening up the "Pipestem," Ladner Creek. His tunnel now is down 150 feet and he expects to strike the lead within another 60 feet. If this property justifies the work now being done it will mean much for the Coquihalla District.

Michael Merrick is working on the "Emigrant," where low values in a large body of ore are said to have been demonstrated.

Work on the "Emancipation" continues. The richness of comparatively small "shoots," off the main vein, persist and the outlet is about the same as at the time Wm. Fleet Robertson, provincial mineralogist, made his report, published in the Annual Report of the Minister of Mines. The large body of ore, carrying uniform values, has yet to be proven but the management is confident of success. Onee this point is demonstrated the rest will be easier than the ease of most properties because transportation and other operating problems are simple.

Trail B.C.

Disadvantages under which the metal industry of British Columbia is laboring because of the "inconsistencies and injustices" of the present tariff on metals and minerals entering Canada are pointed out in a memorial prepared by the Trail Board of Trade and forwarded to the Canadian Minister of Finance.

Referring to the wire rod business it is set out that this material now is imported free of duty "when manufactured by the importers in their own plants." If this situation is continued it is argued that the Trail Smelter Plant, capable of producing 15,000 tons of copper rods per annum, is placed under an unfair handicap. It is asked that rods be protected to the same extent as ingot copper, namely 1 ½ per pound. Without this "there is no chance of the expansion of the refining industry in British Columbia and Canada will continue to pay foreign plants for refining copper used in making rods for Canadian consumption, as well as for rolling the copper into rods after refining."

The extension of the copper item in the tariff to include scrap eopper also is sought because for many purposes it is as good as virgin, a great deal of that left in connection with munition manufacture had been dumped into Canada, and that this might be expected to continue in a modified degree in the near future. Scrap zinc and scrap brass, it is stated, shonld be subjected to a duty for the same reasons are given relative to eopper.

The memorial closes: "In general, the effect of the lack of duty on the above mentioned items is to encourage the building up of refining and manufacturing industries in the United States at the expense of Canada and to delay, for an indefinite period, the establishment of complete copper and zinc industries from the mining of the ore to its use in manufaetured forms."

THE COAL MINES.

Statistics illustrative of the production of the collieries of British Columbia for the first half year of 1921 as compared with the same period of the previous year are not satisfactory. It is shown that coal output has rather considerably declined. In 1920 the first half year's production totalled 1,367,502 tons. This year's figures are 1,231,406 tons. There has been a decline therefore of 136,096 tons. A closer investigation indicates that the decline is not peculiar to any particular section, but no one coal field is responsible for the downward trend of production but that all the collieries are responsible. some to a greater and others to a lesser extent. The Crow's Nest Pass in 1920 up to the end of June produced 433,210 tons; this year's figures show an ontput of 351,759 tons from the same mines. a decrease of 81,451 tons. The Vancouver Island Collieries, or rather the principal producers of the Island field, produced in the first six months of 1920 a total of 857,940 tons while in the same period of this year they have to their credit 799,662 tons, or a decline of 58,278 tons. What explanation lies behind this statement is hard to say unless it be that, in the case of the Island Collieries, the domestic trade has fallen off because of the tendency of the consumers to hold back in purchasing their winter supplies for a possible fall in retail prices, and, in the case of the Crow's Nest Pass, the industries both of this Province and of the adjacent States are not operating on as large a scale as during the early months of last year. Of course the attitude of the domestic consumer would also affect the East Kootenay Collieries but not, perhaps, as much as it does the island operators. In any event there are no labour distnrbances and it is quite possible that the production of the remaining months of the year will show such an increase as to more than overcome what has been lost, as against 1920, during the first half of 1921.

The White Lake Collieries Ltd. capitalized at $400,000, has been incorporated to open up coal lands situated some fourteen miles north of the town of Keremeos, Nicola-Princeton Coal Field. Mr. Benjamin Barlow has been appointed manager of operations. It is the intention to install the plant necessary to begin and to maintain production on quite a substantial scale.

The provincial government reserve on the coal lands has been removed, an Order-in-Council being passed to this effect in the course of the past few weeks. The withdrawal of restrictions in respect to the staking of coal applies to all parts of British Columbia with the exception of the east coast of Vancouver Island, and the Groundhog and Peace River Districts. The action of the government is not expected to have much effect on the coal situation. The east coast of the Island already is well staked, the Groundhog situated in northwestern British Columbia is without transportation, and the Peace River is similarly placed. The reserve was criticised on the ground that it discouraged prospecting. If its removal to the extent indicated has the effect of stimulating the search for new fields it will, in the opinion of mining men, prove a good thing.

Northern Ontario Letter

THE SILVER MINES.

The Cobalt District.

During the last few days of July the quotations for commercial bar silver showed unusual strength, the price hovering around 62 cents an ounce in New York at the time of writing this summary. Measured in Canadian money, the current quotation amounts to approximately 70 cents an ounce.

Such mines as the McKinley-Darragh, Temiskaming and Beaver Consolidated could be profitably operated under present conditions, having in mind the decline in the cost of material and the higher efficiency of the workmen. The margin of profit, of course, would probably be small and the outlook is that they with remain closed for some time longer, pending a further decline in cost of material and a possible further reduction in wages which would bring the aggregate cost of operation back to not far from the pre-war level.

Each of the closed-down mines having ore reserves and milling plants are being kept pumped out preparatory to resuming work at such time as a reasonable profit is believed to be assured, and under conditions which would offer reasonable hope for continuous operation. Were these properties to re-join those already producing at normal capacity, the industrial outlook in the Cobalt field would be very satisfactory.

The mill of the Mining Corporation of Canada is treating a greater tonnage of ore daily than ever before in its history. The equipment is now adequate to handle approximately 300 tons daily. The ore contains an average of about 20 ounces of silver to the ton, thereby indicating a daily production of approximately 6,000 ounces per day. At the current quotation for silver, the indicated production has a value of around $4,200 daily.

With ore reserves containing an average of upwards of 40 ounces of silver per ton, the Nipissing mine is in a position to realize exceptionally large profit under the favorable conditions which are setting in. The fact that at the Coniagas mine a satisfactory profit is being realized on ore which runs only 10 ounces of silver per ton gives some idea of the favorable position of such mines as have ore averaging over 40 ounces as in the Case of the Nipissing, around 40 or 50 ounces on the O'Brien and about 20 ounces on the Mining Corporation.

The daily press in Ontario is making a fairly general appeal to the directors of mining companies with the object of encouraging each company to issue a brief monthly report to stockholders. It is pointed out that such such a report need not go into detail, but could contain a summary of the amount of underground work done, the result achieved, the tonnage treated and the value produced. It is contended that such a policy would create greater confidence between the public and the mining companies and would encourage capital to engage in the mining industry.

During June, according to a regular monthly statement issued to the Journal by Arthur A. Cole, mining engineer for the T. & N. O. Railway, the mines of the Cobalt district shipped 275 tons of ore to Canadian and United States smelters. The Coniagas was the heaviest shipper with 156 tons, the following being a summary :

Silver Ore.

Cobalt Proper	Tons.
1. Bailey	16.91
2. Coniagas	156.02
3. LaRose	10.95
4. O'Brien	32.00
	275.88

The above shipments were made to the following Companies:—

Canada.

Delora Smelting & Refining Co., Delora	32.00
Coniagas Reduction Co., Thorold	153.17

United States.

American Smelting & Refining Co., Perth Amboy	43.80
Pennsylvania Smelting Co., Carnegie	46.91
	275.88

Price of Silver.

June 20th. Highest	59.875
June 6th. Lowest	57.375
Average	58.510

Elk Lake and Gowganda.

There are good prospects of further exploration and development work being done this Fall in the Cane and Auld township section of the Elk Lake district. The Cane Silver Mines contemplate early activity, while the Ontario Solid Silver Mines may resume work after lying idle for the past five years. The Silver Triangle may also be re-opened, this property formerly being the Kenabeek Consolidated.

The future plans of the Trethewey Company on its Castle property at Gowganda are uncertain, no official statement having been issued since the destruction of the company's mining plant by fire some weeks ago.

The Ontario Government is pushing road work on the highway from Elk Lake to Gowganda, and the throughfare will be suitable for motor traffic this Fall. The attitude of the government toward the newer mining areas has improved, and considerable assistance is now forthcoming. This is in the form of the work on roads such as from Elk Lake to Gowganda, from Boston Creek to Skead township, from Kirkland Lake through Lebel township and from the railway to the centre of activity in the West Shining Tree field.

THE GOLD MINES

The Porcupine District.

The Northern Canada Power Company, in an official interview with the representative of the Journal, assures the mines in the Porcupine district of ample hydro-electric power with which to operate unremittingly and at full capacity. The power company is not apprehensive of any shortage of power, and believe it would be entirely unreasonable to expect a recurrence of the drought which occurred in the last half of 1920. Such a drought must of necessity always be attended with power shortage as no reasonable precaution could cope with it.

An official of the power company told the Journal correspondent that by way of taking all reasonable additional precaution against power shortage, a dam has been put in at Lake Kenogamisse so as to raise the water an additional ten feet. Other storage increases are under consideration and will be proceeded with immediately should the mining companies operating in that field express a desire to go into the situation thoroughly and make known their probable requirements. It is obvious that the power company is anxious to co-operate with the mining companies.

On August 12, the Hollinger Consolidated will disburse a dividend of 1 p.c., amounting to $246,000. This will make a total of $1,968,000 paid so far this year and an aggregate of $15,328,000 to date from the Hollinger. The company continues to treat approximately

3,200 tons of ore daily and the gross yield is at a rate in the neighborhood of $10,000,000 a year.

Reports that the Triplex property had shipped five tons of ore to the Ontario Government testing plant at Cobalt and that the ore averaged around $300 per ton are erroneous. No shipment of ore has so far been made to the plant at Cobalt.

An examination of the new gold find at Bourke's Siding as reported in last week's "Journal" proved the find to be of small importance. The pay-streak appears to be not more than eighteen inches in length and about one inch in width. Samples of the ore are among the richest gold specimens ever taken out of property in this country, but unless further work reveals values over greater length and breadth the new find will not be of any importance other than indicating the possibility of other pockets perhaps of greater size in that vicinity.

Kirkland Lake Field.

On August 10, the Lake Shore will disburse a dividend of 2 p.c. This will call for the distribution of $40,000 and will make a total of $80,000 paid so far this year. Since commencing production March 8, 1918, the Lake Shore has paid $320,000 in dividends in addition to developing the property up to a point where a large mill is warranted. This has been done by operating a mill with only 60 tons daily capacity.

The Queen Lebel Gold Mines is the name of a new company which has been incorporated for the purpose of opening up a group of mining claims lying in the township of Lebel south-east of Gull Lake. The company is capitalized at $2,000,000 and has 160 acres of promising mining land. The work of erecting camps will commence this week.

The annual meeting of the Wright-Hargreaves will be held within the next few weeks. The company started its new mill early last spring and is now producing approximately $2,000 daily. Some important information is expected to be given out at the annual meeting.

A diamond-drilling machine has arrived at Boston Creek and will be used on the Miller Independence mine. Drilling will commence about the end of this week.

Mining Commissioner T. E. Godson, K.C., held his regular monthly sittings, last week in the district of Temiskaming. The list included a total of five mining disputes, two of which were in Timmins and three in Haileybury.

Following is a summary of the disputes:

Timmins Court, July 27.

Donald McCulloch vs Duncan McPhail, this being an appeal from the decision of the mining recorder in respect of mining claims No. P. 8285, P. 8285 and P. 8287.

Terry J. Lyons vs Prosper St. Paul, in connection with a dispute affecting mining claim N. P. 8301, situated in the township of Shaw in the Porcupine Mining Division.

Haileybury Court, July 29.

W. H. Smith vs D. A. McPherson, this being a dispute affecting mining claim No. L. 8200, situated in the township of Lebel in the Larder Lake Mining Division.

Re William Hersee Estate: An application for Vesting Order affecting mining claim No. L. 4681, situated in the township of Lebel, in the Larder Lake Mining Division.

J. Potvin vs H. O'Byrne, this being a dispute affecting mining claim L. 9257 situated in the township of Skead in the Larder Lake Mining Division.

COBALT.

Most of the cobalt used in the United States comes from Canada, where it is produced as a by-product from the silver ores of the Cobalt district. The only producer in the United States in 1920 was the Missouri Cobalt Co. which recovered 102,410 pounds of cobalt oxide and cobalt hydrate from ore mined at Fredericktown Mo. Canadians are interested in this enterprise also. At present there is a poor demand for cobalt, but in 1920 the United States took Canadian cobalt and cobalt compounds valued at $731,277.

THE GOLD PRODUCER AND THE EXCHANGE RATE.

R. E. HORE.

It is reported from Cobalt that gold mining companies operating in the Porcupine district are not very keenly disposed to co-operate with a view toward reducing the rate of exchange. Why should they be expected to be desirous of cutting down their profits? If commodities are falling in value and the value of gold is steadily increasing relatively, the gold producer is surely not going to exert himself to keep up the cost to war-time figures. If the exchange rate rises because of trade conditions and brings a premium to the gold producer, is it likely that the gold producer is going to attempt to keep the exchange rate down? Knowing that a very considerable portion of the profit from gold mining in Canada arises from the fact that there is now and is likely to be for some time a premium on gold, is the producer likely to dissipate his profits in an attempt to keep other industries on a war time basis or to waste money in hauling materials long distances in order to make other enterprises appear to be more economically sound than they really are? Surely this is not the purpose of mining.

The industrial depression that has been for several months worrying the people of Canada and the United States is admittedly largely due to the production during the previous years of materials at too high a cost and in quantities which could not be marketed. Even last Summer there was a serious shortage of men at Ontario gold mines because of the ridiculously high wages which were being paid in many industries in a mad attempt to keep down costs by increasing production at a time when the market would not absorb the output. From the standpoint of the worker the wages did not seem so high because of the high cost of living, but the sales managers have long predicted the crash that must come owing to the rapidly failing market for high-cost goods.

Slowly now, but none the less surely, conditions are righting themselves. Gold, the standard of value, is said to be at a premium, which is only another way of saying in these days that it is still worth par in New York funds while other forms of Canadian money are not. Products other than gold are at a discount, not because of the exchange rate on New York, but because they have been produced at too high a cost for the market.

The lowering of the exchange rate is not the business of the gold producer. Shareholders of gold mining companies would not approve of any action by mine operators which would take part of their profits to help the delay of a return to stable business conditions. The business of the gold producer is to produce now as much as he can and get the highest possible price for his gold. A return to production of commodities at pre-war costs will bring with it an opportunity to increase export trade and restore the trade balance and bring exchange to par; but until that time arrives, which will bring with it lower costs for gold mining, the interest of shareholders in mining companies will demand that the exchange rate be taken full advantage of.

There is one way in which gold producers will always be found ready to co-operate with others in bringing down the exchange rate, and that is in working towards decrease in cost of production. Decreased cost of labor and supplies will bring down the exchange rate and at the same time make for increase in gold production by making it possible to mine ore that is now being left in the mines. Decreasing cost of labor must be accompanied by decreased cost of living, for the miner must have a living wage. Decreasing cost of machinery and supplies will result in larger quantities being used and in the opening up of new mines. If anyone has a plan for bringing about a correction of the exchange rate by hastening the decrease in cost of production, he will find the gold producer very much disposed to co-operate with him.

SUDBURY NOTES.

By D. E. CUSHING.

Sudbury.—The report of A. C. Burrows, of the Mines Department on the Goudreau area, which has just been made public (see this issue), has served to convince prospectors that the reports of rich gold in that area, have a basis in fact, and quite a number are going in to stake as a result.

There was some skepticism over the reports at first as the rich finds reported were all made by trappers who had been working in the area. However the Porter interests took an option on the Murphy claims, and the report of their engineer, C. G. Daimpre, was so favorable, that the geologist quickly followed him in.

T. N. Powell, the staker of the Murray-Mogridge has just came out after staking ten claims, and he said that the reports of spectacular gold finds are not one whit exaggerated. He says that the showings are just as spectacular and sensational as they were at the Croesus and extent over a much greater area.

The Algoma Eastern Railway controls the lands on which the finds have been made so that it is not necessary for a prospector to have a license to stake. The conditions of staking are, however, just the same, as are also the assessment work conditions.

Much interest is being taken in the recent discoveries reported at Crerar on the C. N. R. It is said that the formation there is much the same as at Kirkland Lake. A large number of claims have been staked and the Gold Nugget Mining and Development Co., with headquarters here, has been formed to take over some properties. The company is now making preparations to undertake some work on their claims. The Mine Service Corporation of Sudbury, is also in the same field and it proposes to start sinking on a surface outcrop immediately. It has just made a call on its shareholders, one hundred Sudbury merchants, for the funds necessary to carry on the work.

This new gold camp is about 18 miles northeast of Sudbury, in the townships of Kelly, Davis and Rathbun. The formation is mostly conglomerate schist with intrusions of diabase and porphyry. Quartz veins of varying thickness traverse the schists highly mineralized in places and containing some gold.

Several prospectors are now in the area staking claims, and it is believed that by the Winter there will be much activity. Specimens of ore, brought to Sudbury carry free gold. E. S. Bennet, Orillia a prospector, made the first discovery in the camp. E. J. Townsend, heads the Gold Nugget Co. George E. Charsley is secretary-treasurer.

Railroad statistics show that of the total tonnage carried by Canadian railroads over one third originates from mines. American railroads report that slightly more than one half of their freight was from mines.

THE DIVINING ROD.

Instruments Supposed to be Useful in Discovering Buried Treasures, Mineral Deposits, Deposits of Oil, and Underground Water.

The idea of a "divining rod" or some other instrument that may be used as a means of finding buried treasure, mineral deposits, and underground oil or water is a superstition that continues with marvellous persistence in spite of the lack of tangible results from its employment.

It may be said without qualification or exception that no rod or instrument has yet been devised to find buried treasures, nor any instrument that will indicate the presence of gold, silver, copper, lead, zinc, or other nonmagnetic metals, or their ores, that are hidden from view under ground.

Iron, nickel, and some minerals that contain these metals are magnetic, and the dip-needle or miner's compass has been adapted to use in prospecting for these metals. Such an instrument can be purchased, but special training is required to enable anyone to use it successfully. A volume published by the United States Geological Survey Department of the Interior, entitled "Mineral Resources of the United States, calendar year 1911," Part I, pages 144 to 154, contains a discussion of methods of prospecting for iron ore by magnetic surveys and by drills. Although the use of the dip needle is theoretically simple, much practice is required to make accurate observations with it, and after these are made they must be interpreted by the consideration of many factors, so that the unskilled user is likely to be disappointed in his results. The edition of the volume above mentioned available for free distribution is now out of stock at the Geological Survey, but a copy may be purchased from the Superintendent of Documents, Washington, D.C., for 90 cents.

Gold, silver, copper, lead, and zinc are not magnetic, and no instrument now in use will indicate the presence of these metals or their ores if they are hidden from view within the ground. Devices that are supposed to indicate the presence of concealed nonmagnetic ore are usually offered for sale either through ignorance or with intent to defraud. Some honest attempts have been made to prospect for nonmagnetic ores by measuring in different directions the capacity of the ground to conduct an electric current, the idea being that ground containing metallic material will conduct the current better than that which contains none. These attempts, as well as trials with other electrical devices, however, have not been successful, and the various forms of such apparatus could not be used by one unfamiliar with electrical work.

Some measurements of the electric potential of metallic minerals were made several years ago in the laboratory of the United States Geological Survey by R. C. Wells, and the results were published in the Survey's Bulletin 548, entitled "Electric activity in ore deposits," which may be had for 10 cents from the Superintendent of Documents. The results obtained by Mr. Wells, however, do not afford an adequate basis for any method of electrical prospecting, and it is still doubtful whether electrical methods of prospecting for nonmagnetic ores will ever be useful, although they may have limited application in searching for certain kind of ores. Most deposits of the precious and semi-precious metals and their ores are discovered by those who, by experience, have become familiar with the kinds of rock in which the ores are found and who use the ordinary methods of prospecting.

No instrument other than the drill has been devised that will indicate the presence of water or oil underground. In determining the probable existence of underground supplies of these liquids geologists are guided by their knowledge of the relation of beds of rocks visible at the surface to beds that contain oil or water at other places in the same general region. They also make use of the recognized relation of occurrences of oil or water to certain structure (folds, faults, etc.) in the rocks, and of surface indications, such as oil seeps, springs, outflow of gas, etc. The United Geological Survey has published as Water-Supply Paper 416 a report by A. J. Ellis, entitled "The divining rod, a history of water witching," which shows the uselessness of the instrument. This report may be obtained of the United States Geological Survey, Washington, D.C.

THE WORLD'S COAL PRODUCTION.

Reports received by the U.S. Geological Survey show that the world's coal production in 1920 was 1,300,000,000 tons. The production in 1919 was 1,158,000,000 which was less than that of any of the eight preceding years. The United States production in 1920 was about 645,663,000 tons as compared with 546,155,000 tons in 1919. The short production in 1919 resulted in the general alarm in 1920 and the consequent high prices and comparatively poor quality of coal produced. The 1920 production was about normal in quantity, but was produced at high cost and sold at very high prices.

TORONTO COAL PRICES.

Toronto, 3rd August.—The price of slack coal is still stiffening up. It is now anywhere from $1.75 to $2.00 a ton, with the prospect of a further advance. In spite of the stiffening in price, however, buyers are not coming forward in any great volume. Lump coal continues at the same price—about $2.60 to $2.90 a ton—but the demand for it is weak. Anthracite of all kinds advanced 10c a ton on the 1st of this month. That is the usual practice at this time of year—to advance the price of anthracite coal 10c a month for five months from August, so that, other things being equal to the person who buys coal in July gets it at 50c a ton cheaper than the person who buys it in December. The public are still holding off from buying their winter coal believing apparently that a drop in prices will not be long delayed though this the dealers emphatically deny.

TAXABLE SURPLUSES OF MINING COMPANIES IN ONTARIO.

In view of that fact that the annual earnings and the dividends paid by mining companies include return of capital as well as profits, the reported earnings of a mining company and its distributed earnings do not properly represent the earnings and dividends that should be taxed. It is common practice in Ontario to assume that one half the earnings should be applied to reduction of capital, and as such should not be taxed. The operation of a mine must result in removal of the ore and those who are taxed on reported earnings or dividends will do well to inform tax-gatherers as to the nature of the mining business.

In the case of the Dome Mines, Mr. Alex. Fasken, the secretary of the company, has advised shareholders resident in the United States to take note that it is the practice in Ontario to allow one half the net operating profits of a gold mine to be applied to ore depletion and only one half is considered as accessible for income tax.—R. E. H.

THE SYLVANITE MINE—KIRKLAND LAKE.

The completion of arrangements for financing development of the Sylvanite property will doubtless be soon followed by active operations there. The Sylvanite is very favorably located between the Wright and the Tough-Oakes mines, and exploration will very likely result in much ore being found. The property has been for some time idle; but the reported arrangements indicate that a satisfactory basis has been found for the resumption of work. English and American interests will jointly finance and control the operations.

With the Sylvanite operating, the main ore belt at Kirkland Lake will be under development at six mines, Tough-Oakes, Sylvanite, Wright-Hargreaves, Lake-Shore, Teck-Hughes and Kirkland Lake Gold Mines. The latter four are producers and Tough Oakes is equipped with a first class mill.

In view of the fact that the Sylvanite is largely owned by people interested in the Tough-Oakes or Wright-Hargreaves, development of the Sylvanite is likely to proceed rapidly now that terms have been agreed upon.—R. E. H.

EDITORIAL

THE MACKENZIE OILFIELD.

In this issue appears a partial reprint of a description by E. M. Kindle and T. O. Bosworth of the oil-bearing rocks of the lower valley of the Mackenzie, and, by courtesy of the Director of the Survey, some of the photographs and maps accompanying the description as it appeared in the Summary Report of the Survey for 1920. The actual finding of oil, in quantity estimated as being a thousand barrels a day, and flowing under fair pressure, rewarded the geologists of the Imperial Oil Company when a demonstration borehole was put down at a spot not selected with the hope of great production, but because it afforded the most easily accessible location where a hole of moderate depth "could not fail to penetrate the petroliferous formations", and that within the limited time available for drilling. This substantial achievement, following years of work, based on geological reasoning, and indicating the probable existence of a Paleozoic oilfield of continental extent in a remote and inhospitable land, immediately aroused intense interest in Canada. For one reason, the search for oil and its discovery at Fort Norman, brought to public realisation in Canada that the days of great adventure, our "heroic age" as it has been called, are not yet passed. Had a novelist, seven years ago say, described the flight of an all-metal airplane for the cities of Alberta to a flowing oil-well at Norman, vision would have seemed wild and incredible. Yet seven years ago the airplane was a practical invention and the records of the Geological Survey, in numerous places, suggested the presence of oil in the North. A second reason for public interest is the significantly wide appreciation of the value of oil, which is a reflex of an unremitting and slightly hysterical propaganda that for three years has filled the newspaper columns and given the average newspaper reader a viewpoint on the importance of oil that is anything but judicial or correct.

In view of the undoubted importance of the Mackenzie Valley "where the conditions conducive to the formation of oilfields are very favorably fulfilled", the unusual space devoted to Messrs. Kindle and Bosworth's description in this issue is justified by the very general interest taken in this territory.

NORTHEAST LABRADOR AND NEW QUEBEC.

Dr. A. P. Coleman's memoir on the northeastern peninsula of Labrador, between Ungava Bay and the North Atlantic, is a description in accordance with the best traditions of the Geological Survey. It is a note of observations in the country that Dr. Grenfell has made familiar to the public, and is written in a style that combines erudition and the most competent kind of recorded observation with such clearness of diction that the account is readable with profit and pleasure by all.

Dr. Coleman writes of cataracts "falling 1,000 or even 2,000 feet," and of Nachvak Fiord, a typical trough, over 30 miles long, with a depth of water of 110 fathoms, and with walls rising to 4,000 feet in height. The climate is chill and dreary in Summer and extremely rigorous in Winter. Agriculture is impossible, and apart from the fisheries, which are prosecuted on the Labrador coast by Newfoundland fishermen, mining would be the only industry that could attract a population.

Labradorite, a most beautiful stone, is found plentifully, but "in many places it has little of none of that schillerization or chatoyancy which makes it valuable." It is suggested that if got out unfractured on a large scale, so as to be sawn into slabs, schillerized labradorite "should make one of the most beautiful decorative stones imaginable." Metallic minerals believed to be present include copper, iron ore, and pyrite, the last named being common. Graphite is present, but whether in workable quantities is unknown.

Dr. Coleman's general conclusions from the little that is known of the economic geology of the region are so suggestive that they are quoted in full, as follows:

"From the foregoing brief account of the known economic minerals of Labrador it will be inferred that no deposits of great value have yet been found;

but, on the other hand, very little search has been made for them and the slight attempts at prospecting have been made only at or near the coast and usually by inexperienced persons.

The interior has not been touched by geologists or prospectors except at a few points along a band indicated on the latest geological map as 'Keweenawan, Animikie, etc.,' where Low has proved that iron ores exist. The band runs parallel to the coast, as mapped, but is more than 200 miles inland; and north of latitude 55 degrees nothing is known by direct observation of the intervening country. It has been shown in earlier parts of this report that large areas of the Grenville-like rocks extend inland at Komaktorvik and Nachvak bays; that green schists like those of the Keewatin occur, and that probably Keewatin iron formation exists somewhere inland; that rocks resembling the Sudbury or Timiskaming series, the Huronian, and the Animikie and Keweenawan cover large areas; and that in many places basic and acid eruptives cut the older formations as dykes or form sheets among the sediments of the later Precambrian series. So far as can be seen the conditions are similar to those which have caused the economic deposits of the Grenville, Timiskaming, Huronion, Animikie, and Keweenawan series of Ontario and Quebec; deposits which have made Ontario one of the great mining regions of the world.

It is evident that the almost unknown interior of Labrador includes not alone barren granite gneisses, as commonly supposed, but probably also equal areas of other Precambrian rocks of much greater economic promise. It is a region that deserves closer study than it has yet received, and its very bareness and lack of vegetation facilitate such an examination as compared with regions largely hidden under drift or covered with forest.''

PRECIOUS METALS REPORTED IN PATRICIA, ONTARIO.

Reports have reached Toronto of claims being staked in Patricia district for gold, silver and platinum. The discoveries have been made in an area about twenty-five miles north of the English river and ten miles east of the Manitoba boundary. This is the south west corner of the new district of Patricia which forms the north eastern part of the Province of Ontario. The recording office for the mining division in which the discoveries have been made will be Kenora.

No detailed report of the discoveries has yet reached the Department of Mines. The prospectors report that the rock formations are similar to those at Cobalt. No samples of ore have come in however, and it is not known yet whether the chief values are in gold or silver. The probabilities are that the gold-bearing formations are more prominent in this part of Ontario than the silver-bearing rocks and reports of gold discoveries have been expected to result from prospecting in the area.

The available information indicates that the scene of the new discoveries is almost directly east of the Rice Lake gold area and north of Kenora. It is a part of Ontario that is considered to be a very likely place for the occurrence of gold deposits.

Some account of the geological features of the south western part of Patricia is to be found in the 1920 report of the Ontario Department of Mines. Mr. E. M. Burwash spent the field season of 1919 along a part of the sixth meridian and in the vicinity of Wessasaga, Birch Lake and Trout Lake Rivers and his report to the Department gives the results of his reconnaissance survey. Mr. Burwash is at present working further north.—R. E. H.

TORONTO GETS NOVA SCOTIA COAL BY WATER ROUTE.

One of the Dominion Steel Corporation's freighters arrived in Toronto on August 4th with 2,200 tons of coal direct from Sydney, Nova Scotia. One thousand tons of the original cargo had been discharged in Montreal on the upward journey to lighten the vessel sufficiently to go through the 14 ft. locks above Montreal. The vessel will load wheat at Port Colborne for discharging at Montreal on her return trip. While costs may be calculated on paper, and the feasibility of routes and cargoes decided by discussion, there is no exact way of finding out the advantages or disadvantages of a transportation route except to try it out. The Dominion Company has recently done two significant things. It has sent coal to Cochrane, Ont., by water from Sydney to Quebec and by rail from Quebec to Cochrane; and it has sent coal by water to Toronto. Both routes are logical and natural extensions of the St. Lawrence waterway, and the achievement in each instance is a challenge of a general and too easily accepted belief regarding the St. Lawrence route, namely, that so far as Canada west of Montreal is concerned, the St. Lawrence is all right to send freight east, but it is no good to take freight west. It is heartening to see someone try.

U.S. NICKEL IMPORTS AND EXPORTS.

The U.S. Geological Survey reports that nickel ore and matte amounting to 36,568 tons and containing 41,586,108 lb. nickel were imported into the United States during 1920. Of this small quantities came from Austria, Belgium and French Oceania and the greater part 33,182 tons containing 37,737,459 lb. nickel and valued at $7,723,278 came from Canada. Canada also sent to the United States manufactures of nickel valued at $2,179,494. The exports of nickel from the United States in 1920 were only 1,215,232 lb. as compared with 33,404,011 lb. in 1916 and 29,173,088 in the last pre-war year 1913.

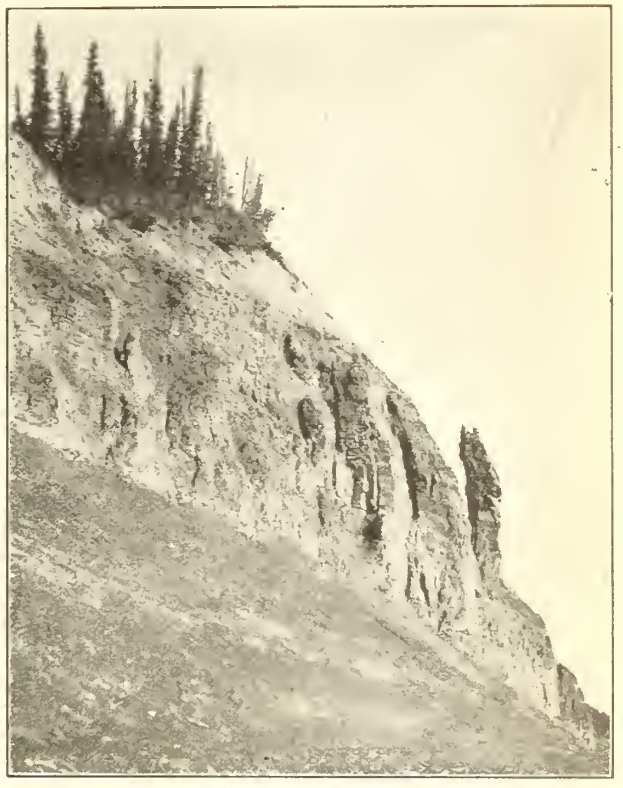
Mr. David Rorison has been appointed manager of the newly opened coal-mine at Whiteside, near St. Peter's in Richmond County, Cape Breton, and has removed to St. Peter's from Stellarton, N.S.

	Certain beds have an abundance of crinoid stems	30±
h.	Grey, hard limestone mostly in 6-inch to strata. Stromatoporoids abundant, other corals much more varied and abundant than in g. Rensselaeria and Stringocephalus also common	95
i.	Bluish grey calcareous shale in strata mostly 1 inch to 3 inches thick with *Chonetes* and *Martinia* abundant	95
	Beds in upper 2 miles dip up stream at about 1 degree; the fall of the river makes them rise in the cliffs in descending the gorge rather rapidly, however.	
	All of the limestone beds in the Ramparts are quite free from small low folds or domes such as those seen on Athabaska river.	

A more typical example of a disconformity than the contact between the middle Devonian limestone and the Cretaceous at the head of the Ramparts would be difficult to find. Not only are three geological systems—the Jurassic, Triassic, and Carboniferous—missing but all of the Upper Devonian as well are absent from the section. The absence of the Devonian formations of later age is probably due to their erosion. The highly irregular surface of the top of the Ramparts limestone furnishes unmistakable evidence of the down-cutting of the limestone surface previous to Cretaceous sedimentation. Erosion in pre-Cretaceous times has in places cut out the whole of the Devonian limestone series. A section of the west bank of the Mackenzie, about 10 miles northwest of Good Hope, shows the Cretaceous shale and sandstone resting directly on the Hare Indian River shale, while the Ramparts limestone has on either side of this section its ordinary development except that it is thinner than in the Ramparts. The presence of the Upper Devonian shale in the sections both north and south of the Ramparts region indicates that its absence at the Ramparts is due to erosion.

The Ramparts limestone forms a scarp along the sides of the valley for several miles north of Good Hope. South of the Ramparts it has been recognized by its characteristic fossil—*Stringocephalus burtoni*—in the Bat hills and Carcajou mountain.

Beavertail Limestone. The thickness of this series is 300-400 feet. The strata consist of hard, thick and



A. Fort Creek shale at the mouth of Fort Creek, Mackenzie river. (Photo by E. M. Kindle.)

thin-bedded, bituminous limestones, with some shaly partings. They are so highly bituminous that their colour generally is almost black.

These rocks contain few fossils; but at the top there is a coralline bed which frequently forms dip-slopes. Its surface weathers grey, but where newly fractured it is seen to consist of grey corallites set in a black bituminous matrix.

A gradual transition upward from the Beavertail limestones into the Fort Creek shales, is well seen in the extensive cliff exposures along the south flank of the Wolverine anticline.

The Beavertail limestones, being considerably more resistant than the overlying formations, form the slopes of the ridges which mark the trend of each of the main anticlinal folds. They are conspicuously exposed in many places between Norman and the Ramparts.

B. Beavertail limestone on west side of Carcajou Mountain anticline, arching down on bank of Mackenzie river. (Photo by T. O. Bosworth.)

On the banks of the Mackenzie they are well seen at Carcajou rock (Plate V B), East mountain, and Beavertail point; they are fully exposed on the hills, and up the creeks entering the Mackenize between Bear mountain and Carcajou.

The character of the upper part of this limestone and its relation to the next higher formation are shown in the following section taken near the northern end of the riverside exposures at Carcajou mountain.

Carcajou Mountain Section.

	Feet
a. Fissile black shale with interbedded bituminous limestone becoming more calcareous in upper 16 feet and splitting into sheets of bluish-black, bituminous limestone	65+
b. Grey limestone	5
c. Fissile black shale	1
d. Dark magnesian limestone of saccharoidal texture and bituminous odour	4
e. Hard, dark blue limestone with one or two thin bands of black slate in lower half	55

This section shows plainly the intergrading of the Beavertail limestone with the black shale of the Fort Creek shales. The beds to the east are considered to represent the upper part of this formation. About one mile up the river from the section, where the limestones stand vertical, about 260 feet of limestone is exposed. *Stringocephalus burtoni* occurs abundantly in the innermost or lowermost 60 feet of these rocks thus indicating the identity of a part or the whole of the limestones on the river bank at this point with the Ramparts series, which forms the base of the Beavertail limestone.

Fort Creek Shale. This series has a thickness varying from 500 to 1,000 feet, of which large parts are fully exposed in many places.

The strata are of very dark colour, often almost black. They consist chiefly of bituminous clay-shale, with thin seams of black limestone and calcareous sandstone. In some of the shales large plants are present, and the limestone bands contain some *Leiorhynchoids*, *Chonetes*, *Productella*, and other fossils.

These bituminous beds are seen throughout a considerable extent of the country between Norman and the northern limit of the map. They are exposed on the flanks of all the anticlines outcropping on the banks of the Mackenzie near Bear mountain, Carcajou rock, East mountain, and also in many tributary creeks.

About the latitude of the Arctic circle, and from thence northward, they occupy a large area, lying almost horizontal. Near the site of old Fort Good Hope they are much exposed to the river cliffs, and in Fort creek and elsewhere.

These shales are so bituminous that their odour is perceptible at a distance. In many places they are undergoing slow combustion and are burnt to a bright brick-red colour.

By weathering, the cliffs of Fort Creek shales are often coated with sulphur, and there are many sulphur springs in the areas underlain by them.

The main oil horizon was encountered in the Discovery oil well, at 783 feet. It is believed to lie in the middle or lower portion of this series.

The following section taken at the type locality of these shales shows the upper part of the formation:

Fort Creek Section.

	Feet
a. Black, bituminous, fissle shale with occasional ⅛ inch of cherty material. *Styliolina*, *Conadonts*, and plant fragments.	120=
b. Black, bituminous sandy slate or slaty sandstone. Sand grains very fine: strong bituminous odour. Splitting freely into large even sheets. Fossil plants common, one 6 inches in diameter (Pseudobornia?) also a few Tentaculites	15
c. Black, bituminous sandstone similar to above but without the slaty cleavage and in beds 8 inches or 10 inches thick	5
d. Drab, argillaceous, soft shale with *Leiorhynchus sp. Productella* (large) *Chonetes* et cetera?	35
(Lower part covered).	

The base of a series of black shales considered to represent this formation is exposed on the northwest side of Bear mountain near the base in the bed of a small brook which heads on the mountain. Fissile black shale 50 feet thick rests on grey limestone, showing an abrupt transition, in sharp contrast with the transition seen in the Carcajou Mountain section.

Bosworth Sandstone and Shale. This important formation has a thickness probably exceeding 2,000 feet, though only the lower 1,000 feet have been found exposed.

The formation consists chiefly of grey-green clay-shales, sand-shales, and sandstones, with other varicoloured strata. Some beds contain marine fossils such as *Atrypa reticularis* and *Accervularia*, in others there are plant fragments and carbonaceous matter.

The basal part, to the extent of some 200 feet, is largely of sandstone beds, and at other horizons also

B. East Mountain anticline. View from the summit facing eastward along the axis of the fold. The ridge in the middle is an arch of limestone, the anticlinal axis trending from background toward the observer and pitching down in the foreground. (Photo by T. O. Bosworth.)

prominent green sandstones occur. At outcrops the sandstones give rise to seepages of oil.

On drilling into the outcropping Bosworth beds, small yields of oil were immediately procured.

These beds occur in the country north of Norman, occupying the synclines or lying low down on the flanks of the antielinal folds.

The best sections are found in a number of creeks which enter the Long Reach of Mackenzie river from the northeast, in the 100 miles between Bear mountain and Carcajou rock.

Along the river side also, between these points, there are several small outcrops of the sandstones, causing seepages of oil. But the only large exposure on the banks of the Mackenzie is on the south flank of the Wolverine anticline, where a few hundred feet of these beds are seen just before the river turns westward, a few miles southeast of Carcajou rock.

The character of the beds exposed here is indicated in the following section:

Carcajou Mountain Section.

	Feet
a. Hard, thin-bedded, grey siliceous limestone weathering brown, with numerous plant fragments, also some invertebrate fossils	5
b. Dark shale and covered	65±
c. Dark, lead-grey shale with much disseminated decomposing Fe, S and Yellow sulphur-stained beds	150±
d. Thin-bedded, irregular, current marked sandstone	5
e. Duplicate of c	75
f. Sandy shale and thin-bedded sandstone with few rounded pebbles in upper beds 4 inches to 8 inches in diameter. Worm trails common	6
g. Dark shale with sandy bands	25
h. Hard, buff, thin-bedded, ripple-marked sandstone	15
i. Dark bluish shale	35
j. Buff sandstone	6
k. Shale and thin-bedded sandstone	75
l. Hard, bluish-grey shale	60
m. Fissile dark shale	100
n. Sandy, bluish-grey shale	150+

Age and Correlation.

A discussion of the geological age and the correlation of the formations which are recognized and described here will be presented elsewhere.

The table given in the first part of this section indicates the correlation of the formations of this region with those of other parts of the Mackenzie basin. The palaeontological evidence on which the table is based, will be presented in later papers.

It may be noted that although the region included in the maps has furnished no fossils from the formation forming the base of the section and here referred to the Silurian, an unmistakable Silurian fauna has been found by one of the authors in the Mount Charles section on Great Bear river, and in the Cap Mountain section, east of Wrigley. Such characteristic Silurian species as *Halysites catenulatus* and *Conchedium* sp. are present in these sections in dolomites which almost certainly represent the formation here called the Lone Mountain dolomite.

The youngest of the Palaeozoic faunas in the section, the Fort Creek shales, has some interesting features among which are a *Pseudobornia* (?) resembling one in the Huron shale of the Ohio Devonian. A conodont fauna was also discovered in this shale—the first which has been found in northwestern Canada.

A large proportion of the faunas of the several formations are new and the discussion of their relation and characteristics must be deferred to a later paper.

Geological Structure.

The Devonian rocks exposed in the Mackenzie valley are part of a great sheet of marine sediments which were laid over much of the northwest quarter of North America.

The original shore-line of these deposits are, as yet, matter for conjecture and the mapping of the boundaries of the preserved portion of the resulting formations is far from complete.

The broader features of the structures developed in these formations by mountain-building forces will be outlined so far as they have been worked out.

Structure Between Norman and the Ramparts.

Twelve miles before reaching Norman, the Mackenzie turns sharply northwestward, flowing along the south flank of Discovery range. This straight course known as the Long Reach, is maintained for 75 miles, parallel with the range, and several miles distant to the southwest of it. The river then turns sharply northward and in a distance of 25 miles it cuts across the trend of the mountains at their western end.

In this 100 miles of the Mackenzie valley, the Devonian formations are much exposed, and mountain-building folds which will now be described are revealed.

Anticlinal structure in this region was noticed first at Bear mountain by McConnell, in 1888. The other folds were found and mapped by T. O. Bosworth in 1914. It was in this territory that the favourable indications and structural conditions were found which have led to the recent strike of oil.

A. View of the northern scarp of the Bat Hills anticline, looking northwest from the southern scarp. Mackenzie river in the background. (Photo by Imperial Oil Co.)

Before a complete account of the tectonics can be written, much further geological work is necessary. The following represents but an imperfect preliminary impression.

The Devonian beds of the Discovery Range district have been thrown into a series of bold unsymmetrical folds, whose axes plunge up and down, steeply and frequently.

In the synclinals, the soft Bosworth sandstone and shale beds and Fort Creek shales, together with the overlying Cretaceous deposits, give rise to flat, low ground. But wherever the upward pitchings of the axes bring the arches of the Beavertain and lower limestones up above the general level of the land denudation has developed these arches as conspicuous anticlinal mountains.

In the area where the Mackenzie crosses the folds, there are four main anticlines, all pitching downward to the west. In order from south to north they have been named:

Wolverine Anticline.
East Mountain anticline.
Bat Hills anticline.
Beavertail anticline.

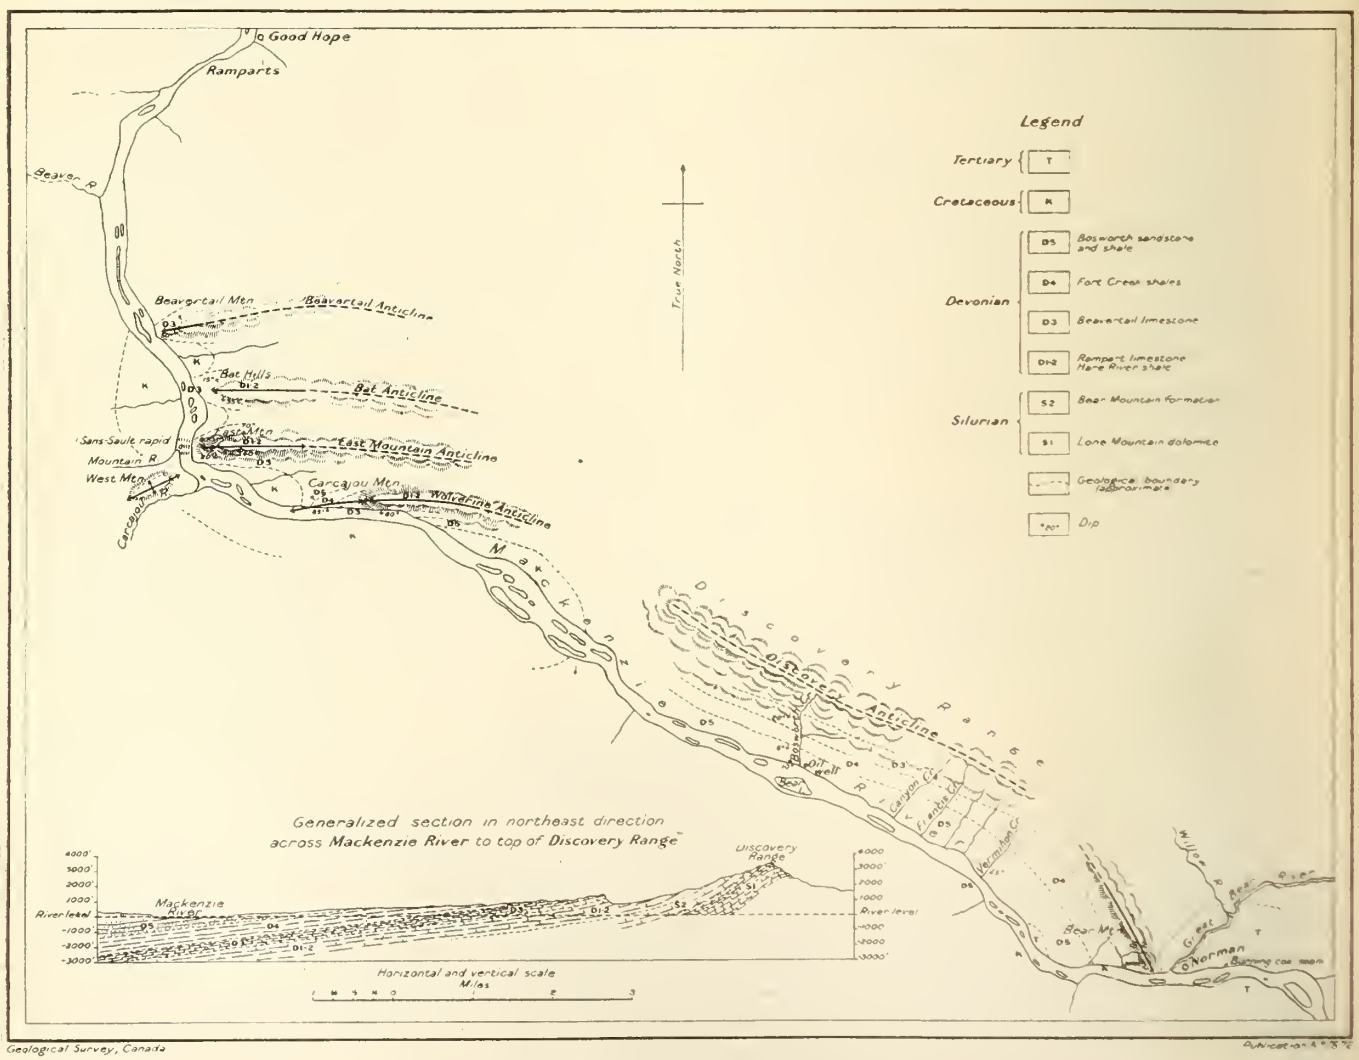
The wave-length of the folds, from crest to crest, are about 7 miles. The amplitude from crest to trough must be of the order of 5,000 to 10,000 feet.

The four folds are approximately parallel. Where the river crosses them, their trend is a few degrees north of east, but east of the river they bend round to the southeast course, which is probably their more important direction.

Far back from the river little exploration has yet been done, and it is not known whether all of the four anticlines are continuous. In the district where their direction crosses the river, it is seen that, owing to their pitching up and down, they tend to cause four ranges of rather discontinuous hills.

Wolverine Anticline. The southern-most of the four anticlines was examined with the most care. It is thought that this axis of folding is continuous from Bear mountan (near Norman) to Carcajou mountain, with a length of about 100 miles. Throughout the greater part of this length, the axis lies 8 miles inland, parallel with the river: but a turn in its direction, at each end, brings it to the river bank.

At Bear mountan which has a height of 1,500 feet, the folding is complicated by faulting and is not yet fully mapped. The core of the arch consists of the limestones with reddish shales and gypsum shown in the section page 45 to which the name Bear Mountain formation is applied. On the west flank, the bituminous Beavertail limestone and Fort Creek shales are exposed.



Sketch map showing approximate geological structure of the Norman-Good Hope area, Mackenzie River, Provisional District of Mackenzie

To accompany Report by E. M. Kindle and T. O. Bosworth, on Summary Report, Part B, 1920

Scale of Miles

Geology by T. O. Bosworth, 1914, and E. M. Kindle, 1920
Formation boundaries approximate

The data available do not admit of any reliable estimate of the well's capacity. It seems likely that the yield may be nearly 1,000 barrels a day. Increased production may be obtained when the well is deepened. It is considered that the Beavertail limestones have not been reached.

Whether the first well will yield a steady production or not is at present quite uncertain: but it has already demonstrated the prospect of important oil fields in the region.

The crude oil from the well is of light colour, low specific gravity, high gasolene content, and low cold test.

An analysis made at the Alberta University (J. A. Kelso), has been quoted as follows:

Specific gravity		0.845 (36° Beaume)
Distillation	70°-150° C.	22.5 per cent.
	150°-300° C.	38.5 "
	300°-350° C.	33.9 "
	350°-375° C.	4.1 "
	Loss	1.0 "

Thus in commercial terms the oil consists of—

Gasolene	22.5 per cent.
Illuminating oil	38.5 "
Light lubricants	33.9 "
Medium lubricants	4.1 "

The seepage oil obtained by digging is of greenish black colour having specific gravity "905 and paraffin base."

The present oil-well is situated far down the flank of an anticline 100 miles in length: and the whole 783 feet of strata penetrated by the drill are petroliferous.

North and east of this anticline other similar anticlinal hills occur, and in the flat ground to the west and north there may be the continuations of these anticlines (and possibly other anticlines besides), their limestone arches being below the general level of the land.

The sum of the geological evidence, together with the result of the test well, indicates an extensive oil region in which a number of oil fields may occur.

The capacity of the wells and the productivity of the fields, are matters beyond present calculation. But they are likely to be comparable to those of other Palaeozoic oil fields.

SUDBURY NOTES.

D. E. Cushing.

Sudbury. — Interest is centred on the reported find of lead on the property of the Gold Nugget Company, a Sudbury organization, made at Crerar on the C. N. R. Samples brought out have brought some favorable comment from mining engineers who examined them. An assay of some of the samples showed a content of 78.10 per cent. This is said to be the highest percentage obtained in any lead find in the North. One made at Sturgeon Falls some years ago ran 25 percent. The assay of the Gold Nugget Co., showed $8 gold value and 20.50 ounces of silver. It is not known whether the assay was from systematic sampling or a picked sample. There is an eight inch galena vein showing on surface, which has been traced 126 feet.

It is reported that another gold strike of importance has been made west of here, at Patricia, north of Kenora. No details of the strike have been given out, but it is understood that a number of prospectors have gone into the field.

Considerable staking is still going on int the Goudreau area. However, the report of rich narrow patches of gold, are such that it will be necessary for some real mining to be done to show that the values of the area are consistent and the ore bodies of some size, before real mining interest will be centred on the area. Values given so far have been of the most spectacular nature, and this fact alone makes the real mining men somewhat skeptical about the camp.

The International Nickel Co. has recently further curtailed operations and it can just be said that the company is operating and that is all. Wages has undergone another fifteen percent cut throughout the whole enterprise and besides many more employees, including some of the veterans, have been let out. The report on operations for the second quarter of this year, shows that the profit on common stock was two cents a share as compared with 75 cents for the same period of last year. The net profit was $179,402. In the same period last year the profits were $1,402,069. The general balance sheet as of June 30, shows a profit and loss surplus of $11,931,890 as compared with $11,659,612 in 1920. Cash on hand this year totals $1,210,260, compared with $4,173,492 and inventory stands at $12,213,948 as against $8,301,832.

METAL PRODUCERS' PLIGHT.

ALEXANDER GRAY, Montreal.

The International Nickel Company barely earned its preferred dividend in the quarter ended June 30. The margin of two cents applicable upon the common stock does not suggest the advisability of surtaxing mineral industries in general gold mines alone are benefitting from current operations. Only four Cobalt companies are active—and they are exceptionally placed. Certainly none of the nickel producers are finding responsive markets — and at least one substantial lot of the refined metal cannot be liquidated.

Otherwise in excellent shape, equipped as it never was for greater outputting, prepared to meet the terms imposed by any market, the International company cannot disassociate itself from universal stagnation. Spot copper at 11½c.—and not a great deal of it going at that price — futures about the low level of March 11th—which was 11 3/4c.—bulk copper held at 12 1/2c. for export—indicates a salvage situation that is not at all agreeable. Only Japan and Germany are in the metal market while other nations are debating reparation and disarmament issues—but even those countries do not seem to want much if any nickel.

Large copper producers will not force the sale of their metal. They cannot produce copper for the price current. No important domestic business is forthcoming — consumers are pursuing a hand-to-mouth policy. Consequently there is no remunerative incentive for production-nickel for the time being is on the waiting list, neither useful nor ornamental.

Trade depression, costs plus taxation, hardly suggest more taxation as a stimulant. The International Nickel corporation is fortunate is having a strong treasury, great reserves of high grade ore, and more of lower grade, besides new and enlarged plants without fixed charges to speak of—but it cannot do the impossible when the world is flouting metals of all kinds.

PERSONAL.

Captain James G. Ross, Consulting Mining Engineer, with the Milton Hersey Company Limited, Montreal, has returned from an extended examination trip to the Northern interior of Quebec.

British Columbia Letter

The Chief Inspector of Mines, British Columbia, has issued a pamphlet on the grades of coal available to the domestic trade of the Province. He shows how each is prepared and for what purpose each is best suited. Six grades are dealt with, namely, "lump or scow run", double-screened lump, nut coal, pea coal, slack coal, and screenings. The former is the product screened over a 1½ inch to 2 inch screen at the mine and "is the coal sold to dealers for distribution in Vancouver and Victoria for domestic use." This, it is gathered, is more economical to the consumer for the reason that it "receives no treatment at the hands of the coal dealers. The scow is loaded with high grade lump at the colliery bunkers, which product is taken direct by the dealers to the consumers' bins after sacking. "Double-screened is that which is re-screened at the dealers' sheds, and being sold in large pieces is especially suitable for open fireplaces. Nut coal is the product that passes through a 1½ inch to 2 inch screen and over a ¾ inch screen. It is washed to take away the impurities and is specially adapted to stoves and heating plants. Pea coal is that which passes through a ¾ inch screen and over a ⅜ inch screen. It also is washed to take away impurities and can be used in stoves and heating plants with narrow openings in the grate-bars to prevent it falling through. Slack coal is that which goes through a ⅜ inch screen which, being washed to do away with impurities, is used for firing boilers and at powder fuel plants, cement plants, green houses, etc. As to "screenings" it is described as being the residue from the re-screening of the coal at the dealers' sheds and is adapted for use in greenhouses, heating plants, etc. Attention is particularly called to the necessity, wherever possible, of 'laying in' the winter supply of coal during the summer, thus eliminating danger of a shortage. "For lack of a market during the summer months" it is stated "the mines have worked only part time which adds materially to the overhead expense of coal mining."

Six of the latest type of Paul Breathing Apparatus have been purchased by the British Columbia Department of Mines for the Cumberland (V.I.) Mine Rescue Station. This is one of the coal mine centres of the Canadian Collieries (D) Ltd.

Victoria, B. C.

George H. Kilbourne, of the Canadian Consolidated Mining & Smelting Co., is reported to be making satisfactory progress in the mineral survey of the E. & N. Land Belt, Vancouver Island, of which work he has charge. He has two parties in the field and the ground is being very thoroughly covered. It is being taken up systematically, section by section. Rivers and their tributaries are being traced to their source. The flowing waters are watched for float and the geological conditions studied. There is a possibility that this scientific prospecting will pass by mineral deposits of merit but it is felt that nothing really big will be overlooked. When the reports of Mr. Kilbourne and his fellow engineers finally are submitted the Canadian Pacific Railway Co. will be in a position to resume negotiations with the Provincial Government with a view to placing the administration of the minerals of the Belt under the sole jurisdiction of the Province.

Mr. Normal Carmichael general manager of the Arizona Copper Co., is visiting his brother Mr. A. Carmichael, of this city. Mr. Carmichael is closely related to Mr. Herbert Carmichael well known for many years as British Columbia's official Assayer and now prominently identified with the mining industry. He formerly was manager of the Granite Mine, near Nelson, B.C., and of the Highland Mine, Ainsworth.

Herbert Addison, vice-president of the Big Horn Collieries Company, of Denver, Colo., has been sojourning in Victoria on his summer vacation. He reports that the coal mining business, both as to production and to market, is fairly satisfactory. The smelter trade, of course, has fallen off because of the lack of activity among the copper smelters.

Prince Rupert, B. C.

James O. Greenan, engineer with the Yukon Gold Corporation at Mayo, is quoted as stating that sufficient work has been done in the Keno Hill Section of Mayo District to assure the production of high grade ore for several years. Nothing, however, has been uncovered to warrant the prediction that such ore will be available in quantity for a longer period. The Yukon Gold Corporation has done several thousand feet of development work and is proceeding as fast with these operations as its facilities permit. Twenty-five hundred tons of high grade ore have been shipped this year by the Corporation. Shipments are being made via St. Michael to the Shelby Smelter at San Francisco, Cal., a distance of 5,000 miles, the greatest distance any mine in the world is transporting crude ore for treatment. Through a special arrangement with the Canadian Government Mayo has been made a sub-port of entry, thus permitting vessels to load ore direct at that point and carry it to St. Michael. Ore now is being mined for transport during the winter, over the snow and ice to Mayo. When navigation opens next year this will be taken out, as is now being done with that which was mined last winter. The Yukon Government now has a crew of men improving the road so that the transportation problem will be made somewhat simpler. Mr. Grenan says that there is a shortage of hard rock miners in the Mayo District, that wages are $5 a day with board and lodging, and that many prospectors are being attracted from other parts of the Territory.

Stewart, B. C.

R. W. Wood, President of the Premier Mine, states that the new Mill at the Salmon River Property has not yet handled any quantity of ore. It has been turned out and is expected to be working soon at its capacity, 100 tons a day. — Considerable development, with promising indications, is being done by the Outland Silver Bar Mining Company on their property, situated on the west side of the Salmon river glacier, about 23 miles from Stewart. A number of attractive prospects are being opened up on Marmot River, among them the Patricia from which a number of high class samples recently were taken, the assay returns carrying big values in gold, silver and lead.

Trail, B. C.

The receipts of ore at the Consolidated Mining & Smelting Co.'s Smelter for the week ending July 21st aggregated 8,405 tons. Two Slocan District mines joined the shippers during this period, the Anna being credited with 20 tons and the whitewater with 36 tons. Two Washington State Mines, the Knob Hill and the Surprise, sent 47 and 283 tons respectively. Properties

owned by the smelting company were responsible for the remainder, 7,977 tons.

Vancouver, B. C.

That the gold production of British Columbia for 1921 will be considerable greater than that of 1920 is indicated by the receipts up to date at the Dominion Assay Office, Vancouver. The total receipts of bullion this year so far aggregate in value $1,2755,000 as against $1,073,000 for the same period last year. The improvement, generally speaking, is ascribed first to the reopening of the Roseland Mines by the Consolidated Mining & Smelting Co. and, second, to the fact that the placer mining areas are working under more satisfactory conditions, there being plenty of water whereas last year there was a notable scarcity of that necessity.

Northern Ontario Letter

THE SILVER MINES.

The Cobalt District.

A favorable feature at the silver mines in the Cobalt field is that at the producing mines it is being found possible to increase tonnage and, at the same time, to carry on operations with a smaller force of men than when operating at smaller capacity. This is resulting in a very material reduction in the per ounce cost of producing silver. The reason for this, is the higher working efficiency of the men.

One great obstacle in reducing costs to the pre-war level is the prevailing high freight rates. The carrying charges are extremely heavy, and the rates have so far withstood all shocks. There is a growing belief, however, that a substantial cut may be made this fall, in which case mining in Northern Ontario would receive added impetus.

Field work in charge of Cyril Knight for the Ontario Department of Mines is proceeding at a satisfactory rate and the re-survey of the geology of the Cobalt district will be completed late in October or early in November. The work commenced early in the summer of 19290. Mr. Knight told the Journal representative that the Cobalt field presents favorable opportunities for further exploration and that in his opinion there are good prospects of intelligent effort being well rewarded in certain sections of this area. This belief is based upon the knowledge that there are sections where little or no work has been done and where the geological structure bears marked similarity to areas where exploration work has resulted in the discovery and development of ore shoots.

After a delay of a week or so in making repairs to a motor which burned out, the Keeley mill is again in full operation, according to advise from Silver Centre. It is also stated that the underground work at the mine continues favorable. Major J. Mackintosh Bell, consulting engineer for the company is in the northern Alberta oil fields in the vicinity of Great Slave Lake and will return to the Cobalt district within the next few weeks.

Milling operations are to be resumed this month at the Hudson Bay mine, according to official advice. It is the intention of the management to treat all the broken ore by going to as little expense as possible in drawing it from underground, following which the directors will be obliged to determine whether it is advisable to institute a further campaign of exploration and development or to close the mine down. The Temiskaming and Hudson Bay holds the distinction of having paid dividends amounting to 25,000 p.c. on its issuer capital, a record which stands out above any other mining enterprise in the world. The company was organized by a group of business men in the little village of New Liskeard over sixteen years ago, the authorized capitalization being only 25,000 shares of the par value of $1 each. The property was found to be so rich that by the time 7,761 shares had been issued at considerably less than their par value, the company was on a self-sustaining basis. Then followed the sale of part of the property held, together with the development of exceptionally high-grade silver ore on the property still held, and the stock soared from a few cents per share to upwards of $300 per share, and the company distributed dividends at the rate of over 2,000 p.c. in a single year in its banner days. Another distinction held by the Temiskaming and Hudson Bay is that in November, 1905, the company paid a dividend of 200 p.c., this being the first profit disbursement made in Cobalt by any incorporated company. In addition to returning such enormous profit to its owners, the company has assisted in the exploration of new fields throughout Northern Ontario, and in 1919 the charter of the Temiskaming and Hudson Bay was surrendered to the holding company known as the Hudson Bay Mining Company, Ltd. This company holds property in Gowganda and Kirkland Lake as well as having financed the Dome Lake Mining & Smelting Company at Porcupine.

The shaft on the Waldman property of the Oxford-Cobalt has reached a depth of between 40 and 50 feet, at which point the silver deposition is highly encouraging, and officials of the company now regard the development as of distinct importance. Silver has been found to occur alternately in smeltite and in calcite, some of the ore being high grade while a substantial amount of mill ore has been placed in sight. It is stated that but for the unfavorable condition of the road, it would now be possible to send out a carload of mill ore for testing purposes. The plans of the management are to continue the shaft to a depth of about 75 feet at which point the contact is expected to be reached, after which drifting operations will be undertaken close to the contact zone. A feature of the favorable developments on the Waldman is that the theory that silver is most likely to occur in the Keewatin overlying the diabase to a distance of up to about 100 feet from the contact is again being proven. The shallowness of the Keewatin at the point where the present shaft is located is accounting for silver having extended to outcrop, namely, about 75 feet above the contact zone. Another feature is that the underlying diabase dips at an angle of about 25 to 30 degrees, and that as the drift at a depth of 75 feet proceeds it will gradually draw away from the contact, but in due time it will be possible to put down a winze from the drift and thereby keep within the zone of mineralization.

The underground workings on the Violet property of the La Rose have been dewatered and work is again under way on this property. As a consequence of this, the scope of operations by the La Rose has been considerably broadened.

During July the Bailey Custom Mill treated 1,043 tons of ore and realized gross earnings of $12,129.51. The Bailey mine itself shipped 1,262 tons of ore, and continued to improve its physical condition. Officials declare there is more ore in sight on the Bailey than at any previous time during the past six months.

With respect to statements credited to Dr. Ami a few

weeks ago, in which the inference was left that a vast amount of platinum was being lost annually in connection with nickel-copper mining in the Sudbury district, it is a matter of surprise in mining circles that Dr. Ami has not replied to inquiries which were made for the purpose of obtaining either a confirmation or a denial of the statements which were sent broadcast through the daily press. The statements which were erroneous, reflected adversely upon the efficiency of the miners in the Sudbury field, whereas it is well known that those engaged at the Sudbury mines rank among the best in the profession of mining and metallurgy.

Elk Lake and Gowganda.

It is expected that the Cane Silver Mines in Cane township maybe re-opened this fall. The arrangements in connection with raising finances appear to be progressing favorably on the strength of the rich surface showings as well as the shaft on No. 8 vein having shown silver values to continue to a depth of 42 feet. During the course of sinking this shaft, about four tons of ore taken out yielded approximately $1,200, in addition to which is a considerable amount of low grade ore.

An endeavor is being made to re-finance the Triangle Silver Mines, in the township of Auld, formerly known as the Kenebeek Consolidated. Interests closely connected with the enterprise are hopeful of being able to resume operations this fall.

Good headway is being made on the Elk Lake to Gowganda road and automobile travel from the centre of activity in Gowganda to the railhead at Elk Lake will be possible throughout the greater part of the open seasons. The possibility of being able to haul material on motor trucks instead of by horse and wagon holds out promise of greatly reduce expenditure in connection with transportations, a factor which has been one of the main obstacles in the way of extensive mining endeavor in the Gowganda district.

THE COLD MINES.

The Porcupine Field.

A most remarkable fact in connection with gold mining is found in the present "one-sidedness" in the trend of conditions under which the metal is being prodneed. Whereas, during the war and for some time after its close, the economic situation gradually grew worse and was one-sided in that respect, the turn in the opposite direction is now equally pronounced. Where activity gradually narrowed down and where prosperity gradually lessener, there is now a steady increases in the scope of work and there is a steadily rising tide of prosperity.

For the first three months of the company's fiscal year, namely April, May and June, the Dome Mines realized a net profit of $235,000, or at the rate of a fraction over 20 p.c. on its issued capital. This was achieved in spite of operations being greatly restricted in April due to power shortage and when even during May considerable time was lost in getting the mill up to anything near capacity. It is now understood that ore is being treated at a rate which would indicate that at least 100,000 tons will go through the mill during the second quarter, namely, July, August and September and that net profits will reach at least $300,000 for the period.

With respect to the information printed from time to time during recent months in the Journal in which the McIntyre-Porcupine was shown to be making preparations to enlarge its mill, the official announcement now comes from the company that the plant will be increased to about 900 tons a day as compared with the present capacity of 600 tons a day. This is expected to result in gross production of over $3,000,000 a year as compared with a little over $2,000,000 a year recently. The ore averages between $10 and $11 to the ton and the net profit amounts to nearly 50 p.c. of the total yield. Even allowing costs to absorb $6 a ton and profit to amount to $3 a ton, the net profit thus indicated would amount to $1,200,000 a year and would be equal to 33 p.c. on the companies issued capital of $3.640.000. The McIntyre will pay a dividend of 5 p.c. on September 1st.

An offer of 20 cents per share has been received by the Porcupine V. N. T. Mines for its treasury stock, but the officials are determined not to sell at such a low figure. It is pointed out that under less favorable conditions than appear to be opening out before the enterprise, the stock was in strong demand on the open market at from 70 to 80 cents a share. The officials believe they will still succeed in arranging for the finances necessary to resume operations this fall at full blast.

Gold mine operators in general in the Porcupine district seem to feel quite confident over the hydro-electric power situation following the official announcement made through the Journal by the Northern Canada Power Company that there is no reason to feel apprehensive over the supply.

Kirkland Lake.

A decision to proceed with the enlargement of the mill on the Teck-Hughes mine is one of the favorable features in connection with the producing mines of the Kirkland Lake district. It is planned to increase the capacity of the plant by about 40 tons daily, the present rate being approximately 120 tons a day. The mine is understood to be on a profitable basis of operation and is expected to soon be in a position to commence paying off its bonded indebtedness.

The work in connection with equipping the Ontario-Kirkland with a mill of 100 tons daily capacity is proceeding satisfactorily. Among other things, a shaft has been provided at a central point by driving a raise from the 300-ft. level.

At Boston Creek, diamond drilling is under way at the 500-ft. level of the Miller Independence mine. Considerable importance attaches to this work.

PORT ARTHUR NOTES.

Silver Islet Mine.

J. J. O'CONNOR.

Silver Islet took on some of the appearance of its old time activities and interest, on the occasion of a visit by the Executive and shareholders of the Islet Exploration Company Ltd., together with a party of friends on the 1st instant.

Tall stacks belching black smoke, and a scene of general mining activity on the Islet, took one back almost forty years to the time when such scenes and similar activities, were part of the daily life history, of fifteen years of the most venturesome and picturesque mining enterprise on this continent.

The party reached the Islet about noon, on the tug "James Whalen" and landed alongside the old bulk head at the mine. In the party were; J. L. Washburn, President of the Islet Exploration Company Ltd., A. McC. Washburn, Vice President, Frank B. Randall, Secretary-Treasurer, A.M. Chisholm, capitalist and mine owner, Dr. D. C. Frood, Head physician to the U.S. Steel Corporation, E. C. Congdon, capitalist and mine owner, P. Field, W. D. Baily, capitalist, F. A.

Cokefair, President Lake Superior Loader Company, R. C. Jamieson, D. C. Peacock, G. M. Baird, capitalist, Memphis, Tenn., Frank H. Keefer, M.P. Port Arthur, Dr. R. J. Manion, M.P. Fort William, G. R. Duncan, Fort William, Mayor Matthews of Port Arthur, and several prominent citizens of the two cities at the head of the Lakes.

Luncheon was served to about thirty five guests in the Boarding House. After the luncheon, about two thirds of the party, including nearly all the shareholders donned miners garb and went underground, under the direction of D. C. Peacock, who is in charge of the operations. After the underground inspection, an informal meeting was held in the office, where an array of rich silver was displayed, running into thousands of ounces per ton.

Mr. Peacock had prepared a working model of the Macfarlane dyke, in which the silver occurs at Silver Islet, showing the old workings to a depth of 1260 feet, together with the lateral working both east and west, together with the great fault, where the silver is deposited, also including the known vein system that exists to the westward, all of which intersect the dyke at points varying from about 400 to 1200 feet westerly from the old workings.

Mr. Peacock addressed the meeting briefly, giving the history of the silver occurrences as found under the old regime, fully explaining the conditions that were met with, and gave it as his studied opinion, that similar conditions would be found at one, or all of the intersections with the dyke, of the vein system known to exist to the westward., illustrating his points by the working model of the dyke, which proved most illuminating.

The meeting was also addressed by President Washburn, who gave an outline of the undertaking, pointing out that the venture was being undertaken by men of capital and experience and that if it should prove a failure, could afford to lose their investment, and that voluntary investors composed the company. Frank H. Keefer, M.P., Dr. R. J. Manion, M.P., and Mayor I. L. Matthews of Port Arthur, also spoke

The Islet Exploration Company are carrying on their exploratory work under the most encouraging and promising conditions. The enormous richness of the area surrounding the intersection of the MacFarlane dyke by the Silver Islet vein was only discovered by the accident of its nine feet exposure above the surface of Lake Superior. Had this portion of the dyke been covered by even a slight depth of water, the millions of dollars that this point produced, might still be there, and the romantic history of its extraction have been lost to the annals of silver mining in Ontario.

The geological and mineralogical conditions surrounding this intersection, have had, during the past year, the most minute and critical examination at the hands of the present operators, until they are now, to them, an open book. They have found, among other things, that graphite, which is present in considerable quantities throughout, is a dominant factor in the deposition of silver in the vein. While it was often found in the old workings without silver, silver was never found without graphite.

A system of veins, similar to the Silver Islet vein, is known to exist, and to intersect the Macfarlane dyke at points varying from about 100 to 1200 feet to the westward of the Silver Islet intersection. The old mine has now been unwatered to a point below the fourth

level. A drift has been started west from this level, in the graphitic portion of the Island, Catholic Point, and Perry Bay veins, and possibly, as yet unknown veins.

This drift is now in 250 feet, on the first instant, a mineralized calcite stringer was encountered in the face of the drift, encouraging the operators to believe that they were in the vicinity of the Burnt Island vein. This drift will be continued until the intersections of all the known veins have been cut. Meantime, the first objective is the Catholic Point vein, as this is the strongest vein in the system, being thirty feet wide where exposed under the water.

The energy and enterprise displayed by the operators is highly commendable, and worthy of an ample reward. They have the best wishes of mining men everywhere, and it is to be hoped that they will bring Silver Islet back to its old status as an outstanding silver producer.

Premier Lloyd George says he can see "the light at the end of the tunnel". A London financial paper asks whether it is red or green? Opinions as to the irreverance or irrelevance of this comment presumably differ according to one's political vision. If Lloyd George sees the light we'll bet it is not yellow, at any rate.

TORONTO COAL PRICES.

(By Our Own Correspondent).

Toronto, 10th August.—The bituminous situation is in an unsettled condition. Business is up one day, and down the next. In this respect, it but reflects the instability of business conditions generally, at this moment. In the United States, the railroads and the steel industries are beginning to pile up their reserves of bituminous coal, but most other industries are still pursuing a hand-to-month policy. In Canada, neither the railroads nor any of the big industries are taking steps to build up their reserves of cial in the normal fashion

As regards bituminous prices, that of lump is at rock bottom. Its price at the mines is from $2.50 to $2.85 a ton, varying with the district and the quality of the coal. The price of slack is still advancing, and is now anywhere from $1.75 to $2.15 a ton. The recent advances in the price of slack are due not so much to the demand for it as to the scarcity of screenings. In other words, with so little demand, as there is, for lump coal, slack is scarce. One thing seems certain—there will be no more cheap slack this year. A point worthy of mention is the immense difficulty that is being experienced in the collection of accounts for coal. Firms that one would not dream could be short of money are showing themselves unexpectedly "long-winded," just now. This tends to confirm the general idea that the financial stringency is both exceptionally acute and exceptionally widespread.

In reference to anthracite, the situation in Toronto is showing some improvement, dating from about the first of this week. The public at last seem to be making up their minds that there is not likely to be any reduction in prices consequent on the reduction that they seem to anticipate in freight rates. A reduction in freight rates, by the way, is not likely to occur until next April—so I am informed by those who claim to speak with some knowledge—and is practically certain not to take place, at any rate, before the 1st of next January. Supposing that a reduction in freight rates should take place on the 1st of January, it would take two or three months from then to become operative, so far as the coal consumer is concerned. However, the public—or, at least, that portion of the public which may be considered well-to-do or moderately so—seem at last to be waking up to the fact that anthracite prices are unlikely to come down.

MR. H. L. OSBORNE IN CHARGE OF MINING.
Specialties Sales For Samuel Osborn & Co. Ltd.

By A. R. R. JONES.

The firm of Samuel Osborn and Co., Ltd. of Clyde Steel Works, Sheffield, England, manufacturers of a variety of high-speed and carbon-steel products, is one of the highest standing in its own line in the whole realm of industry. Established in 1833 ,it has branches in various parts of the world, including Canada, the United States, South Africa and so forth. The Canadian branch is located at 126 Wellington Street West, Toronto. At this branch it has been fortunate enough to secure the services of Mr. H. L. Osborne in charge of its mining sales department.

The lines that Mr. Osborne is handling for this branch establishment—which is known as Samuel Osborn, Canada, Ltd.—include the following specialities: "Titanic" cast steel and "Hand and Heart" crucible cast steel; Osborn's toughened steel castings; cams, beads and tappets, for gold stamp-bateries; swing-stock, toggle-blocks, adjusting-wedges, pitmen machinery; Osborn's "Titan" manganese-steel castings; Osborn's "Titan" manganese-steel bars and forgings and grizzley bars; and drill steel which is a special line.

Few men are better known to the mining industry in Northern Ontario, and few know the Northland better, than Mr. Osborne. In his previous business career, he was with Mussens, Ltd., in Cobalt, and, while with that firm, he sold steel and iron machinery. Subsequently, he started in business for himself, trading in his own name, at Cobalt and bought from the International High-Speed Steel Company. Business expanding, offices were opened in Montreal, Toronto and Sudbury. Having spent the past thirteen years or so in Northern Ontario, it is natural that he should be well acquainted with the mining industry and thoroughly conversant with conditions there. Moreover, having made a considerable success in his former capacities, his joining up with Samuel Osborn and Co. means the association of a first-rate connection with products of first-rate quality. Such an association would seem destined to be a fortunate one. Naturally Mr. Osborne's particular line of endeavor has always been to cater, with acceptance, to the needs of the mining trade. He formed his present connection last April.

In the course of a talk that I had with him relative to business conditions in his particular lines, he told me that business in the North—in the districts of Kirkland Lake, Porcupine and Cobalt—is coming along very nicely indeed. In the Sudbury district, he added, operations have been curtailed, although his firm is doing a nice business there, so far as it goes. "I was in the North about a month ago," he said, "and things there are looking fine, with prospects of a good boom ahead." It should be added that his firm has an office in Cobalt, where it maintains a stock of the lines which he handles. Mr. Osborne said, in reply to a question I put to him, that there is plenty of labor in the North at present and that it is of a satisfactory kind.

It may be mentioned that Mr. H. Southworth is manager of the Cobalt office of Samuel Osborn Canada, Ltd. Mr. Southworth, who is a mining engineer and has had charge of several mines in Northern Ontario, was for some considerable time with the Deloro Smelting and Refining Company, Ltd. While with that Company, he sold "Steelite," both in Canada and more latterly in England, where he had charge of the Company's offices.

CANADIAN ASBESTOS.

The world's production of asbestos in 1919 is estimated at 140,265 metric tons of which Canada produced 88 per cent or 124,070 tons. Canada's output of 152,162 tons in 1920 was greater than that of the world's output in previous years. The present poor market will doubtless make the 1921 record much less satisfactory than that of last year.

EDITORIAL

FUEL PROBLEMS OF THE FUTURE.

Before the Institution of Civil Engineers in London, Sir George Beilby, the Director of Fuel Research in Britain, delivered the 27th James Forrest lecture on "Fuel Problems of the Future."

A condensation of this valuable opinion, by a competent authority, is contained in this issue, and it has much interest from its bearing on Canadian fuel problems. Sir George Beilby regards lignite as a fuel of coming great importance, and states that although it contains from 40 to 60 per cent of water, "it is today by far the cheapest source of thermal units. He advises British coal miners and owners to keep an eye on the development of lignite in Germany and elsewhere. "According to the extent to which Germany can meet her own requirements for heat and power by the development of lignite, peat and water-power, the output of her coal-mines will be set free for export, and she will thus take a more important place in the markets of the world." If it is realised that Canada contains 95 per cent of the lignite of the British Empire and over 31 per cent of the lignites of the world, and has 73 times as much lignite as Germany possesses, this opinion, if applied to Canada, takes on an aspect of surpassing importance. As, according to the most calculations of the Dominion Water Power Branch, we have only so far developed 5.9 per cent of the Canadian waterpowers available, and as we have also fairly respectable accumulations of peat, what applies to Germany in this connection applies to Canada with hundred-fold emphasis.

Sir George uses a term "availability" that will bear some consideration. In some instances—as in the case of motor spirit—he points out that "there is a decided tendency to regard mere convenience as a sufficient justification for use." We are glad to note his warning "that a general recognition of the availibility and convenience of the more costly forms of fuel must not tempt us to overlook the necessity for a critical examination of the uses to which more expensive fuels are being devoted," because, as we have previously pointed out, there is in Canada a tendency to confound the ideal forms of fuel availability and convenience with the potential natural sources of such ideal fuel. This is particularly true of projects for distillation of oil-shales, although as Sir George remarks: "The problem of mining and retorting these shales profitably in competition with petroleum from oilfields has not yet been solved."

The use of natural gas for industrial operations, instead of conserving this ideal fuel for domestic purposes, and the continued use of anthracite for uses to which bituminous coal is adaptable, are two other glaring instances in Canada of convenience being regarded as a sufficient justification for general use.

In taking steps to conserve the natural gas supplies of Ontario, to carbonize and briquette the lignites of Saskatchewan as a substitute for anthracite; to develop the water-powers of Canada for generation of electrical power, and to work the peat-bogs of Ontario and Quebec for fuel; Canadian policy appears to be working along scientifically approved lines, insofar as those areas bare of bituminous coal are concerned.

Bituminous coal, however, is regarded by this authority as likely to remain the chief course of fuel "not only for Great Britain but for the world at large, and the problems of its winning, preparation and use still occupy the foreground in all serious consideration of the subject." In this connection, attention is drawn to the researches of Mr. David Brownlie on boiler efficiency, which have shown that great savings in the use of coal are possible by the use of modern equipment in boiler-plants and in steam-raising generally. To what extent it will be found possible to utilise the waterpowers of Canada in coalless territory as sources of heat, in distinction to motive power, has not yet been shown, possibly because of an unperfected state of electrical knowledge, but for many years to come,

bituminous coal, mined in Canada or imported from across the border, will be the chief source of heat, and Sir George Beilby's conclusion in regard to conditions in Britain is equally applicable to Canada, namely, that for steam-raising, "the cheapest form of fuel is coal or coke if it is used under reasonably scientific conditions, and so long as this is the case, the use of fuels of higher "availability" will be economically practicable only under very special conditions."

The Dominion Water Power Branch states that the present development of waterpowers in Canada provides a source of power equivalent to that which would be available from the use of 18½ millions tons of coal annually, and calculates that if the present rate of additions to waterpower generating stations continues to 1940, the equivalency with coal will be to the extent of 42 million tons. We venture to believe that this output of electrical power will not be found to minimise the importance of bituminous coal of Canada in those vast areas suffering under an inherent fuel insufficiency that the Canada of 20 years from now may expect to see heavily populated. We shall need all natural sources of power, and our peat-bogs and oil-shale deposits when the day of their utilisation arrives.

THE COST OF LIVING.

The tabulation which appears each month in the "Labour Gazette" on the cost of foodstuffs averaged over sixty cities and towns in Canada commenced publication in 1915. The tabulation was the result of the recommendation of a parliamentary committee early in 1914, and it is fortunate that the work of recording and tabulation was undertaken before the War. The tabulation covers the cost of specified items of necessary living expenditures calculated for a family of five with an income (before the War) of eight hundred dollars per annum. From time to time criticisms of this tabulation have been heard. The selection of the items it covers, and the accuracy of the prices upon which the averages are reckoned, has been questioned, but careful checking of the figures and averages will convince any impartial observer that the work has been well and correctly carried out. It must also be allowed that the same selection of items, tabulated over a long period of years, will give a correct account of the rise and fall of living costs, despite any difference of opinion which may arise as to the fitness of the items selected.

The work of the Department of Labour has now continued long enough to make it possible to review the monthly variation in the cost of foodstuffs, fuel and light and rent over a period covering almost eight ysars, and the information available is most ample in regard to foodstuffs. The cost of the weekly budget of foodstuffs in 1914 varied between $7.50 and $8.00, and there was no notable increase in prices until the last quarter of 1918, when the curve began to mount rapidly. At the time of the Armistice the weekly budget had risen to $13.50, and the curve showed a tendency to steady, and even to reverse itself during the six following months. In the last half of 1919 the upward course of prices was accelerated and the curve became very steep, reaching a peak at $17.00 in June 1920. Since July 1920 prices have declined with greater rapidity than they rose, and the latest report for July 1921 gives the necessary expenditure on foodstuffs as $11.00 per week, bringing prices back to approximately where they were in the Spring of 1917. The cost of foodstuffs has therefore dropped in twelve months by a figure that is equal to the rise of the thirty-eight months previous to June 1921.

A continuation of the rate of decline in the cost of foodstuffs manifested since June 1929 would result in the weekly expenditure falling to 1914 figures by the end of the current year. The decline has been so marked and so precipitate that some flattening of the descending curve is not improbable, but there is every reason to believe that the tendency will be downwards for months to come, except as it may be locally influenced by actual failure of crops and transportation difficulties.

The more important wage advances given in the United States dated after the Spring of 1917 and the most far-reaching of the wage advances, that given to the railwaymen under stress of war conditions in the United States, was, somewhat incongruously, extended automatically to Canada; and, combined with the increases given to coal-miners, brought about the most considerable portion of the increased cost of living. It should not therefore pass unnoticed at this time that foodstuffs, representing approximately sixty percent of living costs, have returned to where they were before the United States went to war, and before wage increases had become general.

THE UNWISDOM OF WOODEN BUILDINGS.

At the Fire Chiefs Convention held at Three Rivers, Que, a resolution was put and seconded asking for federal and provincial prohibition by legislation of the use of wooden shingles for the roofing of buildings. The resolution was not further acted upon, but the incident is an encouraging indication that there is a growing realisation of the danger of wooden buildings and a desire to substitute non-combustible materials in building. A recent visit to the Maritime Provinces has given the Editor opportunity to compare certain towns and cities with their state a few years ago, and nothing has been more striking than the ravages of fire. Communities are deprived of hotel accommodation, of school buildings, places of worship, and commercial establishments in a really pitiable manner, and great black gaps in the main streets of large communities represent buildings that were a communal necessity. In all too many instances the burnt buildings are being replaced by wooden structures, and the same conditions of potential loss and danger are being thoughtlessly repeated. During recent forest fires, the wooden building and the

shingle roof must have greatly worried a population that saw their homes exposed to showers of sparks and threatened by every rising wind. In a country that provides such a variety of incombustible building material as Canada it seems advisable that communities and individuals should weigh the smaller cost of wooden erections against the risk they entail and the worry they bring, and it is more than likely that a correct casting up of the things that are for and against wooden buildings would reveal that it is cheaper in the long run to use stone and brick, terra-cotta, asbestos and asbestic, concrete and steel, and the approved materials of modern building that this country so uniquely and so richly provides.

IN a thoughtful address delivered by Mr. Edgar Crammond to the Institute of Bankers in London on June 28th last the speaker defined Capital as meaning "in its ultimate analysis principally organisation." In such matters of negotiation between Capital and Labour as wages and hours—matters in which differences of opinion can hardly be avoided — Mr. Crammond suggests that it would be a piece of incomprehensible folly on the part of Labour, at a period when the world is entering upon an era of intensive competition, to weaken the position of the organisers in the great competitive markets of the world. In regard to Capital, Mr. Crammond suggests that it is of no avail to point out to workers that the war caused tremendous losses which will involve a lower standard of living, but that a constructive policy must actuate any proposals put before workmen.

It will be generally recognised by those who have had to do with employment during the last few years that the questions of rate of remuneration and length of working day are secondary in their damaging effects on business to the general destruction of organization in industrial enterprises. Labour leaders, who need votes to keep in power like democratic politicians, have pandered to the mediocre and least efficient in union ranks, and they have brought about thereby a condition that prohibits the efficient man from demonstrating his real capacity, and strangles productivity to prevent exposure of the inefficient. Even if one admits the full implications of the slogan of the international trade-unionist, namely, "All wealth belongs to the producer," it should be fairly evident that there can be no greater amount of wealth for distribution than is produced by labour. If production is hindered, the creation of wealth is correspondingly hindered. Negotiations between employers and workers in recent years have been marked by a consistent demand on the part of the workers for less work and work of an easier kind. The demand for higher wages, and the granting of this demand, has been more a reflex of inflated paper currencies than anything else, and when remmneration for labour is received in tokens that change in purchasing value, it is really very difficult to gauge the effect of wages upon production. The definition of a "fair day's pay" is difficult, but, in some quarters, the definition of a "fair day's work" is clearly declared to be as little work as possible. This is the view of those who regard the capitalist as the chiefest manifestation of original sin, but there is a large and influential body of workers who cannot see where employment is to come from if the employing agency is destroyed. It might be well borne in mind by both sides to this eternal controversy, in the days immediately ahead of us, that a fair day's work is the only condition which will enable the employer to give a fair day's pay. The pay admittedly is created by the work, and if the work is not done, then the pay will not be forthcoming.

MR. CRAMMOND further comments on the fact that in 1921 the percentage of national income in British which is expended on national services is 23 per cent, comparing with 8½ percent in 1914, and that the amount of money left for replacing depreciation of works and the maintenance of capital investment, for new investments at home and abroad, has dropped from 23.7 percent in 1914 to 5.4 percent in 1921. The mere cost of government and national defence in Britain is now estimated to take 32 percent of the national income. Similar conditions face Canada, the United States, France, Italy, Spain and Japan. A more convincing argument for general world disarmament could scarcely be adduced. Under such conditions it is a disturbing thing to observe that the nations of the world are now feverishly building the biggest warships, the biggest guns, the largest radio-stations; are perfecting the deadliest toxic gases, designing new weapons of precision for bombing from airplanes, developing fast and mobile "tanks", and doing many other things the world is not told about, all in preparation for future wars. The bright spot on the horizon is President Harding's invitation to a disarmament conference. If the Kaiser has a sense of humour — which is improbable — he might sweeten his remorse by indulgence in sardonic mirth at mankind's curiously persistent desire to reduce the population of the world.

NEW QUARTERS FOR MINE INSPECTION DEPARTMENT.

The new home of the mine inspection department of Ontario at Queens Park will soon be ready for occupation. The building had been previously occupied by the Public Health department and the Assay department. The mine inspectors' office is at present in the Parliament Building where there is no room for testing laboratories. The new quarters will provide much needed space. There is at present being installed a Livins-Olsen testing machine for the testing of wire cables used at mines. Previously the department had no apparatus for the making of the tests which will be requiired under the new mining act.

In altering the building, increased accommodation will be provided for the Provincial Assay laboratories which have been for some years in this building.

The new regulations regarding testing of hoisting cables are not yet in force; but in the new act provision was made that they may be put in force at any time by order-in-council.

Fuel Problems of the Future

"Times" Engineering Supplement.
JAMES FORREST LECTURE.

In delivering the 27th James Forrest lecture before the Institution of Civil Engineers, Sir George Beilby, the Director of Fuel Research, chose as his subject "Fuel Problems of the Future."

As a preliminary he reviewed the fuel position of the world as disclosed by figures given for 1920 by the United States Geological Survey. In that year the total output of coal, including brown coal and lignite, was 1,300 million metric tons, an amount within 3 per cent. of the maximum output which was reached in 1915 and 1918. Of the total the United States produced 45 per cent., Great Britain and the British Empire 22 per cent., and Germany 19 per cent. A significant feature is the rapid development in the winning and use of brown coal and lignite in Europe, and particularly in Germany, where the output last year reached 111.8 million tons, nearly 18 million tons more than in 1919. The total output for Europe was 140.7 million tons, and for the world about 143 millions. Though in its natural state a less concentrated fuel than bituminous or anthracite coal, brown coal has many points in its favour, the chief being the low cost at which it can be won as compared with ordinary coal. Though it contain from 40 to 60 per cent. of water, it is to-day by far the cheapest source of thermal units, and its further manufacture by drying, briquetting and carbonization can be carried out close to the point of excavation and under conditions favourable to production on a large scale, and, therefore, at a low cost. British coal miners and owners will be well advised to keep an eye on the development of brown coal in Germany and elsewhere. According to the extent to which Germany can meet her own requirements for heat and power by the development of lignite, peat and water power, the output of her coal mines will be set free for export, and she will thus take a more important place in the markets of the world.

Oil.

Of oil, the other great natural source of fuel, the world's output in 1920 was about 97 million tons, amounting to 7 per cent. of the fuel in tons, or 10 per cent. if reckoned in potential terms. As the United States, which produced 64.8 per cent. of the total, has extensive oil interests in Mexico, which produced 23.3 per cent., it may be taken that last year she controlled 75 to 80 per cent. of the world's output, and it is therefore significant that in official quarters great anxiety has been expressed as to the probable exhaustion of her resources. According to a statement by Mr. J. O. Lewis, Chief Petroleum Technologist to the U. S. Bureau of Mines, indicates that about 40 per cent. of the oil had been brought to the surface, and that the 60 per cent. remaining underground would last barely 20 years at the present rate of consumption. The domestic production, in the opinion of Mr. Lewis, will undoubtedly be spread over a much longer period than that estimated, but on the other hand the peak of production will be passed long before 20 years, and production will thereafter be at a declining rate. He points out, however, that there are enormous undeveloped resources in other parts of the world, and also that oil may be obtained from other sources than oilfields. The U. S. Geological Survey has estimated that the quantity of oil locked up in the richer oil shales of the three States of Colorado, Wyoming, and Utah is perhaps ten times greater than the amount of the reserve in the oilfields, though the problem of mining and retorting these shales profitably in competition with petroleum from oilfields has not yet been solved.

Alcohol.

Sir Frederic Nathan, the Power Alcohol Investigation Officer of the Fuel Research Board, reports that experiments made last year on the cultivation of Jerusalem artichokes indicated that very good yields of alcohol per acre can be obtained from them, and if these results are confirmed by experiments in the present year it may be desirable to consider the possibility of growing this tuber to supply a limited quantity of alcohol for special purposes, such as aviation. Examination of the artichoke stems has indicated that it may be possible to convert them by a simple treatment into paper pulp.

The use of cellulosic materials is not yet possible, because although research work is in hand to find a process that could be employed on a commercial scale in those regions where such materials exist in definite results. Where, however, materials capable of easy hydrolysis exist, as, for instance, in the case with waste rice straw, the recent large scale experiments in Burma Oil Company, appear to indicate that the joint production of alcohol and paper should be a commercial possibility.

Until alcohol can be made from waste materials which can be collected and treated at small cost, it does not seem likely that Empire-produced alcohol can be imported into this country on any considerable scale; it is improbable that it can be produced cheaply enough or in sufficient quantities from materials grown for the purpose in those oversea portions of the Empire, which will no doubt before long produce it in this way for local consumption.

Peat.

In Germany, as a result of experience gained with the Wiesmoor station, which has been in operation since 1910, it is proposed to establish a line of generating stations fired by peat, extending from Konigsberg on the east to Wiesmoor on the west. This scheme appears to ignore the fundamental difficulty which applies to the winning of peat in quantities sufficient to meet the day-by-day requirements of any large central station. When it is realized that the peat deposit in a good bog 20 ft. deep is only the equivalent of a 12 in. or 14 in. seam of coal, it will be evident that even an output of 1,000 tons a day of air-dried peat involves the laying out and development of an enormous surface. At the Zehlonbruck plant, near Konigsberg, it is proposed to use 920,000 tons per annum, or about 2,500 tons per day. Professor Purcell, the peat investigation officer of the Fuel Research Board, states that to win mechanically 900,000 tons of air-dried peat in one season at least 4,500 men, women and children would be required, and the area over which the spreading and drying operations would extend could not be less than 9,000 acres, or say 15 square miles. He suggests that in dealing with any production over 60,000 to 80,000 tons per annum from

any single district the difficulty would increase as the square of the production.

As regards the Fuel Research Board's own work in Ireland last year, peat was cut, macerated, spread on the bog at Turraun, aid-dried, and harvested there, and 100 tons of it were sent to the Fuel Research Station at the beginning of this year. On arrival it contained about 27 per cent. of moisture, which was reduced to about 17 per cent. after it had been kept under cover for some months. This peat is in the form of hard blocks of various lengths up to about 10 in., with a cross section of something like 2 in. by 2 in. Its density is rather under 1, or about twice that of the ordinary handcut sods made on the same bog. The blocks can be sawn and cut like hard wood, and they stand transportwith very little breaking up into smalls. In this respect they contrast very favonrably with the ordinary hand-cut sods, which break down seriously in transport by rail or road. Steam-raising trials have shown that they are an excellent fuel. They also lend themselves admirably to carbonization, whether in vertical retorts at temperatures between 700 deg. and 900 deg. C. or in steel retorts at 550 deg. to 600 deg. The charcoal resulting from carbonization is an ideal fuel for suction gas producers.

"Availability" of Fuels.

As coal is likely to remain the chief source of fuel not only for Great Britain but for the world at large, the problems of its winning, preparation, and use still occupy the foreground in all serious consideration of the subject. The greatest problem of the future is to determine what proportion of the coal—about 139 million tons in Great Britain—now burnt in its natural or raw state it will pay to subject the preliminary carbonization or gasification, with the object of sorting out the potential thermal units into groups of higher availability or greater convenience as fuels—*e.g.*, gas, motor spirit, fuel oils, and coke. Though these operations necessarily involve the expenditure and loss of some of the thermal units of the coal, so that the collective thermal value of the new fuels is less than that of the original coal, yet the loss may be more than compensated for by the increased value of some of the new fuels. At the prices of to day a "therm" in the form of coal costs from 1d. to 2d., while in the form of motor spirit its cost is from 20d. to 25d., and in the form of town gas 10d. to 15d. These figures show the premiums which can be paid for the higher "availability" of special fuels. The general recognition of the value of the availability and convenience of the more costly forms of fuel must not tempt us to overlook the necessity for a critical examination of the uses to which the more expensive fuels are being devoted.

In the case of motor spirit there is a decided tendency to regard mere convenience as a sufficient justification for its use. While for swift transport by air and by road there is no cheaper substitute in sight, there are good grounds for believing that for the heavier forms of traffic motor spirit may be replaced by much less expensive fuels. A certain amount of success has already been attained in the use of small suction gas producers in the slower and heavier classes of motor vehicles. The most hopeful prospect in this direction appears to be based on small suction gas producers which ought in the first instance to be definitely designed for and worked with one definite type of solid fuel. The most important features which must be taken into account are—freedom from tarry or oily impurities, density, inflammability, and the quantity and nature of the mineral ash.

Low Temperature Carbonization.

The carbonization of selected coals at 550 deg. to 600 deg. C. yields a coke which, while still containing 10 to 12 per cent. of volatile combustible matter, burns with a very slightly luminous, perfectly smokeless flame. Undoubtedly if this smokeless solid fuel could be produced at a cost permitting of its being sold at little more than the price of the coal it would replace, it would lead to a complete revolution in domestic heating, and among other good things to the abolition of black smoke from house fires. This attractive prospect has been spread before our eyes for many years by enthusiastic inventors and company promoters, yet its realization seems always to move a little farther into the future.

The problem really has two distinct sides—the technical and the economic. On the economic side the data for a final solution will be obtained only after the technical solution has been reached. Until a fair-sized industrial plant has been carried on continuously over a long period, making and disposing of all the products of carbonization under steady market conditions, no one can say whether or not the business will be a profitable one. On the engineering side, an efficient and not too costly apparatus must be designed and constructed, in the working of which manual labour, fuel consumption, and maintenance costs are all reduced to a minimum. In these respects—as well as in its output capacity on a given ground area—the apparatus must stand comparison with gas retorts and oil shale retorts of the most modern types. Only when this ideal has been practically realized can the future of low temperature carbonization as a business proposition be put to the test of continuous working on a large scale under the labour and market conditions of the day.

If low temperature carbonization is proved to be a feasible operation commercially, it would find its first and most natural application to the 35 million tons of coal used for domestic purposes. Were the coal all carbonized it would produce about two million tons of fuel oil for the Navy, or considerably more than the peace requirements, though considerably less than the war requirements. The motor spirit produced would amount to about 100 million gallons. The capital expenditure required for the installation of carbonizing plant for 35 million tons of coal per annum would be of the order of 30 to 40 million sterling.

The application of low temperature carbonization to raw coal which is used in the industries must necessarily depend on the successful solution of the technical and engineering problems to which reference has been made. In this case also the future possibilities of this application depend entirely on the evolution of apparatus and methods which will reduce the capital and working charges of the operation to a minimum.

Steam Raising.

When coal is used for steam raising under the best known conditions, it is obvious that there is little to be gained in thermal efficiency by any preliminary sorting out of the thermal units of the coal into fuels of higher availability. It is well known that an efficiency of 75 to 80 per cent. is attainable in steady practice. If the coal were submitted to preliminary carbonization and its thermal units sorted out in the

form of gas, tar, and coke, the coke would contain 70 per cent. of the thermal units, the gas 12 per cent., and the oils 11 per cent. The intrinsic thermal loss would be 7 per cent. and the heat supplied for carbonization 6 per cent., so that the net thermal value of the products would be 80 per cent. The high thermal availability of the rich gas would be thrown away if it were used for steam raising; the fuel oil would be a fuel oil decidedly superior to the original coal; and the coke would not be of more than equal value to the coal. Solely from the steam raising point of view, therefore, a thermal loss and not a gain would result from the operation. In special cases this loss might be compensated for if a local market for the rich gas were available, but in most cases the margin of profit would be much too small to justify the extra capital expenditure required.

Practicable Economies.

The investigations of Mr. D. Brownlie have thrown a much-needed light on the use of coal for steam raising. He has divided the existing boiler installations of the United Kingdom into three classes—bad, average, and highly efficient—10 per cent. falling into the first class, 85 per cent. into the second, and 5 per cent. into the third. With water-tube boilers the efficiency of the bad class is 61 per cent., of the average class 69 per cent., and of the highly efficient 82 per cent., while with Lancashire boilers the corresponding figures are 49, 60, and 79 per cent. If 75 million tons is taken as the minimum amount of coal used annually for steam raising the scope for economy is enormous, for even an overall increase of 10 per cent. would mean a saving of 7½ million tons annually.

Mr. Brownlie's facts and figures are well worth the careful study of all who are seriously interested in fuel economy. They show the enormous possibilities in this direction which are actually within our grasp if we will only avail ourselves of the knowledge which already exists. No new and revolutionary discoveries are required for their realization. The problem of the future which awaits solution is how to stimulate the practical interest of the owners of steam raising plant throughout the country. For steam raising in this country the cheapest form of fuel is coal or coke if it is used under reasonably scientific conditions, and so long as this is the case the use of fuels of higher availability will be economically practicable only under very special conditions.

MINE MACHINERY ORDERS ASSIST METAL TRADES.

After being shut down for a few weeks the Canada forge plant of the Canada Foundries & Forgings Limited, has been re-opened to take care of heavy forging requirements for the mining industry.

MICA IN NORTHERN CAPE BRETON ISLAND.

The occurrence of workable deposits of mica is reported from the neighbourhood of Neils Harbour, in northern Cape Breton Island, associated with feldspar and white quartz. The areas are owned by M. J. McPherson and F. T. Lemoine of North Sydney, and negotiations for sale are stated to be under way.

HIGH ASSAYS FROM BINGO MINE IN NORTHERN MANITOBA.

The Pas, Man.

By REECE H. HAGUE.

A very favorable light is cast upon the Bingo property, Herb Lake, Northern Manitoba, in a recent report issued by Professor J. S. DeLury, of the Manitoba University, who recently spent some time examining and sampling the property and includes in his report much useful information regarding various properties in The Pas mineral belt.

The Bingo Mine is controlled by a company headed by Joseph Myers, of Winnipeg, who recently secured an option on the Rex property, half a mile distant from the Bingo. It is said that a large tonnage of ore has been blocked out on the Rex, where a rotary mill with a 20-ton daily capacity has been installed but is at present idle.

A considerable sum of money has been spent on the Rex, but the general opinion of mining men is that the best plan would be to scrap the present machinery and recommence work on a larger scale.

Mr. Myers has associated with him English capital, and leaves for England this month with a view to raising additional funds to carry on work on the Bingo and the Rex, if the option on the latter property is taken up.

It has long been thought that the only favorable solution offered to the problems at Herb Lake is to amalgamate some of the properties there and work them under one management, thus considerably reducing operating and general overhead expenses.

Under the heading "Northern Manitoba as a Potential Metal-Producer" Professor De Lury writes:—"Stretching from the Beaver lake gold-mining area in the Province of Saskatchewan in an easterly direction across Northern Manitoba as far as the Hudson's Bay Railway a distance of 100 miles or more, is a wide belt of country occupied by pre-Cambrian rocks, which carry several promising deposits of ore of the different metals. Just over the boundary in Manitoba, east of the Beaver Lake area, is the huge Flin Flon ore-body, with 15 to 20 million tons of copper, gold and silver-bearing ore blocked out by diamond drilling, sinking, drifting and cross-cutting. South of Flin Flon a few miles is the Mandy copper mine, from which several thousand tons of high-grade ore have been shipped under very adverse conditions for transportation. Other copper properties of promise are located in this general vicinity. Farther east, some interesting gold-bearing deposits have been located in the country around Copper and Elbow Lakes. At the eastern end of the mineral belt is the Herb Lake gold-bearing district with which we are more closely concerned. The lack of railroad facilities is delaying development in the copper areas of the western part of the belt. Competent engineers have demonstrated that both the Mandy and the Flin Flon ore bodies will give a safe profit. Competent engineers have shown, too, that some of the Herb Lake gold veins offer attractive inducements. This area has good enough transportation facilities and only lack of capital is keeping it from becoming a profitable gold-producing camp. The fact that all the mines of the belt with a notable production to their credit and all the prospects with considerable development done on them are very close to the water's edge, is significant for the need of a more thorough prospecting of this large area."

In his summary of a report on the Bingo group of claims Professor De Lury says:—"The Bingo group of

mineral claims is located in the Herb Lake gold district, an area of great promise, at the east end of the mineral belt of Northern Manitoba. The claims are 20 miles, half by road and half by water, from the Hudson's Bay Railway.

"The location of the claims with respect to the rocks of the area is favorable.

"The more prominent vein on the Bingo claim, as the result of careful measuring and sampling shows 11.66 inches of ore in its 170 foot shaft running $145.45 to the ton, besides other values of importance not included in this estimate, together with 100 feet of surface which shows an average of 5½ inches of quartz carrying $258.90 per ton. These values in a vein which is accompanied by several parallel and similar veins, all carrying high values, and the good prospects of the continuation of these veins in depth and along the surface which is now made inaccessible by a swamp, together with the fact that the gold is very uniformly distributed through the quartz in these veins and throughout the length of many of the rich veins of the district, lead me to the conclusion that the Bingo group has worderful mining possibilities and to advise that the necessary capital be expended for the proper development of the veins.

"Mining and milling conditions are favorable. Transportation facilities are excellent for a gold-mining camp. Wood, timber, water, mill-site and dumping space are available and can easily be arranged for.

"An estimate of the costs for veins of the size of the Bingo main vein is $20 per ton. There is a possibility that the tonnage might be enormously increased and the cost per ton reduced by the mining and milling of mineralized rock, most of which shows surprisingly good values where tested."

Professor De Lury goes fully into the geological features and occurrence of gold in the Herb Lake district, the first discovery of which was made on the Kiski property in 1914, since when several gold veins have been found and considerable development work been done, particularly on the Rex, Northern Manitoba, Bingo, Kiski-Wekusko and Dauphin-Elizabeth groups of claims.

"The veins" writes Professor De Lury, "strike north east with the prominent structures of the containing formations. They are mostly steeply dipping at angles of 74 to 90 degrees from the horizontal. Some of the veins are traced for over 1500 feet; others for only a few hundred feet, in most of which cases the outcrops are concealed for some lengths by overburden and the lengths of the veins vary from a few inches in some to as high as 15 to 20 feet in others, with an average in the larger ones of between 1 and 4 or 5 feet.

"There are several kinds of quartz in the area. The best gold-bearing veins are a white sugary variety. The minerals found in these veins are; free gold, arsenopyrite, very small amounts of galena, zinc-blende, pyrite and chalcopyrite; telluride in one vein at least; and tourmaline and feldspar are usually present in small quantities. Free gold is commonly seen in the quartz, the most of it being associated with arsenopyrite. The sulphides in most of the ore make a very small percentage of the whole, usually between one and two or three per cent. The sulphides, largely arsenopyrite, are generally more abundant along the walls of the veins and in little bands in the quartz, some of which are parallel to the walls and others in cross and twisted bands. Some free gold is found in quartz with no sign of sulphides in the immediate vicinity.

"The Rex Mine shows a return of over $30,000 worth of gold, from between 500 and 6000 feet of development work on a vein which averaged 3 to 3½ feet in width for a length of 1,700 feet, with an estimated value of $20 to the ton. The shaft is now at a depth of about 270 feet and the vein is strong in the bottom.

"The Northern Manitoba vein produced quartz, which ran over $80 per ton, from its 125-foot shaft sunk on a vein about a foot wide. Other veins in the district have poorer values but some of them are undoubtedly rich enough to warrant extensive development work.

"On the peninsula at the north end of the lake some small veins and stringers occur in an irregular sheared body of granite. The quartz in these is similar to that in the Kiski volcanics and is quite rich. The whole body makes an attractive prospect.

"In an area near the northwest end of Herb Lake, there is an interesting occurrence of silver-bearing galena and zinc blende which further investigation may show to have commercial possibilities. On the whole, the Herb Lake district wears the aspect of a coming important mining camp."

From 82 samples taken from the Bingo by Professor De Lury, an average value of $145 a ton was secured. The Professor states that the values in the mineralized rock and schist of the shaft were surprisingly high. The sampling of this material should be made one of the definite objects in any future examination of the property, he maintains. A sample of mineralized rock with no quartz, picked from different parts of the dump from the shaft to get an indication of the values in that sort of material; and a similar sample, picked to show what was carried in the same kind of material, carrying small stringers of quartz; gave assay returns so high that they seemed incredible, states Professor De Lury, who asked the assayers to check them over. The assayers advised that the samples yielded considerable free gold on panning, enough to make them guarantee the assays as being approximately correct.

The first of these samples assayed $230.60 per ton and the second $228.40 per ton and Professor De Lury says there is a good deal of such material in the dump, and though these assays may be unfortunately high there is good evidence from them that much of the rock near the veins will be valuable milling ore. These results also help to explain the unexpectedly high results taken from the shaft away from the vein proper. There is a suggestion in the whole results from these extra samples that the entire dump from the shaft might be milled at a good profit.

Asbestos Prices.

We have received from the Asbestos & Mineral Corporation of 1919 Broadway, New York, a coloured chart showing the variations in the price of the several standard grades of asbestos from 1912 to the end of 1920. The chart (which is copyrighted) indicates that the greatest and most lasting appreciation in the price of asbestos has taken place in the case of No. 1 and No. 2 crudes, particularly in No. 2 crude. Long fibre appears also to be much more in demand, judging by the course of its selling price, than medium fibre. The rise in the selling price of all grades of asbestos is most striking, Crude No. 1 for example having risen a little over $225 a ton at the beginning of 1912 to a peak of $3,000 at the end of 1918.

ASBESTOS IN ARIZONA.

The University of Arizona has recently issued a Bulletin on asbestos, with particular reference to the occurrence of this mineral in Arizona, of which the "Journal" has received a copy by the courtesy of the Director, Prof. G. M. Butler, who is a joint author of the Bulletin.*

Arizona leads all the states of the Union in production of chrysotile asbestos and under a recent enactment the Indian reservations of the State have been opened for location, leasing and mining of asbestos, long known to exist in the reservations, but hitherto unavailable.

The distinguishing characteristic of Arizona chrysotile asbestos when compared with the Canadian variety, is the low quantity of iron oxide contained in the Arizona asbestos, with it is suggested might make the Arizona variety more suitable than Canadian asbestos for electric insulation. An analysis of a selected specimen of Canadian asbestos, said to be of exceptionally good quality, showed a content of 2.5 percent of iron oxide, whereas five analyses of Arizona asbestos show iron oxide content varying from 0.51 to 0.88 per cent.

Another characteristic of Arizona asbestos is that "a considerable portion of the fibre is somewhat harsh and splintery as compared with the best grade which is soft and silky". This peculiarity is discussed at some length ,and the opinion seems to prevail that the presence of calcite causes the harshness of the fibre. One authority cites the occurrence of veins of fibrous calcite "in which the asbestos appears to have been so completely replaced by fibrous calcite that the calcite is pseudomorphous and preserves the fibrous structure of the chrysotile". Professor J. T. Donald is quoted from the transactions of the General Mining Association of Quebec in 1891 as suggesting that chrysotile with a high proportion of water is more flexible than specimens with less water, and while it is believed that his conclusions are probably applicable to material found in some localities "there are other factors besides the percentage of contained water that affect the flexibility of the fibres".

The known deposits of asbestos in Arizona occur in serpentine in limestone that has been intruded by diabase. The deposits are shown as occurring near Globe, in the Sierra Ancha, near Navajo and Apache reservations. Full particulars of the existing mining operations are given in the bulletin, together with the names of 21 producers of asbestos.

A bibliography is appended, the principle reference being Fritz Cirkel's monograph. One reference which is quoted from this monograph states that in Canada "several attempts at underground mining have proved failures". It is eleven years since the second edition of Cirkel's was issued by the Mines Branch, and much has happened in the meantime, particularly the development of underground mining in the asbestos regions of Quebec. The extreme paucity of the literature on asbestos is shown by the limited number of references, but the omission of the Mines Reports of the Province of Quebec is noticeable. The latest and most authoritative references to asbestos occurrence and asbestos mining are to be found in these reports. There is however a real need for a revised monograph on Canadian asbestos.

* ASBESTOS by M. A. Allen and G. M. Butler. Mineral Technology Series No. 24 University of Arizona and Arizona Bureau of Mines Tuscon, Arizona, 1921.

NOVA SCOTIA COAL MINING NOTES.

At the Toronto Mine at Little Bras d'Or, Cape Breton Island, a mine examiner was killed by a gas explosion on the 8th August. He was carrying a safety lamp and also a carbide lamp. Only small quantities of gas have on a few previous occasions been noticed in this mine, which works an area of coal with a surface outcropping under fairly shallow cover. The use of mixed lights in a coal-mine is never to be recommended, and there is no guarantee that gas will not appear in a coal-mine, no matter what the previous record of the mine.

Mr. W. Foster Brown, who has recently examined the mining properties of the British Empire Steel Corporation, is Chief Mineral Adviser to the Department of Woods and Forests in Britain, and holds the quaint title of Deputy Gaveller of the Forest of Dean. The Department of Woods and Forests administers all the submarine coal in Britain for the Crown, with the exception of a small area in the Cumberland County field which for some reason was sold to the Lonsdale estate. There are no regulations in the Coal Mines Regulation Act in Great Britain with regard to the mining practice to be pursued in mining submarine coal, and these matters are entirely administered within the discretion of the Commissioner of Woods & Forests, who has the power to specify such mining conditions as shall ensure the maximum extraction of coal. Existing leases are also modifiable to suit the conditions that may be encountered in mining, and there has not been any attempt to lay down hard and fast rules regarding submarine mining practice, as it has been realized that only by trial and actual attempt could suitable regulations be framed. The practice of submarine coal extraction is conditioned by depth and nature of cover, by inclination of seams, by the nature of the sea floor, thickness of coal and the number and spacing of superimposed coal-seams, and by absence or presence of faults or lines of weakness or shattering in the measures. It is fairly evident that the factors vary within such wide limits that no hard and fast rules governing practice are possible, except, of course, the rigid rule that all operations projected or being carried on should have the prior approval of the expert authority representing the interest of the Crown. The submarine mining law in Nova Scotia is statutory and inflexible, and it is probable that the next few years will see considerable modification of the regulations now in force.

Mr. Brown, in the course of his visit, has visited the workings of the various submarine collieries in Cape Breton, and has also inspected the underground workings in the iron-ore mines of the Corporation at Wabana, Newfoundland. He has also looked over the operations of the Acadia Coal Co., at Stellarton, N. S.

The disabilities under which the extraction of submarine coal suffered by reason of conflicting lease rights in the Sydney district have been avoided by the consolidation of the Dominion and Scotia companies, but the submarine workings are now so extensive, and form so large a part of the productive areas of the combined companies, that the best available expert advice has been deemed necessary in consultation with the mining engineers of the Corporation.

Production of coal in Nova Scotia is showing much improvement, so far as capacity of the mines for output is concerned. The Dominion Coal Company's Cape

Breton mines, during the week ending the 13th August, reached almost 14,000 tons daily, which is a recovery from the low level of about 10,500 tons daily, caused by war drain on labour.

Preparations for sinking a new shaft at Glace Bay are proceeding. This shaft will tap the Phalen seam near the shore and will give the best point of access possible for winning of the submarine coal tributary to Caledonia Mine (Dominion No. 4 Colliery), now entirely worked out under the land area. The shaft will be large in size, to provide ample capacity for ventilation and hoisting requirements, and will be concreted, where considered necessary.

A new bankhead for the Florence Mine at Sydney Mines, similar in design to that recently completed at the Jubilee Mine of the Scotia Company at Sydney Mines, is understood to be projected. A large area of submarine coal will be drawn to the Florence Slopes, a condition made possible by the consolidation of coal leases.

It is understood recent borings have demonstrated that the Emery Seam in the Glace Bay basin, which underlies the Phalen Seam at a depth of about 160 ft., and extends underneath and outside the whole area of the Phalen is of greater thickness in the eastern portion of the field than has been the case in the workings on the western side, and is regular in its contours.

During the war period the Dominion Tar & Chemical Company at Sydney was unable to dispose of the pitch (which is a by-product of the coal-tar distillation plant that takes the tar made by the Dominion Steel Corporation's coke-oven plant) owing to inability to obtain shipping. It was necessary to store the pitch in ponds on the ground. Recently a cargo of pitch had been dug up into piles for shipment, and as a result of extremely hot weather and the prevalence of bush and grass fires, one of the accumulations caught fire and burned with great emission of smoke. The fluid pitch ran down a drain and threatened for a time to damage the coke-oven plant, but the fire was finally controlled by earth dams. Some rolling stock was burned and the fire caused the Steel Company's officials much anxiety before it was controlled. The loss of the pitch inflicts a severe financial loss on the Tar Company.

The numerous bush fires which have prevailed in the colliery districts during the early part of August have kept the fire-fighting organization of the Dominion Coal Company very busily engaged protecting houses, dams, transmission lines and much equipment that is scattered throughout a district covered by brush and second-growth timber. The situation was a very anxious one during the first week in August, but heavy rains have removed the danger.

The mining towns in Cumberland County were closely threatened by fire in the same period, and much valuable timber, owned by the Dominion Coal Company in the Springhill and Parrsboro section, was burnt over. The general increase of electrical transmission lines in the mining districts in Nova Scotia has brought about a new hazard from forest fires, and thorough clearing of the transmission lines right-of ways seems advisable to prevent, as far as possible, damage from forest and brush fires.

PORTLAND CANAL MINES.

By ALEXANDER GRAY, Montreal.

New York and London bankers, financiers of all nations, are so keen to increase the output of gold—the world is so weary of "paper" money — there are accumulating evidence of activity in meritorious mining enterprises and gold areas, producing or likely to reach the producing stage in the near future. Gold shares, with operating costs coming down and the purchasing power of gold going up, are confidently expected by the highest authorities to be in greater demand.

Canada in particular is most optimistic as to its gold areas—which have reported a steady advancing output while other countries have been lagging. Already Canada has two or three of the greatest gold mines—and others nearly great. The prestige of Hollinger Gold Mines is universally conceded. Northern Ontario has flattering possibilities. It is in the Portland Canal district of British Columbia, however, singular as it may seem, that the most experienced mining capitalists lately have been concentrating in the belief that the Premier Mine section will be the source of much greater production.

The British Columbia Government officially announces that the Premier Mine "bids fair to become the leading gold-silver producer of the Province". Large ore shoots have been "proved to a depth of 600 feet." The Guggenheim-Trites-Wood-Wilson-Daly interests in the Premier have been acquiring other areas, basing their optimism upon Premier developments and outcropping conditions elsewhere.

Not to be outdone, however, New York capitalists not only have taken over the Big Missouri properties adjoining the Premier on the north, but they have now included in their holdings a one-quarter interest in what is known as the International Group of claims, which adjoins the Premier on the south. This latest acquisition takes in the boundary, Cabin, Crub, Crubstake, Lucky and International Fraction of the Daly Group. The owners of the International are the same—excepting the Guggenheims—as those who own the Premier. Pat Daly, who is understood to have negotiated the Big Missouri deal, owns a one-quarter interest in the International Group—and it is this which he is disposing of to the Portland Canal Mines Company. Upon investigation, it is assumed that the International ground has the same geology and mineralogy as the Premier. Portland Canal Mines, therefore, becomes one of the dominant factors in the Portland Canal district. This fact and the extension of the Guggenheim holdings in the district, sustains the statement of the British Columbia Minister of Mines that the Province anticipates a larger gold and silver output from Portland Canal. "From the developments now in progress", writes the chief of the British Columbia Bureau of Mines," it would seem that in a short time the annual production of gold in British Columbia should increase considerably."

Ontario's metallic mineral production to date amounts to about $650,000,000 in value. The metal mining companies have expended about $750,000,000 in exploration, development and mining operations and have paid $125,000,000 in dividends. The difference $225,000,000, between receipts and expenditures is offset by the present value of the assets of the successful metal mining companies.

ROSEATE OUTLOOK FOR GOLD MINING.

By ALEXANDER GRAY.

Extension of the embargo upon the exportation of Canadian Gold has elicited no more than passisg comment. The significance of Ottawa's action is deeper-seated than is discerned outside of banking circles. That gold production and gold mines capable of contributing the yellow metal are to benefit by immutable economic laws, is the frankly-avowed judgment of those whose responsibility it is to hasten the restoration of the world-over equilibrium. Instead of being in disfavor, therefore, bona fide gold mines—anywhere and everywhere—are believed to have entered upon a period of unprecedented prosperity, contingent only upon reduced costs, which are practically assured.

"The world is so full of paper that the resumption of gold standards and rapid increase in the output of gold are essential", writes one now prominent in the Seats of the Mighty.

"Under no circumstances must anything be done to curtail the production of gold", said one of the three outstanding Canadian bankers when he heard of the proposal to impose additional taxes upon Ontario companies.

More gold mines, lower commodities, a purchasing power for gold that will greatly surpass what it has been, caused Mr. Samuel Evans, Chairman of Crown Mines, Ltd., at the Witwatersrand, recently to remark:

> "I am convinced that the turning point has been reached, that henceforth gold will rise in value, and that, if justice is secured for the industry, working costs will decrease as prices fall. There will no doubt be fluctuations as in the past, but for a great many years to come the general tendency will be in the direction of an appreciation of gold in terms of commodities and services. It is within the bounds of possibility that the time may yet come when the Crown Mines will find it profitable to start again at the outcrop and mine three pennyweight Main Reef."

Were Mr. Evans an academic idealist, instead of the administrative chief of a company which last year produced 671,605 fine ounces of gold valued at £2,852,796:14:2, plus the net premium obtained for this gold, amounting to a further £920,062:1:7, he might be suspected of cherishing the "baseless fabric of a dream". Being a sound economist, identified with a group that accounts for about one-half the world's annual gold production—his fancy never has been permitted to enmesh his economics. Before the great tonnage of three dollar ore and over remaining unmined in the Main Reef — one of the series from which the world has been supplied with the larger part of its gold for nearly half a century, can be dealt with, Mr. Evans fully realizes what changes must be made in operating conditions. Gives these remedies, Mr. Evans bases his confidence in the future of gold mining upon these grounds:

> "The unprecedented fall that has taken place in the purchasing power of gold since 1914 is attributable mainly to the world-wide substitution of paper for gold for monetary purposes. It is true that the United States only departed from the gold standard for a comparatively short period (from September 7th, 1917, to June 10th, 1919), but prices were forced up in that country owing to the arrival there in 1915, 1916, and 1917 of a great quantity of gold (the excess of imports over exports of gold being 1,132,023 dollars equal to £232,926,500) which had been superseded by paper in Europe, and the fact that the newly established Federal Reserve system enabled that gold to be used as a basis for an enormous superstructure of deposit and bank more credit. A further cause of inflation in the United States was the action of the Federal Reserve Bank in withdrawing from circulation gold certificates which were fully backed by gold and replacing them by Federal Reserve notes which only required a gold backing equal to 40 per cent. of their face value. When I last addressed you I expressed the opinion that sooner or later gold would come into its own; that it could not be forced back to a currency, the supply of which is determined by the cost of its production."

Although it holds over $3,000,000,000 in gold, the United States cannot extricate its foreign trade relations from the maze of spurious money. Since 1915 belligerent nations of Europe have lost about £400,000,000 in gold—which they want to recover—or as much of it as they possibly can recover. Actually the United States on July 1st, had in stock $3,223,000,000 in gold — said to be equivalent to 40 per cent. of the monetary visible supply. Of this, $2,462,000 was in the reserves of the Federal Reserve Banks. Ordinarily that would permit of inflation of credits. Instead of this, because of the international trade blockade, deflation has proceeded apace. The gold importations during the first half of this year amounted to about $400,000,000—and they emanated from 56 foreign countries. The States drew from this wide field—and the fact is significant as confirming what Mr. Evans asserts; yet not only has the note circulation of the entire Federal Reserve system decreased $867,000,000 since December, or 25½ per cent., but discounts have been reduced $1,300,000,000 to July 1st. Most of the debtor nations being unable to trade at the premium upon exchange on New York — and having inconvertible paper which creditor nations cannot accept—the States has credit to a phenomenal extent and experienced a setback in its export trade in the fiscal year ended June 30 of $1,213,000,000. The break in commodities, involved credits and debits, have dislocated exchange markets, so gold in South Africa and Canada has been commanding a further premium of late — and whether or not debtor nations will be able to do some financing of a temporary character, it is obvious to bankers that greater gold production and a redistribution of the metal will hasten the restoration of economic equilibrium. Mr. Evans painted a glowing picture.

Lighting River Discoveries.

It is reported from Cobalt that prospectors have discovered high grade ore in the Lightning River area and that some very rich samples have been recently brought out.

The Lightning River area lies south of Abitibi lake and is near the Quebec boundary. It is reached by road from Matheson on the T. & N. O. railway or by water from La Reine on the C. N. R. Most of the work done has been in Holloway and Harkor townships.

Gold was found in this area in 1917. A number of veins carrying gold have since been found by stripping. The gold occurs in quartz veins enclosed in basalt or rhyolite or in silicified basalt.

Some account of the geological features and a description of the early discoveries is to be found in a report on the Abitibi area published by the Ontario Department of Mines in 1919.

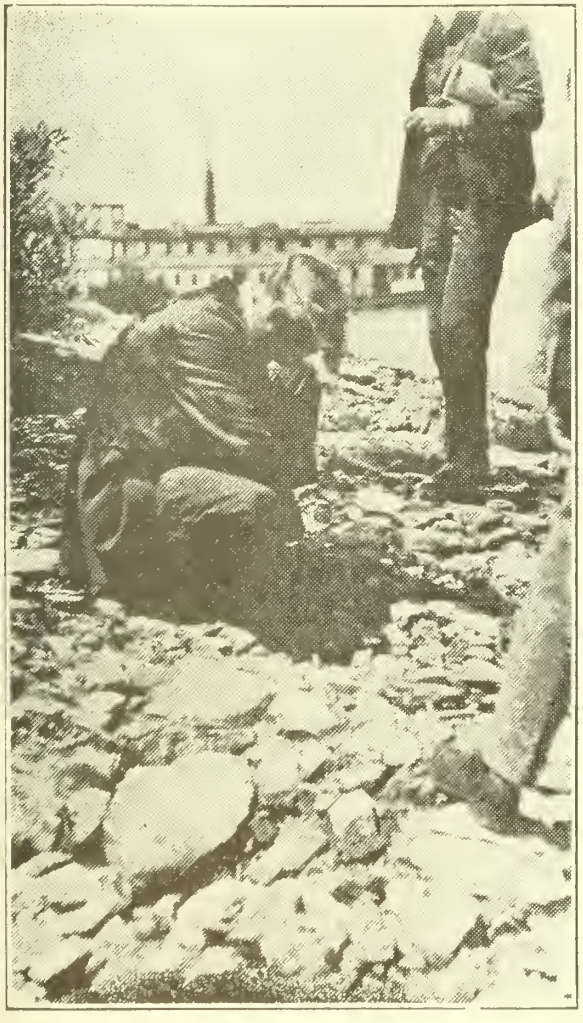
The History and Romance of Oldest Mine in Canada

Found 235 Years Ago by Sieur de Troyes, Commander Of A Detachment Of One Hundred Men Who Found Their Way To Lake Temiskaming.

(By J. A. McRAE, Cobalt.)

Found in 1686; lost in the passing of more than two centuries; found again in 1850—that tells briefly of the finding of what later became known as the Wright Mine, the oldest mine in Canada.

In the National Library of Paris are some notes which deal with the discovery of lead ore in 1686 upon the eastern shore of what is now known as Lake Temiskaming. These notes were taken from the diary of Sieur de Troyes, and are referred to as "Relations and Journal of a journey to the North by a detachment of one hundred men under the command of 'Le Sieur de Troyes', in date of March, 1686."

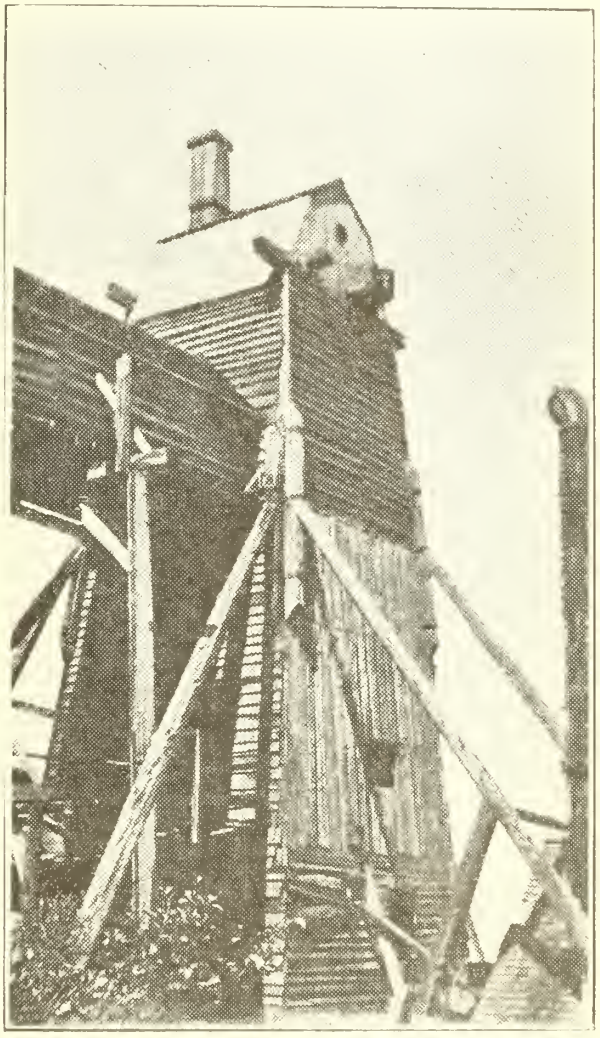


Exact spot where Sieur de Troyes discovered the deposit in 1686. Mining Commissioner T. E. Godson examining the ore.

Thus it was, that at a time when a few venturesome souls, some of them, perhaps, with nothing short of an empire in their brains, and some of them merely the *coureur des bois* of a new continent were engaged in the difficult task of establishing the white race in North Ameriea, that an ore deposit was discovered, only to be lost, they found again after the sway of the Indian tribes had become dissipated before the advance of civilization in Canada.

Names of Officers of the Detachment in 1686.

Chaplain . . . . . Rev. Father Silvie, Jésuite.
Commander . . . . . Sieur de Troyes.
Lieutenant . . . . . Sieur de St. Hélène.
2nd. Lieutenant . . . . . Sieur de Hyberville.
Major . . . . . Sieur de Maricourt.



Shafthouse. Located on the original discovery.

Assistant Major . . . . . Sieur de La Noue.
Board Commissioner . . . . Sieur Lallement.
(Also designed to command a vessel in case we should not locate one to come to Quebeeq).
Captain of the Guides . . . . Sieur de St. Germain.

Narrowly Missed Altering Tide Of Progress In North America.

It is perhaps one of the strangest chapters in Canadian history that while atention was turned to the mineral possibilities of the country as far back as 1686 following this discovery on the eastern shore of Lake Temiskaming yet within three miles of the western shore of the same body of water the fabulously rich silver veins of the Cobalt district actually lay bleaching in the sun until accidentally found in 1903.

Just here, it is interesting to indulge in conjecture as to what influence the discovery of these vast riches in native silver might have had upon early settlement on the North American continent. It seems quite safe to assume that had Cobalt been found in 1686 the attention of the Old World would have focused with great intensity upon this region. It is not unreasonable to suppose that the tide of immigration to North America would have been in this particular direction. It is probable that bitter jealousies would have grown in the breasts of those who were blazing the western trails for France and those who were steering the destiny of Anglo-Saxon influence in the New World.

It is one of the marvels of the opening of Northern Canada that for more than two centuries, white men, armed with all the inquisitive instinct of the race, should have trekked along Lake Temiskaming, camped upon its shores and failed to receive any intimation from their fellows or from the natives of the rich silver veins lying in the very shadow of their camps.

But, to turn again to the history and romance of the Wright Mine: The following are notes as taken from the Commander's diary, dating from May 12 to May 24, 1686, the date on which the lead deposit was found:

The Diary of Sieur De Troyes.

On May 12th.... We reached "Mattawan" which signifies in Indian language "Fork of Rivers": one being at a point that the left is to the South, and the road of Ottawa's to the right, which is North. Consequently my road leads me to Temiskamingue. I arrived at this place of Mattawan very early; this gave an opportunity to the Rev. Father Sylvie to celebrate Holy Mass. We were at a point where the Indians were camped, and were making canoes. They seemed to be greatly surprised to see such a lot of people. It had snowed in the morning, but the evening was very nice: I had dined with Sieur Juchereau that came from Michilmakina, and was going to Quebecq in great hurry, to bring news to Monsieur le Marquis de Denonville. He had arrived as I was having dinner, and continued his journey shortly afterwards, to gain time on his route. In the same time I ordered Sieur de St. Helene with three of our canoes to go and meet Mr. d'Hyberville.

On May 1th.... It rained, snowed and strong wind all day; also continued the next day till noon. Monsieur d'Hyberville arrived, and told me he had uselessly waited for two days for the canoe I had made him wait for.

I was very suspicious of the Indians: consequently, in order to keep my staff on the watch, I had ordered that nobody on the guard should sleep, and on the first alarm, they were to put out a small fire, and in one word, everybody was ready and in order, the arm in hand.

I got a cross erected on the point of the Fork, and our English interpreter opened his leg to the bone with a stroke of the axe. We count from the Island of Montreal to Mattawan: one hundred leagues (or 250 miles).

On May 15th.... We could not start before sunrise on account of portaging we had to do in water which was extremely cold. We left after Mass was celebrated, and having made three portages, we camped one league higher than the first, and three and one half from Mattawan. One of our canoes was broken in pieces in the second portage. Having landed in a rapid, we saved the contents, but we got some of the staff hurt. I got in the canoe of the Captain of our Guides, an Indian that knew the road of the "Bay" perfectly well. I hired him in Mattawan.

On May 16th.... We were camped eight leagues from Mattawan, one league above the fourth portage. The road is very bad and for three hundred feet long, Sieur de St. Helene was dragging.

On the 17th.... We went up again and the place that we name "The Long of the Soo". It is two leagues long and is extremely difficult on account of its great current. We had to pole it nearly all the way, and dragged it in five or six different places. We got some canoes damaged and we camped above the last rapid.

On the 18th.... We left in the morning, and left although there was a big storm that lasted very well near all day. Arrived at the house of Messrs. The Company of the North. This company is on an island of lake Temiskamingue: it may have one half a league of circumference and between two rapids proceeding from a little river called "Matabec Chouan" in Indian, from which some Indians come out to trade. There was fourteen Frenchmen in this house for the Company that were as joyful as we were of our arrival, that we celebrated from parts and others by several shots of guns.

On the 19th.... And the two following days, the weather was very unfavorable. Messieurs de Ste. Helene and d'Hyberville employed with Monsieur de St. Germain business of the Old and New Company, and furs that was in the store where they appointed Sieur Sibille to render accounts of all to the Company. We left him four men to make the trade with very little provisions. Sieurs Guillet and Villedieu stayed for three days at Nipissingue, Savage Nation, to get canoes made and to bring them to Montreal, as for us, we traded with the Indians that were close to our house to replace the ones we had and that we had left there on account of them being too large and too heavy for the balance of our journey. I was very careful to put two good canoe men for every canoe, in order to jump the rapids.

On the 22nd.... It rained a part of the day: this did not stop us from going after celebration of Mass, followed by three canoes to go and visit a mine at six leagues from the house. I gave orders to Sieur de Ste. Helene that I left, to settle the affairs and to join me the next day with the balance of the staff, and to keep in the Lake the route of the North, to facilitaate his joining me. Two leagues from the house, I met three Indian camps that traded a small canoe of four places with me, that I made use of the balance of my journey and for my route to Quebecq. I camped from there on an Island: weather not permitting me to go further.

On May 23rd.... After Mass, we walked to search the mine. The man named Coignac guided us. We met in our search an Indian camp that the people the previous day had killed a big Moose. This gave me an opportunity to camp close to them, and in order that Coignac would find the mine easier. He looked for it uselessly the balance of the day; during this time, the two lieutenants left the house to join me with all our staff, but a big storm separated them, ones took the South and others took the North. One part got on Islands, this was the cause of very few joined me.

On May 24th.... A very heavy wind all day accompanied by rain: but Cognac that had renewed his memory assured me that he recognized himself and that the mine was very close. I got in canoe with him: I paddling in bow and he steered, and did not quit our search, although the weather was very bad to go to the place where Cognac thought the mine was. We found it, indeed this mine is situated to the East and West on the borders of the Lake. West of a rock in form of a half circle that has fifty feet on the edge of the water, ten feet high from the level of the water and one hundred feet deep, having no earth on it and losing itself under a mountain covered with rock. We extracted a few small pieces with great difficulty and returned to the Camp.

Time of the Re-Discovery.

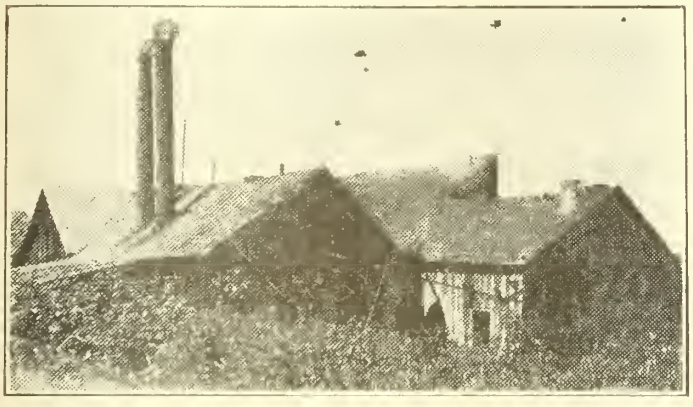
There are no illustrations or drawings in existence which deal with the mine as it appeared more than two centuries ago. Indeed, there is but meagre mention made of the deposit until about 1850. It was about this date that Mr. E. V. Wright of Ottawa, who owned the timber in this locality, re-discovered the deposit.

Wright was engaged in removing timber from his concession, when the calks on his boots chipped off some of the galena and lead-bearing ore. Samples of the ore were taken to Ottawa where they lay for several years on the desk of the discoverer. About 1870, it occurred to Wright to have the samples assayed. The result of the assay was such as to arouse considerable interest. Shortly after this, Mr. Wright, accompanied by J. M. Currier and Mr. Eustis from Boston came up and commenced work, sinking a shaft to a dtpth of about 12 feet. From this shaft, they took out about ten tons of ore. Details of the result are lacking. It is recorded, however, that a second shipment was made by raft, but the crude conveyance smashed up in a mad plunge through the rapids at Deaux Riviers.

Nothing was done until 1885, when George Goodwin, of Ottawa, together with G. T. Bropy advanced sufficient money to pay for sinking the shaft a further 50 feet in depth, as well as installing some mechanical equipment and a five-ton stamp mill. This plant was afterwards burned. No ore was shipped as a result of this work.

About 1890, Robert Chapin, at that time president of the Ingersoll Rock Drill Company, (N.Y.), bought the property and made an option payment on the basis of 125,000. He installed the first air compressor in the country, and built a fifty or sixty ton mill. He continued the shaft to a depth of 250 feet, and did considerable lateral work. This resulted in the shipment of a considerable quantity of concentrates, the value of which seems to be impossible to ascertain at this date. It is said that Mr. Chapin became involved in some bad investments which caused him to abandon this mining project with the result that the property reverted to Wright, the principal holder.

In 1895, Wright sold the property to the Petroleum Oil Trust, of London, England. The new owners sunk



The old Wright Mill.

the shaft another 50 feet in depth and did several hundred feet of drifting and cross-cutting at the bottom level, as well as some work at the 250-ft. level. The mill was also operated, the concentrates being shipped to Swansea, Wales. No figures are available as to the amount of concentrates produced.

The mill and buildings as erected by the Petroleum Oil Trust are still standing, although the machinery has been pretty well all removed. The writer visited the mine, June 18, 1921, together with the members of the Ontario Mining Association who were being entertained by the Temiskaming Mine Managers' Association. The four views presented with this article were taken at that time. Unfortunately, a fifth picture, showing the style of bunkhouses, etc., is too poor to reproduce. These buildings are of the old-fashioned type, features being the many gables as well as having a ground-floor entrance and a second story entrance by stairways leading from the ground.

A few years ago ,the Wright Mine was bought by the Timmins-McMartin interests of Montreal, and is still owned by them. The underground workings are filled with water; the plant is completely dismantled, and the visitor finds difficulty in throwing off a feeling of peculiar sadness as he views this neglected strange link between Canada of the present day and that wild land of 235 years ago, long before Wolfe took Quebec, and even dating back nearly a year before La Salle, greatest perhaps of the French pioneers to North America. It was in 1682 that history tells us that in the name France, La Salle took possession of all Louisiana, from the mouth of the Ohio to the Gulf of Mexico in a resounding proclamation handed down to us. On the column was inscribed "Louis le Grand, Roy de France et de Navarre, regne; le neuvieme Avril, 1682." It was just four years later that the Wright mine was found, thus linking itself with a past about which only a little is known and which occupies but a dim place in the minds of men.

SILVER ISLET MINE.

J. J. O'CONNOR, Port Arthur.

Developments at Silver Islet continue to be of the most encouraging kind. The drift that is being driven from the old fourth level, along the graphitic portion of the Macfarlane dyke, is now in 350 feet. On August 1st, a calcite stringer, carrying pyrites was encountered in the face of the drift, other stringers were met with, carrying galena, zinc-blands and pyrites. The drift is now in a bunch of calcite stringers, aggregating about six feet in width, carrying the above national materials, together with silver, being the first silver to be encountered in the new workings.

While this aggregation of stringers does not amount to a vein, the fact that the ground covered by them is well mineralized, and carries silver, is highly significant, when the further fact is noted that it was in just such ground that the high silver values were met with in the old workings, and not in the more defined portions of the vein. It would seem that the expectations of the Islet Exploration Company, are about to be verified, and that when the great fault is met with at the intersection of the Burnt Island vein, good silver values are almost assured. This drift is to be continued for at least 1,200 feet, or until it cuts the other known value, of which there are, at least two.

The shaft at Edwards Island, nine miles east of Silver Islet, is still in massive arsenical silver, at a depth of 50 feet, there being no change from the surface. The Islet Exploration Company will continue the sinking on this vein to a suitable point, before drifting is commenced.

Dr. Tanton, of the Geological Survey, Mines Branch, Ottawa, has spent part of three Summers covering the coast line in the vicinity of Silver Islet. He has located a vein on Marvin Island, situate about two miles west of Silver Islet, carrying high percentages of nickel. He is now operating in the Loon Lake area 27 miles east of Port Arthur.

THE GRAPHITE INDUSTRY.

The production of graphite in Canada and the United States has not been a source of large profits to the operators and some of the American producers are now urging that import duties be imposed to assist producers in competing with foreign products. In an article reviewing conditions in the industry, Mr. C. L. Miller urges in "Engineering and Mining Journal", Aug. 6, that a more promising plan is to perfect the refining and concentrating methods and so reduce costs that competition with foreign products is not detrimental. He states that while the graphite industry in the United States is at present in a demoralized condition, it is not hopeless, marketing has been haphazard and few attempts have been made to systematize it. Lack of uniformity in product and irregularity of supply has made it difficult for manufacturers to deal directly with producers.

Northern Ontario Letter

THE SILVER MINES.

The Cobalt Field.

Without including the premium on United States funds, the silver-mining companies of Cobalt received an average of approximately 61 cents an ounce for the silver produced during the month of July.

The Nipissing, Mining Corporation, Coniagas and O'Brien produced an aggregate close to 700,000 ounces during the period, according to preliminary estimates, while the La Rose Consolidated, Bailey Silver Mines and Chambers-Ferland continued to produce at a moderate rate, bringing the monthly output up to close to three quarters of a million ounces with an estimated value of about $450,000 from the Cobalt field for the 31 day period.

Following the official statement in the Journal that milling operations were to be resumed on the Hudson Bay Mines, as well as the information that underground work is again under way on the Violet mine of the La Rose Consolidated, various rumors have been rife in Cobalt in respect to some of the other closed down mines being reopened within a short time. Of these, the McKinley-Darragh, Beaver Consolidated and Temiskaming are the three more important properties, but the rumors about any one of them re-opening shortly appear to have originated on the street. Those in close touch with the mining situation believe some further adjustment in costs of material as well as labor will be awaited before a general movement toward re-opening all the mines of the camp may be expected.

Production from the Nipissing mine is steadily increasing, according to the regular monthly statements issued by Hugh Park, manager, a feature being the large amount of cobalt produced as a by-product. Following is the July statement:—

"During the month of July, the Nipissing mined ore of an estimated net value of $166,363 including cobalt to the value of $25,380, and shipped bullion from Nipissing and customs ores of an estimated net value of $223,057. The value of the silver production was estimated at 61 cents per ounce.

"There were no underground developments of great importance during the month. Development work on some small veins was generally satisfactory. Stoping operations were also encouraging. No new veins were discovered by exploration.

"The low-grade mill treated 7,258 tons. The high grade plant treated 185 tons, and the refinery shipped 370,117 fine ounces of bullion.

The value of ore mined in July compares with $162,824 in June and $142,036 in May.

During the second week in August the O'Brien mine shipped 64,000 pounds of ore, this being the only ore sent out from Cobalt during the period.

The shaft on the Waldman property of the Oxford-Cobalt continues to show favorable results. Two small veins occur in a wide fracture, and a substantial tonnage of medium-grade ore is being placed in sight. The stringers themselves are composed of calcite and smaltite, with silver values ranging from a few ounces to as high as 1,000 ounces to the ton. The shaft is down about 48 feet and is expected to reach contact with the underlying diabase at a depth of about 75 feet.

Elk Lake and Gowganda.

Plans for operating the Castle property of the Trethewey Company in Gowganda are being held in abeyance pending the outcome of the projected light, narrow-gauge railway. The company will erect a mill on the property just as soon as transportation and other conditions appear to warrant such a step.

Messrs Hartley and Wescott, discoverers and owners of a high-grade deposit of iron ore in the townships of Yarrow and Morel, about 20 miles north-west of Elk Lake are in Cobalt this week. They were interviewed on the outlook on their property and expressed genuine optimism over results to date. Among other things, it was stated that the surveying of nine mining claims of their own had been completed while two others belonging to another prospector have also been surveyed.

Mr. Wescott states that basing his opinion upon twenty years' experience in connection with iron mining in Michigan and Wisconsin along the Lake Superior Range, he is entirely confident that in their new discovery they have a deposit of big importance. Both Mr. Hartley and Mr. Wescott were pleased about the report which came this week from Sault Ste Marie that a deposit of hematite has been discovered by Col. J. A. Currie at a point about 67 miles north of Spragge, as this lies exactly in a straight line between the great iron ranges along the south shore of Lake Superior and the discoveries made this Summer in the Elk Lake district.

As regards the projected light, narrow-gauge railway for the outlying mining camps, including Gowganda, West Shining Tree, Fort Matachewan, Kirkland Lake and Larder Lake, it is learned by the "Journal" that the promoters of the scheme have completed the sale of bonds to a certain bond house which will proceed with the re-sale of the bonds, agreeing to make a weekly payment to the railway company. It is now the plan of the Northern Light Railway Company to place engineers in the field this week with a view toward commencing construction early in September. Construction work will be carried on both east and west from Swastika, and it is believed the line will be in operation as far east as Victoria Lake before Winter sets in, while it is also hoped to have the line well on its way toward Fort Matachewan by that time. Among other things, an excellent townsite has been located on the shore of Victoria Lake. This encouraging prospect of actual construction of the line holds out promise of greatly benefiting the entire Kirkland Lake area, passing as it will from one end of the field to the other. Its completion through the Gowganda silver area is indicated for the following Summer.

During the week of Aug. 12, the O'Brien mine shipped one car containing approximately 64,000 pounds of ore. No other companies appear on the shipping list for the period.

During the corresponding period, the Nipissing mine sent out two shipments of bullion, making up an aggregate of 74 bars containing 100,725 ounces of silver.

THE GOLD MINES.

The Porcupine Field.

At no previous time in the history of gold mining in Ontario has production been so heavy as at present, and, at no previous time since the industry became established as one of importance has there appeared to be less excitement.

The rising tide of unemployment in certain of the larger industrial centres of Canada and the United States, and the steady increase in competition among the manufacturers who are bidding for the business of

supplying material to the mines is creating a condition which is believed to mean more to the gold mines of Northern Ontario than the general public realises. Indeed, right at the mines, only the careful observers are able to grasp the full significance of the situation.

A dollar now paid to a miner gets a much greater amount of work in return than was the case when a shortage of labor caused low efficiency; a dollar now paid for material buys considerably more than it did a year ago—but, in the meantime, the standard value of gold remains, and each ounce spreads over a greater amount of the cost incurred, thereby leaving a steady increase in the margin of net profit.

The secretary of the Dome Mines has sent out information to stockholders in the United States pointing out that the Canadian Government makes a pracice of taxing only 50 per cent. of the amount of dividends paid by gold and silver mining companies in this country, it being the intention of the government to allow the remaining 50 percent to take the form of capital return. The stockholders of the Dome who are resident in the United States are advised to draw this matter to the attention of authorities in the States and thereby gain the exemption to which they are entitled.

Arrangements have been made by the March Gold Mines, in Deloro township, to commence operations, and toward this end and arrangement has been made with the Coniagas Company to use the mining plant on the Maidens-MacDonald property which is owned by the Coniagas.

It is probable that the construction work decided upon at the McIntyre-Porcupine mine will consist of the erection on an entirely new milling-unit of about 550 tons of ore daily on the north side of Peary Lake, situated close to the main hoisting shaft. The completion of this new plant may then be following by the removal of the present 550 ton plant to the same building in which the new equipment will be housed. At least this is the question which the officials are now dealing with, the alternative being to merely instal grinding equipment on the north side of lake and then ship the pulp across the lake to be treated in the present mill. Everything considered, and looking far into the future, the scheme to build an entirely new unit, followed by the removal of the present equipment to the same building, seems to have many advantages, and this has given rise to the belief that it will probably be in this manner that the McIntyre will increase its capacity to over 1,000 tons of ore daily. With respect to dealing with graphite which occurs in certain parts of the McIntyre mine in close association with the gold, it is learned that a solution of metallurgical difficulties has been found but, for adequate reasons, the details of the process are temporarily withheld. The result of experiments together with actual demonstration of production and the definite decision to double the capacity of the mill combine to assure the McIntyre of production amounting to between $3,000,000 and $3,500,000 annually. As regards the date of completing the new addition, it is learned that foundations and construction work will be completed this year so as to proceed with the installation of milling equipment during the winter months.

The shaft on the property of the Union Mining Corporation, situated in the township of Whitesides, has reached a depth of 250 feet, and is being continued to a depth of 300 feet. In the meantime, a cross-cut has been driven at the 150-ft. level and has encountered a vein about 8 feet in width in which encouraging gold values are reported, although no official announcement has been made as regards the average gold content.

The Ontario Government is stated to have set aside $10,000 with which to improve the 25-mile road from Timmins to the property.

Diamond drilling operations have been commenced on the Gold Island property, on Night Hawk Lake. A. R. Globe, a former assistant manager of the Hollinger Consolidated, together with Jack Gallinan are identified with the Gold Island project.

Normal rainfall has been recorded during recent weeks throughout all parts of Northern Ontario, and the prospects of the storage basins being filled so as to provide ample hydro-electric power for the mines during the winter months are good.

Kirkland Lake Area.

For the six months ended May 31st, the Lake Shore Mines realized net profits of $30,486, according to a half-yearly statement just issued. The issuance of a half-yearly report is a new departure for the Lake Shore, the company having heretofore issued a brief monthly statement of gross output and amount of work done, in addition, of course, to the annual report. The Lake Shore assets are given as $1,349,474 as compared with $1,369,463 at November 30th 1920. Results now obtaining at the mine are better than during the period under review and the net profit for the six months to end Nov. 30th, 1921, promises to exceed that of the first half of the fiscal year.

Surface work is well under way on the property of the Lebel Lode, in Lebel township. Cross-trenching is being done on a fractured zone which appears to be about 300 feet in width and in which a number of veins occur. Officials of the company believe this to be the easterly continuation of the main fracture and ore-bearing zone which passes through the productive section of the Kirkland Lake field.

In all parts of the Kirkland Lake district, considerable attention is being turned to the favorable prospects of the projected light, narrow-gauge railway being constructed this fall right through the heart of the field.

What promises to be an important gold discovery has been made in the Lightning River district, on property belonging to the Lightning River Gold Mines. Gold occurs in spectacular quantities in a vein measuring from three to four feet in width, and over a length of about 200 feet.

The Matachewan Gold Mines, Ltd., is considering the advisability of resuming operations this fall. The company recently purchased a number of additional mining claims, lying adjacent to its main property on the south. The latest purchase was claim No. 5401 this being one of a group which is known as the Robb-Clemens property.

It is reported unofficially from Elk Lake that the Dominion Government is considering the question of improving transportation facilities to the Fort Matachewan district. The plan being considered is the erection of two dams, one at Indian Chutes and one at Fox Rapids, and in that way to enable boats to operate between the railhead at Elk Lake and the Fort Matachewan district, with only two short portages. It is pointed out that such dams would have the added advantage of developing water-power to yield about 10,000 h.p. of electric current.

IRON ORE DISCOVERY REPORTED.

It is reported from Sault Ste. Marie than a large deposit of hematite has been located 67 miles north of Spragge and about 100 miles from Sault Ste. Marie. Col. J. A. Currie and Mr. A. M. Campbell are the locators. The elaims are 35 miles from railroad.

It is stated that the iron deposit was first noted in 1857 by the Herrick survey expedition. An attempt was made to find the deposit in 1903, but it was not found and the project was abandoned until recently.

British Columbia Letter

Metal Mines.

Dawson Y.T.: The Coeur d'Alene Mines of Idaho are reported to have secured options on three large groups of claims in the Keno Hill District of the Mayor Camp.

Stewart B.C.: The Fish Creek Mining Company are doing substantial development on their claims, situated in the Salmon River section about a mile, as the crow flies, from the Hyder-Premier road. A promising vein of ore is reported to have been uncovered through the blasting necessitated in laying the foundations for one of the towers of the Premier Mine's aerial tramway.

Prince Rupert B.C.: George Clothier, resident mining engineer, recently made a trip into the Atlin District and reports that the discovery of some placer gold in the Little Atlin Lake section caused a stampede recently from a number of local centres. Subsequent developments proved that there was no occasion for excitement. There are more men on the long-exploited creeks of Atlin than for the past two or three years. Individual miners are making good wages and there have been several fair cleanups. The smaller creeks now are beginning to show up well. As to lode mining the inactivity of the Engineer Mine, because of litigatio, is holding back progress. Wth the opening of this property Mr. Clothier looks for general mining improvement. A substantial mining company has optioned J. N. Ruffner's Group of Claims on Fourth of July Creek, on which there are good surface showings of silver-lead ore.

Greenwood B.C.: The water rights acquired 15 years ago by the Granby Consolidated Mining & Smelting Co. on the Columbia River at Kettle Falls have been sold. Having ceased its mining operations at Greenwood and Phoenix the Company has no further use for these holdings.

Trail B.C.: Receipts at the Trail Smelter of the Canadian Consolidated Mining & Smelting Co. for the last ten days of the month of July totalled 12,761 tons. Of this 12,196 tons were from the Company's properties, 231 tons from the Surprise Mine of the Republic Camp, and 34 from the Sally Mine at Beaverdell.

Revelstoke B.C.: The largest deposit of hematite from ore known in British Columbia occurs on Fenwick Mountain, East Kootenay, within five miles of Wardner and nine of Jaffray (both stations on the Crow's Nest branch of the Canadian Pacific Railway), and within fifteen miles of Elko where the Great Northern Railway is operating its line from the Fernie and Michel coal fields to Rexford, Montana.

The property derives its name from Bull River which runs at the foot of Fenwick Mountain; and consists of eight elaims of about 50 acres each embracing all the surface exposures of hematite on the summit of the mountain.

The eight elaims are held in fee simple having been Crown granted.

The general structure of the iron-bearing zone is a banded one, bands of iron varying in width from two to eight feet, separated by a barren parting of from 6 inches to one foot: the barren partings are sometimes replaced by a low-grade iron ore carrying from 20 to

45 per cent. metallic iron. The bands of iron are continuous in length and width and show no indications of being lenses or pockets.

About $8000.00 has been spent in running tunnels and stripping the surface. The ore may be divided into three classes as follows: A hard, blue, hematite, slightly schistose in character; and a soft surface-ore.

A series of analyses taken from all the claims resulted in an average of 8.52 per cent. residue, 8.58 per cent. alumina, 1.56 per cent. lime, 1.10 per cent. magnesia, 0.062 per cent. sulphur, 0.0282 phosphorus and 61.35 per cent. metallic iron.

Sufficient development work has not been done to estimate the amount of ore, but enough has been done to prove the surface area of the iron-bearing formation or veins both as to length and width.

A spring and a small lake on the claims furnish enough water for domestic purposes. There is a sufficient supply of timber for mining purposes.

The development work done on the claims has defined the course and dip of the deposits but no attempt has been made to determine the depth to which these deposits extend. This could be cheaply and quickly done by means of a diamond drill. Judging from the outcroppings of the ore the lowest to the highest points exposed measuring 900 feet, it is probable these deposits will be found to continue with depths. The contour of the mountain is such that the deposits could be worked to advantage by the open-cut method.

In a report prepared for the B.C. Dept. of Mines, the Resident Mining Engineer for East Kootenay, Mr. A. G. Langley, says of the well known Sand Creek iron property as follows:

Preliminary exploration has disclosed a vein of hematite running in a north-westerly direction along the south side of Sand Creek. Three claims have been staked along the strike of the vein and are known as the Pearson group, being owned and staked by the present owner, W. Pearson.

Leaving the Fernie road at Jaffray it is possible to drive by motor within six miles of the property. A good trail is then followed up the creek. The claims are easily accessible and a road-grade of not exceeding 3 per cent. is obtainable from Galloway to a point on the creek immediately below the exposures, which are situated at an elevation of from 400 feet to 600 feet above.

The valley of Sand Creek in this vicinity is a beautifully wooded country of timber, principally represented being white pine, hemlock and cedar. On account of the rock outcroppings being covered with overburden, it is only possible to form a very limited idea of the geological structure, or the formation, which apparently consists of quartzites, probably belonging to Cambrian age, and having a dip of 50 degrees to the south-west and a strike of N. 50 degrees W.

The ore, consisting of a massive red hematite, occurs as a bedded fissure-vein replacing the quartzites. The hanging wall is well defined, but on the footwall side the ground is broken and crushed, and in places stained with the characteristic red color of the ore.

At the most southerly working, at an elevation of 4000 feet, a deep open-cut crosses the strike of the vein and terminates in a short tunnel. Here the formation seems to be broken over and the ore, which is more or less crushed, does not appear to be in place, but to have slid over from a higher point up the hill. The ore shows the width of 3.5 feet of a massive red hematite, a sample across which ran: Metallic iron, 51 per cent.; silica, 22 per cent. phosphorus, nil; sulphur, nil.

At a slope distance of approximately 120 feet above this showing a diamond-drill hole was put down by Dr. Ings, of Calgary, some years ago, but no record of work is available except that the results were not encouraging to him. At an elevation of 4000 feet, and at an approximate distance of 300 feet to the northwest, a short tunnel was driven on the vein and a small tonnage of hematite extracted. The ground here is broken at the surface and the tunnel is not of much consequence except to show the persistency of the vein.

Continuing along the side-hill for a distance of about 300 feet, the northerly workings are reached. Here at an elevation of 4,300 feet a short-cut shows a section of the vein to be in-place. The dip, conforming to that of the enclosing strata, is 50 degrees to the south-west and strikes about N. 50 degrees W. The hanging wall of the quartzite is well-defined and there is a good selvage between it and the ore. On the foot-wall side adjacent to the ore, there is a band of about two feet talcose material, and general conditions would indicate that the country-rock has undergone more crushing and alteration on this side of the vein.

The ore is a well-defined band of red hematite lying next to the hanging-wall and having a width of 12 inches, across which a sample ran as follows: Metallic iron, 57.4 per cent.; silica, 15.6 per cent.; phosphorus, nil; sulphur, nil. Although the samples taken show the ore to run rather high in silica, it is undoubtedly of good grade and should a good workable width be developed the mining costs for this class of ore should not exceed $2.00 per ton.

The hillside, sloping at an angle of 30 degrees, affords a number of good tunnel sites, and a depth of 400 feet on the vein could be obtained by cross-cutting from the surface. There is a good camp site with plenty of timber and water, while power might be developed from Sand Creek, which has a flow of about 4 second-feet during the dry season.

It is not unlikely that there may be other parallel veins in this formation, and although the vein is small the good quality of the ore and the easy accessibility of the property are strong factors in its favor, while the possibilities from a geological standpoint appear to warrant further work being done to prove the existence of a sufficient body of ore to be of economical importance.

The preliminary work should consist of trenching and open-cuts along the strike of the vein; then if the results are favorable, a diamond drill might be employed to advantage.

COAL MINES.

British Columbia will be represented at the International Conference to be held on September 1st and 2nd at St. Louis, Mo., under the auspices of the United States Bureau of Mines, for the purpose of discussing the possible standardization and improvement of mine-rescue methods. Robert Strachan, senior mine inspector, headquarters at Fernie, has been chosen to attend on behalf of the Province. As the Hon. Wm. Sloan, Minister of Mines, has been unable to arrange to be present in person Mr. Strachan will read a paper by Mr. Sloan on "The Need of Standardization in Mine Rescue Work." The Province also will have representatives entered in the International First Aid and Mine Rescue Contest for 1921 which takes place from the

1st to the 3rd of September at St. Louis. Arrangements have been made to send to St. Louis the Nanaimo First Aid Team, captained by Mr. W. Barton, who hold the Montizambert Cup, representing the Canadian championship.

The Harewood Mine of the Western Fuel Corporation of Canada, Nanaimo B.C., has been re-opened. It has been idle for some time. The company, however, is reported to have secured contracts that necessitate an increased output. Consequently, not only the Harewood, but the Wakesiah, Reserve and No. 1 Mines must be worked to their capacity.

The Crow's Nest Pass Collieries have been suffering from the widespread depression affecting the coal trade everywhere. The Coal Creek mines worked seventeen days in July. At Michel the mines worked sixteen days and at Corbin only seven. At Coal Creek a large Sirocco fan is being installed. This improvement, including the sinking of a shaft 40 feet deep, 16 feet in diameter and lined with concrete down to the solid rock, represents a considerable outlay. Undoubtedly, however, it will make No. 1 East one of the best ventilated mines in the Province and permit it to assume, in a very short time, if not first, at least second place among the heaviest producers. No definite plan has ben decided upon as to the form of power to be used in driving the new fan. A powerful steam engine is available and, if necessary, can be used. The Alberta & N. C. Power Co., however, is developing the Bull Rivet water power and its installation may be so nearly complete in the course of a few months that the whole south side of the Coal Creek Colliery will be electrified. The present auxiliary steam plant, running No. 3 and No. 1 East fans, in such a case, would be kept in reserve to meet emergencies and the load on the main plant would be relieved to the extent of the power now supplied to No. 1 South fan. Moreover this would mean the saving of quite a few tons of coal of excellent quality now being burned daily under these boilers.

Washington State coal mines, it is reported, will be opened immediately on a closed-shop basis. They have been inactive since March 15. Representatives of the United Mine Workers of America, who have held a convention at Seattle Wn., stated that they would refuse to arbitrate with he employers on the proposal of reducing wages at present. The operators declare that they will not deviate from the Allport Report, recently published, which recommends substantial wage reductions.

Victoria B.C.: The Canadian Geological Survey Branch, Ottawa, has issued a series of maps and diagrams entitled "The Fraser River Investigation Series." The first two of these deal with the float observations of W. A. Johnson in 1919. The third indicates the distribution of surface deposits within the Fraser River Delta. The Ladner and Lulu Island, and adjacent sections, are made up of peat bogs and alluvial deposits while the sites of the cities of New Westminster and Vancouver are glacial till and fluvio-glacial deposits, overlain in places by small thicknesses of marine deposits. The rise and fall of the Fraser River over a period of from fifteen to twenty years is pictured by chart. The highest recorded rise was in 1894 when it reached 25.9 feet. In 1920 the records show that it came to the 21 foot level. An interesting diagram is that marking the gradual change in the river channels between the years 1827 and 1920 and also that portraying the seaward advance of the river delta.

COOLING DEEP WORKINGS.

A refrigeration plant is now in operation at the Morro Velho gold mine in Brazil, cooling the air supplied to the deep levels. At this mine the high temperature has seriously interfered with mining operations and made development work almost impossible at the lowest levels. The driving of a tunnel at the lowest level, at a depth of 6,426 ft., was accomplished with great difficulty and it is unlikely that deeper mining would have been attempted had not the management made arrangements for chilling the air. It is understood that the refrigeration plant will make it possible to continue the use of the present mining plant to a depth of 7,500 ft. Before the cooling plant was installed the heat was sufficient to interfere with the electric motors driving the fans and working conditions were becoming impossible.

The Morro Velho mine is operated by the St. John Del Rey Mining Co. Ltd. At the last annual meeting, held in London June 30, Sir Henry P. Harris reported that the main lode had been cut at the lowest level and found to be satisfactory there. During recent years the ore mined has shown a considerable increase in value. Ore mined during the year ending February 28 1921 averaged 57s. 7¾d. and the cost per ton averaged 47s. 11½d. The profit on the years operations was £167,749.

BOOK REVIEW.

CONCENTRATION BY FLOTATION. T. A. Rickard, 6 by 9 inches. Cloth Boards. 692 pp. with Index.

Mr. T. A. Rickard's ability to compile a treatise on flotation methods is so generally admitted, and the treatment of the practice in the latest book is so comprehensive that a critical review will not here be attempted. The book now issued is a collection of articles by various metallurgists that have appeared in "Mining & Scientific Press" of San Francisco during the years 1915 to 1920. Five of the articles were reprinted in Mr. Rickard's earlier book on this subject, published in 1916, entitled "The Flotation Process" and seventeen articles appeared in "Flotation" by T. A. Rickard and O. C. Ralston, published in 1917, both of which are out of print. In the latest volume, eighteen additional articles are included bringing the subject up to date, and making, as the preface states, "a convenient compendium of the principle literature on the technology of the process". Mr. Rickard points out that no book can assume to be complete and final in regard to a process that is still so imperfectly understood and that continues to undergo such radical changes.

A necessary and very interesting fore-page to the treatise is a glossary of flotation. The first chapter, dealing with the history of flotation, is an enthralling one, and indicates that the scientific theories now elaborated in regard to flotation are later in date than the actual birth of the process itself. The root ideas appear to have occurred to a number of individuals at different times, but a workable process, to use Mr. Rickard's phrasing, "has been developed by the patient empiricism of the mill and laboratory."

Mr. Rickard himself writes on the history and principles of flotation, on flotation litigation, and on the flotation of gold and silver mineral. O. C. Ralston, Glenn L. Allen and James M. Hyde deal with the testing of ores for flotation, differential flotation, mechanical development, and the flotation of oxidized ores. The description of flotation practice in varions parts of the world includes that at Broken Hill, Australia, by E. T. Henderson, R. J. Harvey and C. C. Freeman. W. E. Simpson deals with flotation at Cobalt, the article being dated December 1917. The book is well illustrated and well bound and printed.

WILKES-BARRE MEETING OF A. I. M. & M. ENGINEERS.

The Wilkes-Barre meeting of the American Institute of Mining & Metallurgical Engineers, which is to be held from 12th to 15th September promises to be an unusually interesting gathering, and one that is fairly accessible to Canadian engineers leaving in the East.

One of the trips arranged is an automobile visit through the Wyoming Valley, visiting breakers and mine plants. This district is notable for the large capital expenditure of recent years in modernisation of the anthracite mines, and in the substitution of wet breakers for old-fashioned dry breakers. Papers will be read dealing with this development, and with the general electrification of the mines which has been another feature of recent years. The Wyoming Valley mines supply most of the anthracite that comes to Canada, and the field is interesting in that it is a partially exhausted area that has been rejuvenated by the demand for anthracite which is an accompaniment of its growing scarcity. The programme of the anthracite companies embraces conservation methods of a most intensive kind, and the value of anthracite is demonstrated by the working of very thin seams, and by the salvage of the pillars and stumps left by a previous generation. The antiquity of the anthracite mines of the Wyoming Valley and the age of the charters of the operating companies would be respectable even in Europe. The "Journal" is informed that any Canadian engineers who can visit Wilkes-Barre during the meeting will be very welcome, and will see many things fully worth-while.

PERSONALS.

Mr. Archibald M. Campbell who has been for some weeks engaged in exploration work east of Sault Ste. Marie, have returned to Toronto. He located a large iron ore deposit north of Sprague.

Mr. A. G. Burrows of the Department of Mines, has returned to Toronto, owing to serious illness of his daughter.

Mr. H. H. Sutherland who has been for some months in England has returned to Toronto, Mr. Sutherland has been negotiating in London the financing of Davidson Consolidated Mines.

Hon. Harry Mills, Minister of Mines, and Mr. T. F. Sutherland, chief Inspector of Mines of Ontario, recently visited iron mining districts in Minnesota. They also visited some of the iron ore occurrences in Western Ontario.

The American Institute of Mining and Metallurgical Engineers meets at Wilkes-Barre Pa. Sept. 12 to 15. A meeting of the Society of Economic Geologists will be held at the same time and place.

Mr. Charles Millar has returned to Toronto after a visit to the Mackenzie River oil fields. Mr. Millar is interested in oil exploration in the district and also in transportation on the river.

TORONTO COAL PRICES.

Toronto, 17th August.—There is little change to report since last week in the bituminous situation. Slack, due to the scarcity of screenings, still maintains its price firmly. The demand for lump coal is still small. The buying of anthracite, on the other hand, which set in about a couple of weeks ago, is increasing in volume. But, as buyers generally held off from buying for so long, there is a tremendous amount of leeway to make up before Toronto's coal bins will be in anything like other normal seasonal condition. And the same conditions, generally speaking, that exist in this city prevail throughout the Province. The orders that are coming along for anthracite are, in the main, so the coal merchants inform the winter, of fairly good size.

SEPARATION OF SPHALERITE FROM .. FLUORSPAR.

In experiments conducted by the U. S. Bureau of Mines it has been found that copper sulphate can be very advantageously used in separating sphalerite from fluorspar by electrostatic methods. It is supposed that the effect of the sulphate is to form a thin coating of copper sulphide on the sphalerite. The action is rapid in very weak solutions, and consumption of sulphate need not be more than 1¼ lb. per ton of ore. By wet crushing the ore to 10 mesh and concentrating on tables and the copper sulphating and treating electrostatically a fluorspar product averaging 98.7 per cent calcium fluoride was obtained. This high grade product brings a much higher price than ordinary gravel spar.

EDITORIAL

An Instance of Judicious Use of Breathing Apparatus

There has been a sharp division of opinion among mining engineers as to the extent to which oxygen breathing apparatus could be used in the recovery of coal-mines after fires and explosions, and in the recovery of areas which have been sealed off to extinguish mine fires by creation of an atmosphere in the fire area incapable of supporting combustion. It has been held that no considerations of the time taken in recovery warranted the exposure of breathing-apparatus crews to non-respirable atmospheres, and the bringing of fresh air into the sealed-off areas has been accomplished by slow stages solely with the help of so-called "bare-faced" workers. This attitude proceeds doubtless from a thorough distrust of the protection against non-respirable air provided by oxygen breathing-apparatus, and a genuine disbelief in the ability of men equipped with these rather cumbersome devices to perform any large amount of useful physical labour. The attitude is also a natural revulsion against some of the purposeless and danger-fraught expeditions that have been undertaken by "crews" of men wearing oxygen apparatus, which have on too many occasions resulted in the death of the wearers. There is also no doubt that the earlier types of breathing apparatus, like the earlier types of the submarine and the airplane, were imperfect and dangerous to those who trusted themselves too unreservedly to their protection against conditions which the human organism could not support should the protection, for any reason, momentarily fail.

The earlier forms of oxygen breathing-apparatus have been by this time brought to much perfection, and the use of modern apparatus is not accompanied by such dangers as make their use inadvisable, always provided that the apparatus is in good order, and is used by men physically fit and trained in the wearing and manipulation of the apparatus in non-respirable atmospheres under such conditions are prevail underground. The use of breathing apparatus on a wholesale scale was a feature of the recent war, and the record of occasions under which it has been justifiably and successfully used in connection with mine explosions and underground fires is now so long and undeniable that oxygen breathing-apparatus must be accorded a definite and important place in mine equipment, and more particularly in the equipment of coal-mines.

A recent issue of "Coal Age" contains a description of a mine fire in connection with which oxygen breathing apparatus appear to have been used as they should be used. The article is re-printed in this issue. The rapidity with which the Kathleen Mine was recovered was remarkable, and was made possible by the concrete construction of the mine openings which it was necessary to seal, and by the freedom of the strata from any surface breaks. The experience at the Kathleen Mine strongly recommends the liberal use of concrete and non-combustible building materials in substitution for timber in the construction of shaft-linings and fan-ways. Owing to the general tightness of the seals and the entire exclusion of fresh air from the fire-area, the atmosphere in the sealed-off area speedily showed an analysis that demonstrated the extinction of the fire, and, as the shaft communication and main roadways of the mine were in good order, it was considered proper to send down "helmet-men" into the mine, relying entirely on the protection of the oxygen-apparatus against an atmosphere that would have caused the death of unprotected men in a few seconds. Although the leading of fresh air into the fire area was entirely accomplished by apparatus men in advance, these men were not allowed to go an undue distance ahead of fresh air, and the strictest supervision and checking of their physical condition and the state of the apparatus was maintained throughout the whole operation of recovery.

The recital of this mine-recovery operation by the president and general manager of the company owning the mine in question is a most commendable action, as

it sets forth with full knowledge of all the circumstances a case in which full use was made of breathing-apparatus, mine-air analysis and observations of such barometric and thermometric conditions of the outer atmosphere as might influence the state of the mine air. Breathing apparatus was not used as a "cure-all" or a scientific toy, but under such conditions of precaution and good order as are insisted upon by the submarine commander, the aviator or the diver, and other men who live and work where the unprotected human body cannot live. There is no good reason why mining engineers should deprive themselves of any aid that science can bring them, and before the accumulated weight of useful achievement now standing to the credit of oxygen-breathing devices adapted to mine uses, any purely critical attitude towards the judicious use of these devices should be waived, as the onus of disproof now rests upon those who object to their employment.

There is a very definite feeling in North America that a standardization of breathing apparatus should be undertaken, and conferences to this end are being undertaken during the coming Autumn between representatives of the U. S. Bureau of Mines and the British Columbia Department of Mines. A Committee of the Canadian Institute of Mining and Metallurgy has also reported in favour of standardization, and there is some likelihood that suggestions for closer co-operation between the U. S. Bureau of Mines and Nova Scotia coal companies may result in useful coordination in connection with mine-rescue investigations and some approach at standardization of apparatus. If one type of breathing apparatus were standardized in Canada it would justify the erection of a factory for the manufacture of apparatus and spare parts. It is the difficulty of getting spare parts of the required dimensions quickly that chiefly requires standardization of types. The market for breathing apparatus and accessories is as yet quite limited in Canada, and in Nova Scotia it will never be very large. In Alberta and British Columbia, however, where the possibilities of increase in the number of coal-mines are very great, there will eventually arise a permanent and growing market for mine-rescue and safety appliances in general. Indications are that—as has already been the case with mine machinery and general equipment — the source of supply and the type of material supplied will be western and not strikingly eastern. This tendency, by the way, is one that should attract the attention of manufacturers in Eastern Canada. They have, so far, not made much of a bid for the business of the western coal mines.

THE EDMONTON MEETING OF THE C. I. M. & M.

In this issue will be found the programme of the Edmonton Meeting, arranged for September 14th to 16th. With Mr. Camsell and Mr. Corless in attendance, prepared to talk upon coal, iron and oil, with operating coal-men giving ten minute talks on the coal districts in the West with which they are intimately acquainted, and with Mr. Chappard from the Imperial Oil Company's geological staff to give information on the search for petroleum in Western Canada, this meeting should be as definitive and as epochal as was the Winnipeg meeting on 1920.

It is interesting to note that Mr. Corless, as president of the Institute, is to speak on "Canada's Coal Problem," because it is fairly apparent (and will be more apparent after the meeting) that if any solution to this problem is possible it must come from the West. Sir George Beilby, Director of Fuel Research in Britain, recently said to the Institution of Civil Engineers, "Civilization, on its physical side, is based on fuel". If the responsibility of the West for upholding the Canadian type of civilization is in proportion to its possession of Canada's fuel resources — and we see no escape from the facts— then it is particularly fitting that the president of the Institute should discuss that responsibility at Edmonton, a city situated in the centre of the concentration of Canadian fuel resources which is at once the glory and the heavy responsibility of the people of the West.

ASBESTOS AND INSTITUTE PUBLICATIONS.

The inclusion of Capt. J. G. Ross's paper on the asbestos industry in Quebec in the August bulletin of the Canadian Institute of Mining & Metallurgy is a fair example of the disservice done to the Institute and its contributing members by the delay in publication which occurs through enforcement of the rule that Institute papers must first be published in the "Bulletin" of the annual transactions of the Institute. Capt. Ross's paper was a timely one when it was read, but that is five months ago, and quite a few things have occurred in the meantime. One of the gallant captain's suggestions, namely, that the seller of asbestos should absorb the provincial tax, and that it should not be "rubbed into" the purchaser by surcharge on his bill, has been recently followed, and there are a good many other suggestions made by Capt. Ross that are very much worth the attention of asbestos producers in Canada. Particularly commendable is his advice to asbestos producers to pool their problems by establishing a central bureau for experiment and research. Associations of mine operators in other parts of the world have led to remarkable strides in research in connection with materials of which much more is known than of asbestos, and as will be quickly recognised by those who have seen the recent bulletin of the University of Arizona on asbestos (see page 662 issue 19th August) other producers, in other countries, are not idle.

To revert to the question of publication,—where the papers read before meetings of the Institute are of topical or timely interest, requiring immediate publication and the widest possible distribution among general readers to ensure the publicity and effect upon pub-

lic opinion that is usually the desire of those who contribute such papers, recourse should be had to the technical press, or even to the daily newspapers for purpose of getting quick and wide distribution. We would also point out that a rule which permits immediate publication of *digests* of papers read before the Institute, but forbids verbatim reproduction in the technical press until after the papers appear in the Institute's own publications, is an illogical rule, and it hurts nobody but the Institute and those who present papers at its meetings.

It is also desirable that editorial comment should be made upon papers read before the Institute that warrant such singling out, but if their publication is delayed unduly, such comment savours of the nature of an anachronism. In other words it is "old stuff". The Institute deprives itself of a valuable means of disseminating its news and policies when it virtually prohibits editorial notice of its proceedings by post-dating this to an indefinite tomorrow. We believe the Canadian Mining Institute is now the only scientific body that follows this ancient and musty ruling. Other technical societies, realising that publicity is life and that without it they were better dead, send to the technical press printed and illustrated foreprints of papers to be read, only stipulating that these shall not be released for publication until after the date of the meeting. This, in the case of all but daily papers, means that they are printed a week, or weeks, before the scheduled date of reading. By doing this, technical societies get the widest publicity, they obtain simultaneous editorial consideration and comment, and a concentration of public interest which greatly helps the societies, and also gives some little pleasure to those who have worked for months maybe to write a paper of some merit.

Most persons who present papers to technical societies have something to communicate that is of value. Some perfected individuals, approaching the date of their translation, may write papers with a sole and pure desire to benefit their fellowmen, but most of the unregenerate and decent fellows that compose the membership — of the Canadian Institute for example—like to see their name in print and to hear some comments on their papers, as a reward for good work accomplished; and, such is human frailty, they like to hear it quick and warm after the great occasion of delivery.

Of course, we may be entirely mistaken, and it may be that it is desired that Institute papers should circulate solely among Institute members, constituting an arcanum of professional information, and that publicity should be discouraged. If this is the case, it is only possible to register dissent, and pity that such sentiments should still persist. If, however, it is not the case, as we sincerely believe, then why does not the Institute go after publicity in every conceivable shape and form? There is nothing it lacks more. It has always lacked it.

THE Northern Finance Company, of Montreal, whose advertising of the Pan Extension Gold Mine shares was not of a character calculated to inspire confidence in the financial stability of that enterprise, is now offering through the Montreal newspapers, and by personal canvass of individuals, bonds in well-known German industrial enterprises. A profit of up to two hundred percent is claimed to be possible through investment in these issues. One of the canvassers used as his "approach" to a Montreal city-man the statement that it was necessary the war should be forgotten sooner or later, but made the mistake of adding that one side had been as much to blame as the other in the recent war, with the result that he was asked to get out before he was thrown out. Investment in German bonds, and speculation on the fluctuations of the mark, may or may not prove profitable. For Canadians, however, such transactions are undesirable, if for no other reason than the necessity to provide employment in Canada and to invest Canadian savings in building up this country. There are hundreds of seasoned industrial stocks now purchasable through Canadian stock exchanges that can be bought at the lowest prices of a generation. Canadian bonds, preferred stocks and first mortgages are looking for purchasers, and any reputable broker can advise his clients how to invest savings in Canadian enterprises (and mining enterprises in particular) that should receive the attention of Canadians before the most attractive securities in aniline or electrical companies in Germany. The "ticker" is said to tell the tale, and if German securities are purchasable at low cost it is because those who are in a position to judge have discounted those conditions of political insecurity, war debt, diminished national vigour, diminution of territory, deprivation of natural resources, inflated paper currencies and other consequences that frustrated ambition have laid upon that rather indeterminate territory known as the Republic of Germany. Any transfer of cash for the paper securities so far offered by the Northern Finance Company is, in our opinion, not only undesirable, but indiscreet also.

CANADIAN INSTITUTE OF MINING AND METALLURGY.

PROGRAMME OF ANNUAL WESTERN MEETING.

Edmonton, Alta., Sept. 14th, 15th & 16th, 1921.

Wednesday September 14th.

10 A.M. to Registration and Badges.

12.30 P.M. Address by Minister in charge of Mines.
Welcome from Mayor.
President's Address.
Appointment of Committees.

12.45 P.M. Luncheon.

2.30 P.M. Papers.
"Importance of Coal, Iron and Oil in National Development," by C. Camsell, Deputy Minister of Mines, Ottawa.
"Standardization of Air Drying of Coals" by Edgar Stansfield.

8.00 P.M. Smoker.

Thursday September 15th.

10.00 A.M. Papers.
"Canada's Coal Problem" by C. V. Corless.
Ten minute talks on the Coal Fields of Alberta as follows:—
"Brule and Pocahontas District" by W. G. Healey.
"Crow's Nest Pass District" by W. Stevenson, Jr.
"Drumheller District" by D. A. Macaulay.
"Lethbridge-Taber District" by Moses Johnson.

12.45 P.M. Luncheon.

2.20 P.M. Papers.
Ten minutes Coal Fields Talks continued:—
"Canmore-Bankhead" by L. Stockett.
"Edmonton-Clover Bar" by L. C. Stevens.
"Alberta Coal Branch" by L. E. Drummond.
"Dominion Mining Legislation" discussion lead by Messrs. W. D. Craig, N. C. Pitcher and Dr. John Allan.

8.00 P.M. C. I. M. & M. Banquet.

Friday, September 16th.

10.00 A.M. Papers.
"Recent Development Work Relating to Petroleum in Western Canada" by George Sheppard, Geologist, Imperial Oil Company.
Resolutions.

12.45 P.M. Luncheon at University.
Visit to University.
Meeting of Council.

9.00 P.M. Train to Alberta Coal Branch, visiting Oliphant Munson Collieries, Cadomin Coal Co. Ltd., and others, on Saturday, September 17th.

BOOK REVIEW.

GEOLOGY OF THE BRITISH EMPIRE. Dr. F. R. C. Reed. 6 by 8 1½ inches. Cloth Boards. 480 pp. with Index, twelve folding maps, and thirteen other maps and sections. Edward Arnould, London. Price 40 shillings.

Dr. Reed's book is a monument of geological erudition and a fine example of concentration into small space of the work of many labourers in many and distant lands. The geology of every portion of the British Empire (except the British Isles themselves) is described in this work, and, if the work is as accurate in regard to the other lands included as it is in dealing with Canada, it forms a truly valuable compendium. There is no touch of propaganda in the volume which is entirely devoid of general comment, and contains nothing but an account of the known geology of the countries included in the Empire, with the necessary diagrams and maps, and brief mention of the more important economic minerals. The volume includes, in addition to the better-known parts of the Empire, the geology of ex-German East Africa (the Tanganyika Territory) the British area of the Cameroons and Togoland, ex-German New Guinea, the Bismark Archipelago, and the mandatory regions of Mesopotamia and Palestine. A selection of reference to the literature of the geology of each region is given at the end of each chapter. The geological information thus compiles has never previously been available in such condensed form, it having been, as the preface to the work states, "scattered throughout the pages of scientific journals and government memoirs, or found in foreign publications, most of which are difficult of access for the ordinary student, or too technical in character for the general reader". Much of what Dr. Reed has here collected must indeed have been quite inaccessible to the majority of readers.

While the scope of the work is strictly confined to the political boundaries of the detached areas that form the British Empire, and no general scheme of world geology is even referred to, there are illuminating statements here and there in the volume in regard to stratigraphical relations that could only be attempted by one whose knowledge was wide and accurate, and while the description of each selected locality is restricted thereto, the purview of the writer is so much wider as to enable him to attempt condensation and summarisation of a kind that would not be possible to a writer of narrower—though possibly more specialized—outlook.

The printing and format of the volume leave nothing to be desired.

THE REMOVAL OF DUST IN ROCK BORING.

"Gluckauf," the German mining periodical published at Essen a. Ruhr, Westphalia, contains in its issue of 23rd July an article by Bergassessor Wedding on the disposal of dust from the process of rock-boring underground. The ill effects of exposure to dust depends on the kind and quantity of the dust, the length of the exposure, the age of the workmen so exposed, and the nature and severity of the manual labour; which in its turn depends on the location of the working place and the arrangement of the drilling apparatus in use. Fine dust is more harmful than coarse dust, as it penetrates further into the bronchial tract. On the other hand, fine dust is more easily ejected and its tearing action on the body tissues is less. Sharp particles are of course more dangerous than rounded ones, and siliceous rocks are especially apt to give off harmful dust. The length of exposure to dust greatly increases the harmful effect, because the mucus membrane of the breathing tract loses its moisture through caking of the dust. Fine hair-like processes which cover the mucus membrane are in normal health in constant movement in the direction of the outer atmosphere for the purpose of ejecting dust, but they cease to function if covered with a dust layer, and damage is done to the whole breathing tract, setting up inflammation, swellings and lesions in the mucus membrane, and allowing dust to enter the lung tissues. Strong youthful individuals can withstand the harmful effects of breathing dust better than older and weaker individuals, but they suffer to a certain extent, especially if the type of boring machine used necessitates a more or less bent position, and the work induces rapid and deep respiration.

The nature of the working place plays an important part in the dust danger, as some spots are better ventilated than others. A strong air-current may be disadvantageous, because in restricted passages of the mine, the air-current may whirl about the dust as it falls out of the bore hole. Of especial importance is

the dampness of the strata and the mine atmosphere. The dust is naturally less dangerous under damp conditions.

The hammer-drill, with its succession of swiftly repeated blows, naturally sets up more dust and creates sharper particles than the rock-drill with a slower stroke, or the rotating drill; and, as the hammer-drill is held in the hands, the contact of the worker with the dust as it is ejected from the bore-hole is closer.

There are therefore many factors to be considered, which act in a varying manner to decrease and to increase the intensity of the dust-cloud. Long-continued drilling in dry hard sandstone with the hammer-drill is especially harmful, whereas boring in damp strata and soft shales with rotating-type drills under conditions of good ventilation is entirely without possibility of ill-effects.

Many devices have been tried to diminish the dust danger. The passing of water into the drill-hole entirely settles the dust, but it creates a condition that is onerous for the worker and is technically very difficult to arrange, because at every change of the drill the water-connection must be made anew, and a tight connection is difficult to maintain because of the vibration of the machine. Also the slime from the borehole is so disagreeable, especially in overhead holes, that the driller will prefer the dust to the spilling of water and mud all around and over his person.

The use of masks usually results in their rejection by the wearer because of their interference with his breathing and their general uncomfortableness.

The latest device is designed to remove the dust from the hole, immediately it is created, by means of suction set up by compressed air, and to lead it through a pipe to some place where it can be deposited without danger to the workers.

The Ministry of Trade & Commerce for the Mine District of Dortmund in conjunction with the Mine operators Association has carried out a series of trials extending over three months with devices of this nature. They consist essentially of a hood fitting over the aperture of the bore-hole, in which a sufficient suction is set up to remove the dust, and to transport it along a flexible pipe to the point chosen for deposition. A number of such devices have been designed and put on the market by Westphalian manufacturers of mine equipment, which, while differing in detail of application, are constructed with the same idea of removing the dust danger by removing the dust from the borehole and the vicinity of the worker to a point where it can do no harm.

The devices are said to have been successful in removing dust, but it is admitted that they entail a certain hindrance to drilling and some loss of time in changing the hood. Also in some cases, where the boreholes are placed in positions difficult of access some difficulty has been experienced in making room for the attachment of the hood and dust pipe. A thoroughly satisfactory solution of all the problems connected with the application of this device has not been found, and when the visit of an official has not been expected the workers have failed to attach the device.

Experiments have been made with hammer drills with a backward exhaust, instead of the usual exhaust towards the bottom of the hole, and further information regarding this development is promised.—F. W. G.

HOLLINGER PRODUCING $11,000,000

Indications The Company Will Crush 1,000,000 Tons In 1921.

ALEXANDER GRAY, Montreal.

Those who have the slightest regard for the economics of gold mining will find much that is instructive in the routine interim report of Hollinger Gold Mines for the thirty weeks ended July 29. It covers a period during a portion of which there was a shortage of power and of labor, consequently the increased tonnage milled reflects a reactive loss instead of the gain that would automatically be in effect. While the average daily crushing increased 500 tons and should have resulted in the lowering of cost per ton milled, it is obvious that gold mining operations are very susceptible to conditions, however temporary. For example: Whereas about 100,000 tons more or less went through than in the same period in 1920, the total income was $5,126,050.65 as compared with $4,012,242.28 in 1920. The total expenditure, including maintenance, was $2,786,129.16, as against $1,938,218.63. For a gain of $265,197.84 in net profit, therefore, there was a greater expenditure of $847,910.50—the total income was increased by $1,138,808.37. No doubt the extraordinary expenditure involved in providing coal when the power shortage was acute, is largely responsible for the added outlays—and a recurrence of this is what Hollinger Directors seek to avoid.

Hollinger operations are becoming altogether too important to be subjected to seasonal reverses. To have milled about half a million tons, is highly creditable to the management, in view of the handicaps. The grand total of income indicates a result for the whole year amounting to about $11,000,000 barring interruptions and if the prevailing premium upon gold continues. It would seem that the Hollinger will mill a million tons in 1921. The average daily crushing during the thirty weeks reviewed, was 2,406 tons. In more recent months the crushing have been much nearer to the milling capacity, hence the expectation that the years total will attain approximately to a million tons representing about $11,000,000 in gold and the premium on the same. Yet Hollinger costs will have to come down if the full force or the output is to be completely impressive. Grand aggregates such as the Hollinger offers suggest the utmost economy at the phenomenal properties and a larger appreciation among those who comprehend the import of this yellow metal. Getting the gold out of the ground at the lowest cost possible—and as rapidly as possible—will cure more ills than special taxation that will retard initiative.

BENZOL SCORES A SUCCESS.

The enthusiasts of benzol will be gratified to learn that this alternative motor power scored a distinct success last Saturday in connection with the Aerial Derby, for we understand that the race was won upon a mixture of motor spirit and benzol. This important success lends considerable weight to the popular belief that an admixture of about 20 per cent. benzol with motor spirit tends to increase the efficiency of the internal combustion engine. When one considers the phenomenal speed obtained by the fastest aeroplane in the Aerial Derby, the tip given above should certainly be worth following by motorists generally. —"Petroleum Times."

The Kathleen Coal-Mine Fire

Rapid Extinction of an Underground Fire, and Unusualy Quick Recovery of the Scaled-off Area By the Use of Oxygen Breathing Apparatus.

By EUGENE McAULIFFE, President and General Manager, Union Colliery Co., St. Louis, Mo.

(Reprinted from "Coal Age".)

On February 23, 1921, the Union Colliery Co., in operating in Kathleen mine, located at Dowell, Jackson County, Ill., experienced a rather disastrous mine fire. As usual, many unwarranted statements as to the origin of the fire were circulated. The explosion of a 150-kw. transformer, the presence of a supply of lubricating oil on the main entry and an accumulation of gas, each in turn was advanced as the cause of the fire.

As every transformer under ground was placed in service without repairs when the mine was opened, as no oil was stored or used on the main entry, and as it was impossible for an accumulation of gas to gather in an air-swept haulageway, the hastily-concocted theories as to the cause of the fire were set aside by the mine officials and state inspectors, who were conversant with the operation and its condition. The actual history of the accident and the subsequent recovery of the mine, which may prove of value to others, is substantially as follows:

About 11.50 a.m. on February 23, 1921, the mine engineer and his assistant were making some measurements in the third and fourth north headings turned off the main west haulage entries, these latter consisting of three parallel passages. Leaving the faces of the third and fourth headings where seven men were employed, they proceeded outbye against the air and noticed signs of smoke at a point about 1,900 ft. from the airshaft. Thinking that possibly the trace of smoke came from an overheated cutting-machine cable they hurried to the end of the main entry where a gang was at work cutting and loading coal.

Failing to locate the trouble at this point the engineer and his assistant started toward the airshaft on the center or main haulage entry and encountered dense smoke about 150 ft. from the point where the main entry intersected the third and fourth north and south entries. Hastily returning to the machine gang the engineer, accompanied by his helper and three miners, ran back, going with the air toward where the seven men were working, but were blocked by a dense accumulation of smoke when within about 200 feet of the fourth north entry. The engineer and his party turned and again ran west against the air and, crossing over to the intake or left-hand entry, they started toward the mine bottom. They found the fire breaking through a wood and fiber-plaster stopping at a point about 150 ft. south of the intersection of the main haulage entry with the third south entry.

An alarm was promptly given and a fire-fighting force was quickly organized. Orders were issued to withdraw from the mine all men other than those composing the fire-fighting force. Simultaneously calls for help were made on the state rescue team located at Duquoin, five miles distant. Likewise the neighboring mines were urged to send assistance in the form of apparatus and skilled men.

The first relief force, consisting of the Duquoin mine-rescue team composed of six men equipped with breathing apparatus, reached the mine after about three and one-half hours. In the meantime vigorous efforts were made to extinguish the fire with the aid of chemical extinguishers, scattering assistance coming from every quarter. All the employees were accounted for except the seven men who had been working at the face of the third and fourth north entries.

After every effort to control the fire and reach the seven imprisoned men was exhausted it was decided at 12.0 a.m., Feb. 24, thirteen hours after the fire was discovered, that the only hope of gaining mastery over it lay in sealing both shafts. This work was completed at 5.30 a.m., Feb. 24.

The territory occupied by the seven men, comprising a machine gang and two track layers, consisted of two entries each about 600 ft. long, two panel entries turned from them for a distance of less than 100 ft. and a parting driven in about 70 ft. from the third north entry. With the hope that the men might be able to brattice themselves off for a period at least, a geophone was obtained and used for some days, but without result.

Carbon Monoxide Came from Rescue Borehole.

In the meantime a 6-in. borehole was driven to the parting previously referred to. This hole entered the parting at 8.05 p.m., March 1. A discharge of carbon-monoxide gas under a pressure of 2 or 3 oz. per square foot ended all hope for the rescue of the imprisoned men. As showing the accuracy of both the underground and surface surveys and in support of the conclusions made as to the probable whereabouts of the seven men it should be here mentioned that the borehole entered the parting exactly as anticipated and when the mine was explored the bodies of the men were found about 20 ft. inbye from its point of entry.

Immediately after the shafts were sealed a standard "U"-type of water gage was installed in the seal above both shafts. On March 1, which was six days after the shaft had been sealed, the outside temperature stood at 65 deg. F. A self-recording thermometer located at a point about 4ft. below the top of the airshaft seal registered 62 deg. F. A comparison of temperatures and the variation in water-gage pressures shown in the accompanying table evidences the general trend of fire exhaustion.

The Kathleen mine is a new property, located on the east slope of what is known as the Duquoin anticlinal. The coal bed rises at a grade approximating an average of 5.5 per cent from the shafts toward the west property line. No marked variation in elevation between the north and south developments has so far been experienced. East of the shaft local disturbances which temporarily give off an appreciable amount of methane (CH_4) have been encountered and gas is exhaled from the working places, as is usual in this coal area. Nothing, however, of an extraordinary character has been met with in the

development of the property. The coal is left up for roof, as is customary in the southern Illinois coal field. This is a condition that lends itself readily to the rapid spread of entry fires

Enter Mine Three Weeks After Fire Starts.

Desiring to recover as quickly as possible the bodies of the men still underground, early consideration was given to the opening of the mine. Although rather extraordinary statements were made as to the rapid spread of the fire, the high temperature encountered in fighting it, and the like, it was decided, after careful study, that the mine could be successfully entered by March 18, or twenty-two days after the shafts were sealed.

Preparatory to this opening five state mine-rescue teams, equipped with oxygen breathing apparatus, each team consisting of six trained men, were furnished through their respective captains with a map showing the underground development, the location of the fire and the probable location of the bodies of the seven victims. An airtight lock was constructed over the airshaft, its general dimensions being as follows: Chamber over shaft, 9 ft. 4 in. wide, 9 ft. 4 in. long, 30 ft. high.

Immediately north of this chamber and separated from it by an airtight door an air lock 21 ft. 5 in. long, 6 ft. 3 in. wide and 6 ft. 9 in. high was constructed. This was provided with an exterior airtight door, affording ingress and egress. The inner door was located 5 ft. 2 in. from the shaft curb, the distance between the inner and outer doors being 15 ft. 3 in., which was sufficient to accommodate a timber car loaded with the 12 ft. lumber used for temporary stoppings.

The framework of this temporary construction was of 3 x 4-in. material, the sheeting consisting of 1 x 8-in. shiplap laid double with one thickness of building paper between. The top was covered with one thickness of byrkett lath made airtight with a thick coating

TABLE I. COMPARISON OF INSIDE AND OUTSIDE TEMPERATURES WITH VARIATIONS IN WATER GAGE

1921	Weather	Outside Temp. Hour	Deg. F.	Inside Temp. Hour	Deg.F.	—Max. Range— Hour	Plus Inches	—Water Gage— Hour	Minus Inches

*Taken from pipe extending about four ft. below seal.
†Taken from top of pipe in borehole driven to parting at end of fourth north entry about 600 ft. from where fire started.
Analyses shown as made at Urbana were made by the laboratory of the U. S. Bureau of Mines at Urbana, Ill.: those shown as made by Car No. 6 were made by the engineer in charge of the U. S. Bureau of Mines. Car No. 6, using portable apparatus.

of wood-fiber plaster. Two ordinary house windows were inserted in the wall for lighting purposes.

To forestall any possible failure to raise the cage in the event that a disarrangement of the power line supplying the electric hoist should cut off the supply of energy while the helmet men were below, a steam hoist, a steel line and sinking tub were fitted up, thus making quick emergency egress possible. In this connection it should be stated that the concrete shaft lining and the solid concrete and paving-brick construction employed in the fan house and in the air ducts made it readily possible to provide a thoroughly airtight seal. Beyond doubt this was an important factor in the early reopening of the mine.

After the lock was completed and the restoration forces were thoroughly organized, the airshaft seal was lifted on March 17. An oxygen breathing-apparatus team entered the mine on the following day, March 18, using the cage to descend to the mine bottom 232 ft. from the surface. The mine was found to be clear of smoke and the temperature to be 60 deg. F. The work of establishing a fresh-air base at the shaft bottom was then begun.

Fan, Steam-Driven, Made to Exhaust Slowly.

To this end five seals were quickly constructed of byrkett lath and wood-fiber plaster, and after a brick stopping had been removed the fan was started exhausting and driven as slowly as possible by means of its auxiliary steam drive. Thus pure air soon displaced the gaseous mixture at the bottom of the shaft. The analysis of air samples taken at various points is set forth in Table II.

Steady shrinkage in oxygen content from 8.3 per cent on March 1 to 2.5 per cent on March 17 proved the effectiveness of the two shaft seals as well as that of those applied to the fan chamber. To consume the oxygen within the mine would require the burning of about 50 tons of coal, for the total volume of the void within the mine resulting from the extraction of coal and top material approximated 700,000 cu. yd. The increase in methane (CH_4) content from 4.3 per cent on March 1 to 16 per cent on March 24 was noticeable, suggesting an appreciable explosive hazard deserving the closes attention during the recovery period.

At 9.30 p.m., March 20, a second advance of 500 ft. was completed and at 2 p.m., March 22, five additional seals brought the air into the bottom of the main west entry about 700 ft. from the airshaft. At 2 p.m., March 24, with the completion of ten additional seals, fresh air was brought within 500 ft. of the fire zone. Examination beyond this point showed that all three entries were heavily caved and that, immediately below the falls, the temperature was about 79 deg. F. Three additional stoppings immediately below the fire zone were completed at 4 p.m., March 25.

As no further advance could be made by way of the main west entry, the men were withdrawn from the mine and, after removing the seal above the main shaft, the fan was started on pressure — that is, blowing — at normal speed. On March 28 the gas men entered the mine and made a complete examination. It was found to be free from explosive gas and the bodies of the seven victims were located in the parting off the third north entry, as before mentioned.

After the removal of the bodies on the morning of March 29 an exploration of the west end of the fire zone was made. The fire area was found to be restricted to the three main west entries, not reaching into the third and fourth cross entries. Although no smoke or visible evidence of active combustion was found at the west end of the fire zone the temperature at this point stood at 85 deg. F. With the construction of three stoppings above the fire line the burned area, about 250 ft. in length, was completely isolated. On April 6, with six concrete seals in place and surrounding the fire zone, the production of coal was resumed.

Ascertain Main Haulageway Had Caved Most.

On May 28 the two outside concrete seals at the lower or eastern end of the fire zone were removed after two doors had been constructed below them. Then, with all except two gas men withdrawn from the mine, 20,000 cu. ft. of air per minute was driven through the fire area. The temperature at the time of unsealing was 80 deg. F.

On May 29 a partial exploration of the caved entries was made. This showed that the left-hand or intake entry was heavily caved for 130 ft. of its length. The right-hand or return entry was similarly caved for a distance of 90 feet, and the center or main haulageway was found to be heavily caved for a distance of 200 feet. This entry showed evidence of having been subjected to the most intense action of the fire, the two outside entries being less severely damaged.

With gas men in constant attendance the air movement through the fire area was continued throughout the night of May 29, the temperature of the return air current rising gradually until it reached 170 deg. F. at 10 a.m., May 30. At this point the doors were closed and the concrete seals restored. It was evident that a hot coked or semi-coked mass at some point within the fire area had retained ignition heat. With the resealing of the place the temperature of the gas sampled through a valve in the lower central seal quickly dropped to 70 deg. F. The fire area will be kept sealed for a period sufficiently long to insure the complete exhaustion of all inclosed air and the extinction of the fire. A new roadway, developed to reach the territory beyond the seal area, is now being used.

Barometric Pressure Rises One-Half Inch.

Only one alarming situation developed in connection with the work of recovery. Until the seal was taken off the airshaft an extremely uniform barometric pressure was experienced. At 6 p.m. on March 20, however, the barometer stood at 29 in., thereafter rising gradually, until it reached 29.50 in. after twenty-four hours, this pressure being maintained for sixteen hours. At 10 a.m. on March 20, the barometer stood at 29.51 in. and thereafter gradually dropped for fifty hours, reaching its lowest point, 28.64 in., at noon on March 24. The fall thus occurring in fifty hours amounted to 0.87 in., equal to 11.82 in. of water, or an air pressure of 61.5 lb. per square foot. In the twenty-four hours preceding 2 a.m., March 24, the barometer fell 0.52 in., equal to a water gage of approximately 7 in. or an air pressure of 36.4 lb. per square foot, causing gas to leak past the temporary stoppings, thus forcing the men working without helmets outbye to withdraw from the mine. This experience demonstrated the value of careful barometric studies in the conduct of recovery work.

Top Coal Fell, Bringing Down Trolley Wire.

Any study of this accident would be incomplete without some conclusion being drawn as to the cause of the fire. An empty trip had passed through the main haulage entry about twenty minutes before the fire was discovered. The entry was clean of all combustible material other than coal, no oil or explosives were in the vicinity, and no explosion of any kind occurred at this point.

The conclusion may be reached, therefore, that the trolley wire supported from the top coal, which throughout the entire southern Illinois field is left up to protect the shale roof, became loosened and fell, bringing the wire down onto a new section of track, laid with 40-lb. rail and put in a place only a few hours before, after a derailment. Failure to replace immediately the bonds, which it is the practice to arc-weld into position on the return, made an arc of serious proportions possible, the insufficient return preventing the circuit breaker from operating to cut off the current. Under such circumstances as these the fallen top coal would offer a splendid vehicle for the quick spread of a fire.

The brief period intervening between the sealing of the shaft and the reopening of the mine was made possible to a large extent by the character of the shaft and top construction employed, the fan, fan house and air duct making airtight sealing a reality. While it is not customary to anticipate the sealing of shafts in advance, the engineer designing the top works can without expense readily give consideration to such a contingency..

The Illinois State Director of Mines and his staff conducted the work of recovery throughout and were ably assisted by the representatives of the U. S. Bureau of Mines, which, as before stated made the necessary analyses of gas shown in the accompanying table. This work was thorough and painstaking. Extraordinary precautions were taken to insure that all helmet men were in perfect physical condition and a competent physician and surgeon was in attendance at all times.

Gas Being Plentiful, Unusual Care Taken.

In addition, a man with extensive experience in the use and maintenance of helmet equipment scrutinized every man and the condition of his breathing apparatus as he stepped into the lock chamber. Where it was necessary to take down brick and tile stoppings these were removed by digging the fireclay from beneath them. No sledges were used in the explosive-gas area, and the temporary stoppings constructed of timber were put up with small nails driven with copper hammers.

Outstanding details in connection with the work were: (a) The careful analysis of gas samples taken at frequent intervals, which showed a loss of oxigen content in the mine atmosphere indicating the rapid exhaustion of the fire. (b) The painstaking study and planning of recovery operations done in advance, giving every man connected with the work a full opportunity to acquaint himself, through the medium of the mine map, with the exact situation. No suggestion from whatever source was considered unworthy of careful consideration. (c) Though the helmet crews worked in continuous shifts to accelerate recovery, no undue haste was permitted, and no one was allowed to go an undue distance ahead of fresh air. This made it possible to carry out a man who might from sickness or accident to his apparatus need a quick removal to fresh air.

Well Equipped With Fire Extinguisher.

The foot of the airshaft of the Kathleen mine is equipped with a water line and portable chemical extinguishers are placed at every door and parting. A telephone service is maintained underground. A fire-foam engine is kept on the surface and a duplex carbon-dioxide extinguisher holding eighty gallons of chemical, quickly refillable from a water car, stands at the bottom ready for movement any where within the mine. In addition to these precautions a pressure tank mounted on wheels which will hold about 350 gallons of water under air pressure is being constructed for use in the mine workings. These two underground extinguishers are each equipped with 100 ft. of hose an fire nozzles. Permissible explosives are used for shooting the coal, which is undercut by chain mining machines. No other fire trouble than the one just related has ever been experienced in this mine.

Experience gained in subduing this mine fire is here set forth in detail with the thought that may be of value to mine managers and superintendents generally and that as a result the occurrence of similar disasters may be prevented.

LAKE SUPERIOR CORPORATION.

The annual report of the Lake Superior Corporation for the year ending June 30, 1921 shows earnings of $1,541,293 as compared with $3,722, 152 in the previous year. Raw materials were obtained at high prices early in 1920, before cancellation and suspension of booked orders began. New business was secured later at reduced prices. Suspension of operations for 74 days piled up charges against operation. Under the circumstances it was not expected that the earnings would compare favorably with those of the previous year. The directors expect improved conditions in the iron and steel trade during the coming year.

During the past year the corporation produced 327,906 tons steel ingots. The subsidiary coal companies produced; Cannelton 474,848 tons and Lake Superior 235,933 tons. Coke production was 429,041 tons, limestone 235,399 tons and pig iron 362,805 tons.

BAILEY COBALT MINES LTD.

According to a notice to shareholders a meeting will be held Sept. 23 with a view to having the 'winding up' order terminated and the liquidators discharged and the company permitted to carry on its business.

The property of Bailey Cobalt Mines Ltd was sold to Bailey Silver Mines Ltd a year ago. The 425 000 shares have not yet been received by the shareholder and to obtain the necessary authority to make application for them requires that a meeting of shareholders be held.

LAKE SHORE

At the annual meeting of the Lake Shore Mines Ltd, held Aug. 20 the directors were all re-elected. Mr. Harry Oakes is president and managing director. A. G. Sloght and W. H. Wright, vice-presidents, Dr. W. P. St. Charels, treasurer, Kirkland Securities Ltd, secretary. R. C. Coffey is mine manager.

The Asbestos Industry[1]

By J. G. ROSS.[2]

Recent rumours of proposed provincial legislation to compel the manufacture of asbestos in Canada serve to direct attention to the large part played by the production of asbestos in the mineral wealth of Quebec.

Information relating to producing mines in Canada, foreign production, varieties and uses of asbestos, etc., is clearly and fully detailed in the annual reports of the Quebec Bureau of Mines that it is unnecessary to occupy time and space in repeating these features Certain general aspects of the industry only will be referred to.

Production and Value.

The figures given by Mr. T. C. Denis, Superintendent of Mines for Quebec, for the first half of 1920, show a production of asbestos and asbestic in the province of 82,500 tons, valued at $5,763,000 whereas for the previous 12 months, the output was 160,000 tons, valued at $10,995,000. The total value for 1920 should exceed that for 1919. (A preliminary estimate, published since this paper was written, places the total value of the 1920 output at $14,718,131.)

Valuation.

It would be interesting to know on just what basis these values are arrived at. Three at least of the larger mines are controlled by foreign asbestos manufacturing companies, and two other Canadian companies maintain sales offices outside of Canada.

Do these companies invoice their fibre at cost prices or at full market value, and does the Government collect the full tax to which it is entitled? If it does not, the other companies are carrying an excessive share of the tax burden. If the Government were collecting on the full market value, it might receive the amount which it estimated the industry should turn in to its coffers, and could take more time to study fully the effect on the industry of having manufacture completed in Canada.

Tax.

A Provincial tax is levied on the invoiced value of shipments. During the year, despite the protests of the Asbestos Mine Operators' Association, the tax was increased to 5 per cent from 3½ per cent. All contracts for sales are made plus the provincial tax, so that the buyer pays the tax. The chief argument against the increase in the tax was that higher prices would tend to force foreign dealers to prospect and develop deposits in other countries. Less harm might be done to the industry if this tax were not so definitely brought to the attention of purchasers.

That high prices of Canadian fibre, particularly crudes, have assisted the development of outside resources is shown by the increased development of Arizona properties, larger shipments from South Africa, and the active prospecting being done in California. South African blue fibre is even being used by one manufacturer in Canada.

The effect of higher prices is indicated in the lessened demand for low grade stock, and the use of substitutes and adulterants in manufacturing. On the other hand, the high prices have also forced manufacturers to use the lowest grades, so that products which formerly went to the sand dump have been recovered and shipped at a profit.

Organization.

Another attempt has been made toward co-operation among the companies by the formation of an Asbestos Mine Operators' Association. That there is a need for some such organization has several times been recognized by the formation of similar organizations during past years. Several matters of common interest, such as labour problems and legislation, have already been dealt with satisfactorily. The usefulness of such a body depends on the willingness of the members to work in harmony.

The necessity for getting together is admitted. By doing so, subjects of common interest can be discussed, and solutions mutually helpful arrived at.

A suggestion has been made for a central bureau, which would employ a staff of engineers and geologists. Geological problems common to the district could be worked out in detail, and the benefit of these studies made available for all properties.

Mining systems might be devised suitable to the rock and to the stage of development of each property. Experience gained at one property might be used with profit at several others.

A central experimental mill could not fail to improve methods of fibre recovery. The proper system for obtaining the most suitable grades of fibre from each variety of rock could be devised. Research work done at some of the mills has resulted in such marked improvements in recovery that there is little doubt that the elaboration of such work would have a marked effect in increasing the total value of the product from the district.

Such a central bureau could also keep in touch with outside development in production and manufacture, and advise operators accordingly.

To evolve such a system it would be necessary to regard the whole Canadian field as one unit, as opposed to all outside areas. By close co-operation with the Department of Mines and the Provincial Government, the Canadian asbestos industry might be placed on an independent footing, and all fear of outside competition removed. This should result largely in the elimination of the periods of depression which have had so disastrous effect on the mines, shareholders and workmen, as well as on the revenue to the Government.

The recently organized Thetford District Branch of the Institute will undoubtedly prove beneficial to the industry, since its periodic meetings afford an excellent opportunity for the engineers and staffs of the different mines to discuss local problems together, and interchange suggestions for their solution.

Many engineers from metal-mining camps have recently entered the asbestos district, and with the application of engineering knowledge gained in other fields, improvements to prevailing systems of mining and milling are to be expected.

Geology.

The publication of Dr. Harvie's Geological Report and Map of the District is anxiously awaited, as much prospecting is planned for the coming season. Some

---

[1] Presented at the Annual General Meeting, Montreal, March, 1921.

[2] Consulting Mining Engineer, The Milton Hersey Company, Ltd., Montreal.

areas have been surveyed privately by geologists, and a considerable amount of drilling is being done to prove increased ore reserves.

The successful establishment of another mill in Coleraine has revived interest in the westerly end of the district. Three new mills are in course of construction, and three other old properties in this area are being developed anew.

In the easterly part of the field, where no crude is produced, the outlook is not so promising, and continued profits must be looked for by improved methods of milling and decreased costs.

Mining.

As workings increase in size, the mining methods undergo a normal evolution. The smaller pits are economically worked by derrick hoists or cables; but as a face of sufficient extent is opened, the introduction of cranes reduces the mining cost; while at mines producing no crude, the steam shovel is replacing the derrick with benefit shown on the cost sheet. Underground mining is more of a necessity than an advance, except in the case of glory hole work.

Milling.

Careful research work in some of the mills is resulting in most satisfactory improvements. By means of test runs, and analyses of products, information has been gained on which to plan changes in treatment. At one mill practically no fibre is now being produced lower than a high grade shingle stock, and yet the tails to the sand dump show a loss of less than 0.10 per cent of short fibre.

Present methods of grading are unsatisfactory, and further research is being done to control the grades, both on fibre from mill and from storage, within more narrow limits.

Labour.

Strikes were called at two of the mines, and were the result, principally, of conditions peculiar to the district. As these strikes occurred at a time when labour in general was becoming more plentiful, work was resumed at former rates.

As there was not sufficient labour during the summer to operate night shifts as usual, the production, especially of crudes, was below what was expected. This probably was one cause of prices remaining at a high level.

Two of the larger mines being at present shut down, the labour so released, together with an increased supply from outside, affords full crews to the operating properties. Wages have not been reduced, but there is a marked improvement in the efficiency of the workmen. Moreover, as a result of the men working more days per week than during the past year, the effective labour supply has been still further augmented.

The housing shortage adversely affects the labour situation, as it is difficult to assemble crews of steady men unless suitable accommodation for families is provided. In view of the falling prices of materials, and increased efficiency of the workmen, several companies are now planning housing programmes on an extensive scale.

Prices.

Quotations from "Engineering and Mining Journal," February 19th, 1921, are as follows:—

	Per Ton.		
Crude No. 1	$2,000.00	to	$3,000
Crude No. 2	1,100.00	to	2,000
Spinning Fibres	400.00	to	1,000
Compressed Sheet Fibres	325.00	to	500
Shingle Stock	110.00	to	150
Paper Stock	60.00	to	75
Cement Stock	17.50	to	30
Floats	8.50	to	15

Prices are per short ton f.o.b. Thetford, Broughton and Black Lake mines, Quebec, 5 per cent to be added as export sales tax.

It may be of interest to compare with the above prices those prevailing a few years ago. The following table, taken from the Report of the Quebec Department of Mines for 1915, gives the average value per short ton of the various grades of asbestos in 1914.

	Per Ton
Crude No. 1	$301.96
Crude, No. 2	131.85
Mill Stock, No. 1	60.40
Mill Stock, No. 2	24.93
Mill Stock, No. 3	11.18

The increase in prices has actually been greater than the above figures indicate, as a shorter fibre is now sold as No. 1 Crude, than in 1914, and the average spinning or other stock shows a lower test.

Consumption of Fibre.

With the world-wide depression in trade and the prevailing rates of exchange, it is to be expected that the demand for fibre of all grades will be lighter. On the other hand, with increased supply and efficiency of labour, and new mills, production will increase. The exceedingly favourable weather for open pit work during the winter has already been responsible for an increasing quantity offered.

To take care of an expected increased production, asbestos manufacturing companies have instituted an active advertising campaign in which the mine operators have joined. This campaign is for the purpose of educating salesmen and the public in possible uses of fibre, and to expose cases of adulteration or substitution in articles advertised as being composed of, or containing asbestos.

Manufacture in Canada.

At present one plant at Lachine manufactures asbestos shingles and allied products. A plant at East Broughton has commenced the manufacture of brake lining. In Ontario, one plant is in operation, and two others are carrying on experimental work in the manufacturing of asbestos products.

Outlook.

The immediate future of the asbestos industry is in the hands of the mine operators. If past policies are pursued, former experiences will be repeated. Large stocks of fibre will accumulate, and buyers will hold off. Stocks will have to be sacrificed to meet expenses, and properties, those making low grade fibres first, will be forced to close down with a resulting period of idle mills and unemployment.

If, however, there is co-operation, production can be maintained at market demands only, and efforts can be concentrated on producing the most suitable grades of which a given rock is capable under the proper milling system.

A large production of low grade fibre, with corresponding tailing loss, is not so remunerative as a less production of long fibres properly milled. It is now recognized that, if the best results are to be obtained, the rock in each different area requires its own special method of milling. By experimental milling, a flow

sheet which will give the maximum profit from any given rock should be advised at each mill.

The fact remains that Canada supplies over 80 per cent of the asbestos fibre used, and notwithstanding the incentive of high prices to prospect other fields, the Canadian fibre is still in greater demand and commands a higher price than fibre of equal length from outside sources.

With careful handling of the present situation there is no reason why asbestos mining should not maintain its premier position in the Quebec mineral field.

HYDRAULIC STOWING.

At a meeting of the South Wales Institute of Engineers, at Cardiff, on the 14th inst., Mr. J. Drummond Paton, of Manchester, and Prof. George Knox, principal of the South Wales School of Mines, read a joint paper on "Hydraulic Stowing." Mr. W. Forster Brown, M. Inst. C. E., the president, occupied the chair.

The lecture was illustrated by a number of lantern slides showing some of the installations already in use. Mr. Paton said since 1901, when the first modern equipment on a large and economic scale was erected by Berrygrat Willigar at the Myslowitz Mine in Upper Silesia, the system had been adopted and continuously improved in other Austrian German, Belgian and French mines until it had become a generally accepted practice in modern mining engineering, but no extensive application had yet been made in this country. A small installation had been worked by the Wishaw Coal Mining Co., Motherwell, and a still smaller installation at Crowgarth iron ore mine, and also at the Weymss Colliery, in Fife.

In the early stage of development of hydraulic packing ordinary cast iron pipes were used to convey the packing material and water into the workings, but the rapid internal wear caused by the grinding action of the packing (particularly in the horizontal pipes) led to the use of linings. At first, hard wood linings were used but except in the case of sand packing as in the Transvaal, these were not satisfactory, as they wore out very rapidly and required very large diameter pipes for large volumes of packing material. Mild, ungalvanized steel pipes were then tried, but these also had to be frequently renewed when unlined. The three types of pipe line now in use are: (1) Mild steel or cast iron pipes with steel lining; (2) steel pipes lined with porcelain; and (3) oval shaped linings on the narrow or under-side. Porcelain pipes are estimated to pass 180,000 to 200,000 tons of stowing material before requiring renewal, and iron or steel lined oval pipes will pass 200,000 to 1,400,000 tons of packing material per inch wear of linings.

Mr. Paton stated there was no district in the British coal fields in which the advantages of hydraulic stowing would be more beneficial than in South Wales. In getting a large amount of permanent support in the gob, the squeeze of the overlying rocks would be more evenly distributed thereby increasing the safety from falls of roof and sides and reducing the high cost of initial timbering, and the subsequent repair work. The ventilation was also improved owing to the reduction of leakage through open packs and the filling up of old disused roadways, but the greatest advantage would probably be the lessening of the risk for explosion. If this could be done the greatest problem in the South Wales steam coal collieries, that of coal dust deposits, could be easily solved by a system of watering on the roadways which when combined with the partial laying of dust on the face would do more to render these mines safe than could be accomplished by any system of stone dusting. As subsidence was the cause of producing the need for roof supports, the better regulation of subsidence would naturally appear to be the best way of attacking this problem. The saving effected in the cost of timber would go a long way towards the cost of applying hydraulic stowing if it could be shown that the process does effect better regulation of the subsiding surface. Where hydraulic packing is in use no coal barriers need be left as a continuous pack of flushed material would serve the same purpose. Neither was it necessary to leave ordinary pillars of support for surface property, railways, canals, etc., thereby effecting a large saving in the loss of valuable minerals. Hydraulic packing, for which so many advantages can be claimed, can be applied to the working of any kind of mineral and to almost every method of working them.

In its practical application there were many difficulties to be overcome, but surely British engineers were quite as capable of overcoming these as their colleagues on the Continent had been, and they had the further advantage of making use of long years of pioneering experience already gained in its application.

COAL MINING REGULATIONS.

The Department of the Interior has ready for distribution copies of regulations for the disposal of the coal mining rights in the province of Manitoba, Saskatchewan and Alberta, Yukon and North West Territories, and the railway belt in British Columbia. They supersede with amendments, regulations published in 1918. Lands may be leased at an annual rental of $1 per acre for a term of 21 years. The maximum area of a coal mining location is 2,560 acres. In addition to the rent a royalty of five cents a ton is levied. The lessee is required to commence active operations on his leasehold within one year from the date he is notified to do so, and to produce a minimum tonnage of coal stated in the notification. Leases are subject to provision that settlers may buy coal for their own use at the pits mouth at a price not to exceed $2.75 per ton.

"THOMPSONITE" NOW BEING MANUFACTURED.

All necessary permits having been granted, the Thompson Powder Company, Ltd., manufacturers of high explosives, with works at Deseronto, Ont., and business offices at 163-7 Yonge Street, Toronto, are now manufacturing "Thompsonite," and this product is now on the market. Considerable attention has been given by mining engineers to this explosive. Numerous and stringent tests, with what are claimed to be notably successful results, have been carried out. The capacity at which the Company can produce this powder is at the rate of six tons a day.

WHITE ROCK.

It is reported that some very high grade ore has been encountered in the drift at the White Rock mine, West Shiningtree. The White Rock is controlled by Mr Wm. Vittie of Sudbury.

PLATINUM "LOSS" AT SUDBURY IS EXPLAINED.

J. A. McRAE.

With respect to the press despatches which a few weeks ago set the mining fraternity of all Canada agog with the assertions that $60,000,000 had been lost to Canada annually for the past 25 years in the form of platinum and other metals of the group in the Sudbury nickel ores, the writer has established communication with Dr. Ami, the author of the alleged statement.

Dr. H. M. Ami, who is Acting-Governor of the Imperial Resources Bureau, and Technical Advisor to the High Commissioner in London, says, in part:—

"Mr.————, of the Geological Survey, Ottawa, has transmitted your letter to him asking for the full text of remarks credited to me in respect of platinum metals recoverable from Sudbury ores.

"The amount given was a low one—but the press made me say that $60,000,000 worth of platinum had been lost to Canada "**annually**" for 25 years past. The word annually should be deleted.

"I am specially interested now, in seeing that Canada gets a straight deal with respect to the weights and values of its ores, especially as regards the precious metals recoverable from the ores of Sudbury."

Dr. Ami further states:—"I think that $60,000,000 loss for 25 years is not at all an exaggeration. You have only to read the Royal Ontario Nickel Commission's report to be impressed with hard facts and figures."

Dr. Ami is at present with the Imperial Mineral Resources Bureau, 2, Queen Anne's Gate Bldgs., Westminster, London, S.W.I. The Bureau is at present completing reports covering the mineral and metal resources and production of the Empire for the war period, 1913-19. For comparative purposes the reports have also covered the resources of countries outside the Empire. The Bureau enjoys the services of 148 British chemists, metallurgists, mineralurgists and mining engineers and represents every Dominion and Colony of the Empire except South Africa which is now making arrangements to join.

Where Mistake Occurred.

The despatch is question which misquoted Dr. Ami said, in part:—"In 1916, says Dr. Ami, Canada was only credited with 15 ounces of platinum, whereas one mine alone in the Sudbury district might have produced 15,892 ounces, amounting in value to $1,700,000. Dr. Ami believes that from 3,000,000 to 4,000,000 ounces of precious metals are recoverable from the Sudbury nickel mines. The Bureau, he states, is thoroughly appreciative of Canada's mineral output, which last year reached a total of $217,000,000."

The despatch then dealt with the Australian situation, and continued:

"Reverting to platinum and other precious metals of the same group occurring in the Sudbury district, Dr. Ami says that the Bureau has actively considered this matter with a view to recovering the weights and values which should come from this valuable mining centre. Probably $60,000,000 worth of the platinum metals have been lost annually for 25 years past."

Brief Explanation.

With respect to the above despatch, it will be noted that the word annual in the concluding paragraph should be deleted. This being so, then the estimated annual loss is greatly reduced, although the aggregate for a quarter century is startling. To those familiar with the business of mining, however, it is less imposing than may at first appear.

For instance, it might be well to take the silver field of Cobalt as a comparison. It is recognized in mining that a recovery of 95 per cent of the mineral content of the average silver ore is quite satisfactory. The mines of Cobalt during the past eighteen years produced over 300,000,000 ounces of silver. Allowing for a loss of five per cent. in recovery, the aggregate loss here in silver alone would amount to over 15,000,000 ounces in eighteen years. When the mines of Cobalt were at their best in 1910-11 the annual loss in silver may have reached 1,500,000 ounces annually. In addition to this silver, was unavoidable losses of cobalt metallics, cobalt oxides, and arsenic.

Therefore, Dr. Ami appears to heve made the mistake of classing unavoidable losses at Sudbury with avoidable losses. It is true, perhaps, in fact is the case, that improvement in recovery is being made, but a full 100 percent recovery will probably never be attained and the assertion that vast quantities of precious metals are being "lost" leaves the impression that there is glaring inefficiency, which is not the case.

Dr. Ami is known to be working for the general welfare of the mining industry of Canada, and the impression which his remark has left is perhaps entirely contrary to the intentions of the author. The statements merely become dangerous and dilated when coming to the attention of the novice in the business of mining.

THE FUTURE OF COPPER SMELTING: A FRENCH FORECAST.

In a recent issue of "L'Information Economique," M. L. Moynot discusses the causes of the present depression in the copper-smelting industry, chief among which he includes the rise in the cost of fuel. After explaining the various processes employed in the industry, the writer arrives at the following conclusions with regard to the development which it may be expected to take. The very great increase in the cost of coal and coke, coupled with the slump in the copper market, will force producers to abandon processes which although they have served their purpose, have to-day become too costly to work. The reverberatory-furnace method and that of the water jacket working with coke are alike doomed, and will only be employed in exceptional cases. The same applies to hydro-metallurgy by lixiviation and steam cementation of ores which have been simply roasted. The water jacket with pyritic fusion and bessemerisation, as also the natural slow cementation of the ore, are likely to become more and more popular. Chloride roasting will be found very useful in certain cases. Finally it will be found that one of the best means of reducing the production cost of copper is to make a better use of the other metals by which it is accompanied in complex ores. "Mining Journal", London.

Mr. J. A. McRae, our Northern Ontario correspondent will leave for Manitoba towards the end of August and will visit a part of the northern mineral belt as special representative of the "Journal". The Rice Lake, Elbow Lake and Beaver Creek localities will be visited.

Montreal River in Retrospect and in Perspective

ALEXANDER GRAY, Montreal.

"Warts on my Fingers,
Corns on my Toes,"

Thirteen years ago the men of the Gowganda Trail sang this jingle of the pack, the portage and the paddle, slept in the snow, the lean-too or in one of those double-deck devices which were luxurious to the weary, inconvenient to the overweights—and economical to landlords.

"I don't care how she goes"

was the concluding line of that refrain.

Nor did they. Trudging from "steel" in Summer; staging it by sleigh or "hiking" on snowshoes in Winter; pushing canoes from Latchford or further up the river; those who confidently staked the Temagami Reserve were as buoyant as the devil-may-care of anywhere can be. From Portage Bay and Pork Rapids to Fort Matachewan, and on to Shining Tree, they drove in their discovery and corner posts, made affidavits they had "minerals," the "vein calcite" and "bloom —all "in the diabase"—and the Annual Report of the Ontario Bureau of Mines for 1908 contained this glowing paragraph:

> "Indeed it may be said that at the close of 1908 the excitement caused by the rich specimens of native silver found in the neighborhood of Lake Gowganda have not only raised the hopes of prospectors and mining men generally, but have reinflamed the public mind and paved the way for a recurrence of the Cobalt boom of 1906."

So "mushing it" went on. "Tommy" Torrance was he was raking in fees, adjusting disputes. Government railway receipts were augmented by passenger receipts and general freight. Latchford and Elk Lake City hotels and boarding-houses were crowded. Pork and beans were good enough for the "sour doughs." Becootied stopping places afforded shelter. Prospectors and speculators had the urge, thought in millions, raised the limit when they found "native"—and every foot of ground from Maple Mountain and the Moosehorn to the Mann ridge was "another King Edward," or "Kerr Lake" mine. Companies were incorporated with random capitalizations. Unhallowed is the memory of those resorts which harbored more than humans, although their hospitality was shared by embryotic millionaires and moccasined adventurers whose worldly belongings were what they stood up in or carried a'pack.

Knights of the Snowshoe went and came without regard to the hardships. Tote straps to me were a badge of honor worn by the sturdy who labored through the bush. Breaking trails was part of the daily routine. Then the corduroy eased navigation across muskeg—eventually the sybaritic sightseer arrived in sleighs, coonskins cap-a-pie, wind-shields—and commissariats suited to the epicurean tastes of those who play with their own—or other people's—money. It was exhilirating while it lated. Foliated silver—"rich specimens"—tickled the fancy, but cooling cracks and short ore shoots soon dampened the ardor of the most optimistic—and the Recorder for the Montreal District writing of 1910 had to admit:

> "The work of developing the mining land of the Montreal River Mining Division has not been carried on with the same energy that marked the period of 1909, but those remaining in the district are still of the opinion that it will eventually produce a large quantity of valuable mineral. The counter attractions provided in the Porcupine camp have joined with the operations of unscrupulous speculators in producing depression which usually follows a mining boom. The stringency of the money market and the hesitancy of capital to invest in mining ventures has confined the work of development in this division to an area which is considerably smaller than one worked a year ago, but the optmists who have remained secured very gratifying results during the past summer. The development of the new finds that have been made in Willet, James and Tudhope should enable investors to arrive at a satisfactory estimate of the value of the district during the coming summer."

The "recurrence of the Cobalt boom of 1906" and the "satisfactory" determination foreshadowed by Recorder Skill, as quoted herewith, did not materialize. The "optimists who have remained" through the intervening years have a standard gauge railway to Elk Lake, but there are few records of ore shipments; yet the Mining Recorder of the district, wrote as of 1919:

> "Business in this office during the year has been very good. Many new mining companies have been formed and considerable mining machinery installed on various properties. As several very rich discoveries of gold and silver have been made during the latter part of the year, this division no doubt will recover much attention from the prospector and the mining companies during the coming year."

Eleven years then had elapsed since the discovery of silver in 1908 in the vicinity of Miller, Leroy and Calcite lakes—and the impression still is strong that this district sooner or later will be the chief source of Ontario silver production. No end of head gears serve as tombstones for the ill-matured enterprises. Abandoned shafthouses and surface plants ruefully attest the folly of those who mistook samples in cracks for millions in a fissure. Silver Lake has been given the go-by. The Otisses, Downey, Casey, Devlin, Elk Lake Discovery, Gavin-Hamilton, Langhan, Lucky Godfrey, Mother Lode, Moosehorn, Foster, and their contemporaries, are aching voids. The "considerably smaller" area mentioned by the Recorder in 1910 as represented by the Miller Lake-O'Brien has produced about 5,930,000 ounces of silver, as follows:

Year	Ounces Silver
1910	481,583
1911	468,687
1912	549,976
1913	502,370
1914	399,300
1915	242,229
1916	360,670
1917	1,064,635
1918	638,198
1919	722,564
1920 (x)*	500,000
	5,930,152

* Estimated.

Of that production and its sources, Mr. A. G. Burrows of the Geological Department of the Ontario Department of Mines has authoritatively stated:

"The greater preponderance of the ore shipped has come from northwest of Miller Lake. Several shipments of high grade silver ore have been made from the Mann Ridge west of Gowganda lake. In 1910, 1911 and 1912 the Millerett mine was the chief producer, and since that time the Miller Lake—O'Brien. The latter deposit has supplied most of the silver ore yet shipped from Gowganda. With the exception of an ore shoot in conglomerate in the Millerett mine, which produced about 500,000 ounces of silver, all the ore to the end of 1919 has come from the diabase sill."

The geological chiefs of the Ontario Department of Mines repeatedly have indicated their faith in this diabase sill, especially at or near to its hanging and foot walls, wherever there is a contact with the Keewatin. No doubt it was this knowledge sustained by the outputting records that has encouraged holders of claim areas in and about this sill. One ore-shoot in the Huronian conglomerate held a position that was without another element of encouragement until the Miller Lake O'Brien geology was disentagled and this condition as described by Mr. Burrows was revealed:

"The most important veins known as No. 2 vein system, produced most of the ore in the early days of the mine. Development showed the veins of this system to dip steeply to the west, with the pitch of the ore-shoots to the south. Of this system, the foot-wall veins have been the most productive. The ore shoot in the hanging-wall veins did not extend to the 140-ft. level, whereas the foot-wall ore body continued nearly to the 350-ft. level. Each of these series carried two or more veins, which were sufficiently close together, where the ore shoots occurred, to allow mining in one stope. The veins were generally from two to five inches wide, and in the ore shoots individual veins were not always productive, but where one was barren, a parellel vein would carry the high-grade ore. Very little ore was taken from this system above the 60-ft level. The great proportion of the silver values was confined to the veins themselves, there being only a small impregnation of the wall rock.

This, No. 2 vein system seems to have been delimited by east and west faults, althougt the veins carrying the ore are said to have been only slightly displaced by the faulting. The earlier workings were in the diabase and outcropped at surface, where only a small portion of the sill had been eroded. Upon passing through a Keewatin section, however, work prosecuted in the underlying diabase proved that "silver ore occurs at greater depth from the present surface, depending roughly on the Keewatin-diabase contact, where the silver ore occurs in the upper portion of the diabase sill in proximity to the contact."

Such is the judgment of Dr. Miller and Mr. Burrows. The greater significance of the faulting conditions is apparent in the other or "Flynn" vein system of the Miller Lake-O'Brien where—

"The first ore was encountered on the 350-ft. level. A long east and west drift had crossed a very pronounced north and south fault, dipping 50 degrees east, and a northerly cross-cut had intersected No. 6 vein, which was followed to a second fault, striking east and west and dipping 30 to 40 degrees north. Ore was found in No. 6 vein above this fault. From this discovery the development was extended to a number of veins, the principal of which are No. 6, No. 7, No. 7 N.W., etc., producing the greatest width of high-grade found in the mine, of high-grade silver, smaltite and calcite. Later, in drifting on No. 7 vein on the 350 ft. level, portions of it were high-grade, ore two feet wide. In this rich section of the 'Flynn' system the stope was 14 feet in width, in places, of high-grade veins and mill rock. Development in this part of the mine threw light on the ore relationships. The workings show that the high-grade ore two feet wide. In this rich section of the the veins themselves became more indefinite, branching into stringers carrying galena, copper pyrites and other common minerals."

The lucidity of this description of the structural features at the Miller Lake-O'Brien, and the service rendered to the holders of ground in this locality by the management of this particular property, should have a larger appreciation. Perhaps the owner of the Miller Lake-O'Brien has felt he was not conducting an educational course at his own expense for the benefit of the populace in interest. He took over the Millerct when its owners had about exhausted their high-grade in the conglomerate. With ordinary working capital, the Miller Lake-O'Brien might have been upon the deferred list—and there would have been nothing but spasmodic shipments from the Montreal river district as a whole. Southeastern Coleman having elucidated the idiosyncracies of such contacts and faultings, the funds individually supplied by Mr. M. J. O'Brien proved to be an investment in behalf of all those having acreage in and about the sills—it now looks as if there is more than one sill. As at the Castle property, nearby, the relationship of faults and contacts—the vagaries of mineral contents of closely connected veins—have been profitably educational—and elements of certainty supplied—where Keewatin and diabase are present. One Castle experience in the diabase alone, was disappointing. Another effort under contact conditions resulted in finding high grade and milling rock—which need not be as good as they are at the Miller Lake-O'Brien to be good enough for extended operations.

So the "smaller" area that was inferentially deplored by the Mining Recorder in 1910 as the sole center of activity pioneered and piloted the owners of the larger area throughout the sill who await working capital. All things borne in mind, however, the production of almost 6,000,000 ounces may be regarded as an introductory chapter, once adequate money is available and transportation facilities are improved. Along the contacts there are evidences of precious metal mineralization.

Gowganda ridge, so called, was somewhat of a flash-in-the-pan. The Mann-Ryan no longer is in the limelight, although it was the object of competition during that winter when the nimble Foster rushed laden teams to that property. The Boyd-Gordon and Reeve Dobie fluttered and fell. The Bartlett had an inglorious if not unsavory career. The Armstrong Fraction blossomed into "Silver Limited"—and went to the scrap heap. All the "arms" Gowganda lake could muster were unstretched for public monies — but have not made any return worthy of mention. The Miller Lake-O'Brien remained the Casabianca, as it were, before the Castle joined it and re-attested the merits of the dia-

base sill in contact with the Keewatin. Consequently, the contention of Montreal river pioneers, that "we have 'bloom' and calcite", has been varied—and now there is more significance in the statement that "we have the contact". Otherwise there are merely tantalizing silvers, smaltite low in silver content, "galena, copper pyrites, niccolite and other common minerals".

Having followed the events of those years in which the Montreal River claim-holders floundered in a maze of mismanagement and official indifference toward transportation handicaps, the wonder is the slightest optimism prevails outside of the O'Brien and the Castle properties. Nine miles of road from Elk City to Long Point—the "rocky road to Dublin" from there to Gowganda—are the sum total of Government solicitude since the branch line was constructed from Earlton to Elk City. How much the nine miles of road have cost, is not a tribute to the sagacity or business capacity of those who projected and built it. If the section afforded the bonanza grade of Cobalt's outcrops, hauling bullion to the railway, or the establishment of concentrators and refineries on the spot, might be possible—but teaming in the circumstances is permissible for only the Government — with time and money beyond consideration. Of course the road as it is, favorably compares with the heavy gradients and hog's back of the earlier route via Silver Lake; but claim owners have been so long in suspense they are in a quandary as to whether they will have to take their chances with an highway suitable for wagons and tractors, a narrow-guage light railway—or cling to the hope that they will have a standard-guage extension from Elk City. Minister of Mines Mills during a reeent visit to Wigwam, put it squarely before his audience whether they preferred an automobile road to a light railway. Fearing the latter would preclude a standard guage later on, those interested were divided in their views, the impression being that the temporary expedient of a road that will serve immediate purposes is more to the point than a narrow gnage affair would be as a finality, necessitating trans-shipments. Moreover, the Government having made it clear that no official monetary assistance need be expected for a railway of any sort, those who survived the cost of claim licenses and prospecting, recording fees, surveyors charges, rentals—to say nothing of paying for what was required to ereet camps and timber workings—have all the chills and fevers of anticipation without realization. Meanwhile the cherished Temagami Reserve—timber and game preserve—bears eloquent testimony to the short-sightedness of those who aimed to make a mining section in Arcadia —where there would be no fires and strict observance of game laws. Between Kenebeek and Shining Tree what merchantable timber is standing, is pretty thoroughly burned or scorched—and claim-holders unable to procure capital are sufficiently singed to be ready for broiling or other esculentary purposes. They paid for their own bonfires — and are steadfast in their belief in whatever contains favorable contacts.

In the strictly diabase areas, removed from geological conditions as they exist at and around Miller, Leroy, Everett and neighboring lakes, the outcome is enshronded in doubt. Both the Miller Lake-O'Brien and the Castle—the latter controlled by Tretheway Mining Company of Cobalt, entailed an expenditure denied to others. They are at the northwest of Miller lake and near Everett Lake, the latter being where the Castle after prolonged effort on one area had a stroke of luck in 1919 on Claim R.S.C. 101, from which a first shipment of high grade was made in December of that year. Prior to that the Castle company had done 1,217 feet of cross-cutting, 1,335 feet of drifting, 80 feet of sinking and 40 feet of raising-in the strictly diabase area—and "no ore body of importante was encountered in those workings." On the other hand, hand, the richer discovery, near Everett lake, necessitated only the sinking of an incline shaft to a depth of 109 feet on a vein and there was high grade all the way. Continued development improved the status of this ground. This, as much as anything else, gave fresh impetus to the locality—and it is not to be lost sight of that O'Brien and Castle called for capital with nerve and persistence.

About that time it was thought the Crown Reserve Company, which held on option on the Walsh property on the west side of Miller lake, would be added to the list of shippers. The terms were onerous, the parties to the agreement did not see eye-to-eye, and Mr. Burrows in his review of the situation thereabouts says: "A shaft was sunk to the 200-ft. level with drifts on veins on the 100 and 200-ft. levels. Some small lenses of silver ore were encountered on the 100 feet level." Ordinarily common sense might have dictated an amicable arrangement by which the Walsh could have been developed beyond the fault encountered by the Crown Reserve management. A purchase price of $100,000 and 30 per cent. of the gross production, or something like that, left no alternative to those who where spending their money to ascertain the merits and dimensions of the section. Without the high grade for which Cobalt was noted in its palmy days, this Walsh agreement would have been too one-sided. Even with high grade the terms could not be entertained—for which there is the experience to go by of those companies at Cobalt which were subjected to Temiskaming & Northern Ontario Railway and Provincial royalties — royalties which had to be abandoned before the companies could operate at a profit that would satisfy the working capital. That the Walsh is largely in Miller lake is all the more reason why its development cannot be undertaken by other than those well-prepared for a continuous performance until as much has been accomplished as was necessary at the Miller-Lake-O'Brien and the Castle.

North of Miller lake and around Leroy lake is deserving of more attention than it is receiving. On the west side of Leroy lake the so-called Collins property is being slowly developed by a shaft that is reaching toward the lower contact. Some native silver has been noted. Near the northern outlet of Leroy lake the Dodds property has been taken over by the Silver Bullion company which located an encouraging ore body under contact conditions. A shaft started on an island cut this vein and as it carries native silver, the local faulting makes it all the more interesting. Recent opinions by competent engineers have been favorable to the Dodds as an attractive prospect and one of the things which may do better when depth is attained and the contact rocks are exploited. At any rate such properties as the Dodds, Collins, Chapelle and Symmes-Young are on the roster of the eligibles—but it is obvious they cannot become mines, if the ore is there, without aggressive development and more advantageous operating conditions.

Of the Gowganda lake area on the western end of the diabase sill and the Wigwam-Lost-Calcite lake area on the eastern or footwall end of the sill, there is

little to be written. Geologists insist the sill or sills as presented might be made the object of a series of "Great Adventures," as the erudite Rickard will have it. Local sentiment is averse to the idea of "straight diabase" being at all felicitous. Geologists and engineers accustomed to work out contact situations — uninfluenced by the absence of Kerr Lake and King Edward high grade at out-crop maintain that a diabase sill anywhere is a legitimate speculation — for those who can afford the risk.

Unfortunately the operations of several companies have not been reassuring, Bishop, Calcite, lake and Kell, have not been reassuring, however, inconclusive. A rich shoot was found at shallow depth at the Kell. The Bishop workings have high grade in places, and its vein system extends into the Sanderson areas. At the Powerful, merry-go-round tunnels, winzes, etc., have not been productive of glowing reports. The Calcite lake, or Caleta plant is in an advanced stage of decadence.

Sill, sills, or the silliest cannot alter the fact that there has been no "recurrence of the Cobalt boom of 1906"; that the Gowganda area may have more than is revealed and that if owners revised their standards of value they might not continue to "chew the end of sweet and bitter discontent."

Withal, and if these are to be more mines, the other half of the wagon road to Gowganda should be completed within the next thirteen years.

Northern Ontario Letter

THE SILVER MINES.

The Cobalt Field.

At the end of the third week of August, the quotations for commercial bar-silver had reached 62 cents per ounce. Allowing for premium on United States funds, the producers were marketing the metal for the equivalent of a little over 68 cents per ounce in Canadian currency.

Prior to closing down, the cost of producing silver at the McKinley-Darragh mine had reached a little over 80 cents per ounce. At that time, the efficiency of the worker was at its lowest ebb and the cost was at the peak. It is now a matter of record that efficiency has increased a great deal at the mines which continue to operate, the cost of material has declined very materially and lower wages are being paid. These facts lead to the belief that the cost of producing the metal at the McKinley-Darragh would be sufficiently low at the present time to allow the Company to make moderate profits. At the same time, however, it is believed the management intends to play safe, and await some further adjustment before resuming general operations. This holds true of the Temiskaming and the Beaver Consolidated, where the question of starting up is believed now to be only a matter of time, depending upon the opinion of the directors.

By treating an average of upwards of 600 tons daily, and on account of lower costs of material and lower wages, the Coniagas has succeeded in reducing the per-ounce cost of producing its silver. The full details of the operation are not available, but it is learned that production from the Coniages for the fiscal year to end Oct. 31st, will be the highest for any one year since the twelve-month period ended Oct. 31st, 1916.

The Daily Nugget, which has been printed in Cobalt since 1909, is to be removed from Cobalt to North Bay and will be printed as a morning paper after September 17th. The name of the paper will not be changed.

The municipality of the town of Cobalt is addressing an appeal to the Ontario Government for the purpose of deriving more of the revenue which the Government collects from the mines in the form of taxes. The once very prosperous "silver city" is now burdened with a tax rate of 59 mills and is casting about for some means of deriving the revenue required to "carry on."

The shaft on the Haileybury Frontier property in South Lorrain is nearing the 300-ft. level at which point it is planned to carry on lateral operations for the purpose of locating the downward continuation of veins which carry encouraging silver values at surface.

Considerable interest has been aroused among the original shareholders of the Bailey Cobalt Mines with respect to the "winding-up" arrangement as officially stated in the "Journal." The allotment of stock in the newly incorporated Bailey Silver Mines will place the stockholders in a position to share in whatever net profits may result from the joint operation of the Bailey mine and the Bailey customs Mill, formerly known as the Northern Customs Concentrator.

Production from the Mining Corporation of Canada is coming largely from the Buffalo mine. The ore on this property occurs over considerable width and the mining costs are therefore reduced to a minimum. Advice from the west points out that the Mining Corporation has not yet taken any steps to operate the Flin-Flon mine, although the Corporation is stated to be endeavoring to enlist the support of additional British capital with which to develop and equip the Flin-Flon in a manner commensurate to its size.

Elk Lake and Gowganda.

The Elk Lake and the Gowganda districts stand at present in approximately the same condition as they did five years ago. Work is being carried on in a limited way at isolated points and encouraging results are reported. One promising feature is that the more normal conditions now setting in are serving to create encouragement for property owners to go ahead with more exploration and development work. Plans toward this end are under consideration in a number of instances and the indications are that the sleigh roads of the coming winter will be taken advantage of to get in supplies for the exploration of properties which have lain in idleness for a number of years.

Interesting developments in connection with the affairs of the Trethewey Cobalt Company are expected within the next few weeks. It is learned that the annual meeting of the Trethewey is to be held on the same date with the Temiskaming and the McIntyre-Porcupine. Officials of these two other companies have shown considerable interest in the Trethewey's venture on the Castle property in the Gowganda district, and the opinion is being expressed in mining circles that J. P. Bickell, president of the McIntyre as well as the Temiskaming has in mind a scheme to involve these two companies with the Trethewey in its Gowganda venture.

Mr. Bickell was among the original owners of the Castle property prior to its sale to the Trethewey. The treasury of the Trethewey has been running quite low while the opposite is true of the Temiskaming and the McIntyre.

Further discoveries of hematite iron are reported in the townships of Morel and Yarrow and added optimism has been created among interested in that area.

During the month of July, four Cobalt companies shipped ore over the T. & N. O. Railway, according to

Arthur A. Cole, mining engineer. The Coniagas was the heaviest shipper with 70.25 tons, while the La Rose Consolidated sent out 43 tons, the O'Brien 32 tons and the Kerr Lake 22.59 tons, making an aggregate of 167.84 tons. Of this total, only 54.59 tons went to smelters in Canada, the balance of 113.25 tons going to the United States.

The price of silver during the month reached a low of 58.500 cents per ounce on July 2nd, then touched the high point of 62.375 on July 28th, the average for the month being 60.260 cents an ounce.

During the week ended Aug. 19, the Coniagas was the only company to ship ore from Cobalt, this concern sending out one car containing approximately 86,973 pounds of ore.

During the corresponding period, the Nipissing was a heavy shipper of bullion, the total for the week from this mine being 83 bars containing 111,863 ounces of silver.

THE GOLD MINES.

The entire district of Temiskaming, at least at practically every point where gold finds have been made at one time or another during the past dozen years, the country is alive with activity. This situation is in sharp contrast to the conditions of only a year or so ago.

Instead of the central part of the Porcupine and the Kirkland Lake fields having a monopoly on all the activity in the gold mining districts, these two fields have now so broadened out as to make it difficult to define their limits while in the newer areas there is a steady increase in the amount of interest and each week finds new exploration work being commenced.

Whether at Porcupine, Kirkland Lake, Fort Matachewan, West Shining Tree, Lightning River, Larder Lake, Boston Creek, Skead Township, Bourke's Siding, Matheson or Munro the trend of attention is all the same—that of the exploration for or the development of gold-bearing veins.

Even in the Night Hawk Lake region where the discovery of gold a decade and a half ago led to attention being first turned to the Porcupine district, exploration work has been re-commenced and the use of the modern drill is being taken advantage of. This lies nearly a score of miles east from the producing part of the Porcupine district. Then, turning to the west, at a distance of about 25 miles from the producing part of the Porcupine district a considerable amount of work is being done, one company known as the Union Mining Corporation havig already carried operations to a depth of 260 feet and even now considering preliminary plans in connection with erecting a mill.

In the township of Deloro which comprises a portion of the southern part of the Porcupine field and where some of the earliest Porcupine discoveries were made, the stress of adverse economic conditions caused practically every proterty to close down before their value could be determined. Trails were allowed to grow up with underbush, and the property owners were obliged to simply bide their time. The turn having now arrived, this section of the Porcupine field is again becoming active.

As a result of the farflung gold-mining effort now being put forward, added thousands of men will gradually find employment, added capital will be encouraged to enter into the business of gold mining and added millions of gold will be produced. Prospectors, workers, capitalists, stockholders and the country alike will share in the prizes that lie in store.

A most remarkable feature is the absence of excitement. Individuals and companies are right down to earnest prospecting and exploration and there is less of the careless claim-staking than for many years. Capitalists are getting a genuine run for their money, the prospectors are basing their hopes on merit of their property rather than upon waves of excitement and in every respect the gold mining industry as found in Temiskaming has taken on all the aspects of permanency.

The Porcupine Field.

During the month of July the Hollinger Consolidated treated an average of approximately 3,200 tons of ore daily. Working forces have now reached a total of not far under 1,700 men and total income exceeding $900,000 monthly. Income from Jan. 1st to July 31st having amounted to $5,126,050. it is obvious that the total for the full year may exceed $9,000,000. This achievement is all the more remarkable for the reason that during the winter months the mill was operated at only about half capacity due to a shortage of hydro-electric power.

Progress in connection with the proposed consolidation of the Dome Lake with the West Dome is comparatively slow. There are certain terms upon which an agreement has not been reached, but it is intimated that the prospects are favorable for mutually satisfactory arrangements being made. In the meantime, the deal is holding fire. It is stated in well-informed circles that should the consolidation go through as planned, no difficulty is anticipated in being able to raise from $150,000 to $200,000 with which to place the properties on a reducing basis.

Favorable reports are current with regard to underground developments on the Porcupine-Keora, but no official confirmation has been secured. It is known that a wide mineralized body has been opened up, but the question of whether the gold content is sufficiently high as to make it of commercial grade, or not is still uncertain.

Tunnelling operations are proceeding on the Big Dyke property in Deloro township, and the vein will be reached within the next few days.

Cross-cutting is proceeding at the 150-ft. as well as the 300-ft. level of the Beaumont property, formerly known as the North Davidson. These cross-cuts are being driven for the purpose of locating ore bodies which were previously indicated by diamond drilling.

The officials of the Northern Canada Power Company have reiterated their statements to the "Journal" that they anticipate no diffienlty this year in connection with being able to supply ample hydro-electric energy to operate all the mines of the Porcupine field at full capacity.

Taking into account all conditions, it seems probable that it will only be a matter of a short time, probably not later than the coming spring at worst, when all the mines of the Porcupine district will be in operation. At present, the Hollinger, Dome and McIntyre are producing an aggregate of well over $1,200,000 monthly and by next summer will produce an aggregate of about $1,500,000 monthly, taking into account the big increase being made to the McIntyre plant as well as additions to the Hollinger. Added to these three may be the mills of the Porcupine V.N.T., the Schumacher, Northerown and the merged properties of the Dome Lake and West Dome.

Among the properties in the development stage which will be among the active operations are the Allied Porcupine, Porcupine-Keora, Gold Reef, Beaumont, Goldale, Big Dyke, Clifton-Porcupine, March Gold, Triplex, Union Mining Corporation, Gold Island, and Hayden-Porcupine as well as others.

Arrangements are being made by officials and interested parties in the Lightning River Gold Mines to make a trip to the company's properties during the current week. The trip has been encouraged by reason of the promising gold discovery recently made on the company's claims in the Lightning River district.

The work of de watering the underground workings of the Hattie Gold Mines in the Matheson district is under way. The recently purchased second-hand plant is to be installed and an aggressive campaign of exploration and development work has been mapped out.

At Boston Creek, the Miller Independence mine is being explored by using a diamond drilling machine at the 500-ft. level. The drill core is revealing an interesting geological condition. An intrusion of porpryry formation has been encountered and officials of the company are of the opinion that this may bear some relation to the mineral deposition. The drilling is being done for the purpose of locating the downward continuation of the rich ore-body which was opened up near surface in an inclined shaft.

Kirkland Lake Field.

Higher mill heads at the property of the Kirkland Lake Mining Co. have made it possible to establish a very satisfactory rate of net profits. The more favorable labor supply, coupled with a steady increase in efficiency is placing the mine in condition to assure milling operations at full capacity of an average of 150 tons of ore daily.

Enlargements to the mill on the Teck-Hughes are reported to enable the company to produce upwards of $1,500 daily. The physical condition of the mine is strong, the ore already developed above the 600-ft level being sufficient to keep the plant running for a number of years, and with probabilities of these bodies extending to much greater depth.

The Lake Shore mine continues to treat high grade ore, the average recently having been around $27 per ton. It is believed that the question of further milling additions has been deferred until next Spring at least. The Company's decision to disburse two dividends of 2 per cent each during the last half of the current year has given rise to the belief that no further construction is anticipated for the present. The physical condition of the Lake Shore is said to be the strongest in its history.

In Lebel township, work is going ahead on a number of promising prospects, and the results obtaining are such as to encourage the belief that this part of the Kirkland Lake field will contribute additional producing mines to this area.

At the Argonaut Gold, twelve miles east from Kirkland Lake, work is being centered at the 350-ft. level. The manager John W. Morison, declares that the amount of commercial ore in sight is being steadily increased and that in addition to developing the present known bodies, a plan is being arranged to extend lateral work so as to open up ore bodies which were indicated by former diamond drilling

TORONTO MINING QUOTATIONS.

TORONTO COAL PRICES.

Toronto, 24th August.—There has been quite an increase in the demand for lump coal during the past few days, which may be the beginning of better things. Slack is still at its former price of from $1.75 to $2.15 a ton, while the price of lump remains unaltered at from $2.50 to $2.85 a ton. The demand for anthracite which has been noted as showing an increase in the last two or three weeks, still keeps up, but it is not yet of the dimensions which one would normally expect at this season of the year.

PERSONALS.

Mr. Oliver Bowles, of the staff of the U. S. Bureau of Mines, has been assigned to study means of stimulating production of slate. Mr. Bowles is a graduate of the University of Toronto. Before joining the technical staff of the U. S. Bureau of mines he was instructor at the University of Minnesota and at the University of Michigan. His work has been chiefly in connection with non-metallic minerals.

Mr. Walderman Lindgren has returned to New York from Bolivia. Mr. Lindgren is well known in Canada as well as in the United States as a leading authority on gold deposits.

B. G. Dann, who for the past four years has been connected with the Engineering Department of the Truscon Steel Company in Youngstown, Ohio and New York City, has resigned to accept a position as Manager of the New York Office, 30 Church St., of the Hendrick Mfg. Company, makers of perforated metals, etc. Mr. Dann is a graduate of the engineering department of Lafayette College.

Mr. A. H. Low is at Fort Norman surveying the property of Mackenzie River Oil Fields Ltd. and selecting drilling sites.

Mr. T. A. Link is in charge of the field work of the Imperial Oil Co. at Fort Norman. He went in by aeroplane.

Mr. W. S. Dyer of the staff of the University of Toronto has returned from Fort Norman. Accompanied by Mr. Henderson and Mr. Wm. Ogilvie he made the trip to the oil fields in a small motor-driven boat. This party was one of the first to reach the field this Summer.

Mr. Allan Crawford of Toronto, a third year student in the department of chemistry and mineralogy at the University of Toronto will leave Seattle on August 20 for Norse, Alaska. From there his party will proceed to one of the islands in the Canadian Arctic and undertake scientific and exploring work for the Stefansson Arctic Exploration and Development Co. In July 1922 Mr. Stefansson is expected to arrive there with a large exploration party. Part of Mr. Crawford's duties will be the laying in of supplies for the main expedition.

NEW CRAWLING TRACTOR CRANE.

Industrial Works, of Bay City, Michigan, announce that they have augmented the crane family for which they are noted by the addition of the Type BC crawling tractor crane. They have developed this crane to meet the need for a full-revolving tractor crane which can be developed independently of rails.

The crane is built in two types—the type BC with a capacity of 2,000 lbs. at 12 ft. radius equipped with continuous crawling tractor belts—the Type BT with a capacity of 18,000 lbs. at 10 ft. radius equipped with four broad gauge tractor wheels.

Enlarging Kenora Mining Division.

The Kenora Mining Division has been enlarged to take in that part of the district of Patricia west of the extension of the Thunder Bay boundary line. Beginning August 6, the recording of claims in western Patricia was transferred from Toronto to Kenora. This will be more convenient for the prospectors in the area north of the English river where gold discoveries have recently been made.

EDITORIAL

EDITORIAL CHANGE.

With this issue the direction of the *Canadian Mining Journal* will change, and the retiring Editor asks for his successor a continuation of the assistance of readers and contributors that has been so generously extended to him during the past two years.

The successful publication of a periodical such as the "Journal" is essentially a problem of obtaining first-hand descriptions of technical processes and mining news from those who are numbered among the mining men of Canada, and the duty of an editor has been well defined as consisting in getting others to write, and not in writing himself.

It is perhaps not realised how small a field the mining industry of Canada really is. The typical Englishman who asks a friend going to Halifax, Nova Scotia, to call upon his other friend in Winnipeg is after all not so far wrong in his ideas of community interest, although he may be the holder of curious notions on transportation. There is far more likelihood that a mining man in Halifax will know his *confrère* in Winnipeg than that the English miner at Redruth will know his fellow in Leeds. The mining men of Canada, of all sorts and conditions, probably do not exceed 70,000 in number, and the proportion of those who read technical periodicals will represent a much smaller number. The membership of the Canadian Institute of Mining and Metallurgy, which now stands at its highest recorded number, does not probably exceed 1,700 persons, not all of whom are resident in Canada, but among this number there exists an intimacy and a freemasonry that is probably unexcelled. It is therefore evident that the number of available contributors to a technical periodical of limited national scope is not large, particularly when the reluctance of many technical men to write is admitted. Under these circumstances, we desire to thank those who have assisted in giving a national complexion to this journal by their contributions and personal advice, and would ask to be permitted to point out that a national mining journal in Canada is only possible through the assistance of the mining men of Canada.

The technical journals of the United States are excellent publications, backed by wealthy publishers, and, in recent years, actuated by the consciousness of increasing importance in the world relations of the United States, the leading technical papers of that country have shown wide catholicity in their choice of matter, and have indeed taken the world for their parish. It is natural that Canadian publicists should avail themselves of the prestige and wide circulation of these papers, which are a necessary part of the magazine library of the man of affairs, but we would ask consideration of the national technical publications of Canada from Canadian writers, and, in doing this, desire again to express appreciation of those of our contributors who have supported this periodical. The field which is open to the mining publications of the United States in comparison to those of Canada is sufficiently indicated by a mineral production of 63_4 billions of dollars against one of 200 millions of dollars, and those who, possibly without analysing the conditions, compare the technical excellence and range of contents of the trade papers of the United States with those published in Canada to the detriment of the domestic publication, may be asked to consider that the excellence of Canadian journals is directly dependent upon the goodwill and aid of the Canadian reading public.

The various government bureaus of the United States, we desire to say, show impartiality in their distribution of public documents, not distinguishing between the periodicals published at home and abroad, and a brief editorial experience has served to increase admiration for the U. S. Geological Survey and the Bureau of Mines, and the willingness of these bodies to serve the technical men of North America with fine impartiality and courtesy.

We desire that no criticism of United States trade

periodicals should appear to be intended by these remarks. They are welcome additions to Canadian sources of information, and the true technician will gather his facts irrespective of their origin, and concerned only as to their accuracy. But journalism, and particularly trade journalism, is as proper and necessary a sphere of Canadian endeavour as the trades the journalist seeks to represent, and it is desired to point out, without any inviduous intent, that technical publications in Canada will be successful and will call attention to their merit and individuality in other countries, to the extent, and only to the extent, that they receive the support of Canadian technicians.

To turn to another aspect of this matter, we have in Canada some excellences that arise out of our limitations, not the least of which is the intimate personal friendship of those who comprise the mining fraternity, which is still small enough to remember earlier and less opulent days, and not rich enough to be "stuck-up" and to manifest unpleasant plutocratic tendencies.

Another thing that adds distinction to Canadian mining literature is that we possess a large country, chiefly unprospected in any intensive manner, which can always yield the elements of novelty and surprise, and which even today almost as was the case a century ago, calls for life in the open and pioneering in untrodden wildernesses. Nothing in modern mining has been quite so much after the manner of Kipling as the airplane journeys to Fort Norman, and the Canadian prospector, hard-bitten as he may occasionally be found, is an incurable romancist, and he is not always quite sure whether his lure is gold or "the wind upon the heath."

The writer fully appreciates the privilege of having directed the *"Canadian Mining Journal"* during a period of mining development as remarkable for its new discoveries as any in Canadian history, and also the many kindnesses he has received from the friends of the paper.

THE NICKEL-COPPER INDUSTRY.

The announcement that production of nickel at Sudbury will be temporarily discontinued, while not coming as a surprise, will be the cause of much concern to a large number of people interested in the nickel industry. The operations of the International Nickel Co. are of great importance to the people of the Sudbury district and to the Province. The Creighton mine is the world's greatest nickel mine and is one of the best mines of any kind in Canada. The smelting plant at Copper Cliff and the refinery at Port Colborne are of great industrial importance. That these works must now all stand idle for some time is very unfortunate, particularly for the employees and those in business which depends on activity in the mines and metallurgical works.

It has been well known for several months that the marketing of nickel and copper has been so difficult that operations could not long continue at even half the rate of the past few years. From time to time the working forces have been cut. Some months ago the British America Nickel Corporation discontinued operations, but the older companies being in much better financial circumstance have managed to continue production on a much reduced scale. Now the biggest company has shut down and only the Mond is operating, at far below capacity.

Under any ordinary conditions the International Nickel Co. had little to fear from competitors. The present situation arises from the continued depression in industry. Large quantities of nickel and copper are waiting for a market and it very uncertain how long the producer must wait before conditions will warrant resumption of operations.

It is difficult to get any clue as to how long the steel industry will remain dull. It is worth noting however that such an authority as Judge Gary states that the outlook is not discouraging or doubtful. He says that sentiment is growing better and that there are many good reasons for believing conditions are improving. As most of our nickel goes into use in the form of nickel-steel it is possible that the closing of the mines for a few months will result in material reduction of the quantity of unsold nickel on hand. At present the output is evidently too much for the market, in spite of the fact that it is far below normal.—R. E. H.

RENEWED INTEREST OF BRITISH CAPITAL IN CANADIAN MINES.

The visit of Sir Archibald Mitchelson and his party to Northern Ontario mines is of some significance, if it means that English capitalists are becoming interested in a country where a few remarkable mining successes occurring in a vast territory of monotonously similar geological characteristics suggest that there may be still other and later additions to the goodly company when the north country of Quebec, Ontario and Manitoba has really been intensively prospected.

So far, English investment in the mining districts of the central Canadian north has not been large, in comparison with British Columbia for example; and a reference to London standard mining manuals will reveal the surprising omission of mention of many of our most substantial mining companies. This omission is traceable to the location of the head offices of so many of the asbestos, nickel and precious-metal mines of Canada in New York. Because of the close proximity of the northern mining belt to the United States, and the remarkably fine railway service that gives access to much of the developed part, it is naturdal that American capital should be interested in its development, but it should not be forgotten that British capitalists have never been deterred from investment or investigation by considerations of distance or accessibility, and one is tempted to ask why in the past, Ontario has been so conspicuously overlooked in favour of much remoter parts of Canada. We sincerely hope that the investment which it is stated the visiting Englishmen contemplate making in Northern Ontario will be wisely chosen

and one that will prove profitable, as the moment is in many respects decisive as to the interest British capitalists will manifest in Northern Ontario in the future. The great stretch of country between the Mattagami and the Nelson contains here and there valuable minerals, some of which have been worked to great profit, and some of which have been merely indicated. If British capitalists can be persuaded to investigate this territory we believe that both they and the country will be mutually profited, but preliminary investigation should be of a very thorough nature.

GOLD MINING DIVIDENDS.

The suggestion is being freely made that as the Hollinger Mines are making good profits an increased distribution to the shareholders should be made, and a bonus, to be regarded as a return of capital, is spoken of.

It is suggested in another place that the Hollinger Mine is making fifty percent profit at current running rate.

We submit that the very vaguest ideas are abroad as to what really constitutes profit in a mining enterprise. The balance sheet of a mining company should show its real value, and if such a sheet were drawn up to cover the anticipated life of a mine, arranging for payment of all development out of revenue (and by development is meant every cent spent in developing a mine and sources of motive power) and for complete amortization of the invested capital by the expected date of exhaustion of the mine, plus reasonable allowance for contingencies and working capital, it would be found that few mines justify any such dissipation of their financial reserves as is indicated by "bonus" dividends, whether camouflaged as return of capital, or otherwise. We believe that so far the Hollinger directorate has sanely conserved its capital accumulation, and that it will probably continue to do so, knowing that there are many capital expenditures yet needed at Timmins, such as provision of hydro-electric power, miners' houses, underground equipment etc., that can usefully and profitably absorb any earnings over and above a reasonable common stock dividend. The value of the Hollinger Mine will be reflected in its shares, as the property develops more and more into a steady dividend payer. The ambition of the Hollinger directorate will be, if its past record is any criterion, rather to establish the market value of the shares and to ensure a long period of payment of dividends, than dissipation of funds that may some day be badly needed. A few years ago we witnessed the pyramiding of inventories, when companies such as Atlantic Gulf & West Indies and Central Leather were embarrassed by apparent millions in their treasuries. Today those millions are "all goned away mit der Evigkeit", and we now recognise that they were paper millions, the result of a good time for certain industries. The good time for gold mining is now here, and although its millions (except in regard to the exchange premium) are not of the paper variety, it should be remembered that in the early years of gold-mining there should be accumulated, the large financial reserves and the mine equipment that is necessary to carry on through the lean times that always follow good times, and also to preserve the dividend-paying ability of a mine through the long period of declining activity that precedes final exhaustion.

The Ontario Mining Association could do no better service to its members than to standardize mine accounts with expert advice so that popular conceptions, and consequent administrative blunders and foolish taxes, could be rectified by actual knowledge of what constitutes profits in mining and what the market value of a developed and operating mine consists of. Not one mining man in a thousand but holds erroneous notions on these two points.

MINING COMPANY REPORTS.

From time to time complaints are made by shareholders in Canadian mining companies that they are not sufficiently informed of the results obtained from month to month in the operation of the mines. Recently there have been more than the usual number of such complaints and it is possible that the result may be the issue of a larger number of reports by some companies that in the past. Some of the recent annual reports have also aroused criticism because they fail to give some of the information which the shareholders expected to find in them. More interim reports and fuller information in annual reports is asked for by some of the shareholders.

The criticisms merit consideration. Many mining companies issue no interim reports and give very little information in their annual reports beyond a summary of production, sales and profits or losses. Some such companies, however, when requested for it, give out information freely to shareholders or to the press and are not so much subject to criticism by shareholders. Other companies give out so little information that the shareholder has real cause for complaints.

It must be admitted that the business of mining companies is better known to shareholders and to the general public than is that of most industrial concerns. Mining is rarely carried on in a secretive way. A shareholder who really tries to find out what his company is doing can as a rule obtain the desired information without much difficulty. Criticism cannot then be fairly directed against mining companies as a class. The few cases where the shareholder has reason to be dissatisfied should not be allowed to appear to be characteristic of mining companies. There is no market tendency towards secretiveness in mining and metallurgical operations and fairness to the companies demands recognition of the fact.

All that seems necessary to meet the situation is that the few companies which have not conformed to the usual practice should give out more information than they

have been doing recently. It may not be necessary for the conduct of the business and may not appear to warrant any expense, and yet the course suggested may be desirable because some of the shareholders consider it valuable and the rest of the shareholders are not likely to grumble at the small cost of compilation and publication of brief summaries of the results of operations over short periods.—R. E. H.

THE buckling of the airship ZR-2 and the subsequent explosion of the hydrogen released from the torn envelope is a reminder of the practical nature of the experiments of Prof. J. C. McLennan of Toronto University for large-scale extraction of helium from natural gas emitted by Canadian wells. While no official statement has been made as to the proximate cause of the regrettable disaster it would appear to have been caused by failure of the aluminium-alloy main girder, but the loss of life was certainly caused by the explosion of the enormous quantity of hydrogen released. If lighter-than-air dirigibles of the size of the ZR-2 are to be built for such ambitions work as crossing the Atlantic it would appear necessary to perfect the manufacture of helium as a lifting medium, for the Hull disaster has proved—at a fearfully high cost—that a hydrogen-filled airship is just as dangerous in peace-time operation as when exposed to the incendiary bullets which first caused serious investigation into the possibility of finding a suitable gas with non-inflammable characteristics for combatant airships. As Canadian natural gas was found to have the largest helium content of any of the natural gases analysed, the matter is one of much interest to this country, for it is not to be expected that the Hull disaster will deter further experiments in the building of large airships, or the eventual coming of the airship of commerce and passenger transportation.

RECENT GEOLOGICAL SURVEY REPORTS ON BRITISH COLUMBIA.

Part "A" of the Summary Report of the C. G. S. for 1920 consists of eight interesting reports on British Columbia districts, the most important of which from a current economic view point is W. E. Cockfield's note on the silver-lead deposits of the Keno Hill area, near Mayo, in the Yukon Territory. Much activity has been displayed in this area, and from time to time reports of development have appeared in this journal. Some 600 claims have been staked on Keno Hill, but serious development work has only been done on two or three groups. The most active company is the Yukon Gold Company, and other active operators include Messrs. McKay and Erickson and the Rasmussen interest. The ores at superficial depths are high-grade, most of them rich enough to pay for mining by hand and to stand shipping without concentration. The transverse fissures, in which most of the ore so far mined has been found are short and unlikely to continue to great depths, but the longitudinal veins are more likely to prove continuous with depth. The area has not been prospected to sufficient depth to determine the extent and persistence of the ore. An elaborately contoured map of Keno Hill, with an ideal cross-section accompany the report.

S. J. Schofield and George Hanson report on a continuation of study of the geology of the Salmon River district commenced by J. J. O'Neil in 1919. The conclusions and summary are as follows:

The ore deposits fall into three main groups:

(a) a low-grade, complex type, with values in the base metals, copper, lead, and zinc. (Big Missouri, Hercules, Forty-nine, etc)

(b) a type rich in silver minerals, including tetrahedrite, freibergite, pyrargyrite, argentite, and in some cases native silver. (Premier, Silver Tip, certain ore-bodies in Forty-nine, Big Missouri, and Mineral Hill.)

(c) a pyritic siliceous type, with high gold values. (An ore-body in Premier mine).

The most favourable associations for the occurrence of ore are as follows:

(a) in the quartz porphyry.

(b) at the contact of the quartz porphyry with the tuffs.

(c) in certain beds of the tuffaceous conglomerate.

The slates in general do not appear favorable for the deposition of ore.

The sulphides rich in silver, such as tetrahedrite, freibergite, argentite, and some of the pyrargyrite are considered to be of primary origin and will continue in depth.

The native silver is considered to be of secondary origin.

V. Dolmage reports on the West Coast of Vancouver Island between Barkley and Quatsino Sounds. Although there has been no mineral production from this region in recent years, gold, copper, iron, marble and manganese occur. Shipments of copper are expected from the Tidewater Copper Company's mine at Sidney Inlet.

The Coquihalla area is reported on very fully, about twenty pages being devoted to C. E. Cairnes's report. Gold is the chief ore mineral of economic importance in this area, the Emancipation Mine being best known, and situated about 1,100 ft. above the Kettle Valley Railway in typically rough country. The greater part of the area is devoid of trails, and this fact, combined with dense vegetation, a high timber-line and mountainous characteristics, explains the backward development of the mineral areas. In addition to gold, silver, silver-lead, copper, molybdenum and manganese are noted as occurring.

Of much economic bearing is J. D. MacKenzie's report on the limonite deposits of the Taseko Valley, of which it is hoped to give more detailed particulars, with some photographs in a later issue of the "Journal". The report is extremely full and illustrated with a wealth of maps and sections. The limonite occurs however in an area remote from transportation, and in quantities that are not considerable as iron-ore deposits are today regarded, so that its economic importance is not of much importance as had been hoped from earlier and less exact reprts.

Other reports include a reconnaissance between Taseko Lake and the Fraser River by J. D. MacKenzie, on the Entsuk Lake District, by R. W. Brock, and on the Lardeau Map area by M. F. Bancroft.

The Standardization of Breathing-Apparatus Practice

An Address By The British Columbia Minister Of Mines Prepared For An International Conference at St. Louis, Mo., 1st September, 1921, On Mine Rescue Work.

Hon. Wm. Sloan, Minister of Mines for British Columbia, is a minister that has always taken his duties seriously, realising that he was in charge of that department of British Columbia's industrial activities which is of the greatest importance, whether considered historically or in the light of the future. Mr. Sloan has particularly given his official aid to all matters pertaining to the accomplishment of such comparative safety as mining operations will permit, and he has for some time urged standardization of mine-rescue work and types of oxygen breathing-apparatus.

The following remarks have been prepared by Mr. Sloan for delivery at an international conference at St. Louis, Mo., at which, under the guidance of the United States Bureau of Mines, the various questions of training methods and standardization of types of apparatus and the practice of mine-rescue work are to be considered. It is understood that the calling of this conference was first suggested by Mr. Sloan, and the incident is one of many that have taken place that indicate a commendable community of effort and interest among the mining men of the western States, and of British Columbia and Alberta.

Mr. Sloan's address, delivered in his unavoidable absence from the proceedings of the Conference, stated in part:—

In the calling of this Conference the United States Bureau of Mines has added to its already splendid reputation as an organization keeping in close touch with the world's development of the mining industry and especially with that phase having to do with the betterment of working conditions and with the safeguarding of the lives of those engaged in the particularly hazardous occupation of the underground worker.

I am interested in the work for which you are gathered, not only as the Minister of Mines for the Province of British Columbia, but as one whose long residence in one of the chief coal-mining centres of the Province has brought forcibly home the need of the miner, and of the miner's dependents, of every protection that science can afford. It seems clear to me that, while the Bureau of Mines has done much, there still is room for improvement and advancement by an international exchange of ideas among those technically informed and by an international understanding to take the fullest advantage of the product of the world's brightest scientific minds in respect of apparatus and to apply, by common methods, training systems adjudged the best among the miners and other underground workers.

"The Need for Standardization in Mine-Rescue Work" is the subject upon which I have been asked to address you.

After detailing the extent of the cost deposits of British Columbia and their present development, Mr. Sloan stated it was a matter of first importance that the mining industry, of which the matter of coal production is only a part, should be based in point of the development on right principles, not only in respect of practical encouragement and of administration, but as well in respect of the enactment of enlightened policies, first, for the prevention of accident and next for the rescue of those who may be unfortunate enough to be involved despite measures adopted in their interests. As long as there is a mining industry and as long as there is industry of any form, there will be accidents. All we can do is to see that safeguards are kept well ahead, if possible, of our other industrial advances.

Having been in the business for over half a century it follows that we are not unconversant with its problems and our administrative work of recent years indicates I think, that we are appreciative of the value, in this connection, of applying with unflagging perseverance the principles of "Safety First" and of providing the most thorough educational and mechanical facilities in First Aid and Mine Rescue Work.

British Columbia is an epitome of other mining countries. Our problems are the problems found elsewhere where the industry flourishes. We do not claim to be forging ahead while others lag behind. We do not assert that our desire for advance in protective measures is a singular one. It is not contended for one moment that any one mining district has a monopoly of benevolent humanitarian legislation. For our part the fact that this Conference has been called is significant of the unanimity of the wish to get forward to the limit of present mechanical and mental possibilities in the matter of the protection of the lives of miners.

We have had our serious coal-mining accidents. But in this British Columbia is by no means alone. Wherever there is a considerable coal-mining industry there have been similar experiences. The recollection is sufficient to lend force and point to the objects of this gathering and to induce delegates to bend their energies to the task of finding means of working in unison towards the common goal.

I am happy to be able to say that in our Province in 1919 and 1920 we have achieved record low marks in the matter of coal mine fatalities. The ratio per thousand persons in 1919 was 2.013. In 1920, it was 2.67, in the past ten years it has been 4.053. The year 1919 saw the loss of twelve lives in the industry and last year witnessed the deaths of seventeen in the performance of their duties. Creditable as are these statistics in a comparative sense we are striving and are here to solicit advice and co-operation to achieve a clean sheet.

Mr. George S. Rice, of the United States Bureau of Mines, made an examination of the Crow's Nest Pass Coal Field at the request of the B. C. Government. He, therefore, is familiar with one of the most important of the coal fields of the Province.

In addition to many other preventative measures subsequently taken an order was made requiring withdrawal of men from any working place showing a percentage of 2.5 methane or greater. Later it was established that a 5-16 inch gas cap on the Wolf Safety lamp in a Coal Creek Mine equals 2.5 per cent methane, or the percentage necessitating withdrawal and that a ½ inch cap in the Vancouver Island and Nicola-Princeton Districts equals 2.53 per cent of methane. There also was the recent noteworthy legislation the effect of which

will be to introduce into all coal mines of the Province the electric safety-lamp and to eliminate entirely the open lamp in coal mining in British Columbia.

Now to turn to mine-rescue and first-aid work. Although concentrating seriously on the preventative side of our problem, the other branch, that of the salvage of human life, has been receiving every possible attention. The first self-contained breathing apparatus were introduced into British Columbia in 1919, the machines being of the negative-pressure type and manufactured by the Draeger Company. Government stations then were equipped with these machines. In the past four years, however, there has been a marked advance. It was in the latter part of 1917 that the Gibbs apparatus was perfected and tentatively approved by the United States Bureau of Mines. The advantages of an instrument of a positive-pressure type, with an automatic-breathing arrangement, was readily recognised. There also came the Paul and the later types of the well-known English model the "Proto".

At each of the Provincial Government Stations there are competent men employed for instruction in mine-rescue work and in first-aid. They have all the facilities needed to make their work effective. There are installed at the coal and metalliferous mines and government stations in the province 136 sets of mine-rescue Apparatus and 45 resuscitating devices—one mine-rescue instrument for every 40 persons employed underground and one resuscitating device for about every 175 men employed underground at coal mines. There are today in the province over 500 holders of mine-rescue certificates granted by the Department to those who have taken a course of training in this work. Over ten per cent of the underground employees in coal mines in the province hold mine-rescue certificates and nearly fifteen per cent of the total employees have passed examinations in first-aid work.

Until a few years ago comparatively little interest was taken in first-aid work in British Columbia. Proper encouragement, however, gave it the needed fillip. The appointment of an instructor to be at the disposal of those interested and the granting of financial aid were chiefly responsible. Now over 1,200 of the mine employees have passed examinations in this work. The organization of the miners interested into what are termed the Vancouver Island and the East Kootenay Mine-Safety Associations and the recognition of the value of their educational work both by the Government and the operating companies, have been largely responsible for the noteworthy success of this form of constructive and advanced endeavor. Competitions have been held annually under the auspices of these organizations in mine-rescue and first-aid work and the Government has made it a point to grant all financial assistance possible.

Thomas R. Jackson, one of our Inspectors of Mines, in his 1920 report, says:

"I have much pleasure in being able to report good progress in both first aid and mine rescue work. The Nanaimo Western Fuel Company's "Miners' First-aid Team" (Captain Barton) won the Coderre Cup, which can only be competed for by the miners. In winning this trophy and because thy had obtained the highest number of marks for their work, they also scored a higher achievement in the realm of first-aid by winning the Montizambert Cup, representing the championship of Canada, which is open for competition to all classes of labour, under the auspices of the St. John Ambulance Association," .

It is interresting to note that Captain Barton's team, of Nanaimo, B. C., have taken part in the international competitions held at St. Louis, Missouri. In view of their success in Canada it was felt by the Government and the operating companies chiefly interested, who financed the trip, that their devotion to the work and their success in Canada should be rewarded by the opportunity of testing themselves in this broader international field.

The Desirability of International Co-operation.

As we moved from point to point in the fight against mine fatalities the conviction grew on me that it might be possible to formulate some fixed policy internationally, both in respect of mine rescue apparatus and of the current practices for the training of men in its use, that would bring higher efficiency and more certainty of attaining desired results in emergencies.

There was no clear well-defined plan for the reaching of the desired end. Rather it was a feeling that there should not be a multiplicity of types of apparatus. To choose in the equipping of a mine-rescue station was not easy. Tests were held. Reports by technically qualified men were asked for and received. The types bearing the stamps of approval of the U. S. Bureau of Mines were satisfactory but, to one wishing to select the best under all conditions there was presented a perplexing problem. The circumstances seemed to call for some form of standardization. The difficulty of achieving this in the instrument; viz. that any arbitrary fixing of a standard apparatus would tend to the discouragement of scientific initiative, was and is recognised. But it appeared possible, the adoption of an international policy, that there might be a solution of the problem, such a solution as would give to the world a breathing apparatus, reflecting the highest present-day achievement of our scientists and coincidentally encourage the scientist to further improvement. This is one of the important matters I would submit for the consideration of the Conference.

On July 10th, 1920, there was an accident in No. 2 Mine, Pacific Coast Coal Co., Washington State. Three men, each wearing Mine Rescue apparatus, were overcome and lost their lives. The details of this tragedy are not germane to the question at issue. Two points, however, struck me forcibly in reading the official report issued by the Washington State Safety Board. First, that several models were in use, some old and others new type, and, second, that there was lacking that thorough knowledge of the apparatus that might be expected to lead the wearer to instinctively do the right thing when the emergency arose.

The lessons the Washington Safety Board draws from the accident are significant. They are:

1. That no one using mine rescue apparatus should be allowed to make such a trip except in case of saving life and then only after proper preparation had been made for relief in case of accident to one of the team.
2. That when men are sent in to do rescue work, all men in the party should have the same type of apparatus, that is, one man should not have apparatus with a fixed feed while others have a type that would give them sufficient air to travel or work faster than others in the party.

This emphasizes the need of some action towards standardization. It leads to the opinion that a uniform method of training in the use of recognized and approved apparatus is required. The means of obtaining

this is one of the matters that should be seriously discussed. Certainly the time is ripe for the adoption of a campaign of publicity aimed to place the instruction, at all mining centres throughout the continent of America, on a common basis.

Attention in drawn, in the connection, to the report of a special committee appointed to investigate the advisability of employing a standard form of mine rescue apparatus throughout Canada, an excerpt from which follows:

"Standardization of mine rescue apparatus and the training in the use of the same would result in greater efficiency as well as in greater economy both in regard to apparatus and men.

"In the Dominion of Canada at the present time we have at least five different types of mine rescue apparatus, namely Draeger, positive-type, Draeger, negative-type, Fluess or Proto, Paul and Gibbs, all of which have different parts (necessitating the maintenance of large reserves of these), different methods of circulation in air sysems and requiring different tests as to proofs against leakages.

"This indicates that the methods of training are widely diversified and gives a faint idea of the confusion that is likely to arise should more than one type be brought together in the event of an accident requiring their use.

"The object of mine-rescue apparatus is to enable a person to travel, work or remain for a varying period in an atmosphere incapable of sustaining life, owing to an insufficient supply of oxygen, irrespirable gases, or finely divided solid matter. The apparatus must be air-tight, so that air from the outside atmosphere cannot penetrate to the inside circulation. A number of lives have been lost in using mine-reseue apparatus, especially with the types which have been longest in use, but it should be remembered that constant use is the chief factor in developing machinery; in the case of mine rescue apparatus very little opportunities are afforded for trying them. The result has frequently been that, at the decisive moment, the apparatus has failed to work or the men have lacked the skill to use them. In many collieries, apparatus, necessarily delicate to maintain, is not kept in that state of perfection required for results, and frequently, when the occasion arises for their use, prove to be more dangerous than useful.

"The risks attendant on the use of mine rescue apparatus can only be reduced to the minimum by a proper system of training. Under such conditions, the advantage of a standardized method of training, and especially with a standard mine rescue apparatus, can be readily appreciated. The workman who takes a course of training to qualify him to become a member of a mine rescue brigade shows a considerable amount of self sacrifice and patriotism, for in addition to his ordinary duties, he undertakes a great amount of work, which is by no means of a pleasant nature. Not only does it mean a sacrifice of his leisure time, in qualifying for this duty, but they know that whenever an accident occurs in which rescue work is required, they will be called upon to render assistance, even to the extent of endangering their lives. Not only in the mines where they are employed, will they be called upon to undertake these arduous and dangerous duties, but they may be called upon to do so in other collieries, where their lack of knowledge of the mine workings may add other dangers to the many already present.

"Under these conditions, we feel that standardization of mine rescue apparatus, and mine rescue training, will not only give good results, but will tend to eliminate confusion with its attendant dangers.

"Out of a dozen ways of doing a thing a certain way is the best; when things (let it be training in mine-rescue work, mine-rescue apparatus, or anything else) are not standardized, the result is confusion. The world is gradually awakening to the losses resulting from the employment of so many different working methods for accomplishing identical results.

"One efficient plan, universally followed, is always far superior to a multitude of practices to attain the same end, for in the latter case many of the methods used must necessarily foster waste.

"To attain this very desirable result we feel that it would be in the best interest if the Dominion Government would actively co-operate with the various provinces where coal mining is in operation leading towards an investigation of mine rescue apparatus and mine rescue training."

PORCUPINE-DAVIDSON GOLD MINE NEW FINANCING.

Toronto, Aug. 24. — Details of the arrangements made for financing Davidson Consolidated Gold Mines were made public today after they were ratified at a meeting of shareholders. A new company to be known as Porcupine-Davidson Gold Mines Ltd. will be capitalized at £1,000,000 sterling. The new stock which is paid with the addition of £50,000 cash to the old company is apportioned as follows: £375,000 preferred of which £175,000 is to be subscribed by the new company on completion of the purchase. Of the new common stock £450,000 is to be subscribed by the new company on the completion of purchase and £170,000 to be reserved in the treasury for future use if required. Preferred shareholders will receive two-thirds of the profits until the par value of their stock is paid and then 20 per cent of the profits non-cumulative interest.

The Davidson Consolidated Gold Mines Ltd. will now be a holding company, receiving in exchange for its property £50,000 in cash, £175,000 preferred and £450,000 common stock in Porcupine-Davidson Gold Mines Ltd. The new company will offer £200,000 to the public through Messrs. A. Mitchelson & Co., London at par. The remaining £175,000 common will be in the treasury. The par value of shares will be 5s.

It is stated that of the £200,000 to be provided for working capital £50,000 is already guaranteed and a further £100,000 underwritten and an initial payment of £20,000 has been made. It is announced that dewatering of the mine has already commenced preliminary to resumption of operations within a short time.

SALT WATER IN WINDY POINT WELL.

It is reported that salt water has been encountered in the well being drilled by the Imperial Oil Co. at Windy point on the north shore of Great Slave Lake, and as yet there are no indications of oil. The well is 1,200 ft. deep and it is doubtful whether further work will be done at this place.

PROSPECTORS BUSY IN SOUTH PORCUPINE.

It is reported from South Porcupine that the Mining Recorder there issued more licenses last week than during any previous week since the recording office was established at South Porcupine.

COAL-CLEANING.

("Times" Engineering Supplement.)

Two Recent Developments.

Attention was called by Mr. Robert Nelson at the Civil Engineers' Engineering Conference to the deterioration noticeable since the war in the coal supplied to consumers in respect of the amount of incombustibles contained in it, and he described two processes of recent development which he suggested would in proper combination offer an adequate solution of the problem of cleaning coal.

He stated that 40 separate records from works where a comparison of the ash in pre-war and post-war coal (purporting to be the same class of coal from the same sources) can be directly made indicate that the average increase in the quantity of ash is nearly 63 per cent.: that is, coal that formerly contained 8 per cent. of ash now contains on the average 13 per cent., and coal that formerly contained 12 or 13 now contains more than 20. It has been computed that about 35 million tons of uncleaned slack coal are transported annually in Great Britain, for an average distance of perhaps 50 miles, to be used for steam and manufacturing purposes; and it follows that at least 1¾ million tons of material which is worse than useless are annually transported up and down the country, absorbing labour to load it, to unload it, to fill it into furnaces and to take it out again as clinker. If the whole of this recently added 5 per cent. could be got rid of at the pit head, about 2,000 trucks and 40 locomotives, together with all the man-power released, would be permanently available for some useful purpose.

Froth Flotation.

The chief difficulty in washing coal by the older methods is to deal efficiently and effectively with fine coal. Hitherto, coal-washing has been effected by specific gravity between the coal and the dirt. If the dirt is of the same or nearly the same specific gravity as the coal, these methods fail when applied to material below a certain size. The new flotation process for washing fines coal is, however, independent of gravity. The coal to be treated, if not already fine enough, is crushed until the particles pass through a screen about one-tenth linear inch aperture. It is then mixed with three to four times its weight of water, together with a small quantity of reagent. The reagent may be an oil or coal-tar product, and 1 lb. is, generally speaking, required for each ton of coal treated. The mixture is agitated by a power-driven mechanical mixer, and a multitude of minute air-bubbles is produced. To these the coal particles attach themselves, and by them are floated to the surface of the water in the form of a thick coal laden froth. The coal in the froth is removed by a suitable scraper and dried for use, while the ash-forming dirt sinks to the bottom and is drawn off. Once the proper reagent has been found, the working of the process is simple, and given a steady flow of feed and a regular supply of reagent, a flotation machine, it is claimed, will produce clean coal on the one hand, and on the other a residue which is very nearly coal-free.

Apart from valves and piping and the mechanically-driven mixers and scrapers, the ordinary flotation machine is made entirely of wood. It consists usually of from five to ten "mixing" boxes, each with a froth box connected to it. The material under treatment passes from No. 1 mixing box via No. 1 froth box to No. 2 mixing box and so on through the plant, the final reject coming from the last froth box. A machine to deal with 1,000 tons of coal in a 24-hour day measures approximately 37 ft. by 15¾ ft. by 15½ ft.

Rheolaveur Process.

A process, called the Rheolaveur, for cleaning coal other than fines (from 2½ in. downwards) comes from Belgium. Its first requirement is a strong and steady flow of water. The water is turned into a trough into which the coal to be treated is also led. The flow of water carries the coal along with it, and the separation of coal and dirt is effected by stratification, the rate of the flow of water being so regulated, and the trough made of such a length, as to allow time for the coal and dirt to stratify. Arrangements are made at intervals to draw off the dirt from the bottom of the trough, and the coal is borne along until, at the end of the trough, there is no more dirt to be drawn off, and clean coal is delivered to the clean coal hoppers. at each drawing-off point a cast-iron box is inserted, from the bottom of which a current of water, controlled by a hand-valve, is made to flow upwards into the trough to prevent coal from being drawn off with the dirt, serving a similar purpose to the upward flow of water in the wash-box of the Draper washer. The water is stored in a tank fixed about 20 ft. above the trough and arranged to give a continuous steady flow.

In washing nuts the strength of the upward current in the first box is kept high so as to allow shale only to be drawn off. This shale forms the reject and at once finds its way to the shale dump. In the second box the strength of the upward current is rather less so as to allow the balance of the shale, and it may be a little coal, to pass through the box. This reject is not sent to the shale dump, but is returned by an elevator to the original trough to be rewashed. In washing nuts two boxes only are necessary, and the coal passing the second box, being dirt-free, is delivered via a moving drainage plate to the nut-coal bunker. In washing small coal four boxes and two lengths of trough, one above the other, are needed.

The advantages claimed for the process are low initial cost, low maintenance and running costs, easy control of working, absence of complicated mechanical parts, and economy of space.

STEAMING IN VERTICAL GAS-RETORTS.

A report just issued in London by the Fuel Research Board deals fully with experiments carried on, at H. M. Fuel Research Station at Greenwich, to determine the effect of steaming in vertical retorts. The installation was designed to supply accurate data from which the economic possibilities of steaming could be determined. Mr. George Beilly, Director of Fuel Research, in commenting on the results obtained states that we can now say with confidence that steaming gives not only gain in therms in the form of saleable gas but also in the yields of tar and ammonia. "Some sacrifice in the quantity, and, perhaps, the quality of the coke must be faced, but these disadvantages are more than compensated for by gains in the other products. By moderate steaming at moderate temperature the output in therms of gas is increased and the cost per therm is decreased.

The report gives a full account of the experiments and the results obtained. It is published by H. M. Stationery Office, London. The price is 1s. 6d.

CHARACTER AND EXTENT OF VIRGINIA ANTHRACITE.

The so-called anthracite of Virginia is not really anthracite but is a much softer coal according to the United States Geological Survey, Department of the Interior. The coal mined in some parts of this field compares favorably, except, that its ash content is greater, with the coal from the Pocahontas field, but that from other parts is harder, contains less volatile matter, and consequently approaches anthracite more nearly in general composition. This higher-rank coal, when properly prepared, makes an excellent domestic fuel and during the war found a ready market for this use.

The coal is of lower Carboniferous (Mississipian) age and is found at many places in the ridges of the Appalachian Valley from Potomac River nearly to the Tennessee line. It is best developed, however, in Montgomery, Pulaski, and Wythe counties. It occurs in what has been called the Price sandstone, which outcrops in a narrow belt, dipping south at angles ranging from 20 deg. to 30 deg., at the southern foot of Brush and Little Walker mountains, from a point 6 or 8 miles northeast of Blacksburg to a place almost due north of Pulaski. At that place the outcrop turns to the south, and it pursues a zigzag course around anticlinal and synclinal points to Pulaski, where it passes beneath and is concealed by the Shenandoah ("Valley") limestone. The coal also occurs in Price Mountain, southeast of Blacksburg, where it lies in an anticlinal fold and dips under the Shenandoah limestone in all directions. In Wythe County the coal and associated rocks form an overturned syncline just north of Max Meadows, but its outcrop is largely concealed by a tongue of the Shenandoah limestone that has been thrust over upon it. The coal also reappears at the foot of Little Walker Mountain, northwest of Wytheville, and extends westward nearly to Marion, in Smythe County.

Two beds of coal have been mined in this field, known as the Big or Merrimac bed and the Little or Langhorne bed. The Merrimac bed seems to be present throughout the part of the field mentioned above, with a thickness ranging from 5 to 11 feet, but in every mine the bed contains many shale partings that can be separated from the coal only with difficulty, and consequently the coal as it is put upon the market contains a large percentage of ash. The Langhorne bed is also generally present throughout the field, but so far as known it is thick enough for commercial mining only west of New River and north of Pulaski, where it ranges in thickness from 3 to 5 feet. In that part of the field west of Wytheville the coal beds are generally thinner and more impure than they are farther east.

The chemical composition of the coal is shown by the accompanying analyses. All the analyses represent the Merrimac bed, except that from Little Walker Mountain north of Pulaski, which is from the Langhorne bed.

The analyses show that the most objectionable feature of this coal is its large percentage of ash, which has made it difficult to market the coal in competition with the purer coals of the bituminous fields on the west. If the coal were carefully hand picked and washed the percentage of ash could probably be so much reduced that it could hold its own for domestic use and for raising steam.

The analyses also show that the coal ranges in rank from semibituminous to semianthracite, but that none of it approaches the composition of Pennsylvania anthracite. The rank is determined by the "fuel ratio", the quotient obtained by dividing the percentage of fixed carbon by the percentage of volatile matter. According to the standards adopted by the United States Geological Survey, bituminous coal has a fuel ratio of less than 3; semibituminous coal, 3 to 6; semianthracite, 6 to 10; and anthracite, 10 or more. Those whose fuel ratio is less than 6 should be sold as semibituminous or "smokeless" coals, and those whose fuel ratio is more than 6 should be sold as semianthracite. The present practice of putting them all on the market as Virginia anthracite should not be permitted, as the term is misleading.

An examination of these coals has been made by the United States Geological Survey of Virginia, and the present note is issued to supply information to those who are seeking investments in this field, to operators who are marketing these coals, and to consumers who may wish to know something of their value compared with the standard coals of the country.

Analyses of coal from Montgomery, Pulaski, and Wythe counties.

Location	Moisture	Volatile matter	Fixed carbon	Ash	Sulphur	British thermal units	Fuel ratio
Price Mountain:							
South side	3.6	9.5	67.6	19.3	0.46	11,850	7.12
North side	3.0	10.9	64.2	21.9	0.68	11,670	5.89
Brush Mountain:							
Near Blacksburg	1.9	14.0	68.9	15.2	0.52	12,740	4.92
Poverty Gap, New River	1.6	13.3	61.5	23.6	0.67	11,400	4.62
Little Walker Mountain, north of Pulaski	4.6	10.0	71.3	14.1	0.57	12,520	7.13
Syncline northeast of Max Meadows	3.8	9.4	62.2	24.6	0.75	10,960	6.62

TALK AND SOAPSTONE IN UNITED STATES IN 1920.

Altough talc is a mineral that is most widely known in the form of talcum powder, it is extensively used in the industries. The pure mineral is known as talc and the massive rock that contains it is known as soapstone. Nine-tenths of the talc and soapstone mined is ground and used as a filler in paper and in rubber, as foundry facing, and in many other ways.

The United States is by far the greatest producer of talc and soapstone, and it consumes even more than it produces. In 1919 it produced 68 per cent of the world's supply and consumed 79 per cent.

The production of talk and soapstone in 1920 exceeded that in any previous year both in quantity and in value, according to Edward Sampson, of the United States Geological Survey, Department of the Interior. The sales in 1920 amounted to 224,290 short tons, valued at $3,090,265, an increase in 1920 over 1919 of 21 per cent in quantity and 31 per cent in value. The quantity exceeded by 2 per cent that of 1917, the previous record quantity year, and the value exceeded by 15 per cent that of 1918, the previous record-value year.

The quantity of talc reported to the Geological Survey as ground was 178,505 tons, valued at $2,142,894, or 18 per cent more than in 1919. The value of the ground talc was the highest on record, exceeding that for 1919 by 34 per cent and that for 1918, the previous record-value year, by 15 per cent. The average price of ground talc in 1920 was the highest on record, namely, $12 per short ton, which may be compared with $10.55 in 1918 and 1919 and $8.42 in the prewar year 1913.

The manufactured soapstone sold amounted to 19,707 tons, valued at $709,400, not the highest annual output recorded, but the highest annual value.

Wallace Barnes Company, Ltd., will start the manufacture of springs for the Canadian trade next month in their new factory at Hamilton, Ont., which will be under the management of Mr. T. M. Norton. The parent company is at Bristol, Conn.

NEW BORATE FIELD IN NEVADA.

Deposits of colemanite, a mineral that yields borax, which were recently discovered in southern Nevada, have been examined by L. F. Noble, a geologist of the United States Geological Survey, Department of the Interior, who reports that colemanite occurs in two areas in the Muddy Mountains. One area, known as the White Basin district, lies just east of Muddy Peak, about 15 miles southwest of St. Thomas. Mr. Noble says that the colemanite here occurs in irregular layers interbedded with whitish shale, most of which appears to be composed of very fine, more or less calcareous volcanic ash. In places the shale contains considerable gypsum and thin-bedded limestone, and here and there beds of tuff, some of which is light and pumiceous. Much of the limestone shows concretionary structure and weathers into globular form resembling goose eggs which scale in concentric layers like an onion. These so-called "goose eggs" are of much value to the prospector in locating the horizon of the deposit. Mr. Noble concludes that the deposits of colemanite, some of which contain material whose structure suggests that of ulexite, or "cottonball", were originally formed as ulexite in mud just as ulexite is being formed in the dry lakes or playas of desert basins to-day, and that percolating waters highly charged with lime may have afterward changed the ulexite to colemanite.

The structure of the goose-egg limestone suggests spring deposits built up layer upon layer by evaporating waters highly charged with lime. Volcanic activity in this general region, which is proved by the presence of volcanic ash in many beds, suggests the ultimate source of the boron that formed the ulexite, and the great masses of Paleozoic limestone in the Muddy Mountain Range were doubtless the source of the lime.

The formation that contains the colemanite is known as the Horse Spring formation. This series of beds and the underlying Overton conglomerate are of fresh-water origin and are probably of Miocene age. They rest uncomfortably on older rocks but have been bent and somewhat faulted by folding.

In the White Basin district the layers of colemanite as exposed range in width from a fraction of an inch to a maximum of 2½ feet, and though the district as a whole is considerably faulted there seems no reason to doubt that it contains a large quantity of commercially valuable material. A carload of colemanite has been taken out by the American Borax Co. for shipment from St. Thomas.

The area that contains the largest deposit in the region is known as the Callville district. This deposit was found last December by Lovell & Hartman in the canyon of one of the tributaries of Callville Wash, about 12 miles southwest of White Basin and 6 miles south of Muddy Peak. The bed of colemanite, which forms a part of the Horse Spring formation, has a minimum thickness of 10 feet and a maximum thickness of 18 feet, and its outcrop is visible for at least 3,000 feet along the rim of an eastward-trending canoe-shaped syncline, the east end of which has been made irregular by faulting. The colemanite is interbedded with shales, which lie near the top of a thick series of massive limestones. The horizon of this huge colemanite deposit can be traced all around the inner rim of the syncline for several miles along the outcrop, though colemanite is not visible in considerable amount except in the great lens already mentioned.

The colemanite appears to occur at the same horizon in the Horse Spring formation, both at White Basin and near Callville Wash.

The great deposit near Callville Wash consists essentially of solid layers of colemanite alternating with layers of paper shale or limestone. The bedding in some parts of the shale is wavy and within the "vein" exhibits the typical goose-egg structure, but in others it is regular and parallel. A large part of the deposit consists of massive crystalline colemanite, which, however, is interbedded with shaly material and will probably have to be concentrated. So far as can be judged from the two open cuts already made across it, the deposit or "vein" as a whole may be expected to run at least 30 per cent of pure colemanite and may run as high as 50 per cent.

COL. CURRIE'S IRON FIND.

Further Proof of Intelligent Observation By Indians —And Exaggeration By the Press.

ALEXANDER GRAY.

Colonel Currie M.P. has a new iron ore area about twenty five miles north of Sprague, east of the Soo. It may not be as big as what they have in the northern tier of states over the border—notwithstanding exaggerated reports appearing in the daily press—but it is of sufficient importance to warrant drilling operations and has romantic antecedents to entitle Indians as keen observers to further credit marks as prospectors.

The Indian located the St. Eugene. The same is true of the Helen Mine. About sixty four years have elapsed since Herrick in running his lines with white assistants and Indian guides spotted the Helen—and it was about that time more "float" containing iron was noted. The Indians knew of it. Herrick's notes had references to it, as well as to the Helen indications. Gates took the Helen, when it was staked for him by the Indians—and Col. Currie declined another area offered to him for $500—a fact which he afterwards regretted.

For years the Colonel cherished a mental note about what he heard as to "float" north of Sprague. Having missed the Helen and the Magpie, he concluded another bunch of hematite ore low in phosporous would not be amiss. It happened, however, that conditions for prospecting were not altogether auspicious. Then the War intervened. Anyhow he waited and watched —and a few months ago he was willing to make the effort. Rather he retained Archibald M. Campbell, a Mining Geologist of Ottawa, to make the effort. Mr. Campbell was fortified with Herrick's 1857 field notes, which stressed the presence north of Sprague of a large quantity of boulders in which there was "excellent hematite iron". Other details as to the exact location were somewhat meagre.

But Mr. Campbell has hit a good many trails—and is familiar enough with the red man's lingo to make his way. So, off he went with his guides. In due course he picked up the essential Herrick lines. Then he worked into what had possibilities as iron country. Eventually he got the "float"—and manifestly it had not travelled far. Whence it came puzzled the geologist. Indian reports and Herrick notes had been veridied. Beyond that Mr. Campbell was left to his wits—and those he exercised by examining the striae—the rock surfaces as marked by glacial action. Mr. Campbell called upon the glacial age to bear witness—and that led him across a lake where, in contact with greenstone on the hanging wall and quartzite on the footwall, the "find" of red hematite was made. Two-

and-a-quarter miles was staked for Col. Currie—and the samples taken are satisfactory.

There is "red iron", disseminated specular hematite, and more of the latter in a micaceous formation. According to Mr. Campbell, the iron is where it ought to be—yet he declines to concur in the newspaper tales about this being the precursor of another Gogebic or Mesaba Range. To the contrary, while hopeful, he declares there is no reason why the locality should be unduly magnified. Picked samples have yielded 68 percent metallic iron. The section between the greenstone and the quartzite is about half a mile in width. There is a possibility, owing to its purity, of much of the iron being recovered by concentration—and it is that feature which is giving those concerned most encouragement.

Mr. Campbell says "the truth is all we want. Fiction is misleading."

ENGLISH ELECTRIC COMPANY OF CANADA, Ltd.

Big developments are taking place in the electrical industry in Canada. The English Electric Company of Canada, Ltd., of which Mr. Gordon F. Perry, of Toronto, is President, and which includes among its directors many prominent financial men and captains of industry, is associated with the English Electric Company, Ltd., of Great Britain, is already established and has a continent-wide sales connection.

The Canadian Company holds the exclusive manufacturing rights in perpetuity for the English Company, having the use of all the latter's patents, designs and processes, etc. In addition, it will secure preferred prices on all imported machinery and equipment, also securing the benefit of the preferential tariff and the present favorable exchange rates. It acts as the ageney for the English Company, which is the largest manufacturer of electrical and allied machinery and equipment in the British Empire, and, through it, all selling, engineering and construction work in Canada is done. It further holds the right to sell its own products in the United States.

Some idea of the scope of the operations of the English Electric Company, Ltd., of Great Britain may be gained from the fact that it maintains eight branches in the United Kingdom and ten abroad. Its activities are world-wide, and it is, naturally, exceptionally well placed to produce and sell the machinery, apparatus and appliances requisite for the adequate development of industries and underlakings, which have been delayed for the past few years. It controls and operates the Dick, Kerr Works at Preston, Eng.; the Ordnance Works at Coventry, Eng.; the Phoenix Works at Bradford, Eng.; the Siemens Works at Stafford, Eng.; and the Willans Works at Rugby, Eng. With the exception of the Ordnance Works at Coventry, all these are well-known as pioneers of the electrical industry in various branches.

By means of its association with the English Electric Company of Great Britain, the Canadian Company will be a progressive force in the electrical manufacturing industry of Canada. The increasing use of electrical machinery in all industries; hydro-electric power developments; the extending and re-equipment of our civic tramways and railways; the electrification of our railways; the equipment of our merchant marine with electrical engines; the increasing use of electric appliances of all kinds in the home; motor accessories; —all these will demand a huge amount of new electrical equipment.

Cooperating actively with the management of the Canadian Company are the Research Department and the heads of the Engineering and Construction Departments of the English Company.

It should be added that the entire undertaking of the Canadian Crocker-Wheeler Company, Ltd., of St. Catharine's, Ont., has been acquired, so that all the valuable patents and designs of this last-mentioned Company are available.

PORT ARTHUR NOTES.

By J. J. O'CONNOR.

An old-time gold location, staked in the '80's is again attracting considerable interest. The property is situated immediately south of Gwynne Mountain, near the shore of Worthington Bay, about two ad one-half miles from Schreiber, on the Canadian Pacific Railway.

This property was located by Mr. Peter McKellar, who did some preliminary development work, that gave great promise of the property developing into a valuable gold producer. Mr. McKellar shipped a car-load of the ore taken out at that time, to the Dominion Reduction Works, at Rat Portage (Kenora) which showed a recovery of $21 per ton on the plates. For some reason the property was allowed to fall into disuse, and nothing has been done in the meantime, until Mr. William Longworth obtained a working option in the Summer of 1920. Since that date active exploration and development has been carried on with highly satisfactory results.

A tunnel has been started on the original vein and is now in 25 feet, showing good gold values throughout. Assays from the tunnel and tests pits on the vein gave results varying from payable ore, up to $1,170 per ton in gold.

A new vein was located on the 20th August, about one hundred feet to the eastward of the original vein. This vein is traceable for over half a mile, varying from three to four feet in width, and paralleling the original vein for its entire length. Samples taken from the surface at various points where uncovered, show free gold in good quantity, indicating that the values are continuous. The country rock between the veins is an altered porphyry, carrying small values in gold.

The vein matter in the second vein is a sugary quartz, carrying tellurides and free gold in shot form. Mr. Longworth is now engaged in removing the overburden from the new vein, at points about one hundred feet apart.

This property is in the immediate vicinity of the property, R606, operated some years ago by the Morley Brothers, of Detroit, Mich., from which they shipped a sample cargo of pyrites.

The success that has attended the McKellar, has caused a number of locations to be staked in that vicinity since the opening of this season.

The International Nickle Company announced on the 24th. instant that a reduction of 100 men would go into effect at an early date. A cut down went into effect some time ago, reducing the number of employees to 600. Two hundred men will be retained. The official announcement states that the reduction is being made owing to business depression, and the large stocks on hand, and that they hope to resume at a reasonably early date. Their Port Colbourne refinery will close down, and the Bayonne, N.J. refinery will close down for a period of four months.

TEMPERATURE AND MOISTURE IN DEEP MINES.

Factors of Control.

In the third report of the Committee on the Control of Atmospheric Conditions in hot and deep mines, presented before the Institution of Mining Engineers, Mr. J. P. Rees gave the results of observations made at five pits, selected on account partly of the depth of the workings and partly of the specially adverse conditions which make temperature control difficult.

The collieries in question were Pendleton, near Manchester; Pendlebury, Lancashire; Shelton Deep Pit, North Staffordshire; Bowhill, Fifeshire; and Bentley, Doncaster. The object of the work, which was organized from the Doncaster Coal Owners' Laboratory, was to investigate in detail the operation of causes leading to the existence of high underground temperatures, and particularly high wet-bulb temperatures. In the report the determining factors are analysed and distinguished as far as practicable, and the result are displayed by means of charts.

There are three causes for the rise of temperature in underground workings. The first is the heating due to the compression of the air as it descends shafts or inclines (about 5½ deg. F. per 1,000ft. of descent); the second is conduction of heat from surrounding strata; and the third is formation of heat through oxidation of coal or other minerals and timber. The increase in the moisture contained in the air is due to evaporation of the water that percolates through the walls of shafts and roads or is present in freshly exposed coal or other material. The heat and moisture given off from men, horses, and lamps is scarcely appreciable in a coalmine.

Heating by compression cannot be obviated except at the expense of evaporation; but it can be, and to a large extent always is, averaged over the year in the actual workings of a mine, the walls of the shaft and roads giving off more or less heat to the air according as the external temperature is lower or higher. In exceptionally warm weather the walls may even take up heat from the air.

Heating by conduction from the surrounding strata is reduced to a minimum in shafts and roads when the volume of air passing is sufficiently large, because the flow of heat through the zone of cooled rock which in course of time comes to be formed round a shaft or airway is comparatively slow. If the air-flow is large, the flow of heat from the strata is not sufficient to warm the air more than very slightly, but if the air is flowing very slowly the heat-flow is sufficient to warm it to practically the temperature of the strata. The practical importance of a large flow of air in controlling underground temperatures is thus clear.

In this country the rate of increase of the natural rock temperature with depth is always much greater than the increase of air-temperature from compression. At the collieries referred to in the report the rate of increase in rock temperature is 1deg. F. for about every 60ft. or 70ft., whereas the air-temperature increase from compression is only 1deg. in 182ft. In the Witwatersrand district, however, the rock-temperature increase is only 1deg. in 250ft., so that if a deep mine were dry abundant ventilation would warm it, in contrast to the cooling effect in this country.

Heating by oxidation, which is referred to only incidentally in the report, can evidently also be controlled by abundant ventilaion.

Increase in the moisture-content of the air can usually be controlled as effectively by ventilation, until the actual working face is reached, as can increase in temperature. This is shown by all the charts except one for Bowhill Colliery, which has very wet shafts and roads. But with abundant ventilation the cooling effect of evaporation from wet roads would evidently keep the temperature along these roads low, and thus indirectly control the amount of moisture in the air and the wet-bulb temperature. The very rapid rise in moisture-content of the air as it passes along a working face over fresh and relatively moist coal is shown in all the charts.

PERSONAL.

F. W. Gray, who previously to taking the editorship of the "Journal" was for fifteen years in the service of the several companies now forming British Empire Steel Corporation has joined the headquarters staff at Montreal and his address is 708 Transportation Building.

J. Shanks, Manager of the Brazeau Collieries at Nordegg, Alberta, has recently passed through Montreal on his way to his home in Scotland, where he is to spend a holiday. Mr. Shanks is one of the best-known and most efficient colliery executives in Alberta, and has taken a leading part in adapting electrical haulage to coal-mine conditions.

Mr. O. N. Brown, of the Nova Scotia Steel & Coal Company's staff at New Glasgow, has been removed to headquarters of B. E. Steel Corporation in Montreal. Mr. Brown is a member of the C. I. M. & M. and a graduate of McGill in mining engineering.

Mr. T. O. Bosworth, who played an important part in the exploration of the Mackenzie River oilfield has arrived at New York and is expected to visit the Western Canada oil districts after a trip to Oklahama.

Mr. F. C. Sutherland has returned to Toronto from England.

Mr. Iichiro Omori of the Kumamoto Technical College, Japan, is in Toronto. He is touring Canada and the United States, studying methods of metal production and metal working. He has been recently in Pittsburgh visiting steel plants there. From Toronto he will go to Montreal and New York and then to England and France. In America he has been chiefly impressed by the improved mechanical apparatus for the handling of material.

Sir Archibald Mitchelson, Mr. J. Stanley Holmes, Mr. John Hambley and Mr. G. Whitehead of London have arrived in Toronto on their way to the Northern Ontario gold and silver districts. They are particularly interested in the Davidson gold mine. Accompanied by Mr. H. H. Sutherland, they will spend two weeks in the North, including a few days at Temagami. Sir Archibald Mitchelson is a director of nine important colliery companies situated in Wales and Yorkshire, and is chairman of a number of these companies.

B.C. PLANT TO EXTRACT NITRATES FROM ATMOSPHERE.

The Rossland "Miner" states that the Waneta Power Company is erecting a plant for the extraction of nitrogen from the air and its fixation. The site is at the mouth of the Salmon River, near the U.S. border, and although the newspaper account does not give exact figures, it is understood the undertaking is on a large scale.

Northern Ontario Letter

THE SILVER MINES.

The Cobalt Field.

During the closing week of August, the price of silver reached a point well above the average for any one month since January last. At the time of writing, the metal is quoted at 38⅜d. in London and 61½ cents an ounce in New York. This means that the producers in the Cobalt field are receiving at the rate of between 69 and 70 cents an ounce in Canadian currency.

A strong demand for silver in the Far East, and official statistics which show Mexico to have produced less silver during the first half of 1921 than was the case in the first half of 1920 have served to emphasize the very great scarcity of the metal. Another factor contributing to the influences at work in sending the price upwards is very serious discussion in leading British papers about the advisability of the re-establishment of bimetallism by international agreement as a means of offsetting the shortage of gold behind the paper issues of some of the leading nations.

Upwards of 700 tons of material is being treated daily in the plants on the Coniagas Mines. Of this total some 375 tons daily is coming from underground while the balance is made up of sand and slime tailings from past operations. The company has a total of only 105 men on its pay-roll and the tonnage per man engaged is much greater than at any other precious metal mine in Canada. In mine rock alone, the force engaged in this branch amounts to between four and five tons of ore daily per man, while, including the sand and slimes, the entire force is handling an aggregate of close to seven tons daily for each man on the pay-roll. This record is actually more than double the average at the silver and gold mines of Northern Ontario, it being considered generally quite satisfactory to handle an average of two tons of ore per man daily. This high tonnage rate at the Coniagas reflects an exceedingly high degree of efficiency and is being pointed to as the secret of the company in being able to operate profitably on material which contains less than an average of 10 ounces of silver per ton, valued at from $4 to $6 a ton.

Samuel Cohen of the Crown Reserve Mining Company as well as of the Porcupine Crown Mines of Porcupine is at present engaged in making an examination of property in Northern Manitoba. Among other properties, Mr. Cohen has been looking over that of the Murray Brothers, situated at Elbow Lake and upon which such spectacular discoveries were made a few weeks ago. The result of the assays obtained as a consequence of Mr. Cohen's sampling will determine the question of whether a venture will be entered into in Northern Manitoba, or not.

The special representative of the Canadian Mining Journal for Northern Ontario will spend the first week of September in certain of the mining districts of Northern Manitoba with a view to comparing the outlook in that promising new field with the situation in Northern Ontario. "Journal" readers will be given an opportunity to read the information thus gathered.

Major J. McIntosh Bell, of the Keeley Silver Mines, has returned to the property after spending the past several weeks in the northwest, particularly in the vicinity of Great Slave Lake. Major Bell is deeply impressed with the magnitude of the oil and mineral possibilities of the vast undeveloped territory of the Canadian north-west.

Captain H. Hibbard, of Kent, England, visited the Cobalt district during the past week in the interests of British capital. Among other properties visited were the Dickson Creek mine, about two miles north from Haileybury, as well as the La Santa Lucia and Cartwright Goldfields at Painkiller Lake. Capt. Hibbard is sailing for England this week, and expressed the belief that a great amount of money in England is likely to seek employment in Canada.

Elk Lake and Gowganda.

Although an announcement was made officially some time ago that arrangements had been made for the sale of bonds as a means of financing the construction of a light arrow-gauge railway from Swastika to Gowganda by way of Fort Matachewan and from Swastika to Larder Lake by way of Kirkland Lake, nothing further has been issued in the way of official information relative to construction. As a result of this, various property holders in the districts in question are biding their time, with a view to learning what the method of transportation is to be.

Although negotiations have been under way for some time, nothing definite appears to have been arranged in connection with resuming work on the property of the Cane Silver Mines. The question of the ability of those in control to raise the money required to work the property will probably be determined within the next month or so.

The Silver Triangle and the Ontario Solid Silver Mines, both properties being in the Auld and Cane township section of the Montreal River district are also still lying in idleness. The latter is in strong hands and may be re-opened at such time as the owners decide, while the Triangle is endeavoring now to raise $100,000 with which to get work under way.

THE GOLD MINES.

The Porcupine Field.

Activity in the gold-bearing territory lying round about the Porcupine and Kirkland Lake districts is increasing week by week. In all directions where a few months there were only signs of possible work, there are now numerous operations actually under way.

Reports of new discoveries carry tidings of the reward which is falling to the lot of the pioneers, and with this great spread in prospecting activity it would be a pessimist indeed who would say that a great many more gold-producing mines will not be the final result.

On the Daly claims in the township of Bristol about a dozen miles south-west of the producing section of the Porcupine field an important discovery is said to have been made. Late reports would indicate that in a wide quartz vein the gold content has been found to average about $8 per ton. A feature of the occurrence is that the quartz as well as the geological structure is quite similar to that found in the Hollinger area.

An analysis of the work on the Hollinger Consolidated as based upon official figures up to the end of July, and working at full capacity up to the end of December places the probable income of this company at close to $11,000,000 for the whole of the year 1921. It is estimated that net profits will easily reach $375,000 every four weeks from this date forward or at the rate of over 19 per cent annually on the company's issued capital. This outlook has given rise to the belief that in addition to the regular dividend disbursements of 1 per cent every four weeks, or 13 per cent a

year the company will be able to pay a bonus or a capital reduction of 5 per cent annually.

Interests closely identified with the Dome Mines Company express the belief that the company will not depart from its present dividend rate of 2½ per cent. quarterly, but will continue to make these disbursements, and will at the same time add to surplus at as rapid a rate as full capacity operations will permit. In this manner the indications are that the treasury will be sufficiently strong to commence making capital returns by the end of the company's current fiscal year which will end March 31st. It is believed the company will be able to pay 20 per cent capital reduction annually, plus the 10 per cent in dividends, thus returning a total of 30 per cent a year.

One of the leading mining concerns in the United States has expressed a desire to get behind the Porcupine V. N. T. Mines to the extent of purchasing the 475,000 shares in the treasury and to even go still further toward placing the enterprise on a producing basis on the largest possible scale. On the other hand, the English interests in control of the company have recently evinced an intention to do the financing themselves. In any event, the Porcupine V. N. T. appears to be in line for interesting and important developments.

Arrangements have been made in connection with the financing of the Davidson Consolidated. The company is now to be known as the Porcupine-Davidson, and the preliminary work in connection with de-watering and re-opening the mine are already under way. The former company was capitalized at $5,000,000, this being made up of 5,000,000 shares of the par value of $1 each. The capitalization of the new company will be approximately the same, being 1,000,000 pounds sterling. A sum of 200,000 pounds is to be set aside as working capital, of which 50,000 pounds is already guaranteed, and another 100,000 pounds underwritten.

The La Palm Porcupine interests have notified the Allied Porcupine Company to vacate the La Palm property on the charge of alleged failure to live up to the terms embodied in the merger agreement. The La Palm has refused to transfer its assets and the Allied Porcupine is taking legal action to enforce the delivery.

The Kirkland Lake District.

According to the regular monthly statement of the Lake Shore Mines, this company produced $49,155.26 during July. A total of 1,967 tons of ore went through the mill, this being at the rate of over 63 tons daily, the highest average so far in the history of the mine. The mill ran 92.60 per cent. of the possible running time. Hydro-electric power was off 27 times and resulted in a loss of 4.1 per cent of the possible running time. Work was carried on at eleven different points, seven of which were at the 600-ft. and four at the 400-ft. level. A total of 149 feet of work was done at the 400-ft. level and with 179 feet done at the 600-ft. level. A feature of the report is that in addition to the large daily tonnage treated, the "surface suspense stock" was increased by 321 tons of ore.

Considering spectacular ore has been opened up at the lower levels of the property of the Kirkland Lake Mining Co. The work of placing the mine in condition to produce ore in sufficient volume to operate the mill at full blast has been carried out and the handicaps caused by last year's labor shortage and a heavy cave of rock underground have been pretty well overcome, and the company is now in a position to reap the profits of a long period of stored up effort.

Foundations are in and the structure to house the milling plant o the Ontario Kirkland will be in course of erection within the next few days. The mine is being equipped with a 100 ton mill and is developed sufficiently to assure full tonnage of good grade ore. The Ontario-Kirkland offers promise of taking its place among the profitable producing gold mines of this country during 1922.

Another vein carrying commercial values over a width of close to two feet has been found at outcrop on the King-Kirkland. The vein is less than 100 feet from No. 5 on which a shaft was driven to a depth of 100 feet and on which considerable ore was opened up.

The erection of camps on the Queen Lebel is under way, and an aggressive scheme of exploration and development work has been arranged for.

A limited amount of work is being done on the Costello property, on the east shore of Goodfish Lake in the northern part of the Kirkland Lake district.

Sandy McIntyre, discoverer of the Temiskaming Mines at Cobalt, the McIntyre-Porcupine Mines at Porcupine and the Teck-Hughes Gold Mines in the Kirkland Lake district, has made another discovery of gold in the township of Gauthier a short distance east of the Kirkland Lake field itself.

Encouragement is reported to have been met with as a result of surface exploration by the Crown Reserve Mining Company on property in the Larder Lake district. Assays are reported to average about $4 per ton across a width of 40 feet. The gold content is therefore considered a little too low to make the body of commercial grade under the prevailing conditions in that field, but further explorations will be conducted with a view toward finding out whether higher values may be opened up at depth or at other points along the vein or dyke. The gold occurs in altered basalt.

British Columbia Letter

Stewart and Alice Arm: A first shipment of 20 tons of high-grade ore has been shipped by the Fish Creek Mining Co., whose property is situated on Fish Creek, Portland Canal District. As soon as the road which the Alaskan Administration is building up the Creek is completed it is the intention to instal a compressor. Extensive alterations to the dock at Stewart are being made preparatory to the construction of ore bunkers by the Premier Mining Company. Encouraging reports come from Marmot River where the Patricia Group is being developed together with the Washington, Prince George and other properties. Work on the former is to be continued throughout the winter.—A new strike is reported on the Dolly Varden, Alice Arm. The lead was uncovered on the surface about 20 feet above the old workings and picked samples are said to have assayed 267 oz. in silver.—A. H. Lawry of San Francisco, Cal., recently visited and inspected the Dolly Varden.

New Hazelton, B. C. — The John Gariel Silver Property, Copper River, is being opened up with satisfactory results. A trail is being constructed to the property, finances being furnished jointly by the provincial government and the owner. With transportation facilities, and the ready obtaining of plant and supplies assured, development will be expedited.

Rossland, B. C.—The new concentrator of the Le Roi No. 2 is in operation. The ore on the dumps is to be treated first after which attention will be given to the mining of the property.

Trail, B. C.—The Trail Mining Co.'s property, near Salmo, the ore of which is an oxidized lead containing silver values, has been developed recently by the driving of a 600 foot tunnel. The main lead is 16 feet wide. On the construction of a road it will be possible to commence shipping.

One quarter of a million tons of ore and concentrates were received at the Trail smelter this year up to and including August 7th last. Of the actual total 250,980 tons, 246,140 tons were from the properties of the Consolidated Mining & Smelting Co. and 4,840 tons were custom ore. Ten properties shipped ore to the smelter from August 1st to 7th. There were included the Freddy Lee and the Majestic of Sandon, the Kokomo of Beverdell, the Skyline of Ainsworth, and the Bingo.

Sloean, B.C.—It is likely that the Lucky Jim Mine Company will be re-organized and early steps taken to open up the property. The new company proposes to start development by continuing the 400-foot level beyond the worked-out section and well into the hill. A raise at the point in mind will give 1,000 feet depth and will prove or otherwise the continuance at depth of the ore bodies which outcrop. If these ore bodies are similar to those worked the values will be predominatingly zinc at depth with higher values in lead and silver towards the surface.

Robert Strachan, senior mines inspector of the Province of British Columbia, has been appointed to represent the Province at the International Conference to be held on the 1st and 2nd of September at St. Louis, Mo., to consider the question of standardization of methods of training men in the use of breathing apparatus. Owing to illness Hon. Wm. Sloan, Minister of Mines, will be unable to attend. He has prepared a paper which will be read by Mr. Strachan.

The first aid team of Nanaimo, B.C., holders of the Montizambert Cup representing the Canadian championship, will compete in the international meet arranged to take place at St. Louis at the same time.

The Annual First-Aid and Mine-Rescue Meet of the Vancouver Island Mine Rescue Association will be held at Cumberland, B.C. on Labor Day, September 5th. Entries have been received from all the collieries of the Island and keen interest is being manifested in the events throughout the coal mining centres of the Coast.

DRILLING FOR COPPER AT LITTLE BAY, NEWFOUNDLAND.

S. J. Fitzgerald, president of the Sudbury Diamond Drill Co., and Jack Peer, have passed through North Sydney en route to Newfoundland. The former has two diamond drills in operation at the copper areas of W. A. Mackay at Little Bay, Nfld., which are doing excellent work. Bores holes have been sunk to a distance of over 1,600 feet within the past few weeks, but the results, if any, have not been given out. Drilling operations will be continued all winter, Mr. Fitzgerald states, in order to prove the quality of the ore.

THE BIRD RIVER COPPER-NICKEL DEPOSITS.

(Reprinted from C. M. & M. I. July Bulletin.)

DURING the fall of 1920 and the late winter, the Devlin Mining and Developing Company has been carrying on active operations on a group of nineteen claims. These claims are situated in the Winnipeg mining district, on the Bird river, some eighty-five miles from Winnipeg and thirty miles from Lac du Bonnet, or thirty-six miles by the canal route. There is a daily train service to Lac du Bonnet, whence motor boat is available to Bird Falls, from which point canoes are taken for the remainder of the journey. Five portages must be crossed, the longest a mile and a quarter in length. The winter road is practically the same as the summer road. The canoe journey is a pleasant and beautiful one, the scenery varied by picturesque homesteads on the lower part of the Bird river, and by several spectacular waterfalls.

The main work has been done on the Devlin and Chance claims. A series of test pits of varying depths up to eighteen feet were sunk to get below the oxidation zone, and to determine the nature and extent of the unweathered minerals. This oxidation zone averages about seven feet, due to the ease with which pyrrhotite weathers. The test pits were sunk at varying intervals along the main mineralized zone. This belt is in the noritic rocks which cut the granite a short distance to the north in a series of fingering branches. The contact is generally sharply defined with a slight absorption of the granite by the noritic rocks. The principal economic mineralization is chalcopyrite and pyrrhotite, with copper and nickel values as high as 9 per cent for the combined metals.

Petrography. (a) The noritic types. This intrusive is named provisionally, there being three distinct types and some intermediate forms. Microscopic examination would be necessary to determine whether these are distinct types or phases of the same. The variation often occurs, within short distances, from a very coarse hornblendic rock, like a lamprophyre, to a very fine grained black rock. The third phase is a porphyritic type, with hornblende crystals embedded in a matrix of the finer grained material. On the contact there are minor amounts of rather fine to medium grained material which is similar to the Muskwa river norite. Other phases with a finer grain, have dark parallel lenticular inclusions, about a quarter of an inch long, possibly absorption granite products. The westerly pits on the Chance claim are the best developed.

(b) The granite: The granite to the north is light pink to white in colour. The hand specimen shows biotite, muscovite, clear glassy quartz, and much crushed fel spar. There has been, apparently, a great deal of mechanical crushing during the intrusion of the norite.

(c) Quartzite: There are also inclusions of a fine grained quartz rock with clear glassy quartz blebs one-eighth of an inch across. This rock resembles a typical quartz porphyry, but further examination over a wide range leads to the conclusion that the quartz blebs are secondary, and that the rock is a quartzite member of the Wanipigon series, of which the clayey members gave way to form sericitic and garnet schists.

Description of pits sunk. (These are numbered, for the purpose of this article, from west to east.)

No. 1 is about twenty feet deep, in fine grained dark noritic rock. A twelve-inch quartz vein carrying chalcopyrite crosses the pit at forty-five degrees, and, below the footwall, veins of chalcopyrite cross the shaft. Four veins merge into a two-foot vein at the bottom of the pit.

No. 2 lies 165 feet north and is twenty feet deep, in the same type of norite showing many slickenside slip

faces or shearings. Quartz carrying some free gold, pyrrhotite, magnetite, and chalcopyrite, is found nearby.

The magnetite band, two to three feet wide, runs one hundred and fifty feet north and is opened by pit No. 3 on the Devlin claim, where it is seen to contain minor amounts of chalcopyrite. The granite contact is close to the north. For over a claim length east the country is clay covered, and then there are eight more pits, varying in depth from three to eighteen feet, along the contact. These extend from one side of the Chance claim to the other. They all contain pyrrhotite, with minor amounts of chalcopyrite; the typical black oxidation product of pyrrhotite, purple weathering pyrrhotite, nickel-bloom, and limonite are the common weathering products. The norites are mainly of the porphyritic and coarse types previously described.

To sum up, this is a prospect, favourably mineralized over a long contact zone. The geographical position is extremely favourable, it being possible to reach the property in twenty-four hours from Winnipeg, winter or summer. The proximity of the Point du Bois hydro-electric plant of the City of Winnipeg, less than fifteen miles south, solves the power problem, and there is plenty of firewood and some spruce timber in the vicinity. With these facts in mind, the directors' decision to carry on active stripping operations during the summer, with a view to the future developing of the ore-body by diamond drill, seems to be highly justified.—L. G. T.

BOOK REVIEW.

RECENT PRACTICE IN THE USE OF SELF CONTAINED BREATHING APPARATUS. Lt. Rex. C. Smart, M.C., R.E. 7½ by 5 inches, 243 pp. with Index. Cloth. J. B. Lippincott Company, Philadelphia, U.S.A., and Chas. Griffin & Co. London. 1921.

Lt. Smart's record of the use of oxygen breathing apparatus in trench mining operations during the war is remarkable for its military style and reticence. Reading between the lines, the civilian acquainted in any way with the use of oxygen breathing-apparatus in mine-rescue work, can detect a wealth of human endurance and courage, and some instances of astonishing self-sacrifice. Take the following example, which is quoted as written: "Six men were in the mine at 7 a.m. when 'blow' occurred; in addition, two lives were lost, due to attempts at rescue being made by persons who were not wearing rescue apparatus, but who went into the mine with a life-line attached to them. They were overcome by gas, and when attempting to drag them to safety their bodies jammed in the small gallery, so that it was impossible to move them." For a man who is a certified colliery manager, Lt. Smart's description is an indication of how thoroughly our citizen armies must have become permeated by military discipline, and what real veterans there were in our fighting lines among the civilians turned soldier.

The book is intensely interesting, and the foreword by Sir John Cadman is not at all too appreciative of its importance when he describes it as a "description of the most rigorous and lengthy test to which self-contained breathing apparatus has ever been put," and Sir John Cadman brings out a most important point when he remarks further "The carefully correlated detail of Mr. Smart's book in itself is an example and pattern of the practice that should be emulated by all those who supervise and control rescue operations and have the care of self-contained breathing apparatus under their charge."

The most convincing account of the possibilities of oxygen breathing-apparatus given by Lt. Smart concerns the charging and tamping of a mine containing 6,000 pounds of ammonal by men wearing Proto apparatus in a gassy gallery by seventeen trained men of a company of the Royal Engineers. The atmosphere of the gallery which in part was only 3¼ ft. by 2½ ft., contained 1.65 percent of monoxide, 4.3 percent of dioxide, 1.42 per cent of hydrogen and methane and only 16.77 of oxygen. Gas was entering the gallery continuously from an enemy mine fired two weeks previously. The ammonal was handled in double sandbags containing 20 pounds each. Forty-three hours was consumed in the work, the two shifts relieving each other every two hours. Actually each man did about 10 hours work underground in the 43 hours. In addition to the laying of 6,000 pounds of ammonal at the extreme end of the gallery, some 65 feet of solid tamping, with alternate air-spaces, was done. When one sums up the combined effect of the heavy labour accomplished, the confined space; the nervous strain on the workers, as "enemy activity necessitated a heavy 'blow' as soon as possible"; the unremitting nature of the labour, and the conditions of weight and discomfort under which the very best of breathing apparatus must be worn, the accomplishment is one to be brought over and studied by those who have to do with mine-rescue work in peace-time industrial operations.

Lt. Smart's book deals entirely with experiences with the "Proto" apparatus and the lighter apparatus of the Siebe Gorman Co. known as the "Salvus". The last-named apparatus does not meet with commendation, owing to its limited capacity, and the standard two-hour type of "Proto" apparatus is given preference under all mine conditions.

The greatest value of the book consists in the details of failures of pressure, due to worn valves, rust-clogging, and other defects of mechanism that experience has shown to be likely to develop. The information given on this point is very detained. Similarly full and detailed is the list of physical reasons and personal idiosyncrasies which debar men from suitability for training in the use of breathing apparatus. Some men are too big, and demand too much oxygen for their bodily needs; others develop an unexpected oxygen-deficiency syncope, others are too weak or have cardiac defects or lung trouble. The best type of wearer is a man weighing between 140 to 170 lbs., aged 20 to 37 years, 5 ft. 4 inches to 5 ft. 10 inches in height, always provided the mental capacity and health of the person is suitable.

The book is illustrated by seven folding maps to illustrate the tunneling experiences referred to in the text.

Condensation has been so generally carried out and the details given are so statistical and exact, that thorough review would required wholesale quotation, and the book is therefore recommended as one to be bought and studied by those interested in knowing precisely what oxygen breathing can accomplish, and what the apparatus will stand, under very rigorous conditions so closely allied to ordinary industrial mining conditions, that useful and practical analogies can be drawn. —F. W. G.

ANTHRACOAL.

Anthracoal is a new domestic and metallurgical fuel which appears to have excellent qualities. It is a mixture of small particles of anthracite coal and a matrix of practically pure carbon, formed from the distillation of coal-tar pitch or other suitable bitumen. Some account of tests made on it is given in a paper to be presented by Donald Markle at The Wilkes-Barre meeting of the American Institute of Mining and Metallurgical Institute, Sept 1921.

TORONTO COAL PRICES.

Toronto, 31st August.—An improvement in the lump coal situation, so far as bituminous is concerned, is still noticeable. It is not so much that the actual orders are coming along more freely—although, to a certain extent, this is so—as that the enquiries are far more numerous than was the case a few weeks ago. As soon as the Exhibition is over, it is expected that orders will very appreciably increase in volume. The price of lump remains unaltered. That of slack is from around $1.65 to $2.00 a ton. In Toronto, the citizens seem to be getting in their supplies of anthracite, although belatedly, in a satisfactory way. But the same thing cannot, yet be said of certain outside points where people are reported to be still holding off from buying.

NOTES FROM NOVA SCOTIA COLLIERIES.

The output of the Acadia Coal Company in July was 29,302 tons, the mines having worked only partial time because of the lack of outlet. The Albion, Allan andNo. 3 mines only were in operation during July. For the seven monthes ending July the production totalled 227,262 tons, and it is unlikely that outputs during the remainder of the year will exeeed the average monthly production so far reeorded.

The production of the Nova Scotia Steel Company's eollieries during July was 56,257 tons, from four collieries, whieh included 7,034 tons from the new Colliery No. 7. Output for the aggregate seven months of 1921 was 337,082 tons, and this rate of production is also unlikely to be exeeeded during the closing months of the year.

The sub-lessees of the Port Hood & Richmond Coal & Railway Company's properties at Port Hood have for some months been working an area of rise coal above high-water mark, but during the recent period of slack demand for coal, and since the unfortunate imposition of the export embargo of 1920 on coal from eastern coal mines in Canada, the financial returns have been insufficient to make operations profitable, and as the result of an accumulation of unpaid wages, the miners' union invoked the aid of statutory provisions by placing a miners' lien on the property in order to secure their unpaid wages against other creditors. The status of coal-mining in Port Hood has been very indefinite since the flooding of the mine in 1909, and, as the original owners of the property lost all they had invested in it, their interest has naturally been of the slightest, and no attempt has been made to find out whether the mine is irremediably flooded or not. The parties who have been working the Port Hood areas showed commendable enterprise, and were able to carry on profitably so long as prices for coal remained high, and demand was good, but they cannot continue to mine coal under present conditions of wages and hours of labour and in face of depressed mining conditions without much greater capital reserves than they possess. There can be no permaneney in coal mining in Nova Scotia except through large consolidations of coal areas backed by financial reserves large enough to carry the operators over the dull markets that periodically recur in the coal-trade, and to recover from the accidents and disasters that are apparently inseparable from coal mining.

PROTEST AT FORCED SALE OF WACHMAN MINING & MILLING CO.

Under date of 24th August, a letter has been sent to the shareholders of the Wachman Mining & Milling Co., Ltd., signed by a Committee consisting of Mrs. A. Inec. H. R. Greenwood, Albert Fickler, L. G. Seeber, John G. Coogan, Joseph Stephens, Victor Dehn and Emil Steelheimer, Chairman of 5918 Augusta Ave., Chicago, complaining of action taken by several of the Company's creditors in forcing collection of their accounts through sheriff's sale of the Company's chattels. Appeal is made to the creditors for extension of time of payment, as the committee believe if such extension is given the Company can pay its debts. It is asking for opportunity to raise the necessary money and the Committee believe the shareholders will help immediately. The Committee state that a large number of people of moderate means are shareholders in the Company, and that if time is given by the creditors it will be possible to save their investment and also to pay the debts in full.

CANADIAN MARBLE CO., BANCROFT, ONT.

It is reported that the Canadian Marble Co., Ltd. plans to develop in a larger way the property at Bancroft. The plans include development of water power and construction of a modern mill. It is proposed to install quarrying equipment which will be driven electrically. Mr. W. H. Matthews of Toronto is manager of the company. The officers are J. J. Ashworth, Melville P. White, Frank McMann, J. M. Robertson, D. A. Campbell, Wm. A. Buck and W. H. Matthews.

Much of the marble used in Canada is imported. As there are large quantities of ornamental stone of good quality in Hastings county it should be possible for domestic producers to supply the market. Dr. W. A. Parks who examined the ornamental building stones of Canada for the Mines Department a few years ago reported very favorably on the marbles in Hastings county.

RECENT GEOLOGICAL REPORTS ON MANITOBA.

Part C of the Summary Report of the Geological Survey for 1920 contains three reports by Dr. F. J. Alcock on his investigations into outlying areas of Northern Manitoba, namely, Ospwagan Lake-Burntwood River Area, the Rat River route from Threepoint Lake to Southern Indian Lake, and the Terminal Moraine of the Seal-Churchhill Divide. Dr. Alcock gives some interesting historical information of these largely unpopulated districts and details the geology of the observed localities. The economic geology of these districts is not important and is rendered obscure by the overburden of drift and clays and unsorted gravel and sand deposits of glacial origin.

W. S. McCann reports on the interesting occurrence of copper-nickel deposits near the headwaters of Maskwa (Bear) River in southeastern Manitoba, of which an account was published in the Bulletin of the Canadian Mining Institute by Dr. R. J. Colony and reprinted in this journal.

See issue 26th Nov. 1920, page 967, "A Norite of Sudbury Type in Manitoba. Dr. R. J. Colony.

DEVELOPING LEAD DEPOSIT NEAR CRERAR, N. ONT.

While men were engaged in prospecting for gold on properties north of Crerar, a deposit of galena was found. This is now being developed by the Gold Nugget Mining and Development Co. Mr. Ewen McMillan of Haileybury is at the property in charge of work. Mr. E. J. Townsend of Sudbury is president of the company and Clarks F. Charsley, secretary. C. H. Johns of North Cobalt is a director.

The galena is said to carry good silver values and attention is being devoted to this deposit at present. The properties are in the neighborhood of Koo-ga-gaming late and about four miles from the C. N. R.

FLAME QUENCHING DEVICE FOR BLASTING.

A device for quenching escaping flame from a shot-hole and for minimising the danger of blowouts is the subject of a German patent. The tamping of the explosive is a long cartridge filled with some innocuous tamping material, which is not rammed. At the end of the hole and projecting from it there is fastened a rectangular bag or bundle containing similar material which is a continuation of the long cartridge. The materal in the cartridge being easily disturbed is stated to take up the pressure to such an extent that the protruding and connected "bundle" is in most instances not disturbed. Should the hole develop a blow-out, however, it is claimed that the dust-cloud set up by the "bundle" will so cool and lower the heat of the escaping blast as to render ignition of the gas and dust improbable.

DUST SPRAYING DEVICE FOR COAL MINES.

A German device for hand-spraying of dust has been used at the Zeche Constantin der Grosse at Bochum, Westphalia. It consists of a hopper-shaped bucket which is filled with stone-dust and carried over the shoulders of a workman. A trailing connection to a compressed-air pipe is inserted at the bottom of the bucket, which is equipped with a long spout capable of being pointed in the required direction. An injector sucks the dust out of the bucket and sprays it with much force, and it is possible by this device to efficiently apply a dust coating to roof and sides in any place where a man can walk and where compressed air power is available.

COMPRESSED-AIR MINER'S PICK.

A recent number of a German mining periodical shows an air-operated handpick for miners. The tool is shaped like the ordinary handpick, except it has one tine only, and this a very pointed and straight one, the intention apparently being that the point will work its way by percussive action into coal or rock. The device should be very useful in confined spaces where swinging of the pick is difficult or ineffective. The air enters from the end of the wooden handle and passes upwards through the handle to the head of the pick. The instrument has the formidable name of "Pressluftspitzhaeke".

BRITISH COLUMBIA

The Mineral Province of Western Canada

Has produced Minerals valued as follows: Placer Gold, $75,944,203; Lode Gold, $102,753,823; Silver, $53,668,284; Lead, $46,637,221; Copper, $161,513,864; Zinc, $19,896,466; Coal and Coke, $212,573,492; Building Stone, Brick, Cement, etc., $32,168,217; Miscellaneous Minerals, $1,037,408; making its mineral production to the end of 1920 show an

Aggregate Value of $706,192,978

The substantial progress of the Mining Industry of this Province is strikingly exhibited in the following figures, which show the value of production for successive five-year periods : For all years to 1895, inclusive $94,547,241; for five years, 1896-1900, $57,605,967; for five years, 1901-1905, $96,509,968; for five years, 1906-1910, $125,534,474; for five years, 1911-1915, $142,072,603; for the year 1916, $42,290,462; for the year 1917, $37,010,392; for the year 1918, $41,782,474; for the year 1919, $33,296,313; 1920, $35,543,084.

Production During last ten years, $331,995,328

Lode-mining has only been in progress for about twenty-five years, and not 20 per cent. of the Province has been even prospected ; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those of any other Province in the Dominion, or any Colony in the British Empire.

Mineral locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with Mining Reports and Maps, may be obtained gratis by addressing

THE HON. THE MINISTER OF MINES
VICTORIA. British Columbia

PROVINCE OF QUEBEC

MINES BRANCH

Department of Colonization, Mines and Fisheries

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, etc.

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

MINERS' CERTIFICATES. First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is $10.00, and it is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

WORKING CONDITIONS. During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

SIX MONTHS AFTER STAKING. At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

MINING LICENSE. The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year, and a fee of $10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days labour on each forty acres.

MINING CONCESSION. Notwithstanding the above, a mining concession may be acquired at any time at the rate of $5 an acre for SUPERIOR METALS, and $3 an acre for INFERIOR MINERALS

The attention of prospectors is specially called to the territory in the North-Western part of the Province of Quebec, north of the height of land, where important mineralized belts are known to exist.

PROVINCIAL LABORATORY. Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, MONTREAL, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The Bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

HONOURABLE J. E. PERRAULT,
MINISTER OF COLONIZATION, MINES AND FISHERIES, QUEBEC.

EDITORIAL

WHY NOT ADVERTIZE THE MINING INDUSTRY?

The Canadian National Exhibition is growing in popularity and usefulness year by year, and, as an educational institution, stands second to none in Canada. Several hundred thousand people visit the exhibition each year and become better acquainted with the industries of this country. The exhibits are such as to make lasting impressions and any person can advantageously spend days in profitable, as well as pleasing, sight-seeing at the Exhibition. Under the circumstances, it is singular that so little attempt is made to give the public a better idea of the part the mining industry plays in the lives of the people of Ontario.

Aside from the little collection of minerals, shown annually by the Department of Mines, there is scarcely an exhibit which advertises the mining industry as such. It is true, of course, that a large part of the materials shown are products of the mines, but nothing is done to impress this on any of the million visitors. Why should we be so secretive about our mineral resources? Agricultural products and machinery naturally take a leading part at the Exhibition, and one new building for showing live stock alone covers eight acres. Yet mine products occupy only a few feet in one building and mining machinery is nowhere. The National Exhibition is not a mere glorified country fair, but a place where the industrial activities of Canada are made evident to large numbers of people. At such a place the mining industry should be creditably represented.

Those who are interested in the mining industry have frequent occasion to complain that the general public is not better acquainted with mining, its methods and its progress, and that Governments do not recognize the good that would accrue from more extensive mining operations. Would it not be well to take advantage of the opportunities that offer to tell the people more about the industry? And among such opportunities the Canadian National Exhibition's position is one of unique pre-eminence.

GOLD PRODUCTION SHOULD BE STIMULATED.

Commenting on the expressed opinion of Sir Archibald Mitchelson, a visiting British banker and broker that the revival of the purchasing power of gold and consideration of international finance make it essential that the production of gold within the Empire shall be stimulated, the "Globe", Toronto, editorially calls attention to the fact that "Ontario's gold mines derive a new importance from their bearing on exchange and the balance of trade. The United States is making it increasingly difficult for other countries to pay their debts to it in goods; hence the value of Ontario's growing gold output as a means of offsetting, in part at least, the excess of our imports from the United States."

It is interesting to note that the gold mining industry of Ontario, is attracting the favorable attention of the Press. This is because the industry is coming more and more to be regarded as an asset to the Province as a whole, as well as a source of profit to those who are directly engaged in it. If the people of the Province can once be made to realize that gold mining may easily be made a very big industry that will flourish when it is most needed as it is now doing in a relatively small way, proper encouragement of the industry will doubtless result. Someday we may have a Government that will be progressive enough to take a really prominent part in the development of the industry.

OIL AND GAS IN WESTERN CANADA.

In a paper prepared for the Edmonton meeting of the Canadian Institute of Mining and Metallurgy, Mr. George Sheppard, states that while too much has been said and too little yet demonstrated concerning the Fort Norman oil field, it should soon be possible to give a fair estimate of the potentialities of this field. By the end of the year four wells will be completed and some definite idea will be obtainable as to whether the Fort Norman field is to be a producer or not. The only well drilled last year was brought in at a depth of 873

ft. and while much remains to be demonstrated, the results obtained at this first well are naturally considered as very satisfactory. Mr. Sheppard, however, believes that there has been too much exaggerated comment.

Of the Czar well Mr. Sheppard says that the results are of no commercial value. This hole was drilled to 3,500 ft. at which depth it was in limestone.

Of the Irma district Mr. Sheppard says that, if the gas pressure can be overcome, there is a reasonable hope that oil may be found at lower horizons. At 1,890 ft. a strong flow of dry gas to the amount of 5,400,000 cu. ft. per day was encountered by the Gratton Creek Oil Co. There were showing of oil at 300, 1,215 and 1,582 ft.

In the once famous Dingman field certain leases have been taken over by the Royalite Oil Co. and there is renewed activity.

While the results obtained in the prairie districts do not encourage excessive optimism in regard to the production of oil, there are undoubted gas fields, practically in unlimited quantity, as has been demonstrated at Viking, Irma and Medicine Hat.

ENGLISH CAPITAL FOR GOLD MINES.

The arrangement made by Davidson Consolidated Gold Mines Ltd, with English interests for financing of operations at the Davidson mine, and the statement by Sir Archibald Mitchelson that English capital is now looking favorably on gold mine operations in Canada, are indications that London has still to be considered as a financial centre which may help in the development of our mineral resources.

There has not in recent years been much to indicate that English money would be a big factor in making mines in Canada. To a very considerable extent, we have been dependent on American interests for money to develop our mines. Close proximity to our mining districts naturally accounts for the fact that the interests of Americans in our mining companies are far greater than that of our mother country. In view however of the fact that English capital has long controlled a large percentage of the gold production of the world, it is surprising that Canadian gold deposits have attracted so little attention in England.

The visit of Sir A. Michaelson's party to Northern Ontario has received considerable attention, not only because of its importance to shareholders of Davidson Consolidated, but because so few Englishmen come out to this country to get first hand information about the industry that is growing up slowly in Northern Ontario. There can be little doubt that these visits do a lot of good.

In the interests of the industry, facilities should be made available to enable visitors to become familiar with what has been accomplished by mine operators here, and to permit them to form correct opinions with regard to the possibility of making new mines. We have very promising mineral areas which require large sums of money for their development. There is opportunity in Northern Ontario alone for the spending of many millions with a reasonable chance of success. If we had more visitors from London, English capital would not neglect the opportunities here to the extent that it has done.

THE BELCHER ISLANDS.

Reports of iron ore discoveries at Belcher Islands have been not taken very seriously by many people, but a few interested parties are strong in their belief that the makings of an iron ore mining industry exists in these islands in Hudson Bay. In this issue of the Journal will be found some excerpts from an article by an American iron mining engineer who examined the deposits last summer. His remarks indicate that enough is now known to warrant considerable expenditure in diamond drilling and other exploratory work, to determine whether the deposits are good enough to warrant the heavy expenditures necessary to develop and operate producing mines.

The Dominion Government has evidently been somewhat impressed with the possibilities of establishing an iron mining industry in the Far North, for there is now a geological survey party making an examination of the Islands for the Government, Dr. G. A. Young is in charge of the party and his report should be of interest.

Mr. Woodbridge is not unmindful of the difficulties of transportation and of the inhospitable climate and it is therefore doubly interesting to note that he is confident that the obvious difficulties will be successfully overcome if development is reasonably satisfactory.

ONTARIO MINERAL EXHIBIT.

While there is very little at the Toronto Exhibition to suggest that mining is a very important industry in Ontario, an endeavor is made by the Department of Mines to have on view minerals from the chief producing districts. In the small place allotted to the Department of Mines in the Government building, there are shown nickel and copper ore from the Sudbury district, gold ore from Porcupine and Kirkland Lake and silver ore from Cobalt.

The gold exhibits include some very rich specimens from the Croesus ine and some new ones from the Dome mine. Less spectacular are the specimens from the Hollinger and McIntyre mines and from the Kirkland Lake district. Among the silver specimens are slabs of silver from the Coniagas and Trethewey mines. A novelty is a statuette of silver with a base of silver ore. This was designed by J. D. Kelly of Ralph Clark & Sons and modeled and cast by Canadian Wm. A. Rogers Ltd.

Messrs. Jamieson & Peacock have sent in some specimens of silver ore from the Silver Islet mine, Lake Superior, and W. A. Taylor and W. E. Jones show samples of molybdenite from Eastern Ontario.

Exhibits of non-metallic minerals include feldspar from Eastern Ontario, graphite from Calabogie, gypsum

from Caledonia, fluorspar and talc from Madoc, mica from Sydenham, fireclay from Mattagami river and corundum from Craigmont.

An interesting feature of the exhibit this year is the number of maps which show the locations of mining districts and the geological features of the mining areas.

Mr. Wm. McNeil, Provincial Assayer, is in charge of the exhibit.

THE McINTYRE REPORT.

The reports that will be read with interest by a large number of shareholders and others interested in gold, silver and coal mining are those now being prepared by the McIntyre, Temiskaming and Blue Diamond companies. The gold and silver mining companies operate at Porcupine and Cobalt respectively and both are financially interested in the Blue Diamond coal mine in Alberta. In one next issue we will present a summary of the reports of the three companies. The results of operations during the past year are fairly well known, but our readers will be interested in studying the reports to see how the results were obtained and to form a better idea of the prospects for the coming year.

A PLEA FOR CONSISTENCY IN EDUCATION.

A great deal is spent upon education. Something useful learned, even if purchased at a high price, is a definite gain.

There is, however, a tendency to take too narrow a view of education and to under-estimate the importance of the seemingly minor influences to which the learner is subjected. They are not included in the conventional curriculum but form a branch of education secured by the student himself, apparently without effort, and they attach themselves so securely to his mind that their impressions are never eradicated.

It is towards these influences that we, who love our country and believe that the chief objects of education are to inculate the love of the homeland and adequately prepare its future citizens for its defence, maintenance, and progress, may very profitably direct some attention.

One influence is the presence in universities, colleges and technical schools, of scientific instruments of foreign origin, in excessive proportion. We rightly teach our child that our nation is endowed with originality in design and skill in workmanship, that there are no goods to equal the British, and then prove our point by presenting him with a Swiss watch. In the advanced stages of education, we dilate upon the engineering triumphs of our nation, and present the youth with a German set of drawing instruments. Later on, he sets out to foreign parts and he is to be congratulated if his kit does not contain any instruments except those of British manufacture.

The position is distinctly humiliating. In the stress of war, we were obliged to make scientific instruments and apparatus for ourselves, and surprising advances were made in many branches, old-fashioned firms extending, producing new and improved designs, and meeting exacting demands with everything against them except the financial aspect. If Germany had not given us time to train our workers, we could not have won the war.

We have trained workers, extended and up-to-date works available, but these must be idle because the articles in question can now be purchased from abroad at lower prices. Many thousands of lives were lost and many millions of pounds spent in the early days of the war because we had not sufficient skilled workers available to produce the munitions requisite. A standing army of skilled workers is now available; it is being rapidly disbanded and will soon cease to exist in any but a pre-war condition. This army desires to be self-supporting. It calls upon you and me individually to do our part. Government restrictions on imports may hold some part of it together and may even foster and improve some sections, but real advance will be the result of individual effort. In an ordinary school, no text-book of English history would be countenanced which belittled our country and glorified the foreigner.

It is an essential of education that it shall prejudice youth in favour of its Motherland. In the matter of book learning, this practice is strictly followed and is highly commendable. In the technical schools, where hard facts are taught, we very frequently find foreign scientific apparatus being used, foreign drawing instruments—not always because British are unobtainable, but for a difference in first cost, by which saving the minds of a generation of students are prejudiced in favour of foreign manufactures. Technical teachers have a great responsibility and a great opportunity.

The position of the scientific instrument trade at the present time is that many articles, formerly purchased from abroad, can be made equally well in this country; some are even better than their foreign rivals. Others are steadily improving but need a sympathtic encouragement, and others are in need of considerable financial support to cover the research and experimental work necessary for success.

This article is not a plea for Government protection or subsidy, but for the individual and sympathetic assistance of professors and lecturers.

An alien enemy would not be countenanced in the professional chair. Why, then, tie the students to foreign apparatus and instruments, the very atmosphere of which is charged with prejudice against this country's goods? Manufacturers are ready to consider any reasonable propositions, and some would even lose money for a time on the instruments they supply to technical schools and colleges, sooner than admit the foreign articles.

A start might be made by professors and teachers forming an association for the determination of the best patterns, for placing bulk orders, and distributing advantageously to the various schools and colleges, and for carrying out individually and collectively, such research work for improvement as their disposal will admit. If students leave the technical schools and colleges prejudiced against their own country's manufactures, and placing their reliance and support in foreigners, the technical teachers may rest assured that no plea of apathy on the part of the Government will free them from the condemnation which must fall upon them for neglecting so great and noble opportunities.

—B. J. H. (In "Pitman's Technical Bookshelf.")

DAVIDSON.

The Davidson mine is being dewatered preparatory to resumption of operations. It is expected that development on a large scale will follow completion of the financing arrangements.

Production of Metal Mines and Works

Ontario Returns Show That While Gold Is Increasing The Production of Other Metals Shows a Heavy Falting-Off.

Returns received by the Ontario Department of Mines from the metalliferons mines, smelters and refining works of the Province for the six months ending June 30th, 1921, are tabulated below. For pnrposes of comparison the quantities and values are given for the corresponding period in 1920. Tons throughout are net tons of 2,000 pounds.

first quarter of the year was responsible for curtailing the tonnage of ore treated.

The Wright-Hargreaves at Kirkland Lake joined the ranks of producing gold mines in May when the new 150-ton mill was put in operation. The Argonant mill in Gauthier township was burned on May 29th. However, active development at that property is proceeding.

Summary of Metalliferous Production.— First Half of 1921.

Product		Quantity		Value $	
		1920	1921	1920	1921
Gold	ounces	277,656	286,018	5,690,504	5,761,504
Silver	ounces	4,474,322	4,277,762	5,077,028	2,552,125
Platinum metals	ounces	184	941	12,443	26,317
Copper sulphate	lbs.	89,935	87,382	4,497	3,495
Copper, metallic	lbs.	2,918,153	2,297,732	470,949	272,132
Copper in matte, exported*	tons	4,434	344	1,241,520	55,040
Nickel in matte, exported*	tons	9,527	814	5,338,120	407,000
Iron ore, exported	tons	2,189	22	18,512	99
Iron, pig†	tons	28,771	27,147	738,079	733,568
Cobalt, metallic	lbs.	113,239	30,423	266,045	91,355
Cobalt oxide	lbs.	388,318	99,533	645,783	204,853
Nickel oxide	lbs.	3,491,544	31,078	814,070	65,652
Nickel-Cobalt oxides, nnseparated	lbs.		26,592		29,720
Nickel, metallic	lbs.	4,854,979	21,773	1,696,687	1,479
Other Nickel compounds	lbs.	159,183	111,279	15,308	9,991
Other Cobalt Compounds	lbs.	1,417		1,029	
Lead, pig	lbs.	749,820	1,504,830	71,006	79,322
Total value				$22,101,580	$11,363,652

* Copper in matte was valued at 13 cents per pound in 1920 and 8 cents in 1921, while nickel in matte was valued at 25 cents per pound for both years.

† Total ontpnt of pig iron was 244,346 tons worth $6,602,772. Figures in the table represent proportional ontpnt and value of product from Ontario ore.

General Remarks.

With the exceptions of lead and gold a marked decline is noted in Ontario's metalliferons outpnt for the first half of 1921 as compared with the corresponding period in 1920. The mining industry is experiencing a poor market and a general lowering of commodity prices in common with many other industries. Considering the shortage of hydro-electric power during the first quarter of the year, together with the slnmp in the price of silver, the ontpnt of this metal is creditable. Gold mining which was carried on during the war period nnder adverse conditions, is now on a solid basis, and gives promise of showing a yield for the full year in excess of any record heretofore attained. Details regarding the principal items are given under separate headings.

Gold.

Production of gold for the half year shows an increase of $71,000 in value over the 1920 figures. The significance of the increase will be noted when reference is directed to the output for the first quarter of the year which was $656,514 less than in 1920. Thus the net increase in production for the second quarter of 1921 is $726,514. Hydro-electric power shortage during the

The McIntyre at Porcupine is doubling its milling capacity which at present is 550 tons daily. At the present rate of production, the total outpnt of gold in Ontario for 1921 will be about 13 million dollars, as compared with 1920 when it was $11,665,735.

Canadian nickel-copper refineries recovered 121 ounces of gold worth $2,425. Apart from values given in the table below, gold-mining companies received in addition approximately 13 per cent of the gross value of the ontpnt by way of exchange premiun, amounting to say $750,000. This bonus by which the industry profits is an added stimulus to gold-mining in Ontario. With lowering production costs it is expected that other mines which were forced to close down during the war will soon re-open and join the ranks of the producers.

Nickel-Copper.

Owing to an overstocked market for these metals, the operations of mining nickel-copper ore, smelting into Bessemer matte and refining for the recovery of nickel, copper and subsidiary precious metals, have been greatly curtailed. In the United States practically all the copper mines have closed down, the average New York price of electrolytic copper having declined from 19.01 cents per pound for the first half of 1920 to 12.67 cents

for the period under review. Nickel is in little demand for armament purposes and industrial business is slack. In consequence, the production for the first half of 1921 is much below that for 1920 when a temporary revival in business, stimulated by high prices, was in evidence. At the time of writing, both the Nickelton and Copper Cliff smelters are closed down, as are also the refineries at Deschenes, near Ottawa, and at Port Colborne, belonging respectively to the British America Nickel Corporation and the International Nickel Company of Canada. The Mond Company is operating only one converter and has made no shipment of matte this year to the Company's refinery at Clydach, Wales.

During the period 241,991 tons of ore were smelted from which 12,785 tons of matte were produced. Of this latter quantity 1,403 tons were exported to the United States, and 5,039 tons shipped to Deschenes and Port Colborne. Nickel-copper matte refined totalled 4,069 tons from which 2,297,732 pounds of electrolytic and blister copper were recovered. In addition there was a recovery of 121 ounces of gold worth $2,425; silver, 5,666 ounces worth $3,258, and platinum metals in impure form and also as slimes, 941 ounces valued at $26,317. Aside from the metals 108,915 pounds of nickel plating salts (nickel sulphate) were marketed, also 318,732 pounds of nickel oxide.

Iron Ore and Pig Iron.

With the exception of a small sample shipment of hematite from the Wallbridge mine near Madoc, no iron ore was shipped from Ontario mines. At the Magpie 42,198 tons of siderite ore were raised. Both the Magpie mine owned by the Algoma Steel Corporation and the mine at Sellwood owned by Moose Mountain, Limited, are idle at the present time.

Six blast furnaces of the Algoma Steel Corporation, Midland Iron and Steel Company, and Steel Company of Canada operated for an average of 117 days during the period. A total of 490,224 tons of ore was smelted of which 57,454 tons or 11 per cent were of Ontario origin and 432,770 tons imported. Of 244,346 tons of pig iron produced 153,671 were used in steel making, the output of the latter product being 245,116 tons valued at $9,133,184.

Silver.

The New York price for foreign silver for the half year averaged 59.9 cents per fine ounce as compared with $1.17 in 1920. For the Ontario producer the exchange premium is to be added. Power shortage greatly curtailed production for the first quarter of 1921, but the total for the half year approaches the 1920 output in quantity. Several properties are being reopened following the shut down from power shortage and the drop in silver prices.

Shipments were made from the Miller Lake O'Brien and Castle mines at Gowganda, and from the Keeley mine in South Lorrain. Shippers of over 100,000 ounces are given in order: Nipissing, O'Brien, Coniagas, La Rose and Mining Corporation of Canada. Total shipments by silver mines were 4,224,326 ounces worth $2,520,866. Gold mines recovered 47,771 ounces and nickel-copper refineries 5,666 ounces. Shippers received $19,266 for 83,875 pounds of cobalt contained in ore and concentrates.

Refineries: — During the half year the three southern Ontario refineries treated 1,282 tons of ore and concentrates and 2,251 tons of residues, for a recovery of 2,024,628 ounces of silver, in addition to arsenic, cobalt, nickel, and compounds of the two last-mentioned metals. Shipments of recovered products were small owing to a poor market. In the above table, nickel hydrate and sulphate are included under the heading "Other Nickel Compounds". Nickel sulphate was produced from nickel-copper ore, and copper sulphate from silver-copper ore.

GOLD PRODUCTION.

EXPLORING SILVER ISLET MINE.

Exploration work is well under way at the old Silver Islet mine where an attempt is being made to find ore deposits similar to the one that was worked several years ago. The mine has been dewatered to blow the 250 ft. level and an exploration crossent is being driven at that level in an endeavor to pick up new silver veins.

BAUXITE.

Reports of the production of bauxite in 1920 again show this ore of aluminum is being produced in quantity only in two countries United States and France, the former producing during the year 529,695 tons and France 186,693 tons. The American production is valued at $3,217,345. A good deposit of bauxite in Eastern Canada should find a ready market.

THE GOLD DISCOVERY AT ELBOW LAKE, MAN.

By Professor R. C. WALLACE, Commissioner of Northern Manitoba.

In the Canadian Mining Journal of July 1st, Mr. J. P. Gordon has already described in a brief note the essential features of this discovery. The following details will serve to supplement the facts which Mr. Gordon has noted.

Location.

Elbow Lake is an expansion of Grassy River which flows eastwards through the mineral belt into the Nelson River, into which it empties above Split Lake. The Grassy River, which flows northeastwards into Elbow Lake, makes a sharp "elbow" turn immediately on entering the lake and flows southwards without traversing the main body of the Lake. The discovery was made by the Murray Brothers at the water level on the southgoing arm of the river at the extreme south end of the Lake. The distance N.N.E. of The Pas is 65 miles. By summer travel the district may be reached either through Sturgeon Landing or through Herb Lake, in 2½—3 days travel from The Pas. To Sturgeon Landing there is steamboat connection. To Mile 82, 10½ miles distant from the south end of Herb Lake one may travel by train or gas car.

Geology.

At the south end of Elbow Lake a narrow band of green stone strides in a north and south direction and is intruded by granite on its east and west margins. The discovery was made on the east contact, and on the east bank of the river immediately below the first band after leaving Elbow Lake. The granite, which has intruded the greenstone is at this place a fresh red hornblende granite, itself heavily mineralized with pyrite near the contact. There is no definite line of contact, but rather a contact zone, a quarter of a mile or more in width, in which the greenstone has been partly or completely fused by the granite. The granite has been considerably altered by the process and the rock which in the field has been termed a porphyry, in which the quartz bodies lie, is a porphyritic phase of this intrusive granite, in type almost a quartz porphyry in places. There are other phases of contact rock as well, dark massive syonite, felsites and silicified greenstone; and through the whole zone run irregular veinlets, sheets and masses of quartz. The continuity of the individual bands of quartz, both horizontally and vertically, is very uncertain. The presence of a very considerable amount of quartz in the contact zone is, however, assured. Further in the greenstone, on the west side of the river, the quartz is found in regular veins following the strike of the greenstone. In the contact zone the most typical form is probably sheetlike masses lying approximately horizontally between the layers of "porphyry" rock.

Mineralization.

The discovery was made at what is now the south end of the Murray claim, where at the water's edge there now shows a band of gold approximately three inches by nine inches in a narrow vein of quartz. Immediately north of this very fine showing a trench has been cut across the strike, but does not show any spectacular gold in the line of strike of the main discovery. In this trench, however, and in the main trench on the Murray Claim (350 feet north of the discovery) the masses of quartz carry visible gold, and are of undoubtedly high grade. Six bands or shoots of quartz were noted in the main trench (75 feet long) varying in width up to three feet. The trench cross-sections only the west side of the contact area and might be continued with advantage right across the zone, as the rock on the east side of the hill shows more quartz than in the trench. Again at the north end of the next claim (contact) 3000 feet north of the discovery, considerable quartz occurs in the rock, and has been found to carry free gold.

Pyrite occurs in the granite to the east, in the quartz and in the "porphyry" throughout the property, usually, fine-grained, but occasionally in large cubes which have been formed in drusy cavities. Further south magnetite and galena occur, the former in bands which may be of economic value, the latter sparingly in quartz veins in the intruded greenstone.

Economic Possibilities.

The Murray and Contact claims are staked on a contact zone between granite and greenstone, in which there is a variety of intermediate rock, and irregular quartz lenses and sheets with very high values in gold. Both the quartz and the contact rock carry considerable pyrite. The gold-carrying quartz must be worked, not by itself, but as part of the whole rock body, owing to the fact that the quartz intrusives are irregularly distributed in the zone. It will therefore be necessary by surface sampling to locate sufficiently large bodies of quartz and country rock which may be worked in a large scale way by glory-holing or in wide stopes. Whether this may be possible in the large trench depends entirely on what the country rock will carry in gold to supplement the high values in the quartz bodies. In our opinion the "porphyry" will carry better on the east side of the hill facing the muskeg, as the country rock seems to contain on the whole more quartz in that area. In view of the remarkable distribution of gold in the quartz, there is the opportunity in this property and on this contact generally, for prospecting an orebody of large size with sufficient values for large scale operation. There is the advantage in this rock as well that there is no need to go to the expense of diamond drilling. Surface trenching and cross-channel sampling will give an accurate evaluation of the property for preliminary purposes. The work already done on the property has been well done. To mention a minor consideration, on many properties it would be possible to take exception to the way the lines are cut if regulations are to be strictly adhered to. That is not the case on the Murray and Contact. Further surface trenching will be necessary in order to explore the whole zone, but even at the present stage the property is open for examination.

The eastern contact at Elbow Lake southwards to Island Lake is good prospecting ground and will doubtless be carefully worked over before the summer is over. The mineralization is good, the contact is wide, and there is easy water communication throughout the whole contact belt.

PERSONALS.

Mr. C. E. Macdonald, formerly sales engineer with the International Nickel Company of Canada, Ltd., has severed his connection with that concern and has taken over the Canadian management of the Electrical Alloy Company. As resistance wire which is the large end of the business of the Electrical Alloy Company, consists entirely of nickel alloys, Mr. Macdonald's experience with the International Nickel Company of Canada, Ltd, should eminently fit him for his new position

Relation of Drilling Campaign to Income from Oil Properties

By W. W. CUTLER, Jr., (Petroleum technologist, U.S. Bureau of Mines, Interior Department) and WALKER S. CLUTE (Assistant valuation engineer, Oil and Gas Section, Internal Revenue, U.S. Treasury Department).

An oil-field drilling campaign is used in this paper to signify the spacing of the wells to be drilled as well as the drilling program, which is interpreted as the number of wells drilled in a unit of time. This has an important bearing upon the time of receiving income, as well as upon the amount of revenue obtained. In periods of low prices for oil, such as the present, the margin of profit is at the best very small, and the correct determination of the drilling campaign may be the deciding factor between incurring financial loss or gain during the depressed period.

General Policy of the Operator.

Drilling should be planned by the field engineer to conform with the general policy of the operator. This policy may be one of conservation during the early life of the property, but as mentioned later, this may result in a smaller ultimate recovery. It often occurs that the market price of oil does not warrant rapid development, or it may be desirable to hold in reserve a supply of oil for a refinery. The policy may be to recover all of the oil as quickly as possible, or it may be to maintain a constant and sustained production. In any case, the operator should outline as far as possible a definite policy, and should understand the principles underlying the recovery of oil, the influence of rapidity of drilling and effects of spacing, in order that he may obtain the oil as required with the least expenditure.

Loss of Recovery of Oil From Delay in Drilling.

During the early life of a pool, wells are brought in with large initial productions. As the pool becomes older, there is a marked decrease in initial production of new wells due to a fall in gas pressure. Naturally a loss in recovery per acre follows a delayed drilling program, owing to the smaller initial production of wells and also in some cases to the effect of drainage. The drainage factor is important to the operator if his property has not been protected properly by line wells.

In order to obtain the maximum amount of oil from a tract, a fast drilling program is necessary, thus obtaining wells of relatively large initial production, and consequently large ultimate production. Such a drilling program, however, is often impracticable. The drilling of a large tract must necessarily extend over a number of years. The crude oil market, with its supply-and-demand factor, the cost of materials, the building of roads, the need for drilling offset line wells first, and the financial condition of the company often prevent following the most advantageous drilling campaign.

The percentage loss in ultimate production which an operator will sustain due to delay in drilling will vary with the amount of other drilling in the same pool, the size of the pool, the size of the undrilled tract, the amount of delay in drilling, and the amount of protection which the operator has obtained by offset wells.

Determination of Drilling Campaign.

An operator's first consideration is to drill offset line wells in order to protect his property from drainage by neighboring wells. By staggering his line wells with the neighboring line wells, an operator will develop areas which are less affected by drainage than they would be if the neighboring line wells were directly offset, thus increasing the probable recovery from his protecting line wells.

After this is done, the drilling should proceed according to a definite plan conforming with the general policy of the company. Drilling generally progresses either blanket fashion across a property from proved territory to unproved territory, or may spread outward from test wells used as centers from which adjacent locations are drilled successively.

A scattered drilling campaign consists in maintaining between wells as great a uniform spacing as practicable (for example, 15 to 30 acres per well on large tracts) during the early development period; then, after the scattered wells and the line wells have been drilled, the drilling campaign is completed by sinking intermediate wells whose proper spacing has been calculated by a study of the decline of the producing wells.

This method has two distinct advantages: the initial productions of scattered wells are, as a rule, considerably higher than those of wells spaced according to the usual practice in the oil fields; and production from widely spaced wells is better sustained than that from wells closely spaced. This excess in production is maintained until the drainage areas of the adjoining wells encroach upon one another. At this point, however, the decline of the wells becomes greatly accelerated. A loss in the ultimate production per acre may result from first spacing wells widely, and then interspacing.

Early wells in isolated positions, having relatively high initial productions and following with several years of sustained production, will during these years yield to the producer decidedly greater and quicker returns of revenue than would the same number of closely spaced wells, which are as expensive to drill yet have a lower average yearly production.

When it is necessary to continue drilling during periods of low market prices for oil, the relatively large initial and sustained production of isolated wells results in a reduction of the number of wells necessary to produce a given amount of oil, and the cost per barrel of production. Interspaced wells may later be drilled when the market price of oil warrants the further expenditure.

A scattered drilling campaign, as formerly pointed out, consists in maintaining the greatest practicable spacing between wells during the early development period. It was also mentioned that this may result in a smaller ultimate production per acre. The loss occurs through drainage away from the property and through incomplete recovery by interspaced wells that are brought in later after the gas pressure has decreased; but in some cases such loss may be more than compensated by the advantages that arise from scattered drilling, namely, the earlier return on the investment through large initial and sustained production, postponement of the time when wells have to be pumped, the possible elimination of drilling unprofitable wells,

and a better final spacing of the wells, based upon the production data accumulated during the drilling of the relatively few isolated wells and the line wells.

The production decline of an isolated well becomes accelerated when its drainage area is encroached upon by interspaced wells, as is shown by records from nearly any field. Therefore, the benefit to be derived by drilling scattered wells is negligible if it is followed with a rapid drilling program of interspaced wells. In other words, the scattered drilling campaign may be applicable and of benefit where a large tract is to be covered by a long program extending over a considerable number of years.

An offset campaign consists in drilling wells near wells already producing (one location removed, corresponding to 3 to 10 acres per well), possibly working from one, two or more wells as centers. A scattered drilling campaign of a given number of wells necessarily requires a slightly greater initial investment than an offset campaign, as a greater territory must be developed at one time, including, more extensive road, power, water, gas, and oil pipe-line facilities.

Tight and irregular sands are not affected so materially by scattered or offset drilling campaigns. An extreme example of this is found in the Gulf Coast salt dome fields, where in unusual cases due to irregular sand conditions, wells 100 feet away from producing wells are brought in with initial productions equal to or greater than that of isolated wells, and declines are not affected by near-by wells. This is usually accounted for by the fact that the later well has drilled into a sand which has not been drained by the original wells. In the salt dome fields, also in the districts of California that produce very heavy oil, wells are often properly spaced as close as 1 acre per well. Also in the Mexican fields the underground conditions present such irregularities that the ordinary relations between neighboring wells may not apply.

It may be desirable to an operator from an economic standpoint to produce and market all available oil at the earliest possible time, thus insuring the early return of expended capital for reinvestment. In small tracts this is often accomplished. There is of course a high immediate recovery when a tract is quickly drilled with closely spaced wells in the early life of the field. The wells are relatively large, their initial productions being high, due to unimpaired gas pressures. In such a case, with small tracts or town lots, close spacing is practiced. Too close spacing is detrimental to the field as a whole, since the gas pressure falls off and its sustaining influence is lost to neighboring operators who might otherwise benefit from securing sustained production while their long drilling programs were in progress.

Only an agreement between operators regarding the spacing of wells can gain for the field the benefits to be derived from maintaining gas pressures, thereby securing sustained production for all properties concerned.

It has been noted (Beal, Carl H., White, Norval, and others, "Manual for the Oil and Gas Industry", published by the Treasury Department, 1919. Discussion of Buena Vista Hills area, Midway Field, Calif., p. 115. Beal, Carl H. and Lewis, J. O., "Some Principles Governing the Production of Oil Wells", Bull. 194, U. S. Bureau of Mines, pp. 25-27), that the production of widely spaced wells was more sustained than that of wells closely spaced.

A study of the past performance of wells in fields throughout the United States was undertaken to ascertain the extent of the gain in production from wells that were widely spaced as compared to closely drilled wells. Of the fields examined, the Speechley pool, Butler County, Pennsylvania; the Nowata district, Nowata and Rogers Counties, Oklahoma; the Bartlesville-Dewey district, Oklahoma; the Hewitt field, Carter County, Oklahoma; and the Buena Vista Hills area, Calif., furnish typical examples of the difference in production that may be expected from widely and closely spaced wells. Average production decline curves were drawn both for the widely spaced wells and for the wells in closely drilled areas, which indicated a very considerable increase of recovery per well in favor of the widely spaced wells.

From the tables prepared, an interesting relation is noticeable in both the ratio of ultimate production per well and the ultimate production per acre. For example, in the table of the Nowata District, Oklahoma, wells with an initial production of 6,000 barrels to the acre show with closer spacing, a decrease in the ratio of ultimate production per well as follows: 100-90-84.5; while wells with an initial production of 4,000 barrels have a decrease of 100-89-84.5, which is almost similar to the above. A corresponding similarity (although increase and not decrease) is noted in the column of ultimate production per acre. In both cases this likeness was so marked in these several pools, that the conclusion is that both the percentage of loss per well and also the percentage gain per acre due to closer spacing is almost the same regardless of the size of the wells. The ultimate production for wells of equal size in the same pool, where there is interference (shown by a difference in the production decline curves for different spacing) appear approximately to vary directly as the square roots of the areas drained by the wells. This may be stated that the recovery from wells of equal size in the same pool and producing under similar conditions is proportional to the average distance that the oil moves to get to the well. As no production records were available for very closely spaced wells (1 or 1½ acres per well), it cannot be stated whether this relation is applicable to wells of such spacing.

By employing the relationship above stated, production decline curves for wells of different spacing in the same sands may be derived from a given production decline curve for wells of a known spacing. The present value of the property obtained by discounting the annual returns on the amount of oil that will be received by the spacing in actual use, may first be calculated. Next, the rate of recovery and present value of the tract for different spacings may then be estimated, and thus the spacing determined which would provide the greatest present value.

The initial production of wells to be drilled may be estimated by determining the time of completion and the production that the old wells in the vicinity will be making at the time of bringing in the new wells, as estimated from the available production decline curves. This production figure may be taken as roughly indicating the probable initial production of the new wells. In general, as will be seen by referring to the above tables, the larger the initial production of wells, the closer the spacing may be, the gain in production per acre by closer spacing corresponding with the greater initial productions. If the production of wells in different parts of the tract varies, suitable spacing should be used for these different localities. Close drilling results in a greater recovery per acre, but the added income resulting from closer spacing must be balanced

against the added cost of drilling and operating more wells, in order to determine the spacing that will produce the greatest return in dollars and cents for the tract in question.

The above method of planning a drilling campaign permits an operator to follow his policy, either of maintaining a constant production or of obtaining the greatest profit possible out of his property.

In determining the drilling program for a small tract, or a tract drilled rapidly, the proper spacing may be deduced by considering the average production decline curve of the pool or district, the average spacing it represents, and the size of neighboring wells.

The determination of the proper ultimate spacing for a large tract need not be undertaken until after the protecting offset line wells have been drilled, and for tracts where wells have been drilled according to a scattered program, until after the completion of the isolated or scattered wells. Deferring this determination until line wells and scattered wells have been drilled gives the operator the benefit of accumulated records covering production, and development costs, and a later date of estimation as to the future market price of oil.

Conclusion.

The drilling campaign has a direct bearing on the time of receipt as well as the amount of income which a property will produce.

The drilling campaign must be planned to conform with the general policy of the operator.

A definitely determined drilling campaign enables an operator to plan better the development of a property, and to secure the greatest profit from his investment.

The following program is suggested for drilling in proved acreage:

(1) Protect the property by offsetting line wells of neighboring properties.

(2) Use a drilling program sufficiently rapid to conform with that of other operators in the same field, thus utilizing the high gas pressures which exist in the early life of the field and thereby recovering a greater percentage of the underground reserves of oil.

(3) Determine the drilling campaign by weighing the necessity of securing greater immediate recovery of oil by scattered drilling against the greater ultimate production that would be obtained by offset or blanket drilling.

(4) Determine the proper ultimate spacing of wells by using the production decline curves for the early wells already drilled.—U. S. Bureau of Mines, Reports of Investigations.

EUROPE'S GOLD RESERVES.

While Europe sent to the United States more than two hundred and fifty million dollars in gold during the first six months of the current year above receipts from the United States, nevertheless according to information compiled by the National Bank of Commerce, New York, a slight gain occurred in that period in the total gold reserves of Europe held by central banks or government agents.

Only three of the fourteen chief European gold holding countries showed a diminution in their gold stocks from January 1 to July 1, and these losses were relatively slight, their combined total amounting to less than twelve million dollars. The loss was more than offset by gains among the other eleven countries, the net increase of the fourteen combined amounting to $1,199,000.

Yet between January 1 and July 1, the gold stock held by the Federal reserve banks in the United States increased by $402,601,000 or nearly 20 per cent. of the $2,059,330,000 they held the first of the year, almost two-thirds of the increase being made up by the gold from European shipping points, the rest coming from non-European and domestic sources.

Increments From Three Sources.

An analysis of this gold movement shows that present European gold reserves are not being drained to swell America's holdings but that the increments to the United States hoard since the first of the year, in so far as shipments from European points are concerned, are chiefly accounted for by three great streams of the metal consisting of newly mined supplies from Africa coming by way of London; of gold yielded up by India, also coming by way of London; and of metal thought to have originated from Russian sources, eventually coming to America through various European countries.

Europe's centralized reserves were built up subsequent to the outbreak of the Great War far above prewar figures, and were further increased since the Armistice, by concentrating in them as far as possible all gold privately held. While these reserves have been, by continued government impoundage, kept rigidly stabilized at the points attained as a result of those extraordinary war and postwar measures, in the face of the recent tremendous suction toward America, nevertheless the three great streams have flowed through these countries to the United States with little impediment during the last six months. No material effort has been made in Europe to divert the gold from them for the purpose of building up further the reserves there. The gold has served to reduce European indebtedness in America rather than to aid in restoring the gold standard in Europe.

Russian Gold Came Indirectly.

It was stated in the Federal Reserve Bulletin for June, 1921, that the Director of the Swedish Mint had recently estimated that seventy tons of Russian gold were received in Sweden since 1920. He was quoted as saying that after refining it was re-exported, chiefly to the United States, representing an assayed value here of about $40,000,000. The bulletin also said that not less than another $60,000,000 of Russian gold or its equivalent had found its way to the United States through France and other channels.

The movement of gold from Russia to the United States is not definitely traceable. It is thought to have come to this country indirectly through various continental countries in addition to those mentioned above. At the outbreak of the war in 1914 the Russian State Bank held $779,750,000 in gold; by the end of 1917, the date of the last definite statement of gold held in the bank, the stock had dwindled to $633,000,000. It has been reported that this balance has since been largely dispersed and the amount remaining is unknown, but is thought to be small.

It appears therefore that the United States received, between January 1 and July 10, the equivalent of $106,599,000 of African and Indian gold by way of London and the equivalent of more than $100,000,000 of Russian gold by way of Continental Europe. These three chief sources account for the fact that Europe as a whole has been able to make substantial gold payments to the United States without further impairing her existing centralized gold stocks.

BELCHER ISLANDS ORE DEPOSITS.

The discovery of important iron ore deposits in the Belcher Islands, Hudson Bay, has been commented on several times in these columns. Interested parties have had some very favorable reports on the deposits; but the published reports have not been very favorable, owing, possibly, to the poor impression the deposits made on one writer who visited the Islands some years ago.

Recently, however, one of the engineers who examined the deposits last year gave out some information in an article written for the Engineering and Mining Journal which would lead one to think that the possibilities of establishing an iron mining industry on Belcher Islands are quite good.

Mr. Dwight E. Woodbridge, the writer of the article is a well known authority on iron ore mining and his assistant Mr. Geo. H. Rupp is an experienced iron ore mining engineer.

Mr. Woodbridge says in part: During the summer of 1920 I made an examination of the iron formation of the islands, assisted by George H. Rupp, a mining engineer from Ironwood, Mich. That part of the islands examined consisted of the greater portion of the northern half of the group, roughly speaking lying north of Parallel 56, North Latitude.

Such a journey as I took to the Belchers is unusual and remarkable, for at present the only way to get there is by a roundabout course afforded by rivers large enough for canoe travel, and across the bays themselves. We travelled about 500 miles by canoe and 900 miles, all told, by small motor boat. Hardships and disasters, more or less serious, are sure to be met. There are dense fogs which, in those seas, never shadowing a sail nor beaten by a wheel, with no lights nor aids to navigation, are hazardous in the extreme; there are frequent storms, for these northern latitudes are subject to sudden and severe winds; there is ice, and to run into it from windward in fog or wind is death to a thin-ribbed, river-built motor boat. There is the actual wreck of these boats, perhaps, and the usual untoward incidents always to be expected during a trip into a new and distant region where there are no accommodations nor facilities of any sort whatsoever. But all these would soon be forgotten if the region were to be opened and connected with the outside world. They would make an attractive human-interest story, but are not necessary to a discussion of the mineral possibilities of the Hudson Bay region.

Iron-bearing formations themselves are not usually of a quality that will permit their use in the blast furnace; they are generally too low in iron and too high in silica or other inert or deleterious elements to be commercial. A process of concentration, natural or artificial, must take place. Sampling of the formation at the Belchers, this sampling extending over a length of many miles, showed it to be of a grade comparing favorably with the iron formations around Lake Superior in their entirety. The average iron content of the 125 square miles of the Mesabi district, for instance, is computed to be about 30 per cent iron: about 50,000 drill holes in the Gogebic have given an average of about 35 per cent iron. The comparable average of the Belchers is about 38 per cent iron, with all samples of 50 per cent or better excluded from the computation. In considering this newly discovered area and in comparing it with other and developed districts, one must be mindful that it is a wide extending formation, and not mines, that are the basis of comparison. A spade has never been put into the ground on the Belchers, nor has there even been sunk a drill hole. The whole study is one of geologic possibilities and similarities, with comparisons of the great mass of the iron-bearing formation.

At the Belchers the iron-bearing formation shows a thickness up to 400 or 500 ft. and can be followed along its eroded edges for many miles. My own work included fifteen miles of outcropping, running up to about 400 ft. in thickness. The formation is underlain by quartzites and early limestones and is capped by various recent lava flows, several different flows being discernible. The foldings and the erosions have cut through all these, disclosing greenstones, similar to those of the Lake Superior region, and it is not difficult to formulate an ideal cross-section of the various rocks.

Extensive areas were found in the formation where there had been sufficient concentration of ore to present faces up to 25 ft. in thickness of an average iron content of better than 52 per cent natural iron. The ore is very dense and close grained, blocky, breaking in rhombohedral blocks, reminding one of the Newfoundland ores under the sea at Bell Island, and the moisture content is extremely low, considerably less than 1 per cent. But not enough commercial ore was disclosed by my examination to permit a recommendation that the development of mines, the construction of ships, docks, and a railway, were warranted without further and considerable definite knowledge to be derived from exploration by drill or otherwise. It was reasonably safe to assume the actual presence of commercial ore in minable thicknesses up to a tonnage of not far from a million tons, but this was altogether too little on which to base the large expenditures necessary. It is enough, however, to base thereon a material exploratory campaign. If concentration of commercial ore in such a field, in minable thicknesses, is obtained, the probabilities are that there is vastly more to be found by search, and it is not impossible that on these islands exists one of the greater potential iron-ore fields of the world.

The only inhabitants so far north are Eskimos, and there are thousands of them in the tributary regions, up to Baffin's Bay and Chesterfield Inlet. They are a willing, kindly, trustful, hardworking and happy race, amenable to reason and discipline. This I found not only from my own observations, but from the unanimous consensus of opinion of those who knew them well. They live in daily fear of starvation, without the slightest semblance of comforts or knowledge of the amenities of civilization. True, they probably would not exist long if too much comfort was accorded them, but if properly handled and properly fed with the only supplies they are used to—raw sea products and such other food as is natural to their habitat—and if assured of life from which the fear of starvation and drowning were removed, it is probable that the labor supply would be ample and excellent.

The Eskimos are physically and mentally able. They have to be, or they could not survive. Their life is and always has been a constant struggle against the sea and the climate, and that they exist at all is proof of their adaptability and the sharpness of their intellects. One will note the same condition among northern Norwegians of the older type—that same struggle for life with the sea and the rocks, and their mental alertness and characteristic aptitude are the results of conditions.

not so severe though of like type, as those under which the Eskimos live. These people are so built physically as to warrant the belief that they would make excellent miners. It is fortunate that it is not necessary to consider Indians as miners, for there is as much difference in the mental and physical attitude of the two races as there is between an I. W. W. and a man working on his own.

No timber exists on the islands or on the mainland adjacent, but on James Bay, 100 to 150 miles south, the rivers are channels through magnificent forests of spruce, and as yet of no value at all. Mining timber should cost at the islands not a third of what it now costs in the Lake Superior region.

The possibilities of this newly discovered iron-formation region are truly interesting, and the more it is studied the more clearly do they stand out and the obvious objections fade away.

THE HISTORICAL ACHIEVEMENTS OF COBALT AND PORCUPINE.

Isolated Centres of Production in a Vast Stretch of Territory—Largely Unprospected—Having Similar Potentialities of Mineral Concentrations.

By J. A. McRAE, Cobalt.

Gold and silver production measured in tons is the achievement of the district of Temiskaming, in Northern Ontario.

Less than a score of years ago, a mere stretch of wilderness, without a railway, and now producing three tons of gold bullion and thirty-five tons of silver bullion every thirty days; that is the achievement.

In 1902, Temiskaming was a district of unknown value. There were a few adventurers who believed in its agricultural possibilities and who were suffiently aggressive to encourage the Ontario Government to construct a "peoples" railway through the territory. In doing so, the more optimistic of these pioneers perhaps failed to entertain even an imagination of the enormous wealth which was to bare itself as the two insignificant strips of steel wound their arduous course northward from North Bay toward the height of land and beyond, laying their terminus on the great Clay-Belt which lies just beyond the crest and slopes toward the sub-arctic region of James and Hudson's Bay.

That was the beginning.

Eighteen years ago the existence of silver in the Cobalt district was not known. It was during the work of constructing the railway that the fact revealed itself. In its brief existence, the silver mining industry of Cobalt has enriched Canada to the extent of approximately 315,000,000 ounces of silver valued at $191,000,000.

Nor did success end here. Quite the contrary, the silver mining industry of Cobalt served as a stepping stone, as it were, to further important discoveries. Even now, gold mining has reached such giant proportions as to provide one of the important industries of the Dominion, and in Porcupine just a hundred miles north from Cobalt the richest and the largest gold mine in the Western Hemisphere, the Hollinger Consolidated, is operating and is producing gold at the rate of over $10,000,000 annually.

I have always believed that Canadians are generally quite poorly informed in respect to the mining industry of this country. I also believe the governments are made up of men who have not given the industry the consideration which its importance warrants. It is for these reasons that these details are presented.

The motive in doing this, is not to disseminate a few facts which in themselves now occupy a place in history, but to bring to the attention of citizens of this country the greatness of the industry so far developed and the magnitude of the future which seems to be looming up. Having in mind this fact, and mindful of the opinion of the mining engineers and mining geologists who are familiar with the territory and who point to the fact that where the mineral lands have been developed they have been found to be rich and that where they have not been developed they present an ideal field for prospecting, the situation may be summarized as follows:

Stretching north-east and north-west from North Bay, forming the east and west coasts of Hudson's Bay, also all of Northern Quebec, Labrador to Ungava Bay, and north into Northern Ontario, Northern Manitoba and a large part of the North West Territories up to the Arctic Ocean and Alaska, the country is composed of granites and gneisses, interspersed here and there with patches of Keewatin and Huronian rocks, the whole being known as the great Canadian Pre-Cambrian Shield, the basal formation of the North American Continent.

This great inverted horseshoe, as it were, encompassing Hudson's Bay, is the land of promise for the prospector and miner, for only a small portion of this vast area has as yet been carefully prospected. It contains thousands of square miles and offers to prospectors better chances of locating valuable mineral deposits than can likely be found in any other country in the world. The T. & N. O. Railway only taps the most southerly portion of this great area.

Therefore, measuring present production of precious metal in tons, and the developed area bounded on the east, west and north by territory of equal promise, those who are interested in the welfare of Canada and who desire to participate in the benefits arising as a consequence of the development of these vast resources, cannot well afford to fail to acquaint themselves with the achievements and the opportunities established and beckoning in this, one of the last great precious metal mining areas.

PERSONALS.

Mr. Alex. Richardson principal of the School of Mines, Camborne, Cornwall is returning to England after visiting mining districts in Canada and the United States.

Sir Archibald Mitchelson and party have returned to Toronto after visiting the Porcupine gold district.

Mr. J. E. Harley of Kingston has returned from Ecuador and is leaving now for India.

Mr. E. P. Mathewson has been engaged to examine the property of the Burma Corporation Ltd. He will consult with Mr. P. E. Marmion, recently appointed manager of the company, on policy to be adopted.

Mr. J. A. Holmes of Sudbury is in Toronto.

Mr. A. A. Cole, of Cobalt, is at Alfred, Ont., inspecting a peat excavating machine recently installed by the Peat Committee, of which he is chairman.

Dr. McIntosh Bell has returned to Cobalt after being for some weeks in Alberta oil districts. He is now at the Keeley mine, South Lorrain.

Geological Mapping of Canadian Cordillera

While Good Work Has Been Done in the Last Fifty Years Very Large Areas Still Remain Unmapped.

By ROBT. DUNN.

Dealing with the "Status of Geological Mapping in the Canadian Cordillera," Dr. Victor Dolmage, of the Canadian Geological Survey, states that this geological work was begun in 1859 when Hilary Bauerman began a traverse along the forth-ninth parallel; that his report which appeared in 1884 was unaccompanied by maps; that actual geological mapping was begun in 1871 by James Richardson, who studied the coal fields of Vancouver Island; and that from 1871 to the present over 90,000 square miles have been geologically mapped and about 4,000 miles of water routes traversed.

In the Terms of Union of British Columbia with the Dominion of Canada in 1870 it is clearly set out in Section 5, sub-section II., that the Dominion Government shall maintain and continue the geological survey in this Province. For this reason British Columbia has a special claim to the attention of the Canadian Geological Survey—a claim which it must be admitted has been well recognized of late years, the Pacific Coast Province having had at least its fair proportion of geological and topographical parties allocated to work within its borders.

Huge Work Yet to Do.

Still Dr. Dolmage's findings, unquestionably based on information carefully compiled from the records of the Canadian Survey Branch, is of special interest because it brings home the extent of the task before that organization. The area of British Columbia is placed at 372,630 square miles and yet from 1870 to the present only 90,000 sq. miles of the Canadian Cordillera has been geologically mapped. At this rate it would take at least 150 years to complete the work in this Province. But government officials are alive to the importance of the work now as they never were before. There is no doubt that from this time onward it will be pressed both for the reason that the data is essential scientifically and that it is invaluable as an aid to the economic development of the minerals of the country.

The change that has taken place in methods is explained by Dr. Dolmage when he says that about 42,800 square miles of the 90,000 square miles were done by early explorers on a scale of 8 miles to the inch and that "though some of it may be classed as good reconnaissance survey, much of it is only exploratory work. About 3,100 square miles of good reconnaissance were done on 6 miles to the inch by more recent workers. About 32,600 square miles were done on a scale of 4 miles to the inch, all of which work is good reconnaissance survey and some of it may even be classed as detailed work. About 5,800 square miles were mapped on one mile to the inch, all of which is detailed work and much of it very detailed. About 163 square miles of refined work were done on scales ranging from 400 to 2640 feet to the inch."

Two Classes of Work.

There is a division in the class of work done between that prior and subsequent to the present century. The former was of an exploratory or reconnaissance character; the latter has been nearly all detailed. Earlier period maps cover huge areas done on a scale of 8 to 4 miles to the inch while those of the later period deal with smaller much more thoroughly traversed areas.

The men of the earlier period are described as essentially stratigraphers who accentuated that phase of geology, devoting much of their time to areas underlain by sedimentary rocks. In the second period more stress has been laid upon petrography and the study of of igneous rocks. Economic studies during the earlier phase were largely of coal areas and placer ground—no doubt because those were the resources then receiving general attention and knowledge of which was generally sought—which now more attention is being paid to metalliferous deposits.

Complimentary reference is made to such earlier workers as George M. Dawson, A. R. C. Selwyn, R. G. McConnell, J. Richardson who "laid with skill the broad and secure foundations upon which all subsequent work must be built. Dawson's work," it is stated, "was of an exceptional character, and will always remain the basis for future work in almost every part of the Canadian Cordillera."

In discussing the maps of the first period it is said that they may be divided into three types. The most primitive was made by traversing the great inland water routes of the interior and either mapping the geological formations encountered or merely sketching in the topography and describing the geology. "In this way Selwyn examined some of the proposed routes of the Canadian Pacific Railway in 1871 and 1875, which included parts of the Fraser, Chilliacoo, Pine and Peace Rivers; Dawson examined the Yukon, Stikine, Skeena and Peace; and McConnell, the Yukon, Liard, Porcupine, Omineca and Finlay Rivers." A second type of map covered large areas from 6,000 to 3,000 square miles in extent on a scale of from 4 to 8 miles to the inch, and the work, involving a great deal of topographic surveying as well as geological mapping, usually was completed in one or two seasons and so necessarily was somewhat sketchy. Then there was a third type, a detailed map on a scale of 4 miles to the inch, embracing a small area in one or other of the coal bearing districts.

Greater Accuracy and Detail.

R. G. McConnell, R. W. Brock, O. E. LeRoy, Charles Camsell and others are mentioned as having ushered in the second period. Brock and McConnell's West Kootenay Sheet was the first map in which the change occurred. It was a four mile map embracing over 6,000 square miles and distingnished by its greater accuracy and detail, the result of more complete traversing, and the application of petrography, which differentiated a number of types of igneous rocks.

"After this" Dr. Dolmage proceeds "came a more distinct change in the class of work undertaken, in the methods employed and, consequently in the results obtained. All of the workers above mentioned devoted themselves to the close detailed study of mineral deposits and their immediate vicinity, and after 1907, it became for a time the policy of the Survey to do this class of work. There resulted a great number of small maps covering a few hundred square miles at most, on scales ranging from a fraction of a mile to two miles to the inch. These were executed in great detail, and, though a topographic division had not yet been estab-

lished in the Geological Survey, accurate contour maps were used for most of this work."

Examples of this type of work are given which, it is stated, was followed by a phase during which, though economic geology still took a prominent part, other branches of the science such as physiography, structural geology, stratigraphy and petrology received much attention. The latter began with Daly's work on the Forty Ninth Parallel. Of this it is asserted that "the undertaking was a large one, the time was limited, adequate topographic base maps were not always available, no geographically trained assistant was employed and the work was confined to a narrow strip along a straight line where outcrops were sometimes scarce and fossiliferous exposures still more rare. These conditions necessitated hasty work with insufficient traverses and, as Daly himself says, the quality of the work lies half way between reconnaissance survey and detailed survey. As a natural result the maps now published on the mile-to-the-inch contour maps of the Boundary Commission do not possess the accuracy they would suggest and already subsequent workers have had to make some important changes in the structure and stratigraphy."

The organization of the Topographic Division of the Geological Survey at about this time, and the excellent contour maps it produced, had a decidedly favourable influence on the geological mapping done. Instances are given of much 4 to 6 mile work, partly of a reconnaissance nature and partly of a more detailed nature. Illustrations also are cited of "two-mile" maps, somewhat more refined and it is said that a great deal of work has been done recently on a scale of one mile to the inch and less, all of which has been done in great detail and with considerable accuracy "although not necessarily directly related to mineralized areas."

The period as a whole is characterized as one in which all phases of geology receive about equal attention. The policy in effect since 1918 is to confine the work to areas of known economic importance or to areas at present within easy reach of transportation. Accordingly Mr. Schofield has mapped the Britannia Mineral Belt lying between Howe Sound and Burrard Inlet. J. J. O'Neill began and George Hansen is completing an area in the Salmon River District of Northern British Columbia. W. E. Cockfield has just published a sheet on a scale of four miles embracing Sixty Mile and Ladue Rivers in the Yukon District and is at present engaged in mapping in the vicinity of Mayo Lake. W. A Johnson has just completed a detailed investigation of the Fraser Delta. Dr. Dolmage himself has completed a shoreline map of the west coast of Vancouver Island from Barklay Sound to Cape Scott which was executed on a scale of one mile to the inch. In 1917 Charles Camsell, now Deputy Minister of Mines at Ottawa, made a geological map of a section along the Pacific Great Eastern Railway from Squamish to Lillooet. B. R. Mackay began and W. A. Johnson will continue a detailed map of superficial geology in the Cariboo gold placer belt in central British Columbia. C. E. Cairnes is completing a map of an area along the Coquihalla River which was begun by Mr. Camsell in 1919. M. F. Bancroft is engaged in mapping a large area in the Slocan District southeast of Revelstoke. J. R. Marshall is continuing the detailed mapping in the Elk River District, eastern B.C., which was previously was carried on by Bruce Rose.

It will be quite clear that the Geological Survey is doing an invaluable work in this Province and that already its records, which are available to those connected with the mining business in the West, are sufficiently extensive to be used more commonly than perhaps is now the case for purposes of reference. The policy recently adopted and in effect means thorough, accurate, and authoritative scientific knowledge of mineralized zones will be obtained when and as such zones are discovered, that the geologist and the topographer will follow in the footsteps of the prospector and that generally the more remote sections of the Province will be subjected to the more refined investigation and mapping as transportation makes their resources more readily available for developments.

INCREASED BUYING POWER OF GOLD.

British producers of gold have had, in the past two years, the advantage of obtaining, in addition to the fixed currency of 84s 11½ per fine ounce, the premium of the American Exchange. This premium reached 42s 4d per ounce, or 50 per cent, last year at about the same time that commodity prices attained high water mark. Since that time commodity prices (wholesale) as ganged by the "Economist's" Index Number, have fallen about 41 per cent, while the sum of the fixed currency price for gold, plus the exchange premium, has declined 19 per cent. (May 18, 1921.). On balance, therefore, the buying power of British gold had risen about 36 per cent. While the price of labor has not, as yet, declined appreciably, there is no doubt that a world-wide reduction of wages has commenced and this movement is likely to become accentuated by the general trade and industrial depression.

In the gold producing countries the circumstances may vary in detail, but the principles are the same.

How seriously the world's production of gold has declined since 1914, notwithstanding the remarkably steady maintenance of output by the Transvaal mines (due largely to the employment of unskilled black labor), is shown by the following figures compiled by the Transvaal Chamber of Mines:

	World output £	Transvaal p. c.
1914	92,854,000	38.3
1915	97,700,000	39.5
1916	95,700,000	41.3
1917	87,040,000	44.0
1918	77,528,000	46.0
1919	73,000,000	48.5

COMMERCE COURSES FOR GRADUATE ENGINEERS.

The demand for engineers with business training has led the Faculty of Applied Science of Queen's University, in co-operation with the Departments of Economics and of Commerce and administration in the Faculty of Arts, to establish a special course of a year's work in commerce for engineering graduates of Canadian universities. The new course will be open to engineering graduates of any Canadian university. The Subjects to be studied will include general economics, business finance and business law, economic geography, the financial organization of society, marketing, accounting, problems of labor, industrial management, business statistics, and business policy.

Among those who will deliver lectures is E. W. Beatty, President of the Canadian Pacific Railway and Chancellor of Queen's.

The New Coal Raising and Screening Arrangements at Jubilee Colliery, Sydney Mines N. S.

By Albert Dawes.[2]

JUBILEE colliery has two shafts, one of which is used for the hoisting of men, the other for the hoisting of coal. The former, locally known as Jubilee "A," was sunk some years ago, to tap two seams of coal approximately 560 ft. and 740 ft. below the surface. The latter, known as Jubilee "B", was sunk between 1914 and 1916. A description of the shaft sinking, by Mr. R. Robertson, is to be found in the Proceedings of this Society for 1917.

There is installed at the "A" shaft a large ventilating fan, and a hoisting engine, both electric driven. Fan ducts and housings are of concrete, and the hoisting engine and fan motor are contained in a substantial concrete building, while a steel headframe surmounts the shaft.

By way of contrast, the surface plant erected at the "B" shaft consisted on its completion, of a wooden headframe and bankhead building, with tipple, screen, and picking belts, taken from the discard of the various collieries, some boilers, second-hand hoisting engines, an antiquated box car loader, and a few shacks scattered at random here and there as shelters for other various equipment required for operating a colliery—all of which was not at all in keeping with the equipment at "A," or commensurate with the importance of the shaft "sinking" then just completed. But all this was put together to serve until such time as the coal mined from the colliery would warrant a larger monetary outlay on better equipment.

The increasing development of the mine underground made necessary the purchase in 1918, of a 3,000 cu. ft. electric driven air compressor, which was erected and housed in a temporary building and placed in such a position that the coal hoisting engine house of the future would contain it as well. This machine is the only redeeming feature of the surface equipment at the coal shaft of this colliery.

The coal output has steadily increased, until it now averages 700 tons per day, and the bankhead, hoisting facilities, and mechanical equipment, are all being severely taxed in taking care of this amount of coal. Every part requires constant attention and continual repairs to keep it in running condition; the number of men employed on all the various operations involved in handling the coal, from the pit bank to railroad cars, is very high; and the all round mechanical efficiency is extremely low—these factors have all added their quota in making the cost of producing coal what it is at the present time.

The question of providing a new bankhead with good coal hoisting facilities was taken up early last year, as the inadequacy of the existing equipment was beginning to be then seriously felt; and when, later, large contracts for coal from this colliery were secured, which it would be impossible to take care of unless additional equipment were installed, the Company authorized the monetary outlay necessary for this purpose.

The new surface equipment, which is now under construction, includes two electric driven hoisting engines (one for each seam) housed in a substantial building; a structural steel pit headframe 90 ft. high; a steel and concrete bankhead, consisting of connecting bridges; an auxiliary tipple building; and a main tipple screen and picking belt building equipped with the necessary machines, electric motors, and other appliances which make up a surface equipment of this nature. It also involves the construction of a railway assembling and distributing yard, a blacksmith and tub-repair shop, a warehouse, and an office.

In the consideration of the general scheme, the size of winding engines, of all machinery, and of structures, had to be based, not only on immediate prospects, but on future possibilities, and for this purpose the future maximum output of the colliery was taken as 2,000 tons per day, or 1,000 tons from each seam. The attainment of this output, either from a mine development or a market standpoint, is probably a matter of a few years, whereas a maximum up to 1,000 tons per day is being looked forward to in the near future. The hoisting engines and house, the pit headframe, and other parts had therefore to be arranged, and equipment made of sufficient size, for the larger output; but, in order to cut down initial cost, only half of the eventual main tipple, screen, and picking belt building, and half of the eventual equipment, is now being constructed. The arrangements, however, are such that duplication of the present half can be readily accomplished when required.

The hoisting facilities, as well as the bankhead, have been designed and laid out in such a way as to provide, as far as possible, the best of equipment for handling the coal from the pit bottom to bank, as well as for its classification and cleaning, and, of special importance, its loading as desired into either hopper or box cars. Provision has also been made for the mechanical loading of slack coal into box cars; for readily bunkering the Company's locomotives; for supplying coal from bins for local purposes; and for the disposal of "stone" or "material other than coal" from the mine and the picking belts.

It will be apparent, therefore, that the new hoisting, screening, cleaning, and loading, plant when completed, will probably have cost more money than is usually expended on similar equipment for the same capacity; and emphasis is laid on this, inasmuchas the larger monetary outlay necessitated by the adoption of these special features might be criticized. But, in order to be prepared to sell all the coal produced from this colliery, whether screened, run of mine, or slack, and to dispose of it readily, either into box cars or hopper cars, it was incumbent to provide facilities as flexible as possible now, so as to be in readiness for the time when they might become indispensable.

The work now under construction involves an estimated expenditure of $385,000. Excavations for foundations commenced in October last, and it was expected that the bankhead would be completed by April; but,

[1] Presented at the Annual Meeting of the Mining Society of Nova Scotia, Halifax April 1921, and reprinted from C. M. & M. I. Bulletin for July.

[2] Divisional Engineer of the Nova Scotia Steel and Coal Company.

owing to various causes, such as promised deliveries not being fulfilled, it now seems probable that the work will not be finished before July. The work is being carried on while the present bankhead is operating, and it is hoped that no stoppage of colliery or reduction of coal output will ensue while construction is proceeding. The change from old to new equipment will be arranged for at a week-end.

When in operation, the new equipment will allow of the number of men now employed being reduced by 20, the expensive upkeep of an old equipment will be eliminated, and the operating power cost will be considerably reduced. The present cost for labour, repairs, supplies, and power, in handling the coal from pit bottom to coal cars, should be reduced 25 per cent, which is equal to an estimated saving of $36,000 per year.

Furthermore, as the number of men required for operating the new bankhead for an output up to 1,000 tons will not be more than for 700 tons, and as the electric power charge for operating at the greater output will obviously not increase proportionately, the cost per ton of coal for an output of 1,000 tons per day should be 35 per cent less than the present cost of handling the coal from the pit bottom to the coal cars.

In order that this saving, or reduction in cost, shall become a reality, it is essential that every mine official conscientiously strive to carry out the intentions of those responsible for the new equipment, and especially to see that, where labour can be displaced, that labour shall stand displaced, and not be merely transferred to some other place, except it be the working face.

The undertaking can be classed under three heads, namely:

The Coal Hoisting Equipment and Building.

The Structural Steel Pit Head Frame.

The Bankhead, which includes the bank around the headframe, the connecting bridges, auxiliary tipple building, and main tipple, screen and picking belt building, and the equipment contained therein.

The Coal Hoisting Equipment.

The coal hoisting equipment consists of two single geared hoists, built by the Vulcan Iron Works, Wilkesbarre, and each designed to raise 1,000 tons of coal per day from the respective seams. These hoists are duplicates with the exception of the size of motors and gear ratios, and that one is arranged right-hand and the other left-hand. They are each driven by Westinghouse A. C. motors of the wound rotor type, built for hoist service, and working from a 2,200 volt, 3 phase, 60 cycle, electric power supply. The motors are respectively 550 H.P. and 350 H.P. for lower and upper seams. The gears are machine cut, herring-bone type, and, working in an oil bath, will be practically noiseless. The drums are cylindro-conical, having a small diameter of 7 ft. and a large diameter of 10 ft.

Besides a powerful main brake of the post type, there is also provided on each hoist an auxiliary band brake which operates on the motor pinion shaft, its function being to absorb the inertia of the rotating parts of the motor, and relieve the gears of unnecessary strains. The two breaks are so inter-connected that, when the main brake is applied, the one on the pinion shaft also comes into action. The latter is also arranged so that it can be applied independently.

The air pressure contained in the cylinder of an auxiliary air engine holds the brake in the off-position, and on being released, applies the braking force through the medium of weights. This force is proportional to the air pressure exhausted from the air cylinder.

The auxiliary engine is also provided with a device which automatically applies the brake in case of power failure, overspeed, or overwind.

The speed of the hoist motor is controlled by varying the resistance in the rotor circuit, this being accomplished by the operation of a small master controller, mounted on the hoist platform. The master controller actuates through magnetic contractors, which are governed by suitable current limit relays. Automatic acceleration which is, to a certain extent, independent of the operator, is thus provided for.

The safety features of these machines are such that: the hoists cannot start in the wrong direction, or overtravel in either direction; the brake will not be suddenly applied on power failure, but it will allow of a full application of brake if required, when limits of travel are reached; the brake cannot fail due to worn brake shoes, or the failure of air supply to the auxiliary engine, or grounded control circuits, and the hoisting or lowering of men can be done at reduced speed; as there are very few levers, an inexperienced operator cannot injure the hoist by improper manipulation of levers, neither is it necessary for him to call for assistance or leave his station to reset the safety devices. These features tend to give the operator complete confidence in the hoist under his control, and at the same time they afford the maximum of safety to the men and apparatus—in this respect more than fulfilling the requirements of any mine law enacted concerning such equipment.

The brick building in which this apparatus is being installed is 97 ft. 6 in. long and 39 ft. 0 in. wide. It has been made sufficiently large to accommodate the present 3,000 cu. ft. electric motor driven air compressor, and also a future one of the same size. The building is of substantial construction, is well lighted, of not unpleasing appearance, and, considering that the whole construction was carried out in winter, is very satisfactory. An overhead travelling crane is being built for erection purposes, and for the handling of heavy parts of machinery, when such might be necessary.

The Structural Steel Headframe.

The structural steel headframe consists essentially of six built-up plate and angle columns, the tops of which support a platform on which are mounted the four head pulleys. The columns are so placed about the mouth of the shaft as to form, with their framing and connecting bracings, what are virtually continuations of the upper and lower seam shaft compartments, in which the coal cages are guided and hoisted to the banking floor.

In the design of pit headframes, the main difficulty is not to determine the strength of columns, struts, and stays, for resisting the bending compression and tensile stresses, but to obtain the necessary stiffness and rigidity, and stability, of the whole structure with the least weight of material to withstand heavy loads suddenly applied and as suddenly taken off; all of which factors are affected by the loads, the acceleration, and the height of the structure.

It is the common practice in pit headframes to have back "stays" to resist the tension of the ropes from drum to head sheave, but in the headframe under construction at the Jubilee colliery there are, instead

front stays, the lower portions of which are anchored to solid concrete foundations, and serve as building columns of the bankhead structure. Hence the weight of that part of the bank structure helps to reduce to some extent the amount of concrete in the anchorage necessary for stability.

This departure from type was made in order to give an uninterrupted passage-way for the empty tubs returning to the bank, and also to avoid complications due to one of the present steam driven hoisting engines obstructing the best position for the feet of back stays. This construction made possible a reduction in the total height of the headframe, and, as tension members are obviously lighter in construction than compression members, it also permitted of a considerable reduction in weight, and hence in cost, of the steelwork.

A system of beams is arranged for supporting the "safety detaching hooks" against overwind. Another set of beams is provided for the chairs or keps supporting the cages at the banking floor, and there will be a substantial stairway leading from the banking floor to the top platform supporting the head pulleys.

As the new headframe is being constructed around the present timber headframe and bankhead, its erection will be attended with difficulties. To facilitate erection, each of the columns is being made in sections.

The total height of the headframe from surface to centreline of head pulleys is 90 ft., and the estimated weight of steelwork, including front stays, is 110 tons.

The Bankhead.

On being hoisted to the banking floor, which is 40 ft. above the ground, the two full coal tubs contained in the cage run by gravity along the connecting bridge and through the "auxiliary tipple building" to the "main tipple house." The coal is there dumped by means of an automatic power driven revolving tipple into two weigh tanks situated below the floor. The empty tubs then continue the down grade into a dip, where a creeper hauls them up a grade sufficiently high to allow of their returning by gravity to the bank, thus making a complete circuit.

The weigh tanks into which the coal is dumped are each equipped with gates operated by air cylinders. After being weighed, the coal is fed on to a horizontal reciprocating conveyor type screen. This screen is supported on rollers and receives a "slow" forward, and "quick" return motion, by means of special driving gear.

The screen is built with three decks, the screen plates of the upper being perforated with holes of sufficient size to allow nuts and slack coal to fall through the middle deck, and this, having plates likewise perforated but with smaller size holes, allows the slack coal to fall through to the lower deck. The coal is thus classified into "screened" on the upper, "nuts" on the middle, and "slack coal" on the bottom deck. The screen is arranged with the usual dead plates for run of mine coal, and with suitable gates through which slack and nut coal may be diverted on to conveying belts or into chutes, as desired, thus giving flexibility in the disposal of products.

At the outer end of the screen, a breeches chute diverts the run of mine or screened coal on to two picking belts equipped with the usual swinging jibs, and so arranged that when in the "up" position they discharge the coal into a feeding bin for eventual loading into box cars by means of a mechanical loader, and when "down," into hopper cars.

The slack coal for loading into box cars, for which a mechanical loader is provided, is conveyed from under the screen on a rubber belt to a feeding bin, the arrangement being such that hopper cars can be loaded when required.

As a market for nut coal is more or less a matter for the future, the conveying belt provided for this purpose will, for the present, serve for conveying small size lump, nut, or slack, coal into a large bin located under the auxiliary tipple floor from whence it can be taken for locomotive bunkering, or for domestic and local use.

The revolving tipple located in the auxiliary tipple building is primarily for the disposal of stone from the mine, and which comes up the shaft in coal tubs. The stone will be dumped into a special stone bin under the floor, from whence it will be discharged into hopper cars for removal to the colliery dump. This tipple will also be used as an auxiliary for coal, for, by means of a suitable gate in the tipple chute, coal may be diverted into the above mentioned large coal bin located under the floor.

The stone taken from the picking belts is to be delivered by means of a bucket type conveyor into the stone bin under the auxiliary tipple floor. With the exception of the picking belts, which will both be driven by one motor, all parts of the mechanical equipment are to have their own driving motors. These are 25 H.P. for the propulsion mechanism of the screen, 25 H.P. for the two picking belts, and 5 H.P. for each conveyor. The countershafting is being arranged so that when the future half of the equipment is added, the picking belts and screen of the new half may be driven by the motor of the other.

For the mechanical loading of coal into box cars two conveyor belt loaders have been purchased from the Ottumwa Box Car Loader Company. These loaders are practically identical except that the one for loading run of mine or screened coal is equipped with a steel conveying belt, whereas the other, for slack coal, is being furnished with a rubber belt. These two machines will each be operated by 25 H.P. alternating current slip ring type motors. All operations of these machines are entirely mechanical. They will permit of the loading of the coal near the centre of the car, or out towards the extreme ends, and, by being able to load close to the floor or high up in the car, coal may be placed in any desired position in the cars. All the motions are power operated, only one man, the operator, being necessary for loading the cars. They are each guaranteed to load at the rate of 150 long tons per hour.

The structural steelwork of the bankhead is being fabricated by the Canadian Bridge Company. All columns of plate and angle section are supported on substantial concrete foundations. The floor system is composed of I-beams, or channels. The trusses, purlins, bracing, and girts are of angles, no thickness of metal being less than 5-16-in. The total weight of steelwork will be approximately 350 tons.

The floors are to be of reinforced concrete, minimum thickness, 4 inches. Triangular mesh reinforcement is being used. That portion of the floor under the driving mechanism of the screen will be about 14 inches thick, in order to present a solid mass against the inertia of the reciprocating parts of the screen.

The buildings are being covered on roofs and sides by 20 and 22 gauge galvanized corrugated sheeting.

and are being furnished with plenty of windows. The latter are generally made to slide back so as to give a full, or part, window opening as desired. In addition, over those portions of the buildings where coal dust is mostly encountered, that is, over the main tipple and the picking belts, Robertson Patent Roof Ventilators will be fixed, so that good ventilation is anticipated during the summer weather.

As the bankhead is built entirely of steel and concrete, and is therefore fireproof, no insurance on either buildings or equipment will be needed. This means a considerable amount saved in yearly premiums, and at the same time it insures against that loss in output which invariably results when a fire occurs on a bankhead constructed of wood.

It goes without saying that colliery bankheads are not usually picturesque, but they can be made so as not to be unsightly. Ruskin asserted that man has no more right to disfigure landscapes with ugly buildings than he has to putrify the atmosphere with obnoxious smells. Bearing this in mind, and that Jubilee colliery is situated in the middle of the town of Sydney Mines, it has been the aim to erect an equipment which will be the equal of the best of its kind, and not unsightly; such an equipment as both the town and the company may be, with reason, just a little proud.

SUDBURY NOTES.

By D. E. CUSHING.

Sudbury.—While many mining men have ignored the Goudreau area, believing that the paystreaks are narrow and patchy, although it cannot be said that sufficient work has been done to show how the viens are at depth, there is considerable more staking going on there than most realize. An area extending for two miles wide and for six miles east and west, with the Murphy claims as the centre, has practically all been taken up, while in the vicinity of the McCarthy-Webb claims considerable staking has also been done.

Practically all the area wherein the staking is taking place, is owned by the Algoma Central Railway. C. H. E. Rounthwaite of the Lands Department of the railway recently visited the area, he reports that most of the holders of claims are working them to the limit.

Probably the most satisfactory results have been achieved on the Murphy claims where at 14 feet, a good grade of ore was found to continue, although nothing startling has been accomplished. The Keeley claim, a find reported some weeks ago, has not lived up to the first claims made for it, in that very little free gold has been found. Keely is hard at work however and may produce results yet.

The A. C. R. man stated that there is no great rush to the district. He says that some free holders of claims are not working them and are holding them for a boom or rush.

However the outlook for a boom is remote. Money is too tight for anyone to go into a district that has not been worked and shows no result, when there are so many excellent properties in other camps open for purchase.

The Silver Islet Exploration is meeting with encouraging results. The long drift, being run on the fourth level to cut the dyke which contained the excellent silver values when the property was worked years ago, is now in close to 400 feet. The first favorable sign which was encountered was a calcite stringer carrying pyrites. Later a stringer carrying galona, zincblende and pyrites followed and the work has just passed a number of six inch calcite stringers, all containing the above minerals with the addition of silver, the first to be encountered. The chief encouragement however, is not the amount of silver contained in these stringers, but the fact that the whole area cut through is well mineralized. Records of the old work also show that it was just in such a formation in the old workings that the high silver values were met with.

All in all, those in charge of the work are daily becoming convinced that their hopes are soon to be realized. The drift is to be continued for at least 1,200 feet.

The shaft at Edward's Island, nine miles east of the silver Islet is now in massive arsenical silver at a depth of over fifty feet, this having continued from surface. The work is also being done by the Silver Islet Exploration and it will continue sinking for some time before lateral work is undertaken.

The International Nickel Corporation has followed the lead of the British American and Steel Co's. shop. The result is that in a very short time Copper Cliff and Creighton like Nickelton, will be almost abandoned. Only the Mond Nickel remains in the operating field.

It is not surprising that the International has closed. It was piling up a tremendous stock of raw material, the overhead charges of which might easily eat up a good portion of the profit in a low priced market which, it would seem, will obtain for the next couple of years. At Copper Cliff, Port Colbourne and at its big refinery in the States, the International has a heavy stock in the various stages of treatment. At Copper Cliff the one oven operating could not handle or keep pace with the underground production with the result that besides the make on hand there is also a large tonnage of broken ore on surface awaiting treatment.

The outlook for the International however, is brighter than for the others, inasmuch that the Corporation expects to have its new steel plant going in the U. S. by next spring, and its demand on the product of the mine will, it is said the officials believe, mean that the mine will be obliged to resume in about three months after.

Over 400 hands were laid off when the plant shut down.

NEW CRAWLING TRACTOR CRANE.

In our issue of the 26th, of last month, an error inadvertently crept into a paragraph relative to the new crawling tractor crane which Industrial Works, of Bay City, Michigan, have added to the crane family for which they are noted. The paragraph in question stated that the type BC had a capacity of 2,000 lbs., at 12 ft. radius. This is an error which we have no doubt was obvious to many of our readers. The type in question has a capacity not of 2,000, but of 20,000 lbs. at 12 ft. radius, equipped with continuous crawling tractor belts, while the other type—type BT—in which the crane is built, has a capacity of 18,000 lbs. at 10 ft. radius equipped with four broad gauge tractor wheels.

This new crawling tractor crane has been developed to meet the need for a full-revolving tractor crane which can be operated independently of rails.

LAKE SHORE.

Lake Shore treated 1,967 tons or in July yielding $49,155, an average of $24.99 per ton.

BLACK LAKE ASBESTOS.

Further information concerning the affairs of the Black Lake Asbestos & Chrome Co. has been made public by the President, J. A. Jacobs, who explains that sales have fallen off seriously of late. There is, nevertheless, still a good surplus of liquid capital. Mr. Jacob's letter is as follows:—

"At the meeting of directors of the above named company, held August 11, reports on the company's operations and financial statement for six months ending June 30, 1921, were submitted and approved. After careful consideration it was decided not to pay the interest coupons on the income bonds due Sept. 1, 1921, as the company had not earned same.

"Since the new Board of Directors was elected last March, a general business depression occurred which was unexpected. The sales of the company's product was less than 40 per cent of the previous six months, although the production at the mine has greatly increased, and it therefore required considerable financing to keep the mine operating.

"Extensive repairs, alterations and extensions have been made to the mine buildings and plant, and a sum amounting to over $52,000 has been spent to date. An additional amount of about $13,000 has been expended on new developments with satisfactory results.

"The mine is now being operated at a considerable saving in costs, and we have every reason to believe that as soon as business improves the earnings will be more than sufficient to take care of the income bond interest.

"The company's financial position is as follows:

Quick assets	$363,186.23
Current liabilities	91,372.60
Surplus	$271,813.65

Some description of the mining methods at Black Lake is given by Mr. W. D. Hubbard in an article on the Black Lake Asbestos area, written for the Engineering and Mining Journal. Mr. Hubbard writes in part: "Mine and mill are situated near the top of a serpentine ridge about 400 ft. higher than the railroad. A dirt road about a mile long serves for transportation. Pits are sunk in the side of the hill. The largest of these, No. 9, is about 150 ft. deep by 500 ft. long and 200 ft. wide. The entrance is 300 yds. from the mill hoppers.

"The mill itself stands on a level about sixty feet below the bottoms of the deepest pits. It is rated at 850 tons' daily capacity and is supplied from bins built below the tracks leading from the various pits. The primary bin will hold about 350 tons. A machine shop stands above and to the west of the mill, the tracks from the pits leading directly into it. Practically all the local repair work of the mine is performed in it.

"Operations in the pit are about as follows: The rock is drilled by tripod drills, holes averaging about twelve feet deep. These holes are spaced about eight feet apart and twelve feet from the wall, breaking the rock in benches. Large chunks too small to be hoisted separately are blockholed with plugger drills. None of the drills require water, as the rock is comparatively soft. Broken rock is hoisted by nine cable derricks, the reason for this large number of hoists being that, although a cable derrick is almost unlimited in longitudinal reach, it is decidedly limited laterally. Hence to cover the whole pit efficiently many derricks are used. Each derrick has a separate electrical hoist, which means that there are nine hoistmen. These hoists are situated back from the edge of the pit, and consequently the hoistman cannot see when to raise and lower his boxes. This necessitates having men stationed at the pit edge to signal the hoistmen. One signaler is sufficient for two derricks and one man dumps the boxes from two derricks. Three to four men are employed shovelling rock into the boxes. Three boxes are used with each derrick, enabling each hoistman to complete between ninety and one hundred loaded trips per ten-hour day. The boxes hold a ton and a half, and three of them fill a car.

"As the cable derricks cannot cover the whole pit without an almost impossible network of cables, a steam crane is used to pick up boxes in places outside of the cables' reach. This crane runs on a track about twelve inches wider gage than the ore trains, which necessitates an extra rail coming into the pit. It also limits the usefulness of the crane, because the new track has constantly to be laid.

"It can be seen from the above that the minimum number of men working in the pit under normal conditions would be distributed as follows: Number of hoistmen, 9; number of signalers, 4; number of dumpers, 4; number of loaders (3 to each derrick) 27, a total of 44, not including trip-riders, cranemen, bosses or engineers.

"The hoist motors for each derrick are electric and are rated at fifty horsepower. The horsepower of the crane is not known, but it must be at least seventy-five. This gives a total of 525 hp. It would seem that two electric shovels could reduce costs and speed up operations to a marked degree."

COAL MINING EQUIPMENT NOW MADE IN CANADA.

The Canadian Austen Machinery, Limited, of Woodstock, Ontario, in addition to manufacturing in Canada the complete Austen line of earth-moving and concrete-mixing equipment, also announce the addition of the Fairmont Mining Machinery Line, which is the most complete organization in America devoted to the manufacture of coal mining equipment exclusively. It is a particularly opportune time, in view of the development of the Canadian Coal Mining Industry, that the various companies operating throughout Western and Eastern Canada can secure from a Canadian manufacturer such a full line of equipment necessary to their requirements.

Among the lines manufactured are Steel Mine Ties, Portable Gallery Pumps, Railroad Box Retarders, Box Car Loaders, Power Coal Augers, Mine Cars, Steel or Wood Mine Car Trucks, and the well-known Fairmont Tipple Equipment.

LICENSING OF MINING ENGINEERS.

An endeavor to secure expressions of opinion on "Licensing of Engineers" has been made by a committee of the A. I. M. M. with the result that only five were found who are unconditionally in favor of the licensing system. Only 128 letters were received in response to the request for opinions and of these 81 are unconditionally opposed. Twelve would favor uniform state laws with reciprocity or general Federal law. Four would accept licensing as a matter of expediency and would join in attempting to steer legislation. The committee would recommend that independent action be not taken, but that the society co-operate with others to oppose licensing legislation.

A VISIT TO ANYOX.

Mr. Geo. Mackenzie, secretary of the Canadian Institute of Mining and Metallurgy, describes in the August bulletin of the Institute his recent visit to the Granby copper mine and smelter at Anyox. He says in part: "Arriving in Anyox, I was greeted by a fair day and also by Mr. E. J. Conway, Chairman, and Mr. H. M. Roscoe, Secretary of the North Coast Branch. Mr. Roscoe then took me for a tour of inspection through the smelter and power plants, and from there we proceeded to the Hidden Creek mines, where I was shown the shrinkage method of working large ore bodies on a grand scale. It is beyond me to attempt a description of the Hidden Creek mine in these short notes. I will merely say that to anyone interested in the cheap mining of large ore deposits the methods pursued at Anyox are inspiring and instructive. During the month of May some eighty-eight thousand tons of ore were delivered to the smelter and while it is improbable that this will be equalled in June, an inspection of the mine gives one the impression that if pushed for production the mining staff are in a position to smother the smelter with ore on comparatively short notice. One of the large stopes I was in was simply awe inspiring. The great width and length of this opening, containing not a stick of timber, gives one the impression that a glory hole has been turned upside down; and then, when one climbs through where an old stope has been opened to the surface, one gets an idea of the size of the ore body that has been extracted. The smelter is supplied with coke from a by-product plant situated in the town of Anyox, and the coke is made from a mixture of 85 per cent Cassidy and 15 per cent Alberta coal. The by-products, consisting of ammonium sulphate, tar, and benzol (the latter excellent for motor fuel), are produced in considerable quantities. The by-product ovens are of the American type, and the whole plant is a model of excellent design, and is operated with a minimum of trouble. On the evening of June 9th, a meeting was held in the Community Building, where I gave a short talk concerning Institute matters, and presented eight or nine lantern slides descriptive of the interior economy of the Institute. On Friday, the 10th, I prowled about the mine and coke ovens in company with Mr. Roscoe, who generously gave me a great deal of his time in order that I might not miss anything of interest. After a most enjoyable evening, with the Elks, I was lifted bag and baggage and transferred by Mr. J. A. Bancroft to his private residence, where I was most graciously entertained by Mrs. Bancroft and her lesser half. Buster Bancroft is right into the smelting copper business up to his neck, and roams around Anyox from one end to the other—goodness knows how many times a day—all dressed up in his khaki working clothes from seven o'clock in the morning until five o'clock at night; and what's more he appears to like it. I really believe he does like it, because he is always smiling, and I would like to bet that if any copper ore at Hidden Creek evades being smelted it won't be Buster's fault. I met Mr. H. S. Munro, the General Manager, for a few minutes only, on Thursday, as he was leaving on the same boat that brought me in. He, however, assured me that I could roam to my heart's content, and that I was in capable hands with Messrs. Bancroft and Roscoe.

TORONTO MINING QUOTATIONS.

Quotations on Active Stocks on Standard Stock Exchange on September 6th, 1921.

Silver	High	Low	Last
Adanac Silver Mines, Ltd.	2	2	2

SAWARD'S ANNUAL.

This standard statistical review of the coal trade has appeared for 1921, and continues publication of an annual that is considered a necessary desk companion of all those interested in the coal trade in North America. Price is $2.50 per copy, bound in red cloth, and obtainable from the compiler, F. W. Saward, at 15 Park Row, New York.

METAL QUOTATIONS.

Following are the fair average prices for ingot metals (in less than car-loads):

Toronto.	Cents per lb. Aug. 31st	Sept. 7th
Copper, Electric	17	17
Copper, Casting	16¾	16¾
Tin	35	35
Lead	6¾	6¾
Zinc	7¼	7½
Aluminum	27	27
Antimony	9	9

Montreal.	Cents per lb. Aug. 31.	Sept. 7.
Copper, electric	17	17
Copper, casting	16¾	16¾
Tin	33½	33½
Lead	6¼	6½
Zinc	7	7
Aluminum	28	28
Antimony	7	7

TORONTO COAL PRICES.

Toronto, 7th Sept. — Coal prices remain absolutely unchanged. So far as lump coal is concerned there is a little more tonnage being placed, and the situation gives indications of further improvement. Slack is still rather scarce. The demand for anthracite is on the upgrade, so far as Toronto is concerned, but is still not of the magnitude that it should be at this season of the year, and this latter remark is applicable, with greater emphasis, to other points in the Province.

PERSONALS.

Mr. Bernard Cripps of the engineering staff of the Hollinger had his foot badly mangled when he jumped from a moving train near Aurora. It was necessary to amputate all the toes on one foot.

A party of American geologists from Michigan is visiting the Sudbury and Cobalt districts this week.

HUDSON BAY.

The mill at the Hudson Bay silver mine is again in operation, treating about sixty tons a day.

INTERNATIONAL GEOLOGICAL CONGRESS.
To Be Held In Belgium In 1922.

At the meeting of the International Geological Congress in Canada in 1913 it was decided to hold the next Congress in Belgium in about three years time.

The Belgium Committee of Organization has just issued a circular in which they say:

"The brutal invasion of our soil in disregard of agreements, the ruin and destruction caused by the war, the distress of the whole country have caused the prolonged adjournment of the meeting. But sympathetic requests, coming from all quarters, have induced us to delay no longer.

"In the name of the Committee of Organization, we have the honour to inform you that an International Geological Congress will be held in Belgium during the second part of the month of August, 1922, and to invite you to take part therein.

"Excursions will take place before, during and after the session; they will extend to all parts of our country, of which the geological features are so varied and have already been studied in great detail.

The President of the Congress is M. Jean Lebacqz, Director General of Mines, and the Secretary is M. Armand Renier, Director of the Geological Survey. Circulars concerning the Congress may be had by addressing the Secretary, Palais du Cinquantenaire, Brussels.

PRODUCTION OF UNITED STATES ASPHALT INCREASES.

The quantity of native asphalt and native bitumens sold in the United States in 1920 was 198,497 short tons, valued at $1,213,908, according to the United States Geological Survey, Department of the Interior. This was an increase of 125 per cent in quantity and of about 78 per cent in value over 1919. Gilsonite was reported from Uinta County, Utah, wurtzilite (or elaterite) from Duchesne County, Utah, and grahamite from Pushmataha County, Okla.

The sales of manufactured asphalt obtained from domestic petroleum amounted to 700,496 short tons, valued at $11,985,457, or $17.11 a ton. Compared with 1919 these figures indicate an increase of 14 per cent in quantity and 37 per cent in value.

The sales of asphalt manufactured in the United States from Mexican petroleum in 1920 amounted to 1,045,779 short tons, valued at $14,272,862, or $13.65 a ton. This was an increase of 55 per cent in quantity and of 85 per cent in value over 1919.

SOME FIRES IN MINING CAMPS.

During the past few weeks of unusually hot weather, mining and lumbering camps in Northern Ontario have to a large extent escaped serious damage by fire. Experience in other dry summers has resulted in much clearing around all camp buildings and in better fire fighting equipment in towns and at mines. The great heat has, however, made the forests ready for fire and numerous bush fires are reported. Two weeks ago the transmission line of Associated Gold Fields was damaged by fire, but was soon repaired. Fire threatened the plant at Raven Falls, but was successfully fought there. At Bourkes, fire has destroyed some of the buildings of the Bourkes Mining Co. The Argonant mine suffered from fire a few weeks ago which damaged its mill. Considering the very dry weather, however, and the large number of small fires, the mining districts have not suffered very heavy damage.

MINING TANKS MADE IN TORONTO.

Among mining men one often hears high, and, one may add, deserved, encomiums passed on the Toronto Mining Tanks manufactured by the Ontario Wind Engine and Pump Company, Ltd., of Toronto, and with branches at Calgary, Regina, Montreal and Winnipeg. Those in a position to know speak enthusiastically of the service given by these tanks—a service which they attribute, first, to the excellence of the material from which they are built, and, secondly, to the first-class workmanship that goes into their construction.

These tanks are specially constructed for the Cyaniding process. They have to retain heavy and precious liquids as high as 80 lbs. pressure to the cubic foot. They are made of British Columbia Fir, Redwood, Gulf Red Cypress, and also in White Pine. All Toronto Tank stocks are air-dried. This process necessitates a greater expenditure of time than does kiln-drying. But it means longer life and superior material in every way—for it means absolutely and perfectly seasoned material.

The Ontario Wind Engine and Pump Company, Ltd. not only manufactures agitator and thickening tanks, but also supplies tanks for Water Supplies, or any other purpose for which tanks are needed, in any shape or size or kind of wood.

It may be added that Toronto Mining Tanks have been supplied to the Dominion Reduction Company, of Cobalt, Ont.; the Shumacher Mines, of South Porcupine, Ont.; the McIntyre Mines, Ltd., of Porcupine, Ont.; the Kerr Lake Mines, Ltd., of Cobalt, Ont.; and many others.

CROWN RESERVE.

On the Crown Reserve claims at Larder Lake a number of men have been engaged in surface exploration this summer. It is said that some diamond drilling will be done by the company.

ASSOCIATED GOLDFIELDS.

Development of the Kerr Addison orebody is being steadily carried on by Canadian Associated Goldfields at Larder Lake. The shaft is being deepened and lateral development is under way.

Hollinger will pay a dividend of 1 per cent Sept 9. This makes a total of $2,214,000 so far this year.

EDITORIAL

MR. GRAY ACCEPTS IMPORTANT POSITION.

Rarely does a publisher enjoy the services of a man of such excellent qualifications, both from training and experience, as are combined in Mr. F. W. Gray who has just resigned his position as editor of the Canadian Mining Journal and of Iron and Steel of Canada.

The fields of these two journals, while in a sense distinct, are yet so closely related that it is a distinct advantage to have the editorial work in the hands of a man who so thoroughly appreciates the various situations in both industries and can immediately make the most use of changes in conditions which he, as a leader and moulder of opinion, must be able to do if the journal is to function at its maximum efficiency. The Industrial and Educational Publishing Company takes this opportunity to express its very deep and hearty appreciation not only of Mr. Gray's exceptional ability but also his untiring, conscientious efforts to serve in every possible way, the best interests of Canada's mining and metallurgical industries.

Mr. Gray was born in England and came to Canada in 1904 when he entered the services of the Dominion Coal Company and remained with them for 14 years, holding the position of confidential assistant to various general managers. He received his early practical experience in the South Yorkshire coal mines under the late G. Blake Walker who was also recently President of the Institute of Mining Engineers. In 1918 Mr. Gray went with the Nova Scotia Steel and Coal Company where he remained until he became editor of the Canadian Mining Journal and Iron and Steel of Canada in 1919. Mr. Gray's work has brought him in constant contact with the steel industry and this with his studious disposition, has made him a master of many phases of that great industry. He is a thorough optimist with regard to the future of Canada's mining and metallurgical industries. He has made careful studies of Canada's fuel supply from every phase of that subject and has contributed many valuable papers to the scientific organizations to which he belongs, principal among which may be mentioned the Institute of Mining Engineers, Canadian Mining Institute, and the Engineering Institute of Canada, of which society he has been a council member.

Mr. Gray's outstanding ability has naturally brought him many opportunities for industrial positions and it was his good fortune to be offered the position of Assistant to Mr. D. H. McDougall, Vice-President of the British Empire and Steel Corporation.

The publishers of Mr. Gray's magazines because they have indeed acquired a character due to his inspiration and contact, wish him every success in his new work. Fortunately for those with whom he now severs his business connection, Mr. Gray will continue to reside in our community.

THE BLUE DIAMOND MINE.

Owing to the fact that the Blue Diamond coal mine is controlled by companies which have a large number of shareholders, the story of its development is of exceptional interest, and considerable space is given to it in this number of the Journal. The mine is the property of the Blue Diamond Coal Company Ltd., and the whole of the capital stock of this company is owned by McIntyre Porcupine Mines Ltd. and Temiskaming Mining Company, Ltd.

The venture of these Eastern gold and silver mining companies into the Western coal mining business has been the subject of much comment, favorable and unfavorable, as might naturally be expected when it is borne in mind that comparatively few of the several thousand shareholders of the holding company have been previously interested in coal mining in Alberta. Diverse views as to the policy of expansion of opera

tions are to be expected, regardless of the fact that the life of most mines is short, for some of the shareholders have little desire to take part in the making of new mines, while others are chiefly interested in mining enterprises, because of the chances of making large profits by taking the risks that development of a new mine necessitates. The latter group of shareholders will probably find in the report, information that will give them much satisfaction, while the other group will merely see, in the statement of "profit and loss", evidence that the investment was unwise.

Some of the difficulties that have been encountered and overcome are set forth fully in the report. The statements concerning labor difficulties are particularly interesting, since they record happenings in a very trying time in the history of industrial enterprises.

The story of the development and equipment of the mine and of the preparation being made for increasing the output to 2,500 tons per day shows that much good work has been done, and that the company intends to have one of the big coal mines of Alberta. Particularly pleasing are the statements concerning the quality of the coal opened up during the year and the favor of the mine product has found with the railways.

President Bickell and his associates are to be congratulated on their enterprise. We hope for them that they will be as successful in the coal mining business as they have been in gold mining.

GOLD MINING IN SOUTH AFRICA DECLINING.

The thirty-first annual report of the Transvaal Chamber of Mines, covering the year 1920, contains a wealth of information concerning the gold mining industry of South Africa, the world's greatest gold-producing country. The Chamber of Mines is an active body having held a total of 420 meetings, during the year,—four general meetings, forty-five executive committee meetings and 371 sub-committee, etc., meetings. Its activities are such that the Chamber has a great influence on the industry. Its reports are authoritative and present an exceptionally good summary of the results obtained during the year.

It is because of these facts that unusual interest is attached to the address of the president, in which he states, in moving the adoption of the report, that "it has to be recognized that gold mining in the Transvaal is at present a shrinking industry. Every year since 1916, when the production was 9,295,538 oz., the output has been smaller than that of the previous year; and this year's production of 8,154,172 oz. is the smallest since 1910."

To a considerable extent the decrease is due to natural causes which cannot be affected by the action of operators, for mines must be worked out sooner or later. It will be possible to prolong the life of some of the mines, if the cost of living continues downward and permits decrease in wages, and some of the mines will produce large quantities for years at present costs, but several mines are operating at a loss and the Simmer Deep, Knights Deep, Jupiter, New Heriot and Princess Estate are closed down. It is obvious that the cost of mining in South Africa is not leaving a sufficient margin of profit and that the workmen will have to be satisfied with less wages if they wish the gold mining industry to prosper.

The gold mining industry of South Africa is one of large magnitude, and it is to be hoped that means will be found for greatly extending its life by increased efficiency and lower costs. The war time costs and the period of high wages which followed the war have been hard on the industry, and will prove to have been hard on the employees, if they do not meet the operators half way in the attempt to put the industry again on a sound basis. There were employed during 1920 by the mining companies operating in the Transvaal 20,821 whites and 175,128 colored workmen. There was milled during the year 24,096,277 tons ore yielding 7,949,585 oz. gold, or about one half the world's output. To maintain this output is a difficult task, and the best that can be expected is that the co-operation of owners and labor leaders may be obtained in an effort to prevent the production from declining rapidly.

DR. R. C. WALLACE.

The resignation of Dr. R. C. Wallace, Commissioner of Northern Manitoba, took effect on September 1st. His successor has not yet been named.

When the post was created, a few years ago, and Dr. Wallace was appointed, it was believed that Northern Manitoba would benefit greatly. Results of his work were soon apparent and much was done in the way of obtaining and publishing reliable information concerning the natural resources of the very large area that came under his supervision. Our correspondent at The Pas, which has been Dr. Wallace's headquarters, tells on another page something of the nature of his work. As a pioneer in new ground the first commissioner gained the confidence of men interested in mining, pointed out opportunities and helped prospectors and mining companies in many ways. He returns now to his work at the University of Manitoba, and his interest in the Northern part of the province will leave its mark on his students and associates there.

The successor to Dr. Wallace has not yet been named. It is to be hoped that there will be no let up in the work begun by him. An active Commissioner can do much towards helping in the development of resources.

While licensing of engineers appears to meet with little favor among mining engineers, there are now nineteen states which require engineers practicing within their borders to be licensed and sixteen other states have such laws under consideration.

INSTITUTE MEETINGS.

Two meetings are being held this week that will interest a numer of mining engineers. At Edmonton the Western branch of the Canadian Institute of Mining & Metallurgy is holding its annual meeting. At Wilkes-Barre, Penna., the American Institute of Mining & Metallurgical Engineers is holding its semi-centennial meeting. It is unfortunate that the meetings clash; but, owing to the distance apart of the places of meeting, this should not affect the attendance at either seriously. A number of Easterners will be much interested in the Edmonton meeting, but will be unable to make the long trip. The Journal is making arrangements for a full account of proceedings.

REPEATED SHUT-DOWNS OF COKE OVENS.

In "Iron Age" of 14th July appears a useful and practical article by J. M. Hastings Jr. recording a series of frequent shut-downs of by-product coke-ovens which occurred at a plant near Wheeling, W. Va., and by reason of the taking of proper precautions resulted in no injury to the oven linings. It has long been a tradition among coke-oven operators that if a battery of ovens were allowed to go cold, heavy repairs would be required to remedy the damage resulting from contraction, and it has often been necessary to incur heavy expenditure to maintain sufficient heat in by-product ovens to prevent the consequences of shutting-down the ovens completely. The type of oven, and the provision of ties and stays permitting adjustment to varied stages of expansion and contraction, is probably a deciding factor, and, where the necessity for shut-downs is apprehended, it would appear advisable to give consideration to this point. Mr. Hastings' article is reproduced in this issue.

EDITORIAL NOTES.

While development of mineral resources in Canada is largely dependent on outside capital, we make a better showing than South Africa in the case of gold mining. According to Sir Lionel Phillips, practically all the money provided for the development of the mines of the Transvaal, until a production of 200,000 oz. a month was reached, came from overseas. In Canada considerable sums of money have been raised for development of mines, though we are still very largely dependent on United States capital.

The Federated American Engineering Societies has developed an employment service that is reported to be of great service to engineers and employers of engineers. About one hundred men are placed each month.

Reports from Cobalt indicate that good results are being obtained in development work at some of the mines. Such results if accompanied by a rise in the price of silver will lead to renewed activity in the silver area.

Mr. JAMES A. RICHARDS.

Mr. James A. Richards, Inspector of Mines of Alberta, being, says the Bulletin of the Canadian Institute of Mining and Metallurgy, the son of a Cornishman, it would be difficult to say whether he chose mining as a profession, or whether mining had already adopted him as one of its own long before he was capable of making any conscious choice. In either case, he has worthily upheld the traditions both of Cornwall and of the mining profession. For a period of more than thirty years he has had a rich and wide experience in most of the important coal-mining districts in British Columbia and Alberta, and his advancement in the profession has marched step by step with the rapid development of the coal-mining industry in these provinces.

Mr. Richards' father removed from England to Canada in 1884, and five years later, young Richards, having then left school, came out to join his father in Wellington, B.C. There he obtained employment at the mines, and almost from the first had the good fortune to work under the late Mr. Alexander Sharp, from whom he received his first real instruction in mine surveying and general mining engineering. Richards proved himself an apt pupil, with the result that, in 1893, he was placed in charge of mine surveys at the Wellington collieries, a position he retained for the following six years. At the end of that period he went to Nanaimo as Assistant Surveyor, and two years later, in 1901, he received further promotion and was placed in charge of survey work at the mines there. This position Mr. Richards relinquished in July, 1904, to accept an appointment as fireboss at Cumberland, where he remained until 1907. From there he went to Michel, in the Crowsnest, but within three months of his arrival there, he was offered, and accepted, the position of Manager for the Royal collieries at Lethbridge.

Thus, after eighteen years very active work in the collieries of British Columbia, Mr. Richards crossed the Rockies into Alberta, and he has been true to his new love ever since. He remained at the Royal collieries until 1909, and then, during the following five years, was in charge, as manager, of various mines in the Edmonton and Lethbridge districts, until, in 1914, he was appointed District Inspector of Mines for the Province of Alberta; at first in charge of the Crowsnest Pass district, then in the Calgary district until April, 1916, when he was transferred to the Edmonton district. Mr. Richards continued in charge of this district until 1918, in which year further promotion came with his appointment as Senior Inspector of Mines for the province; and in 1920, during the absence through ill-health of Mr. J. T. Stirling, the Chief Inspector, he very ably filled the breach and became Acting Chief Inspector. In addition to field-work, Mr. Richards' official duties have included, since 1917, the important task of compiling the Annual Report of the Alberta Mines Branch.

ACCIDENTS IN IRON MINES.

Reports received by the United States Bureau of Mines from operators of iron mines throughout the country show that accidents in the year 1920 resulted in 106 deaths and 9,072 non-fatal injuries. The figures represent decreases of 33 fatal and 26 non-fatal accidents as compared with the previous year. The iron mining industry employed 45,990 men. The figures indicate a fatality rate of 2.34 and an injury rate of 200.49 per 1,000 men employed.

Losses from Leakage in Compressed Air Lines and Apparatus with some notes to their Detection and Prevention

By F. A. McLEAN, Assoc. M.C.I.M.M.

Very few people fully realize the extent of the losses due to leakage of compressed air; yet a hole one-eighth of an inch in diameter will cause the loss of more than 25 cubic feet per minute, or enough to run a small riveting, chipping or caulking hammer; a quarter-inch hole will allow over 100 cubic feet per minute to escape, or enough to run a fair-sized air hoist, large air tool, or a modern self-rotating hand hammer-drill or stoper.

Leakage from holes as large as 1/8 or 1/4 inch can hardly go unnoticed very long, but a multitude of smaller leaks may remain undetected for some time and yet waste as much, or even more air than two or three large ones. The importance of frequent inspection of air lines is evident from a little study of the following figures, showing the actual cost of leakage losses from small holes in dollars and cents per year.

If we assume that 1 cubic foot of air per minute at 100 pounds pressure from a motor-driven compressor costs $5.00 per year, with electricity at one cent per Kw. Hr. (a figure that will be too low in some cases) interest and depreciation at 10%, and a year has 300 eight-hour working days, a 1/64" hole will waste .40 cubic feet of air per minute, or $2.00 worth a year, a 1/32" hole 1.61 cubic feet per minute or $8.00 worth a year, and a 1/16" hole 6.45 cubic feet per minute, or $32.00 worth a year. Further calculation of the possible losses through leakage in air lines may be made by applying the above constant to the discharge volume shown in the table in Figure 1.

Where leakage is suspected, the compressor may be run during noon-hour, or at some other period when the machines or tools are idle, in order to determine how many r.p.m. it must make in order to take care of leakage alone since, when the machinery is idle no effective work is being done. If it requires 50 r.p.m. of the compressor to keep up the pressure with all machines idle, it is evident that if the compressor is normally run at 200 r.p.m. only 150 r.p.m. are actually furnishing air for efficient use, the other 50 r.p.m. merely compensating for leakage. Where such conditions exist, the obvious remedy is to find and stop the leaks.

Method of Detecting Small Leaks.

There are a number of rough and ready methods for detecting small leaks, one of the oldest being a lighted candle held at the pipe joints, hose connections or other suspected points. Soapy water swabbed around the joints is also quite effective and reveals the presence of escaping air by bubbling. Another method is to inject some substance with a strong odor, such as oil of peppermint, into the air lines and then have the pipes inspected. The location of the leaks will then be revealed by the odor. Pipe lines may be tested for drop in pressure from leaks or friction during transmission, by placing a gauge near the point of use and comparing its reading with that of the gauge on the receiver.

Losses From Worn-Out Equipment.

If we multiply the figures covering the cost of small leaks in dollars and cents per year, as previously given, by the number of leaks likely to be found around the average plant and add to this the loss of time and inconvenience caused by too low a pressure at the tool, it is easy to see that leaks are rather an expensive proposition; and when one stops to consider that losses from worn-out equipment with its high air-consumption and low power are likely to be just as costly, the value of some simple and reliable means of detecting these losses is apparent.

Practical men can judge the work performed by drills, tools and other pneumatic appliances, but there is no way of "judging" when the air consumption of individual machines becomes excessive. The rated consumption of an air tool or appliance may be exceeded

by 100% or more and yet the device will work fairly well. Losses of this kind are not as easy to find as those in pipes, hose couplings, etc., which manifest their presence by the air of the lighted candle, soapy water, etc., and the only accurate way of detecting them is to measure and compare the actual volume of air consumed by the tool with the manufacturer's rating.

There are various types of air meters on the market, among which may be mentioned, the Westcott, the St. John, and the more recently developed New Jersey. The latter, on account of its simple, rugged construction, reliability in operation and the convenience with which it may be moved about, is particularly adapted to use around the machine shop or foundry, on construction jobs and in mines and quarries.

The New Jersey Meter — Fig. 2 — is unique in that it has only one moving element which floats on air and is practically frictionless and non-wearing. There are

Fig.2.
A small Air Meter designed for use with small drills and pneumatic tools, and hence called a Tool-Om-Eter.

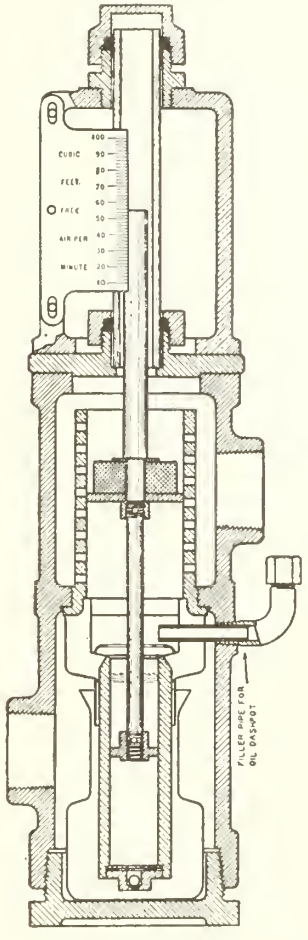
no rubber or leather discs, pockets or diaphragms, bearings, gears, valves or other parts to wear, break, leak or get out of adjustment and change the accuracy of the instrument, nor, it is claimed, can it be put out of order by a flow of air in excess of its measuring capacity.

Corrosion is taken care of by bronze parts where necessary, and the meters are supplied in two sizes with 1'' and 2'' inlet and outlet connections. The 1'' size, or Tool-om-eter as it is called—Fig. 3— is suitable for use where the flow of air to be measured does not exceed 100 cubic feet of free air per minute at pressures of 100 pounds and under. Its principal application, as indicated by its name, is in connection with the measurement of air consumed by various pneumatic tools, such as riveting and chipping hammers, metal-drilling and wood-boring machines, sand rammers, plug drills, and other pneumatic appliances rated by the manufacturer at not over 60 to 100 cubic feet of air per minute when new.

The 2'' New Jersey Meter, is called Drill-om-eter and has a capacity of 300 cubic feet of free air per minute at 100 pounds and under. It is adapted to metering the air consumed by mounted rock-drills, coal cutters and punchers, sand blasts, air-lift pumps, air hoists, pile drivers, air motors, submarine drills, etc., where the actual consumption is not over 300 cubic feet per minute.

Principle of Operation.

The volume of a definite compressed fluid or gas,



PATENTS PENDING

Fig. 3.
Cross-section of the new Jersey Air Meter showing operating principle and simplicity of construction.

flowing under a small constant head through multiple orifices of the same shape and size, is directly proportional to the number of orifices exposed to the flow, and it is this principle or natural law that is made use of in the operation of the New Jersey Air Meter.

In operation, a small head or difference of pressure is established between the interior of the cylinder and the outlet chamber, the pressure difference (but a few ounces) being fixed at the exact weight of the single moving element and the area of the pistons on which the difference of pressure acts. (See Fig. 3.) The moving element rises until its weight is exactly supported by the difference in pressure; the pistons and rod are then floating in a static balance in a position corresponding to the volume of air flowing, the number of holes exposed and the height of the top of the rod in the sight glass. The meter thus automatically adjusts itself to

the conditions required, by the principle or natural law as previously mentioned.

The New Jersey instrument is not a velocity meter that would give readings proportional to the square of the volume flowing, but is a direct volume gauge with a uniform scale on which one cubic foot is represented by the same distance, whether working at low or high capacity.

Use of Scales at Various Pressures.

The scales of these instruments are accurately calibrated by comparison with a standardized instrument and are graduated for use on pressures of 80 pounds and under at the inlet connection. If the actual pressure at this point is above or below 80 pounds, the capacity of the meter will be raised or lowered in the ratio shown by the *constant* corresponding to the given pressure in the following table, (See Fig. 4) which is based on 14.7 lbs. absolute pressure and a temperature of 60' Fahr. Example: A Tool-om-eter or Drill-om-eter is operating under a gauge pressure of 30 lbs. with its scale reading 100 cubic feet of free air per minute. Corrected reading will be 68.7 cubic feet of free air per minute.

It might be thought that when left floating on the line the resistance of these meters would cause some drop in pressure, but by actual experiment this has been found so small that it cannot be detected by a gauge and they are adapted to the detection and measuring of leakage in air lines, valves, hose cocks, etc., the determination of net volume of air produced by compressors for comparison with nominal rating or displacement. They will show at a glance how much air is used by drill, riveters, chippers, air hoists, pumps, etc., when they are new, six months, or a year after, before and after overhauling, or whenever it is desirable to know.

How To Obtain The Greatest Benefit From The Use Of Air Meters.

To get the best results requires systematic and frequent tests so that the effect of use and the necessity for repairs can be determined. Some types of tools will deteriorate rapidly, others hold up longer in service. A single test on one tool is not conclusive as to whether it is of better type than another. It is necessary to get the life history of as many tools of each kind as are available and analyze the results. A book to assist in keeping records in permanent form so that the necessary information as to life, economy and cost of maintenance can be accumulated, is well worth the little trouble and attention it requires.

With some types of tool the flow is very jerky and, if the indicating rod tends to pulsate, conditions may be improved by using a long hose (50 feet or more) of a size larger than the regular hose commonly used with the tool. Another method of accomplishing the same result is to connect a small storage-tank into the hose between the meter and the tool: this can be made of a piece of 4-inch pipe about 3-feet long for the small meter or a 6-inch pipe 4 feet long for the larger size. The kind of oil used in the dashpot has a considerable effect: a heavy machine-oil or cylinder oil will have a greater dashpot action than the thinner "air oils."

The meter reads direct in cubic feet of free air per minute at the usual working-pressure of 80 pounds per square inch, with a correction of approximately 5 per cent for each 10 pounds variation in the air pressure. The exact correction factor is given on the scale plate for pressures from 60 to 100, and is shown in the table Fig. 4 for other pressures. The air pressure on the supply pipe at the inlet of the meter should be taken with a good gauge and recorded with the scale reading of the meter. The air consumption of most devices varies considerable according to the pressure used.

Tests should be made with tools working under similar conditions at different times. Riveting hammers can be tested on actual work or striking on a block. Piston and rotary metal drills used for drilling, reaming, etc., can be tested accurately with a brake load. Take the speed and the net weight in pounds on the brake to figure out the foot-pounds work per minute, or the horse-power, which gives a positive measure of the work done by the drill. Another method is to use a twist drill of a certain size and in good condition, drilling a hole in a cast-iron block and measuring the metal removed per minute in comparison with the air consumed. In drilling steel it is difficult to feed the drill reg-

10000	20.43	10.05	1.577	1.503	1.427	1.345	1.258	1.165	1.069	.951	.824	.673	.583	.522

ularly enough to maintain a steady speed on the drill and a uniform air-consumption.

For rock drills of the piston type, consumption varies with the nature of the rock, depth and direction of hole, etc., and to get consistent comparative results tests should be made under standard conditions. One common method is to have the drill strike straight down on a steel block or a hardwood block with a steel plate on top, using a short piece of soft-steel rod in the drill chuck.

In measuring the consumption of air-lift wells the flow is very regular, with little tendency to pulsate, and if desired the dashpot may be filled with water instead of oil to avoid any possibility of getting oil into the well.

Metering Air At High And Low Temperatures.

The meters are calibrated in terms of air at "standard" conditions, that is, at sea level, or 14.7 pounds per square inch absolute pressure and 60° Fahr. or 520° absolute temperature. If air is warmer the meter will over-register approximately 1 per cent for each 11° Fahr. in excess of 60°. It is not necessary to take account of this ordinarily for pneumatic tools, etc., as the air consumption of a tool is also influenced by the temperature. For close measurements, where temperature has to be considered, multiply the meter reading by a temperature coefficient K=2 520 T + 460 in which "T" is the temperature in degrees Fahr. of the air passing through the meter.

From the foregoing it is evident that through the use of a good air-meter it is possible to tell whether or not a compressor is living up to its guaranteed rating and by showing up losses due to leakage, wear, poorly adjusted or inefficient apparatus, etc., they enable the progressive executive to get rid of "air eaters" and thus in many instances obtain more air without the purchase of additional compressor equipment.

DOMINION COAL OUTPUT.

The August output of the Dominion Collieries was 381,000 tons, the largest output in many months. Depressed trade conditions are not conducive to large monthly outputs, and although the Dominion collieries are fast getting into condition for almost old-time outputs yet these must wait on the market.

In two months No. 24 mine which is now being equipped with a new surface plant—will become a producer again with an output of 600 tons per day.

To meet the anticipated increased demand of the coming improved coal trade plans are well under way. Several new shafts will be sunk at points close to the sea-shores in order to win every ton of coal possible from the under sea areas. One of these now in process of sinking is thirty one feet four inches by thirteen feet two inches wide a very large shaft indeed. In the New Waterford district another shaft similarly situated on the shore line will be sunk. Other shafts will follow as the trade warrants.

A united effort is being made by management and miners to place clean coal in the market, and much improvement has taken place lately. Altogether the Glace Bay and Sydney Mines District are ready for big business when it comes.

NIPISSING MINES DIVIDEND.

N. Y. — Nipissing Mines Co. declared quarterly dividend of 3 per cent, same as three months ago, payable Oct. 20 to stock of record Sept. 30.

MANGANESE.

The Imperial Mineral Resources Bureau has published a note on Manganese covering the period 1913 to 1919 inclusive. Definitions of manganese-ore minerals, and a list of their uses are given. About 95 percent of the world's production of manganese ores, manganiferous iron-ores, and manganiferous zinc-residuum is used directly or indirectly in the manufacture of steel as a deoxidizer.

British India is the world's most important producer of manganese, although before the war Russia was foremost. Russia's record production of 1,234,900 tons in 1913 is now seen as forecasting some later events. Whether Russia is producing manganese ores or not at this time does not appear to be known. The more important producers during 1913 and 1919 were as follows:

Production of Manganese Ore (Long Tons).

	1913	1919
Russia & Georgia	1,234,900	.....
British India	815,047	534,995
Brazil	120,335	319,777
Spain	21,247	65,514
Italy	1,596	30,345
United States	4,048	55,322

Great Britain herself produces a little manganese ore, 17,456 tons in 1918 and 12,078 tons in 1919 having been mined in the United Kingdom. British countries producing manganese include also the Gold Coast, Union of South Africa, Australia, but Canada has not in recent years produced more than a few hundred tons annually. In Egypt (West-Central Sinai) valuable manganiferous deposits are reported.

The Report states that during the war Brazilian and other available ores were imported into the United States without the regard for cost that would have influenced buyers in normal times; but, with improved railway transportation from the State of Mines Geraes to Rio de Janeiro and better facilities for loading at that port, the Brazilian manganese ore industry, while continuing to find its best market in the United States, may perhaps become a more formidable competitor with India and Russia in European markets, although, when normal conditions are restored, Germany will certainly again obtain practically all her manganese-ore supplies from Russia.

The particulars regarding occurrence and development of manganiferous deposits in all parts of the world are very full, and accompanied by a mass of statistics.

The monograph can be obtained from H. M. Stationary Office, London, price 3s. 6d. plus postage.

At a recent meeting of the employees of the Western Fuel Corporation of Canada, Ltd., Nanaimo, B.C., an application by medical men, under contract to attend coal-mine employees in cases of necessity, for an increase in their remuneration of 50 cents per man per month was received. It was unanimously rejected.

Instead the miners decided to reduce the amount paid 25 cents per man per month. The resignation of the present medical staff also is to be called for the same to the effect in the lapse of six months and applications are to be called for, applicants to state the salary expected.

The Blue Diamond Coal Mine

In a report to the shareholders of McIntyre Porcupine Mines Limited and The Temiskaming Mining Company, Limited, the Directors of the Blue Diamond Coal Company Limited say:

"An exhaustive examination was made of the mining leases and property owned by the Blue Diamond Coal Co. Ltd., early in June of last year and the purchase of the whole of the capital stock by the McIntyre Porcupine Mines Ltd., and the Temiskaming Mining Company Limited, in equal shares, has been completed.

"An option was at the same time secured in favor of the Blue Diamond Coal Co. for a period of fifteen (15) years, from the Canadian Coalfields Limited, covering their holdings at Hay River and the bituminous and anthracite coal seams which extend at intervals for a distance of over forty (40) miles north-west on the coal measures beyond that point.

"It should be borne in mind that the present management were in control for less than ten months of the period, under review, during which time operations were suspended for a considerable time owing to labor difficulties which finally resulted in the Company obtaining open shop working conditions.

"The operating costs may appear misleading as regards operations since we took over the property, for they include losses of approximately $69,000 incurred for July and August (our production commencing on August 23rd, 1920) and also include retroactive pay to employees, owing to the ruling of the Director of Fuel Operations. The heavy expenditures incidental to exploration and development necessary to bring production to our present capacity are factors the immediate results of which are not yet apparent but which the Directors believe will very soon be manifested in satisfactory profits."

General Manager's Report.

General Manager Gordon F. Dickson says in part:

Mining operations were originally commenced on the Blue Diamond property in 1914 and approximately 650,000 tons of coal were produced to the 30th June, 1920, the whole being extracted from tunnels above drainage level. Practically no development work had been carried out and the tonnage of coal available in the workings at the time the property was taken over was negligible. There was, however, undoubted evidence, based on geological data and on an analysis of averages that the property was capable of producing a large and continuous output of high grade bituminous coal, if a thoroughly comprehensive scheme of development was adopted and the mine equipped with suitable plant and machinery for economical working. An important additional recommendation was the geographical position of the mines on the main line of the Canadian National Railways, distant 568 miles from Vancouver and 754 miles from Prince Rupert, at which ports it can confidently be assumed the future chief market for the coal will be found, outside of the Railway's requirements.

Labor Troubles.

The Company, having resigned membership of the Western Canada Coal Operators Association, was not a party to the general agreement concluded by that body with the United Mine Workers of America in June of last year and there was some delay before a final settlement as to the schedule rate for Contract Miners and Company men could be effected due to the necessity of submitting certain points in dispute to arbitration by the Director of Coal Operations. The question of granting "closed shop" to the United Mine Workers of America was carefully considered and eventually agreed upon as the best policy to adopt at that particular juncture, being in accordance with the attitude of the whole of the mines of the district, and in accordance with the recommendations of the Director of Coal Operations who had the power to fix the rates of pay and the selling prices of coal.

Prior to the conclusion of the agreement which was ultimately made with the United Mine Workers of America, the Blue Diamond Coal Co. Ltd. had been paying average rates for contract work equal to over 14 per cent more than the other bituminous mines of the district. The concessions gained, as the result of protracted negotiations and the ruling of the Director of Coal Operations, brought the rates down to a fair equivalent of those prevailing at mines working under similar conditions.

Work was resumed on the 25th of August after a stoppage of seven weeks and a limited production of coal from development was commenced. The necessary equipment of plant, machinery and buildings was pushed on rapidly, and as development progressed the tonnage output increased, until from two hundred and fifty tons (250) per day in August the production had reached eight hundred and fifty tons (850) daily in February of this year.

An organized attempt was made at this time by a section of the Miners to disrupt the successful progress of work by taking advantage of the fact that no Dockage Clause was included in the working agreement. Repeated efforts by the Company to have the usual understanding in this respect were ignored and the deliberate inclusion of rock with the coal eventually, necessitated the company taking a firm stand by refusing to accept coal containing an excessive quantity of rock from contract miners unless the question of dockage was fairly discussed and the customary deductions allowed.

Without any notice the miners ceased work thereby violating one of the principal clauses of their agreement and compelling the company to refuse further negotiations with the United Mine Workers of America under the "closed shop" conditions, which undoubtedly supplied means for organizing the trouble. After six weeks stoppage of production the men returned to work under "open shop" conditions, which have continued with absolute satisfaction since.

Development and Equipment.

Notwithstanding stoppages and delays, good progress has been made with development and equipment of the mine and it is now in shape for the delivering of 1,200 tons per day, which will be increased to 2,000 tons per day by the beginning of next year and eventually built up to 2,500 tons per day.

Exploration and development work include extensive Diamond Drilling and the driving of four slopes and one main level tunnel. Eventually all haulage will be done through one Main Slope which will be connected with the three seams already opened up, and through the Main High Level Tunnel. The former will be equipped with a steam haulage plant having a capacity of 1,000 tons per eight hour shift. The High Level Tunnel connected with the new Incline Tramway will have an output capacity of 1,000 tons per shift.

The whole scheme of equipment and development has been designed with the object of attaining a minimum cost for mining and handling the coal to the railroad cars. The results of diamond drilling and development work during the period have proved the existence of a much larger tonnage of coal than was originally estimated when the property was purchased. The coal now being opened up in the deeper ground is of generally higher quality than that near the surface and in heat units compares favorably with the average of the best imported steam coals.

The natural destination of the mine's product is to the Pacific Coast for bunkerage, as well as export, but with reduced freight rates it should have a wide distribution to important centres in the East as well.

The Blue Diamond Company's property consists of 3,359½ acres of coal lease on which four parallel seams of coal have been proved to exist over the full length of four miles. Plant, machinery and buildings are valued at $440,838. Townsite buildings consisting of General Store, Meat Market, Hotel, Recreation Hall and dwellings are valued at $180,580. The amount spent on equipment, buildings and improvements by the Blue Diamond Company since August last is $281,746.

Diamond Drilling was commenced in September last year and was continued to the middle of December when the work had to be stopped owing to weather conditions. It was resumed again in April of this year and is still in progress.

The amount of information gained from these drill holes is very valuable and has enabled laying out the extensive scheme of development now in progress.

The coal seams conform to the bent and folded condition of the enclosing strata forming a series of basins with intervening anticlines more or less removed by surface erosion. The pitch of the seams is to the northwest and the principal method of development is by Slopes driven downward from tipple level at a suitable angle to reach the bottom of the basins, from where levels are extended on both sides, or limbs, of the trough.

The development so far carried out has been partly of an exploratory character but designed to furnish necessary important information for the permanent scheme, while at the same time assisting production. The permanent plan of development is divided into two principal groups of workings, viz: High Level Tunnel and Slope on the upper sections of Nos. 2 and 3 seams. Main Slope on lower sections of Nos. 2 and 3 seams.

The workings of the High Level tunnel are already well advanced but the Main Slope has not yet been commenced, the work being delayed until certain definite necessary information is available from Diamond Drilling now in progress, as to the exact position of the bottom of the basins.

Both these main openings will command a very large tonnage of coal and will each be equipped with Haulage capacity for handling one thousand (1,000) tons per shift. The High Level tunnel is connected with tipple level by an inclined Self-Acting Tramway for delivery of all coal from the upper workings.

Results of Development Work.

The total footage of Slopes and Levels driven during the year was 5,323'. Generally the results of development work to date have been highly satisfactory. The seams in the deeper ground are consistent in width proving a larger available tonnage than anticipated and have shown improvement in quality as compared with the coal nearer the surface. Care has been exercised in handling the coal for supplying a clean product and obtaining for it an established reputation in this respect.

Due to strike periods and reduction of orders by the Railways the actual time the Mine was operated amounted to two hundred and four (204) days or 68 per cent only of the total possible working days for the fiscal year. The coal produced for the year was 115,718 tons.

Costs.

While opening up the mine for a largely increased production there is a considerable amount of work of a developmental character besides that charged directly to development account. This tends to increase working costs, as the proportion of pillar coal and coal above counter levels, extracted from newly opened areas, has been very small, while counter levels and raises, charged to working costs, have been pushed well ahead to furnish the necessary places for the future large output. The reduction in working costs per ton should be in direct proportion to the increase in tons produced.

Plant, Machinery and Equipment.

Up to July of last year, when the property was acquired, all coal had been mined from tunnels above drainage level, there being no machinery of any kind and insufficient power available for carrying out development in the deeper ground, or for the more efficient handling of the coal to effect necessary reduction in cost of operation. The erection of the additional plant, machinery and equipment was, therefore pushed on rapidly to further the development work and satisfactory progress was attained.

The following are particulars of the principal items of plant, machinery and equipment installed:—

Power House—Sullivan Compressor, R. T. Boiler, 72" x 18'. R. T. Boiler, 66" x 16'. Allis Chalmers Engine Generator, 110 K.W. Webster Feed Water Heater, 1000 H.P. 2 Feed Pumps. Complete new extra heavy steam piping for all boilers. Underwriters Fire Pump, 750 gals. per min. 2 new Water Storage Tanks, each 15,000 gals. capacity.

Addition to Power House Building.

No. 3 South Slope.—Allis Chalmers Electric Hoist, 75 H.P., 60 H.P. Boiler, Loco. Type. Pumping Station Cameron 10" x 5" x 13" Pump. Electric Fan, 40,000 cu. ft. per min. capacity. Ingersoll Rand 10" x 12' Steam Hoist, substituted for Electric Hoist. Air and Steam Pipe Line.

No. 2 South Slope—Jencks Double Drum 10" x 12" Hoist. Air and Steam Pipe Lines from Power House.

No. 1 South Tunnel—Flory 10 x 12 Double Drum Hoist. Ottomwa 8 x 10 Endless Rope Engine.

No. 2 North 6" x 8' Hoist and Pump.

High Level Tunnel—Inclined self-acting Tramway equipped with C Wheel. Brakes and Drum. 6" x 8" Hoist and Pump.

Complete telephone system has been installed throughout the surface buildings and underground, including a line laid and connection made with Brule Railway Station, $2\frac{3}{4}$ miles distant. Endless Rope Haulage was installed between No. 3 South slope and the tipple, necessitating heavy excavation and the laying of 1,800' of double road, erection of Framework, Pulleys, etc. For the Main Slope at No. 1 South a 20" x 42" First Motion Hoist with 6' Drums and Walker 200,000 cu. ft. Fan have been purchased and will shortly be installed with two 250 H.P. Water Tube Boilers.

Canadian Coal Fields Limited.

The claim holdings at the Hay River comprise 7,040 acres and have a length of approximately eight miles

on which three parallel seams have been proven to exist. The middle seam has been opened at iregular intervals and altogether has been exposed over a length of five miles crossing three spurs of the foothills. The average thickness of this seam is 40' and the average height above river level can be safely calculated at 450'. A conservative estimate of the Tonnage content above drainage level is 18,000,000 tons.

Of the two parallel seams, one distant about 400' to the south-west, appears to have an average thickness of about 12', and an estimate of the tonnage content above drainage level may be placed at 5,000,000 tons. Less prospecting work has been done on the third seam lying to the north-east and although its course does not run through so much high ground as those on the south-west side of the river a considerable tonnage of coal may be safely calculated as an addition to that estimated above.

The character of the coal varies from that in the Blue Diamond Mine, there being a higher percentage of volatile matter and less evidence of heat and pressure throughout the greater proportion of hard lumpy coal showing in the different surface exposures. It is an excellent bituminous coal and well suited for domestic use as well as for steam purposes. There is no doubt that the coal at depth should show corresponding improvement in condition and quality to that proved in the Blue Diamond Mine.

A survey has been made of a proposed extension of Spur Line from Brule, the distance being 35 miles to the centre of the Hay River properties. The maximum grade is 1¼ per cent and the country through which the line will pass is of unusually favorable character, there being no engineering difficulties whatever.

The natural advantages for cheap mining and handling of the coal to a Railway are exceptional, due to the situation of the seams and the general topography of the country, and with a comparatively small amount of development the Mines could be placed on a large producing basis.

The claims north of Hay River comprise a total of approximately 6,240 acres on the Sulphur and Smoky Rivers and Sheep Crek. A considerable portion of this area contains anthracite coal equal to the best American product. The proposed Railway route via Hay River from Brule passes within close distance of the seams and there are excellent natural facilities for cheap mining. The Dominion Government has withdrawn from location the unlocated territory in this district.

Conclusions.

In spite of unusual handicaps through labor troubles and the subsequent effects of the general depression causing phenomenal reduction in traffic on the railways, with lessened demand for coal, the general progress for the year has been good.

The development work accomplished in the Blue Diamond Mine has fully confirmed all the most conservative coal tonnage estimates and there is now proved a much larger quantity available in the seams so far opened than was at first calculated.

The mine is now in a position to supply 1,200 tons of coal per day and as the present programme of development advances the capacity is daily increasing. It is estimated that with certain construction work completed a 2,000 ton daily output will be reached by the end of the year.

The quality of the coal has shown improvement in the deeper ground and as the result of consistent effort to furnish a clean run-of-mine product it has been highly approved for Railway use. Owing to the demand of the C. N. Railways at the close of last year for the whole of the mine output no effort was made to find a market outside of their requirements. There is no doubt that the Blue Diamond Coal will find a ready market, when sought, on the West Coast for bunkerage, manufacturing and export purposes, on account of its high calorific value and excellent steaming qualities. Being a good coking coal it can be readily turned to a good profit in this direction also.

The extensive construction programme, to attain the output of 2,500 tons per day at the lowest possible cost, is partly accomplished. Notwithstanding the satisfactory progress made with the work there is still a good deal to do before the whole is completed. The marked saving in working expense anticipated will, however, rapidly redeem the additional capital expenditure.

The Hay River coal has the additional advantage of suiting a domestic market through the large proportion of lump material in the seams.

The anthracite claims however, to the north offer a wide prospect of supplying a much desired domestic fuel which should be able to compete favorably with American anthracite on the prairies and should have a very wide distribution on the Pacific Coast.

If the efforts of the growing population of farmers and producers of the Peace River District are successful in obtaining a Railway, by the direct natural route from Grande Prairie to Brule, for the shipment of their grain by the C. N. Railway to the Pacific Coast it will enable the opening up of these mines for profitable production.

In summing up the value and prospects of the Blue Diamond Company's property and holdings the important features are:—the large territory controlled by the Company on which coal has been proven; the undoubted quality of the coal; the unusually favorable situation of the mines at Brule for wide distribution of the product; the favorable prospects for opening up and operating the properties at Hay River and further North.

General Manager's Report.

Manager Gordon F. Dickson says in part:

The scheme of development and improvement in equipment of the Mine planned at the close of 1919, and warranted by the then existing price of silver was continued during the early months of 1920. In addition to opening up a sufficient quantity of ore to keep the mill running at a full capacity, a commencement was made to accumulate a reserve of broken ore in stopes of such grade as would insure a satisfactory margin of profit.

The maximum price of $1.32 per ounce was realized from shipments made in January but in February a downward trend began which continued through the year until, in October, the market quotation had reached such a low figure as to preclude profitable operation in view of the continued high cost of labor and supplies.

The general prevailing belief at first was that the drop in price of silver was temporary and that there would be an improvement later, so, to minimize the possibility of loss, the expenditure on exploration and development was at first curtailed but subsequently was stopped, the supply of ore for the mill during October and November being entirely from broken ore reserves.

In November the shortage of power due to the dry season also necessitated further reduction and these combined circumstances eventually compelled the [illegible] of the mine altogether.

[illegible] addition of this plant was decided upon in August the price of silver was 90 cents per ounce, but in November, when the mine had to be closed down through lack of power, the market value was further reduced to 70 cents per ounce. Even at this price the results of a number of practical tests showed a safe margin of profit available from the separate treatment of the tailings but it was considered preferable to suspend this work until this spring, when with sufficient power to continue operations in the mine and keep the mill supplied, there would be enhanced profit. The continued fall in the price of silver to the low mark of 58 cents, however, left the question of profit from mining operations so much in doubt that the property has remained idle to the present.

The following is a summary of the Development work accomplished during the year:—

Drifting	573′
Cross-cutting	377′
Raising	366′
	1,316′

The chief sources of supply of ore were as follows:—

From No. 2 and No. 3 Veins, 200′ Level	21,850 tons
D Vein, 400′ Level	967 tons
No. 6 North, No. 2 and No. 1 South Veins, 500′ Level	3,510 tons
No. 1 South, No. 6 North, No. 8 South, and No. 19 Veins, 575′ Level	9,493 tons
Total	35,820 tons

The Mill ran 80.47 percent of the possible running time during the year. The chief causes of stoppage were due to the shortage of water, time required for repair work and to the closing down of the Mine in November.

The necessary alterations were made to the Mill with the addition of one unit of the flotation plant for an estimated capacity of one hundred and twenty-five (125) tons per day. Almost the whole of the plant and material for the second unit are purchased and at the mine ready for erection. The lateness of the season and the necessity of suspending operations at the mine compelled the stoppage of the work of erecting the balance of the plant.

Notwithstanding the satisfactory results from development work, the complete establishment of economical methods of working as a result of alterations and improvements to the plant both of which enable keeping the mill supplied at full capacity, the unexpected fall and ultimately low price of silver prohibited the possibility of reopening the mine this spring for profitable working.

At the time the mine closed down through shortage of power in November of last year the price of silver was 70c. per ounce which was sufficient to leave a

margin of profit. The further fall since then to the neighborhood of 60c per ounce, would be barely sufficient, even with the increased extraction from the tailings plant, to allow of carrying on the necessary exploration and development work and the mine has, therefore, remained closed to the pres-

Semet-Solvay plants have been shut down for varying

Shut Down of Coke Ovens

By J. M. HASTINGS, Jr.
(From "Iron Age".)

The impression seems to have gained considerable credence that a by-product coke-oven plant cannot be allowed to become cold without serious consequences and more or less complete rebuilding before it can be started again. Some owners are even going to heavy expense to keep their oven plants hot, or are selling coke at a serious loss to avoid a shut-down. A report recently received from a plant of by-product ovens near Wheeling, W. Va., shows that a correctly designed plant may be shut down completely without serious injury.

In 1918 a plant of 60 Semet-Solvay ovens was built for the Riverside Iron Works, now owned by the National Tube Co. at Benwood, W. Va., just outside of Wheeling. Two years later 60 more ovens were added. The plant was built on the flat land along the Ohio River, and although the records of high water were carefully studied for a long period, the progressive denudation of the forests made these records of little value, and three years after the first ovens were started the plant was put out of operation by high water. During the twenty years from April 24, 1901, when this first shut-down occurred, to March 16, 1921, the date of the most recent shut-down, the Benwood coke oven plant has been closed down and started up again twenty distinct times.

Seven times in that period the Ohio has flooded the district and effectively put the ovens out of commission. Most of these interruptions were for relatively short periods, although in each case the plant was kept in operation until water entered the waste heat flues. In March, 1907, however, flood water was high enough to enter the sole flues and reach the oven floors proper, causing an 18-day shut-down, and in April, 1913, the worst flood in the history of the river brought the water into the lower heating flues 15 in. above the floor of the ovens. On this latter occasion a shut-down of 25 days resulted, largely because natural gas for starting up again was not available for some time after the flood subsided.

In addition to interruptions caused by floods, the plant has been down four times on account of coal shortage, twice for repairs to the hydraulic mains and seven times on account of business conditions. Duration of shut-downs from this last cause has ranged from one month in 1914 to a year and seven months in 1907 to 1909.

During its entire twenty-two and a half years' existence, the Benwood plant has been shut down 1958 days, or a total of 5-1/3 years up to March 16 of this year, since which date it has again been cold. Several other construction of this type of oven, with the well-known strong division wall between the ovens, was so substantial that any injury occasioned by these vicissitudes has been of a minor nature, as is shown by the following records.

Of all the ovens built in the United States, No.30 oven in block No. 1 at Benwood, holds the record for low repair costs. This oven has been in operation 17 years and out of running 20 times for a total of over five years, and to date has required no replacements whatever in its lining or brickwork. No. 60 oven in block No. 2 is a close second, having required less than $20 expense for brickwork repairs. It should be further noted that the two ovens mentioned at Benwood are both end ovens, which is the point where injury to the structure of the blocks often first appears. The repair records of these two ovens are of course exceptional, but the record of the entire plant has been remarkable, despite the numerous interruptions.

In addition to these repair records on the ovens, the yields obtained at the Benwood plant have been very satisfactory and compare favorably with those from the best modern plants. For the five-year period from Jan. 1, 1915, to Jan. 1, 1920, during which time the plant enjoyed fairly continuous operation, the average results were as follows:

Analysis of Coal Charged.

Volatile	29.9 per cent
Fixed carbon	62.2 per cent
Ash	7.9 per cent

Yields Obtained

Total coke	78.2 per cent
Sulphate of ammonia	24.5 lb. per ton
Light oil	3.11 gal. per ton
Tar	10.0 gal. per ton

These records show conclusively that that plant has not suffered by reason of its many shut-downs and the same should be true for any correctly designed oven plant. Of course it is necessary to exercise care and to take certain precautions when closing down a coke oven plant for an indefinite period. The process is, in general, just the reverse of that employed in starting up a block. The heats should be lowered gradually by a gradual reduction in the supply of fuel gas, so that the contraction of the block will take place slowly and regularly. As this contraction progresses, the tie rods should be readjusted and a close watch maintained to guard against cracks developing.

If the coke is left in the ovens, as is sometimes done when a long shut-down is not anticipated, the greatest care must be used in sealing the ovens as nearly air-tight as possible. The door frames must be kept tight against the brickwork uptake pipes maintained in proper position and charging hole covers sealed tight. With an experienced operator in charge there is no reason why a block of ovens of correct design cannot be shut down for a longer or shorter period, without extraordinary labor or heavy repair expense on starting up.

Dr. WALLACE RETIRES FROM COMMISSIONERSHIP OF NORTHERN MANITOBA.

By REECE H. HAGUE, The Pas, Man.

No permanent appointment of a successor to Dr. R. C. Wallace, whose term as Commissioner for Northern Manitoba expired on September 31st, has yet been made.

Mr. J. A. Campbell, M.P., is temporarily acting as administrator of New Manitoba, but the Provincial Treasurer for Manitoba, Hon. Edward Brown, has stated that Mr. Campbell consented to act for only three months in order to give the government an opportunity of finding a permanent encumbent for the offiee.

The people of the north have received an assurance that the prestige of the office of Commissioner of Northern Manitoba will not be lowered when the question of a successor to Dr. Wallace is decided. The government has several men in view, all of whom are of reeognized geological attainments.

Deep regret is felt in the north at Doctor Wallace's departure, but attempts to induee the retiring eommissioner to secure a further leave of absence from the Manitoba University were unavailing. Three years ago Dr. Wallace was loaned by the University for two years to act as administrator of New Manitoba, and as a result of a deputation of citizens of the north to the Board of Governors of the University, last year, his leave was extended. It was the desire of the people of Northern Manitoba to ask this year for a further extension of leave, but Dr. Wallace was adamant in his decision to return to the University and earry on with his work there as Professor of Mineralogy and Geology.

During his term as Commissioner of Northern Manitoba Dr. Wallace has done invaluable work for the mining industry of the distriet north of The Pas. Coming straight from a University chair it was hardly to be expected that he would display the administrative ability which has been so pronounced a factor of his work in the north.

Scholar and Man of Affairs.

It is a fact that men of academic attainments are frequently lacking in business acumen, but this has by no means been the case with Dr. Wallace, who has handled the affairs of the north wisely and well and interested himself with considerable success, in every matter, large or small, appertaining to the welfare of the tremendous area over which he has had control.

Dr. Wallace's efforts have not been confined exclusively to the mineral aspect of Northern Manitoba, but this phase of his duties has taken up no small part of his time. During his sojourn as Commissioner he has visited every property of merit in his territory and given every assistance to those desiring it, from the mining magnate to the most humble prospector.

In his official capacity Dr. Wallace has attended and addressed gatherings of the flower of the mining life of Canada and has never failed to impress his audience with his remarkable grasp of the subjects which he discussed.

Confined to the narrower sphere of the University it would have taken Dr. Wallace many years to achieve the reputation which the last three years in a larger field have gained for him.

To a certain extent it is the opportunity which makes the man, but there are few men who could have grasped their opportunity in the whole hearted and competent way which has been so noticeable in Dr. Wallace.

The retiring Commissioner has left the north with the goodwill of every citizen of the territory and there was hardly a man in the 178,000 square miles which comprise Northern Manitoba, who did not heave a sigh of regret when he realized that his friend and guide was leaving the district.

As a token of their appreciation of his services the residents of the north tendered a farewell picnic to Dr. Wallace on the eve of his departure for Winnipeg, at which he was the recipient of a large case of silver and an illuminated address, in the course of which the people of New Manitoba attempted to give the departing geologist some idea of the esteem in which he was held.

His Faith in Northern Manitoba.

In the address special stress was laid upon the work done by Dr. Wallace to further the mining industry in Northern Manitoba and in the course of his farewell message Dr. Wallace assured the citizens of Northern Manitoba that he would continue to work for the future of the country with every means in his power and would take the opportunity of again visiting The Pas mineral belt as opportunity offered.

Dr. Wallace expressed unbounded confidence in the future of Northern Manitoba and said that it was a matter of great encouragement that the important mining centres and mining capital now looked so favorably on the district of New Manitoba. The results would be felt, he was sure, as soon as economic conditions began to improve.

"The Flin Flon property and the district are firmly established," said Dr. Wallace, "and what could not take place in 1921 will most assuredly take place when economic conditions of the worlds business will permit. We may hazard the guess that this will be within the next two years. In the meantime the financing of our gold industry is finally taking a stronger tone, and Herb lake should witness real industrial progress next year; and that progress will, we trust, extend westwards across the belt."

The speaker contended that, in order to co-ordinate the various phases of northern industrial life, a concerted effort must be made to assist the project of developing power at the Whitemud falls on the Nelson river, transmitting through the whole of the mineral belt.

Nothing, he said, would more rapidly stimulate the Northern Manitoba gold industry than the assurance that power would be available from this transmission line at practically any point on the whole belt.

Dealing with the question of securing capital for feasible development projects in the north, Dr. Wallace maintained that as far as mining was concerned the wisest policy was to elicit the interest of the larger mining corporations of British Columbia, Ontario or the western States and to work through well established business organizations and eliminate the company which began with no capital at its back. When solid mining was successfully established there was then room for all companies, but not at the present time, he stated.

Wallace Barnes Company, Ltd., will start the manufacture of springs for the Canadian trade next month in their new factory at Hamilton, Ont., which will be under the management of Mr. T. M. Norton. The parent company is the Bristol, Conn.

British Columbia Letter

Dawson.—The 25th anniversary of the discovery of gold in the Klondyke was celebrated on August 17th last. Sourdoughs from all over the territory gathered at Dawson for re-union and convivial observations of the occasion.

Stewart B.C.—The Fish Creek Mining Company has made a trial shipment of 20 tons of ore valued from $500 to $600 a ton. The development of the Idaho group of mineral claims on the Marmouth River is proceeding with good results. New ore has been broken into, samples of which show splendid values on assay. There are eight claims in the property which is situated on the north fork of the Marmot about six miles from tidewater. The first shipment of concentrates from the Premier Mine, Salmon River was made a few weeks ago. It consisted of 160 tons estimated as being worth about $1750.00 a ton. A trial shipment of from two or three tons of ore is to be made from the Silver Bar property situated on Salmon River. The Silverado Mining property, Portland Canal District has been acquired by a syndicate headed by J. J. Coughlin of Vancouver. This prospect is situated on the west side of Portland Canal opposite the mouth of Bear River and the town of Stewart. The new owners intend building a light tramway from the showings which are at an elevation of about 4200 feet down to 2200 foot level. From this point a trail will be built to tidewater. The plans also include the construction of a permanent camp in order that actual mining and necessary development may be continued during the winter.

Alice Arm B.C.—The North Star has made a shipment of ninety tons to the Smelter at Anyox. As development proceeds this property increases in promise and there are indications that it will become one of the regular shippers of the district. There is a compressor at the mine and other mine equipment. Action has been brought against the Taylor Engineering Company in the Supreme Court of British Columbia by George Wingfield of Reno, Nevada, for the recovery of $182,322.00. This money it is alleged is owing to Mr. Wingfield and his associates by the Company on account of liabilities undertaken when the Dolly Varden Mine came into the possession of the Company. It will be recalled that the Provincial Legislature Company subscribed itself. One of these was the payment of $150,000.00 which it now is claimed has never been paid. The difference between that amount and the amount sought through the Courts consists of interest. Considerable interest is taken locally in recent developments on the Toric group of mineral claims, Kitsault River. A body of ore is said to have been opened up that is as rich as any found in the district. The Toric is situated on the Dolly Varden railroad grade and not far from that mine. While the development has not advanced far enough to permit an estimate of the tonnage of this ore the indications certainly are gratifying and the optimism that has resulted among the mining men interested in the district would seem to be justified. The claim is made that it now is demonstrated that the richness of ore of the Dolly Varden will be repeated in other mining properties in the same locality and that all that is necessary is systematic and thorough exploration.

Anyox B.C.—The question was recently put before the workmen of the Granby Consolidated Mining & Smelting Company as to whether that company's plant at Anyox should close down or a reduction in wages be put into effect. There was a vote taken on the issue by the men, the result being a very substantial majority in favour of the continuance of work. The copper smelter of this Company therefore will remain in blast at least for the present.

Cranbrook B.C.—The project for the meeting at Cranbrook of members of the American Institute of Mining and Metallurgical Engineers and of the Canadian Institute of Mining and Metallurgy has been abandoned. It was proposed by the British Columbia Prespectors' Association that while the American Engineers were in the west they should be invited to the Kootenay Section of this Province in order to become acquainted with the larger mining enterprises of that country and and to obtain a closer knowledge of the problems of mining operators and prospectors not only in British Columbia but as well in the States of Washington, Montana and Idaho. The response to the invitation, however, does not appear to have been sufficiently satisfactory to warrant the attempt to carry out the programme that the Prospectors' Association had in mind. Much is expected in East Kootenay of the Federal Mining Company which for the first time has entered that field having bonded the Stemwinder property near the Sullivan Mine. This Company plans to start diamond drilling in the hill, operations of which will be continued through the winter. It is reported that the same Company has acquired the North Star Mine and is interested also in other properties in the same section.

Trail, B.C.—Reductions in freight rates and indications of reductions in treatment and refining charges are bringing closer the revival of mining among independent operators in the Slocan and other Kootenay Districts. The Bunker Hill Smelter recently reduced its treatment charges on British Columbia lead ores $1.00 per ton. With an assurance of a reduction in the freight rates on ore and concentrates from Slocan points to Bradley, Idaho, the same to become effective on or before September 15th, and with the reduction already effective on freight rates between Bradley and the Atlantic seaboard. It is estimated that the total charge against British Columbia lead ores will be reduced $4.55 per ton. This it is hoped is but the beginning. Those interested are looking for further developments not only in respect of the cost but also in regard to the improvement of market quotations. Pending an improvement in the prices of lead, silver and zinc the Rambler-Cariboo Mines, Ltd. has decided to suspend all work. While production has been at a standstill recently, some men have been engaged on development work.

Nelson B.C.—The Reno property, Sheep Creek, is showing up very satisfactorily, according to the management of the Reno Gold Mine. Mr. R. Leahy, Manager of the Mansfield Mining Co., and owner of the Horn Lead Group of 6 claims, Lardeau Creek, reports that development is continuing with good results on the former property. A crosscut is being driven to tap the main vein at depth. Assays show values in gold and silver. Mr. Leahy states that the Silver Cup Mine which has made several shipments recently to the Trail Smelter has struck a vein of Galena ore, averaging $150.00 a ton. Placer mining is being revived on the Lardeau River by a veteran prospector, Dan Savoy. Savoy is constructing sluice boxes on tested ground capable of yielding it is said $5.00 a yard. If the ground maintains $1.00 a yard Mr. Savoy declares that

he and his associates will equip a dredge and instal other up to date machinery. The Mountain Chief Mine, an old shipper is being re-opened.

Revelstoke B.C.—A strike of silver lead ore on the noble Five Group, Trout Lake District, is reported. A large sample of the ore has been brought in averaging $200.00 to the ton. The body just uncovered is said to be substantial and the result no doubt will be renewed activity in the development of this property. Mike Penrose, an old time prospector, claims to have discovered on Canon Creek a few miles to the south of the town of Golden, a vein of free milling gold 25 feet in width which he traced 6000 feet. There is no report yet as to the assay returns on his samples.

Victoria B.C.—The report of J. D. MacKenzie of the Canadian Geological Survey on the limonite deposits of the Taseko Valley, B.C. has been published. Mr. Mackenzie confirms the findings of J. F. Crossland who in 1920 conducted an exploratory party into the district on behalf of the Provincial Government. It was found that the deposits were not of sufficient importance to warrant development. The total tonnage is placed by Mr. MacKenzie at 669,350. There are several deposits of varying quantity. The deposits consist of brown limonite of varying shape, size and thickness, built up of thin layers of brown, cellular, and generally loose textured limonite, lying parallel to the surface of the ground on which they rest. The limonite when dug, forms a large percentage of fines, most of it breaking into pieces of less than half an inch, and much of it breaking into the fineness of sand. The iron is derived from finely divided pyrite, which impregnates greatly silicified and sericitized tuffs on the Taseko formation. The iron sulphate solutions formed by the oxidation and leaching of this pyrite trickle down the mountain slopes and deposit at the first favorable location, building up a bed of limonite.

Field observation was sufficient to determine that replacement of organic matter, which played such a large part in the deposition of the Zymoetz limonite (Northern B.C.) is here of negligible importance and no certain instance of it was observed. The occurrence of considerable quantities of wood in the form of branches and twigs in certain zones often deep in the limonite and quite unaltered except for a blackening of the outer layers is evidence that the iron solutions are not of a nature to replace vegetable matter with limonite. The report of considerable length, is illustrated with maps and diagrams. Mr. MacKenzie also contributes to the geological survey publication, covering 1920, an article entitled "A reconnaissance between Taseko Lake and the Fraser River." On that trip the remains of an old volcano were encountered near the head of Relay Creek in the Lillooet district and the formation of the surrounding country showed traces of volcanic origin.

Other reports are made by W. E. Cockfield on the silver-lead deposits of the Keno Hill area; S. J. Schofield and George Hanson on the Salmon River district; V. Dolmage on the west coast of Vancouver Island; C. E. Cairnes on the Coquahalla area; R. W. Brock on the Eutsuk Lake district; and M. F. Bancroft on the Lardeau map area.

Regarding the Eutsuk Lake district Mr. Brock after referring to the possibilities of the district in general discusses the plateau, a feature of this part of central British Columbia, in the following terms. "It is true that no important mineralization was observed above the instrusives near Ootsa Lake, but in some cases the easily replaceable tuffs on the porphyrite series will certainly be found near the contact of the intrusives and are likely to be mineralized. Northeast of the railway, toward Babine Lake, promising deposits have been found, and from what was seen of the geological conditions of the country to the southwest of it, it is reasonable to expect this experience to be repeated. A possible difficulty in the way of prospecting may be to find sufficient outcrops away from the intrusive itself."

Doctor Victor Dolmage whose work last year was in the west coast district of Vancouver Island, refers to a large deposit of marble at Deserted Creek and Tarsis Canal. It has a thickness of several thousand feet and outcrop over a distance of more than a mile. The marble is coarsely grained and varies in color from pure white through shades of grey to black. In 1908 the Nootka Quarries Co. quarried marble at this point, and produced and sold some $3000 worth of stone. After this the plant was closed, and no work has been done on the property since. Presumably the operations were not financially successful. The company clearly demonstrated that the marble could be quarried in large blocks, free from flaws, and that it could be sawn, turned and polished, and was in every way suited for ornamental and building purposes. It is possible that the development of the property was a little ahead of the demand, and that in the near future so valuable a deposit of marble may receive the recognition that it undoubtedly deserves. He concludes his report with a reference to the alunite deposit at Kynquot Sound. Alunite from this district, according to analysis by five independent chemists of samples taken by W. M. Brewer and P. B. Freeland at the investigation of the Minister of Mines, contains only about 2.6 per cent of water-soluble potash, which is far too small a quantity to be of commercial value. To be profitable for the production of potash it is necessary that alunite should contain not less than 9 per cent of water-soluble potash, and it is doubtful under present conditions whether even that quantity would pay the cost of extraction and refining. Dr. W. H. Collins, Director of the Canadian Geological Survey visited British Columbia a few weeks ago. This was his first official trip through the Canadian West since his appointment to the position. He defined the object of the work of the Geological Survey in this Province as being, first to make base maps of the country that can be used for all sorts of purposes; second to aid prospectors in locating mineral discoveries; third where such discoveries are made and are found to be of sufficient importance to investigate them and thus aid in their exploitation. Dr. Collins made a tour of Vancouver Island the lower mainland of the Province and has gone to Prince Rupert on his way east. There have been many and varied ingenious expediences tried out, some with success and others fortunately without such results in the effort to obtain money illegitimately by the appeal of alleged gold mines. One of the most flagrant instances of this has recently come to light. Evidently it has its genesis in New York and Chicago. A prospectus indicates that the Promoter proposes to sell gold to those who invest for future delivery at $4.50 an ounce. He states that refined gold is worth $20.67 at the mint and unrefined gold worth $18.00. It would appear that the authors of this scheme take the position that they are selling the gold in the ground at $4.50 and can afford to de-

liver it at the standard figure when sufficient capital is obtained to develop the property. The truth, however, is that no such Company as is named has placer leases in British Columbia, nor is there any such Company incorporated under the laws of this Province. Apart, therefore, from the fantastic nature of the project it is clear that the whole thing is nothing but an unmitigated fraud designed to filch the innocent among the public. John A. Dresser, Consulting Mining Geologist of Montreal, has left for the Peace River District on behalf of the British Columbia Government. He will visit the scene of oil drilling operations near Hudson's Hope. This well now has reached a depth of 800 feet.

The collieries of Vancouver Island are working practically at full time. The domestic market is improving with the approach of winter. There is a strong demand from the State of Washington where the coal mines are producing but little. With both local and foreign trade brisk the prospect is that the British Columbia mines will be worked to capacity at least for the next six months. Already there is a suggestion that a coal shortage is likely to develop in the northwest and consumers are being advised to make their purchases without delay.

Under the laws of British Columbia the Collieries are required to pay wages in fortnightly periods. The Pacific Coast Coal Mines Ltd., operating on Vancouver Island and which ceased work some months ago owing to financial difficulties, was guilty of a breach of this statute. Recently action was taken against the company through the Courts on behalf of twenty men whose wages were not paid within the time limit defined by legislation. Judgment was secured and the Company fined $25 in respect of each employee named, or a total of $500. It is said that the case will be appealed.

A coal mine situated near Cenaralia Wn. has reopened on a co-operative basis. The men have been given shares in the Company. They have gone back to work. Elsewhere in the State there is little or no coal mining for the domestic market. The U.M.W. of A. has refused to accept proposed reductions in wages and the Operators have announced that they will open open the mine on the "open shop" basis.

Diamond drilling is in progress on the Chu Chua coal deposits near Kamloops B.C. The purpose is to thoroughly explore the field and, if warranted, to make the investment necessary for further development.

Officials and employees of the different Collieries of Vancouver Island were well represented at the Annual First Aid and Mine Rescue Competitions held on Labor Day at Cumberland B.C. All events were well contested and both in First Aid and Mine Rescue Work the efficiency of the Competitors was the subject of favorable coment on the part of the judges.

The complete results follow:

Mine Rescue Competition, six entries: First prize, shield and six gold watches, won by Cumberland, William Gallis, captain; L. Francesini, Jonathan Taylor, William Evans and A. Watson; second prize, six gold watches, won by Nanaimo, R. Laird, captain; C. Parkinson, J. Sutherland, F. John, A. Courtenay and J. Hodgson.

Department of Mines Cup and Gold Medals, eight entries: Won by No. Four underground team, Cumberland, Wm. Beveridge, captain; Jonathan Taylor, R. Reid, L. Francescini, J. Williams; second prize, gold medals, won by No. Four surface team, Cumberland, A. J. Taylor, captain; J. A. Quinn, H. Boffy, J. G. Lockhart, C. Nash.

Coulson Cup and Medals, eight entries: First, Simpson's team, Nanaimo; second, McLauchlan's team, Granby. Cumberland No. Four underground ran a close third.

Two Men Events, seven entries. First prize, gold rings, won by Quinn and Lockhart Taylor, Cumberland; second, Simpson and Thorpe, Nanaimo.

One Man Event, eight entries: First prize gold rings, won by Beveridge and Reid, Cumberland: second, Kay and Thorpe, Nanaimo.

Ladies' First Aid Event, three entries: First prize $25, won by Mrs. Nicholls, captain; Mrs. Tait, Mrs. Scott, Mrs. Carnelly and Mrs. J. Swan: second prize, $15, won by Mrs. Douglas, captain; Miss McGarrigle, Miss James, Mrs. Davis and Mrs. Witsworth. All teams come from Nanaimo.

Junior Cup, three entries; First prize, Nanaimo team: second prize, won by Ladysmith.

Northern Ontario Letter

THE SILVER MINES.

The assertions recently made by the Journal that a number of the mines in the Cobalt district are on the verge of conditions which offer promise of a general resumption of operations are borne out in the annual statement of the Temiskaming Mining Company which has just been issued. The statement says, in part:

"At the time the mine was closed down through shortage of power in November last year the price of silver was 70 cents per ounce which was sufficient to leave a margin of profit. The further fall since then to the neighborhood of 60 cents per ounce would be barely sufficient, even with the increased extraction from the tailings plant, to allow of carrying on the necessary exploration and development work, and the mine has therefor remained closed to the present. The likelihood of discovering any quantity of high-grade ore in the old workings is small but there is scope for opening up a considerable tonnage of medium grade ore which, under the late improved conditions of working, would show a reasonably good profit with silver at 70 cents per ounce."

With regard to this, it should be pointed out that a wage reduction of 15 p.c. went into force since the Temiskaming closed down and that the abundance of labor now available has greatly increased working efficiency and has reduced operating costs very considerably at the producing mines. It is considered not improbable that such mines as the Temiskaming, Beaver Consolidated and McKinley-Darragh could operate profitably, even at the present price of silver, provided there was the assurance that the price would not recede, and provided further that another wage reduction of 15 p.c. could be arranged.

Bailey.

Total gross earnings from the Customs Mill of the Bailey Silver Mines amounted to 13,179.20 during the month of August, according to official advice to the Journal. The mill treated 4,296.40 tons of ore, the increase being 200 tons above the July record and the increase in gross earnings being over $1,000. The Bailey Mine itself shipped 1,360.12 tons of ore to the mill, this

being an increase of nearly 100 tons over the July record. With respect to development work on the Bailey it is learned that results at the 4th sub-level are favorable and that a substantial quantity of 23-ounce ore has been opened up in which a pay-streak of about two inches of high-grade ore occurs.

Elstone-Duncan.

Reports that the Coniagas had purchased control of the Elstone-Duncan property in the township of Gauthier have no basis in fact, according to information obtained by the Journal representative after making careful inquiry.

La Rose.

Recent developments at a depth of 570 feet on the Violet property of the La Rose are such as to encourage the hope that this property may share to some extent in similar conditions existing on the adjoining O'Brien mine where a large amount of high-grade ore occurs. The vein at the 570-ft. level is said to be from six to nine inches in width and is the downward continuation of a vein which contained good ore at a depth of 370 feet. It is understood the output from the La Rose properties for the current year will be the highest for some years and that a substantial margin of net profit will be shown.

THE GOLD MINES.

The Porcupine District.

For their size, there are perhaps no other industrial centers which show such great activity in any part of Canada as do the towns which lie in the midst of the gold mining activity of Northern Ontario. Porcupine and Kirkland Lake are names which are now firmly fixed in the minds of mining men, and the steady growth of the mines constitutes the keynote to general construction.

People are flooding into Timmins and Kirkland Lake at a rate which has taxed the housing accommodation to its full limit. In Timmins, especially, the big town is actually over-flowing with population, and each train coming in is carrying a human cargo which experiences diffienlty in finding accommodation.

In spite of the gold mines of Porcupine having been compelled through power shortage to operate at only about half capacity for the first four months of this year, the gold output for the first half of the year is the highest in the history of the camp. This also holds true of Kirkland Lake.

A fact worthy of note is that the Dome treated an average of only 840 tons of ore daily, or actually at a rate of a little less than two-thirds of its proven capacity of 1,350 tons daily. This tends to show that a production of over $3,000,000 a year is in sight for the Dome, and net profits of between 20 and 30 p.c. annually appear to be assured.

Clifton-Porcupine.

The annual meeting of the Clifton-Porcupine is to be held this week in Toronto for the purpose of electing officers and directors for the ensuing year as well as dealing with whatever other business may be properly brought before the meeting. It is believed an arrangement may be made to get the property under operation within a reasonably short time.

West Dome.

In respect to the proposed merger between the West Dome Consolidated and the Dome Lake Mining and Milling Company, there are certain details which have up to the present thwarted the efforts of the promoters of the scheme. It is stated in usually well informed circles, however, that progress is being made.

THE KIRKLAND LAKE FIELD.

Wright-Hargreaves.

Some interesting information has been secured in connection with the Wright-Hargreaves mine. The mill on this property was first set in operation in May, and by the end of June had treated 8,156 tons of ore from which $103,518 was produced. This shows an average recovery of $12.69 per ton, and is regarded as a most remarkable achievement during the period of tuning up the equipment. Taking the premium on United States funds into consideration, the Wright-Hargreaves realized a gross income of $13.96 from each ton of ore treated during the first two months of operation. This corresponds with official intimation last spring that the ore would average about 15 per ton. The mill has a rated capacity of between 160 and 170 tons daily, but, after making liberal allowance for possible loss of time, the average may be conservatively figured on a basis of 150 tons daily and an income of $14 per ton, thus indicating a yearly income of $766,500.

There is every indication that this high average will be maintained for a number of years before it will become necessary to include low grade ore and bring the average down to around $15 per ton.

on and after September 15th the price of the treasury shares will be increased to 40 cents each, as compared with the former selling price of 25 cents.

Boston Creek Area.

A meeting of the directors of the Miller Independence was held at the mine late last week. The financial statement read by the secretary showed $50,000 had been raised through the sale of bonds, and that the company is in a position to carry out the full exploration program arranged some months ago. The general manager, W. E. Simpson outlined the result of work to date and referred to the outlook with confidence. The results of diamond drilling operations at the 500-ft. level are most encouraging.

MAMMOTH MINING EXHIBITION AT CHICAGO.

The twenty-fourth annual convention of the American Mining Congress and National Exposition of Mines and Mining Equipment will be held at the Coliseum, Chicago, from the 17th to 22nd October next, inclusive. This convention bids fair to excel in importance almost any previous convention of a great business organization. The program, under the direction of a committee representing all branches of the industry, wil be strictly confined to industrial problems vital to the industry—and to the public.

The Exposition will be the most notable exclusively mining show ever undertaken. The Government of the United States, Canada and Mexico—all countries in which mining is an industry of increasing importance—and all mining districts, including those producing

[illegible] Mining Journal to be represented by a booth of which Mr. H. W. Thompson, our Western Manager, will be in charge, and where all our friends and their friends will be heartily welcome. Any who may desire information

C. P. R. EXTENSION TO DRUMHELLER.

One of the most important of the material developments of Alberta, in relation to the rest of Canada will says the Calgary Bureau of the Financial Times, be the completion of the C. P. R.'s extension to Drumheller—the big and convenient soft coal field—which D. C. Coleman, the manager of the Company's western lines, has announced will be completed by this autumn.

TORONTO COAL PRICES.

Toronto, 14th Sept.—There has been no change in coal prices since last writing. Slack still continues somewhat scarce. Dealers report that there are enquiries in plenty with regard to lump. The trouble of it is that comparatively few of these enquiries are, so far, leading to orders. The truth probably is that the enquiries themselves are mainly the result of a pretty energetic campaign of circularization on the part of the coal men. These latter, when circularizing, do not quote prices—many of them, at any rate, do not. Consequently, the parties circularized start making enquiries in the hope of being able to pick up some cheap coal to "get something for nothing," as the coal men put it. But when they find the price unaltered, there's "nothing doing."

MACKENZIE RIVER OIL FIELD.

The "New Oil Fields of Northern Canada" is the title of an interesting pamphlet on the Mackenzie District that has recently been issued by the Department of the Interior through its Natural Resources Intelligence Branch at Ottawa. The report contains a description of the area of the new district, a resume of progress and development, a synopsis of the regulations and other valuable information regarding routes of transportation, communication, climate, sources of supply, accommodation and such details.

A route map of the district accompanies the pamphlet which may be obtained free of charge, upon application to the Superintendent of the Natural Resources Intelligence Branch, Department of the Interior, Ottawa.

PORT ARTHUR MINING NOTES.

By J. J. O'CONNOR.

The executive, and fifty shareholders in the Palatine Mining & Development Company, visited Port Arthur on the 29th and 30th of August. The party came in in autos, over the Scott Highway from Duluth, Minn.

An inspection of the blast furnace and waterfront property of the company was made by the members, accompanied by Mayor Matthews and the city Aldermen, and a large party of prominent citizens.

They were entertained by drives about the city, and points of interest in this vicinity. On the evening of the 29th Mr. James Whalen gave a banquet at the Prince Arthur Hotel in their honour, which was largely attended by citizens. On the evening of the 30th President Mierziniki returned the compliment by inviting the citizens to a similar banquet at the Prince Arthur.

On both these occasions announcement was made by the members of the party, that it was their fixed intention to carry out extensive industrial development in this city, based on the iron and steel industry. The further announcement was made that they contemplated agricultural colonization on an extensive scale in this vicinity.

The party left by special train on the Canadian National Railway, on the morning of the 31st on a visit to the Paulson Mine, in Cook county, Minn. for the purpose of inspecting the mine, and ore lands under their control. They expect to return to Port Arthur on Sept. 5th.

The tunnel being driven to intersect the vein at the Jackson gold property, TB.3326 TB.3327 and TB.3354, situate two miles east of Schreiber, on the Canadian Pacific Railway has now reached its objective.

The vein where encountered is carrying very high values in gold. Tarpaulins and blankets are being used at every blast, in order to recover the whole of the shattered vein matter, all of which contains good gold values.

The success that has attended the development work at this property, is of the most encouraging kind, and gives promise of this prospect developing into a good producer.

Mr. Peter McKellar has just returned from a visit of inspection to the McKellar-Longworth mine, BJ.122, two miles south of Schreiber, where a new vein was uncovered on August 20th. The work of stripping and testing this vein is proceeding with the most satisfactory results. Good gold values are being obtained at every opening, the average of which, will easily place this vein in the high-grade class, is maintained.

Mr. McKellar is highly pleased with the developments on No. 1 vein, and together with the splendid results so far obtained on the latest discovery, feels that this property will give a good account of itself at an early date.

The option held by Clement K. Quinn on the Atikokan Iron Mine, has been allowed to lapse owing to financial stringency in the United States.

There is a well defined rumour current in Port Arthur, that the Palatine Mining & Development Company have purchased the Atikokan Mine, outright, and that the work of mining iron ore will be commenced when they are in readiness to operate their furnace.

FORD-BURNS COAL PROPERTIES.

An interesting rumor, to which publicity is given by the Calgary Bureau of the Financial Times, is to the effect that H. A. Ford, whose anthracite and bituminous coal properties in the Highwood River Valley, have been the objects of interests for the last ten years, has disposed of his interests to an American syndicate, which has in mind not only the development of Winnipeg, which has been the principal hard coal consumer of the western provinces, but also the briquetting process and the creosoting of ties, so much needed from Port Arthur west. It was currently believed that Ford and P. Burns would ultimately merge their interests and that control of these tremendous enterprises would remain vested in local hands as they are contiguous, and it may be that the new interests will combine with Burns and build a main road of steel up the Highwood River Valley and link up the deposits with the C. P. R. at Calgary or at Okotoks. With these properties working together, it is said that the cream of Alberta's coal products will be made available to the rest of the Dominion.

Mr. Bradley Stoughton, who until recently was Secretary of the A.I.M.E., has resumed his practice as a consulting engineer. He is making a specialty of Financial investigations and reports to bakers, investors, directors, trustees and examining accountants.

Mr. J. J. Warren, president of Consolidated Mining Smelting & Power Co., has returned from a trip to the Orient. His company's operations are chiefly in British Columbia. He crossed the Pacific in connection with the company's business in the Far East.

EDITORIAL

A SUCCESSFUL GOLD MINING COMPANY.

The summary of the report of McIntyre Porcupine Mines Ltd. which appears in this issue contains much information that will be interesting to a wider circle than the shareholders of the company. The tabulated record of results of operations since production began tells a story of mine making which is worth noting. The figures are especially illuminating to those who recall the early years of operations at the McIntyre; but of themselves, they show how the property has advanced from a little struggling enterprise to a big, well-established one that is about to expand into one of double the present size. The detailed reports of costs of mining and milling show that good work has been done during a period of abnormally high costs, and give reason for the conclusion that it will prove possible to mine much ore in the future, in addition to that which is at present classed as ore. The biggest item is shown to be labor, which cost $1.40 per ton, and this may be expected to be reduced as the cost of living comes down. The other large items will also doubtless show marked reduction in the coming year.

Of interest to the metallurgist is the statement concerning plant for treating carbonaceous ores. Mr. Ennis is evidently satisfied that the company has found a simple way to satisfactorily treat ores containing carbonaceous matter. The ore will be given a preliminary treatment in the mill circuit, which will put it in condition for cyanidation without danger of premature precipitation of gold. The additional 500 ton per day capacity will permit, by utilizing this process, the treatment of large quantities of ore which could not be satisfactorily handled by the present plant.

Perhaps the most interesting feature of the report is that which is devoted to results of development work. Perusal of paragraphs showing results obtained in this work will indicate why the company considers that the milling capacity should be doubled. The results of work at the 1,250 ft., 1,375 ft. and 1,500 ft. levels are particularly interesting and indicative of a big mine at and below those levels.

A BAD YEAR FOR THE PRODUCER.

Unusual interest is evidenced this year in reports of production and sales of minerals and metals. The failure of old markets and the scarcity of new ones, the groping for information that will give some clue as to future demands, the attempts to estimate how long the producer must be prepared to wait for good markets for base metals, the difficulties of financing established enterprises through the period of depression, the scarcity of money for new enterprises, the discouraging reports on conditions in other countries, and many expressed hopes and fears leave one's mind in a muddle, at a time when we should all be particularly alert and ready to act promptly when the proper moment arrives. Under the circumstances, it would appear to be more than usually worth while to keep oneself informed as to the facts that are ascertainable relative to the conditions that exist in the industry here in Canada and also in the other countries where mining is a big industry and in those countries where the products of our mines may be consumed.

Most of us are well aware of the fact that it is at present almost impossible to market large quantities of the base metals at a price which will pay for their production. Just how seriously this condition has affected the several branches of the industry is reflected in the record of production this year. Previous records of production did not so well reflect conditions because of the boom market which followed the war and the failure to recognize soon enough that the market could not absorb the product. Mounting costs had made profitable mining impossible, in many cases, long before production was cut down to meet the demand.

Any doubt as to conditions will be removed by noting that our metal production for the first half of this year

was only $24,264,423, as compared with $75,737,472 in the corresponding period of last year. It is worth noting, too, that the depression has affected the various metals in markedly different degree. Gold is being produced in larger quantity than last year, and gold mining is really active. Lead found a fairly good market at a lower price. Zinc also was marketed fairly well. Copper was difficult to sell even at low prices. Nickel and cobalt were almost unsaleable.

While metal mining has fallen off seriously, coal production during the half year does not show such a bad record. Petroleum production is about the same as in the previous year, the small quantity being the result of lack of developed oil fields, imports of petroleum being larger than last year. The asbestos industry is feeling the results of business depression in the United States, and is naturally dependent on activity in the building trades.

The story of production during the first half of the year is not one which fairly shows Canada's ability to produce minerals. It does not adequately illustrate the extent to which our mines are developed and equipped. It does, however, show what we were able to produce with a reasonable chance of selling, and it gives some idea of what we are likely to produce during the next few months. Some of our mines were operated, last year, for several months, when they might better have been idle, owing to hopes that markets would improve. In the United States, also, there was heavy accumulation of metals, partly owing to unfulfilled hopes and partly owing to unwillingness of operators to dismiss employees until such action became imperative.

The mining industry is not especially unfortunate at the present time; but its condition is of most particular concern to readers of this Journal. The reports of production and the reports of poor markets are not very pleasant reading, but it would be folly to ignore them. Believing that we can get into a better position more quickly by taking prompt advantage of improved conditions, we have to know the ascertainable facts even if they make dull reading. The preparation of this report by the Dominion Bureau of Statistics is therefore considered very commendable.

SHOW MINING MACHINERY IN OPERATION.

At the National Exposition the National Railway's big locomotive was critically examined by boys who clambered all over it. Why not let the boys have a chance to run a machine drill, watch a diamond drill bit setter at work, have a ride in a train car hauled by an electric or gasoline locomotive, ride in a mine cage, watch a battery of stamps and ball and pebble mills in operation breaking ore?

An exhibition of mining and milling machinery in operation would help our people to appreciate that mining is an industry requiring skill and energy. Most people have only a very hazy idea of mining operations and it would be worth while to educate them to a better understanding of one of the real productive industries of our country.

The "Northern Miner" remarks that the exhibits which attract are those in motion and making a noise. Can you think of anything more suitable than a battery of stamps? A ball mill would perhaps be less objectionable than the stamps, but not of as much educational value, unless made of glass, like Mr. Hardinge's little models.

FUTURE FUEL SUPPLY OF CANADA.

An official report of evidence taken during the Session of 1921 by a Special Committee of the House of Commons, which made enquiry into the future fuel supply of Canada, has been printed. It is a voluminous report of seven hundred and eighty pages, and in it appear statements by many who are interested in the coal mining industry. The committee held 26 sessions and examined 37 witnesses well known in the industry. Among those who gave evidence, were Hon. L. J. Cote, Minister of Mines of Alberta, Professor N. C. Pitcher, of Alberta University, R. M. Young, secretary Western Coal Operators, L. E. Drummond, of Edmonton, J. Dougall of the C. P. R., Roy M. Wolvin, president Dominion Steel Corporation, Alex. Dick, sales agent D.S.C., D. McLennan, D. H. McDougall, President of Nova Scotia Steel & Coal Co., R. Baxter and J. R. McLachlan and W. P. Delaney, Labor representative of Glace Bay, I. D. McDougall of Inverness, J. G. Scott, British Columbia Coal Co., Hon. J. E. Michaud of New Brunswick, H. A. Harrington of Toronto, J. M. Daly of London, B. A. Caspell of Bradford, Wm. J. Halpin, of Ottawa, J. M. Harcombe, Ottawa, Louis Simpson, of Ottawa, Alfred Rogers, of Toronto, and J. G. P. Hudson of the Department of Mines.

After hearing these and several other persons the Committee made several recommendations to the House. Among these were: that a Government officer be appointed to keep in close touch with the fuel situation; that our water powers be developed to the greatest possible extent; that railways be electrified in certain districts; that efforts be made to reduce the cost of transportation by water; that people be encouraged to use domestic fuels, instead of imported anthracite; that consumers be urged to buy coal in summer; that operators be urged to produce and store large quantities of coal at certain points; and that a campaign of publicity be maintained for the purpose of encouraging people to use domestic coal.

The recommendations are such as might have been expected, the reason for them being more or less obvious without special enquiry. The book of evidence may form the basis for conclusions which will be a real help in solving the problem. The Committee did good work in getting the evidence. Someone else will have to make use of it, if it is to prove worth the trouble involved.

EDITORIAL NOTES.

The metal production of Canada during the first six months of this year had an estimated value of $24,264,423. This is only a fair output for Ontario alone. The metal production of Ontario during the first six months of 1920 was $22,101,580.

The market for silver appears to be livelier. Coupled with the good results being obtained at Cobalt the prospects of the silver mines now look brighter than for some time.

According to the "Northern Miner", Hon. Harry Mills has not failed to notice what a poor representation is made of the mining industry at the National Exposition. Mr. Mills' suggestion that a mining building, having the shape of a shaft house, be erected for mining machinery exhibits, is a good one. Every youngster who visits the fair should have an opportunity to see and explore a "mining building" that houses a creditable exhibit.

An article by the Editor of "Northern Miner," in the issue of September 17th, describes gold deposits at Lightning River as being very promising. This area is some distance from the railway, but as there is easy access by water it should not fail to attract attention. The description of properties visited by Mr. Pearce will be found well worth perusal.

According to "Mining & Scientific Press" the recorded testimony, briefs, arguments and decisions in the several froth-flotation patent suits in the various courts of the United States exceed 15,000,000 words. There will probably be a few million more before a clear definition of the scope of the patents is arrived at. It is unfortunate that the mining industry has had to spend so much money on this litigation. The metallurgists who devised the process made a big contribution to the industry, but the costly patent litigation has, to a large extent, nullified the value of the process to the industry.

Those who are anxious to tax mining companies when they are making large profits, show little interest in the same companies during periods of stress. That a mining company should be allowed to make as large profits as possible is illustrated by the present position of Anaconda Copper Mining Co. This company is disbursing $500,000 per month while its mines are closed down. It is keeping 2,600 men employed. Anaconda has big assets and can keep the property in readiness for business.

ROD MILL AT HOLLINGER.

It is reported from Timmins that a rod mill is now in operation at the Hollinger mine.

HARDINGE COMPANY REVISES SECTION 1 OF ITS No. 7 CATALOGUE.

Owing to the large demand for literature, the Hardinge Company, of 120 Broadway, New York, has found it necessary to revise section 1 of its No. 7 catalogue, which is now available. This section deals with the principle of operation of the Hardinge conical mill; and gives a general description of its uses in the industrial, mining and special fields. Those wishing copies should state in what class of grinding they are interested, in order that they may receive information dealing with their particular requirements.

It may be mentioned that Mr. H. W. Hardinge, a consulting engineer of thirty-eight years' experience, first introduced the conical mill in the field of grinding for the concentration of ores. Since the time the mill was first introduced, it has effected economies in almost every field in which grinding is being undertaken. The reason for the wide range of uses is due to the extreme flexibility of operation, coupled with the fact that the mill lends itself well to working in combination with other devices which aid in obtaining a product conforming to the specifications.

Among the materials being ground successfully in Hardinge mills in all parts of the world, the following are included: gold ores, silver ores, copper ores, lead ores, zinc ores, tin ores, tungsten ores, chrome ores, graphite ores, manganese ores, iron ores, molybdenum ores, platinum ores, limestone, cement clinker, bituminous coal, silica, coke, graphite, anthracite coal, slag, glass, mica, pigments, talc, clays, feldspar, phosphate rock, barytes, fullers earth, sulphur, chemicals, colors, foundry waste, lead skimmings, zinc skimmings, aluminum dross, copper skimmings and iron borings.

There are two distinct types of Hardinge mills—the ball mill and the pebble mill. The ball mill is designed to use steel or iron balls as grinding media, and the pebble mill to use flint pebbles or other similar grinding bodies. These types are used for either wet or dry grinding. The general shape of the two is the same and they are built in nearly the same sizes. The construction of the two types differs, to some extent, on account of the difference in the character of the work which each type is intended to perform.

RICH SILVER ORE AT ALICE ARM MINE.

Now comes another Alice Arm property with ore richer even than the famous Dolly Varden. In opening up their Torie property, which is near to the Dolly Varden, John and Gus Strombeck the owners came across some native silver ore, near to the surface. The Alice Arm Herald says the Torie native silver ore runs 9,600 oz. to the ton. On the No. 2 ledge of the Torie, where this natural silver ore was found, a short tunnel has been driven, and a crossent from this struck a vein three feet wide. The 22 inches of this next the foot wall is high grade, running as high as 209 oz. silver to the ton. The Torie group consists of four claims located in 1914, situated next the North Star, in which McAleenan and Zarelli are interested and which adjoins the Dolly Varden.—Resources Monthly.

PERSONALS.

Mr. L. W. Gibson, Deputy Minister of Mines of Ontario is at Edmonton for the Western Branch meeting of the Mining Institute.

Mr. Robt. Bryce is on a trip to Eastern Canada and New York.

Annual Report of McIntyre Porcupine Mines

The report of McIntyre Porcupine Mines Ltd. for the year ending June 30th 1921, shows net profits were $1,088,514. Shortage of power during three months materially decreased profits. Production was $1,904,326 from 171,916 tons ore which had a gross value of $2,005,672 or $11.67 per ton. Recovery was $11.08 per ton of ore treated.

Operating profit during the year was $815,562. To this is added $269,570 interest and exchange and $3,381 miscellaneous earnings.

There has now been produced by McIntyre a total of $11,035,564 from 1,152,150 tons ore treated.

Development work and exploration during the year included 6,334 ft. drifting, 1,457 ft. cross cutting, and 8,464 ft. diamond drilling.

Ore reserves are estimated at 624,422 tons averaging $10.25 per ton, a total of $6,392,394.

There was treated in the mill 171,716 tons ore. The average recovery was 94.9 per cent. Tailings average 59 cents per ton milled. The mill capacity is to be increased from 500 tons to 1,000 tons per day.

Analyses of mining and milling costs are given by manager Ennis in his report.

THE PRESIDENT'S REPORT.

President J. P. Bickell says in part:

"The total net earnings of only $1,088,513.91 compared with $1,280,232.37 for the previous year is due entirely to the curtailment of our operations from December 26th, 1920, to April 7th, 1921, necessitated by the inability of the power company to take care of the company's requirements. A comparison of the results obtained during this period and the time when sufficient power was available, clearly indicates the seriousness of power interruptions. To safeguard the company's operations the right has been acquired to develop Sturgeon Falls on the Mattagami River, thirty miles distant, and unless we are satisfactorily assured of an adequate permanent supply of power it will be necessary to proceed with this development.

"Notwithstanding the scarcity of labor during the first half of our year, followed by the shortage of power, the development work accomplished has been sufficient to add materially to the ore reserves. The favorable general improvement in our underground development, the downward trend of the prices of commodities and of labor, should enable us to increase the scope of our underground development which will make available a greater tonnage than is required by our present milling capacity. We therefore feel warranted in increasing our milling facilities by the addition of a new 500 ton unit, part of which will be used in treating carbonaceous ores, bringing our production up to 1,000 tons of ore per day."

Profit and Loss Statement
YEAR ENDED JUNE 30th, 1921.

EARNINGS:		
Bullion Recovery		$1,904,326
OPERATING COSTS:		
Mining, Development and Exploration	$615,310.	
Transportation of Ore	39,841.	
Milling	207,190.	
Heating and Maintenance of Buildings and Camps	28,929.	
Employees' Insurance and Welfare	44,169.	
	935,440.	
ADMINISTRATIVE AND GENERAL EXPENSES:		
Management and General Expense—Mine Office	61,732.	
Administrative and General Expense—Head Office	76,712.	
Insurance—General	14,878.	
	153,323	
TOTAL OPERATING COSTS—before providing for taxes and depreciation		1,088,763
NET OPERATING EARNINGS—before providing for taxes and depreciation		815,562
NON-OPERATING REVENUES:		
Interest and Exchange Earned	269,570.	
Miscellaneous Earnings	3,380.	
		272,951
		1,088,513.
APPROPRIATIONS:		
Provision for Municipal, Provincial and Dominion Taxes for current year	64,525.	
Reserve for Plant Depreciation	207,326.	
Holdings in adjoining mining properties written down	1,131.	
TOTAL APPROPRIATIONS		272,983
NET PROFIT FOR THE YEAR, TRANSFERRED TO SURPLUS		$815,530

GENERAL MANAGER'S REPORT.

Manager R. J. Ennis, says in part:—

During the year 171,916 tons of ore were treated having a gross value of $2,005,672 and an average value of $11.67 per ton. Bullion containing 91,330.26 ounces of gold and 19,806.40 ounces of silver valued at $1,904,326 were recovered or $11.08 per ton of ore treated.

An operating profit of $815,562 and a non-operating profit of $272,951 or a total of $1,088,513.91 was earned during the year. An amount of $272,983.79 has been appropriated for depreciation of Buildings, Plant and Equipment and Municipal, Provincial and Dominion Taxes accruing during the period, leaving a net profit of $815,530 transferred to surplus.

Mining.

The total tonnage of ore hoisted through the Main Shaft was 174,030 tons, 153,267 tons were mined in Stopes and from Development, the balance being drawn from Broken Ore Reserves.

The shortage of labor during the first half of the period and the shortage of hydro-electric power from December 26th, 1920 to April 7th, 1921 compelled us to curtail work in the stopes. The labor and power available was used in mine development and milling operations. The result has been the reduction of the Broken Ore Reserves in Stopes from 113,511 tons at June 30th, 1920 to 929,748 tons at the end of the fiscal period. With the improvement in the labor situation and full power being available the breakage of ore in stopes is now 50 per cent in excess of mill requirements.

Ore Broken in Stopes	134,530 Tons
Ore from Development	18,737 Tons
Ore Hoisted	174,030 Tons
Waste Hoisted	21,899 Tons

Summary Of Ore Hoisted

LEVEL	TONS	ASSAY	VALUE
600	2,138	7.00	$ 14,966
700	1,623	9.25	15,012
800	4,433	14.75	65,386
1,000	47,731	13.85	661,074
1,125	53,022	9.85	522,266
1,250	31,356	14.15	443,687
1,375	30,565	9.15	279,669
1,500	3,162	9.00	28,458
	174,030	11.58	$2,030,520

Development.

Development work done during the year was confined to the 1,125, 1,250, 1,375 and 1,500 foot levels. The carbonaceous schist encountered in the lower levels of the mine occurs in a series of south dipping thrust faults intersecting No. 5 Vein for a distance of 350 feet on the 1,250, 420 feet on the 1,375 and 435 feet on the 1,500. Drifting in this faulted zone opened up sections of No. 5 veins of good stoping width, but in mining this ore will be diluted with carbonaceous material requiring special treatment before cyanidation.

Considerable development has been carried on to the west and below the carbonaceous zone on the four lower levels and on each level No. 5 Vein has been found to continue below the zone without appreciable change of values, three stopes now producing ore from this section of a value of from $13.00 to $16.40.

On the 1,125 a crosscut south in the Jupiter claim

Production Since the Commencement of Milling Operations in 1912.

intersected No. 7 Vein and developed 290 feet of ore of an average grade of $11.60 over 10 feet in width.

On the 1,250 foot level 1,227 drift was continued on No. 5 Vein 630 feet to the west property line, 200 feet being carbonaceous ore averaging $6.00 over 7 feet and 430 feet in ore averaging $14.35 over 9 feet. 1,226 drift was continued east 145 feet on $7.00 ore. A crosscut south on this level cut No. 7 Vein, which has been drifted on for a distance of 250 feet showing more or less erratic assays. No. 7 Vein at this horizon runs into the overlying porphyry and values are not expected to continue into this formation.

On the 1,375 foot level 1,327 drift was advanced 735 feet to the west property line. 115 feet in the carbonaceous zone developed 74 feet of ore averaging $9.80 over 7 feet and 650 feet underlying the carbonaceous zone developed 527 feet of ore averaging $16.85 over 10 feet in width. 1,326 drift was continued east 420 feet extending 200 feet into the west Jupiter lot and developed 217 feet of ore averaging $8.10 over 10.4 feet. A crosscut was run south to No. 7 Vein and a total of 840 feet of drifting was accomplished on this vein system. 740 feet of ore was opened up of an average value of $9.00 over 10.1 feet. A crosscut to the south 360 feet from the west property line has opened up an important westerly extension of No. 7 Vein. This ore lies in the contact between the porphyry and the greenstone schist and development shows it to be 28 feet wide and averaging $14.50.

On the 1,500 foot level 1,527 drift was advanced 330 feet developing 113 feet of carbonaceous ore averaging $6.35 over 5.7 feet. The drift was advanced to the west and opened up 200 feet of ore of an average grade of $11.10 over 9.6 feet. 1,526 drift was advanced to the east 525 feet developing 179 feet of carbonaceous ore averaging $6.30 over 8.3 feet and 265 feet of ore averaging $8.50 over 7.3 feet. This drift extends 140 feet into the west Jupiter lot and continues in good ore. A crosscut on this level was run south 450 feet to the contact and No. 7 Vein system. Two veins were intersected, the north branch was developed for a distance of 360 feet in medium grade ore, the south or contact branch was developed for a distance of 370 feet in ore averaging $9.75 over a width of 8 feet.

The Main Shaft is being sunk from the 1,500 foot level, and new levels will be opened up at 1,625, 1,750 and 1,875 feet. A main haulage level will be established on the 1,875 with ore and waste pockets. Ore passes will be run to the intermediate levels so that all hoisting may be concentrated on the main haulage level. The Main Shaft has reached the 1,610 horizon.

Exploration.

Below the 1,250 foot level the contact between the greenstone-basalt schists and the porphyry, which strikes southwest, flattens out and the area of favorable ore-bearing formation is increased. Diamond drilling from the lower levels to delimit this area is progressing rapidly.

No. 5 Shaft is being raised from the 1,375 to the 1,000 and when completed will be sunk to the 1,500 foot level to facilitate the development of the lower levels.

MILLING RECORD—TONS MILLED, 171,916

	$1,088,763	6.3331

Estimated Ore Reserves

	Tons	Assay	Amount
McIntyre Claims	224,586	10.55	$2,366,524
McIntyre Extension Claims	205,007	10.50	2,153,981
Jupiter Claim	102,081	7.95	813,275
Broken Ore Reserves in Stopes	92,748	11.40	1,058,614
	624,422	10.25	$6,392,394

In the above estimate of ore reserves, ample allowance has been made for the reduction of values due to barren schist inclusions in the vein and dilution of broken ore by wall rock.

Milling.

The increased quantity of carbonaceous ore in the mine made the problem of finding a successful method of milling this class of ore of considerable importance. Experimental work and a study of the question has resulted in the development of a process that will satisfactorily treat ores containing carbonaceous matter without the aid of flotation. After a preliminary treatment in the ball and tube mill circuit the ore can be safely sent to the cyanide plant without danger of causing a premature precipitation of gold.

The milling capacity of the plant will be increased by the addition of a new 500 ton unit equipped to handle carbonaceous ores.

Additions to Buildings, Plant and Equipment

New Refinery	$25,285

Underground Equipment	12,185
	$216,517

Underground mine development during the year has continued to give satisfactory results, and if we are assured of a continuous and adequate power supply the development work for this year promises to be equally satisfactory.

SOME INTERESTING COAL MINE EQUIPMENT IN WEST VIRGINIA AND KENTUCKY.

By C. H. McL. BURNS.

Every mining field has its individual problems, but even these vary greatly in the same field and from time to time. To be in the best position to cope with the ever changing and entirely new conditions met with from day to day, the mining man should find it of considerable value to keep more or less in touch with the problems existing in other fields, and the methods adopted for their solution, even if they appear for the time being very dissimilar to his own.

In Nova Scotia, probably the most striking feature of coal mining is the underground development and equipment of its submarine mines and the very diffieult problems met with in their operation. Throughout the anthracite regions of Pennsylvania the visitor finds the mine itself overshadowed by the elaborate surface plants for the preparation of the coal for a diversified and exacting market. In the bituminous fields of the Virginias and Kentucky, the newness of the field—and it is the newest coalfield to be developed in the east—the remarkable development of its mines in the last few years and the very modern and in many cases rather novel surface arrangements are the most interesting.

The coal is bituminous and, taken as a whole, of a superior quality. The seams range from two feet and under to twelve and fourteen feet thick, although the largest percentage of the coal mined comes from seams from four to six feet thick. The mountains are very much broken up by gulches, down which flow the numerous creeks and rivers which divide the ranges into their many ridges, and make the country accessible to railways. As soon as a railway extension is constructed up a creek and new timber and coal lands, tapped, mines are opened and tipples constructed, in many cases ready to ship coal before the railway. The seams as a rule lie at very flat inclinations and the mine openings are by drifts into the side of a ridge at varying elevations above the creek bottom. In many places a number of superemmbent seams are worked from the one hillside. The mines are, practically all, electrically equipped throughout with coal cutters, rock and coal drills, mine fans and mine locomotives. Approximately sixty five per cent of all coal mined in West Verginia and eighty five per cent of that mined in Kentucky is machine coal. All the rest is from hand picks, practically no coal is shot from the solid.

As anthracite monopolized the domestic market, little attention was paid for a number of years to the preparation of the coal. It was practically all used for steaming and cooking purposes and was shipped from the mine over crude tipples, as run of mine. In recent years the rapid development of the field, together with very efficient equipment and modern methods of production underground, has resulted in very high production and consequently keener competition for the markets. Many of the operating companies have been quick to realize the necessity for a superior product to meet this competition and the definite specifications of a discriminating trade and have rounded off their well equipped underground plants with equally modern and efficient surface plants for the preparation and shipment of their coal, and have incidentally discovered that these plants, besides increasing the value of and market for their coal, handle it

more economically than the out of date methods previously employed.

The older method of switch-back, or inclined tramway, which delivered the coal in trips of mine cars to a dump house at the railway siding, with its intermittent delivery, its high speed of operation and consequent breakage and risk of accident, its excessive wear and tear on equipment, necessitating high maintenance charges, has been relegated to the past, and instead of the older and inefficient methods, retarding conveyors are used which handle the coal from the mine to the tipple at the railway in a continuous stream with a minimum of breakage, and eliminate entirely that bugbear to efficient operation, alternate rush and idle periods. Some of these conveyors are operating on grades as steep as 35 to 40 degrees and over a quarter of a mile long. In many cases the same conveyor has a loading point at two or more mine openings on the hillside and delivers the coal from all mines to the same screens and loading plant. In cases where the coal from different seams varies considerably in its coking properties, two conveyors are used delivering the coal to separate screens and loading tracks. In these installations the coal is brought from the mine, usually with electric locomotives, and run over a mine car dump at or near the mine opening. The coal is fed from here by means of an apron or reciprocating feeder, continuously and at a moderate rate to the conveyor, which carries it to the screen house at the railway siding, where it is screened and picked, then delivered to the railway cars on loading booms, so in the whole journey from the mine face to the railway car, the coal is subjected to the very least possible dumping and breakage. This is especially advantageous in marketing a soft bituminous coal.

One method often adopted might be mentioned here. In many of these installations the coal is picked before it is screened or sized. This eliminates more picking tables and men than are absolutely necessary to handle the tonnage. The coal is discharged over a gravity bar or lip screen from the retarding conveyor to the picking table or tables, and a large percentage of the slack removed and placed on the table back of the lump coal to prevent breakage and facilitate picking.

Another point is the extensive use of lip screen plate as compared with the ordinary perforated plate on both gravity and shaker screens. It gives much better results with bituminous coal than either perforated plate or wire mesh.

The mine car dumps are worthy of notice. Practically all of the standard cross over and rotary dumps are represented. The tendency is of course to speed up this operation to the limit and return the cars to the face. Three compartment rotary dumps operated by gravity are used which almost approach continuous operation, but they are rather large and unwieldy and seem to be in the same class with another type in successful operation, which is of the single compartment type, but long enough to dump a whole trip of twenty-five cars at a time. This, however, is going to the extreme and it is very doubtful whether or not the time saved warrants the rather expensive equipment involved. The dump most in favor and probably the fastest of all is the power operated, single compartment rotary dump of the standard type with some accessories, which dumps one, or at the most two or three, cars in tandem, without the necessity of uncoupling the trip. Swivel couplings are used on the cars and the centre of the dump is made co-incident with the couplings of the car. Its successful operation depends on securing the proper grade of the track entering and leaving the dump, and the proper control of the trip by means of a series of automatic car stops, which take the impact of the oncoming loaded trip and the pull of the empty cars, allowing the dumping car perfect freedom in action, and at the same time imparting sufficient momentum to the empty car to move it away quickly. These dumps have actually attained a speed of seven cars a minute in continuous operation. The cars are also handled in train over the scales, by a similar arrangement of grades and stops.

A very good example of many of these new tipples is that of the Powhatan Coal and Coke Co., at Powhatan, W.Va. This company has been operating since 1889 on the No. 3 Pocahontas Seam in the heart of the famous Pocahontas coal region. The coal seam outcrops at an elevation of about 325 feet above the lines of the Norfolk and Western Railway. The mining is by the double entry panel system with two main drift openings and the mine is electrically equipped. The accompanying perspective drawing gives a very clear idea of the equipment for this tipple, which has a capacity of 450 tons per hour. As can be seen from the drawing, the tipple is divided into two parts; the low building over the tracks is for the screens and picking tables, while the high one to one side contains the pea, the slack and the refuse bins.

A very unique and interesting surface layout, designed to overcome a rather serious and difficult problem is that of The Eureka Coal & Mining Company of Prestonburg, Kentucky, which in developing the property, found the mines separated from the railway by a stream of considerable size, with a soft muddy bottom. The mine openings were in the side of a hill along the Big Sandy River, on the Big Sandy division of the Chesapeake & Ohio Railway. The river, at this point, is about two hundred feet wide with banks on one side about forty eight feet above low water. The ground here back to the mine openings is practically level, a distance of about two hundred yards. The opposite bank is the side of a very high hill along which the railway runs through a rock cut at approximately the same elevation as the side on which the mines are located. The river is navigable at this point and, under the ruling of the U. S. War Department, either a draw bridge or one with an eighty foot clearance above low water had to be adopted. The expense of a railway draw bridge at this point made it out of the question, as was a railway bridge eighty feet above low water, or approximately thirty feet above the railway grade. An aerial rope tramway was at first considered, but was dismissed on account of its low capacity. On the railway side the rock cut was very narrow and left very little room between the main line and the river bank for a tipple. The problem was eventually solved by the engineers of the Link-Belt Company, by dividing the plant between the two sides of the river and carrying the coal across on a belt conveyor, which in turn was carried on a light suspension bridge. The coal is brought from three mines by electric locomotives, of the trolley type, to a dump house near the river bank. The coal is fed from the dump hopper to a flight conveyor by a reciprocating feeder and carried up a 45 degree incline by this conveyor to to a head house, where it is discharged to the belt conveyor over a lip-screen chute,

which places a considerable amount of slack on the belt, just behind the lump discharge, and minimizes the breakage, due to this transfer, to a minimum. On the railway side of the river, the coal is discharged to shaker screens of the lip-screen type and thence over picking tables and loading booms to the railway cars. The whole construction is timber, the oak being cut and sawed on the ground. The towers are sixty eight feet high from their foundations and one hundred and fifteen feet above low water. The bridge is two hundred and fifty feet, centre to centre of towers. These are built of six by twelve inch timbers and supported on reinforced concrete and masonry foundations. The suspension cables are each two inch galvanized bridge cables under a stress of 110,000 lbs. each, from which the bridge floor is suspended by Ernst patent hangers, spaced five feet, six inches, apart. The wire rope work was designed and erected by the A. Leschen & Sons Rope Company. The plant has a capacity of two hundred and fifty tons per hour.

Although many of the coal companies employ engineers of their own they seem to find it more economical in the long run to entrust the design and construction of their plants to engineering concerns with a large number of specialists on their staffs and a long record and broad experience back of them. In such cases the firm taking the contract guarantees the successful operation of the plant. Practically all of the large plants in this field have been designed and built by engineering companies specializing in that line of business. There is no doubt but that the experience and suggestions of the operating company and its engineers, coupled with that of the firm of specialists, results in a more efficient design than could be worked out by either individually. In recent years these companies are getting more and more of the tipple business and many contracts are placed with them without resorting to competitive bidding, because the operators realize that low first cost does not necessarily mean a saving to their company and that money wisely spent at the outset does mean low maintenance costs and therefore insurance on the investment, while competitive bidding nearly always results in a design and construction cheaper in first cost than is warranted by good practice, simply because the best is apt to be too expensive for success against less reliable competitors. It is doubtful whether an operating company could design and erect the same plant at as low a cost as the firm of specialists.

REMEMBER THE CONVENTION AT CHICAGO.

As the date for the twenty-fourth annual convention of the American Mining Congress and National Exposition of Mines and Mining Equipment draws nearer, it becomes increasingly clear that it will be an affair of outstanding importance and magnitude—one thoroughly representative of the countries, districts and associations interested in all phases of the mining industry. The convention will be held at the Coliseum, Chicago, on the 17th to 22nd October next, inclusive. The Canadian Mining Journal will be represented by a booth, of which Mr. H. W. Thompson, our Western Manager, will be in charge, and where all who may desire information, with respect to any branch of the industry are asked to bring their enquiries.

INDUSTRIAL ACCIDENTS.

How a billion dollars a year can be saved to the industries of the United States by the prevention of the 20,000 deaths caused annually by industrial accidents, and the thousands upon thousands of injuries sustained by workers in industry, will be demonstrated at the Tenth Annual Congress of the National Safety Council which is to be held in the Massachusetts State House, Boston, September 26th to 30th. A billion dollars a year is the cost of industrial accidents, the National Safety Council has shown, and it has been proved that these accidents can be prevented, and this sum saved through effective safety work. The problem of maintaining effective safety work during the present business depression and accomplishing this enormous saving, more important to industry than ever before during these times when every possible economy and retrenchment is being made, is one of the main topics set for discussion at the safety congress. The solution of this problem, it is expected, will be found at this conclave of the foremost safety leaders in the United States.

Prominent among the hundreds of speakers on industrial safety subjects are H. S. Firestone, President of the Firestone Tire and Rubber Company, Akron, Ohio; C. W. Galloway, Vice-President in charge of operation and maintenance, Baltimore and Ohio Railroad; Ida M. Tarbell, well-known industrial writer, New York; Dr. R. R. Sayers, Chief Surgeon, United States Bureau of Mines; Brigadier-General Charles E. Sawyer, Medical Reserve Corps, U. S. A. (President Harding's personal physician); W. E. Worth, Assistant Manager of Industrial Relations, International Harvester Company, Chicago; F. W. Wilcox, Chairman, Industrial Commission of Wisconsin; Charles B. Scott, General Manager, Bureau of Safety, Chicago; David S. Beyer, Vice-President and Chief Engineer, Liberty Mutual Insurance Company, Boston; E. L. Bair, Vice-President, Benefit Association of Railway Employees, Chicago; Dr. Lucian W. Chaney, United States Bureau of Labor Statistics; Frank B. Gilbreth and Lillian M. Gilbreth, consulting engineers, Montclair, N. J.; and H. W. Forster, Vice-President, Independence Bureau, Philadelphia.

CANADA LEADS IN SOME MINERALS.

Substantial evidence of Canada's importance as a mineral-producing country is found in a statistical summary issued by the Imperial Mineral Resources Bureau of the British Government, entitled, "The Mineral Industry of the British Empire and Foreign Countries," covering production, imports and exports for the years 1913 to 1920. From the last available figures, Canada occupies foremost place in the yearly production of asbestos, mica and nickel ore. In 1920 Canada produced 149,760 long tons of asbestos, with Southern Rhodesia coming second at 16,806; in 1919 the production of mica amounted to 2,459 long tons, India being next at 2,289; in 1920 nickel ore mined in Canada totalled 27,293 long tons, with New Caledonia second at 7,400. Canada stands second in the list of countries producing the following minerals for the year 1920: arsenic, 2,150 long tons; felspar, 32,907; gypsum, 411,030; pyrites, 156,021.

MOOSE MOUNTAIN.

Some experimental work is being carried on at the Moose Mountain iron mine at Sellwood, Ontario.

Mineral Production in Canada

[The following account is extracted from the Preliminary Report on the Mineral Production of Canada issued by the Dominion Bureau of Statistics].

The value of the economic mineral production of Canada during the first six months of the present year reached a total of $24,264,423 as compared with $75,737,472 for the metals produced during the twelve months of the calendar year preceding. The value of the production for the half-year period was thus slightly more than thirty-two per cent of the annual production just recorded. In point of value, therefore, if present conditions continue until the end of the year, the production of metallic minerals in 1921 will not be much in excess of the similar production of 1911, which reached a total of $46,105,423.

Among the metals, lead was easily the leader during the half-year. The quantity produced was more than ninety-one p. c. of the total during the entire calender year 1920, and even at the lower price which prevailed for this metal during the half-year the value of the production exceeded fifty-eight per cent of that assigned to the calendar year output for 1920. The demand for the metal has been fairly good, a considerable quantity finding its way into the manufacture of type metals, babbits and solders, and for the manufacture of corroded white lead as well as in the production of lead shot and other forms used as ammunition. The silver-lead ores of British Columbia furnish by far the greater part of the lead during the period, but appreciable amounts were also recovered from lead ores mined in Ontario and Quebec. Canada foreign trade in lead shows an appreciable decline in imports during the six months period, the total for this year being only about one-tenth of the value of lead and its products imported during the calendar year 1920. Exports on the other hand during the six months were more than double the amount of the twelve months of the preceding year. It will be seen that the lead mining industry in Canada has been able to maintain its position even in the face of declining prices and commercial depression.

The production of zinc is closely allied to the production of lead, most of these two metals being produced from the silver-lead-zinc ores of British Columbia. During the six months, the production of zinc amounted to more than seventy per cent of the quantity produced during the calendar year 1920, and to almost forty-five per cent of the value of that year's production. As in the case of lead, prices showed a great decline, the average for zinc was nearly three cents lower than the twelve months in 1920. The production therefore of more than twenty-eight millions pounds of zinc was very profitable. Foreign trade was maintained at about the same rate as during the first six months of 1921.

The leading metal industry in point of view of value produced during the six months was gold. This industry has enjoyed a considerable impetus during the past year, and the rate of production established in 1920 was easily maintained. One of the reasons for the activity in gold mining is the fact that all sales of Canadian gold are paid for in New York funds and the exchange situation between this country and the United States has enabled the gold producers to obtain approximately three dollars an ounce more for their gold than with exchange at par. At the time of writing the gold camps of Ontario are operating to capacity. More than eight million dollars worth of gold was produced in Canada during the first half-year and the output was almost fifty-two per cent of the quantity and value of the entire 1920 production.

Silver ranked fourth among the metals produced in Canada during the first six months of the present year considered in relation to the output for the twelve months of the calendar year preceding. The total production amounted to more than 49 per cent of the quantity and to more than 29 per cent of the value. Prices which slumped rapidly have been fairly stable during recent months, and while the average for the six months has been only 59.8 cents per ounce, as compared with 100.9 cents per ounce during the calendar year 1920, the steadiness of recent markets has enabled the operators to plan more definitely for the future. A number of closed mills will in all probability renew operations shortly if present conditions continue. Ontario was the principal producer, the output being obtained by the South Ontario smelters and the large reduction plants in the Cobalt area from ores mined in the Cobalt district. Exports of silver bullion during the last six months increased by more than one million ounces, and imports of silver in the several forms declined to about one-eighth of the value of silver products brought into Canada during the calendar year 1920.

Copper produced during the first half of the year amounted to only 31.5 per cent of the quantity recorded for the calendar year 1920, and to only 22.5 per cent of the value of the metal for the same year. The price of copper showed a gross decline of more than 5½ cents per pound from that prevailing during the first nine months, of 1920 and this slump has carried the price down until at the end of the half-year now reviewed, the price quoted for copper is more than 2½ cents per pound lower than the average price prevailing during the ten-year period preceding the war. The hesitant and subnormal market prevailing throughout 1920 has settled somewhat this low level to a point which it is expected will remain stable. While the output of copper during the half-year amounted to nearly 26,000,000 pounds, the quantity of copper held in stock has increased to such an extent that the prospects for the industry in the immediate future are not bright. The principal producing provinces were British Columbia and Ontario, the former producing slightly more than twice as much as the latter during the period.

Nickel and Cobalt follow in the order named, the former producing an amount equivalent to 21 per cent of the 1920 output and the latter about 20 per cent. The markets for nickel and cobalt have been dormant during the period and prices nominal.

Of the Non-Metallics, coal was, as usual, the most important. The output for the period amounted to only 86 per cent of the quantity produced during the same six months of 1920, but the value per ton determined as the average for the whole of Canada and without regard to kinds of coal produced, was $5.75, which is somewhat higher than the average recorded for the calendar year preceding.

Copper.

The decline in the price of copper which set in about September, 1920, continued to the end of the year at which time the price had reached the low level of

thirteen cents. During the six months ending June 30, there was a further slight reduction so that the average for the six months period of the current year was 12.501 cents a decline of more than two and one-half cents from the ten-year period preceding the war. Considered in relation to the first nine months of 1920 the drop was about five and one-half cents per pounds, with the result that in Canada as in other copper producing countries, production during the past six months suffered a decline. The fluctuations of the market have caused some anomalous conditions. For instance, the quantity of copper produced in 1920 was greater than was produced in 1919, but the average yearly price of the metal was so much lower that the value of the product of the metal was less than in 1919. Large stocks accumulated during the last three months last year and many copper producers found it necessary either to close down entirely or to curtail operations. Until the industrial demand for copper is restored and the stocks of new and secondary copper and copper alloys are actually used up, it is apparent that there is little prospect of activity for the copper industry. Undoubtedly, however, the development of hydro-electric enterprises, the electrification of railways, and the promotion of other large copper-consuming enterprises will cause a reaction.

The Dominion production from all sources for the period was 25,707,301 pounds which at the average price of 12.5 cents has been valued at $3,213,413. During the twelve months of 1920, production was 81,600,-691 pounds, worth $14,244,217. The principal producing provinces were British Columbia and Ontario the former producing 68,63 per cent and the latter 31.19 per cent of the total.

There was also a small production during the period from pyritic ores of Quebec which were mined as usual for use in the manufacture of sulphuric acid and the cinder exported for the recovery of copper.

Gold.

The total gold production of Canada during the first six months of this year amounted to 396,391 fine ounces, worth at the standard value for gold, $8,194,-129. The period's production, therefore, represented 52 per cent of the whole amount produced during the preceding calendar year, and at the time of writing, the gold mining industry throughout the Dominion is in a flourishing condition. A feature of the market for gold is that all sales to the Royal Mint, Ottawa, are paid for in New York funds. Exchange on the Canadian dollar in New York has remained fairly constant around 12 per cent during the period, so that gold producers benefited considerably.

Ontario is the premier gold-producing province of the Dominion, the output from this province alone, during the past six months constituting 73.5 per cent of the entire Canadian production. At the present time, the gold mines of Ontario are being operated to capacity and the industry is prosperous. During the earlier months of the year, however, the productive capacity of these mines was curtailed principally because of the shortage of hydro-electric power. The mild winter and the unusually light snowfall left the rivers and streams with little of the customary reserve water supply in the spring.

British Columbia ranked second as a gold-producing province and accounted for 22.9 per cent of the total produced. Compared with the gold output recorded for the province during the year 1920, the production for the six months showed a remarkable gain in spite of the fact that several of the larger mines operated during 1920, were idle during the half-year period just closed.

The Yukon, which for so many years led the way in gold production, has long conceded first and second place, and for the period now reported ranked third among the producing areas. The whole production in the Yukon was, as usual, from placer deposits, and while most of the gold was obtained by two large operators, considerable quantities were recovered by the three hundred or more individuals, or partnerships, also working in the Territory.

Quebec, Nova Scotia and Manitoba followed in order, for the six months period, but the combined output of gold from the three provinces amounted to only about one thousand fine ounces in all, an almost negligible amount in comparison with the production by the leaders.

Lead.

Notwithstanding the general decline in prices during 1920, and the half of 1921, the quantity of lead recovered by the Canadian smelters and contained in shipments exported has shown a notable increase. The producing provinces namely British Columbia, Ontario and Quebec have made very creditable showings as compared with the year 1920. The price of lead per pound in hundred pound lots on the Montreal market, which was 11 cents in March, 1920, had by December of the same year fallen to 6.75 cents per pound. During the period now reviewed, the average price was 5.73 cents. Lead is probably in the strongest position of any metal; the buying movement while not strong, has been fairly constant, the paint, ammunition and white metal industries absorbing considerable quantities.

The Dominion production from all sources equalled 32,875,616 pounds which at the average Montreal price of 5.73 cents had a value of $1,883,773. The production for the calendar year 1920 was 35,953,717 pounds, average price 8.94 cents with a value of $3,214,262. As compared with entire year 1920, the production for the half-year period was therefore 82.4 per cent of the quantity and 58.6 per cent of the value of the previous year's production. British Columbia produced 30,659,-410 pounds or 93.2 per cent of the Canadian output; Ontario, 1,513,774 pounds, or 4.6 per cent; and Quebec, 702,432 pounds or 2.1 per cent.

Nickel.

Considering the total lack of markets, the production of nickel during the period in Canada has been considerable. As usual the principal output was from the nickel copper area of Sudbury, Ontario, supplemented by a small production derived from the treatment of silver cobalt ores. Due to the overstocked condition of the world's nickel markets and the consequent comparatively small demand for nickel, large stocks piled up during the two years following the armistice, but the Canadian output during the last six months was creditable. Compared with the quantity and value of that for twelve months of 1920, the output for the period was 21.11 per cent of the quantity and 21.44 per cent of the value.

Silver.

Judging from returns for the first six months, the production of silver in Canada for the year 1921 bids fair to equal if not surpass that of the previous year. The uniform price of silver during recent months, while still below last year's average has tended to stabilize the industry and enable operators to survey the situa-

tion and plan their action with some degree of confidence. Declining costs of materials and wages have each contributed towards a greater margin between cost of operation and value of metal produced.

These factors have affected the situation to a greater extent in Ontario than in the other provinces where silver is more or less a by-product in the recovery of other metals. The Cobalt district is credited with the major portion of the production and during the latter part of the half-year period showed signs of renewed activity. During the early months of the year the low price of silver, the high cost of production and the power shortage caused a great depression. A number of companies operating on low grade ores were forced to close down. The Mining Corporation took advantage of the situation and closed its mill in March to make alterations with a view to an increased capacity when more favorable conditions should prevail. The mill was re-opened in May with brighter prospects for profitable production. The close of the half-year saw a number of the smaller companies in operation in addition to the four leading companies — the Nipissing, Mining Corporation, O'Brien and Coniagas. A number of former producers have every prospect of an early renewal of operations should the price of silver hold steady and the expected decline in operating costs take place.

The production of silver in Canada from all sources during the first six months of 1921 totalled 6,545,481 fine ounces, which was 40.10 per cent of the total production for 1920, when 13,330,357 ounces was reported. The average price in 1920 was 100.9 cents per ounce and the total value computed at this rate was $13,450,330. In 1921 for the first half year the average price dropped to 59.81 cents per ounce, and the value on this basis to $3,914,852, which is 29.1 per cent of the value for the year 1920. Computed from these data the estimated total production for 1921 would be 98.20 per cent of the quantity, but only 58.2 per cent of the value of that for 1920.

As in the past, Ontario was in the lead with 4,718,537 ounces, or 72.08 per cent of the total production. British Columbia came next with 1,819,827 ounces or 27.80 per cent of the total. Silver contained in ores exported from Quebec, together with that in placer gold from the Yukon Territory amounted to 7,089 ounces or only 0.11 per cent. A small quantity, only 28 ounces in all, was recovered from Manitoba gold ores.

Zinc.

As indicated by smelter recoveries, the production of zinc showed a remarkable increase in comparison with the record for 1920. The shortness of demand and the slack metal market did not decrease the output. The Canadian production for the period was entirely derived from British Columbia, and was nearly all produced by the Consolidated Mining and Smelting Company principally from company-owned mines. During the past six months, neither Ontario nor Quebec produced any zinc.

The prices of all metals were held up to a fair and uniform price during the first nine months of 1920 when a simultaneous drop of about 40 percent occurred. As a result of this, with a total lack of market and the closing of United States smelters which formerly treated considerable amounts of Canadian ores, many small operators were compelled to discontinue for a time. The range of average yearly prices for the last four years on the St. Louis market, as published by the "Engineering and Mining Journal," were as follows: 1917, 8.730 cents; 1918, 7.890 cents; 1919, 6.988 cents; 1920, 7.671 cents. During the period reviewed the average price for the six months on the same market was 4.849 cents per pound. The New York quotations are usually one-half a cent higher, the difference being due to the freight charges. While the general trade in the metal has not been strong during the period it was noted that considerable sales were made, the paint and galvanizing industries absorbing fair amounts.

Of the total Canadian production of 28,236,103 pounds, the production of refined zinc by the Trail Smelters amounted to 28,218,000 pounds or 14,109 tons and it has been estimated that 18,103 pounds was recovered from zinc concentrates exported, an allowance of 20 per cent of the metal contents being made to cover losses in smelting.

At the average St. Louis price of 4.849 cents, the 28,236,103 pounds had a value of $1,369,168. The total production for the 12 months of 1920 was 39,863,912 pounds valued at $3,057,961. The figures for the period show, therefore, that this half-year's production represented 70.83 per cent of the quantity and 44.77 per cent of the value of zinc produced during the calendar year 1920.

The total imports during the 1921 period were valued at $201,958 as against $284,289 during the same period, 1920.

The exports showed a considerable increase for the half-year. From January to June, 1921, the total value of zinc and its products equalled $642,135 or almost six times the value of zinc exports for the same period in 1920.

Iron Ore.

The production of iron ore in Canada during 1921 will probably be the lowest on record. Of the large operating mines, the Magpie, operated by the Algoma Steel Corporation reported having made no shipments, although 42,198 tons of siderite ore was mined. The Moose Mountain magnetite mine was reported idle, and made no shipments. Only one small shipment was made from Ontario by the Wallbridge Mine which consisted of 20 tons ore mined in other years. Of the large operators in Nova Scotia the Dominion Iron and Steel Company and the Nova Scotia Steel and Coal Company reported no operations in Canada, although both firms mined iron ore in Newfoundland, producing during the period 334,102 tons of hematite averaging 5.15 per cent iron. Shipments amounted to 36,419 tons, part of which came to Nova Scotia, the balance being shipped to Europe.

N.B.—Since going to press a report has been received that 740 tons of magnetite ore averaging 60 per cent iron was mined and shipped from British Columbia.

Pig Iron.

Beginning with January, 1921, a monthly record of the production of pig iron and ferro-alloys in Canada has been obtained by the Bureau, and the data have been published in the Monthly Report on the Production of Iron and Steel. These monthly records do not show the values of the iron made, but the reports give in detail the grades produced, and as the iron producers follow the recognized markets in the United States, the outputs shown seem to supply all the information which is required for the guidance of the trade. More complete statistics will be prepared for the annual report.

Blast furnaces were operated during the period by

the the Algoma Steel Corporation at Sault Ste. Marie, the Steel Company of Canada at Hamilton, the Canadian Furnace Company at Port Colborne, the Midland Iron and Steel Company at Midland, in Ontario; and by the Dominion Iron and Steel Company at Sydney. All plants used imported iron ores.

At the end of June, six furnaces were in blast, three at Sault Ste. Marie, one at Hamilton and two at Sydney.

The average output of pig-iron of all grades for the six months' period was 52,000 long tons, the lowest monthly production being in April. The total for the period was 309,206 long tons, as compared with 449,810 tons in the same period of 1920. The output for the first six months of this year was, therefore, only about 69 per cent of the amount made during the corresponding period of 1920. Of the pig iron made, 249,008 long tons was produced from blast furnaces by firms for their own use in further processes of manufacture; 59,897 tons made in blast furnaces was produced for direct sale. Of the 301 tons of electric iron made during the period, 222 tons was made for use and 79 tons of iron castings was made for sale as such. An analysis of the pig iron output for the six months ending June shows that 71 per cent of the total was basic iron; 21 per cent foundry iron, and 8 per cent malleable iron. Coke was the only fuel used in the manufacture of pig iron in Canada during the period.

The production of ferro-alloys, including the several grades of ferro-silicon, and also spiegeleisen, amounted to 10,781 tons during the half-year.

Steel.

The total production of steel ingots and direct steel castings during the six months ending June amounted to 295,140 long tons, of which 284,197 tons was produced for use in further processes of manufacturing by the makers; the balance, or 10,943 tons, was made for sale. By far the greater amount of steel made was produced by the basic open hearth process, the total for this item amounting to 282,648 long tons, of which 280,839 tons was in the form of steel ingots and was used by the makers, and the balance, or 1,809 tons, in direct steel castings. Of this latter amount, 1,423 tons was made for sale, and 386 tons for the use of the producers. Electric steel production amounted to 10,938 tons, of which 9,585 tons was produced as direct steel castings, and 1,353 tons was in the form of ingots. Nearly eight thousand tons of the direct steel castings made from electric furnaces was marked directly as finished product. Very little acid open hearth steel was made during the six months' period, the amounts recorded being 239 tons of ingots made for further use, and 256 tons of direct in all. Converter steel production amounted to 1,059 tons, most of which was made for direct sale as steel castings.

The average monthly production of steel ingots and direct steel castings for the half year ending June 30, 1921, amounted to slightly more than forty-nine thousand long tons, the total output for the period being 295,000 tons. During the same months in 1920, the average production was ninety-one thousand tons, and the total, 547,000 tons. The monthly average for the eight-year period, 1907 to 1914, inclusive, was sixty-two and one-half thousand tons.

Asbestos

From a review of the statistics collected for the first six months of 1921, it is apparent that the asbestos industry is passing through a period of quietness. The present condition is attributed to the state of the asbestos market which, when compared to the activity displayed during 1920 has experienced a considerable falling off. The United States manufacturers have had difficulty in disposing of their output in European markets due to some extent to the rates of exchange between European countries and the United States, and partly to the slow revival of the building trades during the half-year. The majority of the mines were working with reduced forces for much of the time. Shipments during the latter part of the period were very low as compared with those of the first three months of the year which are usually the smallest months for production. However, towards the end of the period a more plentiful supply of labour was obtained and a livelier market opened up due to the increased activity of the building trades and the gradual absorption of stocks held by manufacturers.

The Canadian production was as usual from the deposits in the Eastern townships of Quebec. The amount of asbestos rock mined during the first six months of the current year was 1,101,201 short tons of which 988,446 tons was milled. The total mill output for the period was 67,783 tons. The weight of asbestos recovered per ton of rock mined and raised during the period amounted to 123 pounds, as against 109.1 pounds from the ore mined and raised in 1920 and 100.8 pounds per ton in 1919. The weight of fibre extracted per ton of ore milled during the period was 139 pounds. Sales were made to the United States, Canadian and European markets, and for the period included 42,680 tons of asbestos fibre valued at $2,708,338, the average value per ton being $63.45. Of the total sales mentioned above 537 tons was crude asbestos, grade 1 and 2, and had an average value of $768.60 per ton or a total of $412,737. As compared with final figures for the sales made during the calendar year of 1920, namely, 199,573 tons with a value of $14,792,201 the percentages are 21.38 per cent of the quantity and 18.3 per cent of the value.

Coal.

The output of coal from Canadian mines during the first six months of this year declined to 86 per cent of the amount produced during the corresponding period last year but was 5 per cent in excess of the output for the same period during 1919. With the exception of New Brunswick, none of the provinces showed an output equal to the 1920 record. New Brunswick produced 104 per cent of its 1920 output and the other provinces follow in the order named: Saskatchewan, 94 per cent; British Columbia, 91 per cent; Nova Scotia, 87 per cent; Alberta, 79 per cent.

The total value of coal shipped during the period amounted to $32,882,953 and the average selling price reported from the different coal-producing areas ranged from $2.43 a ton for lignite coal in Saskatchewan to $8.53 a ton for anthracite in Alberta. The average for the Dominion was $5.75.

Having regard to importations, Canada as a whole imported 10 per cent of the amount of anthracite coal brought in during the same period in 1920, and 132 per cent of the bituminous. Quebec was the only province which imported less anthracite during the six months than in the same period, 1920, but even then, that province imported 96 per cent of the anthracite coal received in the half-year of 1920, an increase of 12 per cent over the figures for 1919. Manitoba and the Head of Lakes imported 169 per cent of the 1920 quota of

anthracite; Noval Scotia, 140 per cent; New Brunswick, 128 per cent; Prince Edward Island, 108 per cent; and Central Ontario, 107 per cent. In every case also the figures show that more anthracite was imported during the past six months than in the corresponding six months in 1919.

BOOK REVIEW.

THE METALLURGY OF THE COMMON METALS. By Leonard S. Austin, formerly Professor of Metallurgy and Ore Dressing, Michigan College of Mines. Fifth Edition revised and enlarged. 6 by 9 inches 615 pages, with Index and 178 Figures. Cloth. John Wiley and Sons, Inc., 423 Fourth Avenue, New York, and Chapman and Hall, Ltd., London. Montreal, Renouf Publishing Co. Price $7, postpaid.

This fifth edition of "The Metallurgy of the Common Metals", by Prof. L. S. Austin, which has now been published has been rendered necessary by the radical changes and improvements which have been made in the metallurgy of the common metals—gold, silver, iron, copper, lead and zinc—since the issue of the fourth edition in 1913. Indeed, to bring this valuable book into harmony with present practice, and to ensure that the fund of information which it contains shall be up-to-date, it has been found necessary largely to re-write it.

In consequence of the revision which the work has now received, at the hands of Prof. Austin, its value, both for everyday use in actual practice and also as a text-book for the classroom, has been greatly augmented. It has been the author's avowed aim to set forth underlying principles clearly, and, at the same time, to give the details of methods and of metallurgical equipment, and their cost. Such information is unquestionably essential at the present time. For (as the preface to this edition states) owing to the rapid advance in prices, the costs of operation have lately been subject to serious modification. One chapter is devoted to the question of the cost of plant and equipment, and deals with this subject under the respective headings of costs of metallurgical plants, unit construction costs in 1914 and composite costs. It is stated that the costs in 1920 can be calculated as being double those given for the cost of plant as the latter were based upon figures of 1913 to 1915, when prices were comparatively stable, but that, "when the present abnormal labor costs again return to the older figures, then plant costs will be correspondingly decreased."

Indeed, the author emphasizes the fact that, "when prices of labor and supplies go down, then we may expect an increase in mining." He gives a chapter to the general economic situation as it affects the business of metallurgy, in the course of which he discusses the labor situation, in its relation to the mining industry. Organized labor, he says, has seized the opportunity of making "demands under pretence of needing a 'living wage', that is money enough to meet the necessities, but also many of the luxuries of life. Often the strikers have not cared whether they worked or not; a holiday would well suit them. As a result, capital, whose rewards depend upon uninterrupted operation, has lost seriously and the 'marginal mines'—by which expression are described those mines that, normally, can just pay their way—are having to shut down." After setting out, at some length, the shortcomings of the workingman, he gives it as his view that the employer's best plan is imitate the methods of the Union. The mining, smelting and milling industries should, he says, unite to (1) form a union to which all should liberally contribute, probably small and large alike, and (2) establish propaganda based upon exact and statistical information; and "finally, even as the Union man will strike and starve to gain his ends, so must the company do, confident that by lockouts a permanent improvement can be made. Where one or two out of many shut down, it is but fair that they should draw compensation from the general fund."

Owing to the advances being made in many districts, the chapters on milling practice already need some revision. The description of Canadian plants are in some cases not at all good. The book is nevertheless worth a place in the library.

DIRECTORY OF CHEMICAL INDUSTRIES.—

The Dominion Bureau of Statistics has just issued a second edition of the Directory of the Chemical Industries in Canada, listing the names, addresses and products of over eight hundred Canadian firms manufacturing chemicals, or other products in which the processes used are essentially dependent upon the agency of chemical change.

The first edition of this publication issued two years ago met with such a cordial reception that within a few weeks the entire supply was exhausted. Since then, the subject matter has been entirely revised and added to so that in the present edition nearly three hundred new names appear.

It has come to be a well accepted truth that scientific progress is essential to the true development and material welfare of any country, and in Canada, where many of our natural resources are as yet almost unknown, the importance of laying sound foundations cannot be over-estimated. Some of the possibilities of industrial chemical development were made apparent by the remarkable accomplishments along these lines in Canada during the war, and consequently popular sentiment now favours the idea that this country should, to a large extent, be freed from dependence upon other countries for our chemical needs. In order that this idea might be guided along well advised lines, it was essential that a survey of our chemical industries should be made, and the bulletin now referred to represents one phase of this work.

The Directory is in two divisions: (1) an alphabetical list of the various concerns, the head office address of each, together with a detailed list of their products, including in the latter chemicals and products resulting from chemical processes; (2) a list alphabetically arranged of the chemical products manufactured in Canada showing the names of the various firms engaged in their manufacture.

The Directory has been published in a limited edition, and as a great number of requests for copies have already been received, it is probable that the available supply will soon be taken up. Requests from those interested should be addressed to the Dominion Bureau of Statistics, Ottawa.

STAKING NORTH OF SHINING-TREE.

It is reported that gold discoveries are being made in the townships north of the Shiningtree area and west of Duncan lake. This is regarded as likely territory for discoveries.

The Third Annual Western Meeting of the Canadian Institute of Mining and Metallurgy

By T. B. WILLIAMS, Convention Secretary.

The Third Annual Western Meeting of the Institute was held in Macdonald Hotel, Edmonton, on September 14th, 15th and 16th, 1921. This was the first occasion on which an Annual Western Meeting was held in the city of Edmonton, and let it be recorded that the members of the Rocky Moutain Branch and the Northern Alberta Branch have demonstrated in no uncertain manner their capacity to stage a typical Annual Meeting in true western style and to carry it through with snap and vigor. The local committees are to be heartily congratulated upon the well merited success which crowned their efforts; and we are confident that all those in attendance will join with us in extending our appreciation of the instructive and pleasing program that was presented for our entertainment. To those who could not, and even to those who would not, attend we commend our brethern of Edmonton, and suggest that if they (who could not, or would not) would "know the west" they would be wise to accept all future invitations to the general meetings of the Institute in Western Canada.

The attendance of members and guests was 125. Mr. O. E. S. Whiteside presided in the absence of the President, Mr. C. V. Corless, who was obliged to proceed to England about the last of August.

Wednesday, September 14th.

The sessions were opened by an address of Welcome from Mayor Duggan, of the City of Edmonton, who, in the course of his remarks, stated that the Institute might consider itself in possession of the City, even to the extent of taking over the street car system. The Mayor was followed by the Hon. Mr. Greenfield, Premier of Alberta, who, in lamenting the fact that he was a mere farmer, made a characteristic and forceful speech emphasizing the fact that those who followed the industries of farming and mining were working together for the betterment of the country, and he trusted they would long continue these amicable relations in the cause of industry.

The Presidential address, which had already appeared in the September "Bulletin" was then read by the Secretary Treasurer, Mr. G. C. Mackenzie.

Mr. O. E. S. Whiteside was Chairman at the luncheon at the University of Alberta which was partaken of by about 80 of the members who were privileged in listening to an address by Dr. Tory, President, of the University of Alberta. This will be published in next week's Journal.

After luncheon the members were escorted by members of the University staff, viewing the University buildings. Considerable interest was manifested in the work of the Mining department, which, under the direction of Prof. N. C. Pitcher, is busily engaged in research problems in connection with the utilization of Alberta lignites. The members were also interested in Prof. Clark's experimental work in connection with road materials, and in his description of the difficulties that had to be surmounted in overcoming the evils of Bentonite.

The afternoon session commenced at 3.30, Prof. N. C. Pitcher, Chairman. Mr. Edgar Stansfield presented a paper entitled: "Standardization of Air Drying of Coals." This paper was followed by some lively discussion in evidence of the fact that the problem was of considerable interest to those in attendance.

Dr. K. S. Clark then gave a short talk on Road Making Materials in Alberta, illustrating his remarks with mixed samples of clay and clay and gravel which had been rendered impervious to moisture through the addition of approximately 5 per cent tar which had been extracted from the tar sands of Northern Alberta.

The Smoking Concert at the Macdonald Hotel was commenced at 8 P.M. under the able Chairmanship of Dr. J. A. Allan. This Smoking Concert was a decided innovation insofar as the experience of the Institute in entertainments of this kind, as it consisted almost entirely of music and songs contributed by local members. The quality of this entertainment was such that we fear no contradiction in stating that the professional artists, who have been engaged in the past for similar functions, were by comparison mere amateurs in vocal effort with the Welsh and Scotch members of the Northern Alberta Branch.

Suitable refreshments were served about half way through the program. Then followed a five minute talk by the Secretary-Treasurer on the Institute, after which the second half of the musical program was concluded and the Smoker broke up shortly after midnight by singing "God Save the King."

Thursday, September, 15th.

Chairman, Dr. Dowling.

The morning session was taken up entirely by ten minute talks on the Coal Fields of Alberta by the following members:—Lethbridge-Taber District,—by Mr. Moses Johnson. Canmore-Bankhead District,—by Mr. Lewis Stockett. Drumheller District,—by Mr. D. A. MacAulay and Dr. J. A. Allan. Edmonton-Clover Bar District,—by Mr. A. C. Dunn.

There was considerable interest taken in the coal mining districts under discussion, particularly that of Drumheller. It was pointed out by Mr. D. A. MacAulay, that there was a large amount of slack coal being wasted at the present time because of the lack of market, and that while the Drumheller operators had made application to the Lignite Briquetting Plant at Bienfait for a test run on Drumheller slack they were disappointed to learn that a Federal Order in Council prevented for the time being at least, the granting of their request. Some interesting discussion also took place on the possibility of mining the upper coal seam at Drumheller through mining of the upper. Dr. Allan expressed the opinion that there was very little danger of losing any large amount of coal because of mining methods already adopted, although his point of view was not altogether satisfactory to Mr. W. Shaw.

At 12.30 P.M. the members of the Institute were graciously entertained at the Macdonald Hotel, at luncheon by the Rotrary Club of Edmonton, and after the inner man had been provided for, the Institute members were introduced, one by one, by the Vice-President of the Rotary Club, Colonel Primrose. Then followed a Community chorus in which both hosts and guests joined most heartily. We think that the bright sunshine and transparent air of Alberta must be the

contributory cause of this delightful habit which Albertans have of singing on every possible occasion.

The Chairman then introduced the Hon. Mr. Greenfield, Premier of Alberta, who held the attention of all for ten minutes with a most interesting and informative speech regarding the aims and activities of the United Farmers of Alberta.

The Premier was followed by Dr. R. C. Wallace of the University of Manitoba, who proceeded to enlighten our hosts, the Rotarians, the Premier—and it may as well be admitted, some of our own members—as to what the Institute represented and what it was trying to accomplish for the betterment of the country and the industry of mining. Dr. Wallace emphasized the point that in this National Institute of Mining no section or class of the community was represented in preferment over that of any other class, but that the Institute constituted on organization in which the prospector, the miner, the engineer, the scientist, the business man and the capitalist could rub shoulders and work together for the betterment of all economic conditions affecting the mineral industry in Canada. The luncheon concluded by singing "God Save the King."

The afternoon session commenced at 2.30 P.M. Mr. John R. MacDonald acted as Chairman.

Mr. John McLeish of the Mines Branch, Ottawa, presented a semi-annual statement of mineral statistics compiled by the Federal Bureau of Statistics, Ottawa. Mr. McLeish's paper was followed by Dr. R. C. Wallace, who presented his paper on the "Control of the Mineral Resources of the Prairie Provinces." This paper proved most interesting to the members, and was followed by a lengthy discussion in which the leading part was taken by Thomas W. Gibson, Deputy Minister of Mines for Ontario, Dr. J. A. Allan, of the University of Alberta, and several other members. Then followed ten minute talks on Dominion mining legislation contributed by Mr. W. Dixon Craig, Prof. N. C. Pitcher and Dr. J. A. Allan. The speakers showed conclusively that existing regulations were poorly framed and required amending in the interests of the mineral industry. Some of the points raised by Mr. Dixon Craig and his colleagues illustrated the absurdities existing in mining regulations and caused much laughter.

The banquet held in the Macdonald hotel on the evening of September 15th, was a most enjoyable affair. It was as informal as is the great west itself, and because of that the eastern members quickly discovered that they were adopted, lock, stock and barrel, into the western family. The chair was occupied by Mr. O. E. S. Whiteside, who gave the toast to the King and read a telegram of regret from His Honor, the Lieutenant Governor, who was unable to be present. Mr. Whiteside then introduced the Hon. George Hoadley, Minister of Agriculture, who represented the Government in the unavoidable absence of the Premier. Mr. Hoadley made the suggestion that members of the Government would at all times welcome invitations to attend Institute meetings so that they might secure the helpful advice of mining men in regard to the administration of the mineral resources. Other speakers were the Honourable Chas. Stewart, who spoke on "The Undeveloped Resources of Western Canada" and promised his support in furthering the mining industry of Alberta; the Mayor of Edmonton, Mr. Duggan, and Mr. A. U. G. Bury, who lamented the fact that so wide a gulf separated art from mining.

Under the direction of Mr. Howard Stutchbury, a number of Community choruses were rendered, including the battle hymn of the Institute: "Drill Ye Tarriers, Drill" and that soul stirring lament "Gone are the days when we had our rock and rye". Several solos and duets were sung by Edmontonians: in fact the musical program was quite up to the high standard that had been set at the smoker. The banquet terminated at 11.30 P.M. with "God Save the King."

Friday, September 16th.

Chairman, Mr. Thos. W. Gibson.

The morning session was opened with the reading and discussion of Mr. George Sheppard's paper on "Recent Development work relating to Petroleum in Western Canada." This was followed by short talks on the "Geological Structure in Fort Norman District" by Dr. Dowling and Dr. Williams. The geologists present gave a touch of spice to the proceedings by indulging in a little warm debate concerning the work of the Canadian Geological Survey.

At 12.00 noon, the members assembled at the front of the Macdonald hotel for the purpose of having their photo taken, and were delighted to find that the Hon. Mr. Greenfield, Premier of Alberta was anxious to identify himself with the Mining fraternity by joining the group. After the photographer had done his deadly work the members were entertained at luncheon by the Edmonton Board of Trade, at which Mr. S. B. Woods, K.C., President, presided, and introduced as the principal speaker, Mr. Thos. W. Gibson, Deputy Minister of Mines for Ontario. In the course of his remarks Mr. Gibson spoke of the impressions he had received in travelling to Edmonton, and during his stay in that city. He reminded his audience of the vast coal resources of Alberta, comparing the mining industry of Ontario with that of the former province and concluded by stating that as long as the administration of Canadian public affairs remained in the hands of our best public spirited citizens he felt confident that all would be well with the Dominion.

Others speakers included Dean Fearnsides of Sheffield, England, and "Spike" Mackenzie.

Prof. Fearnsides gave a brief resume of his trip from the time he left the Old Country. He had been greatly impressed throughout the whole of his itinerary, and stated that "The Prairies were not as level as a table, as was generally supposed by the citizens of England." "The thing that impressed me most," said Prof. Fearnsides, "is the magnitude of your country. "We, in England, have a great variety of scenery in small patches, while yours is on a much grander scale. We might be said to deal in retail while you deal in a wholesale way."

Mr. Mackenzie was asked for for the Nth time to sing the war song of the Institute: "Drill Ye Tarriers, Drill." Our Secretary is about ready to blossom forth as a poet, because in singing this song he always has a new rendering. In his remarks he stated that he would return to the east to tell some of its wise men that they must stand at attention and be prepared to shake a leg, or they would be out-classed by the members of the west. In quoting Mr. F. W. Gray, former Editor of the Canadian Mining Journal, at a Canadian Club luncheon in Montreal, he said: "The day will come when there will arise in Alberta a bigger city and a bigger industry than there now exists in Montreal. This will inevitably follow the development of the coal resources in that part of the Dominion."

The afternoon session commenced at 2.30 p.m. Mr. Thos. W. Gibson, Chairman.

Prof. Wallace, convener of the Resolutions Committee, presented the following three resolutions which were carried:—

Resolved: That the Canadian Institute of Mining and Metallurgy in Western Session at Edmonton, express their appreciation to the Federal Minister of Mines and the Minister of Mines for Ontario that representatives from their Departments were present at the Edmonton meeting and made very material contributions to the success of the meeting.

Resolved: That owing to the great need for an office of the Geological Survey in Edmonton, the Canadian Institute of Mining and Metallurgy in session at Edmonton respectfully request the Minister of Mines to take steps to re-open the Edmonton office and place it on a similar footing to the office at Vancouver.

Resolved: That whereas the well-being of an industry is dependent upon the character of the law applicable thereto and whereas the law relating to the mining industry in Manitoba, Alberta, Saskatchewan and the North-west Territories is instable, and in need of revision;

And whereas this Institute did in past years vigorously press upon the Government the desirability of the enactment of a Dominion Mines Act.

The members of the Canadian Institute of Mining and Metallurgy assembled in the Third Annual Western Meeting of the Institute do hereby resolve that the Institute should commence and carry forward such proceedings as the Council may deem advisable to effect the enactment of a Dominion Mines Act;

And it is further resolved that pending the attainment of the above object the Council do appoint a special committee to investigate the present mining regulations and bring in a report thereon for the next annual meeting.

Mr. Emerson and Mr. Robert presented the following resolution of condolence to be forwarded to the widow of the late Mr. W. P. Williams.

Resolved: That in the death of Mr. W. P. Williams, the Canadian Institute of Mining and Metallurgy has lost a valuable member whose calling away is a serious loss to the mining industry of Western Canada, and that this meeting extend to his widow and family the sincere sympathy of the Institute for them in their great bereavement and also that a copy of this resolution be forwarded to the widow and family and that same be embodied in the minutes of the Western Annual Meeting.—Carried.

Professor Wallace moved and Dr. Ferrier seconded a vote of thanks and appreciation to the Western Members for the success of the entertainment that had been provided.

Mr. Whiteside mentioned the fact that it was the members of Edmonton and vicinity, especially, who were responsible for the success of the Convention.

Dr. Allan, Vice-President of the Northern Alberta Branch replied that a large portion of the success arose from the papers and discussion by outsiders. Mr. Dunn seconded Dr. Allan's remarks, but stated that members present were keenly appreciative of the work accomplished by our Convention Secretary. Mr. T. B. Williams, who for the past six weeks had been working 16 hours a day and had really borne the burden of the Convention, and that a hearty vote of thanks should be accorded to him. Mr. Dunn's motion was seconded by Mr. Gibson, and carried.

On motion of Dr. Allan, seconded by Mr. Shaw, the meeting adjourned at 3 p.m.

On Friday evening, the 17th, about 55 members of the Institute entrained in standard sleepers at Edmonton and were taken via: Canadian National Railways to what is locally known as the "Coal Branch" of the C. N. R., just east of Jasper, where the members were entertained and shown various phases of this new coal field by the officers of The Cadomin Coal Company, the Sterling Coal Company, and the Yellowhead Coal Company. More complete details of this trip will appear in later issues of the Bulletin. The thanks of all those who took part in this most delightful excursion are due to the Edmonton Railway officials and more especially to the officers of the various coal companies who received and entertained the visiting members in a most warm hearted manner.

A full report of the proceedings of the Edmonton meeting will appear in the next issue of the Journal.

HIGH GRADE ORE AT MAYO.

James O. Greenan, engineer with the Yukon Gold Corporation at Mayo, is quoted as stating that sufficient work has been done in the Keno Hill Section of Mayo District to assure the production of high grade ore for several years. Nothing, however, has been uncovered to warrant the prediction that such ore will be available in quantity for a longer period. The Yukon Gold Corporation has done several thousand feet of development work and is proceeding as fast with these operations as its facilities permit. Twenty-five hundred tons of high grade ore have been shipped this year by the Corporation. Shipments are being made via St. Michael to the Shelby Smelter at San Francisco, Cal., a distance of 5,000 miles, the greatest distance any mine in the world is transporting crude ore for treatment. Through a special arrangement with the Canadian Government, Mayo has been made a sub-port of entry, thus permitting vessels to load ore direct at that point and carry it to St. Michael. Ore is now being mined for transport during the winter, over the snow and ice to Mayo. When navigation opens next year this will be taken out, as is now being done with that which was mined last winter. The Yukon government now has a crew of men improving the road so that the transportation problem will be made somewhat simpler. Mr. Greenan says that there is a shortage of hard rock miners in the Mayo District, that wages are $5.00 a day with board and lodging, and that many prospectors are being attracted from other parts of the Territory.

COAL BY CHEAP WATER ROUTE.

Soft coal, in large quantities, is being imported into Montreal by the cheap water route by the British Empire Steel Corporation. No coal was brought in, last year, in this way, but the company's coal carriers, known as the Black Diamond Line, have unloaded more than 500,000 tons, so far, this season. Mr. J. E. Cookson, of the British Empire Steel Corporation, stated last week, that, owing to the over-production in the United States, that country is now dumping soft coal into other markets at the low price of $2 a ton at the pit mouth, and selling it at that price, plus the freight charges, at Montreal and along the Great Lakes shores.

Bring the Mining Industry to Public Notice

A better Understanding of the Mining Possibilities Would Lead to Greater Utilization of Our Mineral Resources.

By J. J. O'CONNOR.

If there is one thing more than another, in connection with the resources and development of this Province, that requires to be impressed upon governments, the so-called interests, the farming interests, the manufacturing and business interests, and the man on the street, it is the magnitude and importance of the mining industry, and its relation to the upbuilding and maintenance of a prosperous industrial future for this section of Canada. Little understood by the average man, it is apt to be looked upon as, at best, a gamble, something into which one may safely put what he is prepared to lose, or, as in some cases, in the hopes of getting-rich-quick at small outlay. Mining has advanced at such a rapid rate, and is now on such a substantial basis as a going concern, that confidence may be felt in its stability and permanence. Sufficient has been proven in Northern Ontario, to convince the most skeptical that we have mineral wealth almost beyond computation. The expectations and predictions of the most experienced geologists, mineralogists and mining men, have been far exceeded during the past ten years. Portions of this Province that were unknown and untrodden wildernesses twenty years ago, are today hives of industrial, business and mining activity, affording employment to thousands in the various lines of endeavour.

This change in the mining status, has been brought about mainly by the character of the pioneer mining men engaged in this development, some of whom have passed to their reward, but whose names will be permanently associated with the story and romance of the phenominal results achieved from their early, persistent, and sane optimism. Undeterred by the obstacles and difficulties that beset such undertakings, both physical and financial, they plodded on until they reached the climax of success and blazing the trail for the prospector into new fields, until now the productive area of Northern Ontario has extended to the proportions of a Kingdom, the confines of which are as yet unknown, and unbounded.

Twin Cities Likely Point.

The same energy and intelligent application of methods, that has made such a pronounced success of gold, silver and nickel that has brought Northern Ontario into a ranking world class as a producer of these metals, applied to the iron ore industry, will build up an iron and steel industry, that will place Canada in an independent industrial position. There is every confidence in the minds of men, informed as to the iron ore resources of Northern Ontario, that such an industry will be established in the near future. Just where that enterprise may be undertaken, is a matter of secondary consideration. The enormous deposits tributary to the Canadian National Railway, and the head of the lakes, point to the twin cities as the most likely point. The geographical position is admirable, being, roughly, one thousand miles nearer the growing western market, than any common shipping point in eastern Ontario, affording substantial advantages in the matter of transportation, which is at the base of all industry, and a paramount governing factor in all manufacturing undertakings.

Kind of Publicity Needed.

There would seem to have been a lack of the right kind of publicity, propaganda if you will, in impressing this on governments and the public. The governments both Federal and Provincial, are the wardens of a great estate. The men whose daily intercourse brings them into touch with the possibilities of that estate, have a duty to perform, in bringing these possibilities to the notice of governments, in the most forcible kind of way. The cares and responsibilities of government, do not permit an intimate knowledge of the requirements necessary to the full and complete development of the country's resources, therefore, those people engaged in the mining industry have a responsibility placed upon them to bring the mineral possibilities to public notice, to the end that they may receive their due.

The Canadian National Exhibition affords one of the finest mediums for this purpose. Were an exhibit placed there that would do justice to the actual and prospective possibilities, it would be viewed by a million people, and have a lasting effect on the minds and serve to correct the all too prevailing idea that mining is a gamble.

Display by Larger Operators.

While the prosperous and productive mines of Northern Ontario are independent of all outside aid in their own spheres, yet they are concerned in the general prosperity of the mining industry, and anything that will aid it, is distinctly in their interest. Therefore, it would be well if the larger operators in gold and silver, would make such a display, at not only the C. N. E. at Toronto, but at the principal fairs throughout the Province. This would do more than anything else to educate the public to the importance of our mineral wealth. No one in this country is more directly interested in mining than the farmer, although he may not know it, until the fact is brought to his notice that it provides one of the most profitable outlets for his produce. Mining machinery should also be in evidence at these fairs. Nothing is more impressive than the means by which the values are extracted from the ores, and the country's wealth laid bare.

A Popular Policy Suggested.

The shocking fact, that, notwithstanding our extensive deposits of workable iron ore, there is not one pound of iron being raised from the ground to-day, throughout the whole of Canada, should arouse both governments and people to the pressing urgency of the iron situation.

Emergency Tariff Bills, Fordney Bills, and the trade situation generally, demand that something be done to remedy present conditions, and make Canada self sustaining in the matter of iron and steel.

The most popular plank that could be placed in the platforms of the various parties and groups, that are about to appeal to the country for support, in the forthcoming general election, would be one for a de-

termined, and business like policy for the exploitation of our mineral wealth.

Such a policy would not only appeal to the thinking electorate, but would do more to stabilize exchange, solve the railway and unemployment problems, and cause agriculture and industry to go hand-in-hand, than any other policy that may be adopted.

In this connection, it may be said that our vast mineral and water-power resources are of sufficient magnitude and importance, to warrant the Federal Government erecting a separate Department, under a responsible Minister, who would care for and administer these twin industries. The Province of Ontario, together with other provinces of our confederation, have established the precedent. Why not the Federal?

40,000 TONS RAIL ORDER.

Phila.—Algoma Steel Mills, of Lake Superior Corporation have received an order for 40,000 tons of steel rails from Canadian National Railway. This together with recent order for 25,000 tons of rails from Canadian Pacific, will assure activity in the rail department of steel plant for the balance of the year. The outlook for business is regarded by the company as having distinctly improved.

DIAMOND DRILLING AT GOLD ISLAND.

Exploration work is being carried on by Pittsburgh people at Gold Island, Night Hawk Lake. Mr. J. Callighan is interested in the property.

EASTERN RAND IS PROMISING SOURCE OF GOLD

In an article on The Transvaal's Gold Outlook in this week's issue of "Barron's" R. Mabson, formerly editor of the London Statist, and author of annual review and text book, "Mines of the Rand," points out that although what is known as the "Old Rand," of the South African gold fields is giving indication of smaller annual yield, during the past 12 or 15 years value of the long, previously ignored extension of the gold region to extreme east of the 41 miles of the "Old Rand" lines of mines has come to be recognized, giving promise of great potential output in future years.

"The once despised Far Eastern gold field," he says, "has made great strides in the past ten years. The area contains at varying depths what may be described as half a dish like deposit of flat ore body that over 200 square miles—of average 10 miles from east to west and 20 miles from north to south—is workable to the depth of 5,000 feet, and all the score of shafts sunk by a dozen companies to the present time have intersected reef at less than 5000 feet from surface. The area contains not only zones of good ore but also extensive area where reef has not proved to be payable. As a whole the payable zones have proved to contain far better average grade and width of ore than the ore of the old Rand."

LA ROSE.

According to reports from Cobalt some very good ore is being developed by the La Rose mining company at the Violet mine. High grade and good milling rock are being opened up.

PALATINE MINING AND DEVELOPMENT CO'S. ENTERPRISE.

By J. J. O'CONNOR, Port Arthur.

Robert E. Hogan, representing the Palatine Mining & Development Company, the purchasers of the Atikokan Iron Company's blast furnace at Port Arthur, has arrived in the city, and has opened offices at the furnace plant. He announced officially that all matters pertaining to the acquirement of the blast furnace, from the former owners, had been closed, and that negotiations with the Canadian National Railway management had been satisfactorily concluded, whereby his company are to rebuild that portion of the P. A. D. & W. Railway, between North Lake and Gunflint, a distance of sixteen miles, and from Gunflint to the Paulson Mine, in Cook County, Minnesota, a distance of five miles, twenty-one miles in all. The Palatine Mining and Development Company will operate this portion of the railway under a ten year lease from the Canadian National Railway. The latter company has undertaken to relay with eighty-pound steel, and otherwise put in shape that portion of the P.A.D. & W. Railway between its junction with the C.N. Railway main line, and North Lake, and to have it completed and ready for heavy traffic in two months. In addition to the new steel, this undertaking entails the relaying of the entire distance with new ties, the construction of new bridges, and a general lining up of the road-bed.

Mr. Hogan gave out the statement that the mining company would be in readiness to begin the shipment of iron ore over the railway, on the completion of the above undertakings, and that at least two, and probably more, trains of ore would be sent over the road daily.

The daily capacity of the furnace will be 500 tons of ore, when the enlargement now underway is completed. It is the intention of the company to have a large reserve of ore in stock-pile at the furnace.

That portion of the railway between North Lake and Gunflint skirts on the shores of lakes for the entire distance, instead of building construction camps, for the accommodation of the men on construction work, the Palatine M. & D. Co. have constructed house-boats on scows, that may be conveniently moved from point to point, as the work proceeds. Labour is plentiful, at thirty-five cents per hour, with board and lodging at one dollar per day. It is the intention to have this enterprise fully underway by July 1st next.

PATRICIA IN KENORA MINING DIVISION.

The western part of Patricia is now part of Kenora Mining Division.

The Order-in-Council respecting Patricia is:

"Upon the recommendation of the Honourable the Minister of Mines, the Committee in Council advise that owing to important discoveries of mineral reported from that part of the District of Patricia, lying north of Kenora, and for the convenience of prospectors and the public generally, the following territory, namely, all and singular that certain parcel or tract of land and premises, situate, lying and being in the District of Patricia, Province of Ontario and consisting of the most westerly portion of the said district, more particularly described as follows:

"Commencing where the boundary line between the Districts of Thunder Bay and Kenora intersects the southerly shore of Lake St. Joseph; thence extending north astronomically 315 miles more or less to the northern boundary of the District of Patricia being the Inter-Provincial Boundary between the Provinces of Ontario and Manitoba; thence south-westerly and southerly following the said Inter-Provincial Boundary to the north boundary of the District of Kenora, thence in a general course easterly following the said northerly boundary of the District of Kenora through Winnipeg River and Portage to Lake St. Joseph and the southerly shore of Lake St. Joseph to the point of commencement:—be added to, and form part of the Kenora Mining Division, as and from the 6th day of August proximo."

COPPER WILL COME BACK.

William A. Paine, president of the Copper Range company, after a recent visit to the company's Michigan mines said: "One must not lose faith. Copper always has been a necessity in industry and will continue to be. Copper must and will come back, stronger than ever." Mr. Paine would venture no opinion as to whether or not there will be a general resumption of mining operations this year. He commented, however, on the fact that the biggest producers of copper discontinued output to remedy the dislocation between supply and demand, and that June was practically the first month in which the effect of the mine shut-down was noticeable to any extent so far as decrease in production of refined metal is concerned: no improvement has yet been shown in demand. On the other hand, it will take at least four months, after the mines resume, to bring refinery production up to normal figures. Copper consumption, Mr. Paine believes, largely depends on the return of general prosperity. Approximately 70 per cent of the business now being done by the rolling-mills is with the automobile industry, which goes to show the extent of the depression in other industries which normally use large amounts of copper.

SCOTIA'S NEW COLLIERY.

Excellent progress is being made in the development of No. 7 colliery, the newest of the Scotia Company's chain of coal producers. The sod was broken for this colliery in September, 1920, simultaneously with the closing down and dismantling of the Scotia colliery, which became worked out. No. 7 is in the vicinity of the old Scotia, so that the men who formerly worked at the Scotia colliery were transferred to No. 7 thus continuing them at work at a convenient distance from their homes. The first coal was hoisted from No. 7 in October last. The mine is now giving an average daily output of 400 tons. Rapid work has been done in bringing the new colliery into line as a substantial producer of coal.

The mining is done by machines and not only is the mine very well laid out for economical capacity production, and convenient working but the mechanical equipment is excellent. The seam is about five feet thick, and the coal of splendid quality.

This opening is one of the most important advances made in the Sydney Mines coal field during the regime of Alex S. McNeil as general superintendent, after whom the new opening has been named "Alexander Mine".

TORONTO COAL PRICES.

Toronto, 21st Sept. — As regards the bituminous situation, there is a little more business being placed just now, but not in sufficient volume to afford strength to the market. The price of slack, which continues somewhat scarce, is from $1.60 to $1.90 at the mines. That of lump is from $2.25 to $2.75, according to quality and district, at the mines. The cold snap of the last few days seems to have aroused the householder to some fuller sense of the necessity of getting in his supply of anthracite, while yet there is time. Coal men say that orders for domestic fuel are now coming thick and fast—but there is still a whole lot of leeway to make up.

WACHMAN ORE EXHIBIT.

The Wachman Mining & Milling Company have set an example that might well be followed by other mining operators, by making an exhibit of their ores at the Thunder Bay Agrienltural Society's Fall Fair, now being held at the Society's grounds between Port Arthur and Fort William.

The samples shown are by no means picked ones, but represent a fair average of the ores taken at intervals from the collar of the shafts, down to a depth of 100 feet in shaft No. 2, and to a depth of 50 feet in shaft No. 1.

Visitors to the Fair were treated to panning exhibitions every hour, from the ore on view, in order to demonstrate the values contained therein. Very little mineralization is to be seen in the ore. There are small quantities of chalcopyrites, and some iron pyrites. In the bulk of the ore shown, no mineral whatever is to be seen. While the panning exhibitions were in progress, the writer saw tails of gold colour two inches long, panned from small samples of what appeared to be absolutely barren quartz.

The main vein, on which the development work is being done, has a surface width of from 4" to 3', and outcrops on K-646 for a distance of 1,060 feet. No. 1 shaft is 5 x 6 feet, and is down 50 feet. No. 2 shaft is the same size, and is down 100 feet. Drifting has begun at the 100 foot level, to connect the shafts.

A PRECEDENT WORTH FOLLOWING.

A new ceramic laboratory, in which investigative work regarding the clays of the Northwest will be conducted, is to be installed at the Northwest Experiment Station of the United States Bureau of Mines on the campus of the University of Washington at Seattle.

COMFORT-KIRKLAND.

A contract has been left for the sinking of a shaft on the Comfort-Kirkland property at Kirkland Lake. The shaft will be sunk to a depth of 150 ft. and exploration crosscuts run at that level to pick up extension of the veins on Ontario Kirkland. Local capital is interested in this enterprise.

LEBEL AND GAUTHIER.

Good reports of results of exploration work east of Kirkland Lake are coming to Toronto. This area is regarded as a promising one by many who have visited it.

TORONTO MINING QUOTATIONS.

MINERS' DELEGATES AT INDIANAPOLIS.

Miners' delegates from the coalfields of the United States of Canada and the United States are meeting in convention at Indianapolis this week. Interest in this convention of the United Mine Workers of America centres around the demands in respect of wages, which the miners of the bituminous and anthracite fields will submit to the operators to replace the present agreement, which will expire on the 31st March next.

EDITORIAL

POWER FOR THE GOLD MINES.

At the annual meeting of shareholders of McIntyre-Porcupine Mines Ltd., it was announced that tentative arrangements have been made for the quick installation of an auxiliary steam plant, should one be found necessary. Evidently, the experience of last winter is not to be repeated, if preparedness can prevent it.

Then the shortage of power came very unexpectedly and the mining companies had little time to find substitutes for water power. It was thought probable that one or two of the companies would develop new water-powers this summer, but this has not yet been done. The Hollinger and McIntyre companies both acquired rights to develop and did some preliminary work, but are not yet ready to meet shortage by use of their own water powers. It is evident from the statement given out at the McIntyre meeting that the power problem is still a matter for serious concern at Porcupine, but that those interested are fully alive to the situation.

To a considerable extent, the production of gold next winter will be influenced by the amount of rainfall during the next two months. Ordinarily, we have a considerable fall of rain in Northern Ontario at this time. Last year we had very little and a water shortage resulted. The present summer has been a long, dry one, and, if this kind of weather is not soon succeeded by wet weather, there will again be a shortage of water. The mining companies in former years gave little attention to the water supply, leaving that to the power companies. During the past year, however, they have had good reason to be concerned about the weather, and have, doubtless, made plans to meet a possible shortage of water.
