ADVANCEMENT OF SCIENCE.

The fact that the American Association for the Advancement of Science selected Toronto as its meeting-place last month should give a much-needed impetus to the cause of scientific research in this country. The last fifty years have witnessed enormous strides in scientific development and in the application of scientific discoveries and inventories to commercial and utilitarian purposes. The aeroplane, the motor-car, the telephone, electric lighting, wireless telegraphy—all these inventions (and many others) have taken place within the past half century.

But much yet remains to be done in the domain alike of scientific research and of its practical application to industry. The war, it is true, gave to the chemist and the physicist unexampled opportunities for research work of which they were not slow to avail themselves. Some of the discoveries made under the stress of war are already showing themselves of well nigh inestimable value to those engaged in the pursuit of peace. But of the scientist's thirst for knowledge it may truly be said that "*Vires acquirit eundo.*" The more he learns, the more he becomes conscious that there is still much more that, if he is to be faithful to the light within him, he must yet seek to know. And it is well—vastly well—for the progress of the world that it should be so. For in the life of the researcher there is no failure except ceasing to try.

Sir Robert Falconer, president of Toronto University, addressing the members of the American Association for the Advancement of Science, emphasized the desirability of wealthy institutions and individuals becoming sufficiently interested in the cause to establish endowments for the advancement of scientific research generally. No doubt it is to be desired that such should be the case. But at the same time the Government should address itself in earnest to the task of aiding research work. Last year, members of the House of Commons passed the Research Institute bill which, modest as it was, gave considerable promise of being a real help to those engaged in scientific research. But, although the bill was a Government measure, it was met with a point-blank refusal to pass it at the hands of the Senate. It appears that this ill-advised action—as we feel bound to consider it—on the part of the Senate was based on economical grounds. But if such grounds were really the basis of its action, then it offered to the world a glaring example of false economy. And not merely of false economy, but of illogicality also. For it seems to us highly illogical that, at a time when millions upon millions of public money were being expended on the Government railways—which, it might fairly be argued, showed little prospect of becoming self supporting—the Senate should have refused to sanction the expenditure of only $1,000,000—we refrain from calling it a "paltry" $1,000,000, as that war time mode of expression is now happily obsolete—on a project in many ways so essential to the industrial life of the country.

We believe the Senate's action in this matter to have had an adverse effect, be the same more or less, on practically all the big industries in Canada. For with all of them intense concentration on the costs of production was an urgent need, and with some of them a vital need, if they were to maintain their export trade. Moreover, the action in question assuredly betokened a culpably inadequate understanding of the necessity of governmental co-operation with industry under present-day conditions. In almost any European country the comparatively small assistance which was asked for would have been given gladly [illegible] could not fail to help [illegible] stimulate the industrial life of the whole country. [illegible] profound regret that the non-Conservative [illegible]

will lose no time in introducing a bill of similar purport, and that, if it does so, the Senate will show itself more alive to the exigencies, industrial, commercial and scientific, of the days in which we live.

GOLD MINING IN CANADA.

A very interesting review of metal mining in Canada was presented by Mr. Thomas W. Gibson to the Engineering Section of the American Association for Advancement of Science at the Toronto meeting last week. Mr. Gibson's paper is reproduced in this number of the Journal. It will be noted that the production of the several metals reached very large figures: gold $455,617,107; silver $251,292,685; copper $263,529,237; nickel $164,473,403; lead $50,967,802; zinc $18,600,000 being the most notable. These figures give the value of the metals produced up to Dec. 31, 1920 and another years output has already to be added.

The figures will be increased during the coming year by many millions despite the general depression in industry. Particularly promising for the coming year is the gold mining industry concerning which Mr. Gibson has made some important statements. It is worthy of note that there is at least one industry which can at this time be referred to optimistically. Gold mining in Ontario became firmly established during a period of adverse conditions and one may well be confident that it will thrive under the more favorable conditions. Canada has now produced about $470,000,000 in gold and while alluvial mining has declined, the output of lode gold is rapidly increasing. The record of the past few years is a remarkable one, for the conditions were such that gold mining on a profitable basis seemed almost impossible and only a few survived. It is reasonable to expect that other properties will now be developed and that many new producers will appear during the next few years.

Owing to the poor market for metals, the capacity for output of Canada's nickel, copper, lead and zinc mines is not evident from the years' production record; but it is obvious that even under the unfavorable circumstances a considerable output is being made. Gold is, however, in the preferred position now.

RESOURCES OF JAMES BAY AREA.

The Ontario Government's decision to proceed with the construction of a railway northward from Cochrane, is renewing interest in the possibilities of an area that has important natural resources and which on development may soon become of great industrial importance. There are known mineral, pulpwood, fur and trails that make travel fairly easy for the explorer tion and the provision of transportation facilities will lead to the establishment of several industries and the settlement of a country that, while not far distant, is practically unknown to the people of Southern Ontario.

The inaccessibility of the area has hitherto prevented its development. Fur traders and Indians have travelled its highways for generations; but the rivers and and trails that make travel fairly easy for the explorer have not yet developed into busy highways. The building of the railway will bring about great changes. More definite information concerning the resources will now be sought and the utilization of them will not be long delayed.

In the "Toronto Star" of Dec. 24, there is an illustrated article on the area which will be served by the extension of the Ontario Government railway. The writer comments on the potential mineral, agricultural and forest wealth and the water powers.He considers the undertaking to be of great importance and predicts that great good will come from the opening up of this section of the hinterland. We are pleased to note such articles in the daily press, as it is evidence that larger numbers of our citizens are taking an interest in the development of natural resources.

GOLD INCREASING IN VALUE.

There has been in the United States during recent years much dissatisfaction with the conditions under which gold mines were operating. The high costs which have prevailed have made it impossible to derive a fair profit from the business. The force of the arguments in favor of subsidizing the industry has been diminished considerably by the downward trend of costs and the conviction that the problem will be solved by the increasing purchasing power of gold.

In this connection the recent report to Congress by the Secretary of the Treasury is of interest. The Secretary, referring to the McFadden bill said:

"Due to the unfavorable influence of high prices and consequent high costs of production on the mining and reduction of gold, there have been further discussions of proposals for subsidizing the gold-mining industry. A bill has been introduced in the House of Representatives (H. R. 5025) 'To provide for the protection of the monetary gold reserve by the maintenance of the normal gold production of the United States, by imposing an excise, for revenue and other purposes, upon all gold used for other than monetary purposes, and by the payment of a premium to the producers of newly-mined gold, and providing penalties for the violation thereof.' The Treasury does not approve this bill or other measures for subsidizing the gold-mining industry, believing that the problem will ultimately adjust itself and gold mining become more remunerative as the purchasing power of the dollar increases."

The chief producing gold mines in Canada were able to do fairly well during the period of high prices. Production was curtailed and plans for expansion postponed, some mines were forced to close down, development of new properties slackened, costs mounted to dizzy heights and labor became inefficient; but for-

tunately a few mines were able to continue operation and the industry survived. Lower costs will make it possible to mine profitably more and more ore that is now being left in the big mines and which would never be mined at the high costs that have prevailed. Lower costs will also lead to greater activity in developing new mines.

During the past year there has been a notable increase in the value of gold. The cost of other commodities has dropped sufficiently to warrant reduction in wages. With lower cost of living there will be increase in the amount of work that can be profitably done at gold mines and the position of the miner will be bettered. There is good reason for the belief that the gold mining industry in Canada, and particularly in Northern Ontario will grow rapidly during the coming years.

MINERALS IN SASKATCHEWAN.

Regina, Dec. 28.—"Our second annual exploration party into northern Saskatchewan has just returned, and their preliminary report further confirms the general impression that the north country gives promise of great future possibilities," says Hon. C. A. Dunning, Minister of Labor and Industries for Saskatchewan.

"Last year we sent north our first exploration party which, of course, made but a reconnaissance survey of the territory, noting features or formations worthy of further study. This year's party, therefore, was for the purpose of closely studying one of the features selected by last year's party, namely, the Bear Hills district."

Among the more important minerals (metallic and non-metallic) discovered in the vicinity of the Bear or Wapawekka mountains, the last season, by the Saskatchewan Government Survey party can be listed:—

A wide variety of clays and shales, limestone, granite and sandstone for building purposes, small amounts of garnet sand, glass sand, builders' sand, large tracts of bog iron ore, numerous deposits of yellow ochre and other paint materials, and several springs of mineral water.

That the northeastern portion of Saskatchewan is rich in clay and shale deposits for the manufacture of building brick, paving brick, and other lines of structural slay ware is clearly shown by the great beds of Benton shale to be seen at several points. There are exposures of this material ranging in height from 80 to 100 feet of pure shale, without a single band of non clay material intervening, representing millions of tons of structural building material.—Toronto Globe.

SHIPPING NOTES.

By J. J. O'CONNOR.

An important addition is about to be made to the Canadian Lake fleet of bulk carriers, that will aid considerably in bringing back the proper proportion between it and the United States Lake tonnage, as it existed 40 or 50 years ago on the inland waters.

The Mathews Steamship Company, of Toronto, have awarded a contract to the Port Arthur Shipbuilding Company, of Port Arthur, for the construction of lake freighter, 550 feet over all, 58 feet beam, and 31 feet in depth. The contract was signed in Toronto on the 22nd instant, and was announced by the Port Arthur Shipbuilding Company on the 27th.

According to the design, the new ship will be the most modern vessel on either side of the Great Lakes.

She will be of steel construction throughout, equipped with a triple expansion engine, 25½"x41"x67"x42" stroke, the steam being furnished by three Scotch boilers, with three interchangeable Morrison furnaces. The boilers will be 13' 6" in diameter, by 11' 2" in length, allowed 185 pounds pressure. The d.w. capacity will be 12,000 tons, or in terms of wheat, 400,000 bushels.

The construction will be under the personal supervision of Mr. J. H. Smith, of Cleveland, O., formerly general manager of the Port Arthur Shipbuilding Company, and will be built to classify "A 100" at Lloyds, and the American Bureau of Shipping. The contract calls for delivery September 15th, 1922.

Work on this contract will proceed immediately, pattern makers and others will be put to work at once in preparation for the work of construction, and the keel will be laid just as soon as material can be assembled.

This contract will furnish employment for from 800 to 1,200 men constantly from now on to the date of completion, and will be of substantial advantage to the ranks of unemployed and greatly relieve the present situation in both skilled and unskilled labor.

President Whalen states that he is hopeful of securing further shipbuilding contracts in the near future.

At present the plant is chiefly employed in ship repairs, and the manufacture of paper mill machinery, employing 250 men.

BRITISH COAL IN NEW YORK.

New York, Dec. 28.—British coal, equal in quality to the best American coal, arriving in New York harbor and offered for sale at wholesale at $4.75 a ton, has perturbed the coal barons in their souls.

The British coal comes here as ballast. The shipowners find that it is cheaper to load with coal and sell it over here than to load ordinary ballast. Each ship carrying coal ballast brings from 800 to 1,000 tons.

As American coal of similar quality is not sold at below $6 a ton, American coal men are now insisting upon a reduction in freight rates which will enable them to meet this new competition.

Washington, Dec. 29.—In announcing that a survey of the entire bituminous coal situation in the United States will be undertaken by a special staff of the National Unemployment Conference, to be appointed next week, Secretary Hoover to-day declared British coal was making inroads in the United States markets.

Mr. Hoover declared that the British now were selling coal at less than cost in anticipation of greatly increased production in English mines. More British contracts for coal, he stated, had been let in the West Indies and some British coal was making its appearance on the Pacific Coast, although mainly in the form of bunkers and was not regarded as a serious competition to United States coal there.

COL. W. E. THOMPSON, ARBITRATOR

Sydney, N. S., Dec. 28.—Col. W. E. Thompson, of Halifax has been appointed by the Department of Labor as a member of the Board of Arbitration granted the United Mine Workers of America of District No. 26 to inquire into a 33 per cent wage cut announced by some of the large coal operators of Nova Scotia for January 2. Mayor King of New Waterford is the miners' nominee.

Metal Mining in Canada

By THOS. W. GIBSON.

Canada comprises the larger part of the North American continent, its area being 3,729,665 square miles as compared with that of the United States which, including Alaska, is 3,617,673 square miles. It includes all the British territory in this part of the world excepting the island of Newfoundland, and a narrow strip of land on the adjacent coast of Labrador, which remain as a separate colony.

Geologically, a large part of Canada is of a very ancient origin, for in the great basin of Hudson Bay it is believed the first dry land appeared above the primordial seas. Whatever of mountain and valley may have characterized the original physiography of this region, glacial action has reduced the surface to a vast plain, leaving no heights more than 2,000 or 2,500 feet above the sea. Other topographic provinces are recognized in the Laurentian peneplain, the Arcadian and St. Lawrence basins, all draining into the Atlantic Ocean, the interior continental plateau, whose rivers flow into Hudson Bay and the Arctic Ocean, and the Rocky Mountain or Cordilleran ranges, which form the western flanks of Canadian America.

In so vast a region there cannot but be a great diversity of geological conditions, hence we find practically all the known geological horizons represented. The pre-Cambrian formations are the most prolific of metals, where fracturing or disturbance of the earth's crust has provided favorable conditions. In them are found the chief metal deposits of Central Canada, including the nickel and copper of Sudbury, the gold of Porcupine and Kirkland Lake, the silver of Cobalt, and the iron ranges of Michipicoten and other localities. All the metals found occur in Canada in commercial quantities, save tin, of which little more than traces have yet been recognized.

Gold.

The precious metals, especially gold, have played an influential part in the history of the human race. These metals make a strong appeal to the senses because of their beauty and their comparative scarcity and adaptability as media of exchange have contributed to make them the objects of universal desire.

Gold deposits are of two types, alluvial and lode. The stocks of gold possessed by the ancients, and, indeed, down to comparatively recent times, were derived almost solely from alluvial sources, and to this may be attributed the fact that in those parts of the earth's surface which have been longest and most fully occupied, alluvial deposits are now scarcest. The placers have been worked out. But in comparatively new countries, like the United States, Canada, Australia and Siberia, important deposits of placer gold have within late years been found and more may yet be looked for. The romance and lure of gold-diggings, where a man by his own muscles may win from the ground an immediate, and it may be a great reward, invest placer fields wherever found, with an attraction to which no other kind of mining can lay claim. From 1848, when the California diggings were located, to 1875, it is estimated that 87 per cent. of the gold produced in the world was obtained from placers. At the present time from a tenth to a fifth only comes from this source.

British Columbia and the Yukon have been the scene of the greatest gold-washings in Canada. A little gold has been won from the Gilbert and Chaudiere rivers in Quebec and from the sands of the Saskatchewan, but the central Provinces of Canada appear to possess little gold in placer form. In the case of Ontario this may seem somewhat remarkable in view of the extensive glacial erosion to which its precious metal deposits have been subjected, but beyond doubt, the immense quantities of glacial detritus have been sufficient to scatter and bury any gold or silver derived from the erosion of deposits in place. At any rate, nowhere yet has been found gold or silver in any important quantity, in the sands or gravels of Ontario.

The California discoveries in 1848 led to a tremendous influx of prospectors who found their way into British Columbia, where in 1858 and succeeding years, they located alluvial fields on the Fraser river, and in Cariboo, Quesnel, Cassiar and elsewhere. These fields yielded two to four million dollars' worth of gold annually for ten years, then declining, as do all placer and other mines, to much lower levels. Up to the end of 1920, the alluvial gold production of British Columbia is given at about $76,000,000.

The second great alluvial gold find in Canada was made on the inhospitable banks of the Klondike in 1869, and the story of the incredible hardships endured by the way and in the field, especially by the first ranks in the rush that followed, is yet fresh in the minds of the present generation. Discoveries spread to other creeks, and, in 1900, the population reached 30,000 souls, and the yield of gold $22,275,000. This was the peak year, and from that time the output decreased annually. In 1920, it had fallen to $1,500,000. The total output from the Klondike field has amounted to 8,443,774 ounces, worth $172,532,000. It is rather curious that there has been very little production in the Klondike of lode gold.

In British Columbia lode gold-mining began in 1890, with the discovery of the Rossland ore bodies, which carry both gold and copper. This was followed by the location of the large low grade copper-gold deposits of the Boundary camp. Nearly all the copper ores in British Columbia carry more or less gold. The principal gold-producing areas are Boundary-Yale and Rossland. There are also the Skeena, Coast, Lillooet and others.

In Ontario, gold was first discovered in 1866, in the vicinity of Madoc. A rich pocket was found in place, but though numerous gold-bearing veins have been located in Eastern Ontario, gold-mining has not been successfully established there. The Lake of the Woods and Seine River Districts in Northwestern Ontario, likewise contain gold occurrences spread over a large area, and several mines, notably the Sultana, Mikado, Golden Star, Regina and others, have yielded considerable bullion. These fields are not at present being actively worked.

Gold may be said to be scattered over many parts of northern and northwestern Ontario, but it was not until 1909 that gold mining in this Province was placed upon an enduring basis. In that year the first finds were made in the Porcupine field. This camp is now one of the most important on the continent and gives promise of being a still larger producer. The principal mines are Hollinger Consolidated, McIntyre-Porcupine and Dome. The Hollinger is one of the largest

gold mines in the world, its production this year will be about $9,000,000, and the yield of the entire camp upwards of $13,000,000. Kirkland Lake is another gold area which is undergoing rapid development, there are now six plants producing gold, and the output this year will be over $2,000,000.

Northern Ontario is showing itself to possess all the elements of success for the gold mining industry. It is easily accessible by rail, prospecting is by canoe and the country abounds in water-courses. There are no mountains, the climate, though cold in winter, is healthful and invigorating, and there is plenty of wood water and labor. The ores are moderately rich, running from $7.00 to $25.00 per ton but averaging say $9.00 to $10.00. The ores are free milling, the standard process of reduction being in stamp or ball mills, preferably the latter, followed by cyanidation. A significant feature is the numerous discoveries of gold and the widespread area over which they have been made. There are a number of camps not yet actually producing bullion but in various phases of the development stage; these include Matachewan, West Shining Tree, Larder Lake and others.

Nova Scotia has produced a fair amount of gold, over $20,000,000, but the yield has for a number of years been declining, and is at present very small. The gold-bearing rocks of that Province vary in width from ten to seventy-five miles, and extend some two hundred and sixty miles in length along the Atlantic coast. The deposits are in saddle-shaped quartz veins, resembling those at Bendigo in Australia. Northern Manitoba has recently been shown to contain gold, some spectacular specimens having come from there and a little bullion having been produced.

A unique feature of the gold mining industry is that it is not a competitive one, the price of gold being constant at $20.67 per ounce. When wages and supplies rise in price, the increased cost of production cannot be shouldered on the customer, as in other industries and with other metals. Hence conditions such as obtained during the war, told heavily against gold mining and brought about a stoppage of operations where the margin between expenditure and income was almost or entirely extinguished. Conversely, when labor, as now, is more efficient and wages and commodities have gone down in price, gold mining benefits by the change. In addition, gold produced in Canada, being paid for in United States' funds, the mine owners profit by the difference in exchange. In the great gold fields of the Transvaal this premium on gold is very important, and it is stated that a considerable number of mines there will be obliged to close should exchange return to normal conditions and gold again be valued at the old price of 85s. per ounce.

The declining output in gold throughout the world is occasioning some anxiety among men of finance. In 1915, the yield was $468,724,918, and in 1920, $331,987,610, a fall of nearly one-third. About two thirds of the whole comes from mines in the British Empire, the Transvaal furnishing about forty per cent. Canada is almost the only exception to the rule of declining production, her output going up year by year. Ontario is now producing more gold than any State in the Union, including California, and her yield is about twenty-five per cent. of that of the United States.

Summing up the gold production of Canada from the beginning of operations until December 31st, 1920, it appears that more than one-half the total has come from alluvial sources. This is due to the great outpouring from the Yukon creeks, but the preponderance is now shifting to lode gold, because of the increasing importance of the Ontario production. Following are the figures by provinces:

	Alluvial	Lode	Total
	$	$	$
British Columbia	75,944,000	112,753,000	188,697,000
Yukon Territory	172,532,800	.....	172,532,800
Ontario	.....	72,982,307	72,982,307
Nova Scotia	.....	20,155,000	20,155,000
Quebec (estimated)			750,000
Saskatchewan (estimated)			500,000
Total			$455,617,107

Silver.

The silver output of Canada has so far, come practically from two Provinces only—British Columbia and Ontario. In the other Provinces a little silver has been recovered in refining copper and other ores, but the amount is relatively small.

In British Columbia the chief source of silver is argentiferous galena, a large part of which is worked for lead, but considerable quantities are also recovered in treating the complex gold silver copper ores found in various parts of the Province. The silver-lead ores vary in character, in Kootenay the ore bodies are large and the silver content low; in Slocan district the ores are higher in silver, averaging perhaps seventy-five ounces per ton; in other districts are found the so called "dry" ores, containing little galena, the values being in native silver and silver sulphides.

The silver ores in Ontario, on the other hand, are worked mainly for that metal. It is true these ores contain also nickel, cobalt and arsenic, also a little copper, and these substances are recovered in the processes of treatment, but they may be regarded as incidental or by-products. There have been two eras of silver mining in Ontario; the first beginning with the finding in 1868 of very rich ore on Silver Islet, a tiny speck of land off Thunder Cape in Lake Superior, followed afterwards by discoveries on the mainland. From Silver Islet silver worth $3,250,000 was taken and from the mainland the output was valued at $1,885,681. None of these mines are now, or have for many years, been in operation, an exception being made of Silver Islet, where attempts to re-open it were under way during the present year. The second era was opened in 1903 by the finding of phenomenally rich silver deposits in what is now known as the Cobalt silver area. The veins here are narrow, mostly short and rarely deep, but to compensate for these disadvantages, they have proven to be numerous and exceptionally valuable. In the early years of Cobalt, ores carrying 6,000, 8,000 and even 10,000 ounces of silver per ton were not uncommon. 2,000-ounce ore was plentiful. Carloads of ore weighing 25 or 3 tons have been shipped out bringing to the owners a return of $100,000, $120,000 or even $130,000. The values were largely in native silver, the proportion of sulphides or galena being inconsiderable.

The geology of Cobalt was worked out at an early stage by Miller and Knight. The predominating influence in the formation of the silver deposit was a sill of diabase, intruding formations of Keewatin and conglomerate rock. The greater part of the silver production has come from veins in the conglomerate, but rich deposits have also been found in the Keewatin and diabase.

Mining at Cobalt began in 1904, and the production increased year by year until 1911, when it reached upwards of 31,000,000 ounces. Since that time there has

been a steady, though not rapid, decline, the yield in 1920 being about 11,000,000 ounces. The life of the camp has been prolonged by the high price of silver prevailing during several years of the war, and by improvements in metallurgical processes, notably the flotation method. These two factors combined to convert valueless dumps and wall rock into pay ore. Discoveries of new deposits continue to be made in old and supposedly exhausted mines. For instance, in South Lorrain, a subsidiary camp, the Keeley mine, practically given up years ago, is now producing silver at the rate of 100,000 ounces per month. Other subsidiary areas are Casey, Elk Lake and Gowganda, where the assemblage of minerals is the same. In the last named camp, the Miller-Lake O'Brien mine rivals in richness the deposits of Cobalt proper.

A feature of silver mining in Cobalt by the operating companies is its profitable character. Out of a total value produced up to 31st December, 1920, of about $200,000,000, there had been returned to the shareholders in dividends or bonuses, upwards of $82,000,000. Many of the companies paid back in dividends an amount equal to several times the original capitalization. The total silver production of Canada to 31st December, 1920, was as follows:

	Ounces	Value
British Columbia	87,017,673	54,608,653
Ontario	314,431,329	192,719,032
Quebec, Yukon and Manitoba (estimated)	6,500,000	3,965,000
Total	407,949,002	251,292,685

It may be noted that North America yields annually about 75 per cent. of the total world production of silver. While the west produces the silver, the east in large part consumes it, approximately one-half of the entire production going annually to India and China, where it largely disappears from view.

Copper.

British Columbia is the chief copper-producing Province in Canada. The most important districts are Skeena, Southern Coast, Boundary-Yale, Trail Creek. The ores are of varied composition and differ in their geological associations, but in the main are sulphides; the principal mineral being chalcopyrite, though bornite and other varieties also occur. The ores all carry more or less gold and some silver, and are treated in smelting plants in the Province. At Trail the Consolidated Mining & Smelting Company of Canada produces refined copper, lead and zinc, also gold and silver.

In the Province of Quebec large bodies of pyrite and chalcopyrite at Eustis and Capelton and other places in the Eastern Townships are operated chiefly for their sulphur contents, the ore being exported to the United States for the manufacture of sulphuric acid.

Along the north shore of Lake Huron and the east and west shores of Lake Superior in the Province of Ontario, are numerous occurrences of copper sulphides. A large deposit at Bruce Mines was opened about 75 years ago and worked with greater or less success for some time. Other deposits in the same neighborhood that have been operated are Rock Lake, Massey Station and Superior. These ores are all highly siliceous and carry from 1 to 2 or 3 per cent. of copper. The chief source of copper production in Ontario, however, is the nickel-copper ore of the Sudbury area. These mines are worked mainly for nickel, but carry from 1 to 3 per cent. of copper.

In Northern Manitoba copper sulphides of unusually high content are found in the Mandy mine, and a large body of low grade ore is contained in the Flin-flon. The latter mine is awaiting railway facilities before being operated.

The copper production of Canada to 31st December, 1920, may be given as follows:

	Quantity Lbs.	Value $
British Columbia	959,128,920	175,994,278
Ontario	469,259,209	77,534,959
Quebec, Manitoba, etc., (estimated)	....	10,000,000
Total		$263,529,237

Nickel.

In the mines of the Sudbury District, Ontario possesses the source of 85 per cent. of the world's supply of nickel. The ore is essentially a pyrrhotite mixed with chalcopyrite, and containing pentlandite as the nickel-bearing mineral. It occurs in large masses at or near the contact between norite and granite or other country rock. There has been much controversy as to the origin of these ore bodies, some geologists holding them to be the result of magmatic segregation and others of precipitation from hot solutions.

Discovery was made in 1883, during the building of the Canadian Pacific Railway. The ores were first regarded as those of copper only, and the presence of nickel was not recognized until difficulties were encountered in smelting. Jas. Riley's epoch-making discovery of the value of nickel in toughening and hardening steel led to the adoption of nickel steel armourplate for battleships, and ultimately to a large range of usefulness for nickel for industrial as well as military purposes.

There are at present three companies operating the mines, the International Nickel Company of Canada, Limited, the Mond Nickel Company, Limited, and the British America Nickel Corporation, Limited. The ores are mined and roasted, either in the open air or in sintering furnaces for expulsion of sulphur, and are afterwards smelted in blast furnaces into low grade matte. This is then bessemerized in converters into high grade matte, containing about 80 per cent. of nickel plus copper. Part of the matte is refined in Canada, part in the United States, and part in Wales. It is worthy of note that the three companies employ distinct and separate methods of refinement. The International Company use the Orford process, a combination of chemical and smelting methods; the Mond Company the process invented by Dr. Ludwig Mond, the founder of the company, based on the affinity of carbon monoxide for finely divided nickel, and the British America Corporation, the Hybinette or electrolytic method.

Ore similar to that of Sudbury is found at the Alexo mine in the Porcupine area, and nickel is a component of silver ores of the Cobalt camp. The quantities obtained from these sources are small in comparison with those from the mines at Sudbury. Reserves of ore at the latter place are estimated at 150,000,000 tons.

During the war the demand for nickel and copper was insatiable, and the signing of the Armistice found large stocks of both in the hands of the Allied Governments, their contractors and the mining companies. The slow process of reconstruction has not as yet permitted the absorption of these stocks. In consequence, the Sudbury mines and smelters are idle, or nearly so.

and production for the time being has almost ceased The usefulness of nickel for niekel-steel, coinage, electro-plating, Monel metal and other alloys, and other industrial purposes, which before the war employed at least 50 per cent. of the output, will when manufacturing has again attained its normal proportions, assure this metal coming into its own.

Lead.

Most of the lead produced in Canada has come from the argentiferous galena ores of British Columbia, many of which carry also zinc. Active operations in that Province began in the Ainsworth camp in 1886, and discoveries in 1892 in the Sandon camp and East Kootenay extended the industry to these localities. The Fort Steele and Slocan districts are at present the largest producers.

An ore body remarkable for its size and quality, containing lead and zinc, is now being worked in the Sullivan mine, north of Cranbrook Station on the Canadian Pacific Railway. The ore is shipped without concentration to the smelter of the Consolidated Mining & Smelting Company at Trail, where a very successful method of selective flotation and subsequent electrolytic refinement, has been worked out by that company.

In Ontario galena ores carrying little or no silver have been worked on a small scale at the Frontenac and other properties in Eastern Ontario. Smelting works were erected over forty years ago, but operations have been sporadic and on a small scale. In recent years a small mine and smelter have been successfully worked at Galetta near Ottawa.

The output of lead in Canada up to 31st December, 1920, was as follows:

	Quantity, lbs.	Value, $
British Columbia	1,040,486,931	50,179,202
Ontario	8,772,000	786,600
Total	1,049,258,937	50,967,802

Zinc.

British Columbia produces practically all the zinc mined in Canada. There are lead-zinc deposits in Ontario and Quebec but their size and production are insignificant in comparison with those of the Pacific Coast, where in general, the ores are closely associated with lead. A successful solution of the metallurgical problem long presented in the separation of zinc from lead, has given both these branches of mining a distinct impetus. The production and marketing of zinc as a separate metal is practically confined to the last few years.

The output of zinc, up to the end of 1920, from British Columbian deposits was 22,734,207 lbs., valued at $18,600,000, plus a small production from Quebec and Ontario.

Iron.

There is an important iron smelting industry in Canada, but it is almost wholly dependent for its supplies of ore on outside sources. At Sydney, Cape Breton extensive plants for the manufacture of pig iron and steel have been erected in proximity to the coal beds that are located there. The iron ore charged into the furnaces comes from Bell island, Newfoundland, perhaps one of the largest and best deposits of iron ore known.

In Quebec a small charcoal iron industry for many years made use of the bog ores found in that Province. Ontario produces most of the pig iron made in Canada but makes 95 per cent. of it from ore imported from the United States. From Port Arthur to the Pacific Coast no iron ore is smelted.

This condition is not due to lack of iron ore deposits, for such exist in nearly every Province. Two chief causes may be assigned for the slow development of an iron mining industry in Canada; first, the quality of our deposits, many of them being low in grade, and secondly, the ease with which ironmasters can supply their wants from long-established sources elsewhere. With regard to the first cause, the Province of Ontario has numerous and extensive iron ranges in the north and northwest, containing on the aggregate, millions, perhaps billions of tons of ore. For the most part, the ores are too siliceous for present use. They contain from 30 to 40 or 45 per cent. metallic iron, and in their natural condition cannot compete with the excellent ore which can be obtained of almost any desired composition from the mines of Michigan and Minnesota, delivered, too, by water carriage.

The iron ranges of Ontario are mostly of magnetite or a mixture of magnetite and hematite, but there are also siliceous hematites and much siderite. Various forms of beneficiation are used to render these ores suitable for present furnace practice, and this, of course, adds to the expense. May it not be that inventors should turn their attention to the other side of the problem and endeavor to adapt a process to the ores, rather than the ores to the process?

Iron deposits of good quality, however, do exist, and have been worked in Canada. Eastern Ontario contains a number of such, from which considerable shipments have been made. Here, sulphur and titanium are the objectionable ingredients rather than excess of silica. At the Helen mine in Michipicoten, some three million tons of good ore were extracted. This ore body resulted from the alteration of siderite, and it is believed other deposits of like character exist in that region. At the Magpie mine the siderite when roasted, makes first class blast furnace material, and so does the magnetite at Moose Mountain when concentrated and briquetted.

Iron ores are found in Nova Scotia, New Brunswick, Quebec, Ontario and British Columbia. The prairie provinces contain hematite, limonite and clay iron stone, but so far have furnished no production of iron.

Minor Metals.

The silver ores of the Cobalt camp contain cobalt which is recovered as cobalt oxide in the refineries. Before the war a large trade was carried on in this article with England and the continent of Europe where it is extensively used in the manufacture of china and porcelain. Metallic cobalt is also made and is used in making an alloy called stellite which has been found very useful for high speed tools.

There are deposits of chromium in Quebec and some production took place during the war, but the development has not as yet been extensive.

The nickel copper ores of Sudbury carry appreciable quantities of platinum, osmiridium, and other metals of the platinum group. The platinum occurs as the arsenide sperrylite but the palladium mineral has not been isolated. A proportion of these metals is recovered in refining the matte, the production in 1920 being 8,400 ounces of platinum and 10,000 ounces of palladium.

Northern Ontario Letter

THE SILVER MINES.

Prices and Wages.

As time wears on and with the price of silver remaining quite steady at around 65 cents an ounce, the feeling is taking form that this may mark the approximate average price for some time to come. Calculated upon a basis of current consumption, inclusive of the purchases being made by the United States Treasury, the visible supply of the metal would encourage the belief that the demand might soon become greater than the supply and thereby cause quotations to rise. As to this, however, with certain of the leading nations in a state approaching impoverishment in a monetary sense, it at once becomes obvious that a barrier exists to any general demand for commodities other than real necessities.

With these views in mind, the operators of silver mines in the Cobalt district are found estimating the value of the mines on silver at from 60 to 65 cents per ounce. The avenue to profitable operation of certain of the mines which as yet remain closed lies along the gradual decline in the cost of supplies and probably another substantial reduction in wages.

Installing Plant at Haileybury Frontier.

The Mining Corporation of Canada has completed arrangements to instal a larger mining plant on the Haileybury Frontier property in South Lorrain. Towards this end, the electrically-driven hoist as well as compressor from the old Cobalt Lake plant is being removed at once to the Frontier. The plan of operation consists of further work at the point where former development work has been going on as well as diresting considerable attention to an endeavor to pick up the continuation of the "Woods" vein which is believed to extend onto the Frontier from the Keeley Silver Mines. Work on the Frontier up to the present amounts to less than 1,000 feet of underground work, as a reward for which a number of small ore shoots have been found. Work on a wide scope such as that planned by the Mining Corporation holds out promise of interesting results.

Victory Silver Mine.

In a report made by J. A. McVichie, the geological structure on the property of the Victory Silver Mines is shown to be very favorable. Reasons are given why the keewatin formation overlying the diabase became fractured, how the shearing occurred and all of which created a condition which would permit the silver bearing solutions from the intruding diabase to pass through and leave the precious metal in the fractures, thereby forming veins. Recent work at a depth of 185 feet has resulted in the discovery of a wide vein on which lateral work is now in progress and in which the prospects appear to be good for finding ore in substantial quantities.

Nipissing Explorations.

The Nipissing Mining Company recently examined property in the Sault Ste Marie district, but found nothing of particular interest. In the meantime a great deal of staking has been done in the district on the strength of the reports that the Nipissing had become interested.

On the other hand, the Nipissing is meeting with considerable encouragement in the work of exploring the Rochester property in the Porcupine district. Six holes have been drilled by diamond drills and a seventh is now down about 300 feet. In holes No. 2 and 5 the ore showed commercial values across good stoping width and the seventh hole, which will be driven to a depth of between 500 and 600 feet, is for the purpose of proving the continuity of the zone of mineralization. The formation has been found to consist of basalt, red porphyry and quartz porphyry, thereby resembling the adjoining Hollinger Consolidated. The Nipissing's option is for $250,000 and holds good until early spring, provided a certain amount of work is performed monthly.

Hudson Bay.

No announcement has so far been made in regard to whether the Hudson Bay will interest itself in the Cane Silver Mines, or not.

Coniagas.

The Coniagas has been mentioned as being identified with negotiations for an option on the old Ruby property, situated in the township of Bucke.

Trethewey.

Further reports are current in connection with the Trethewey Company, in connection with the plans of the company to secure funds with which to operate the Castle property in Gowganda as well as instal a small mill. It is intimated that a new company may be incorporated, either that or an increase made in the capitalization of the present company. In the meantime, stock traders have appeared to register their disapproval of the scheme, and the quotations for the shares declined to around five cents each during the closing days of December.

A number of small properties are deriving the benefit of sleigh transportation and considerable exploration work is being done in certain sections of the Gowganda field. The continued high wages, however, without compensation in the way of high quotations for silver, has militated against any general expansion in activity.

THE GOLD MINES.

McIntyre.

Work in connection with putting the property in shape for greatly increasing its production in the spring is proceeding at a rapid rate on the McIntyre-Porcupine. The mill continues to treat about 550 tons of ore daily and is producing at the rate of between $5,000 and $6,000 daily. The new milling unit now being installed for the purpose of treating the high-grade carbonaceous ore found in one section of the mine will have a capacity for handling 250 tons daily and will be ready for operation in the early spring, thereby increasing tonnage to 800 tons daily and resulting in a production of at least $8,000 every twenty-four hours. This means that the McIntyre will then be able to produce approximately $250,000 every thirty days, or at the rate of around $3,000,000 a year. A conservative estimate of net profits, based upon achievements already recorded, may be placed at $100,000 monthly, or well over 30 per cent a year on the company's issued capital of $3,600,000.

Moneta and Inspiration.

The good results of the Rochester property, which are referred to in greater detail under "The Silver Mines" in a preceding paragraph of this letter, are such as to encourage hope on such properties as the Moneta and Inspiration, both of which also lie in such a position as to likely share at least a part of the geo-

logical condition under which the Hollinger finds its ore.

Hayden.

Operations are actually under way on the Hayden-Porcupine after an idle period of several years. This is only one of the many signs of a general revival in gold mining activity, even among the properties in the prospective and development stage.

Triplex.

Reports that the Triplex had purchased a second-hand 20-stamp mill was premature, as such a plan has not yet passed beyond the point of negotiations. In the meantime, work is being carried on steadily.

Dome.

Continued heavy production from the Dome Mines is pointed to in well informed circles as assuring a realization of at least $1.00 per share as capital return not later than the end of March. This "disbursement" when made will be in addition to current dividends of 10 per cent annually and will not be subject to taxation. The report printed in certain sections of the press that selenium had been found in some of the ore on the Dome is not of any special significance. The only feature in connection with the presence of this material is that it causes a slight problem in connection with getting a high percentage of gold recovery. By reason of some undetermined agency, possibly selenium, the gold content of the tailings is found to fluctuate, but not to any alarming extent.

Davidson.

The curtailment of operations on the Davidson mine are stated to be temporary, and it is believed general operations will resume in the spring. Diamond drilling from surface will be carried on during the present winter on a section of the property heretofore unexplored.

Lake Shore.

During the month of November the Lake Shore Mines established new records, in spite of the mill having operated only 92.36 per cent of the possible running time.

A total of 1,810 tons of ore went through the mill, from which an average of $30.02 was recovered from each ton, or a total of $54,343.51 for the month. Therefore, in point of average values as well as total output, the November achievement was the best so far in the history of the mine.

A feature of work during the month was the exceptionally favorable results at the 600-ft. level where the ore deposition in vein No. 2 has been found to be even greater than found at the 400-ft. level. Assays of $50 and $100 per ton are not uncommon in certain sections of the vein over a length of 600 feet.

As work proceeds, the Lake Shore is looming up as a much larger mine than has generally been supposed.

Bidgood.

The vein on the Bidgood property where cut at the 400-ft level has been found to have a width of over 20 feet, although values are comparatively low. Lateral work will be carried on for the purpose of proving the downward continuation of ore found at the preceding level.

Shareholders of the Teck-Hughes Gold Mines availed themselves to a large extent of the opportunity to subscribe for newly issued stock in the company. At the time of writing, the full amount subscribed for has not been announced, but it is understood that whatever balance is left of the 1,722,000 shares will be taken up by the bondholders. The indications are that the indebtedness of the company will be reduced from $635,000 to about $312,000.

British Columbia Letter

Stewart, B.C.—Heavy snowfalls have stopped almost all mining activity in the Portland Canal District. Work continues, of course, on the Premier Mine and such other properties as are well advanced in development and have made preparations for winter operations. On Fish Creek, for instance, the Fish Creek Mining Company has a gang of men busy. A crosscut tunnel on the upper lead is said to have shown the vein to be 11 feet in width and within its compass are three distinct shoots of high grade ore. The vein filling all is reported to be good milling material. A winze now is being sunk on the vein. The high grade is being sacked as it is broken down and will be shipped over the snow. The aerial tramway to the Silverade Group has been completed and a considerable quantity of high grade ore is to be sacked and shipped.

Esperanza.

Alice Arm—The Esperanza Mine, which lies at an elevation of about 800 feet about one mile north of the town of Alice Arm, will ship approximately 100 tons of ore in the course of a few weeks. D. Jeremierson of Vancouver, and associates, are the present owners of the property and it is their intention, providing the first shipment is a success, to continue the work during the winter.

Utica Mine.

Kaslo, B.C.—O. C. Thompson, who is in charge of development work on the Utica Mine, states that much has been done in opening up and generally putting in shape for operation purposes the old workings of the property. New ore has been blocked out in different places and a car has been loaded ready for shipment. Mr. Thompson expects to be on a regular shipping basis soon.

Shipments to Trail.

Trail, B.C.—Shipments to the Trail Smelter of the Canadian Consolidated Mining & Smelting Co. for the week ending December 21 were 5,756 tons, distinctly under the average of the past few weeks. The Josie of Rossland, was the only independent shipper being credited with 102 tons.

The Britannia Flood.

Vancouver, B.C.—The charges laid against Messrs. E. J. Donoghue and C. P. Brownlee officials of the Britannia Mining Company of criminal negligence in connection with the flood catastrophe that practically destroyed the mining community of Britannia with much loss of life, have been dismissed. The magistrate observed that the Crown had not presented evidence to show who was in control at the time of the disaster and there was nothing to indicate that anyone had thought there was any danger. The water only rose before it had come to the top of the culvert, the warning mark of which was alleged to have caused the flood. This did not seem to have been any lack of precaution. The company had exercised its best judgment and the only thing that could be charged was an error of judgment.

Engineers Will Lecture.

Victoria, B.C.—The resident mining engineers in charge of the six mineral survey districts into which the Provincial Government has divided the Province have received instructions to deliver a series of lectures to mine operators and prospectors in the several centres of their respective zones of responsibility. This policy was inaugurated last winter and the addresses were much appreciated. These talks by the engineers do not pretend to exhaustively cover the technical phases of mineralogy, geology, or chemistry. The consist more of practical pointers to those interested as prospectors or in other respects in the mining business. They also give interesting information on the minerals of the Province.

THE BETTY COAL SEAM.

A Primising Coal Seam on Telkwa River, British Columbia.

In a report of the Aveling Coal Property, situated on Telkwa River, Northern British Columbia, John D. Galloway, provincial resident mining engineer, refers optimistically of the possibilities of this practically undeveloped coal field.

He says. "The main coal showing on the property, known as the *Betty* seam outcrops along the edge of the Telkwa river. Two tunnels, the longest being over 100 feet have been driven into the seam. The seam is a large one, as the thickness is at least 20 feet; of this 20 feet over 18 feet is coal and a good deal of this is an excellent quality of coal. At the present time a band of coal 2 feet thick is left on the roof as it makes a better roof than the soft friable shales. Below this top coal is a band of 18 inches of coal that is being sold as blacksmith coal: an average analysis of this is:—Moisture, 1.8 per cent.; V.C.M. 31.0 per cent.; Fixed Carbon, 63.6; Ash, 3.6.

At the present time two main bands of coal are being worked, the top one being 6 feet thick and the bottom one 4 feet. There is coal above and below these bands and they are separated by about 4 feet of coal in which there are some shale bands.

As has been previously said the coal is of good quality; this is well illustrated by the following analysis which is a calculated average of six average samples taken across different bands of coal in the mine:—Moisture, 2.1; V.C.M., 26.1; Fixed carbon, 66.8; Ash, 5.0. By applying Dowling's Split Volatile Ratio to this analysis the coal would be classed as a bituminous coal but lies very close to the classification of high-carbon bituminous. The moisture content of these analyses is probably higher than will be found in the coal when at some distance from the surface. One noteworthy feature of this coal is the low ash content, which is considerably lower than most coals now being sold in British Columbia. It is apparent that this coal will make excellent steam coal and should also prove to be a very suitable domestic fuel. Coking tests have not as yet been made on the coal.

The Betty coal seam has not as yet been traced for any great distance on the surface, nor has any drilling or other deep development been done. According to Leach's geologic map covering this area there is at this point an exposure of 3 to 4 square miles of coal formation and if this Betty seam is continuous throughout this formation it is apparent that there is in the field a large tonnage of coal.

The opening up of this coal property would be greatly expedited by diamond drilling and, if the results were satisfactory, the building of a branch railway from Telkwa. No such plans are however being considered. The leasers intend to mine coal and ship by wagon, sleigh, or tractor haulage, and to gradually develop the mine by advancing the tunnels. A good market for this coal is available at Prince Rupert. The cost of hauling over a poor road for seven miles leaves but little margin for mining the coal. However, it is expected that with good sleighing conditions this winter that steady shipments will be made. As the lease held by Gillespie & Wilson can be terminated at any time on thirty days notice in the event of the property being sold, there is not much inducement to them to make any heavy capital investment in road or other improvements.

The quality of this coal and the price that Gillespie & Wilson quote for it laid down f.o.b. the railway cars at Telkwa is such that this coal can compete very successfully with Vancouver Island or Alberta coal. As yet, of course, the amount sent to Prince Rupert has been insignificant but still the coal dealers of that city are very anxious to secure a steady supply of it. It is apparent that if this coal can be mined and hauled over seven miles of indifferent wagon-road and sold at a profit that there are great possibilities for the property if opened up and equipped for large scale mining and provided with railway transportation. In addition a plentiful supply of good coal at a reasonable price would have a stimulating effect on all Northern British Columbia.

The tonnage shipped from this mine for 1921 is estimated at 865 tons.

MINING INSTITUTE ANNUAL MEETING.

The Twenty-fourth Annual General Meeting of the Institute will be held in Ottawa on March 1st, 2nd and 3rd. It will be recalled that the last Annual Meeting had been scheduled to take place in Ottawa, but, owing to an epidemic of small-pox in that city, it was deemed advisable to transfer the meeting to Montreal. Several important papers have already been promised for the forthcoming meeting, and these will be printed in the January and February Bulletins. Members who propose to contribute papers are reminded that, in order to ensure publication prior to the meeting, as is desirable, manuscript must reach headquarters in Montreal not later than January 10th.—Institute Bulletin.

LABRADOR.

Professor A. Coleman, of the University of Toronto, gave a graphic description of the north-eastern corner of the continent when speaking on the subject, "Frigid Labrador," before the members of the Geological and Geographical Section of the American Association for the Advancement of Science at a session yesterday in the Mining Building, Queen's Park. The title of his address was "The Geology and Surface Features of the Torngat Mountains in Northern Labrador."

North-eastern Labrador, he said, was a treeless region and had been carved by rivers and glaciers into the wildest mountains of Eastern America. Its climate, with less than two months of summer, is the most rigorous to be found on the mainland of North America, and its small population of Eskimos is confined to the shore, depending on the swarming life of the sea.

In the area visited there is very little cover on the rocks. There are no trees and very little soil. Archean rocks are exposed over large areas and the formation can be examined under exceptionally favorable circumstances. There are very few people in the district and there is little known concerning the mineral resources.

Underground Loading Devices in Metal Mines

By C. LORIMER COLBORN, (Mining Engineer, U.S. Bureau of Mines).

(Continued from last week)

The machine has been in operation in the mines of the National Lead Company, St. Francois, Missouri. The record for the month of February, 1921, was an average of 96 tons of ore loaded in an eight-hour shift with one operator and one helper; 3,360 tons was loaded during the month. These two men not only load the cars but push the empty one-ton capacity cars to the machine and deliver the loaded cars to the motor haulage loop.

A labor cost of 9½c. per ton was reported for the February operation. To this should be added the cost of power and repairs. The management expects to reduce their present loading costs of 16.64c. per ton by using this machine.

The Conway shovel loader consists of a boom mounted on the forward end of a steel frame. An electric motor and the necessary mechanical parts are also mounted on the steel frame, which is on a truck and can travel anywhere on the regular mine track. A dipper slides back and forth on the boom. The boom can be swung to either side or up and down.

The machine is controlled by an operator who stands to the right of the machine. The movement of the dipper and boom is controlled by two levers. The dipper is pulled into the pile of material and after filling itself is raised over the car, placed on the track to either side of the machine. As soon as the dipper is over the car, the door in the bottom is tripped by the operator pulling a rope.

During 1920, at the St. Louis Smelting and Refining Works of the National Lead Company, St. Francois, Mo., 169,351 tons of ore was loaded by seven of these machines, which made an average of 62.4 tons loaded per shift, at a cost of 16.64 cents per ton. The costs were distributed as follows: Operating labor 14.9 cents, repair labor 0.30 cents, supplies 0.92 cents, power 0.41 cents, total 16.64 cents per ton.

The Shuveloder is a shoveling machine operated by compressed air, which drives the dipper into a pile of loose material, lifts the loaded dipper and empties it into the car which is brought up immediately behind the machine. The dipper, together with the four air cylinders that operate it and the mechanical parts that impart motion to the dipper, make up what is known as the main body of the machine. All these are mounted on a truck which can be moved on the ordinary mine track. The machine is hand-propelled. Immediately above the truck and beneath the main body is a turntable which provides lateral movement. The Shuveloder is the latest model of what was formerly known as the Armstrong Loader. Its overall length is 6 ft.; overall width 4 ft.; overall height 4 ft. The weight is approximately 4,300 lb. The dipper is 30 in. in width, and the head room required for operation is 6 ft. 10 in. The manufacturers state that it takes from 150 to 175 cu. ft. of free air per minute at 80 lb. pressure to operate the machine. It will load material in any car of a height 50 in. or less above the top of the rail.

The machine is controlled by three levers on the right-hand side of the machine. The operator stands on the ground. The Shuveloder is not of continuous operation type but each motion has a separate control which is reversible. The mechanism is driven by three series of cylinders. The air is admitted successively into the bottom cylinder, two centre cylinders, and then the top cylinder. The bottom cylinder gives motion to the body pushing it forward, crowding the dipper into the pile of loose rock. The two centre cylinders turn the two rope sheaves which raise the dipper up through the pile. The top cylinder then pulls the crosshead back, causing the dipper to swing over the top of the machine and to discharge the material into the car in the rear. Simultaneously with the operation of the upper cylinder, the bottom cylinder receives air, which causes it to pull the body piece back to the starting position. The air is admitted to the rear end of the other cylinders in their turn which brings them all back to the starting position. There is no movement to the truck, which is clamped to the track. The lateral movement to the machine which is provided on the turntable is obtained by a ratchet worked by hand. The machine has a reach of 5½ feet to either side of the centre of the track, and always discharges into the centre of the car behind, from any lateral position of the body piece.

One man is required to operate the machine and one man can switch the cars. In some places where digging is quite difficult, a third man is used as a helper. At one mine the loader was used intermittently. Working on rock it shoveled 72½ cars of 2-4-5 tons capacity in 35½ hours, at a cost of 25.09c. per ton. This included tramming the cars 370 feet. The actual time of loading was 16¼ hours. The delays were due to tramming, switching, loader off track, and repairs. In another test, working on soft iron ore, 208 cars were loaded in 139¼ hours at a loading cost of 12.97c. per ton. The actual loading time was 21½ hours.

An Armstrong No. 11 shovel was in use at the Colby mine of the McKinney Steel Company, Bessemer, Mich., to load broken rock in driving drifts. The drifts are 7 ft. high by 8 ft. wide, and the pile of rock is about 19 ft. long and about 4 ft. high at its deepest place. There were about fourteen carloads of 32 cu. ft. capacity to the pile. Two men were used in loading; one operator and one attendant who switched the cars. The machine was observed during the shoveling of one of these piles of material with the following results:

Total time of setting up machine, 10 minutes; time of loading fourteen cars, 58 minutes; 12 move ups of loader, 30 minutes; switching twelve cars, 92 minutes. Total, 190 minutes. Total number of cars loaded, 14; total cubic feet, 448; total number of move ups, 12; total number loader dippers, 232. Average number of loader dippers to cars, 16; average number of loader passes per minute, 4; average time for loading cars, including move ups, 6 minutes; average time for loading one ton of rock, including move ups, 2.4 minutes. Total time required for setting up the Armstrong shovel, loading and tramming of the rock, broken from an average break of a round of holes took one hour and 45 minutes.

(To be continued)

MINING IN ALBERTA.

A novel method of mining coal was described by Mr. James McEvoy at the Toronto meeting of American Association for the Advancement of Science. Concerning this method Mr. Long said: "The beds or seams of coal in the district near Edmonton do not lie flat, but are inclined rather steeply, and advantage of that fact has been taken in the mining. From the hoisting shaft a tunnel is run along the under-side or floor of the bed practically on a level. From this main tunnel, narrow angles or drifts are run through the coal along the floor up the inclined bed to a point where mining is to commence. At intervals of 40 to 50 feet along these main angles, back angles are driven from the sides in such a way that the coal when loosened will move toward the main angles. These back angles may be carried some distance from the main angles and along these at the same intervals of distance crosscuts are driven. So that the whole area to be mined is divided into blocks of coal 40 to 50 feet square.

"The mining or drawing of the coal commences at the highest or top row of the blocks or pillars. A few shots placed at the foot of one of these pillars loosens the coal and it starts running down throught the angles and chutes to the main tunnel where it is loaded in cars placed under the chutes, and taken to the shaft to be hoisted. Each pillar is taken in turn until the row is finished then the next row of pillars is similarly treated."

U. S. BITUMINOUS PRODUCTION.

Production of bituminous coal during the first 302 days of the past five years, the period over which records of weekly output extend, has been as follows:—

Years of Activity.	
1917	542,191,000
1918	569-178,000
1918	569,178,000
1920	543,049,000
Years of Depression.	
1919	446,951,000
1921	401,051,000

It will be seen that from the viewpoint of soft-coal production, 1921 is behind all recent years. The output to date is 46,000,000 tons less than in 1919, also a year of business depression and one in which the situation was made worse by the occurrence of the great strike. As indicated by incomplete reports for the final week of the year, the total output for 1921 will be about 408,000,000 tons.

IRON ORE.

The iron ore mined in the United States in 1921, exclusive of that which contained more than 5.5 per cent of manganese, is estimated at 29,547,000 gross tons, a decrease of 56 per cent as compared with the output in 1920. The shipments of ore from the mines in 1921 are estimated at 27,009,000 gross tons, valued at $89,688,000, a decrease in quantity of 61 per cent and in value of nearly 69 per cent as compared with the shipments of 1920. The average value of the ore per gross ton at the mines for the whole of the United States in 1921 is estimated at $3.32; in 1920 it was $4.11. The stocks of iron ore at the mines, mainly in the Michigan and Minnesota, apparently increased from 11,378,794 gross tons in 1920 to 13,872,000 tons in 1921, or 22 per cent. The output of iron ore in 1921 was the lowest since 1904, when 27,644,330 tons was mined.

U. S. ANTHRACITE PRODUCTION.

The anthracite industry has at length felt the combination of industrial depression and the warm autumn, and production is steadily declining. As against an average of 35,000 or 36,000 cars in recent full-time weeks, the nine anthracite carriers reported loading 30,813 cars in the week ended December 17 (Table III). On this basis it is estimated that the total production including mine fuel, local sales, and the product of dredge and washery operations, was 1,611,000 net tons, a decrease of 5 per cent, from the preceding week, and of 16 per cent when compared with the week ended November 19. A year ago a production of 1,998,000 net tons was reported.

ZINC PRICES IN 1921.

Early in January zinc concentrates containing 60 per cent of zinc were selling in the Joplin district at $28 a ton, having dropped from $60 a ton at the beginning of 1920. The price dropped to $21 by the beginning of March, rose to $26 by the begining of May, dropped to $21 by the middle of June and remained at that point until late in August, when it reached bottom at $20 a ton. Through the last quarter of the year there was considerable improvement in price and at the end of the year concentrates were selling at $28 to $30 a ton.

LEAD AND ZINC IN 1921.

The mine and smelter output of lead in the United States in 1921 each fell off abont 20 per cent and the mine and smelter output of zinc declined nearly 60 per cent, according to a statement by C. E. Siebenthal and A. Stoll, of the United States Geological Survey, Department of the Interior, compiled from reports and estimates by producers and others.

DOME MINES.

New York, Dec. 29.—Dome Mines treated abont 30,000 tons of ore in November. Mill heads averaged $8.40 a ton, operating costs were about $3.50 a ton. This resulted in a profit of about $145,000, or three times dividend requirements at the current rate. One of the interesting things about Canadian mining companies is that they are among the corporations in Canada which are aided by the depreciation of Canadian exchange in terms of dollars.

J. A. CAMPBELL ACTS AS COMMISSIONER.

Winnipeg, Dec. 29.—J. A. Campbell, former Member for Nelson, has been appointed acting Commissioner of Northern Manitoba for a period of one year, it was announced here to-day. Mr. Campbell has been acting Commissioner since Prof. R. C. Wallace retired from the post four months ago.

HIGH GRADE AT LA ROSE.

Cobalt, Dec. 27.—In opening up a new section of the stope from the 90 foot level of the University, La Rose last week, broke into the best ore located on the property, states the Northern Miner. It is about four inches wide, very high grade ore. It is yet too early to say whether this is merely a patch or something of size.

The winz being sunk from the 530 foot level of the Violet should be down to the 600 by January 1st. Forty or fifty feet of crosscutting will have to be done before the vein is reached. On the 530 foot level this vein has an ore shoot 225 feet long, with ore still in one face.

Caveins have given old La Rose property some trouble, but the damage has been exaggerated.

WAGE REDUCTIONS FOR GOLD MINES.

The "Northern Miner", published at Cobalt, says:

Wage reductions are coming in the gold camps. Regardless of opinions held to the contrary, the Porcupine will bring this capital in, and mines now closed will mines will have to cut wages. Northern Ontario gold camps are probably the highest wage mining camps in America today, and the Ontario mining industry cannot stand it forever.

"High wages are a cause of unemployment. Those who have jobs will be hit by a reduction, but the many whohaven't jobs are going to be greatly benefited. Considerable needed capital is delaying investment in gold mining because of the high cost. A cut in wages open, and undeveloped properties will be worked. A wage cut at Porcupine will create jobs. Hundreds of thousands of tons of rock now classed as waste will be metamorphosed into ore when the cost of recovering the gold contents is cut. Moreover a reduction is becoming inevitable. Shareholders will force the hands of managers, especially of those mines that have a low average grade of ore. Another factor is the decline in the exchange premium; it is to-day one-third what it was a year ago, 6½ per cent. against 19 per cent.

"So many influences are working for lower wages in the gold camps; the desire of the mines to treat a lower average grade of ore, the fact that new capital wants lower costs before embarking on employment-giving mining enterprises the decline in exchange premium, that The Northern Miner is willing to predict a wage reduction will come very shortly."

EDITORIAL

LIFE'S LITTLE WORRIES.

As we go to press, the strike which took place on the 7th instant, at the plant of the Garden City Press, Ste. Anne de Bellevue, where this journal is published, still continues. The circumstances leading up to the strike are made sufficiently plain in the correspondence between the publishers and the Montreal Typographical Union No. 176, which we publish elsewhere in this issue.

At the moment, this journal is, naturally, being produced under substantial handicaps owing to this occurrence. Accordingly, should it not reach its usual standard for a few weeks, we must ask the indulgence of our readers and advertisers and friends generally. There is the best reason for believing that, in a very short while, the difficulties, at present attendant on its publication, will have been completely overcome.

POWER FOR THE GOLD MINES.

There is a growing belief that a solution of the power problem in Northern Ontario will be found shortly. One journal the "Northern Miner" ventures to predict that by Jan. 15th "the power difficulties of Porcupine camp will be solved and all operators will be able to plan future expansions and resumptions of work on as large a scale as they please". We hope that the "Miner" is right, for in our opinion there is nothing that will help the gold mining industry so much as a satisfactory solution of the power problem. Every day that there is a shortage of power there is a loss to the mining companies and to the people of the Province. Every day's delay in proceeding with the expansion of mining operations that can only be undertaken if additional power can be found is an important loss. An end to the power shortage will be hailed with delight not only by the management and shareholders of mining companies, but by every citizen who realizes what the possibilities of the mining industry are and the direct or indirect benefits that will result from increased activity.

More power means greater production of ores such as are being mined and production of ores that may under conditions be left unmined. Greater production means increase in number of workmen and larger pay rolls. Greater production means additional millions of dollars to be disbursed by mining companies for supplies. Merchants and manufacturers as well as shareholders of the operating companies and of others that may operate will be benefited by the finding of the additional power required.

The fact that gold mining companies at Porcupine need more power and that one of the companies has been endeavoring to obtain the rights to develop more power has been well known for many months. The fact that many industries are in difficulties owing to lack of market for products is as well known as the fact that there is no glut in the market for gold. The fact that many men are out of work is as well known as the fact that the gold mining companies could and would employ more men if they could obtain the power they need. The fact that the Ontario Government has been in a position to materially assist in increasing production and in providing employment is as well known as the fact that it has delayed action for such a length of time that it has shaken faith in the minds of men who have believed that Ontario knew enough about the mining industry to require that the things which can be done by Government to aid in development should be done.

In defence of the Government it should be stated that the power rights applied for by the Hollinger company had previously been applied for by a pulp and paper company and were also considered as a possible source of power for the electrification of the Ontario Government Railway. It is easy to understand that the division of power rights to satisfy the demands of industries and the needs of the railway would require some serious consideration and that it might take a little time than necessary and that further delay will be seriously on those responsible for it. Prompt action

would enable us to continue to claim that Ontario has not only great mineral resources, but a people who appreciate the benefits that will come from their development. The delay that has already occurred has caused some to doubt whether the present Government realizes that the lack of power is holding in check plans that call for great increase in production and which in their fulfilment will in many ways assist in the development of districts tributary to the Government railway. This may have been the case last summer; but the Government has had plenty of opportunity since to become informed as to the situation.

The recent announcement that investigation was to be carried on to determine the power needs of the Government railway and the power available near the railway has a bearing on this matter. It has been learned that decision on the Hollinger application is to be withheld until the Government has a report on the results of this investigation. This seems a plausible explanation of the delay, but is not a very satisfactory one. Power for the railway must be found if it is to be electrified; but there is as yet no shortage of undeveloped waterpowers north of Cochrane.

When it is borne in mind that the successful development of this district and the successful operation of the railway depend very largely on the success of mining and pulp and paper industries, it is obvious that the power requirements of these industries should receive prompt consideration. Where interests clash there should be real effort to find a solution without undue delay. If the Government can show that it is making an energetic effort to obtain the information necessary for a decision that will remove the check on development of resources, it should do so.

That the present Government is not unaware of the possibilities of the north is indicated by its decision to proceed with the extension of the Government railway north of Cochrane. This extension will give access to an area well stocked with pulpwood, open up additional agricultural land, and provide transportation to a point on the Abitibi river where there are great power resources. The mineral resources of the area to be traversed are as yet unknown and will not easily be determined, owing to the fact that a thick clay blanket covers the Archean rocks of the area. Further extension will bring the railway into the area of sedimentary rocks in which gypsum has been found and will open up a new field for exploration for oil. Then further extension will bring the steel to tidewater and a new era of development will begin on the shores of Hudson Bay. The Government is to be congratulated on its decision to undertake to carry out this enterprise.

The extension of the railway and the operation of the present line will result in profit or loss according to the speed with which the natural resources of the area are developed. The establishment of new industries and the success of the present industries will determine the success of the railway enterprise. Under the circumstances the Government cannot properly avoid the responsibility of encouraging development. The problems will be many and varied and the Government will find it necessary to move faster in dealing with them, if it wishes to attract enterprising men to explore and develop the country.

CHANGES AT HOLLINGER.

It has been known for some time that the Hollinger management is seriously considering important changes in crushing plant. As at other gold mines in Northern Ontario, there is accumulated evidence at Hollinger that the desired increased capacity can best be obtained, when there is power available, by a change in crushing methods. Manager Brigham has been watching the performances of crushing mills very carefully and doubtless with a view to determining whether the company should continue its present practice when making additions to plant. Our impression for some time has been that the experience of other companies operating gold mines in Northern Ontario was decidedly in favor of the McIntyre type of mill. The early tests at the Hollinger were apparently more favorable to stamps and consequently stamps were installed. Since then there has been more evidence in favor of ball mills and the champions of stamps in Porcupine are not many. Mr. Brigham has naturally wished to make his milling plant as highly efficient as possible, but has doubtless hesitated to make radical changes under the conditions which have confronted gold mine operators in recent years. We were not surprised to hear him say publically in Toronto last week that the plans for increasing capacity at the Hollinger call for important changes in crushing plant.

An inovation at Porcupine will be the filling of stopes with tailings from the Hollinger mill. This Mr. Brigham states has been decided upon. It will provide waste filling of suitable character and will to a considerable extent lessen the tonnage of tailings that must be stacked.

OPPORTUNITIES AT PORCUPINE.

Now that the three big gold mines at Porcupine are making a showing that contrasts sharply with industrial inactivity in many parts of the country, there is more general recognition of the fact that gold mining is becoming an important industry. The possibilities of developing more mines at Porcupine have improved. As Mr. A. F. Brigham said recently:

"The Porcupine district should be carefully and minutely examined by intelligent and hardy men, assisted in every way by the Provincial technical departments and other public service organizations."

It will not be surprising if during the coming year there is a renewal of exploration activities in the Porcupine area. Recently there has been evidence that two undeveloped properties will be tested this summer. It is quite possible that important discoveries will be made on properties that are close to the producing

mines. There is much to be learned, before it will be safe to place limits on the possibilities of Porcupine. For some years there has been comparatively little exploration work in the area, and it has been to easily assumed that the good ore deposits have all been found.

ON TO THE BAY.

We append a description of a part of the area north of Cochrane which will be traversed by the Ontario Government railway which is reaching out towards Hudson Bay.

From Cochrane the road will run north through Glackmeyer and Blount townships, crossing the Abitibi and its tributary Sucker river. Then turning to the west the railway will cross Jawbone Creek and then Trappers creek and follow along the east bank of the Abitibi river for a few miles. Then below the Carrying Places the railway will cross to the west bank. Then at a distance three or four miles west of the river it runs roughly parallel the river, almost due north, to Burntwood portage, which is a few miles above New Post.

With the exception of the river crossings, the route selected will make construction easy. The grades are moderate and the cuts mostly clay. Good agricultural land, liberally supplied with lime from the Paleozic rocks to the north, will be traversed for the greater part part of the distance. The rivers crossed will be advantageously used in bringing out pulpwood from large areas.

The rocks underlying the area are Archean. The clay covering is very thick and rock exposures are few. Description of the rock exposures and of the clays will be found in a report recently published by the Ontario Department of Mines. "The Abitibi and Mattagami Rivers". This report by J. G. Cross, M. Y. Williams and Joseph Keele is accompanied by a map of a large area. Copies of the report and map can be obtained on application to the Department of Mines, Toronto.

Tenders for construction of the first section of the railway have been called for and are to be opened today, January 9th. It is expected that the work will be carried on energetically this year.

SPROUTING PORCUPINE "QUILLS".

By ALEXANDER GRAY.

Accompanying semi official confirmation of our forecasts that Hollinger Consolidated Gold Mines crushed more than a million tons in 1921—how much more cannot be ascertained at the moment—is the announcement that the Nipissing Company drilling at the Rochester Veteran claim has been productive of significant results and that the Platt Veteran claim is about to be taken over by Montreal interests.

If the million tons taken out of the Hollinger area was replaced in a year of confusing operating conditions—owing to power difficulties and labor shortage during the earlier months—perhaps some one in authority, other than Old Reliable Gibson will register the honest to goodness opinion that these mines are wholesaling in gold and branching out in the business. This does not imply that Porcupine retail mines are not faring well and in due proportion. But extracting more gold in the year than others have altogether in their estimated reserves — and then having the warehouses replenished — when it is borne in mind that the Hollinger was handicapped in the first half of the year, gently suggests, ever so gently suggests! that Bankers and Business men devote a thought or two, possibly a day or two for a visit to Hollinger-McIntyre-Dome areas, if not to those at Kirkland Lake. Hollinger is abreast of the best.

Rochester Veteran claim results, however inconclusive as to actual tonnage, are welcomed because they may mean the active co-operation of Nipissing capital and technical skill in Porcupine affairs. Off and on for twelve years Nipissing tried ground here and there, to find it wanting in desirable attributes. It always has been regrettable that this company did not entertain one or two central Porcupine sections more seriously. However, the Rochester Veteran, drilled and discarded ten years ago, has disclosed features of more merit than previous holders surmised, and it has escaped comment that the Nipissing enterprise has increased the importance of the Hollinger- Millerton northern area, and may be of the town site owned by the Canadian Mining & Finance Company, the Hollinger holding company. Is the Timmins-McMartin-Dunlap luck going to have another exhibition? If so, the purchase of a bit of the sand belt for townsite purposes would prove most fortuitous. On the other hand, Charlie Flynn and those of his principals who drilled the Rochester will be entitled to commisseration.

As for the deal with the Platt Veteran claim south of Pearl lake; it is in process of consummation. There, again, earlier drilling and prospecting were undeterminative. An influential group of railway contractors and manufacturers have held this ground. Had the Schumacher come up to expectations, the Platt might have been further along. Plenaurum also was a disappointment on the north side of Pearl Lake and on its eastern axis. Drilling on the Goldale ground east of the lake having given encouragement, it is not improbable the Platt will assert itself more affirmatively.

ALBERTA COAL IN B. C.

Alberta coal is coming into competition with the product of Vancouver Island and the Nicola-Princeton Fields. Evidence of this has been marked in recent weeks, in fact ever since a reduction in freight rates was announced. Operators of the adjacent prairie province are having their coal tested in a number of the vessels engaged in the mercantile trade of the north pacific. They believe that, if it can be shown that their fuel is as good for steaming purposes as that on the Island, it will be possible, by underselling, to obtain a grip upon the market now controlled by the collieries of the coast.

A few weeks ago a reduction in the retail price of domestic coal was announced in Victoria and Vancouver. The drop amounts to 50 cents a ton. Dealers report that [illegible] coal is now [illegible] at $12 a ton and [illegible] at $13 a ton.

LEBEL CRYSTAL.

Mr. H. S. Ross, president of Lebel Crystal Gold Mines, who was in Toronto recently on his way to New York, reports that very good results have been obtained in surface work at the property. The company holds a block of eighteen claims in Eastern Lebel Township, south of the Moffatt Hall property.

Strike at Garden City Press

Correspondence between the Publishers of the Canadian Mining Journal and the Montreal Typographical Union No. 176.

Editorially we make mention of the fact that there is a strike at the plant where this paper is published. The principles at stake are made clear in the following correspondence which sufficiently explains itself.—Ed.

The Union Ultimatum.

Montreal, December 17, 1921.

To the Board of Directors
Garden City Press:

Gentlemen:—

Notwithstanding the fact that the management of the Garden City Press has not at any time signed an agreement with this Union, it has nevertheless always conceded and operated under the terms of the contract made between the employing printers' associations and the Union.

One of the clauses embodied in all of these contracts is as follows: All employees of the composing room... shall be members of Typographical Union No. 176...

Previous to the expiry of the most recent of these contracts on June 30th last an effort was made to inaugurate the 44-hour week, and the Garden City Press was one of a number of offices where the shorter work week was then established. Because of the failure to procure this condition in other offices a proportion of our members was barred from working in these offices. Anticipating such a contingency the advisability of creating a defence fund was foreseen and an assessment of ten per cent. was levied on all earnings.

Advantage of the situation thus created was at once seized by certain parties to extend the activities of the National Catholic Syndicate to the printing industry, and four of our members of the Garden City Press were influenced into joining this Syndicate, and the reason or excuse given for their action was that they found it impossible to continue paying the said ten per cent. assessment.

Repeated attempts were made by the officers of this Union to dissuade these men from severing their connection with the I. T. U. and the President of the Garden City Press himself pointed out to them the inadvisability of their contemplated severance. Argument and persuasion, however, were of no avail and apparently these men could not be made to see that they were refusing to support their fellow-members in an effort to procure what they themselves were enjoying. Investigation proved that in one case at least it was a repetition of history as the same trouble was encountered in the struggle for the 48-hour week. At that time, of course, there was no Syndicate into which to drift.

The argument that the action of these men was likely to disrupt the relationship existing between the management and the Union was likewise unheeded. The men evidently felt secure in their position and were callous to the results of their action on the other 75 per cent. of the employees in the composing room and on the management.

With set purpose of endeavoring to re-establish former conditions, and of maintaining, if possible, the friendly relationship, no steps were taken to withdraw the members of the Union from this office. Until Tuesday of this week, December 13th, there were excellent hopes that the situation could be adjusted, but on that day two other men were added to the composing-room staff who were not members of this Union, and it was then decided that as matters seemed to be getting worse instead of better, our members should be withdrawn.

As the result of an interview with the President of the Garden City Press, it was agreed that yet another effort should be made to adjust matters, and a request was made for a statement from the Union setting forth the minimum conditions under which an agreement might be reached, and that such statement would be placed before a specially summoned meeting of the Board of Directors. This statement is herewith set forth:

> That the composing-room staff shall be restored to its former standing and only members of the Typographical Union be employed therein; this to imply that the four men first mentioned above may re-establish their membership and the two men recently engaged be discharged or, should they prove to be competent printers, make application for membership.

It may be permissible to state further that we have, for the past three weeks, borne the railway expenses of our members who are travelling from the city daily, and this may be taken as an indication of our willingness to do our utmost to save the situation.

It is the sincere desire of the members of the Union that the previous cordial relationship between the management of the Garden City Press and the Union may remain inviolate.

Truly yours,

THOS. BLACK.

Montreal, December 31, 1921.

J. J. Harpell,
President Garden City Press,
Ste. Anne de Bellevue, P.Q.

Dear Mr. Harpell:—

Owing to developments in the situation at Garden City Press, and having regard to the fact that the action out of which the trouble originated, is not likely to be favorably adjusted, it is the opinion of the Strike Committee that our members can not longer be permitted to work under existing conditions, I have therefore to notify you that the members of this Union now working at Garden City Press will be withdrawn on the evening of Thursday, January 5th, 1922.

The situation can only be saved on the understanding that conditions immediately revert to those existing at June 30th, 1921—namely, all members employed shall be members of Montreal Typographical Union No. 176, and conditions of contract as verbally agreed to shall be observed.

Very truly yours,

2 THOS. BLACK.

The Publishers' Reply.

Gardenvale, Jan. 4, 1922.

Mr. Thos. Black,
President, Montreal Typographical Union 176.
Room 35, Herald Bldg.,
Montreal, Quebec.

Dear Mr. Black:—

The ultimatum submitted with your favor of the 31st, just received, comes as a great relief. It puts an end to a situation that is becoming intolerable.

So that there may be a chronicle of the facts leading

up to this condition, I will rehearse them here and if I make any statement to which you take exception please let me have your version.

Up to the 30th of June and for a month thereafter the relations between our company and your Union were most friendly. We were the first and the only large printing plant in the district of Montreal to grant a forty-four hour week; in fact, we gave it without being asked. We have always paid better than your scale of wages and working conditions in our shop are of the best.

All went well while our men continued their membership in your Union and submitted to the tax of ten per cent of their wages to support those of your members who were on strike from other shops that had refused the forty-four hour week. Your Union had given its members to understand that five weeks would be the limit of this tax and all our men here continued to pay to the end of and even beyond this period, but when your Union failed to keep its promise your working members began to grow restless and many of them, both here and elsewhere, dropped their membership. Some of the French members of your Union took out membership in the National Catholic Syndicate. At that time we gave your officials access during working hours to the men in our plant who had dropped their membership in your Union. In fact, we did what we could to help you persuade them to renew their membership. This we did against our better judgment: first, because we realized, as did your seceding members, that when a strike is allowed to drag on beyond a reasonable time it becomes increasingly difficult to secure a settlement in the interest of the strikers. Those who take the place of strikers become more and more efficient while men on strike suffer a lapse of skill and acquire habits of indolence and indifference that make them less desirable when they are ready to return to work. This is particularly true of men in receipt of such handsome weekly allowances as your Union has been paying it's strikers.

Our second reason for feeling that your Union did not deserve the assistance we gave it in trying to persuade the men in this shop to continue their membership in your Union was supplied by your Vice-President, Mr. Hayes of Indiana, U.S.A., when he swore, at our meeting with him in Montreal at the Windsor Hotel, last autumn, a determination to "teach the Catholic Church a lesson" for what he interpreted as their interference in labor matters. Whatever may have been Mr Hayes' grievance against the Catholic Church or any other church, we did not consider that we had any right to assist him to teach them a lesson.

When you failed to persuade your men to renew their membership by peaceful means, you appealed to us to use coercion by threatening them with dismissal. This we absolutely refused to do. From this time on there was a very noticeable persistent demand on the part of our superintendent here for more men, although there was no increase in our work. With the advent of every increase in our force there really seemed to be a decrease in the output and our costs began to mount until within a short time they had increased by 52 per cent when the writer found he had to interfere. When the costs continued to go up we found it necessary to dismiss our superintendent. The next man we dismissed was a man on the night staff who was giving a production of less than 500 ems an hour, whereas the minimum, as you know, is from eight to nine times this, according to your own statement. At that time we felt we could not afford to reduce our force so the writer appealed to you for another man to work at night. Instead of one you sent two, a Mr.... and a Mr.... who, you claimed, were very rapid typesetters. The first night their work was fairly satisfactory but the second night they came out well supplied with liquor which they consumed between them and in company with our night pressman. The next morning we dismissed these two men and our night pressman, a man who had been with us for several years and who before that occasion had done his work and conducted himself satisfactorily. The next man we dismissed was a Mr...., an old man of 54 years, who, I understand, has been in the habit of tramping about from place to place and drinking very heavily, with the result that he is never in a fit condition to do a fair day's work. His largest production here in any one day was less than 1,500 ems an hour and some days he went down to below half that per hour. The next man we dismissed was a monotype operator whom we were very glad to be rid of. He did not earn his wages and in many respects was highly undesirable. The last man to go was dismissed because he either did not know his work or he loafed on the job. With all these dismissals we have a larger output today than we were able to secure with the larger staff.

What was very noticeable during the writer's interview with all the above mentioned dismissals was the very great readiness on the part of the men to go. There seemed to be a decided preference on their part to be on strike rather than to be at work. On more than one occasion men whom you have sent out here to look for work have refused a salary of $36.00 for a forty four hour week and declared their preference to walk the streets and receive strike pay of $25.00 a week.

We are rather glad that the break is coming for another reason, namely that it will leave us free to handle our apprentices in the future in the way we think they should be looked after. The unreasonable regulations of your Union regarding apprentices have shut out the best class of young men and women from the business of typesetting and resulted in a rapidly increasing preponderance of old men in your organization. There is nothing more unsatisfactory than your regulation which limits a shop of the size of ours here to three apprentices in five years. And it was very annoying a few weeks ago when we took on the fourth boy in five years to have the head of your Chapel come to my office and request that he should not be allowed to go to work. In order to avoid trouble I acquiesced and the boy was sent away. We have many bright young boys in this community who are anxious to learn the business of typesetting but they will be old men and women before the opportunity comes to them if we continue to recognize the apprenticeship regulation of your Union. Since [illegible] are anxious to start a school for apprentices and it is good to look forward to a beginning of this sort.

I trust you have not been led to believe by the statements presented above that we are in a mood to throw up our hands and quit. This we are not in the habit of doing until the last gun is fired in an effort to do our whole duty and we feel that we still have a duty to the members of your Union who have been with us [illegible] years and who are satisfied with conditions here and with the fellowship of their co-workers who are also members of your Union. They have to-day said and everyone signified their willingness to continue in our employ if a strike is not called.

As a final effort at an amicable settlement we have approached the Department of Labour at Ottawa with the request that they communicate with you in the hope of gaining your consent to the appointment of a Board of Arbitration and Conciliation for the arbitration of the question on which you threatened to call a strike, or

your letter of the 31st. In order that they may have all the facts of the case we are by concurrent mail writing them as per enclosed copy herewith and sending them a copy of this letter, together with a copy of your letters of the 17th and 31st of December.

Yours very truly,

J. J. HARPELL.

Union Comments on Publishers' Letter.

Montreal, January 10th, 1922.

Dear Mr. Harpell:—

In your letter to me of date Jan. 4, in which you ask to chronicle the facts leading up to the present situation existing in your plant, you ask that if I take exception to any statement to inform you of same. I now avail myself of that privilege and would seek to correct some misstatements in the hope that the chronicle may finally appear strictly according to fact.

Referring to Paragraph 4 of your letter I must emphatically deny that this Union gave its members to understand that the ten per cent. assessment would not extend beyond five weeks.. You evidently have been misinformed on this point.

In Paragraph 5 allusion is made to a conversation with Mr. J. W. Hays. I was not present at the time of the conversation but Mr. Whitaker and Mr. Gauthier inform me that what Mr. Hays did say was that "If the Catholic Church or any other church or any other organization sought to interfere in Labor matters the I. T. U. would teach them a lesson."

Paragraph 6 contains numerous statements that I am unable to refute or confirm. It would be difficult to adduce necessary evidence. Speaking personally I cannot recollect suggesting coercion. However, this is a fine point and does not materially effect the matter. In reference to the superintendent of the plant it is my opinion that Mr. Philip and myself were informed at the time that the superintendent of the plant had resigned and had asked that his resignation might take immediate effect. It was also stated that the superintendent had been requested to take two or three weeks vacation instead of resigning his situation. This opinion was confirmed by the superintendent on Saturday, Jan. 7.

Regarding these two operators referred to, I must say that two men were sent at the request of the management of the Garden City Press.

So far as their first night's work is concerned, the statement that their work was "fairly satisfactory" is not a generous statement, the work of one of the men that night was regarded as an extraordinary night's work. The second night's work was unsatisfactory and I sincerely regret the attested cause.

It is impossible for me to attach the blame for this supply of liquor.

So far as Mr.... is concerned, he states that the condition of the machine was the cause for the small output. How far this is correct I cannot say. I believe, however, that an investigation will show that this particular machine is not in a satisfactory condition and that continual trouble is encountered with the electrical appliance.

On taking up the matter covered in Paragraph 9, our members inform me that none were willing to continue at the Garden City Press under existing conditions. Were former conditions to obtain they admit that they would certainly have been pleased to remain.

In reference to the suggested appointment of a Board of Arbitration, I have to state that: As it was a principle that was involved, and not hours or wages, the matter could not be submitted to a board. This was explained personally to the Minister of Labor.

In conclusion, let me say that the Union did not hastily decide its final action. Every effort has been made to have matters amicably adjusted and the final decision was come to only after mature consideration and much patience.

Might I ask that in the event of your chronicle being modified according to the explanation herein set forth, you will forward such to the Minister of Labor so that the previous chronicle may be withdrawn.

Yours truly,

THOS. BLACK.

Publishers' Rejoinder.

Gardenvale, Jan. 12, 1922.

Dear Mr. Black:—

Really I cannot see much, if any, difference between the account given in my letter of January 4th and that set forth in yours of the 10th instant, just received.

The statement about the five weeks was made in your presence by Mr.... and you did not correct it. But this is not a material point. The fact remains that the only reason given by your seceding members was that they refused to continue to pay the strike assessment your Union was levying.

As regards Mr. Hayes' statement, your version of it suits the reference made in my letter of the 4th.

The word "coercion" was my own, and used to interpret your demand that I should force the seceding members back into your Union by threatening to dismiss them. This was the cause of the whole trouble, for when I refused to dismiss or even to threaten them with dismissal, you called a strike.

The facts concerning the superintendent leaving were these. On Saturday, December 17th, I told him that matters were getting into such a condition that I would have to take charge of the work myself until things were adjusted and that during this period I did not want him around. If he would go away on a two or three weeks holiday the company would pay his expenses, but if he refused to do that he would have to hand in the keys on the following Monday morning. He handed in the keys on the following Monday morning.

I consented to two men because, as you will remember, you thought one might be lonely. As it turned out they proved to be jovial companions, particularly when they had a supply of liquor. I used the words "fairly satisfactory" because the production of these two men at no time was over 4,000 ems per hour per man, which is the minimum an average man might be expected to set.

The machine Mr.... used has been continuously operated since he left with satisfactory results.

I can only repeat that each and every one of those who went out from our shop when you called the strike told me they were well satisfied with conditions here and that they would not quit unless they were called out by the Union. Of course, the fact that they did continue to work right up to the time when the Union called them out is evidence in itself that that was the only cause for their quitting. They were free to go at any time they wished.

I consider your version does not contradict but corroborates the statements made in mine of the 4th.

Yours truly,

J. J. HARPELL.

Mr. Percy Hopkins has prepared for the Ottawa meeting of the Mining Institute a paper on the gold deposits of Ontario.

GENERAL PURPOSE CRAWLING TRACTOR CRANE.

An Account of the Development of This Product of Industrial Works, Bay City, Michigan.

The type BC "Industrial" Crawling Tractor Crane, illustrated in the accompanying photograph, manufactured by the Industrial Works, Bay City, Michigan, has been developed to meet the need for a full-revolving tractor crane which can be operated independently of rails. The crane is built in two types—the type BC, with a capacity of 20,000 pounds at 12 ft radius, equipped with continuous crawling tractor belts ft. radius, equipped with four broad gauge tractor wheels.

the type BT, with a capacity of 18,000 pounds at 10

These cranes, backed by half a century of crane-building success, are pre-eminently adapted to the needs of road contractors, coal dealers, gravel, sand and stone producers, foundries, lumber yards, railroad storage and reclamation yards and moderate-size manufacturing plants. The capacity and speed of these cranes make them ideally suited for doing such jobs as moving coal, sands, gravel, etc., and for excavating duty. Within the limits of their capacity they will serve with the same efficiency as the railroad crane.

The maximum utilization of yard storage space is realized with the use of these cranes because their field of usefulness is not limited by railroad tracks, as is the case with the railroad crane. Having exceptionally large capacities in ordinary lifting they prove a valuable adjunct in the many erection jobs which are inaccessible to the railroad crane. They can be equipped to handle a hook and block, grab bucket, drag scraper bucket, wood grapple, electric lifting magnet shovel dipper and pile driver leads with drop hammer.

Operation is by means of an internal combustion engine which has the advantage of being always ready for immediate use. When not in operation no fuel is consumed and it is not necessary, as often with a steam operated machine, to have a licensed engineer as operator.

The utmost care has been used to combine the necessary strength with the light weight essential to a tractor crane and convenience in operation and maintenance have been provided to the highest possible degree. Realizing the vital importance of ease of operation in getting the most work out of locomotive cranes study has been made of the requirements of the operator and everything arranged with a view to making the operation and maintenance of the crane as easy and convenient as possible.

The crane is equipped with a thirty-foot boom, made up of two channels strongly latticed with angles and tie plates. Also, if desired, crane can be equipped with 35 ft. or 40 ft. boom. With straight boom not to exceed 30 ft., the crane standing on firm level ground, the following loads may be safely hoisted and slewed in a full circle:—

20,000 pounds at 12 ft.
15,000 pounds at 15 ft.
10,000 pounds at 20 ft.

Can be Handled on Single Line.

7,500 pounds at 20 ft.
6,000 pounds at 30 ft.

A steel cab, neatly and substantially constructed, is furnished. This has necessary doors and windows giving protection and comfort for the operator, yet unobstructed view of his work.

The slewing motion is accomplished through a system of spur and bevel gears working into the rack on the carbody. The direction of rotation is controlled by two friction clutches of very substantial design and is entirely INDEPENDENT OF ALL OTHER MOTIONS. A foot brake is provided to prevent involuntary rotation of the crane.

Raising the boom is accomplished through a friction drum on the main drum shaft. The motion is positive in its action, and is easily controlled by the operator.

Type BC "Industrial" Crawling Tractor Crane.

by means of a single hand lever operating both a friction clutch to hoist the boom and a brake which lowers and holds the boom. Full rated loads may be raised or lowered by this mechanism with ease and safety.

The steering of the car while propelling is accurately controlled by the operator from his position in the revolving upper-works, by manipulation of the friction clutches and brakes controlling the motion of each tractor belt, while boom is swung at any angle with the car. By means of these clutches and brakes either belt can be readily and instantly disconnected from the motor while the other belt continues travelling at a normal rate of speed. The disconnected belt can be held stationary by applying the brake, can be allowed to coast with the brake and clutch both disengaged or the clutch can be allowed to slip, thus allowing the operator to turn as sharp or as wide a corner as he may select. Crane will turn within a radius of approximately its own width, depending somewhat on the nature of the ground. All the clutches, brakes and lever mechanism for steering are located in the revolving upper-works with separate and independent driving mechanism for each tractor belt. This arrangement is simpler and much more accessible than when a portion or all of these clutches, brakes and lever mechanism is located below the car-body.

The propelling and steering mechanism is a new and exclusive feature of the "INDUSTRIAL" CRAWLING TRACTOR CRANE, and is fully protected with patents applied for. It enables the operator to propel and steer the crane, INDEPENDENTLY OF ALL OTHER MOTIONS, with the greatest possible ease and accuracy.

The propelling mechanism is especially powerful in the "INDUSTRIAL" CRAWLING TRACTOR CRANE, allowing it to travel up steep grades and over heavy going. The large tractor belts distribute its weight so it travels with equal facility over city pavements, ordinary dirt roads and industrial storage yards. These belts allow the crane to readily pass over railroad tracks and larger obstructions. Of especial convenience to contractors, is this crane's ability to propel itself up an inclined skidway onto a flat car, where it may be transported without dismantling further than to remove the boom and the projecting muffler.

The overall height of the crane with muffler removed is 12 ft. 6 in. The width over tractor belts is 9 ft. 9 1-8 in. The rear end will slew within a circle of 9 ft. 6 in. radius from the centre of revolution.

The surprisingly low cost of owning and operating a crane of this type affords the smaller industrial institutions an opportunity to handle bulky materials speedily, safely and economically.

Northern Ontario Letter

THE SILVER MINES

Information coming to hand through reliable mining circles confirms earlier statements in the Journal that officials of the British Government early in 1921 made suggestions to the United States Government, looking to some arrangements whereby the price of silver might be stabilized at a reasonably high price. However, no action appears to have been taken and the quotations for the metal have appeared to find their level at not far above the average prevailing during the decade immediately preceding the recent war.

Metal authorities continue to point to the fact that the consumption of silver is still far greater than current production, and this is the one factor which continues to encourage the hope that the price of the metal may record a substantial advance during the current year. The more conservative mining men, however, believe that the law of equilibrium will work out along the lines of decreasing cost of production resulting in more intensified effort and a general rise in output.

Nipissing

Production of not far under one million ounces of silver during the last quarter of 1921 placed the Nipissing in a still better financial position, the company now having a surplus of around $4,000,000. The company will pay a dividend of 3 p.c., plus an extra disbursement of 3 p.c. on Jan. 20th, the double payment calling for the distribution of $360,000. The indications appear to be that the Nipissing will continue to pay 3 p.c. dividends at intervals of every three months, plus the 3 p.c. extra disbursement in January and an extra of the same amount in October, making a total of 18 p.c. for the year.

Oxford-Cobalt

High grade ore has been encountered in a two-inch vein at the 75-ft level of the Oxford-Cobalt property, and a limited amount of ore has already been bagged which contains an average of about 500 ounces of silver per ton. The vein lies in the diabase formation and is composed of calcite, cobalt and native silver. Plans are under consideration to continue the work to a deeper level and explore the vein in a part of the keewatin-diabase basin at a lower horizon.

Coniagas

During the fiscal year ended Oct. 31st, the Coniagas Mines established the outstanding record of having handled an average of 3.38 tons of ore per day for each man on the pay-roll. Production for the period amounted to 1,301,515 ounces of silver, as compared with 994,235 ounces during the preceding year, the increase being due to an increase in the tonnage of ore treated. Net profits for the year totalled $422,238 compared with $512,380 in 1920. The ore was mined and milled at an average cost of 33 cents for each ounce of silver produced, compared with a cost of 48.98 cents during the preceeding year, this being the most remarkable part of the year's achievement. Dividends during the year amounted to $800,000, making a total of $10,840,000 to date.

Including the treatment of sand and slimes, the tonnage handled amounted to 4.2 tons per man on the pay-roll of the Coniagas. A favorable feature of the report is that mill heads average 11.30 ounces of silver per ton. Another favorable feature is that a large tonnage of low grade milling ore was developed during the year, although the amount of broken ore on the stulls was reduced by 2,300 tons. Altogether, the year's operation was entirely satisfactory.

After making allowance for depreciation, the company shows a surplus of $1,695,889.78 at the end of its fiscal year.

The Coniagas now has a total production record of 29,490,277.73 ounces of silver.

Right of Way

John Matheson, formerly with the Aladdin-Cobalt has been engaged to superintendent work on the old Right of Way property. The Right of Way Company recently went into liquidation and the property is now being operated by the Right of Way Syndicate.

South Lorrain

Arrangements have been made between the Mining Corporation of Canada and the Keeley Silver Mines to have the Temiskaming Telephone Company erect a telephone line to the Haileybury Frontier property and the Keeley mine, the companies going fifty-fifty on the cost estimated by the Telephone Company.

Trethewey

It is stated that the Trethewey-Cobalt Company will endeavor to raise additional finances by the incorporation of a new company with an authorized capitalization of $2,000,000 made up of 2,000,000 shares of the par value of $1.0 each. There are 1,600,000 shares outstanding in the present company and the proposal is to eall in four of the old for each one of the new issued. This would only absorb 400,000 shares of the new company and would leave 1,600,000 in the treasury. It is proposed to sell these treasury shares at 10 cents per share and thereby realize $160,000 with which to pay off the present indebtedness of some $40,000. and the balance to finance further work

Promise of power development at Fort Matachewan is considered to be important for the Gowganda district should a revival of aetivity take place.

La Rose

It is understood that production of silver from the properties of the La Rose Consolidated exceeded 100,000 ounces during the year just ended. It is also intimated in unofficial circles that net profit exceeded $5,000 per month, as compared with a total of $1,000 during the year 1920. Good results have recently been reported on the University, while the shaft on the Violet property has been deepened to a new level and with promise of lateral operations proving the downward continuation of important ore shoots. The La Rose has shown a substantial decline in the cost of producing silver and this will be reflected in the balance sheet for the year.

Hollinger

Perhaps the outstanding piece of information coming to the attention of the Journal representative during the current week is the fact that the Hollinger Consolidated Gold Mines, not content to handle 4,000 tons of ore daily, is not only considering an increase to 5,000 and 6,000 tons but is actually aiming at a maximum of 7,000 tons This information was secured from reliable sources, following a visit to the property by Noah Timmins, president, together with Jules Timmins, director, and a number of other interested parties During the visit at the mine the party, which was made up of between 20 and 30 members, were shown some moving pictures which have been taken by "Pathe's" and which are understood to be excellent It was also learned that provided the requisite hydro-electric power is available and which now appears to be probable, the Hollinger will establish a record in the current year which will not alone eclipse its 1921 achievement but will actually outstrip its only world rivals on the Rand and will lead the world in point of output.

Northcrown

Action is being taken by creditors against the Northcrown Mines of Porcupine, something like $100,000 being involved. This is believed to arise as a result of the failure of the Thompson-Krist interests to meet their obligations. By way of explanation it may be well to point out that the Northcrown Mines Company with an authorized capital of $3,000,000, made up of 3,000,000 shares of the par value of $1.00 each was incorporated for the purpose of taking over the Porcupine Crown and the Thompson-Krist mines, the arrangement being that the Porcupine Crown would receive 2,000,000 shares of the new company and the Thompson-Krist would receive 1,000,000 shares. The scheme was carried through, and the Northcrown commenced the operation of both properties. Cash on hand was limited and arrangements had to be made to borrow money. The Porcupine interests advanced a certain amount, but the Thompson-Krist was unable to advance its share and this led to other credit being secured. Subsequent failure of the Thompson-Krist to make good has resulted in action being taken against the Northcrown by a Toronto Trust Company.

McIntyre

Order for equipment in connection with the installation of a new unit in the mill of the McIntyre have been placed and the prospects of the mine's production being increased in the spring at the rate of another million dollars a year are good. Application has been made to list the stock on the New York market and this is serving to advertise the enterprise to the end that the value of the stock on the open market has recently experienced a very substantial advance.

The power dispute

This week has witnessed the launching of the action of the Hollinger against the Northern Canada Power Company for alleged failure during the winter of 1920-21 of the power concern to supply the full requirement of its contract to provide all the energy that the Hollinger might require. Until the trial advances it will be difficult to outline the basis of defence on the part of the power company, but the general opinion in the district is that the defence may be based upon the statement that it was only by act of Providence that more power was not available in that the season was one of the driest in the past half century and not only resulted in power shortage at Porcupine but also made itself felt seriously in practically all parts of eastern Canada where hydro-electric energy was being generated Something like a million dollars is stated to be involved in the action.

Lake Shore

On January 6th the Lake Shore mine sent out one of the largest shipments of gold bullion in its history the total amounting to approximately $71,000 and representing over five week's production It is also learned that during the month of December the mine produced upwards of $57,000, thereby establishing the biggest record for any one month's production in its history, this achievement comparing with over $51,000 in November which was heretofore the record The feature of present results on the Lake Shore mine is that mill heads are averaging well over $30 per ton, and that development work is proceeding in an important way to the size of the mine.

Wright-Hargreaves

During the month of December, the Wright Hargreaves mill showed a still further increase in the amount of ore treated, the daily average being 175 tons and the total for the month approximating 5,425 tons. Mill heads ranged between $11 and $12 to the ton and thereby indicate an output of upwards of $62,000 for the month.

Ontario-Kirkland

Following the breaking of a gear on the hoisting machine on the Ontario-Kirkland mine which resulted in two delays, the hoist was again set in operation on January 6th and the mill turned over again on the 7th. About 1,000 tons of ore already in solution as a result of the two short periods of operation, and with the plant now under steady operation the first clean up will take place in February. The indications appear to be that owing to the ore being softer than on the mines along the main break, the mill may reach a capacity of around 110 to 120 tons instead of 100 tons daily as designed. Also, the indications appear to be that the ore will average around $11 per ton and would indicate an output at the rate of not far under $40,000 per month when running steadily. Two ore shoots at the 300-ft. level are each about 200 feet in length and contain good values across a width of about five feet. At the 450-ft. level, there are three ore shoots, two of which are each quite close to 200 feet in length and one being 70 feet in length. At the present time a working level is being opened up at a depth of 150 feet and this will provide a total of three levels from which to draw ore. This week the work of connecting the 450-ft. level with the 300-ft. level will be completed and by the end of the month ore will be drawn from the 450-ft. level through the main shaft.

Wages reduced

Not far under four thousand men now employed at the gold mines of the Porcupine and Kirkland Lake districts will experience a wage reduction of about 10 p.c during the current month. This reduction is the first to be made in the gold mining districts of Northern Ontario since the upward trend commenced during the war. This reduction compares with a 15 p.c. cut in the silver mining districts last spring, and a 12 p.c. reduction on the railways recently.

The operators of gold mines deferred the cut until such time as the cost of living showed a substantial decline and, also, until suffering a substantial shrinkage in income resulting from the premium on gold sold on a par with United States Currency.

The total pay-roll at the gold mines has recently exceeded a rate of $5,500,000 annually, and will, under the new rate, amount to over $5,000,000 a year.

EXPLORING FOR OIL IN MACKENZIE AREA.

Results Disappointing, But Not Discouraging.

Efforts to develop commercial production of oil in the Mackenzie River basin have so far proved disappointing but not discouraging, according to A. M. McQueen, vice-president of the Imperial Oil Company, who recently made an exhaustive survey of attempts to discover commercial oil in the Canadian far-north before the session of the Engineering Section of the American Association for the Advancement of Science in the Electrical Building of the University.

"In summing up our experience," said Mr. McQueen. "I can only say that we are disappointed, but that we are not discouraged and we are going on in the hope that we may some day feel that we have contributed to making Canada independent in its resources of a commodity of vital importance.

"Despite the amount of capital which has been invested and the engineering and drilling problems which have been encountered, the company has not been successful up to the present time in developing a commercial production of crude oil. In the Fort Norman, No. 1 well, we obtained a small production, which only demonstrates the fact that oil exists in that region. Under more favorable conditions at some other location in that territory we hope to obtain a larger production, but time only can justify this prophecy."

It was a romantic story the speaker told of the fight between the forces of modern science and industry and the difficulties imposed by nature over a territory where the temperature was as often as not forty degrees below zero. One example aroused the intense interest of the audience. A crew of one of the big monoplanes used in maintaining communications became stranded 900 miles from their hangar with a broken propeller. With the aid of an old cabinet-maker, who happened to be a resident of the district, a new propeller was fashioned out of oak used for Eskimo sleds and glued together with glue obtained from the hide of a moose. The make-shift proved to be successful and the plane returned to its base none the worse for its mishap. It was such instances as that declared Mr. McQueen which demonstrated the difficulties of operating over thousands of miles of practically deserted country.

TRUSSED CONCRETE STEEL CO., OF CANADA, LTD., WALKERVILLE, ONT.

Due to the resignation of Mr. G. B. Reynolds, who has left the Company's employ to engage in other pursuits, a change has been necessitated in the management of its Montreal office. Effective January 1st, 1922, Mr. A. St. C. Ryley, formerly General Sales Manager of the Company, succeeded Mr. Reynolds as Manager of the Montreal territory with offices at 323 Drummond Building, 511 St. Catherine St., W., Montreal.

THE MINISTER OF MINES.

Hon. Charles Stewart, ex-Premier of Alberta who has been appointed Minster of the Interior and Minister of Mines, is a farmer who has taken an active interest in public affairs in Alberta. He has served as Minister of Public Works and as Minister of Municipal Affairs in his Province. Mr. Stewart was not a candidate in the Federal elections and he will have to secure a seat in the Commons. Mr. Stewart was Prime Minister of Alberta previous to the provincial elections last Summer, which returned the United Farmers to power in his place, although he himself was elected by acclamation for Sedgewick, and it had been expected that he would take his place in the Provincial Legislature as leader of the Liberal Opposition.

Alberta returned to Parliament eleven Pogressives and one Labor candidate, who had Progressive endorsation.

PERSONALS.

Mr. Hugh L. Kerr, elected to the Board of Education in Toronto, in the recent civic elections, is well known in mining circles, and was in at the first rush to the Cobalt district. He was one of three University of Toronto men who staked out the University Mine, and a short time later sold out to a syndicate for approximately $1,000,000. Mr. Kerr graduated from the University of Toronto in 1903, and was a lecturer there for two years.

METALLURGICAL MILLENIUM IMMINENT.

By ALEXANDER GRAY

Being the greatest of the Genii of the Lamp, Thomas A. Edison is an iconoclast. His scientific achievements relegated many graven images to the refuse heap. Not so long ago he could exterminate whole armies were it not too terrible for words to have him attempt it. Earlier than that he contemplated making cobalt continuously commercial and saleable in huge quantities; so he bought a property in the Portage Bay district, of unhallowed memory, thinking to use cobalt in the perfection of his storage batteries. Latterly, having become intimate with Henry Ford—who was obsessed with the idea that all he had to do was to go over and stop the war before a certain Christmas, Mr. Edison is convinced the transmutation of metals, is about to be demonstrable. It having been chemically proven that lead, instead of being "a single metal, as has been supposed, contains two ingredients instead of one," Mr. Edison proceeded to exterminate the gold standard and to dethrone gold as a precious metal, in this ruthless manner:

> "Discovery of how to make gold artificially may be made any day. I have said this for years. This new discovery is part of the solution of the problem I have always felt that the gold clause in bonds is dangerous. This clause provides that the bonds shall be paid in gold of a certain degree of fineness. What would the people who own railway bonds say if they should wake up some morning and find that gold could be manufactured as cheaply as we now make pig iron? Well, that is exactly what will happen some day—and it may happen any day."

Synthetic diamonds, rubies and other gems, cultured pearls, manufactured diamonds, are trivialities in contrast with the triumph of wizardry foreshadowed by the necromancer of Menlo Park. Mr. Edison never has been an alarmist. Ramsey, however, within recent years was equally positive transmutation was being effected. Kelvin, another scientific idealist, chased chimeras until his worldly belongings were dissipated. Werndier thought Lemoine was upon the eve of producing diamonds in quantities to order.

Of course, telephony has been revolutionized; Tesla, Edison and Marconi worked magics; but to take away the foundation stone of international credit, and make of gold a cheap, artificial metal, would leave bankers and bondholders so speechless that they could not make reply to Mr. Edison's query.

Gold has been the cherished standard of value since gold, frankincense and myrrh were gifts for and from the gods. The craving for it is accredited with being the cause of all good and ill. Possession of it, or its equivalent, has been the motive power behind the nations. A non-corrosive, convenient, governed by factors of cost of production and comparative scarcity, it has been the surest medium of giving and obtaining value for value—now Mr. Edison serves it the mustard gas and is a "bear", a "crab" on gold mining! He does not intimate—nor could he at this stage—the first cost of gold. Factory prices would govern. Perhaps too, manufactured rarer metals will make radium and platinum bu gain day features. Research, too, may provide the means for replenishing the earth with minerals ready to be mined and transmuted.

In that event, another wizard—a Ukranian electrical engineer, Chayko—will have supplemented Mr. Edison's pentecostal pronouncement in behalf of bimetallism without limit. Chayko is not inimical to the gold factory as Mr. Edison foresees. By a "simple apparatus" he sends sourdoughs and hardy annual prospectors to the hump by "grouping what are termed the 'locked power lines' of the magnetic field into parallel rays which can penetrate mountains, thereby avoiding the necessity of high antennae," all of which "will enable the location from the surface of metal deposits," etc., etc.

Even the tolerated geologist is to be innocuous disuetude, as President Cleveland once put it, when the magicians of the laboratory and the furnace bring the world to the end of the rainbow, switch on the Chayko apparatus—the spot light instead of the twig, or divining rod—and supply the raw material in place. Means for quantitive and qualitative analyses without resort to the diamond drill or development will eliminate unessential mining engineers.

Science classes—not overlooking faculties—then will concentrate on the whichness of wherefores—and degrees may be conferred for theses on the Nothingness of Past Sciences. Meanwhile the Cross with Palms goes to Chayko. Edison must bring the proofs—in car lots!

CALIFORNIA'S GOLD OUTPUT.

California's gold production in 1921 was 761,660 oz. valued at $15,744,910. For a time in July it looked as if the mines along the Mother Lode, particularly those near Nevada City and Grass Valley, which are among the largest-producing deep mines in the State, might be forced to close because of labor troubles. These troubles, however, were finally adjusted, and a wage scale was established to hold until June 30, 1922. This scale $4.25 a day for machine men and $3.75 for shovelers, has been more or less generally adopted throughout the State.

RUSH TO ELBOW LAKE.

The Pas, Man., Jan. 5. The rush to Elbow Lake gold camp, 75 miles north of here, continues, and nearly 500 claims have been staked. Many prospectors have gone in and during the last week 11 two horse freight teams and approximately 50 dog teams have left here with supplies.

The Hollinger Company of Porcupine, holder of the $150,000 option on the Murray claims, have taken in complete supplies and a gang of 25 men, who will start immediate development of the property.

A number of claims near the original Murray discovery, which had been overlooked owing to heavy timber surrounding it, have been found by G. R. Bancroft and he has accepted an offer of $75,000 from a Toronto syndicate for his holdings.

NEW WAGE SCHEDULE.

Sydney, N.S., Jan. [illegible] That only actual miners will be included in the new schedule of wages and working conditions to be made by the Dominion Coal Company with the United Mine Workers of America, is the notice No. 26, was the statement here last night by H. J. McGuire, Assistant General Manager. According to Mr. McGuire the company wishes to eliminate from the contract [illegible] men, railway tractioners and others not connected with actual mining operations, but who have been entered on previous United Mine Workers' schedule.

British Columbia Letter

Mines did well under adverse conditions. Large lead output. Small decrease in zinc. Large gold output. Decrease in copper. Decrease in silver. Slight decrease in coal.

By ROBT. DUNN.

It is estimated by Hon. Wm. Sloan, Minister of Mines, that the value of the Mineral Production for 1921 will approximate $25,780,608. This is $9,762,476 less than in 1920, or a decline of about 27 per cent.

These figures, it is stated in the course of the annual review in which Mr. Sloan discusses mining conditions in British Columbia during the past year, are most encouraging. That there should be a reduction was to be expected. The general prediction was that it would be much greater for the reason that the metal markets for months have been so weak that many of the large smelters and refiners of the American Continent have found it impossible to keep their plants in operation. Under the circumstances it is considered remarkable that this Province should have been able to so well maintain the general average of production.

Outstanding Features.

There are several outstanding features in connection with the 1921 history of the industry. One is the record of the Sullivan Mine at Kimberley, which is strikingly reflected in the statistics relative to the output of lead and zinc; another the splendid performance of the Hidden Creek Mine and the Anyox Smelter, which is shown in the volume of the copper production; and a third in the development in the Salmon River Valley, Portland Canal, of a gold and silver producer of first importance, the contribution of which to the precious metals produced by British Columbia for the first time gives an indication of what may be expected from this and other properties being opened up in this comparatively new northern mining section.

During most of the past year, and still in marked degree, world conditions from the viewpoint of the metalliferous mining have been unsatisfactory. Europe, which consumes the greater proportion of the world's copper product, has been unable to buy the metals of America and, as a result, the largest producers of copper in the world reduced their output to about 20 per cent of normal. Much the same has applied to lead and zinc. These facts remembered it is the more remarkable, and gratifying, that the 1921 production of Lead is estimated to be 3,668,782 lb. greater than in 1920, the figures being: 1920, 39,331,218 lb.; 1921, 43,000,000 lb.; that Zinc will drop in volume only about 2,208,268 lb. in comparison with the records of the previous year; and that even in Copper, for which there was little or no market, the decrease was not greater than approximately 10,607,676 lb.

Mr. Sloan observes at this point that the manner in which this Province has held her own in respect of three of the basic commercial metals, in the face of almost unprecedented adverse conditions, is a convincing commentary on what can be done when the trade winds are more favourable and furnishes an admirable illustration of what the future holds for the mining industry of the country. It was only a few months ago that at an International Mining Convention at Portland, Oregon, the American delegates held a session apart from the Canadian delegates to formulate resolutions advocating a tariff against Canadian lead and zinc. That the mining men south of the line then were beginning to realize that British Columbia was becoming a factor to be figured with in competition on the world's markets was evident. Their fears, it would appear, are justified for the industries of this Province still are producing and marketing notwithstanding the slight margin between profit and loss under present conditions.

A detailed statement in which the 1920 output is compared with the estimated production of 1921 is given as follows:

	1920		1921		
	Amount	Value	Amount	Price	Value
Gold-placer	.....	$ 221,600	.....	$20.67	$ 220,000
Gold-lode	120,048	2,481,392	136,000		2,935,140
Total Gold		2,702,992			3,155,140
Silver	3,377,849	3,235,980	2,550,000	60.23	1,611,152
Copper	44,887,676	7,832,899	34,280,000	12.4	4,127,312
Lead	39,331,218	2,816,115	43,000,000	4.08	1,754,400
Zinc	47,208,268	3,077,979	45,000,000	3.83	1,723,500
Total Metall.		$19,665,965			$12,371,504
Coal	2,595,125	12,975,625	85 p.c. of 1920		
Coke	67,792	474,544	Estimate by Chief Inspec.		11,432,644
Total for Collieries		13,450,169			
Miscell. Minls	.....	250,490			200,000
Bldg. Materials	.....	—2,176,460			1,776,460
		$35,543,084			$25,780,608

Estimated decrease in value from 1920 .... $9,762,476
Approx. 7 per cent.

Gold Output Increased.

In reference to the precious metals it is mentioned as a matter for congratulation that there is a probability of an increase in the production of gold, 136,000 ozs. as against 120,048 ozs., this applying to lode mining. The figures as to the placer fields are not yet available to such an extent as to permit an estimate. The output should, however, be about the same as in 1920 so that the total yield is expected to be in excess of the previous year.

There were months during which silver was quoted on the world's markets at an exceedingly low figure and over this period many of the mines, small and large, of the Kootenay and the Boundary District were compelled either to close down or to curtail operations to nothing further than development. More recently the demand for the white metal has been reviving, largely because of the Oriental demand, in which part of the world distrust of currency is more than usually deep rooted. This has resulted in a rising market and increasing activity in the silver mining camps with a more promising outlook.

Attention is directed to the marked difference in metal values as between 1920 and 1921 as proving that the expected decline shown by the past year, in a monetary sense, is not to be taken as a fair estimate of the comparative achievements of the two years as to production. On this point a self-explanatory table of average metal market prices is given:

Average Market Prices.

	Silver	Copper	Lead	Zinc
1920	100.9	17.45	7.95	7.67
1921	63.4	112.41	4.53	4.62
Percentage drop in 1921	37.17	28.94	43.10	39.77

Value of 1920 Production at 1920 prices $16,962,973
Value of 1920 Production at 1921 prices $11,674,980
Theoretic diminution of value due to lower prices $ 5,287,993
Percentage 31.2 p.c.

These figures show that should the output of those metals in 1921 exactly equal the quantity produced in 1920, the metal prices for 1921 would reduce the money value of such output by 31.2 p.c. This means that in 1920 on an average the miners received nearly 50 p.c. greater an amount than for a similar quantity of metals in 1921.

This is the financial handicap from outside sources that our mines have had to meet throughout the year. To partially meet this there has been a slight decrease in the cost of wages and supplies used in mining.

(To be continued)

NORTH EASTERN B. C. SHOWS INCREASED PRODUCTION,

That, despite adverse conditions, there will be an increase in the tonnage mined in the North Eastern Mineral Survey District of British Columbia is the encouraging report of Mr. George Clothier, resident mining engineer. This section comprises the mining divisions of Bella Coola, Skeena, Queen Charlotte, Naas River, Portland Canal, Stikine, Liard and Atlin. The first three are on the coast and the latter lie behind what is known as the "Alaska strip." Included in the area are the Premier Gold Mining Co., The Dolly Warden and other Alice Arm properties, the Granby Company's Mine and smelting plant at Anyox, and the placer mining fields of Atlin.

Increase in gold, silver and copper.

It is estimated that the increase in tonnage mined will amount to about 75,000 tons. The gold output, exclusive of placer which will just about equal last year, will show an increase of approximately 30,000 ozs., or about 60 p.c. greater than last year. This is due to the gold production of the Premier God Mining Co. of Stewart. The silver yield for this year will be about 1,500,000 ozs., or about 125,000 ozs., greater than last. This is due entirely to the output of the Premier Mine for the Dolly Varden which gave over 800,000 ozs. last year produced practically nothing this year. The Premier's output of silver will be over a million ounces alone. The copper production will exceed that of last year by nearly 9,000,000 lbs., an increase of about 33 p.c., and due altogether to the Granby Co. at Anyox.

Notwithstanding the deflation of the prices of metals, the total value of the three metals produced in this District, (gold, silver and copper,) will be greater than last year. In fact, taking quantities, not values, into consideration, this year,s will be the greatest production ever made in this district.

Granby produced 34,280,000 lb. copper.

The Granby Cons. N. S. & P. Company's output is slightly less in gold and silver but away ahead in copper. It is estimated that their production this year will be about 34,280,000 lb.. of copper against 25,405,000 in 1920.

The goldskeish Mining Co., though operating only a small property, has doubled its gold and silver output.

The Dolly Varden has been the disappointing mining feature of the year, shipping only what ore was left broken in the stopes and chutes.

The Premier Gold Mining Co. of Stewart will produce about $1.750,000 in gold and silver, divided about evenly, in 1921. This should be indicative of her capacity for some years.

The Belmont Surf Inlet Mining Co. produced about 10,000 ozs. less in gold than last year, with silver and copper about the same.

The placer output will be about the same as last year.

The Maid of Erin, in the Rainey Hollow section, has shipped some ore but the exact tonnage is not yet available. This had to be hauled by tractor about 60 miles to tidewater at Haynes. Development work on the property this summer has made it look very promising.

Activity in the Kitsumgallum Lake section is assured for next season and the section is giving good promise.

It must be concluded from the foregoing that the general financial depression and deflation of metal value has had practically no deleterious effect on the mining industry in this part of the Province, in so far as operating and shipping properties are concerned. It, however, would have been a different story had such a calamity as the closing down of the Granby plant at Anyox occurred. With the increasing price of copper this property now should have no difficulty, comparatively speaking, in keeping the wheels moving. About the only notable difference between this year and the past two or three years has been the lack of capital for the condition of development by the smaller operators, and for new undertakings.

EDITORIAL

THE STEFANSSON EXPEDITION.

Exploration in the Far North is difficult under any circumstances but it can be made absurdly difficult by mismanagement. The stories that are being published concerning the Stefansson expedition should result in better organization of future expeditions to the frozen seas. The men who did the work on the expedition have refrained from public criticism for a long time but are now aroused by the explorer's criticism of their actions. An enquiry into the matter will be necessary and is expected to reveal an interesting story.

In an interview published in the Globe, Mr. J. J. O'Neill one of the party says:

"When we reached Nome, Alaska, our starting point for the Far North, we found a terrible old whaler awaiting us. We were astounded, for we had been specially told that a modern, well-equipped vessel was to be put at our disposal. Stefansson had made the purchase, which he evidently considered good enough for us, but he had taken great pains to make the Karluk, the northern party's vessel, the finest fitted-out ship that ever left for Polar seas.

The Alaska, as ours was called, was in such a dilapidated state of preservation that the inhabitants of Nome were actually making wagers as to how long it would remain afloat. But what could we do? If we drew back at that stage of the game we would undoubtedly be accused of cowardice.

"Then came the question of receiving our share of the supplies which had been stored at Nome prior to our arrival. Stefansson took nearly two-thirds of these, and practically all the provisions. He had purchased, for example, with the Government's money, approximately seven tons of pemmican, a specially prepared food. Of this huge supply he generously allowed us 1,000 pounds. Clothing, etc., secured by the Department of Naval Service, he distributed on a four-to-one ratio. But this was not all, he also appropriated every available sled and dog that Scotty Allan, the celebrated Nome 'musher', could find. He excused himself by saying that we could easily get along without them, as our work would not take us off the continent.

"I have not yet read his new book, but I have been given to understand that he has made an attack on me for criticizing his actions at this place."

"After the loss of his Karluk," said Prof. O'Neill "he joined our party at Collision Point. As it was his intention to form a new enterprise to explore Beaufort Sea via the ice route, he demanded what was left of our 1,000 pounds of pemmican, etc. Our refusal to allow ourselves to be crippled so that he might be outfitted afresh, I believe he describes as 'insubordination,' if not actual 'mutiny'. In fact, I have been advised that in his book he attributes his failure to accomplish more to the manner in which we kept 'continually hindering him.'"

"I am not surprised that Dr. Anderson, no longer able to keep silent under these unjust accusations, has publicly denounced him. The Government may now consider a full inquiry justified."

THE OLD STORY AGAIN

Commenting on the revival of interest in gold mining, a Toronto newspaper recalls that some years ago an eminent British scientist said that the existence of gold in Ontario was geologically impossible. Every now and then someone tells this story, with variations to suit the circumstances. On occasion the reference is to silver instead of gold. The purport of the story seems to be to discredit science in its relation to industry.

Now we make no claim that scientists do not make mistakes. We have no doubt that there have been eminent scientists who do not know very much about gold deposits and that there are others who do not know very much about the geology of Ontario. We doubt very much, however, whether any eminent scien-

tist stated that "the existence of gold in Ontario is geologically impossible." Some pseudo scientist may have made such a statement, but no scientist worthy of the name presumes to dictate to nature. He may draw conclusions from observed facts; but he cannot pursue scientific studies without realizing that theories are but a means of grouping together known facts and that the tenability of a theory depends entirely on the known facts.

That gold exists in Ontario has been known for many years. Its existence was never an impossibility. Any person who said it was so, must have been in a peculiar mental condition. He would properly be designated by two words of four letters each. If it was an eminent scientist who made the statement, it must have been received by his friends with more concern for his future than for the gold industry.

We refer to this matter because we believe it not to be in the best interests of the industry that science should be discredited. The gold mining industry in this country is only possible because science has been applied to it to a marked degree.

A NATIONAL PROBLEM.

Elsewhere in this issue will be found an article by Mr. W. M. Goodwin on the Canadian iron industry and what he very aptly terms the national problem that it presents for our consideration. We commend a perusal of this article to our readers. Not only is is (if we may say so) written with admirable lucidity and precision but it is also admirably constructive in purpose. Some of our readers may disagree, in part, and perhaps in large part, with the conclusions at which Mr. Goodwin arrives and with the solution he suggests of the well-known difficulties which have hitherto defeated the attempts to found an independent Canadian iron industry. But, in our view, it is undeniable that he has made a contribution of considerable value to the discussion of a subject which is of national importance.

Whether or not the methods which Mr. Goodwin describes as having been so eminently successful in solving a not dissimilar problem in Sweden would meet with a like measure of success in this country is a question on which, in the absence of more amplified information than we possess as to the details of the operation of the iron industry in the former country, and (we may add) without fuller consideration than we have been able to bring to bear on this aspect of the subject, we should not like to commit ourselves. But, *prima facie*, Mr. Goodwin has made out a case which challenges attention and investigation. And, speaking generally, we find ourselves in hearty accord with his contention that the bringing together of as many as possible of those directly or indirectly interested in our iron and steel industry with a view to forwarding the interests of the same is the right way to go to work. It is sound in principle and should not prove too expensive in practice.

We are all of us too apt to think of industrial problems as admitting only of known solutions. The truth, however, as most of us, if pressed, are constrained to admit, is, of course, quite otherwise. Great as have been the accomplishments of science in its relation to industry, particularly (as we point out editorially elsewhere in this issue) within the last fifty years, we are yet, in all probability, but on the threshold of many of its most brilliant triumphs in this regard. The seemingly impracticable of today may be the veriest common-place of tomorrow. For science never speaks its last word. What science may have to say on the question of new methods of smelting especially adapted to our natural resources may, very possibly, be well worth our hearing as a solution of the problem of our iron industry. But, at least, we should strain every nerve to catch its accents.

As our readers are well aware, we have consistently emphasized the necessity of adequate tariff protection for the iron and steel industry while we are under the necessity of importing iron ore and coal into Canada. Not less consistently have we maintained that the existence of an iron and steel industry of our own is demanded by Canadian national sentiment. But, at the same time, we should heartily rejoice if Canada could have a flourishing iron and steel industry of her own without being under the necessity of importing iron ore or coal. If a radical and drastic revision of our smelting methods should obviate the necessity for the use of imported coal for smelting; and if new smelting methods could be devised whereby the use of domestic ore might be made a commercially paying proposition, then science would have made an outstanding contribution to the solution of a baffling and perplexing problem. Until then, at any rate, protection, by means of the tariff, is essential. But science should certainly be given its chance to do what in it lies to solve the problem along the lines indicated.

TROUBLE ON THE RAND.

The great gold mining industry of South Africa is passing through a critical period. The high cost of production and the inefficieney of the workers, white and colored, is causing the mine operators much concern. It is anticipated that important changes will have to be made to avoid closing down more of the mines.

The proposed changes relative to the employment of white and colored labor, are evidently not liked by the miners. At this distance, however, it would seem necessary that changes that will bring greater efficiency must be made and that the employees will have to meet the operators half way if the industry is to flourish again.

It has been announced that a conference, presided over by Gen. Smuts, is to be held shortly. We hope that good results will come from this and that we will soon find more pleasant news in reports from Johannesburg. The Government realizes the seriousness of the situa-

tion and will doubtless make every effort to help operators and workers find a way out of the present situation.

THE FUTURE OF GOLD MINING.

In an article contributed to the Annual Industrial Review published by the "Globe", Mr. A. F. Brigham, manager of Hollinger Consolidated Mines Ltd., states that with reasonable encouragement the production of gold in Ontario may be advanced to such a figure that the performance of 1921 will look in retrospect like a small beginning. To bring about such progress there must be an "intelligent understanding of gold industry problems by the public generally, and a practical sympathetic attitude on the part of the public's servants." When it is recalled that Ontario is now producing about $1,200,000 gold per month, some idea of the possibilities of gold mining in the Province as viewed by Mr. Brigham may be grasped. We have some large producing gold mines, but under favorable circumstances it is likely that we will have many more and larger producers.

COPPER MINES REOPENED.

The Calumet and Hecla Mining Company has announced that it will open four of its Michigan copper mines about April 1st. This company operates the Calumet and Hecla mine and several mines of subsidiary companies. The four mines referred to are the Calumet and Hecla, Ahmeek, Allouez and Isle Royale. These are all mines that were operating on a large scale a few years ago and resumption of operations will mean employment for a large number of men in the copper district who are now experiencing great difficulty in finding work. In the Michigan copper mining district the news will be as welcome as would be in Sudbury an announcement of resumption of work at the nickel mines. It is an indication of improvement in the copper market and evidence of faith in the future of the mining industry.

NEW MODDERFONTEIN AND HOLLINGER.

An Informative Analogy.

By ALEXANDER GRAY.

To those of us who have survived the switchback of Mining — with all its rough riding — experienced its thrills and chills — the receipt of a report such as the New Modderfontein company of the Witwatersrand present, vividly recalls emotions akin to those of the moment when it was my indelible privilege to hand to Dr. Molengraaf — an outstanding Crystallographer — the Cullinan Diamond, and to say to him:

"Name the baby, Doctor"!

The tall, scholarly Hollander, ex-State Geologist of the Kruger Government, took the lustrous lump, fondled it, adeptly focussed it, scrutinized the structural lines of that more than 3,000 carat crystal, made a rough sketch showing the two planes of fracture, and then pronounced it to be a magical gem, worth millions according to established bases of valuation, with the greater portion flawless. Those Molengraaf keen blue eyes sparkled, as a mother's would with her first-born, it was with manifest reluctance that he passed the limpid bauble to "Tom" Cullinan. The biggest of its kind was not for the Doctor's collection. It went to the Crown Jewels.

New Modderfontein data, the record doings of a mine that will surpass all previous performances at the Rand, with which the Hollinger Consolidated Gold Mines of Porcupine have begun, only begun, mind you, to vie, are no less exhilarating. To June 30, the company had paid £7,000,000 in dividends, which compares with £12,000,000 from the smaller area of the Robinson. The difference being, however, that New Modderfontein is not at maximum virility, while Robinson is being interred. After producing about $100,000,000, and distributing better than a third of that, conservative estimate makes the ore reserves between 25,000,000 and 28,000,000 tons, worth approximately $225,000,000 to $240,000,000. Ultimately, about twenty years hence, New Modderfontein may have contributed a third of a billion dollars. Those who revel in comparisons will have a clearer perspective as to what that big and aggregate means, when they think that New Modderfontein as a profit may contribute in value as much as Cobalt silver and all Ontario gold mines have at this writing. From 28 per cent of its claim area New Modderfontein last June had milled 9,750,000 tons for $100,000,000, so the remaining developed and undeveloped 903 claims may provide a further $250,000,000 from which a divisible per ton profit of £1 is possible. Dividend visitations are assured. In 1920-21, the distribution was 100 per cent.

Yet there are those who will have it that "a mine is a hole in the ground with a liar on top", that all precious metal mining, like vice, is a "monster of such hideous mien: to be hated needs but to be seen". Of course Witwatersrand areas lend themselves to close approximations as to ore contents. Not every area though, is a New Modderfontein a Robinson, Ferreira, Crown Reef, or even a Robinson Central prize-winner in tabloid. Nor are there many companies recovering 98 per cent of the gold although it is a common-place to have technical men invariably decry Rand Engineers and Managers. Such high an extraction is worthy of attainment by others provided the cost of the added saving be economical or balance.

Because Hollinger crushings and plants are undergoing revision upwards these New Modderfontein results have special interest. In one respect present Hollinger shareholders have the advantage in that they have received 55 per cent in dividends, taking their shares at parity, whereas those shares were issued at 5/- or New Modderfontein has paid 185 per cent.

From now on, Hollinger holders, owing to the larger capital of Hollinger Consolidated, are looking for still better things. Undoubtedly expansions are of the making. In this connection it is pertinent to dwell upon the fact that the largest claim holders at the Rand are discarding stamps and amalgamation processes. Consolidated Mines Selection and the New State Areas of the Barnatos realize the great savings to be effected in cost of installations and operations. Hollinger is moving in the same direction. New Modderfontein crushing capacity is about 107,000 tons per month. Hollinger current crushing capacity exceeds that. What will it be before the end of 1922? The limit is off, if the power barrier is removed.

The Canadian Iron Industry

A National Problem.

By W. M. GOODWIN.

The story of our failure to develop an independent Canadian iron industry has been repeated so often that now the only valid reason for further public discussion of the matter is the inclusion of some constructive idea. In this article an attempt is made to present an idea that, though not new, has not been clearly understood by many interested in the problem. In order to present this idea in the proper light, a brief outline is given of the efforts of our pioneer iron-masters, then the building of the present plants is referred to. Instances are given of the unsuccessful attempts to found a truly Canadian industry, and present-day efforts to the same end are mentioned. Finally, the solving of a problem similar to ours in Sweden, two hundred years ago, is described, and a solution of our own problem suggested.

First Attempts at Iron Smelting.

Our pioneer iron-masters were mainly men who had learned their trade in the Old Country, and attempted to apply their knowledge in the new land. If Nature had provided similar conditions, there is no doubt that their efforts would have resulted in permanent success. In Nova Scotia, where coal and ore are in close proximity, we have such a case of continuous development from the pioneer furnace to the modern plant. It is only the discovery of the cheaper Wabana ore that has altered this self-contained Canadian undertaking, though this has likewise allowed of much more extensive operations. Elsewhere we have no such example of continuous development.

A number of the earlier furnaces in central Canada were operated successfully as long as there persisted some special conditions that gave them an advantage over foreign competitors. At first the cost of importing iron from England and the United States allowed a number of the furnaces in Ontario to make money. The failure of supplies of bog ore, and of cheap charcoal, the improvement of transportation facilities on the importation routes, and the development of the modern blast-furnace using coke, in England and the United States, all combined to cause the failure of the furnaces in Ontario and Quebec. Those that made only an average quality of iron quietly succumbed; special quality, commanding enhanced prices, gave a longer lease of life. A number of furnaces making charcoal iron especialled suitable for chilled car-wheels had honourable careers. At Radnor Forges, special quality spelled success, and only recently has metallurgical development encroached upon the market held by its charcoal iron. In general, it can be said that nowhere in central Canada have natural conditions allowed of competition on equal terms with our foreign competitors; and if special advantages exist within our borders that may allow of a native iron industry, we have failed so far to develop them.

Present Iron Industry.

Twenty-five years ago some promoters and politicians, and some business men decided that we should have an iron industry in central Canada. So, under shelter of a tariff, furnaces and steel plants were built, following American practice, and using American ore, but with the hope and expectation that similar ore would be found in Canada in sufficient quantities to meet our needs. This hope has not been realized, and we can now hardly expect our unexplored iron ranges to contain large deposits of hematite. Thus we have left on our hands large plants completely dependent upon American coal and American ore, whose continued operation is possible only on account of an adequate protective tariff. It is true that these plants constitute a natural part of the mid-continental iron industry using Lake ores; but that does not help us Canadians with our problems.

Attempts to Found a Canadian Industry.

Numerous atempts to develop an indigenous Canadian iron industry have been made of late, by both miners and metallurgists.. After exploration had destroyed the confident hope that our iron ranges would be similar to those south of the border, a number of our deposits were opened up and the ore tried in the blast-furnaces. These were uniformly rejected by the furnace operators. In most cases, this was no doubt warranted by the facts; in a few unimportant instances it is still a matter of dispute whether or not the ore can be profitably used.

When the raw ore proved unacceptable at the furnaces, serious attempts were made to "beneficiate" it. The Magpie roasting and nodulizing plant represents a bold experiment that we hope will be of permanent value to the country. By the way, a large part of our fraternity hope that the administrators whom we have placed in charge of our public affairs will see the wisdom of aiding this undertaking by means of a sufficient bounty to ensure its continuance. The Moose Mountain attempt has been revived, and now has the official backing of our Advisory Research Council. The eventual success of the Trenton plant seems more uncertain, as its resources of ore are smaller and less uniform than the other two. The thorough-going attempt to use roasted Stikoban ore having fallen short of commercial success, those interested in the really extensive deposits of the Part Arthur district seem to have adopted a policy of "watchful waiting".

New Smelting Methods.

It is not a new idea that we Canadians should work out methods of smelting specially suited to our natural resources. Dr. Haanel is credited with being the first to push vigorously the idea of the electric smelting of iron ore, which has lately been applied so successfully in Sweden and Norway, Japan and elsewhere. Sjoitedt's atempt to make use of the iron of the nickel ore at the Gertrude mine, with sulphur as fuel, is said to have come very near to success. A somewhat similar attempt is the production of "Nicu" steel at Niagara Falls from lean Sudbury ore or smelter slag. The Tivani experimental plant at Belleville attests an effort to make steel direct from ore. These efforts, and others, have so far failed to result in permanent commercial enterprises. Nevertheless the work goes on, as experimenters and researchers have more than a normal amount of the hope that springs eternal.

Electric Smelting.

The proposal that has been most prominent lately in iron and steel circles is electric smelting. Its

possibilities in British Columbia have been examined recently by Dr. Stansfield. His inability to recommend the venture in that favoured locality would seem to dispose effectually of any such attempt in central Canada, where iron is so much cheaper. The small margin of superiority of electric smelting over other methods, even where conditions are most favourable, is shown by recent events at Domnarfvet in Sweden.

A number of electric blast-furnaces are used there to supplement charcoal furnaces. Just before the war the smelting capacity of the plant was to be increased, and a new blast-furnace to use coke was decided upon. But the war intervened to charge the situation. The price of coke went up, the half-finished furnace was let stand, and electric blast-furnaces were installed instead.

To allow of the establishing in central Canada of an electric smelter ,some new and favourable factor must be brought to light. If the production of "sponge metal" by means of cheap fuel should prove feasible, the electric current will finish the operation; but that will be melting, not smelting. The main posibilities would seem to be in the production of high-priced material, such as alloy steel.

The Problem.

Our problem in central Canada may be reduced to a few simple elements.

1.—We have at present no natural resources that will allow us to compete on equal terms with the iron masters of the United States, while using their methods of smelting; nor are we likely to find them in unexplored territory.

2.—So long as we are content to import iron ore and coal, we can have a flourishing iron and steel industry, provided we protect it with a sufficient tariff.

3.—We must continue to use imported coal for smelting unless we revise radically our smelting methods.

4.—In order to make possible the use of domestic ore, we must either pay a bounty on its production or use, or else devise smelting methods whereby its use is profitable.

Thus it is obvious that the ultimate solution of our problem lies in metallurgy, the bounty being merely a temporary expedient to stimulate metallurgical effort.

There are two lines along which our efforts may be directed; we may try to make our ores suit the existing blast furnaces, and we may search for smelting methods particularly suited to our ores. Here again we have a question of expediency. As the present furnace plant represent a huge investment, it is probably wise, and certainly easier, to try to alter our ores to suit them. But I am convinced that the sound and far-sighted policy will be to search out smelting methods specially adapted to our ores whereby we can use them to the fullest advantage.

The Problem in Sweden.

Two hundred years ago the iron masters of Sweden faced a problem somewhat similar to ours of today; and they solved it. From ancient times there had been a flourishing iron industry, and the product of the primitive forges and furnaces had carried the name of Sweden throughout the world. Competition from Britain, where cheap coal-made iron originated, resulted in a large part of the Swedish production becoming unprofitable. The iron-masters came together in conference, united for self-defence as "Jernkontored" (Swedish Iron Masters' Association) and then called in science to their aid. The result of a scientific direction of their efforts and of a combination to stimulate trade, has been to keep in operation from that day to this an iron industry that is well-founded and takes full advantage of what Nature has provided. This has been done in the face of difficulties that probably were much greater than those that face us in Canada today.

A Possible Solution.

How can we go about the solving of our problem? I believe we can well take example from the Swedish iron-masters of two hundred years ago. Our iron-masters can unite to study their problems, and can invite the co-operation of the best scientific talent they can find. If one examines the situation today, one finds our iron-masters "sitting tight", after a number of desultory, sometimes poorly-directed, and uniformly unsuccessful attempts to solve the problem, each for himself. What effort is being expended is mainly by men outside the industry, principally those interested in deposits of ore. Why cannot all these get together, and work together consistently until the end of each and all is attained? The problem is a huge one, far beyond the capacity of a single company, not to say a lone individual. The rewards of a successful effort would be so large that there would be something for all concerned, and added self-respect and independence for Canadians of all degrees.

To be more specific, I would suggest the formation of a trade association similar to those that have been formed and operated with such signal success in Britain upon the instigation of their Advisory Research Council. Our own Research Council has stimulated the formation of a Pulp and Paper Association, with research, trade and other departments, and it is reported to be doing very good work. Such an association for our iron and steel trade would be what the C. M. A. is to Canadian manufacturers, and a good deal more as well. It would keep under review trade conditions, tariff, and other matters of common interest. It would examine continuously methods of manufacture and sources of raw material, to keep the whole trade abreast of the times and on the "qui vive" for special advantages. It would supervise and direct in a broad way whatever original investigation seemed necessary. Its officers would act as a competent and sympathetic authority for consultation with independent researchers, and men with ideas. All this, and more, is being done by trade associations in various countries, we have just begun to form them in Canada.

To sum up—I believe the soundest, as well as the least expensive way, to forward the interests of our iron and steel industry will be to bring together as many as possible of those directly or indirectly interested, so that these may pull together toward a result that will be for the benefit of all. A trade association along the British lines offers the best means to this end. Thus we will have a competent authority to shape policies, direct research, and in general get the most of what Mother Nature has to offer us.

Kingston, Dec. 31st, 1921.

PLANT INSTALLED AT PAINKILLER

The properties of Cartwright Goldfields and La Santa Lucia Mines on the shore of Painkiller Lake, have been merged in a new company known as Blue Quartz Mines Limited. Machinery to replace that lost in the fire of 1916 has been installed. Twenty men are employed and we are advised that development is to proceed at once under the supervision of Mr C. H. Taylor.

Interest in this district was a result of the discovery of very rich ore at the Croesus. Surface work last summer resulted in the discovery of several veins. One of these, opened up by test pits, disclosed very rich ore. One shipment of ten bags of ore from this vein to Timiskaming Testing Laboratories (owned by the Ontario Government) averaged $85. gold per ton and 7 oz. of silver. Later test shipments ran $110 and $118 per ton gold. At a depth of 20 ft. in a test pit the vein was twenty four inches wide and one of the miners describes it as being plastered with gold. Following the surface prospecting some diamond drilling was done to locate the veins underground. Seven veins have been uncovered on the lake shore, all carrying visible gold. These veins vary in width from a few inches to two feet.

No. 1 vein, wich was about two inches wide at surface, widened out to a width of 22 inches at a depth of 18 feet. The several veins being nearly parallel, the company intends to run a crosscut to cut all of them. The shaft has been dewatered and retimbered and is now down 110 ft. It is intended to sink to 400 ft. Two drills are now in operation and a considerable amount of lateral work will be done during the coming months. We are further advised that sufficient funds have been raised in Toronto and England to carry out an extensive development program.

The Company is assured of the finest executive management for their organization includes H. C. Crow, President, and C. H. Taylor, Vice-President, Mr. Taylor will supervise all work at the mine and that in itself is sufficient to guarantee that the work will be well done. He is well known in Northern Ontario for the excellent work he accomplished with designing and installing the Hydraulic Power Plant at Ragged and Hounds Cutes which is now operated as the Northern Ontario Light and Power Co. Previous to this he had a wide mining experience in all parts of the American Continent.

Cartwright Goldfields still own two claims of 80 acres North of the Painkiller Lake adjoining the Hattie and it is the intention to commence operations here in the Spring. Cartwright Goldfields owned six mining claims on the south shore of Painkiller Lake, while La Santa Lucia consisted of one claim adjoining. These seven claims have been merged and will be known as the Blue Quartz Gold Mines, Limited., having an authorized capitalization of $3,000,000 made up of 3,000,000 shares of the par value of $1.00 each.

It is authoritatively stated that attractive offers for the property have been refused and that the company will proceed with its plans for development and has under consideration construction of a mill.

MIKADO MINE TO RESUME.

Kenora, Ont. January 14. — Colonel H. A. C. Machin has succeeded in securing the requisite capital to re-open the old Mikado Mine, on Shoal Lake. He has also secured options on the Tycoon and Bulletin properties. The total acreage of the three is 765 Acres. As is well known there is a fairly complete plant on the Mikado and it should not involve any heavy expense to get stamps dropping again. It is said there is enough ore in the bins and blocked out to run the mill (20-stamps) for five months. The tailings are thought to hold gold to the value of $120,000 — assay value $4 a ton.

The Mikado ran in days when simple amalgamation was thought sufficient and ball mills were in the future; it is likely that much closer saving of gold will now be possible.

The outlook for a gradual resumption of mining in this district is bright, but it is to be hoped the wildcatter will not be allowed to spoil it, as happened before; every raseality was practised and every mistake made, but that there are mines, and good ones, as yet to be developed, no one conversant with conditions may doubt.

The Rice Lake gold field in Manitoba, which is after all but a prolongation of this one, to the north west, being on the same general line of outcropping, has two bona fide mining outfits at work this winter. The usual flamboyant advertising is happily absent, but good, steady development is being done. In due time something may be heard of the properties in question.

CHAS. A. BRAMBLE.

Headframe and Buildings Recently Erected at Blue Quartz Mine.

British Columbia Mining In 1921

(Continued from last week).

By ROBT. DUNN.

Little Change in Coal Output.

Comparative little difference is apparent in the production figures for 1920 and those estimated for 1921 in connection with the Coal Mining Industry. In 1920 the output was officially placed at 2,696,774 tons and for the past year it is estimated to be about 2,624,000 tons, a drop of 72,774 tons. The generally slack conditions industrially explain, in a general way, this decline. There is no doubt that in the last few months the competition of foreign fuel oil has had a detrimental effect on the demand for British Columbia coal. When oil was short and high in price coal was required for most of those uses to which the liquid fuel had been applied. Oil burning vessels were converted into coal burners, oil heated buildings were provided with steam furnaces, and the coal mines of Vancouver Island, as well as of the eastern sections of the Province, were kept working at full capacity, giving employment to all who would work, and circulating capital for the further development of this and other industries. With the presence in America of oil in greater quantity than the home market of the United States can absorb the producers naturally have been reaching out for other markets. That they should come to Canada, close at hand and a considerable consumer, was to be expected, but in the case of British Columbia, where there is so much unemployment and where capital is needed so seriously for the development of natural native resources, it would appear to be a matter warranting comment that so many of those who will not make substantial material gain by the change have once more discredited British Columbia Coal in favour of Foreign Oil.

The nature of this competition is further emphasized by the fact that Fuel Oil now is quoted in Vancouver at $2.75 a barrel whereas less than two years ago it was difficult to obtain at any price and the lowest quotation given when available was $3.50 a barrel. Ordinarily it is estimated that it takes three barrels of oil to equal one ton of coal in heat producing values.

The great importance of the coal mining industry on Vancouver Island can be appreciated when it is considered that between 4,000 and 5,000 employees of the companies mentioned find continuous employment underground and on the surface under normal conditions the year through. During 1921, the conditions can hardly be considered to have been normal because the demand for coal has been quite irregular, so much so that the Harewood Mine at Nanaimo, of the Western Fuel Corporation of Canada, was closed down from the end of February until July, and the Pacific Coast Coal Company, which employed a total of 286 employees during 1920, has been idle during the year 1921.

In the Crow's Nest Pass Coal Field the mines have worked steadily, although the periods during which production to the limit of possibilities have not been extended. The Nicola-Princeton Field also has seen considerable activity and some areas have been subjected to development, the results of which promise to be of first importance. It is interesting to note that in the north there are indications that coal mines will be opened up that will further strengthen the position of the Province as a producer of coal, one of the first industrial essentials. A seam is being opened up in the district bordering on the Telkwa River that is described as containing exceedingly high class steam and domestic coal.

Following are the general production figures for 1921 by coal areas, the returns for the month of December being estimates; together with those for 1920 which are given for purposes of comparison:

While from these it will be seen that there is an estimated decrease of 72,000 tons as compared with last year's production it should be remembered that the figures for 1920 are the *corrected figures* and the output submitted for 1921 is likely to be reduced when the annual returns are made.

The most notable differences are in the operation of the following mines:

The Pacific Coast Coal Mine which during 1920 produced 94,000 tons did not operate in 1921.

The Corbin Coal & Coke Co. which produced 147,000 tons in 1920 produced 71,774 tons in 1921, a decrease of over 75,000 tons.

Outstanding above the Granby Consolidated M. S. & P. Co. increased their output from 701,491 in 1920 to 766,817 in 1921 and Coalmont Collieries increased from 298,[illegible] tons in 1920 to 72,689 [illegible] in 1921.

Nanoose Collieries also increased from 27,000 [illegible] to 58,500 during the same period.

Regarding the larger operating companies the Crow's Nest Pass Coal Co. have a slightly increased output in 1921 as compared with 1920 while the operations of

ESTIMATED OUTPUT OF COAL FOR BRITISH COLUMBIA DURING 1921.

Assuming that the output for December equal that of November the total output for the Province during 1921 will be 2,624,774 tons as against an output of 2,696,774 tons in the year 1920. By districts the output will be:

	Vancouver Island	East Kootenay	Nicola Princeton & Telkwa
1921	1,633,500 tons	796,500 tons	194,000 tons
1920	1,698,254 tons	811,389 tons	187,130 tons

Vancouver Island District.

Canadian Collieries

	Western Fuel	Comox	South Wellington	Extension	Nanoose	Granby	Pacific Coast
1921	490,000 tons	426,354 tons	82,700 tons	99,846 tons	18,500 tons	266,800 tons	Nil
1920	575,633 tons	455,944 tons	90,389 tons	196,104 tons	27,000 tons	261,189 tons	94,994 tons

East Kootenay District.

	Crow's Nest Pass Coal Co.		
	Coal Creek	Michel	Corbin
1921	131,686 tons	200,127 tons	71,774 tons
1920	130,783 tons	600,297 tons	147,944 tons

Nicola Princeton District

	Middlesboro	Princeton Coal Co.	Coalmont	Tulameen	Telkwa
1921	73,319 tons	31,886 tons	72,689 tons	16,114 tons	Nil
1920	87,602 tons	32,122 tons	59,985 tons	6,422 tons	100 tons

Canadian Collieries at Extension and the Western Fuel Corporation of Canada, Nanaimo, show a slight decrease.

Optimistic Reports from Northwest District.

Reports of an optimistic character are given of the Northwestern Mineral Survey District, which comprises the mining divisions of Bella Coola, Skeena, Queen Charlotte, Naas River, Portland Canal, Stikine, Liard and Atlin. This section comprises the mining divisions of Bella Coola, Skeena, Queen Charlotte, Naas River, Portland Canal, Stikine, Liard and Atlin. The first three are on the coast and the latter lie behind what is known as the "Alaska strip". Included in the area are properties of Salmon River, Bear River, Alice Arm, and Anyox.

Granby and Premier Mines Make Large Output.

It is estimated that the increase in tonnage mined will amount to about 75,000 tons. The gold output, exclusive of placer which will just about equal last year, will show an increase of approximately 30,000 oz., or about 60 p.c. greater than last year. This is due to the gold production of the Premier Gold Mining Co. The silver yield for this year will be about 1,500,000 oz., or about 125,000 oz. greater than last. This is due entirely to the output of the Premier Mine. The Premier's output of silver will be over a million oz. alone. The copper production will exceed that of last year by nearly 9,000,000 lb., an increase of about 33 p.c., and due altogether to the Granby Company at Anyox.

Notwithstanding the deflation of the prices of metals, the total *value* of the three metals produced in this district, (gold, silver and copper), will be greater than last year. In fact, taking quantities, not values, into consideration, this year's will be the greatest production ever made in this District.

Placer Gold Output.

Conditions in the Northeast Mineral Survey District, within which are the four mining divisions of Omineca, Cariboo, Quesnel and Peace River, have been better than might have been expected.

While but little lode-mineral production was made, a substantial increase in the placer gold output as compared with 1920 is an encouraging sign for the future. With a return to normal market conditions for the different metals a resumption of lode mineral shipments from the District will probably soon take place.

Development of mineral properties was proceeded with in many parts of the District and more prospectors were in the Hills than for some years past. Besides the actual exploratory work of looking for new mineral discoveries much work is done in the course of a season by prospectors on the properties that they own. In done this summer the showings of ore have been impquite a number of instances of work of this nature proved and the general results very satisfactory. There are now in the Northeastern District a considerable number of prospects, carrying a great variety of ores and metals, which should prove attractive to those who are looking for prospects that have some chance of developing into profitable mines.

Placer mining was vigourously prosecuted in the Cariboo and the indications are that the yearly placer gold production of that section will soon again increase to equal that of pre-war years. Particularly interesting is the re-opening of the old *Bullion* mine at Quesnel Forks, which property was at one time the most important hydraulic mine in British Columbia.

Southern District.

The effects of the lack of a strong market are reflected in the situation in the Southern Mineral Survey District which includes the mining divisions of Grand Forks, Greenwood, Osoyoos, and Similkameen. Here the indications are that, as compared with 1920, there will be a drop in the output of the metalliferous mines, although this is offset to an increase in the production of the coal fields. In 1920 the tonnage production of the metal mines of the district aggregated 103,032 and it is estimated that that for 1921 was 26,750. It should be noted that one of the best developed copper mines of the Province is situated in this section, that it is equipped with plant capable of making a substantial daily output, and that it may be expected to be in operation as soon as the market rises to assure satisfactory returns. This concern did not operate during 1921 but the indications are that it will become a steady producer this year. The coal production jumped from 35,533 tons in 1920 to 97,767 tons last year which is an indication that the Nicola Princeton Field is beginning to receive the attention that its possibilities merit.

The prospectors of the district have been confining their efforts generally to searching for gold and high grade silver ores, together with making a careful study of the old Crown Granted Mineral Claims which have reverted to the Government through the non-payment of taxes. Some diamond drilling has been undertaken by outside capitalists on an old group of claims in the Fairview Camp and the results are being awaited with interest.

East and West Kootenay.

With a few notable exceptions the slump in metal prices made it impossible for the mines of the Eastern Mineral Survey District, which broadly speaking comprises East and West Kootenay, to maintain production or at least to continue the work of mining and shipping on the same basis as in the past. However, there is every indication that these affected have grappled with their difficulties courageously, that properties unable for the moment to pay the costs of mining, freighting, treatment, etc., and yield a fair profit have been subjected to systematic development during the period of temporary slackness. Their owners are looking forward to the improvement that the future surely holds with confidence and when it comes—and the signs of its early approach are already at hand—they will be in shape to take the fullest advantage of the changed conditions. The recent healthier tone of the silver market has tended to stimulate mining and create a more optimistic sentiment among the silver-lead operators than existed earlier in the year. Activities of leasers, prospectors and small operators have been on the increase during the past few years and the last year has been no exception to the rule. There has been a decided revival of intrest in gold properties, both lode and placer mining.

Coal Mining in Western District.

As to the Western Mineral Survey District, embracing the Mining Divisions of Alberni, Clayoquot, Nanaimo, New Westminster, Quatsino and Victoria, it is pointed out that, with no production of copper from the Howe Sound Company, the metaliferous output has been ne-

gligible. Coal Mining has been the only phase of the Mining Industry within this area that has been engaged in shipping. However, there has been much prospecting, a number of important West Coast properties have been under development with good results, and the iron ore deposits of the area have been further explored and investigated both as to the quality of the ore and the tonnage available. In this connection under authority of the "Iron Ore Supply Act, 1919" there were shipped during the month of May 502 sacks of Magnetite to Thomas Summerson & Sons Ltd., Darlington, England, for experimental purposes. This ore was taken from the Lake Mine, Texada Island, owned by the Puget Sound Iron Company. A systematic exploration of the minerals of the E. & N. Land Belt, Vancouver Island, also has been in progress under the instructions of the E. & N. Railway Co. The information that will be obtained is designed to facilitate the arrival at an agreement between the Provincial Government and the Railway Company for the elimination of the present objectionable system of dual control of the minerals within the area in question. At present the E. & N. Railway Company is the owner of all coal and base metals within the boundaries of the railway belt, with the exception, of course, of such of these holdings as have been alienated, while the title to previous metals within the belt is vested in the Crown. This condition, it is maintained by the Minister of Mines, has had the effect of retarding the opening up of the mineral wealth of the Island and he has been bending every endeavor to effect an adjustment that will remove the obstacle to free prospecting and unrestricted staking of claims in accordance with the terms of the Mineral and Placer acts.

Construction of roads, trails and bridges.

The policy of extending financial assistance in the construction of roads, trails and bridges to mines, or deserving mineral claims, has been continued in accordance with the terms of the Mines Development Act. This has been done where the resident mining engineers have reported favorably upon applications for aid. That this co-operation by the Mines Department in the development of the mineral resources is appreciated has been indicated in many ways, but, perhaps, the need is best shown by the number of properties, proven to be of merit, that have been helped from the prospect stage to the point of clear demonstration of value by the provision of transportation facilities. From the date of inauguration of this policy to the 22nd March, 1921 there were authorized for expenditure on mines roads and trails $425,015 of which there were expended $378,319. Similar authorizations from the 1st of April 1921 to the 30th December of the year totalled $21,561. In the course of favorable comment on the effects of this phase of the Department's activities a mining man of East Kootenay observes: "Mine trails are the arteries through which flows the life of any mineralized and undeveloped area. An old trail full of windfalls and grown over with underbrush is worse than no trail at all."

Accidents in 1921.

Thirteen fatal accidents occurred in 1921 in connection with the mining industry, ten of which happened in coal and three in metalliferous mining. This is a remarkably fine record in a comparative sense and one of which the Minister of Mines, who has been consistent in his efforts to provide adequate safeguards for the lives of those working underground, is especially proud. The ten coal mine fatalities, figuring on the basis of an employed force of 6,500 in and around coal mines, shows a ratio of 1.54 per thousand as against 2.67 per thousand in 1920 and 2.03 in 1919. The three fatalities in metal mines, placing the number employed at 3,341, gives a ratio per thousand of .9. The latter, however, is not official because the exact number of those engaged in the metaliferous industry during 1921 is not yet available.

When, in 1919, it was reported that there had only been twelve fatal accidents in the coal mines of the Province in that year it was pointed out that the record had never before been equalled in the coal mining history of British Columbia and that it had been paralleled but once in twenty-one years. This was in 1905 but in considering the statistics of that year it must be remembered that there were little more than half as many men employed then in and around coal mines. But, while the record of 1909 was better than any of the past everything considered, that of 1921 stands by itself, a new mark, and the result of stringent regulations, strictly enforced, as well as the earnest co-operation of the coal miners and others directly affected. The same comment applies to the metal mines.

It is worth noting that during the past year the regulation the effect of which has been the removal of practically all flame lamps from the coal mines of the Province has been enforced. The electric lamp, a much safer as well as a better means of illumination, has been introduced and from all reports appears to be most popular.

While, however, no suggestion for the prevention of accident to underground workers has failed to receive the best attention of the Department, it has been recognized that the occupation is a hazardous one and that, as long as there is mining, there are likely to be some mishaps. The endeavor to improve and to keep up to date in point of equipment and efficiency the Mine Rescue Branches has never been allowed to slacken. Much has been accomplished through the training stations established in the different coal mining fields, the action of the collieries in obtaining modern mine rescue apparatus, and in the policy of extending support to competitions in Mine Rescue Work. There are today in the Province over 500 holders of Mines Rescue Certificates granted by the Department to those who have taken a course of training in this work.

Rescue Apparatus and First Aid.

There are installed at the coal and metalliferous mines and Government Stations in the Province 130 sets of Mine Rescue Apparatus, and 15 resuscitating devices. There is one Mine Rescue apparatus for approximately every 10 persons employed underground and one resuscitating device for about every 17 employed underground at Coal Mines. Over [illegible] per cent of the underground employees in Coal Mines in the Province hold Mine Rescue Certificates, and nearly fifteen per cent of the total employees have passed examinations in First Aid Work.

Through its system of [illegible] Department of Mines has been successful in arousing interest in First Aid Work. Training in the very [illegible] various mining centres [illegible] resulted in the passing of examinations by over 1200 mine employees. One striking vindication of the attitude of the Government in this worthy form of [illegible] activity was the fact that last year teams representing the Canadian Western Fuel Corporation of Nanaimo and the Crow's Nest Collieries [illegible] won every [illegible] honors in the Canadian National First Aid Competitions under the

pices of the St. John's Ambulance Association. In the Open Contest for the Montizambert Cup, No. 1 Team, First Aid of the Canadian Western Fuel Corporation scored a higher percentage of points than any of its competitors and so obtained the Canadian Championship. In the First Aid Contest for miners' teams, the award being the Coderre Cup, No. 1 First Aid Team, Nanaimo, secured first place while second place went to the Cumberland First Aid Team. In recognition of this splendid performance, the winning teams were awarded special medals by the Department of Mines and the Canadian Championship team was assited to make the trip to St. Louis to compete in the International Competitions where they were among the higest in score and won general laudatory comment.

The standardization of methods of training in the use of Mine Rescue Apparatus, as well as of the instrument itself as far as possible, has been one of the objects of the Minister of Mines for several years. He made the suggestion, following a deplorable fatal occurrence in Washington State Coal Mines, to the United States Bureau of Mines. The result was the calling of an International Conference to discuss the points raised. This took place at St. Louis, Mo., and British Columbia was represented by Andrew Strachan, senior mines inspector. Committees have been appointed to make further investigation and the question is to be further discussed at an early date.

Lecturing to Prospectors and Miners.

Mr. Sloan announced that the policy of having a series of instructional addresses delivered by the mining engineers in their various districts is to be continued during the present winter. These lectures cover rudimentary chemistry, mineralogy, geology as applied to mining, ore deposits, and favourable districts for prospecting.

This programme was carried out during 1920-1921 with very gratifying results. William M. Brewer, whose headquarters are at Nanaimo, travelled from one end to the other of Vancouver Island, lecturing to prospectors and miners in each of the centres. All his meetings were well attended and judging from the comments of those who took advantage of the opportunity, and from the tone of the newspaper accounts of the lectures, Mr. Brewers's talks were very much appreciated as well as being considered of much value to those interested in a practical way in the industry. Much the same may be said as to the results of Mr. P. B. Freeland's winter tour of the Boundary Districts.

In the Kootenays Mr. A. G. Langley, Resident Mining Engineer with headquarters at Revelstoke, in his lectures at Revelstoke, Nelson, Cranbrook and elsewhere was received by large numbers of prospectors. That his instructional addresses were appreciated is conclusively indicated by telegrams, letters and Press comment from various parts of his District. The British Columbia Prospectors' Association of East Kootenay wired from Cranbrook as follows, under date of March 8th, 1921:

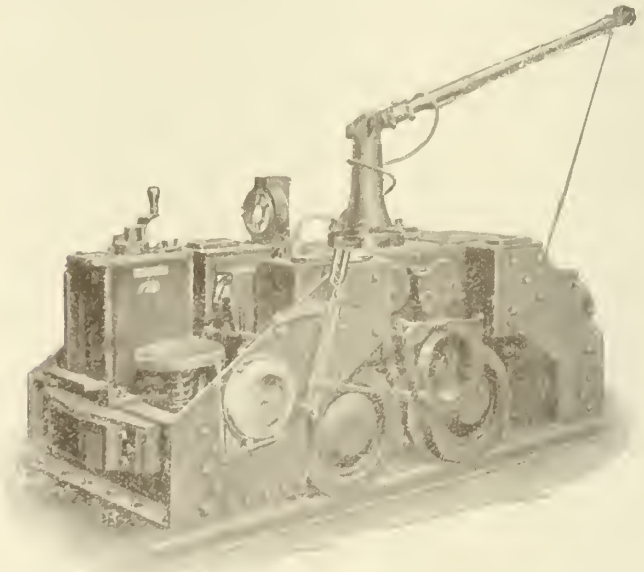
"Mr Langley's initial lecture here last night was most effective, and a second lecture desired as soon as possible."

In the North Mr. J. D. Galloway, Resident Mining Engineer, with headquarters at Hazelton, also delivered similar lectures with equally gratifying results.

Another step taken for the benefit of the prospector and the small mine operator is the granting of a rebate on the cost of powder used in the development of mineral claims. This concession is given under certain conditions which are enumerated in a form available on application to the Mining Recorders in all divisions. The privilege has been largely taken advantage of, is clearly much appreciated, and should be of much assistance to those engaged in the work of proving up mineral properties.

A SHORT LOCOMOTIVE FOR SPECIAL PURPOSE.

At the Hollinger mine electric locomotives are used to haul the ore cars. To avoid delays due to locomotive breakdown it was decided recently to purchase a special locomotive which could be easily moved from level to level in case of need. To enable quick transportation on the man cage, it was required that the locomotive should not exceed 96 inches in length. The gauge being 18 inches and the length being so short a single motor locomotive was decided upon. A 3 ton Goodman single



Goodman Single Motor Locomotive Used at Hollinger Mine.

motor locomotive has been installed as most suitable for the conditions. The one armature of this locomotive is geared to all four wheels, which operate as a single unit, giving a maximum tractive effort per ton of locomotive weight. This locomotive has a 24 inch wheel base, enabling it to negotiate curves of only 8 ft. radius. It has a 30 h.p. motor, giving 10 h.p. per ton of weight, and is admirably adapted to the conditions.

WINTER STAKING AT ELBOW LAKE.

BY REECE H. HAGUE.

The biggest winter rush yet experienced in Northern Manitoba is at present under way when all roads lead to Elbow Lake and every day finds parties of prospectors hiking out to what they dream of as the new El Dorado.

During December 78 claims were recorded at the Lands Office at The Pas, the greater number of them being situated in the Elbow Lake zone, and according to present indications the stakings during January will considerably exceed this total.

The action of the Hollinger interests of Ontario in taking over the Murray claims at Elbow Lake gave considerable impetus to staking in that district and the reports of still other seemingly important finds has added to the excitement.

Racing teams are being utilized for taking prospectors and prospective stakers out to Elbow Lake,

the latest mining men to leave including G. R. Bancroft superintendent of the Mandy Mining Company and Canadian representative of the Tonopah Company. Mr. Bancroft staked several claims and returned to The Pas to record and then hastened back to watch developments, taking with him his train of dogs which finished third in last Year's Pas Dog Derby and which are in training for the forthcoming race.

Walter A. Ukyser, of the London Exploration Co., London, England, left for Elbow Lake on the same day as Mr. Bancroft. Mr. Ukyser, who is a well known mining engineer, is attached to the American office of the London Exploration Co.

Prospectors are leaving the town singly and in groups, as many as seven dog teams having started out in one party. The Hollinger interests have a number of men at work stripping and trenching on the Murray claims, under the supervision of Jack Rutherford, of Porcupine.

A number of properties have been taken up by eastern interests styling themselves the Elbow Lake Mines Ltd., and several small sales have been negotiated in different quarters. Claims in the Elbow Lake region seem to be in fairly good demand and local residents are taking good care to get in on the rush. The majority of the prospectors in Northern Manitoba are at present at Elbow Lake, and the Murray claims is staked for miles. The activity is extending to Copper Lake and Island Lake in the same area where promising finds have been made.

With the advent of spring there should be considerable activity at Elbow Lake as with the heavy snow fall there is little chance of intensified prospecting at present.

It is two and a half years since the Gordon find At Copper Lake, eight miles from Elbow Lake caused considerable stir in mining circles. Mr. Gordon brought some remarkably spectacular samples of free gold into the town, which resulted in considerable staking around Copper Lake.

Late the same season T. Webb made a promising free gold discovery at the north end of Elbow Lake, and attention was directed to that district.

In the meantime Mr Gordon had his big lode diamond drilled and an ore body carrying satisfactory values proved up; but it was decided to temporarily suspend operations until better transportation facilities were available.

Then in June last came the Murray brothers find, and once more interest revived in Elbow Lake. So rich were the samples brought to The Pas that at first it was thought that possibly the Murray brothers had merely struck a rich pocket, but reports of eminent mining engineers who visited the property set this fear at rest.

Mr. Samuel Cohen, who secured the Murray claims for the Hollinger interests, stated that the find was important and that if it would average it was the greatest thing he knew of. He did not attribute the enrichments to secondary or surface deposition. Some of the quartz exposures, Mr Cohen said were from 10 to 20 feet wide and it was in these that values ranged from the payable to the pyrotechnic. The quartz bunches and veinlets, or stringers, lay that. This condition might continue with the varying result characteristic of such occurrences. At any rate he said the find was important and deserved the treatment it would receive.

The anticipated construction of a railway to the Flin Flon property will be of vast importance to the Elbow, Copper and Island Lake districts. From where this line will cross Cranberry Portage, eighty miles from The Pas, there is a good water route to all these areas and the distance is short.

Properties in the Athapapuskow Lake district will also be opened up by this railway and it is being advocated that construction of the line to Cranberry Portage be commenced immediately and that it be continued on to Flin Flon as soon as the Canadian Mining Corporation is prepared to commence operations on this enormous copper body.

Northern Ontario Letter

THE SILVER MINES

Greatly reduced costs of producing silver as shown in the statement of the Coniagas Mines for the fiscal year ended October 31st has given rise to the belief that a number of the other mines which are lying idle may now be operated profitably. Among these would be the Beaver Consolidated and the Temiskaming, and it is believed that with the arrival of warm weather in the spring these mines may be again numbered among the active operations.

McKinley-Darragh.

There is evidence that certain New York brokers are making an effort to induce stockholders of the McKinley-Darragh to send in their shares for exchange in some other unknown concern, apparently with the object of winning a place of influence in the affairs of the McKinley-Darragh. It is reported that these brokers are sufficiently ambitious to possibly make a bid for control of the company. The impression seems to be, however, that in spite of the stock of the McKinley-Darragh being distributed among an exceptionally large number of stockholders that the scheme now on foot will be a success only should the directorate of the McKinley wish it to be so, and this is considered to be entirely unlikely.

Trethewey.

A meeting of the Trethewey-Cobalt is to be held Jan. 19th for the purpose of considering the question of incorporating a new company, some of the details of which were outlined in the Journal last week. It is planned to incorporate another company with an authorized capitalization of 2,000,000 and to issue one of the new shares for each of the 1,600,000 now outstanding. This would leave the company with 1,600,000 shares in its treasury which would be marketed with a view to securing funds with which to pay off the indebtedness of something like $40,000 as well as to provide working capital.

Cane Silver.

It is now considered doubtful about the Hudson Bay Mines going into the Cane Silver Mines in Cane township on the Elk Lake branch of the T. and N. O. Railway. Certain of the interested parties in the company paid a visit to the property during the past week.

Crown Reserve.

The Crown Reserve is going ahead with plans to erect a mining plant on property in the Larder Lake district in which it is interested. The gold content of the ore on this new property is such as to encourage the belief that it may develop into a commercial proposition, and shareholders are watching this new venture with interest.

Nipissing produced 3, 100,000 oz.

During the year 1921, according to the regular monthly statements for the period, the Nipissing mine produced approximately 3,100,000 ounces of silver. Of this amount, about 1,115,000 ounces was accounted for during the closing three months of the year. Development during the year proved numerous veins to carry ore beyond their previously known limits, while a number of new veins were also discovered.

South Lorrain.

A meeting was recently held of stockholders and interested parties of the old Maidens property in South Lorrain, and it was believed advisable to consider the question of incorporating a new company with a view toward placing a substantial number of shares in the treasury with which to endeavor to raise finances for general operating expenses. The property has always been regarded as a promising prospect and is one that attracted considerable attention in the early days of activity in the South Lorrain district. By reason of the success on the Keeley Silver Mines, new interest is being turned in that direction.

While the Keeley mine itself is occupying the centre of greatest interest in South Lorrain, yet the somewhat similar geological conditions on the Haileybury-Frontier and the intention of the Mining Corporation of Canada to explore that part of the Frontier property where occurs the line of weakness which passes over the Keeley onto the Frontier is regarded as of extreme importance.

Gowganda mine produces five million ounces silver.

Steady production is being maintained by the Miller Lake-O'Brien mine at Gowganda, which property now has a production record of over 5,000,000 ounces of silver to its credit since the discovery of the first important deposit of ore in 1912. This company makes regular shipments of high grade ore as well as concentrates.

Triangle.

An effort is being made to raise money with which to re-open the Triangle property, situated in the township of Auld in the Elk Lake Mining Division. This property was originally known as the Kenabeek Silver Mines and later was changed to the Kenabeek Consolidated, after which it went into liquidation and became known later as the Triangle. More or less silver occurs on the property, a shaft having been put down to a depth of about 200 feet, and with a first class mining plant installed.

Bailey Leases Silver Cliff.

During the month of December the Bailey Customs mill realized gross earnings of $11,488.97, the mill having treated a total of 3,827 tons of ore. The Bailey mine itself contributed 1,160 tons. A feature of the regular monthly statement was confirmation of the announcement made recently in the Journal that the Bailey had taken a lease on the old Silver Cliff mine. It is stated that 247 tons of ore were taken from the Silver Cliff during December and that upwards of 8,000 tons of ore lie in the stopes.

Nipissing in December.

The Nipissing maintained its extremely favorable production record throughout the month of December, when the output amounted to 365,700 fine ounces of silver and $13,755 worth of cobalt, making a total value of $251,467 for the period.

Development work proved the mineralization to extend beyond its previously known limits, the following

being the regular monthly statement from Hugh Park, manager, to the president and directors:

"During the month of December the company mined ore of an estimated net value of $251,467 and shipped bullion from Nipissing and custom ores of an estimated net value of $204,869. The value of the month's silver production was estimated at 65 cents per ounce.

"There were no unusual developments underground. Development work on some small veins at the first and ninth levels of 73 shaft was productive of good results. Additional ore was also developed at vein 61.

"Sinking from the second level on vein 251 at the 63 shaft is now under way. The winze was down 38 feet at the end of December and has shown two or three inches of ore assaying several thousand ounces of silver per ton all the way.

"The 128 shaft has been de-watered and further exploration will be done in the surrounding area. This shaft was flooded at the time of the labor strike two years ago and was allowed to remain so. About 500 feet of exploration had been done at the 125 foot level, without favorable results. A new level will be established at 75 feet.

"The low grade mill treated 6,631 tons. The high grade plant treated 199 tons. The refinery shipped 302,833 fine ounces of bullion. The following is an estimate of the net production for the month of December:

Silver production	$237,712
Cobalt	13,755
	$251,467

THE GOLD MINES.

Wage Reduction.

At the time of writing, the wage reduction of six cents an hour promises to go into force at the end of this month without any opposition at the Hollinger mine. This promises to save the company about $300,000 annually, and will be a big factor in making up for the "loss" in income resulting from the lower rate of exchange on United States funds.

Exploring Rochester under option.

Reports were current this week that the Nipissing had exercised its option on the Rochester property, adjoining the Hollinger and that shaft sinking would commence immediately. It has been learned however by the Journal that the working option holds good for the balance of the winter and the Nipissing is still pursuing an exploration policy. Results have been encouraging as was announced exclusively in these columns recently.

Hollinger Shareholders.

Directors and their immediate friends hold approximately 75 per of the shares of the Hollinger Consolidated according to official advice. This fact has had a good influence on favorable sentiment toward the security.

McIntyre Prospering.

With regard to the McIntyre-Porcupine, apart from the exceedingly favorable results on the mine, and the prospects of production being increased by another million dollars early in the coming summer, it has been learned that good reports are coming from Alberta and that the coal mining enterprise in which the company is involved promises to be self-sustaining, and has the appearance of being likely to develop into a big asset.

Moneta.

Reports are current that the Moneta-Porcupine may figure in a deal of importance and that one of the leading mining companies is anxious to become interested in a scheme to re-open the property, owing to the strike of the ore bodies of the adjoining Hollinger being in that direction.

Dome.

Development work on the Dome continues to strengthen the physical condition of the mine, a feature being that the high grade sections have to be left for the present until suitable milling arrangements may be made. This situation holds out big promise for the future and seems to assure the Dome of a high average grade of ore for some time to come. In the meantime the mill is operating at full capacity on ore of the high average of between $7 and $8 per ton.

Davidson.

Mr. Hugh Sutherland, identified with the Davidson mine, was in the district during the past week and was optimistic in regard to the future. Mr. Sutherland is also identified with a scheme to develop hydro-electric energy in the Fort Matachewan district on the Montreal River at a point about 50 miles south-east of the Porcupine district. As to whether, the scheme is assured of the necessary finances has not been ascertained at the time of writing.

The Light Railway.

A wave of criticism has recently developed against the Canadian Light Railway Construction Company, a concern with an office at Swastika and which planned to construct light lines toward the east and west to the outlying mining areas. It has been alleged that men have had to go without their pay and that severe hardship has been experienced. No grading has been done and no rails appear to have been purchased and the whole scheme seems to have developed into a "cropper."

Teck-Hughes.

Ore being treated at the Teck-Hughes Gold Mines has recently averaged well above the average during 1921. It is understood that production for a period of a few days was upwards of $15 per ton of ore going through the mill. Now that the bonded indebtedness has been greatly reduced, and owing to the sound physical condition of the mine, the Teck-Hughes is believed to be on a fair way to completely retire the bonds against it and to in due time win a place among the dividend paying mines.

Kirkland Lake Proprietary.

Detailed official advice to the representative of the Journal goes to show that the Kirkland Lake Proprietary (1919) Ltd., is on a fair way to achieve its objective and to place the merged Tough-Oakes and Burnside mines on a profitable basis of operation.

Ore is being opened up at a depth of 400 feet on the Burnside in the "main break" along which the important gold producers are producing their ore. Assays range from $10 to upwards of $20 per ton and the management anticipates no difficulty in being able to establish millheads of between $11 and $12 to the ton.

A feature of present operations is that shaft No. 3 on the Burnside is being converted into the central shaft. A double-drum electrical hoist is now in course of installation and arrangements are being made to instal

crushing equipment at this point. From the crushers, the ore will be conveyed by belt-line conveyor up into the mill building on the Burnside and will be deposited in a 250-ton bin. From this point, an aerial tramway will be erected to the Tough Oakes mill and will carry the ore to that point for treatment.

With regard to development work, arrangements have been made to continue the central shaft another 150 feet in depth and to open up the downward continuation of the new ore body which is rapidly placing the enterprise in a strong physical condition.

A force of about 60 men are already on the pay-roll and underground operations are proceeding at the rate of upwards of 500 feet per month. Heretofore five stations have been in operation and a fifth was added this week.

Work is proceeding in connection with placing the mill in shape for resuming general operations in the early spring. The plant will treat from 110 to 120 tons of ore daily and may possibly be brought up to 140 tons daily before the end of the summer.

Goldfields.

The annual meeting of the Canadian Associated Goldfields, Ltd., will be held in Toronto today to receive the statement and the report of the directors and auditors for the ensuing year.

George MacKay, president, makes this statement:

"The directors have pleasure in submitting the balance sheet of your company as at October 31st, 1921, showing cash and Victory bonds on hand, $614,630, development and office expenses $140,177.

"Mr. George Gray, our engineer on the property, who has been in charge since January last, will not have his report on the properties ready for about three months, after which time a meeting of the shareholders will be called and a full report presented."

A financial statement will be presented today which will show assets of $21,953,603, the outstanding item of which is $20,985,398, which appears under the heading of "Mining Properties, including development, timber limits and power rights at Raven Falls and Windego, at value at which acquired from vendors (satisfied in part by the issue of capital stock.)"

The other big item is cash and bonds as referred to by the president.

The company is capitalized at $30,000,000 made up of 30,000,000 shares of the par values of $1 each, and the liability column shows issued trust receipts for 21,934,096 shares of $1 each, fully paid, $21,934,096.

METAL QUOTATIONS.

(From our Toronto Correspondent)

Non-ferrous metals, less than car lots. Toronto, Jan. 18th:

	Cost per lb.
Copper, Electrical	18
Copper, Electrolytic	18
Tin	38½
Lead	7
Zinc	7½
*Aluminum	23
Antimony	9

* Due to foreign metal coming on the market price of this metal is depressed.

The general situation is rather buoyant and there is a feeling of greater freedom in buying.

ACCIDENTS IN ONTARIO MINES

During the year 1921, at all the mines, metallurgical works, quarries, clay sand and gravel pits regulated by the Mining Act of Ontario, there were 1286 accidents reported to the Department of Mines up to January 10, 1922. Twenty-four of these accidents were fatal.

Four fatal accidents at the quarries were due to carelessness or ignorance in the handling of explosives and of the three fatal accidents at gravel pits, two were due to undermining and the third to material falling from a face which was 16 feet in height. A knowledge of explosives and a strict observance of the Mining Amendment Act would have prevented all these accidents.

PERSONAL AND GENERAL

Mr. H. P. De Pencier, manager of Dome Mines, is in Toronto this week.

The Toronto branch of the Canadian Institute of Mining and Metallurgy will hold a meeting Saturday, Jan. 21. One of the subjects for discussion will be "Iron Ore of Ontario".

The Toronto branch of the Association of Women of the Mining Industry will hold a meeting on Friday Jan. 20 at the residence of Mrs. W. E. Segsworth.

The annual Meeting of the Engineering Institute of Canada will be held in Montreal, Jan. 24-25.

The Annual Meeting of the Canadian Institute of Mining and Metallurgy will be held in Ottawa, Mar. 1-3.

Mr. C. R. McLaren has been appointed underground superintendent at the Kirkland Lake Gold Mine. Mr. McLaren was formerly superintendent at the Magpie iron mine which is now not being operated.

EDITORIAL

IRON ORE MINING

According to the "Iron Trade Review" business in the iron ore mining districts will be very much better this year than last. During 1931 the Lake Superior district produced 22,735,726 tons (net ton or little under that one third the normal output which is around 60,000,000. It is predicted that production this year will be about 40,000,000 tons. Lower freight rates are expected and better prices will doubtless prevail.

Such predictions are interesting in that they doubtless are based on some knowledge of the anticipated needs of furnace operators. If fulfilled, the iron mining will benefit largely and a big step will have been made toward recovery from the depression.

While we have no operating iron mines in Canada just now the increasing demands for ore are of great interest to owners of iron mines and prospects. There is at present little incentive to develop new iron mines and development here can be expected only when there is a better market for ore than there is now.

GOOD ORE AT DEPTH

The December output of the Lake Shore mine was a notable one. There was recovered 870 oz. of gold during the month, which is the best performance yet. The ore treated averaged over thirty five dollars per ton.

The Lake Shore experience, coupled with values recently from other gold mines at Kirkland Lake and Porcupine, will help to dispel the impression that was made by early attempts at gold mining in Ontario, and increase confidence in the future of gold mining in this Province. Those who are familiar with the facts have good reason to be optimistic. There have been few cases where a gold mining enterprise has been undertaken in Ontario that the results of development have not been at least as good as the earliest showings indicated. There have of course been many small shoots of high

ed One cannot satisfactorily demonstrate the quality and extent of an entire gold deposit until the ore has been all mined and milled We cannot be reasonably sure of either the downward or lateral extent or the contained values of any ore deposit not completely developed. And yet from the ascertainable facts we may have reason to believe that the most important asset of a particular mine is the ore not yet developed, or only partially developed. Having watched developments in Northern Ontario gold areas we have confidence in the future, a confidence that is based on the known facts, but which more particularly has reference to facts yet unknown. In other words we are led by the result of operations to believe that gold deposits of Ontario can be made to yield gold for many years at a higher rate of production than the present.

Even if we should assume with our New York contemporary that the mines were approaching exhaustion and that the outlook was as gloomy concerning new discoveries, there are known facts which assure us that even under such circumstances gold production will be increased. The known ore is in any case to be mined in larger quantity during the coming year. Capacity of plant has been recently increased and is being increased. Production will certainly be increased this year and next year it will be largely increased. If owing to any unforeseen circumstances this does not happen, it will not be because of lack of ore.

Our own opinion, and statements concerning ore yet undeveloped must be considered as expressions of opinion, is that the determined facts indicate that very much more ore than has yet been developed will be found in the mines now producing and that many new mines will be developed. There have been many pleasant surprises for those who undertook to develop the mines at Porcupine and Kirkland Lake and the most important of these has been the finding of better ore at depth than near the surface. It must not be concluded that surface indications were lacking, for there was good ore at surface on most of the properties; but it is quite proper to say that results have been better than was expected and that there is much more ground for hope in the results of future development than there was in the early days of mining at Porcupine.

We are optimistic with regard to the future of gold mining in Ontario and not without reason. While quite unable to demonstrate how much ore will be found, we are nevertheless of the opinion that it will not be the fault of the ore deposits if gold is not produced in very much larger quantities during the next generation. Enterprising men,willing to venture where there is a fair chance of success, will find in Canada plenty of opportunity to develop mineral deposits.Our future production will depend not only on the size and quality of our ore deposits, but on the men who undertake mining enterprises. The men who have made the mines in this country must realize that their opinions concerning the unknown facts were quite as important as the determination of the ascertainable facts. The results of operations during the past ten years have given such men more reason for holding favorable opinions.

OUR IRON RESOURCES

At last Saturday's meeting of the Toronto branch of the Association for the Advancement of Science, there was read a paper by Mr. R. H. Flaherty on our Iron Resources. Mr. Flaherty who is an authority on iron ore deposits and who knows the iron ore ranges south and north of Lake Superior better than most men is quite optimistic over the possibilities of establishing an iron mining industry in Ontario. Such a thing is much to be desired; but there is in many quarters little confidence that it can be accomplished unless assisted to some extent during the early years of the industry.

It would appear from Mr. Flaherty's paper that the possibilities are greater than is generally believed.

It has been pointed out that one of the difficulties encountered in using our carbonate ores is the increased cost of coal. This is a serious matter because the process was devised when coal was cheap and the necessary use of large quantities of fuel was not such a burden when the process was decided upon.

Similarly in other cases there is a possibility that process suited to the conditions may be found and that we may yet use our iron ores to advantage.

UTILIZATION OF LIGNITE COAL

On another page will be found some account of the work being done in Dakota by Dr. E. J. Babcock, on carbonizing lignite. The results being obtained from investigations in Dakota are of interest in Western Canada, where in addition to an abundance of high grade coal there are large deposits of lignite coal. These lower grade fuels, while in the raw state not comparable with the coals that are mined in Western Alberta, can be made into excellent fuel by carbonization and briquetting. To do the beneficiation economically is the problem that Dr. Babcock has been working on, and it is interesting to note that he has made good progress, and that the University of North Dakota and the U. S. Bureau of mines are cooperating in carrying on investigations to find the type of carbonizer most suitable for the process.

A USEFUL VOLUME

We have just received from the Department of Mines, Ontario, a very useful volume. It is a general index to the reports published by the Bureau of Mines in the twenty five years 1891 to 1916. Everyone interested in mining in Ontario has found the reports of the Bureau to contain much valuable information.

Consequently this volume which will serve as a key to the contents of the reports issued during a period of twenty five years is sure to be warmly welcomed.

The compilation of the index was largely the work of Mr. Frank J. Nicolas. Mr. H. Mortimer-Lamb completed the work when Mr. Nicolas went overseas. Mr. P. A. Jackson and Mr. W. R. Rogers of the Bureau read the revised galley proofs and Mr. Rogers read the page proofs and ran the Index through the press. An index prepared in this manner may confidently be expected to be unusually accurate.

Among the important matters to be considered in preparing a general index to reports covering several years is the fact that many new townships have been surveyed, new districts formed and boundaries of districts changed. The index not only helps one to find the reports on subjects and places, but assists in location in accordance with the present geography of the province.

Many of our readers have had occassion to hunt up all the printed references to a mine. With the aid of the index all the Bureau's references to a mine can be very readily found. Similarly all the references to a place or district can be quickly found. The advantages of using such a compilation of data are obvious.

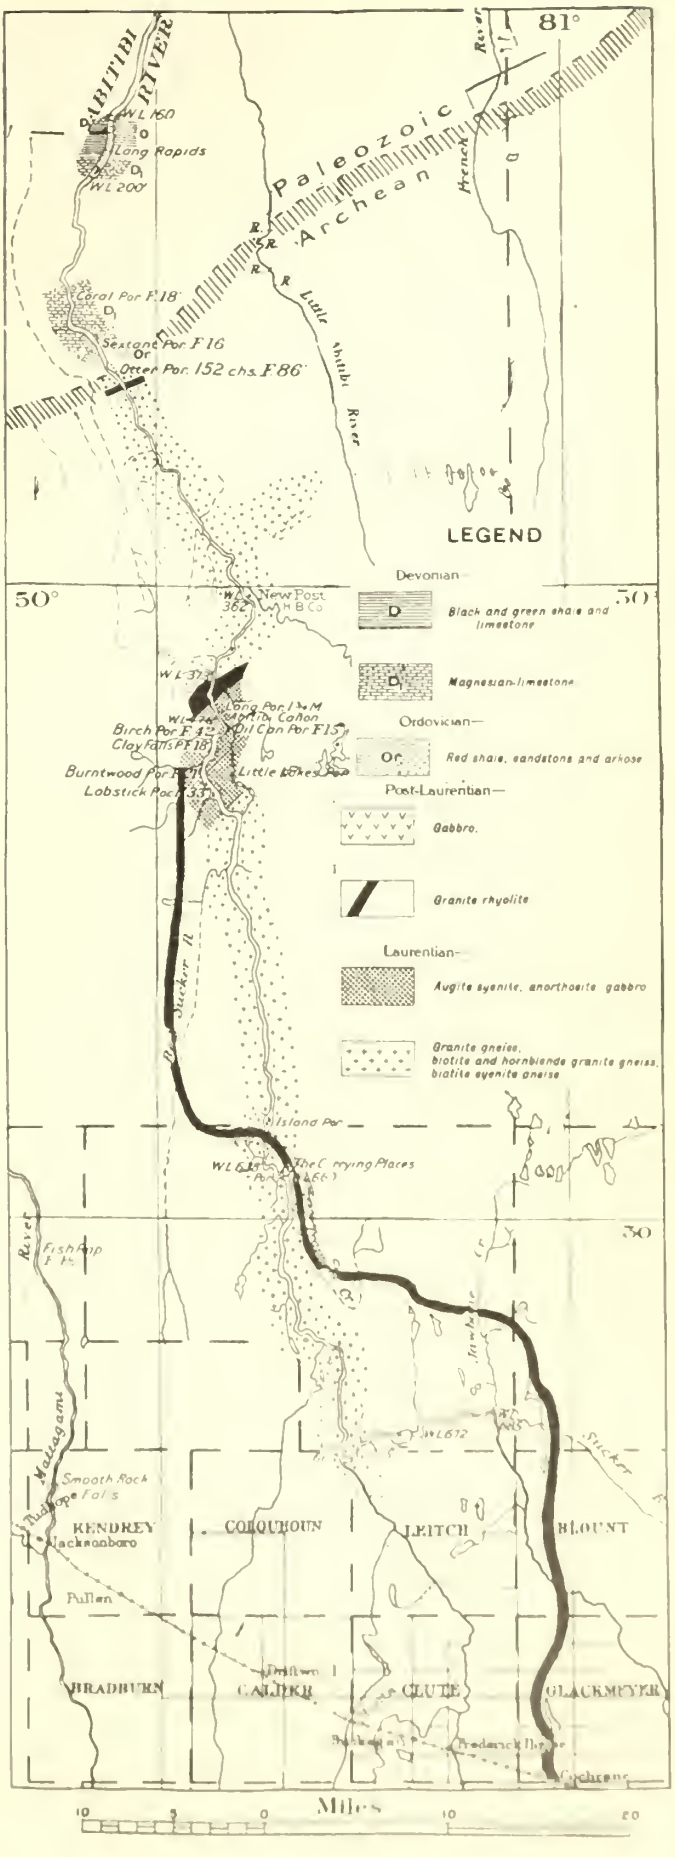
Interesting features of the volume are the map showing the countries and districts of the Province as at present constituted, and the geological sketch map of Ontario showing the areas of pre-Cambrian rocks. With the maps are presented a few facts about Ontario which are worth noting. During the period covered by the index the mineral production of the Province increased from $4,705,672 to $65,303,822.

The index is well printed on good paper and well bound. It is complete and yet not burdened with useless matter. The 871 pages are all and each useful.

As year by year the mining industry grows in Ontario and the reports become more numerous, increasing difficulty is found in learning all that has been published on any one subject. The index now before us has not come before it was much needed. It is to be hoped that it will soon be supplemented by a volume covering the years since 1916. The Bureau had expected the present volume to be ready long ago, but owing to war and other circumstances it has appeared later than anticipated. We would advise our readers to secure their copies soon as there is likely to be a good demand for such a volume.

Milling Operations Resumed at Silversmith.

Sandon, B.C.—The Silversmith Mine and Mill have resumed operations. The new Mill, the basis of which is the old Ivanhoe Mill, purchased by the Silversmith, is now handling from 100 to 125 tons of ore. Three shifts are being used and with new equipment, newly built tram, and the necessary electric power available the plant is running smoothly. Work underground has been confined to development for several months.



The above map shows part of the area north of Cochrane which will be traversed by the Ontario Government Railway which is reaching out towards Hudson Bay. We gave some description of the project a couple of weeks ago.

Lignite Carbonization.

By W. W. Odell, (Fuel Engin., U. S. Bureau of Mines).

Of recent years interest in the development of lignite fields and the production of beneficiated fuel has become more general or widespread, simultaneously with the increase in price of high-grade fuel. Not only is it recognized that our supply of high-grade anthracite is limited, but cognizance is taken of the fact that in many localities the average quality of the fuel now being purchased is not so good as that bought under the same name a number of years ago. This difference is primarily due to the increasing amount of incombustible material that is permitted to pass into a coal shipment as coal. The natural result of this higher ash content, and resulting lower heating value, in conjunction with a higher price for such fuel, is that the clean lower grade fuels automatically become relatively more valuable.

The development and utilization of low-grade fuels is not new, but on this continent conditions have not heretofore been favorable to such enterprises. The abundance of the available supply of lignites in this country in locations where other fuel is only obtainable by a long freight haul from distant sources, has made the "lignite problem" a serious one for domestic consumers in such localities as North and South Dakota and Texas.

Work done in North Dakota.

For many years it has ben recognized by Dr. E. J. Babcock, Dean of the Mining Engineering Department of the University of North Dakota, that the solution of the "lignite problem" is of vital importance to the State of North Dakota, and to the development of certain industries in that State. Towards this goal Dr. Babcock has for years been directing experiments in carbonizing and briquetting lignite and in briquetting the carbonized residue, and has made notable headway. In addition to being Dean of Mining Engineering at the University of North Dakota, he can well be regarded as Dean of lignite development in this country. At the mining substation of the University, which is established at Hebron., North Dakota, experiments have been conducted on a semi-commercial scale wherein investigations conducted at the University laboratory at Grand Forks, are amplified.

The studies made under his guidance include briquetting the raw lignite, briquetting the dried and partly carbonized lignite, drying and carbonizing lignite in rotary dryers, horizontal retorts, bee-hive ovens, kilns, and in inclined ovens. Some of the results obtained previous to 1916 are published as Bulletin 89, U. S. Bureau of Mines, "Economic Methods of Utilizing Western Lignites".

If briquets are made simply from dried lignite, other complications are met with in handling the material, such as the strong tendency for the dried lignite to ignite spontaneously. Also, the dried lignite does not lend itself well to briquetting.

The conclusion reached in these studies by Dr. Babcock, was that the best manner of produeing a highly beneficiated fuel from lignite is to briquette a carbonized residue. The aim in general is to produce a fuel for domestic use which, on combustion, will liberate the greatest amount of heat per unit weight of fuel, compatible with an economic method for its manufacture. It is appreciated that a fuel approaching anthracite may be desired for some purposes, whereas briquets capable of giving a longer flame on burning are desired for other uses. The problem as taken up at the University of North Dakota is naturally divided into two phases: First, the carbonization of lignite, so as to make a suitable material for briquetting, and second, the briquetting of the carbonized residue with the minimum amount of a suitable binder to form a firm, resistant and even-burning fuel.

At the present time there are no large commercial plants on this continent where carbonized lignite is briquetted. While much interest has been shown in the experimental work, individual investors in the past have been wisely slow to back schemes for the production of a processed fuel. This has been true not only because of doubt regarding the yields, quality and quantity of products, binder requisites, costs, etc., but perhaps also on account of the many failures in the fuel processing industry. The increasing price of good fuel furnishes much better conditions for the success of such enterprises.

Experiments at Hebron.

During the past summer (1921) experiments were conducted at the Hebron, North Dakota, sub-station under a cooperative agreement between the University of North Dakota and the U. S. Bureau of Mines, for the purposes of ascertaining what results might be expected commercially from a particular type of oven; what methods of control should be used; what yield of gas, tar and ammonia might be realized, and to learn more about the design of a carbonizer best suited for lignite. It is obvious that in erecting or designing a complete plant it is necessary to know the capacity of a unit carbonizer as well as that of the briquetting equipment, and in order to produce the finished product at the lowest possible cost, it is desirable to obtain the maximum capacity in the operation of the carbonizer. These and other important details were given particular consideration during the cooperative tests.

The plan of the work was to carbonize approximately 1,000 tons of raw lignite by continous operation of the carbonizer, briquetting the residue into a firm, solid fuel, and to obtain meanwhile as much data as possible relating to the following:

1. Quality and quantity of gas obtained.
2. Quantity of gas required for carbonizing.
3. Behavior of lignite during processing.
4. Capacity of carbonizer.
5. Quality and quantity of residue obtained under various conditions.
6. Analyses of lignite, residue and the briquets made therefrom.
7. Binder requisites.
8. Character of briquets made.
9. Control methods.
10. Cost of briquetted residue.
11. Quantity of by-products.
12. The design of apparatus suitable for carbonizing lignite.

This program was adhered to as nearly as possible throughout the experiments.

The Lignite Carbonizer.

Various types and styles of retorts and carbonizers have been in use at different times during the previous investigations made by Dr. Babcock and associates at the University of North Dakota and the substation, the

present construction being their most recent result of the continued study of the characteristic properties of lignite, and its behavior when heated. The ordinary gas retorts and the ovens commonly used for the carbonization of bituminous coal, are not suitable as at present designed, for the carbonization of lignite. The carbonizer used during the cooperative tests consisted of twelve inclined retorts (a double row of six). The upper ends are open, and a pile several feet high, of raw lignite, is maintained above them. The carbonized product is drawn off periodically from the lower ends, after being partly cooled by contact with the air ducts or recuperators at the bottom of the setting. Exhaust steam is used to complete the cooling, and is supplied so as to be in contact with the residue at the time it is discharged into the conveyor beneath.

The gas liberated is taken off into a hydraulic main, where a uniform seal is maintained so as to keep a uniform and controllable pressure condition in the retorts. An exhauster draws the gas from this main and forces it through a cooling system, where the tarry vapors are removed, and on to a manifold supplying gas to heat the retorts. The gas is supplied to the lower flues, and preheated air is used for its combustion.

The capacity of such a carbonizer depends on the kind and quality of lignite used, as well as on operating conditions, size of retorts, and other variables. Twenty tons per day of raw lignite were carbonized in this particular unit. A complete report of the results obtained during the experiments is now in preparation by the cooperators.

The briquetting equipment would briquet two tons of mix per hour. Belgian rolls were used, with twenty-two inch face, three rows wide, giving a pillow-shape briquet weighing approximately two and a quarter ounces. Satisfactory briquets were obtained which, while not entirely smokeless, held up nicely in the fire, burned evenly, and withstood severe tests.—U. S. Bureau of Mines Reports of Investigations.

CONSERVATION OF FUELS.

To aid in the conservation of fuels, research into their use in heating and ventilating plants is being conducted at the Pittsburgh Experiment Station of the Bureau of Mines under a co-operative agreement with the American Society of Heating and Ventilating Engineers.

Work on the following problems is now in progress under this agreement:

Standardization of the measurement of dust particles suspended in air.

Study of combustion in domestic heating boilers.

Checking results obtained in the application of the testing code covering house-heating boilers.

The effects on health of temperature, humidity, and motion of air in buildings and plants.

In co-operation with the research bureau of the American Society of Heating and Ventilating Engineers, tests have begun at the Pittsburgh Experiment Station to determine the heat transmitted to the fire-pot alone of a small house-heating boiler when a definite quantity of coal is burned. Later additional sections will be added to the heater and the increase observed in the quantity of heat transferred.

TRAGEDY, COMEDY, AND ROMANCE.

Daily newspapers announce the stoppage of work at Silver Islet, because the vein was a delicate one. Exactly how frail the thing was is inferable. There have been "blind", "gash", "Bilsky", and a whole lot of promising, unpromising, lost and found veins, but the "delicate" variety is something posterity will associate with Silver Islet.

Meanwhile the merrily melodramatic are snowshoe-staking the country-side around Elbow Lake, Northern Manitoba.

T'was ever thus! "One shall be taken and the other left". Larder Lake was staked on the ice. Therefore history is repeating itself. Blanketing the snow blanket—it is just possible—may be the antithesis of two negatives being equivalent to an affirmative. Twin affirmatives, however, let us fervently wish, may not work out as a negative.

Meanwhile, it is not strictly correct that the Hollinger owners have taken on the Murray properties. Individual Hollinger Directors and their friends have entertained the properties, are going to determine the chances, and do not know whether they have a mine or so much moose pasturage. Certainly the outcrops are attractive and deserve all a private syndicate will bestow upon them.—A. G.

What Consolidated "Smelters" Did in 1921

Preliminary figures from the Consolidated Mining & Smelting Company convey their own tribute to the mines and management that could produce over 110,-182,380 lbs. of metals-lead and zinc-even though their average spot value be 4 1c for 1921 as compared with 7.2c. for 1920. Not only did the grand aggregate of these metals produced by the Consolidated company exceed that of the whole Province of British Columbia in any previous year for the same metals, but the value placed upon the lead and zinc and information as to the nature and extent of the ore reserves containing those metals may serve as an ultimatum to competitors that Canada is prepared to cater to the broadest markets. The results of the year's operations are all the more prismatic when it is clearly understood that the increase of almost 57,000,000 lbs. of metals represented a relative loss in the f.o.b. valuation of $28,020. Evidently there is a cross and a crown in the grand total, the company having to contend with distressed metal markets and to liquidate inventories and the banking position. Anyhow, while the "foolish virgins", as it were, among base metal producers were somnolent, the Consolidated trimmed the lamps and went after big business mainly in the Orient, in this fashion:

QUANTITY.

	1920	1921.
Gold, oz.	42,636	51,037
Silver, oz.	1,097,930	1,173,890
Copper, lbs.	4,501,594	3,556,517
Lead, lbs.	26,474,652	57,051,110
Zinc, lbs.	36,995,394	53,131,270

VALUE.

	1920.	1921.
Gold	$ 902,714	$ 1,083,232
Silver	1,281,549	791,985

Lead	1,730,024	1,960,999
Zinc	2,810,890	2,551,895

How much of the 408,346 tons received at the Trail Metallurgical Works of the Consolidated company came from the Sullivan Mine no doubt will appear in the detailed annual report. The drop in copper production leaves it to be inferred that all but a minor fraction of the tonnage treated came from the Sullivan, where developments continue to be exhilarating. Dividing the tonnage of metals produced, by the ore receipts, an approximation of the lead and zinc contents per ton may be reached. Applying that to the millions of tons in place-proved and indicated—it is possible to arrive at an estimate of what the Sullivan Mine means to the company and to Canada. Whether it be a million or two million tons of metals — worth anything the market will take them at — there is no disputing that the mine is making a class for itself on this continent. The most recent reports are so consistently optimistic the company cannot do otherwise than adopt a one speed policy, to which end a large capacity concentrator at Kimberley as well as hydro-electric power are first essentials.

During the past year the customs business with private producers amounted to only a fortieth of the tonnage from the company's properties — and that is another reason why the Trail Metallurgical Works may have to expand for the benefit of the province of British Columbia as a whole. Without the Trail establishment as now organized, the 1921 outputting record might read like a casualty list, notwithstanding the declination of the Granby company to remain in hibernation. That the current year opens auspiciously is shown by the Trail tonnage receipts, which are about ten per cent. higher than the average of the 1921 weekly periods. Of the 8,933 tons received at Trail in the opening week of the year, 124 tons came from other than the Consolidated company's mines. When copper is moving an all Canadian rounded out copper, zinc and brass industry ought not to be a remote possibility, notwithstanding the limited domestic markets and exclusiveness of neighbors. "First catch your hare," is an old maxim, and before copper-zinc finished products are attempted in great bulk something besides present sources of copper, within the organization is required.

A year ago the Consolidated company had a heavy carry-over in metals and a banking position that prompted what has been happening, a huge turnover and aggressive marketing operations. Ample credit facilities always have been accessible to the company, and a good deal of the borrowing having been on capital account, it will be funded in due course when financing can be done upon better terms. With such a mining outlook, not only at the Sullivan but elsewhere, and capital expenditure being completed at Trail, the security behind any issue, in any form should satisfy investors. Prices of zinc and lead have touched low and are going higher. Sources of supply combined with what has been provided at Trail make the Consolidated self-sufficient. It has taken troublesome years to bring this about. That the tributary mines are ready and the metallurgy of the ores satisfactorily solved, that the company can report such an output and make profits when metal markets were so disconsolatory, is reassuring. Furthermore, the concentrator to be erected at Kimberley ought to pay for itself in short order.

The Cruelty of it.

In his remarks at the annual meeting of the Bank of Hochelaga, Mr. Beaudry-Leman was forcefully informative as to leaks in our national economies. In running the scale he omitted several of the higher notes, especially with regard to gold and base metal production, but he touched others, of which this is a whole octave:

"Our efforts should be directed towards reducing our foreign purchases, which, in 1921, amounted to $94,-000,000 for coal; to $67,000,000 for cotton; to $113,-000,000 for steel and iron, etc."

That $207,000,000 for coal, iron and steel is a long way from being neutralized by exports of lumber, pulpwood, pulp, and paper, which are variously denounced in the daily press as so many mediums for profiteering. The sum total of Canada's mineral production is dwarfed by the imports of basic materials, including oils.

Argonaut Gold Financing.

The widespread publicity given to Argonaut possibilities has aroused curiosity regarding the properties. Undoubtedly the assay plans are more substantial than most of the advertising. It is not disputed there are ore shoots of encouraging grade; but the methods employed in raising additional capital invite inquiry as to exactly what was the agreement of the former Huronia Company with the Argonaut Company, which is obligated to erect a mill of a stated capacity, in a given time. If the ore being developed is in Huronia territory, what

was or is the consideration, past, present, or ultimately, for which the Argonaut will have the continuous right of possession? This question is raised. A distribution of shares is being made. In the interest of the Argonaut company, and of the shareholders, the doubt existing is herewith publicly stated, without intentional prejudice, merely to remove the doubt.

Dome Redemption of Capital.

The phrasing of the Dome Mines declaration of the "repayment" of capital to the extent of $1 per share, was studiously devised, no doubt. Return of capital in that form hardly is taxable. Aside from that, however, the precedent is strongly commended. In a sense it is a reversable of the precept that "you cannot eat your cake and have it, too." Capital remains as it was, dividends will apply upon it, shareholders may have their money back in ten annual installments, while they also are having returns based upon the nominal capital of the company at parity. All of which is not an enervating innovation. Furthermore, a word of commendation is due to Mr. De Peneier for his management of the Dome, where operating profits of nearly a million, current assets equivalent to about 50 per cent. of the capital issued, and working capital of about $2,000,000 make safe the dividend position.—A. G.

BRITISH COLUMBIA DID WELL IN 1921.

In discussing the record of the mining industry in British Columbia for the year 1921, Hon. Wm. Sloan, Minister of Mines, places the value of the production at $25,750,608 as compared with $35,543,084 in the previous year, a decline of $9,762,476 or approximately 27 per cent.

These figures show some changes in comparison with those available some weeks ago, increases being apparent in the values attributed to gold, silver, and some of the base metals. The explanation is that the northwestern mineral survey district, which includes Portland Canal, Alice Arm, Queen Charlotte Island, etc., has done better than was expected.

It is estimated that the increase in tonnage mined in this District will amount to about 75,000 tons. The gold output, exclusive of placer, which will just about equal last year, will show an increase of approximately 30,000 ozs. or about 60 per cent greater than last year. This is due to the gold production of the Premier Gold Mining Co. The silver yield for this year will be about 1,500,000 ozs., or about 125,000 ozs. greater than last. This is due entirely to the output of the Premier Mine as the Dolly Varden which gave over 800,000 ozs. last year produced practically nothing in 1921. The Premier's output of silver will be over a million ozs. alone. The copper production will exceed that of last year by nearly 9,000,000 lbs., an increase of about 33 per cent and due entirely to the Granby Company at Anyox.

Notwithstanding the deflation of the prices of metals the total value of the three metals produced in this District (gold, silver and copper) will be greater than last year. In fact taking quantities, not values into consideration, last year's will be the greatest production ever made in this District.

Commenting in general terms on the results of mining activity in 1921, and the prospects for 1922, the Hon. Wm. Sloan, Minister of Mines, is quoted as follows:

"There are several outstanding features in connection with the 1921 history of the industry in British Columbia. One is the record of the Sullivan Mine at Kimberly, which is strikingly reflected in the statistics relative to the output of lead and zinc; another the splendid performance of the Hidden Creek Mine and the Anyox Smelter, which is shown in the volume of the copper production; and a third in the development in the Salmon River Valley, Portland Canal, of a gold and silver producer of first importance, the contribution of which to the precious metals produced by British Columbia for the first time gives an indication of what may be expected from this and other properties being opened up in this comparatively new northern mining section.

"It is remarkable and gratifying that the 1921 production of Lead is estimated to be 3,668,782 lbs. greater than in 1920, the figures being: 1920, 39,331,218 lbs; 1921, 43,000,000 lbs; that Zinc will drop in volume only about 2,208,268 lbs. in comparison with the records of the previous year; and that, even in Copper, for which there has been little or no market, the decrease was not greater than approximately 10,607,676 lbs. the figures being: 1920, 44,887,676 lbs; 1921, 34,280,000 lbs."

Mr. Sloan observes at this point that the manner in which this Province has held her own in the face of adverse conditions almost unprecedented, is a convincing commentary on what can be done when the trade winds are more favourable and furnishes an admirable illustration of what the future holds for the mining industry of the country. It was only a few months ago that, at an International Mining Convention at Portland, Oregon, the American delegates held a session apart from the Canadian delegates to formulate resolutions advocating a tariff against Canadian lead and zinc which was an indication, since justified, that British Columbia's competition in the world's markets was respected.

New Plants for B. C. Mines.

Mining men look forward to important developments during 1922 in connection with the British Columbia Mining Industry. Some of the notable projects anticipated follow: The reconstruction of the Britannia Mining and Smelting Co's concentrating mill at Britannia Beach, the capacity of the new plant being 2,500 tons a day; the re-opening of the Canada Copper Company's Mine and Mill; the construction by the Canadian Consolidated Mining & Smelting Co. of a 500 ton Mill at the Sunloch Mine, Vancouver Island; the construction by the same Company of a 250 ton Mill at the Old Sport Mine, Elk Lake, Vancouver Island; the resumption of operations by the Hedley Gold Mining Co. at Hedley; the construction of the first units of a proposed 5,000 ton Mill to handle the ores of the Rossland Mine by the Consolidated Mining & Smelting Co. and it also is possible that this Company will undertake the first units of a proposed 20,000 ton Mill in connection with the Sullivan Mine at Kimberley. There is expected to be a marked revival of activity on the part of the silver-lead-zinc properties of the Sloean and the Ainsworth as well as an uninterrupted and important development of the Portland Canal District. The placer fields also are likely to be subjected to exploitation of a character in point of intensity not seen for years.

Mr. J. H. Stovel is in charge of the mining department of the E. J. Longyear Co.

Mr. C. O. Stillman, president of the Imperial Oil Co. received scalp injuries in a motor accident in Toronto last Monday.

Northern Ontario Letter

THE SILVER MINES.

La Rose.

Favorable results on the properties of the La Rose Consolidated reflect the general downward trend in the cost of producing silver. The Journal has authentic information that profits from the La Rose operations during 1921 amounted to a little over $120,000. This compares with only $1,000 in profit during 1920. The better showing is due in part to the stronger physical condition of the mines and in part to the big reduction in operating costs. Work has been conducted in a highly efficient manner, the management having taken full advantage of extensive exploration and development work carried on during the past year or so.

Crown Reserve.

Encouraging results on property owned in the Larder Lake district has led to the management of the Crown Reserve ordering the removal of part of the machinery and building material on the old Crown Reserve mine to this new seat of operations in the Larder Lake field. Although the ore on the Larder Lake property is comparatively low grade, yet it is believed to warrant aggressive exploration and development work.

McKinley-Darragh.

No new developments have been reported this week in respect to the reports that New York brokers were making an effort to work themselves into a position of vital influence in the affairs of the McKinley-Darragh. In the meantime, the general opinion is that the mine may be re-opened in the early spring. The stopes alone contain at least 25,000 tons in broken low grade ore.

O'Brien Shipments.

During the month ended Dec. 31, a total of 63 tons of ore were shipped over the T. and N. O. Railway from Cobalt, according to the regular monthly report of Arthur A. Cole, mining engineer. The O'Brien was the heaviest shipper with 33 tons to its credit while the Conjagas sent out 30 tons. The price of silver during December reached a high point of 68 cents an ounce on the 1st, and touched a low of 63¼ cents on Dec. 8th, the average for the period being 65¾ cents an ounce.

Power and labor at Cobalt.

Workmen are plentiful at the silver mines and the supply of hydro-electric energy is abundant. Added to these favorable factors is a slow but gradual decline in the cost of material and supplies. It is believed that as a result of this favorable situation the average cost of producing silver from the mines in the Cobalt district as a whole may be considerably less than 40 cents an ounce for the current year. This preliminary estimate is of necessity governed by the uniformity of operations, regarding which there is every evidence that not only will work continue unremittingly but further favorable adjustment in economic conditions may induce operators to enlarge the scope of work.

Temiskaming.

Reports have been current that the Temiskaming mine would be opened at an early date. Such reports are at best quite premature, although the prospects of general operations being resumed in the early spring are considered to be good. Temiskaming interests are interested in the information coming from Alberta that excellent progress is being made in the development of the Blue Diamond Coal mine, in which the Temiskaming holds a half interest along with the McIntyre-Porcupine Gold Mines. Late advice tends to show that recent achievements on the Blue Diamond show a constant improvement.

Canadian-Kirkland.

It is stated in reliable circles that the question of resuming operations on the Canadian-Kirkland Gold Mines is under consideration by officials of the Crown Reserve Mining Company of Cobalt, which concern interested itself some years ago in the enterprise.

Castle-Trethewey.

With regard to the Trethewey company's operations on the Castle property in the Gowganda district, it is learned that a decision has been reached to incorporate a new company to be known as the Castle-Trethewey, with an authorized capital of $2,000,000, along the lines as previously outlined in the Journal. These shares will be allotted to the present company at the rate of one of the new for four of the old and will leave 1,600,000 shares in the treasury. The present stockholders will be allowed to subscribe for new shares at 10 cents each to the extent of share for share of stock already held. The proceeds are to be used to pay off present indebtedness of about $40,000 as well as finance the reconstruction of a plant and to carry on further underground work.

May develop Sanderson.

A party of interested men visited the Sanderson property this week in connection with the pending deal. It has been learned by the Journal on good authority that the prospects are good for sufficient funds being made available to conduct work on an aggressive scale for a period of at least two years, by which time it is believed the result of work will be such as will make further financing unnecessary. The property is regarded as one of the more promising of the undeveloped groups in the Gowganda district. It is planned to make a start this winter so as to take full advantage of the good sleigh roads in transporting supplies and material to the mine.

THE GOLD MINES.

Hollinger production.

During the four weeks ended Dec. 31st. the Hollinger treated a total of 109,265 tons of ore, the average rate being approximately 3,900 tons daily. This corresponds favorably with the former four-weekly period and is the highest daily average so far in the history of the mine. At times, the daily rate was well above 4,000 tons per day.

The power shortage case.

The case of the Hollinger Consolidated Gold Mines against the Northern Canada Power Company for alleged damages for more than two million dollars has been concluded. Judgment being reserved by Justice Middleton.

The action engaged the attention of a veritable galaxy

of legal talent, the Northern Canada Power Company being represented by R. S. Robertson, K.C., W. N. Tilley, K.C., Hon. Wallace Nesbitt, K.C., and Alex. Fasken, K.C. The Hollinger was represented by D. L. McCarthy, K.C., and J. B. Holden.

Expert evidence, including engineers from New York were examined on behalf of the power company, and the case was perhaps the most interesting of its kind ever heard in the Dominion.

Power development at Sturgeon Falls.

Pending the handing down of a decision in the case between the Northern Canada Power Company and the Hollinger, it is believed no definite action will be taken in regard to arrangements for additional power in the Porcupine district. The heavy snowfall of the current winter assures an abundance of water in the spring and the supply of hydro-electric energy for this year appears to be assured. In the meantime, however, anticipating an increased demand, it is reported on the street that the McIntyre-Porcupine is seriously considering the advisability of erecting a power plant at Sturgeon Falls on the Mattagami River. It has been learned by the Journal representative from officials of the McIntyre that the estimates place 7,000 h.p. as the amount of energy that may be developed at this point. The cost has been officially estimated at approximately $1,100,000. It is also learned that a decision was reached some time ago to proceed with this development, but that in view of the staff at the mine not being in a position to undertake the work, the scheme was left in abeyance. Mining and power development being quite different, it is believed that should the McIntyre decide to go ahead with power development, the work will be placed in charge of experts in the business of hydro-electric development.

Dome disbursements.

On April 20th, the Dome Mines will pay $1.00 per share as "capital return." This comes in addition to the regular quarterly dividend of 2½ per cent, the double disbursement amounting to $1.25 per share or a total distribution of approximately $595,000. Heavy as is this disbursement, it leaves the treasury in a strong position. A feature of present operations at the Dome is that while mill heads are being maintained at between $7 and $8 per ton, there is a substantial amount of extremely rich ore which cannot be treated to best advantage in the present mill and which is being held in reserve pending the making of necessary milling arrangements. This rich ore lies as a big asset for some future date. In an interview with the correspondent of the Journal, H. P. De Pencier, general manager, made the statement that he did not anticipate any power shortage this year.

Porcupine, V. N. T.

Within the next sixty days, the general preparations to re-open the Porcupine V. N. T. Mines will probably be in full swing. This property is the centre of considerable interest in view of the fact that operations were suspended just at a time when work at the 600 ft. level was revealing the presence of high grade milling ore in large quantities. That is to say, the vein at the 600-ft. level was drifted on for a length of only 100 feet, over which distance it showed an average gold content of $9.60 per ton across a width of 11 feet, while the average in the two faces across this width was $11.50 per ton.

Platt Veteran.

A deal is pending for the Platt Veteran claim, the indications being that funds may be provided with which to carry on a comprehensive scheme of exploration and development work. The property derives considerable merit from lying in close proximity to the McIntyre-Porcupine and the Schumacher.

Kirkland Lake road.

There is considerable agitation in favor of the Ontario Government continuing the Kirkland Lake road in an easterly direction through the township of Gauthier to Beaverhouse Lake where the Argonaut Gold is meeting with successful developments. This road would have a total length of about 20 miles from Swastika on the T. and N. O. Railway, through the producing section of the Kirkland Lake district, thence through the township of Lebel where new mines are being opened up, and, finally, through the township of Gauthier which has been staked out solid across the full width of the township from east to west and for a breath of about two miles from north to south. This highway would lie entirely in good mining territory and would serve hundreds of property owners. The first six miles of this road has already been built and macadamized, while the next four or five miles has been cleared and partly gravelled. It is the general hope that the government will proceed during the coming summer to macadamize this last four or five miles and also proceed with continuing the highway right through to Beaverhouse Lake.

Miller-Independence.

The annual meeting of the Miller Independence Mines will be held in Dayton on Feb. 2nd. The general manager, W. E. Simpson, will be present to submit his report.

Option dropped.

According to advice just obtained, the Hollinger option on the Burke claims, at Granite lake has been dropped. This advice has reference to property which was optioned last fall and on which some drilling has been done. No details are available, but the general understanding is that the amount of encouragement met with did not in the judgment of the company, warrant the consummation of a deal.

Teck-Hughes increasing output.

A gold bar worth between $10,000 and $50,000 was sent out this week from the Teck Hughes Gold Mines and the indications point to a greatly increased output of gold from this property as compared with last year's achievements.

Competent management and several years of preparing the mine for highly effecient operation is placing the enterprise among the leading gold producers of the Kirkland Lake field.

Recent development work at the 600 ft. level announced exclusively in these columns recently, tends to show that the ore is increasing in richness materially as depth is attained.

With regard to this [illegible] prominent mine manager stated to the writer that the main zone of mineralization which passes from [illegible] through the Tough-Oakes, Wright-Hargreaves, Lake Shore, Teck Hughes Ore Gold Mines and Kirkland Lake offers probabilities of continuing to great depth in such quantities as may appear to [illegible] eclipse the results heretofore recovered near [illegible]

Coal Trade of N. S in 1921.

By F. W. GRAY.

Last year's review of the coal trade of Nova Scotia put the output capacity of the Province at 6¼ million tons, but stated that a forecast of the actual production for the year "was more difficult to make than at any time since 1914 because there is not the same assurance of insistent demand and uninterrupted outlet for coal that has existed for the past six years."

5,150,000 Tons Produced.

A conservative estimate of the production of 1921 is 5,150,000 tons, so that the assumed capacity of the coal mines was not reached by a tonnage in excess of one million tons. The forecast of a diminished demand was unfortunately only too well fulfilled, and 1921 will be long remembered as a year in which coal demand in North America receded to the figures of fifteen years ago.

Depression in Steel Industry Affects Coal Output.

A very large part of the abnormally low demand for coal is associated with the small production of iron and steel products. The steel industry in 1921 reached the lowest point of production in relation to capacity that has ever been recorded, and while there are signs of revival of the industry, there are no really good reasons to expect more than sub-normal conditions in the iron and steel trades of North America in 1922, particularly in the case of the primary producers. Fabricators of iron and steel and machinery manufacturers may be busier than they have been, but no boom is on the horizon. So far as stimulation of the coal industry by greater activity of the steel industry is concerned, therefore, there are no good reasons to anticipate much greater demand for coal in 1922 than was the case in 1921.

Capacity of Output.

The capacity of the coal mines of Nova Scotia for output was not notably increased during 1921, and may be still assumed at 6¼ million tons. It is probably amply sufficient for the demand that 1922 will see.

The term "capacity for output" is not in this instance only a matter of the physical condition of the coal mines, which has been much improved during 1921, but is chiefly determined by the number of faceworkers. For the past five years, the writer has pointed out that the reduction in production of coal in the Province is exactly related to and precisely proportional to the reduction in the number of the faceworkers which took place during the war, chiefly by reason of disproportionate enlistments of faceworkers.

Surplus of Labor But Shortage of Miners.

The number of actual "miners" of coal, i.e., men who cut and load coal at the working face, is lower today in the Province by some 1,200 men than it was in 1916. Until the number of miners is restored to that of 1916 it should be fairly evident that the coal production of the Province cannot regain the figures of the years from 1913 to 1916.

To those unfamiliar with coal-mines organizations it may seem anomalous that shortage of miners can exist alongside a surplus of mine labor, but this is a condition that now exists, and has existed since 1917 in Nova Scotia. There are too many non-productive workmen at the coal mines and too few coal producers at the working faces. During the year 1921, however, there has been a readjustment of the working forces that has improved the balancing of the organizations, and the proportion of producers to non-producers is greater than for years past, but nothing but immigration, or the coming of a new generation, can replace the actual numerical shortage of miners in the Province when compared with 1916 and the years that preceded the heavy drafts made by the Army upon the miners that commenced in the Spring of 1916.

Production Record.

The trend of production is shown below:

	Output (Long tons)	Percentage of decline below 1913.	Percentage from Cape Breton Is.
1913 . . .	7,263,485	....	81½%
1914 . . .	6,650,031	8½%	81½%
1915 . . .	6,709,951	7½%	82½%
1916 . . .	1,171,434	15%	81%
1917 . . .	5,665,177	22%	77%
1918 . . .	5,211,000	28%	77%
1919 . . .	5,160,000	29%	75%
1920 . . .	5,725,000	21%	74½%
(est) 1921 . . .	5,150,000	29%	77%

While the tendency of production to rest around 5¼ million tons is to be seen from this tabulation, it should be pointed out that the output of 5,211,000 tons in 1918 represented the maximum productivity of the mines in that year whereas the similar figure achieved in 1921 represents from 1,000,000 to 1,200,000 tons below what the mines could have put out in 1921 had the demand permitted them to work steadily throughout the year.

It may be further remarked that the decline of production in Cape Breton to 75 percent of the provincial total did not represent any remarkable increase in the equipment or productivity of the mainland collieries, but was occasioned by the severity with which war conditions pressed upon the larger companies operating in the Island of Cape Breton.

British Empire Steel Corporation.

Writing at the end of 1920, although the arrangements for the consolidation of the coal and steel companies which now form the British Empire Steel Corporation were only mooted, and no certainty existed that the Corporation would be formed, the writer ventured to state, arguing from purely technical premises, that such a consolidation was "a foreordained inevitable event of the future", and if the British Empire Steel Corporation has been formed, it is because it was a proper and necessary proceeding, which should have been undertaken many years ago. The restoration of the original edifice of the General Mining Association is now complete, and it is a thousand pities for Nova Scotia that it was ever disturbed.

Advantages of Merger.

The justification of the fusion of the coal and iron—ore properties of the Dominion and Scotia companies is that, in the minds of the men who are directing the winning of coal and ore, all questions of conflicting lease lines have been wiped out, and there are now no man-made and artificial difficulties, such as formerly existed, to be added to the quite sufficiently difficult conditions of coal extraction from the areas of these two companies. The plans and projections of the combined companies are now made solely with regard to the completest possible extraction of coal, at the lowest possible price, over the maximum life of each mine area, and the conditions of lease conflict which at one time

threatened to greatly lessen the extractable amount of coal, to increase the cost of mining, and to put a premature ending to the life of many mines, have all been removed.

The St. Lawrence Market.

The shipments of coal from Nova Scotia to the St. Lawrence market in the season of 1921 totalled about 1,100,000 tons, which included coal taken by the Canadian National Railways in the Government's own vessels. All of this coal came from the mines of the British Empire Steel Corporation, and it serves as an instance of the flexibility which has been given to the coal-trade by the consolidation to mention that the St. Lawrence shipments, in addition to the usual cargoes from the Sydney collieries, included coal from the Acadia and Springhill colieries on the mainland, and it was possible to give the mainland colieries additional employment in this way which would, under separate control, have been denied to them.

A significant happening of the year was the shipment of two cargoes of Nova Scotia coal by water to Toronto.

The annual shipments of Nova Scotia coal to St. Lawrence ports in pre-war years ranged from around 1,750,000 to 2,000,000 tons. As the consumption of bituminous coal in Quebec has undoubtedly increased in the past seven years by growth of population and concentration of industries in the Province, it would appear likely that the sales of Nova Scotia coal at St. Lawrence ports should increase, always provided it can be sold at a price to meet competition from the coalfields of the United States.

Labor and Wages.

At the end of 1920 the coal miners in Nova Scotia were given an increase in wages which raised the rate of wages from 120 to 130 percent above the rates of 1916. At the time this increase was being negotiated, commodity prices had attained their absolute peak, and coal was selling at the highest figure it attained in recent years. At the date of writing, approximately fifteen months later in time, coal prices have declined to merely nominal figures, spot mine prices in the United States having declined to figures as low as $1.25 per ton. This is a condition largely brought about by over development of the bituminous mines of the United States, which could, if pressed for output over the whole twelve months of a year, probably produce a billion tons of coal. The actual consumption in 1921, admittedly subnormal, will not reach four hundred million tons, and general idleness at the soft coal mines of the United States is a necessary consequence of this disproportion between capacity of supply and available demand. The abnormally small demand is a reflex of high costs of coal production, manufacturers not being able to pay the price asked for coal, which, in its turn, is the result of the maintenance of war time rates of wages in the unionised fields in the United States. It is fairly evident that when the wage contract of the United Mine Workers comes up for revision in the Spring of 1922, the inability of manufacturing industries to function under prevailing conditions will force a reduction in wages sufficient to enable the bituminous mines to sell coal at a price which, while low enough to revive manufacturing, will yield the operators a profit. Present absurdly low spot mines prices for bituminous coal in the United States represent sacrifice sales of so-called "distress" coal, and they are chiefly important to Canadian producers of coal as evidence of acute excess supply over demand in the United States coal trade which will intensify American competition with Nova Scotia coal in the Montreal market next Summer.

The coal-miners in Nova Scotia have refused to entertain any reduction in wages, and the coal companies included in the British Empire Steel Corporation have announced that a reduction in wage rates will be made effective on the 1st of January 1922. As a result of this situation a Board of Conciliation has been applied for under which circumstances further comment would be out of place here.

PORT ARTHUR MINING NOTES.

By J. J. O'Connor.

Developments on the McKellar-Longworth mine, in the Schreiber gold area, are meeting the highest expectations of the operators. The latest spectacular discovery is mid-way between the East and West shafts. The shaft at this point is down 35 feet, and has shown free gold from the collar to the bottom, and is now in extremely rich ore. The West shaft is down 55 feet, on a ten foot vein. Good showing of free gold are constantly being encountered in this shaft.

Half a mile to the westward, another shaft is being put down on the same vein, showing that it is uniform in width, and carries the same character of ore.

At a point, one thousand feet west, from the East shaft, a tunnel has been driven into the hill for a distance of 83 feet. Cross-cutting from the head of the tunnel is now in 60 feet to the north, and 30 feet to the south, for the purpose of cutting the various veins that have been encountered in the prospecting work.

The old Empress Mine, located about 15 miles east of Schreiber, on the same contact as the McKellar-Longworth, has been dewatered, in the interests of Duluth parties.

This mine was originally opened in 1896, when some of the most spectacular gold ore ever seen in the district, was taken from the surface of the vein, and good values continued for a considerable depth, the shaft being bottomed at 93 feet, on a strong, well mineralized vein, carrying fair gold values.

There is an up to date ten stamp mill, in prime condition, on the property. It is understood that active developement work will be proceeded with at an early date.

MAP SHOWING NATURAL RESOURCES

Attention is now being directed towards the country's natural resources, as never before, since it is generally recognized that only by a more widespread utilization of Canada's undeveloped lands, mines, forests, water-powers and fisheries can present day economic problems be solved.

The Natural Resources Intelligence Branch of the Department of the Interior has published a map showing the leading natural resources of each province. In Nova Scotia mixed farming, coal mining and fishing predominate; in Prince Edward Island fur farming and agriculture. New Brunswick has large areas of timber, while mixed farming and fruit growing are outstanding interests. In Quebec may be found a wealth of timber for pulpwood, also minerals such as asbestos, graphite and molybdenite, while in Ontario there are great assests in farms, mines, and forests.

In the Prairie Provinces the prospective settler or investor may obtain adequate returns on capital and labour in either grain growing, mixed farming or ranching, while in British Columbia mining, lumbering, fishing, and fruit growing are among the leading industries. In Alberta there are large resources of coal and many mines have been developed there.

British Columbia Notes.

Active season expected at Stewart.

Stewart, B.C., — Regular shipments of sacked high grade ore are expected from the Silverado Group of Mineral Claims within a few weeks. It will be transported across a gulch by aerial, thence to the lower camp by team, and from that point will be rawhided to tide water. Apart from properties that are being worked as is the Silverado, development being continued and some of the better ore sent out for treatment, the Premier Mine is the only substantial shipper from the district at present. However many miners and prospectors are wintering at Stewart and Hyder and reports from authentic quarters are that the season of 1922 will see important advances made in this important and comparatively new mining section of the Province. George Clothier, the resident mining engineer, is advocating more trails and it is assured that government assistance, as far as finances will permit, will be extended where it is recommended. The regions of Salmon River, Fish Creek, Marmot River, and the more distant Unuk river will see much prospecting and more development on promising properties in the prospect stage than ever before.

The Premier Mine.

Describing recent activities of the Premier Mining Company, Salmon River, Portland Canal District, T. J. Shenton, District Mines Inspector, says that officers in charge at the Mine have been busy during the year in the erection of buildings for the accommodation of the employees, consisting of bunk houses, dry, and wash rooms; in the installation of a steam apparatus for heating purposes and the erection of a hospital which now is completed. In addition the one hundred and fifty ton mill has been completed and has been in operation for several months, the aerial tramway of eleven and one half miles in length likewise has been completed and began operation on the 20th of December last. Further two large compressors, coupled to two Diesel units have been installed and now are in operation, and a concrete foundation has been constructed at the foot of Cascade Creek ready for the erection of housing for the machinery of the main power house which, it is expected, will be finished, early this year.

"The average number of men employed per day for the year was 382, the total tonnage mined 15,129 tons, the total length of tunnel and drifting 4,027 feet, the total diamond drilling done, 6,821 feet. About fifty feet from the entrance of No. 2 tunnel a small shaft, 5 x 6 feet, has been sunk to a depth of 420 feet connecting Nos. 3 and 4 workings. It is supplied with steel cage, guides and the required safety devices, and is used for the purpose of hoisting of lowering men, material, supplies etc."

Mr. Shenton, in concluding, pays a high compliment to the staff officers of the Company who have done efficient work in making ready for an increased output. He predicts that the next year of operation at the Premier Mine will see past records broken.

Hidden Creek Mine

Referring to the Hidden Creek Mine and the smelter operations of the Granby Consolidated Mining & Smelting Company the Inspector of Mines states that low copper prices compelled two cuts in wages during the year, that the number of the employed had to be cut materially, and that the loss by fire of main crusher No.2 at the Mine necessitated the rebuilding and the installation of a new crusher. This was completed in October. "The structure is concrete and fire proof and is a very creditable piece of work." The average number of men employed per day during the year is given as 212, as against 385 for 1920, and the output in wet tonnage from the Hidden Creek Mine for the year is placed at 914,000 tons as against 802, 667 tons for the previous year, an increase of 112, 333 tons.

Belmont Surf Inlet Mine

In regard to the operations of the Belmont Surf Inlet Gold Mines Ltd. the Inspector makes an interesting observation as to development. He says that the Pugsley Mine, which adjoins the Belmont and is owned by the same Company, may be considered an established producer. Ore bins have been built for the handling of the output of the Mine and an aerial tramway installed form these to the bunkers at the head of Surf Mine. The tram is a two-bucket, high-speed reversible type, capacity per bucket 1500 pounds, span between buckets 2,300, operated by a 25 h. p. motor. The elevation between terminals is 390 feet and the capacity per eight hours 100 tons.

Slocan

Slocan City:—Some rich ore is being taken from the Arlington Mine, under lease and bond to R. R. Hedley, and from the Anna Group, owned by Kurt Zimmerman. It is suggested in connection with the former property that there is an opening for the pofitable operation of a cyaniding plant as there are thousands of tons of ore available for such a mill with plenty of power available. With regard to the Ottawa mine, under lease and bond to L. H. Biggar and associates who have had a tube mill in operation during the past year, a few shipments have been made to the Trail Smelter but difficulties have had to be overcome in the completion of the plant, chiefly in the obtaining of pebbles and lining. Now, however, a new steel lining has been acquired and a change made from pebbles to steel balls. The ore put through has shown a saving fully up to the expectations of the leases and shortly the Mine will be operating on the basis of a materially increased output. The Black Prince, Hampton, E. & R. Group, Tamarac, Lilly B. and the Richmond Gronps are other properties that have been under development of late.

Prospectors Protective Association

Nelson B.C. :—At the recently held annual meeting of the British Colombia's Prospector' Protective Association officers were elected as follows: Honorary President, Hon. Wm. Sloan; president, J. W Mulholland; vice president, J. C. Riley; secretary, F. A. Starkey; treasurer, R. J. Elliot; executive committee, W. W. Moore, J. Rodway, and J. P. Sherran.

An outline of the achievements of the Association during 1920 was given by Mr. Mulholland after which it was decided to urge the Dominion Government to establish a plant for the experimental treatment of the complex ores of the Kootenay and to petition the Provincial Government to take over the Granite Poorman Mill, or some similar plant, and operate it

for the benefit of small property owners, giving advance payments on shipments in order that development might proceed. It was pointed out in this connection that there are in eastern British Columbia a large number of properties that could be operated on such a basis.

Ore receipts at Trail

Trail B.C.—Ore receipts in gross tons at the Trail Smelter of the Consolidated Mining & Smelting Co. were 8933 from the 1st to the 7th of January. Of this 8809 tons were from the Company Mines. Other shippers were the Horn Silver, Similkameen; Knob Hill, Republic; and Whitewater, Retallack.

Tidewater Copper will resume

Sidney Inlet B.C.—Operations will be resumed soon on the Tidewater Copper Company's property, Sidney Inlet, Vancouver Island. Important ore reserves are said to have been blocked out during the period of inactivity at the plant.

B.C. Chamber of Mines

Vancouver B.C.—An appeal has been entered by the Engineer Mining Company against the recent judgment handed down by the British Columbia Courts which leaves the property in the hands of the heirs of the late Allan I Smith. It is said that the action will be carried to the Privy Council before the litigants will be content to consider the issue settled.

The case involves title to the Engineer Mine of Atlin District B. C., believed to be the richest free milling gold property in the Canadian West. At the annual meeting of the British Columbia Chamber of Mines held recently reports were submitted of the past year's activities and optimistic predictions made as to the future of the industry in the Province. Officers were elected as follows: Honorary president, Hon. Wm. Sloan; honorary vice-president, Mayor Tisdall; president, Ald. Frank Woodside; first vice-president, H. P. McCraney; second vice-president, E. J. Donohue; treasurer, W. M. Rooke; executive, P. N. Anderson, H. L. Patten, E. E. Bland, K. J. Burns, G A. Collins, S. J. Crocker, F. J. Crossland, G. S. Eldrige, R. Gelletly, R. R. Hedley, E. H. Lea, J. M. Lay, N Thompson, A. M.Whiteside, and Blake Wilson.

Geological Congress

Dean R. W. Brock, of the University of British Columbia, who is the secretary of the International Geological Congress, announces that this organization will meet at Brussels, Belgium, from the 10th to the 19th of August, 1922. The last Congress took place in 1913 at Toronto, Ont., Canada. Plans had been made for a meeting in Belgium in 1916 but the Great War made a postponement necessary. Nine years ago geologist and mining men assembled in Toronto from many countries, and took advantage of the invitation of the Dominion Government to visit places of interest from a scientific point of view, throughout Canada. Tours were arranged by the geological survey department, and delegates were shown portions of the maritime provinces, the Cobalt Sudbury and Porcupine Istricts and other mining fields of Ontario, much of British Columbia, and some of Alaska, including the Bering Sea. Expeditions throughout the Pacific Coast province covered the Crows Nest area, the costal region, Vancouver Island, and territory adjoining the Grand Trunk Pacific Railway main line.

On that occasion an important and authoritative pamphlet on the world's coal resources, complied by officers of the Canadian Geological Survey was read. The editors were Mr. D. B. Dowling, Mr. William McInnes and Mr. W. W. Leach, since deceased. The result was the assembling, in concise form, of valuable information concerning coal fields in all quarters of the globe. Practically all the civilized nations contributed, and essays in nearly all the languages had to be translated for the convenience of the editors in their huge task.

For the enlightenment of the guests guide books had been prepared by the survey department, which contained much information relative to mineral fields and mining conditions in the vicinity of the Canadian Railway routes.

Prior to the Canadian congress a similar meeting was held in 1910 in Sweden, when iron deposits throughout the world formed the principal subject of discussion.

At the Brussels meeting, representatives of every country, probably with the exception of Germany, will attend. The head of the survey department, Ottawa, will be Canada's spokesman. Dean Brock will attend from Vancouver.

A suggested list of subjects for discussion is as follows.

1. The tectonics of regions with Hercynian folds. 2. The geology of the carboniferous period. 3 . The relations between folded zones and down-warped zones. 4. The geology of Africa. 5. The relations between the geological and palaeontological evolution of the southern hemisphere and that of the northern hemisphere. 6. The tectonics of Asia. 7. The lithology of sedimentary rocks. 8. The geology of petroleum.

The congress will be in session from August 10 to August 19. During the week preceding the convention various excursions are to be held.. There will be excursions through Central Belgium, from Arlon to Brussels, taking in the valleys of the Semois, the Meuse, the Orneau and the Dyle, and through Eastern Belgium.

During the session the visits will be to the district about Soignies and the Ecaussines, to Quenast, to the grottoes of Han and De Rochefort, to the grotto and surroundings of Remouchamps, to Liege, to Spa, to the valleys of the Sennette and the Somme, to the district surrounding Namur and the Fault of Samson, to Lan delies, and to Louvain. The tertiary of Brussels will be investigated.

After the session, from August 21 to September 3, the programme comprises studies of the cretaceous and tertiary of Mons, the region of Bastogne, the general tectonics of the palaeozoic of Belgium, and the stratigraphy of the Westphalian of Belgium.

Testing of magnetite.

Percy Scott Leggatt, of Thos. Summerson & Sons Ltd. , passed through British Columbia recently on his way to New Zealand where he is interested in planning the establishment of an iron and steel industry. Mr. Leggatt is quoted as asserting that in New Zealand he proposes making immediate arrangement for the erection of a plant to handle titaniferous magnetites by the electro-thermic method. It is said that in this way iron sands of New Zealand have been successfully converted into qig iron and high grade steel. A few months ago the British Columbia Government sent twenty tons of magnetite ore to Thos. Summerson & Sons for treatment and Mr. Leggatt reports that the results obtained were satisfactory.

EDITORIAL

BRINGING HUDSON BAY CLOSER.

We published in the last number of the Journal a map showing the route of the T. & N. O. railway north from Cochrane towards Hudson Bay. Contract for the construction of this seventy mile extension has been let, and the new district will doubtless be quickly opened up.

It will be noted that the area traversed is for the most part underlain by Pre-Cambrian rocks. Unfortunately for the development of its mineral resources, these rocks are well hidden by a thick blanket of clay. There will be few if any rock cuts necessary along the seventy miles of railroad and there are few rock outcrops in the area.

While not very promising as a mineral area, the country is well suited for agriculture and for forest products industries. It is also well supplied with water powers, which are as yet undeveloped. As a means of easier access to Hudson Bay, the railroad has however, part to play in the development of mineral resources.

Explorations of the area traversed by the railway show that it is for the most part good agricultural land, the clay being more liberally supplied with lime than the soils further south. This lime content has doubtless resulted from weathering of the Palaeozoic limestones that occur a short distance to the north. The glacial muds here are naturally higher in lime than those well down in the areas of Pre Cambrian rocks. It has been pointed out by Mr. Jos. Keele, who studied the clays, that they are quite similar to those of the southern peninsula of Ontario, which is a limestone area.

The forests will furnish the railway with most of its business for some time. There will doubtless soon be activity in wood cutting, and pulp and paper mills will have a new source of raw materials. The railway taps several streams that will be useful in lumbering operations over a large area.

The mineral resources of the Hudson Bay area will not be immediately tapped by this railway extension, but they are brought appreciably nearer and exploration of them will come more quickly now. Owing to lack of transportation the Bay has always seemed much further away than it really is. It is well to remember that the extension of the line will at New Post bring the railway only to the latitude of Winnipeg. Ninety miles further north, brings us to Moose Factory and tide water. The exploration of Hudson bay area with a view to the establishment of industries other than the fur industry is only beginning.

OIL AND OIL SHALE

In the resume of Canada's oil problem published in this issue of the Journal, emphasis is laid upon production from wells. This is logical, as it is from oil wells that the world draws its present supplies. On all sides one hears of diminishing resources in known oil fields, and the life of the present oil industry is limited by pessimists to a few score years, optimists extend this limit a trifle.

The uses of oil in large quantities have lately been extended surprisingly, considering the limited reserves assured. It may be merely matters of expediency and of temporary economy that have induced shipping companies to introduce the use of fuel oil in their fleets, and that have substituted a valve for the locomotive fireman's shovel. But we prefer to think better than this of the men who are directing some of the world's largest and most important business enterprises; we suggest that they have in view sources of oil supply that will serve them far beyond the exhaustion of the present oil fields.

A bulletin just received [Oil Shale — a Resume for 1921 by Victor C. Alderson, President Colorado School of Mines] presents a stimulating review of the efforts of oil shale enthusiasts during the past year. Salient features are the large amounts of oil shale of good quality available for exploitation, the wide geographic li-

[illegible] of these deposits, and the number of experimental plants at present in operation. Canada is credited with "commercial beds of oil shale" in New Brunswick, Nova Scotia, Quebec and Queen Charlotte Islands, and Newfoundland has claim as well. Our only experimental plant is the one near Moncton, New Brunswick, which has been alluded to in previous issues of the Journal.

This bulletin suggests that there is at present not a wide difference in price between well oil and shale oil, if the latter should be produced from the better deposits and in large quantities. With a comparatively small increase in the price of oil, production from shale will supplement the present production from wells, and the world will be assured of cheap motive power for its automobiles, ocean liners and aircraft for an additional few score years.

From published information, it would appear that the attention of oil shale metallurgists is being confined solely to the development of retorts particularly suitable for each of the various types of shale. As usual, some proponents of special retorts have waged a wordy war upon the advocates of other types. It might have been better worth while to have reviewed in a general way the metallurgical field involved. It might be that retorting is not the only possible means of profitably treating oil shales. We shall draw an analogy as a means of defining this suggestion.

For many years miners and metallurgists struggled with the problem of producing sulphur profitably from the limestone beds of Louisiana and Texas. All efforts went for naught until there came along a man with an idea and the pertinacity to put his idea into effect. Hermann Frasch had become well acquainted with the characteristics of sulphur when he invented and applied the means for removing it from Canadian crude petroleum. When, in 1890, he proposed to melt sulphur in its native beds and bring it to the surface through a pipe the idea was ridiculed. Efforts lasting for ten years proved the commercial value of the idea. Today sulphur recovered by the Frasch method dominates the world's markets.

Is it not possible that the mining or quarrying of oil shale may be unnecessary, and that the oil can be recovered without seriously disturbing the strata in which Nature has it in store? The Journal would welcome a discussion of this idea.

INSTITUTE POLICY.

In the January bulletin of the Institute of Mining and Metallurgy there is an interesting article by the secretary, Geo. C. Mackenzie, on Institute Policy. While this is a matter of special concern to the members of the Institute it is a matter of concern to others also. Briefly, it is an argument in favor of making membership in the Institute attractive to all those in mining or allied industries who are in responsible positions, whether in the technical or financial operation of mining companies, metallurgical companies or allied industries. It is well known that for some time there has been undue stress put on technical qualifications in considering applications for membership. Adoption of Mr. Mackenzie's policy would make the Institute more truly representative of the mining industry.

A GOLD SESSION.

It is announced in the January bulletin of the Canadian Institute of Mining and Metallurgy that one of the features of the annual meeting will be a session on gold. This will include a series of papers dealing with the economic aspects of gold production. Other papers will deal with the geology of some of our gold deposits and with mining methods. Through the courtesy of the Ontario Government, a moving picture taken at mines in the Porcupine district has been secured for the meeting.

The meeting of the Institute is to be held in Ottawa on March 1st and following days.

CANADA'S MINERAL RESOURCES.

In this number of the Journal we publish a letter from Mr. C. M. Campbell on the mineral wealth of Canada. Mr. Campbell criticizes a statement made in our Dec. 9th number and gives reasons for believing that our mineral resources are extremely limited.

We are willing to agree with Mr. Campbell that compared with the known mineral resources of the United States the known resources of Canada could not properly be said to be huge. We are also of his opinion that the word "illimitable" is not a good one to use without qualification. We are also willing to agree with him that the limits of some of our ore deposits have been determined. We do not dispute his statements of fact and we recognize that his opinion is one that has been founded on experience in searching for ore deposits which his company might profitably work. Anyone who thinks that it is an easy matter to find a good ore deposit will do well to read Mr. Campbell's letter.

While we agree with much that Mr. Campbell has to say, we are nevertheless of the opinion that much more ore will be found in this country, that some of the ore deposits are known to be very large and that their limits are far from determined yet. We are much more familiar with the situation in Ontario than with that in British Columbia; but we have little doubt that the Western Province will do better than Mr. Campbell would have us believe, for discoveries are being made there that have a bearing on future production.

Development of some of the recent discoveries may prove that they should be classed as "discoveries of outstanding importance". We do not forget that the discoveries at Sudbury, Cobalt, Porcupine and Kirkland Lake were not considered of much importance until development had proved that they were. It is only after

much work has been done on an ore deposit that its tonnage can be estimated with any degree of accuracy, and consequently one seldom knows whether a recent discovery is of "outstanding importance" or not. We may have opinions based on experience and knowledge of the facts; but demonstration of facts requires years of work.

It is worthy of note that practically all, if not all the metal mines operating in Ontario to-day are working deposits discovered during the past twenty years. Most of them are drawing their ore from deposits discovered during the past ten years and many from discoveries made during the past five years. It may be true that these deposits do not compare favorably in size with some of the big American copper mines; but size is not the only thing that determines the importance of ore deposits.

Mr. Campbell's comparison of Canada's known mineral resources with those of the United States should, as he says, remind us that we have little to brag about. We agree with him that our present output is relatively small; but we are satisfied that the possibilities for the future are more in our favor. The mineral output of the State of California, in 1921, thanks largely to oil, was valued at $244,856,910, or more than that of all Canada. We are in very unfortunate circumstances with regard to some imporant minerals, notably, iron and petroleum, and it is well not to forget the fact. We have made such frequent reference to our shortage of oil and iron ore and to our lack of coal in Central Canada that our readers will know very well that our confidence in the future of mining is not based on the assumption that we have these very valuable minerals in quantity or locality where we most need them. We would make much greater progress in Canada if we had the iron and oil resources of the United States; but our shortage of these minerals should not make us pessimistic with regard to other minerals. The recent mining history of Ontario shows that we have much greater mineral resources than could have been demonstrated a few years ago. We need enterprising men to find and make use of our ore deposits. We need to have warnings from men of experience like Mr. Campbell, so that the difficulty of finding and successfully developing ore deposits will be understood. The men who make mines know these difficulties better than most men, they know that new mines, like any new business enterprise, result from the persistent efforts of men who realize that it takes money and labor to determine whether any ore deposit can be profitably worked or not. The results of such work as has been done in recent years in Northern Ontario should be enlightening to anyone who thinks that we have already found and delimited any considerable part of our mineral resources.

Mr. Campbell calls attention to the fact that some formerly important mining districts have ceased to be productive. And why should they not? The business of mining is to recover valuable constituents of ore deposits at the greatest possible profit. The life of most mines is short, but it would be much shorter if we knew at the beginning of operations all that is later learned about the ore deposits. Length of life of a mine is largely determined by opinions concerning the unknown parts of ore deposits, opinions that influence financing and plans for extraction of ore, opinions that are modified as daily development work brings out additional facts and as methods of treatment improve and as prices of mine products change. Ability to determine the facts in advance of the work would in most cases result in shortening the life of a mine and increasing the profit. It is no discredit to a district that its mineral resources have been worked out and utilized in a short period of years. It is to a considerable extent lack of knowledge and scarcity of enterprising men that results in delay in converting ore deposits into useful commodities.

In expressing the opinion therefore that we have large mineral resources we are not bragging. We are calling attention to the fact that Canada appears to have an abundance of minerals that are not being turned to account as rapidly as they should be. Those who undertake to develop mines will not all succeed, they will experience difficulty in finding promising properties at low cost and difficulty in deciding what amounts of money should be spent in testing operations and difficulty in obtaining the money necessary to carry out their plans. Such things are however, not peculiar to mining, for they occur in the growth of any new enterprise. If it were not for such difficulties all our ore deposits would have been found and mined long ago and our mineral resources could then be properly said to have been limited. We have a long way to go yet before we will know definitely what our mineral resources are. We know that they are large and from what we know we hold the opinion that they are very large.

POWER FOR THE GOLD MINES

It appears probable that the work of harnessing more water powers for duty at the gold mines will be proceeded with soon. There are still difficulties in the way of those who wish to get ahead with development but it will not be surprising if during this year the power situation is very much improved.

There will likely soon be a decision in the case between Hollinger Consolidated Mines Ltd. and Northern Canada Power Co. in which the mining company claims damages owing to power shortage. There should be soon a report from the Temiskaming and Northern Ontario Railway Commission that will have a bearing on the application of the Hollinger company for power rights on the Abitibi river. There is already reported, but not confirmed, an agreement for development of water power at Sturgeon Falls on the Mattagami river by the Northern Canada Power Company.

The importance of the proposed development of water

powers lies in the fact that all the available power is now required and that plans for increasing gold production at Porcupine are dependent on increase of power.

THE PREMIER MINE.

A story from Vancouver is to the effect that a rich strike has been made at the Premier mine at Stewart, B. C. This mine has been doing remarkably well lately and made a large production during the past year. What importance is to be attached to the news of a new strike is doubtful; but it lends new interest to the good reports that we have recently had on the Premier. From this distance the Premier looks like a coming big mine.

HOLLINGER PLANS.

It has been announced that the plans for expansion at the Hollinger call for increasing the output to seven thousand or eight thousand tons daily. This would double the output of ore and very largely increase the output of gold. We assume that the larger scale operations would be accompanied by some reduction in average value of ore treated, as some ore now left unmined will doubtless be extracted when conditions are more favorable.

These plans cannot be carried out until more power is available; but there will doubtless be little delay in preparing for expansion once the power problem is settled.

VENTILATION OF MINES.

The use of compressed air blowers as an aid to ventilation in mines was recently made the subject of investigation by the U. S. Bureau of Mines. The results of study indicate that the blowers are far less efficient than small fans. The investigators found that by use of small unit fans and galvanized iron pipe a supply of fresh air to mine openings is obtainable at about one-hundredth the cost of that obtained by the use of compressed air blowers. In many cases the more costly method gives practically negligible results compared with that of the fan method.

The use of blowers is sometimes justified as a temporary expedient; but publication of this report should make installation of permanent ventillation systems in mines a matter that will receive earlier attention than it does in many cases.

The Late R. W. Thomson

Announcement was made recently of the death at Kamloops B. C. of R. W. Thomson, who was appointed resident mining engineer in charge of the Central Mineral Survey District of this Province in 1917. While in good health Mr. Thomson rendered effieient service and was highly respected and personnally very popular among the mining men of his district. Mr. Thomson graduated from Toronto University in 1893 with the degree of mining engineer and Bachelor of Aplied Science. From 1895 to 1907 he was employed in all departments of mining work in South Africa, progressing from a sampler to a mine manager. His South African experiences included service with the British in the Boer War. Coming to Canada in 1907 Mr. Thomson was engaged for two years in operating and reporting upon properties in the Cobalt district. From 1909 to the time of his death he had been identified with the mining industry of British Columbia. Mr. Thomson was a member of the Canadian Institute of Mining and Metllurgy.

THE IRON INDUSTRY

By J. J. O'Connor

There are few, if any, more practical contributions toward the solution of that seemingly age-old problem, of how to establish an independent, self-reliant iron industry in Canada, than that offered by Mr. W. M. Goodwin, in a recent issue of the Journal. The key note is co-operation of practical business men with the highest scientific knowledged obtainable, in order that methods may be evolved, and means provided for the utilization of our own ores, as a basis for the industry.

Mr. Goodwin's suggestion, that an iron trade association be formed, is both feasible and pratieable, and could be brought about at comparatively small expense. No great trade enterprise of today is conducted without such an organization, in full co-operation with the best that science offers, in every detail pertaining to the operations.

That the manufacture of iron and steel is worthy of such an organization, is beyond question. The many ramifications of the industry multiply the necessity for such assistance, in trade, legislation, sources of raw material, the application of science, and greater, than all, the present condition of the industry in Canada.

The precedents for such action are limited only by the number of manufacturing interests in this and other countries, where the fullest advantage is taken of all that science and practical business methods is capable of accomplishing.

If permissible, advantage should be taken of the meeting of the Canadian Institute of Mining and Metallurgy, at Ottawa, in March next for the furtherance of the timely suggestion of Mr. Goodwin. A representation of the men interested in metal mining and metallurgy would be present there, in greater numbers than would be likely to attend a conference called for this especial purpose, Both the time and the place would be opportune. Cabinet Ministers and Members of Parliament could attend, and learn much of the requirements necessary to place Canada in an independent industrial position, and the possibility of promoting the iron and steel industry through legislative channels.

PACIFIC COAST PIPE

The Pacific Coast Pipe Co. Ltd. of Vancouver has issued a catalogue describing wood stave pipe, tanks etc. The company has made many installations of wood stave pipe, for water supply, hydro electric power etc. and a large number of wood stave tanks for the mining and pulp and paper industries. Many companies use their B. C. fir tanks. The company has been in business in Vancouver since 1904 and its products all well known in all parts of Canada.

The Influence of Rock Structures
ON QUARRY METHODS.

By Oliver Bowles

Much has been written and said on the relation of rock structures to problems in the development of ore deposits, and many eminent geologists and engineers have devoted careful study and untiring energy to the solution of such problems. It is generally recognized that a proper interpretation of rock structures is essential to success in metal mining, particularly where complexities are liable to arise through faulting and folding. It is noteworthy however that a diligent search of literature, and contact with many consulting geologist and engineers, have revealed a striking lack of similar activity in the broad field of non-metallic mining. This is the more remarkable in view of the tremendous importance of the non-metallics in the economic life of every community. It seems appropriate to mention that the Canadian Department of Mines has surpassed similar oranizations in most other countries in the volume of published work on non-metallic mineral mining.

The inefficiency of operation, and the high percentage of waste that characterize a number of the non-metallic mining industries is due in some measure to a lack of understanding of the structural features of the deposits, and a failure to take these features properly into account in working out the best mining methods. A knowledge of the geologic structures of rock is just as essential a factor in quarrying as it is in the mining of metallic ores. Furthermore the quality of many non-metallic products is largely controlled by the structural characteristics of the parent rock, while such characters have little or no influence on metallic products. Gold bars are similar whether derived from lode or placer, but granite blocks whether red or gray, coarse-grained or fine-grained, sheets of mica stained or clear, or masses of asbestos whether brittle or pliable, must retain throughout their entire lives, the inherent physical characters they possess when first discovered in the earth, and their value depends to a very great extent on these characters. Rock structures have, therefore a profound influence both on methods of operation and on the quality of the non-metallic products. The purpose of this paper is to emphasize the influence of such structures on the quarrying and mining of non-metallic minerals, with particular reference to various types of stone.

Quarrying of Limestone

Even in the quarrying of rough stone such as limestone for road building or cement manufacture, the structural features of the rock may have a definite influence on quarry efficiency.

For example, drill holes for blasting should be arranged in accordance with joint systems, for if an open joint occurs between the drill hole and the open face, it will cushion and diminish the disruptive force of the blast beyond the joint, thus necessitating excessive secondary blasting. The presence of open joints may also have a decided influence on drilling, especially if the joints are inclined from the vertical, for if a drill meets a joint at an angle its course may be diverted so that the drill will bind, and the hole may be lost. Where a drill is thus diverted from its perpendicular course so that it binds, it is customary to throw small pieces of iron into the hole, for hard obstructions retard the downward progress of the drill, permit it to enlarge the the hole and straighten its course. Such procedure is destructive to drill bits, but it is deemed better to take drastic measures than to abandon a costly drill hole. A knowledge of the trend and dip of open joints would enable drillers to avoid much of the loss incurred through forced abandonment of unfinished drill holes.

The dip of the beds is another structural feature to which insufficient attention is given in opening up limestone quarries. If the quarry is developed in such a way that the face is advanced in the direction of dip, blasting forces the blocks up the slope of the beds, and the upper beds bind the lower ones. It is comparable to an attempt to remove shingles from a roof beginning at the eaves rather than at the ridge. For efficient blasting the quarry should, therefore, be planned in such a way that the face is advanced in some direction other than the direction of dip.

Dimension Stone

It is, however, in the quarrying of dimension stone that rock structures have the most profound influence on quarry methods. Brief reference may be made to the influence of joints on the process of quarrying marble. The proper direction and spacing of the cuts by which marble is dissected into blocks are governed chiefly by the direction and proximity of joints. Many quarrymen fail to realize that joints tend to occur in two systems, commonly crossing each other approximately at right angles, and failure to take this fact into account results in cutting out the blocks in such a way that joints cross them diagonally, resulting in excessive waste. The operator who makes a careful study of joint systems, and maps them accurately, is enabled to plan the direction and spacing of channel cuts and lines of wedge holes in a way that results in reducing waste to a minimum, and is obtaining a maximum number of sound blocks.

Slater Quarrying

In slate quarrying, to which the writter has devoted much study for several months, rock structures are of first importance. The fissility or ease of splitting known as slaty cleavage, which is developed in the rock by geologic processes, is the one feature above all others that gives to slate its economic value. Next in importance to slaty cleavage is bedding, which depends on sedimentation. The attractiveness and durability of slate depend in a large measure on chemical or mineralogical composition and texture and as slates were originally deposited in sedimentary form in deep water individual beds were fairly uniform over large areas. Therefore, wherever high grade slate is found, a continuance of the deposit is to be sought by following the bed in which it occurs. Great difficulty may be encountered in this process for as in the Slatington District of Pennsylvania folding may have carried the desired bed below workable depth and operations must be conducted along the strike on the opposite limb of the fold.

Presented at the Toronto Meeting of the A. A. A. Sc.

*Published by permission of the Director of the U. S. Bureau of Mines.

even on an adjacent fold. The intelligent operator is therefore obliged to depend for the successful solution of his problem on the proper interpretation of the folds, and through complexities of deformation this may be no easy task.

The attitude of the beds is the chief factor governing the depth and lateral extent of slate quarries. Where the bedding is nearly vertical as at Monson, Maine or in eastern Northamton County, Pa., the quarries are deep and relatively restricted in lateral extent, for following the good beds results in vertical extension. Where the bedding is inclined at angles of 30 to 60 degrees from the horizontal as in Vermont the excessive overburden encountered in following the dip usually precludes deep quarrying, and development must take place along the strike. Thus quarries in such a region tend to be wide and shallow.

It is not to be assumed therefore, that deep and relatively narrow quarrying in Pennsylvania, and Maine; or wide and shallow quarrying in Vermont, are occasioned simply by preference of operators, for they result entirely from differences in the attitude of the beds.

The difficulty encountered in removal of heavy overburden may be overcome by the following underground methods, but here again the structural features of the rock constitute the controlling factors governing the feasibility of such projects. If the rock is badly broken up by many intersecting joints underground methods may not be possible, for slate is too cheap a commodity to justify expensive timbering. If on the other hand, the beds overlying the good slate are sound and strong, tunneling may be conducted in safety, if pillars of slate are left at intervals for roof support. A mining method has been pursued with success at West Pawlet, Vermont, for in this deposit the rock structures are advantageous. A series of parallel vertical joint planes approximately 30 feet apart provide walls for 6 steeply inclined shafts, following the bed, with 30-foot supporting pillars of undisturbed slate between them. The cost of sinking shafts is therefore relatively low where open joints may be utilized to take the place of wall cuts. All rock structures should receive very careful attention in working out the most logical plan of development.

The slaty cleavage in many regions governs the inclination of the quarry floor. Where it is horizontal or inclined at a moderate angle the floor is maintained parallel with it. In some quarries the floor is inclined at an angle as high as 45 degrees to conform with the dip of the cleavage. At Monson, Maine, and Delta, Pennsylvania the slaty cleavage is vertical, and the quarry floor follows open horizontal seams.

Open bedding planes, (termed "loose ribbons" by quarrymen) or open joints are of great assistance in the removal of the rock, for they may be utilized to take the place of channel cuts, or fractures made by wedging or blasting. The experienced quarryman utilizes such natural planes wherever possible. In some of the tunnels and drifts at Monson, Maine, the ceilings formed by horizontal joint planes are as smooth and uniform as the ceilling of a room in a dwelling house. It is commonly found that horizontal joints occur at intervals of 6 to 14 feet, and in best quarry practice the channel cuts are projected always to the level of the seam, thus utilizing it as a bench floor.

The "grain" of slate is another structural feature that has a definite influence on quarry methods. The term "grain" is applied to a second direction of splitting, less pronounced than the slaty cleavage, and usually approximately at right angles to it. Major vertical fractures are always made in the grain direction, and attempt to force a fracture in a direction inclined to the grain would result in excessive waste. In some qarries near Pen Argyl, Pa. the three important structural features, bedding, (marked out by "ribbons") slaty cleavage, and grain approximate the three dimensions of space, the ribbon and grain being vertical and approximately at right angles to each other, and the slaty cleavage horizontal or inclined at a low angle. By quarrying always in conformity with these structures the best quality of product is obtained, and the proportion of waste is always greatly reduced.

To the quarryman, monument manufacturer and paving stone cutter the rift or direction of easy splitting in granite is similarly a structural feature upon which the success of his operations is largely dependent. The origin and nature of rift in granite are little understood, and it is probable that a thorough petrographic study would open the way to more efficient methods of quarrying and dressing the rock.

These are but a few of the simpler examples of rock structures that play an important part in economic problems of quarrying and mining of the non-metallics. It is apparent to any careful observer that great improvement in method could be brought about by a better understanding of rock structures. There is, therefore, in the vast field of the non-metallics an opportunity for the geologist and engineer to render practical service of inestimable value, in solving structural problems, and in pointing out the influence of rock structures on methods of operation.

DIRE DEVELOPMENTS IN GOLD INDUSTRY!

BY ALEXANDER GRAY.

"Cheer up! The worst is yet to come!"

The only consolation in sight for producers is that Edison and his contemporary collaborators are going to have competition when they come to patenting synthetic gold processes. To that extent the sun may rise blood red for gold mine owners and set suspiciously for some of them.

A valorous British officer who saw service in the fever belt in the Cameroons (somewhere around there) veraciously has vouchsafed that he saw a West African umfaan (a native youth) transmute metals, make gold, and he bought specimen nuggets, lest there be those who would scoff at him.

The nuggets were put through "while you wait", according to the martial narrator, who disclaims being a romancer, and who chides the world-famed metallurgical highbrows for their vaunted pre-eminence and pre-disposition to lay the flattering unction to their exclusive selves that they know it all.

Crude utensils, perhaps the commonplace kaffir pot so revered by those of us who used to cherish it as the chief factor in our commissariat, may-be a daub oven and admixtures of snake juice and weird invocations accompanied by violent gymnastics with assegais and shields, are alleged to have been the formulas. The British officer did not say this but no kaffir would undertake feats without those concomitants and the right temperature, of course, irrespective of the undertaking on the part of the Dutch Government that it will restrict the traffic in strong liquor on the West

Coast. Anyhow, the demonstration netted the dusky son-of-a-sea-cook enough gold to start something in the nuttery of the Staff Captain.

No wonder the home-brewed gold bullion stirred up the valiant eye-witness and prompted him to write about it to the press of two continents. He did this as an act of kindness to holders of gold-secured bonds, of gold-backed paper everywhere, because the Arcadian alchemist is daily or weekly transmuting metals, when he is not making snuff or resting while his umfazi-wife or wives, is or are emulating the Man With the Hoe.

Nor was the bullion wrought out of nothingness in value, of the amber two-per-cent. variety. Not at all. It was superfine; that was why the Military Observer purchased some of it and brought it to London.

Therefore, why not yield prirority to wonder-working kaffir! Generally it has been the experience that the "raw" kaffir preferred his "Bass's"-master's pantaloons, shirtts, or shoes, when he contemplated reposeful sojourns at his kraal. Occasionally he is an adept artisan, but concocting charges for primitive retorts and practically proving that he is a synthetic conjurer with the crucible is worth this space and what sugar and limbo-colored cotton it must have cost the Staff Officer, if for no other reason than to satisfy the audience that all the "nuts" are not in Brazil.

Once I depleted my surplus visibilities on a missionary "culled" man who exhorted his racial affinities to flee from the wrath to come. He vociferously volunteered to illustrate his divine attributes by turning water into wine. His thirsty compatriots found their patience exhausted at the expiration of a week. The synthetic invigorant did not arrive. It is said to have been otherwise in this matter of jungle gold that really jingled. Consequently Messrs Edison and Ford have a better thing in the offing than Muscle Shoals nitrates if we are to have solid gold jitneys at the price of a thousand or two cowrie shells. However, they should worry!

It is a coindence that this revelation should become public property simultaneously with Mr. Edison's grim forebodings as to the future unworthiness of gold. Beyond that, there is no analogy between the event that accompanying the prospecting of a farm in what was then the Orange Free State. The Boer farmer who would not admit that he had either diamonds or gold on his place, has yet to be discovered. So, when three alert prospectors came along and put the question whether there were any diamonds about, the vrouw, simple soul that she was! modestly affirmed, and was not sworn to it. Consequently an option was granted, conditioned on a small cash payment and work being done. Upon returning with a testing plant, a promising area was located and in due course a diamond found. Efforts were redoubled and another diamond turned up on the sorting table. To the trio it looked like a sure enough diamond mine. The vrouw blandly congratulated the embryo magnates and accepted cash for the provender essential for their daily sustenance. Washing operations proceeded with increasing alacrity. Weeks elapsed. The operators exhibited their two "finds" but were obliged to hold them and give them to the owners of the farm in case the work was abandoned. Working capital became perilously scarce. Finally no other diamonds having been recovered and being without funds, the trio decided to forego the option. When they sought the vrouw and tendered to her the two stones with the explanation that the results were disappointing, she waxed indignant and indiscreetly exclaimed:

"You lie! Where is the other diamond?"

She had "salted" the thing by planting three stones and she thought there was a "hold out" as to the missing one.

Really, though, the West Coast nuggets may have been indigenous, and if so, they are less deceptive than those kaffir curios acquired by English tourists as barbaric emblems, whereas they were made in Birmingham or Sheffield.

PATENT FOR MINE FILLING

Dr. Adolph Goebl, 6,535 Lorain Ave, Cleveland, Ohio, has patented in the United States a process for filling underground excavations with sand. The material is mixed with water and carried down in pipes.

REDUCTION OF DOME'S CAPITAL STOCK.

The bold move being made by the management of the Dome Mines towards the redemption of the capital stock during the life of the mine has an interest that is not only local, but will set talking the world of miners and investors in mines. It has long been an axiom to mine managers that the investment must be returned, along with interest, by the time the ore-deposits have been worked out. When the return of capital investment is made as additional dividends, the rate seems large as compared with the dividends from other investments, and the average investor is prone to labour under a delusion as to his actual rate of return. The commendable action of the Dome officials in adopting a means that will help to clear away this misunderstanding, and consequently aid the investing public to gauge more correctly the value of mining shares, may prove to be epoch-making in the the history of investment in mines. The following news item gives particulars of the move.

"A special general meeting of the shareholders of the Dome Mines Company, Limited, will be held on Saturday, February 11, for the purpose of ratifying recent by-laws passed by the directors. One of the by-laws deals with the capital return of the stock, and is for the purpose of authorizing the directors from time to time, as they see fit, to pay out of capital such sum or sums as deemed advisable all such payments to be made pro rata among all shareholders, and a due proportionate amount to be set aside to provide in the same way for shares now allotted but not issued, and to be paid as and when such shares are issued to the holders.

"The second by-law will empower the directors to make application from time to time to the Lieutenant-Governor-in-Council of the province of Ontario for supplementary letters patent decreasing the par value of the shares of the company issued and allotted by the amounts so to be repaid out of capital on account of each share.

"The desire is to decrease the capital stock from the sum of $5,000,000 to the sum of $1,000,000 and authorize the repayment to the shareholders of the sum of $4,000,000 and reduce the par value of the shares of the capital stock from $10 to $2 per share."

At Latrobe, in Tasmania, there are extensive beds of oil shale with a promising content of gas and oil. More than one commercial plant to treat the shale is mooted.

Northern Ontario Letter

THE SILVER MINES

With the end of the current winter coming reasonably close, and with general conditions in connection with mining in this country showing a steady improvement, there is a feeling in Cobalt that the slack period of the past few months may soon give place to a quite general revival of activity in many of the smaller mines.

Crown Reserve

The Crown Reserve has encountered even better encouragement in diamond drill work on its property in the Larder Lake district than was the case in surface work. Whereas surface assays showed a gold content of around $1 per ton in gold, it is understood the core from one of the diamond drill holes showed gold values of nearly double that amount across a good stoping width. The proposition is considered to be well worth opening up by shaft sinking to a depth of 300 or 400 feet and toward this end the Crown Reserve is removing part of its machinery from its old Cobalt property to the new scene of activity.

Larder Iake

While the Crown Reserve is thus carrying out its plans for aggressive work, the Coniagas and the Canadian Associated Goldfields are both carrying on exploration work. Diamond drill results on the Costello property of the Goldfields were not altogether reassuring, but the result of shaft sinking has at least been encouraging. It is learned that the Coniagas this week took under consideration another property in this district.

Haileybury Frontier

Roads to South Lorrain have not been very good during the past couple of weeks on account of heavy wind having caused the snow to drift. However, the Mining Corporation has been making good progress in the work of taking machinery from its old Cobalt Lake property to the Haileybury Frontier, the latter of which is held under working option. The electric hoist is already in operation. In view of the attention of the Mining Corporation being directed largely to the exploration of the area on the Frontier through which the main break from the Keeley is expected to pass, this work is looked upon as being highly important from the point of view of all property holders in the South Lorrain district.

Coniagas

Although the cold weather caused the Coniagas to curtail that branch of operations dealing with the re-treatment of sand tailings lying on surface, yet the general operations are continuing at full blast and all signs point toward 1922 being another prosperous year for this company.

Genesee

Arrangements will be made to resume operations on the Genesee property at Cobalt. At a recent meeting, the directors decided to authorize the sale of a certain block of treasury shares and in this manner to endeavor to secure the necessary money to pay for continuing cross-cutting operations at the lower level.

Trethewey

At a recent meeting of the shareholders of the Trethewey-Cobalt, a by-law was passed, authorizing the incorporation of a new company on the basis recently outlined in the Journal. The new company, known as the Castle-Trethewey will assume all the liabilities of the Trethewey as well as the assets and will pay the Trethewey 400,000 shares. The shareholders of the vendor company will be given the right to subscribe pro rata for the balance of 1,600,000 shares at 10 cents per share. Thirty days were allowed within which to subscribe for the treasury shares, and it is believed the result will be that sufficient money will be raised to quickly pay off the indebtedness of around $40,000 as well as provide working capital.

Triangle Silver

Captain Jeffries is busily engaged in an effort to arrange the affairs of the Triangle Silver Mines Company so as to resume work this winter or in the early spring. It is stated that prospects are good for the finances being raised within the next few weeks.

White Reserve

J. A. McAndrews of the White Reserve Mine is on a visit to the property, having gone in to the Maple Mountain district by way of Elk Lake. No work is being done at present.

Cable regulations

Regulations in connection with cable used in mine hoisting will go into effect at various dates during the first half of 1922 as shown in the following summary received from the Department:

Testing Hoisting Cables.

Rule 68, Section 164, of the Mining Amendment Act 1919, being Part IX of the Mining Act of Ontario, is as follows:

"Testing portion of rope.

(68) At least once in every six months the hoisting rope shall have a portion not less than six feet in length cut off the lower end. With the exception of the cutting at the end of the first six months the length so cut off shall have the ends adequately fastened with binding wire to prevent the disturbance of the strands and shall be sent to a reliable testing laboratory for a breaking test. The certificate of such test shall be kept on file. This rule shall not come into effect until proclaimed by the Lieutenant-Governor in Council.

Copy of an order-in-Council, approved by His Honour the Lieutenant-Governor, dated the 9th day of November, A. D. 1921.

Upon the Recommendation of the Honourable the Minister of Mines, the Committee of Council advise that Your Honour may be pleased to issue a Proclamation bringing into force Rule 68, as laid down by Section 164 of the Mining Act of Ontario as enacted by the Mining Amendment Act, 1919, Section 13, with regard to the testing of hoisting ropes or cables in mines as follows:

In the Mining Divisions of Kenora, Fort Frances, Kowkash and Port Arthur, on the first day of January, 1922:

In the Mining Divisions of Sault Ste. Marie, Sudbury and Parry Sound, on the first day of February, 1922;

In the Mining Divisions of Temiskaming, Coleman, Montreal River and Gowganda, on the first day of March, 1922;

In the Porcupine Mining Division, on the first day of April, 1922;

In the Larder Lake Mining Division, on the first day of May, 1922;

And in all other parts of the Province, on the first day of June, 1922.

THE GOLD MINES.

Will Develop Power at Sturgeon Falls.

While it was officially stated some time ago that the McIntyre Porcupine had prepared estimates in connection with developing about 7,000 h. p. at Sturgeon Falls on the Mattagami River, but that the company would be willing to step aside and permit power company officials to take up the project, yet it was reported unofficially a week ago that the McIntyre might go ahead with the work on its own account. This report was quickly followed by another that the McIntyre had sold its rights to the power site to the Northern Canada Power Company. It is now understood that the development of this energy will likely be commenced by the power company soon after the outcome is known of the recent litigation between the Hollinger Consolidated Mines and the Northern Canada Power Company.

Dome Mines

The best news coming this week from the gold fields of Northern Ontario has to do with achievements at the Dome Mines where the amount of gold being recovered per ton during the first three weeks of the current month was actually higher than any other mine in the Porcupine district. Those in close touch with the situation believe the Dome will experience no difficulty in realizing net profits of $125,000 per month, or at the rate of over 31 p.c. on the company's issued capital. Among the more optimistic are those who believe there will be no difficulty in making net profits of $150,000 monthly, or at the rate of between 35 and 40 p.c. yearly. The reason for the recent increase in mill heads is that by a sleight change in milling practice it has been found that the plant makes an excellent recovery when dealing with more high grade ore than had previously been treated satisfactorily. The first capital return of $1.00 per share on April 20th, plus the regular dividends of 2½ p.c. quarterly assures the stockholders of returns of 20 p.c. this year, and with good prospects of the fiscal year beginning with the end of March being marked by the payment of a second capital reduction of $1.00 per share, or a total of 30 p.c. for the period.

Paymaster

It is stated in Porcupine that Dr. Walter Harvey Weed, well known United States geologist, who recently visited the Paymaster mine was favorably impressed with what he saw and recommended that the shaft be continued to deeper levels. It was announced recently in the Journal that the work of continuing the shaft to a depth of 100 feet is already under way.

Teck-Hughes

In an official statement to the representative of the Journal D. L. H. Forbes, general superintendent declares that gold tellurides were encountered during November and December on the 600 ft. level of the mine and this resulted in a big increase in production. Mr. Forbes presented figures to show that mill heads during the last half of December averaged about $21 to the ton and the mine produced about $32,000 for that period. The figures also show that mill heads during the first half of January averaged upwards of $17 per ton and resulted in an output of over $20,000 for the period of 15 days. These mill heads were the result of taking from 15 to 25 tons of rich ore along with not far under 100 tons of the ore of regular grade from other parts of the mine. It is now planned to carry the shaft to a depth of 980 feet and open up levels down to that depth. In the meantime, no stoping will be undertaken at the 600-ft. level in the new ore until work on the lower levels is under way.

Kirkland Lake Proprietary

In an official statement issued in connection with the Kirkland Lake Proprietary (1919) Ltd., some interesting details are given in connection with the properties held by this company. One outstanding feature of the report is that a total of 56,000 pounds or approximately $250,000 has been borrowed with which to finance the work of again placing the properties in condition to resume production. Another feature is that the present plans are to re-open the mill in April and place the enterprise on a profitable producing basis, this being assured by the volume of good ore already in sight.

Bidgood

Official advice to the Journal that the vein at the 400 ft. level of the Bidgood Gold Mines carries about eight feet in width of good ore has caused a general wave of optimism in regard to properties in this eastern part of the Kirkland Lake district.

Goldfields

Information from the Larder Lake field shows that the Canadian Associated Goldfields has met with encouragement during the course of shaft sinking, while the Crown Reserve, as stated elsewhere in this summary, has indicated the presence of commercial ore at depth by use of diamond drills.

Power rights

Late reports from Porcupine, totally unconfirmed at the time of writing, have it that the Hollinger Consolidated has at last secured the right to develop hydro electric energy on the Abitibi River.

Lake Shore.

Lake Shore again set a new high record during December according to the regular monthly report for December. It had been unofficially stated recently that the December record has reached $57,000 which would have been the highest record in the history of the mine, but the official statement just received shows a production of $70,851.37 thereby far exceeding any previous month.

The mill treated an average of close to 65 tons a day daily in spite of having been in operation only 90.15 of the possible running time, while the average gold content of the ore was $35.35. This compares with a former average of about $25 a ton and a former high average for one month of a little over $30. The achievement is one of the latest sensations in connection with mining in the Kirkland Lake district.

NEW ORE BODY STRUCK.

Premier Mine at Stewart, B. C., Value at $80,000,000

Victoria, B.C.—Striking of a large new body of ore in the famous Premier mine at Stewart, B.C., has increased the value of the property to $80,000,000 according to a message received here from Stewart. Officials at the Department of Mines express surprise at the estimate. It has been known officially for some time that the company had $10,000,000 actually in sight before undertaking recent explorations.

The Guggenheims and President W. B. Wallace of the Crow's Nest Pass Coal Company engaged the mine which is now believed to be the richest silver and gold mine in North America.

Oil Exploration

By ALEXANDER GRAY.

Whether it be deep-seated prejudice against whatever has to do with the development of mineral resources, or a wide-spread suspicion that the exploitation of mineral deposits is surcharged with what Pandora turned loose, it is inscrutable that the remarks of President Stillman at the annual meeting of the Imperial Oil Company evoked neither commendation nor apprehension lest Canada fail to disclose oil fields comparable with those over the border. Perhaps the silence is due to embarrassment or to an indisposition to advertise the disappointments met with during two years of activity in the quest for oil in the west and northwest. May be the degree of indifference synchronizes with the abstention of all but the Imperial company among the great interests in the industry, from extensive operations in the endeavor to find oil. Whatever the reason for the negative public attitude toward a domestic supply of oil, it is not impertinent to quote a few of Mr. Stillman's salient sentences.

"It is desirable to round out our organization by procuring a domestic production of petroleum. Dependence upon foreign sources of supply for crude has caused great anxiety in the past, especially during the war, but the company's relation with other large producing companies in the United States has enabled it be obtain a continuous and sufficient supply.

"While this is reassuring when we contemplate any possible recurrence of such a shortage in the future, there exist many disadvantages in the fact that we are forced to import about 98 per cent. of our raw material. High freights are, of course, the most important of these, but in addition to this, we have been heavily penalized in the past two years by the depreciation in Canadian exchange. In order to buy funds with which to pay for our raw material abroad our expenditure in the past year has been about four million dollars, or an amount almost equal to that paid out in dividends. It is for these reasons and because we have felt that a moral responsibility rested upon us as a semi-public service corporation, that we have endeavored to develop a production of petroleum in this country, and we have considered our operations in the Canadian West and elsewhere, while entered upon primarily for the benefit of our shareholders, as partaking of the nature of a National Work."

Frankly stated, the Imperial Oil chief broadly defined the purposes and duty of this corporation. Evidently the conception of that duty was put into execution before the Imperial company executive officers talked about it, beyond an occasional note of optimism. As a further reason why a wholly home-made oil industry should be a national institution, Mr. Stillman also dealt with economic conditions as affecting marketing operations which, he said, had resulted very much more satisfactorily than they expected six months ago. "In all my forty years connection with the oil industry", he avowed, "I do not recall a period in which occurred more drastic readjustment of values, more rapid variation in conditions, nor which called for more courage and resource that the year 1921." Notwithstanding which there was a display of optimism in the provision of tankers and tank cars, the erection of more refineries, and of sporting spirit in the exploration campaign throughout the Northwest, the cost of which is unstated, but which was entered into as a "national work."

Those who can smile when combined conditions are so perverse are not to be deterred. That the volume of business transacted had been "fairly well maintained" while fluctuations in the price of crude were too volatile to be otherwise than "trying" and exchange and freight constituted onerous surcharges, sustains the complimentary remarks of Wallace Nesbitt, K.C., to the effect that it is fortunate to have experienced experts departmentally in charge and directors who are not culpably perfunctory. Mr. Stillman, however, who was buoyant last year as to the outlook for a domestic supply of oil, left it to Vice-President Victor Ross guardedly to describe in more or less detail the nature and extent of the National Field Work performed by the company. Feeling, no doubt, that pessimism is no part of the Imperial programme, Mr. Ross made the best of a thus far unprofitable experience. Whereas hope had run high that the Fort Norman Discovery Well was the harbinger of greater developments to Canada, Mr. Ross deftly disposed of that phase of his subject by stating:

"It is not to be expected that anything further will be heard of the Fort Norman operations until the Spring, and it may be years before results of commercial value are found there."

From this there is no other deduction than that the cause of the furore on the Mackenzie river has not proved commercially attractive. About three barrels daily instead of the estimated flow when the first well was brought in subscribers more romance than reality to what has transpired, even though the intimation that the last word has not been written about the section lends too remote a factor of affirmative expectation. As it is a year and a half since the Fort Norman development seemed to confirm horizontal assumptions that petroliferous areas were as broad as the prairies, and then the foot-hill and Pacific slope country might have a shade the best of it, the inferences conveyed by Mr. Ross suggest that the National Work of finding oil be undertaken by others as well as the Imperial Oil Company whose millions are being expended for their individual benefit and for patriotic purposes.

Between the Montana boundary and the Arctic Circle, not counting those in the Fort Norman district, four wells were abandoned during the past year and fourteen are in various stages of progress. Mr. Ross did not specify the discarded sections. Some of them were in eastern Alberta, western Saskatchewan, and at Great Slave Lake, one was at Twin Butte, in southern Alberta, when a depth of 3,975 feet was attained. Territory so expansive and the non-participation of other important oil interests, left the Imperial company to its own resources, practically unaided. That some of the fourteen wells now proceeding are "regarded as fairly promising", according to Mr. Ross, precludes final judgment and provides an argument for immediate co-operation by the Dominion Government in order to hasten the proving process. Abandonment of the Czar-Monitor section; discouragement at Great Slave Lake; stopping of the work at almost 4,000 feet at Twin Butte, where great depth in any event would necessitate greater production than ever was obtained in Southern Alberta, make imperative a round-table conference at Ottawa and a revision of National Policy. At Pouce Coupe a 10,000,000 feet daily flow of gas for which there is no market, is substantial inducement for the continuation of drilling, although there is a plenitude of oil and a paucity of gas in the Irma section. However, Pouce

Coupe has possibilities, and the irony of it is that President Smith of the subsidiary International Petroleum Company reports that production has increased in Peru while Colombia prospects are brightening.

So, with Canada providing only two per cent. of its domestic requirements, and a tone of interrogation permeating the official utterances of Imperial company executives, it devolves upon those with vision large enough, to give more momentum to aggressive explorations. The scope of this National Work is altogether too narrow as at present conducted. Directed by Imperial experts there is maximum efficiency and heavy outlays upon field forces and equipment, and, until lately, a disposition to interpose impediments. That the testing of Canadian petroliferous areas will require years of unremitting effort, is more generally appreciated. The cost of the Fort Norman Well is not to be considered as a criterion. Otherwise it would take a century or two to reimburse the Imperial company, even though the production become marketable. Recent advices are that very promising areas are offering themselves in the Far Northwest. Ponce Coupe is accepted upon approval. Southern Alberta and Saskatchewan call for intensive drilling to depths which must yield oil commensurate with the cost of the wells. In our National prospectus wells are no less vital to Canada and its internal economies than the Wilsonian "points" were as the basis of international amity.

Messrs. Stillman, Smith and Ross have not overstated the situation. Canada is little better off in the matter of a domestic supply of oil than it is in regard to the supply of iron ores to its furnaces; and means must be devised whereby more Canadian coals will find home markets. Imperial Oil officials do not despair of developing Canadian oil fields. They cannot offhand do all the necessary exploring in a great expanse of territory. It is contrary to the scientific conception of the geological ages as they are revealed or believed to be represented that large deposits of iron ore and the large reservoirs containing oil stopped at the border.

Thus far it has not been demonstrated that the states of Wisconsin, Minnesota, Montana, North Dakota and Oregon have proved or possible oil areas comparable with those of Wyoming or Colorado. At the lower end of the great lakes, Ohio Pennsylvania and New York led in the development of the American oil industry which in 1920, as Mr. Victor Ross stated in his "Evolution of the Oil Industry", then represented an aggregate investment in the production, transportation, refining and distribution of petroleum and its products of $7,310,000,000. What really began in Pennsylvania in the fifties of the past century, and spread over the adjoining states, eventually including over forty states resulted in 1919 in a total production of 377,000,000 barrels of crude oil, besides which 53,000,000 barrels were imported, mostly from Mexico. Toward the immensity of the oil industry, states adjacent to or bordering upon Canada have contributed in large measure. Washington Geological Survey experts last week reported the following as the remaining estimated supply:

States	Millions of Barrels
New York	100
Pennsylvania	250
West Virginia	200
Ohio	190
Indiana and Michigan	70
Illinois	110
Kentucky, Tennessee, Northern Alabama and Northeastern Mississippi	175
Missouri, Iowa, North Dakota, Wisconsin and Minnesota	40
Kansas	425
Oklahoma	1,340
Northern Louisiana and Arkansas	525
Texas except Gulf Coast	670
Gulf Coast Texas and Louisiana	2,100
Colorado, New Mexico and Arizona	50
Wyoming	520
Montana, Nebraska and South Dakota	100
Utah, Nevada, Oregon, Washington and Idaho	80
California	1,350
Eastern Gulf, Coastal Plain and Artlantic Coast States	10
Total	9,150

As annual production by the States now is nearly 500,000,000 barrels, and "annual consumption already well beyond the half billion mark", the conclusion of the American scientists who have canvassed the situation is, that the assured American supply is sufficient for twenty years, provided it can be recovered as fast as wanted. That other fields will be discovered, is not doubted, and the Director of the Geological Survey has this by way of further explanation:

"The estimates of oil in 'possible' territory, are absolutely speculative and hazardous, and that, although they represent the best judgment of the geologists, they nevertheless may be, at least in part, wildly erroneous. The questions involved are not only how much a particularly doubtful region will yield, but whether it will furnish any oil whatever.

"On the whole, the estimates are undoubtedly the best that have ever been made for the United States, and better than have hitherto been prepared for any oil country or district of the world.

"Of the total estimated oil reserves of the United States amounting in round numbers to 9,000,000,000 barrels, 5,000,000,000 barrels may be classified as oil in sight and 4,000,000,000 barrels as prospective and possible. Rather more than 1,000,000,000 barrels should be assigned to the heavy oil group. These oils will be recovered mainly in the Pacific Coast, Rocky Mountain and Gulf States. The contents of the Lima-Indiana region, which yields oil of a distinctive type, are estimated at 10,000,000 barrels. In general, the so-called paraffin oils of medium and high grade, as contrasted with the heavier oils, amount in all to about 5,000,000,000 barrels. The estimated reserves of high grade oils of the Appalachian States are about 725,000,000 barrels.

"These estimated reserves are enough to satisfy the present requirements of the United States for only twenty years, if the oil could be taken out of the ground as fast as it is wanted. Should these estimates fall even so much as 2,000,000,000 barrels short of the actual reserves, that error of 22 per cent. would be equivalent to only four years' supply, a relatively short extension of life.

However, the Committee expressly warns the [illegible] common assumption that, because the estimated reserves appear to be sufficient to meet the needs of the country at the present rate of consumption for twenty years, therefore the reserves will be exhausted at the end of that time, or at least a few years. This assumption is absolutely misleading, for the oil yet to be found within that length of time, and the wells will be opened over many years as the pools are found, and the wells cannot be pumped dry so quickly."

Whatever consolation one can find in the estimates of the oil reserves of all the States, the Director of the Geological Survey hastens to repeat the assurance that not

all of the nine billion barrels or more may be discovered, must be produced, within the specified twenty years. Meanwhile the "independence" of the States is assured and the life of the domestic supply will be prolonged "if foreign oil can be procured". Failing the latter, it is admitted that American "dependence is sure to grow greater and greater as our own fields wane, except as artificial petroleum may be produced by the distillation of oil shales and coals or some substitute for petroleum may be discovered".

Of the likelihood of improved methods of recovering additional oil from the ground, it is prudently held that this is contingent upon so many factors that further forecasts "would probably contain errors enormously greater than those inherent in the estimates made on the basis of methods now in use"; because it is only in northwestern Pennsylvania and southwestern New York that geologic conditions are so well known, and the experience with improved methods on a commercial basis so extensive, as to justify the formulation of estimates based on the results obtained.

Urging that the Government at Washington give most serious study to the more complete extraction of the oil from the ground, as well as to the avoidance of waste, either through direct losses or through misuse of crude oil or its products, the signatories to this compendium have made clearer the full import of Mr. Stillman's statement about Canada's "dependence upon foreign sources of supply for crude oil". Knowing the producing and consuming capacity of the United States, and having foreknowledge of what is going to happen if the United States derives no supplemental supplies from Mexico and elsewhere throughout the next twenty or twenty-five years, Imperial Oil subsidiaries are busy in Central and South American areas; the parent company in Canada is spending more than is admitted in the search for domestic oil, and the Standard of New Jersey and Indiana are conducting world-wide operations.

Canada is singularly remiss in its appreciation of the urgency of this National Work. Interest is confined to those who hold millions of acres on the off-chance that the other fellow will prove up something. Three barrels per day is the grand aggregate of actual new production. It may take years to locate a field such as the midwest, of a half dozen square miles, if there are not many more to be had, that will be of "commercial value", yet him the meaning of Mr. Ross. At this writing those who know most about their National Work and its probable results, may be in doubt as to whether they are courageous or foolhardy, yet they have that twenty year finding of Washington experts confronting them and even Columbia and Peru are not despicable as lines of industrial defence.

All the eligible country held by the Government and the railroad systems make a respectable "jackpot" for a high stakes game.

CORRESPONDENCE

Our Mineral Resources.

To the Editor, Canadian Mining Journal:

Sir,—

In an editorial in your issue of Dec. 9th you stated: "Canada's known and ascertained mineral wealth is large. Her potential wealth of this character is possibly, judged by the standards to which we are accustomed, almost illimitable."

It seems almost impossible these days to pick up a paper without reading something extravagant in regard to the mineral resources of our Dominion. There is some excuse for this in the daily papers, whose writers are in the same class with the public, which considers a mountain synonymous with mineral wealth, but in the Canadian National Mining Journal the facts should be set out with becoming moderation.

While our mineral wealth may be "huge" when compared with the reserves available at Confederation it can hardly be considered so when the amount of prospecting that has been done since then and the size of the country covered is considered. Compared with the United States, a country of similar size, our reserves show up rather poorly. Why protest against the boom language of the promoter when you use such words as "illimitable" to describe resources which are, from the evidence that has been piled up, extremely limited?

I would like to draw your attention to a few points not generally considered. In British Columbia we have a continuation of the ranges that have produced the great ore-bodies in the United States. British Columbia was for many years advertised as "The Mineral Province of Canada" and it is only natural that it should occupy that pre-eminent position. It has been the home of numberless prospectors and the operating ground of numerous capable and enterprising mining companies. Its mineral districts have been examined in detail by hundreds of engineers, some of them representing these companies and others representing capital in different parts of the world. It has produced many million tons of ore and if there is one place in the Dominion where there should be "illimitable" mineral wealth that place is the Province of British Columbia.

Do you know, Sir, that in this province, during the past quarter of a century, there has not been one solitary discovery of ore of outstanding importance?

There are only two areas in British Columbia that have produced mines of this class. One is the strip along the southern boundary and the other is the strip along the coast. The main line of the C. P. R. has been in operation since 1886 and has never tapped anything worth while. There are not only no large mines along the Canadian Northern main line, the Grand Trunk Pacific main line, the Pacific Great Eastern or the Interior Waterways, but the mines of any kind in the areas covered by these routes are almost negligible and yet these railways and waterways block out the greater part of the province.

* * *

The chief point I wish to make however, is that it does not take long to go over the outcrops in a district and the important deposits are soon located. After that it is only a question of determining the size of the big mines when the date of the wind-up can be approximately arrived at. It can, in fact, be stated as a law, and doubtless has been, that the mines in any district are all located within a very brief period.

* * *

The first fifty years of our national life has been the period of Exploration and Discovery of our mineral resources over our accessible areas. It has also been the period of Consumption of a large amount of them. A very large area of country has been covered and the outcrops examined. In the best areas much intensive work has been done in the way of trenching and diamond drilling. The result has been that the total of our ore reserves is far from commensurate with the important position we would like Canada to take in the world and this should be a matter of alarm and consideration rather than misrepresentation.

Doubtless there will be, due to the covering of recent

geological deposits, and forest growth, many deposits that, like the flowers that are born to blush unseen, will never be uncovered. This is to be deplored but, with our present system of prospecting, it cannot be helped.

I have said that the Boundary ore-bodies contained 20 million tons. I am subject to correction, but I do not believe any other similar area in Canada, with the exception of the Sudbury district is known to be capable of producing appreciably more than that tonnage, and I am inclined to believe that the operators in some of the areas would be glad if they were sure of half that tonnage. This is not "huge". It is small compared with the 200 millions of the Braden, the 350 millions of the Chili Copper or the 400 millions of the Utah Copper. Mr. Corless' evidence before the Nickel Commission is to the effect that the Sudbury area, as a whole, has 70 million tons blocked out and that a possible tonnage of twice that figure is very doubtful. This tonnage, taking into consideration the grade, indicates Canada's most valuable mining asset, but with three large smelters working on it, its life is obviously limited.

The Boundary mines lasted 20 years. That is but a brief period in a nation's life. The Cornish deposits, now exhausted, lasted 2,000 years and the British are still a virile race. At the present rate of production the exhaustion of all the large Canadian deposits is therefore in sight. With the exception of the Flin-Flon there are no recent developments that will add appreciably to the tonnage and it is doubtful if the Flin-Flon, even after fully developed, will produce more than 20 million tons.

The Flin Flon is the representative of the Huronian, a formation not found in British Columbia. Much is expected from these mineral areas that are found at intervals in the Laurentian from Lake Huron to the Arctic. The Flin Flon, discovered about ten years ago is still in a class of its own in Northern Manitoba. It is doubtful, however, if all the outcrops in this particular Huronian area have been examined, as the war and the inaccessible location of the country have handicapped prospecting. The outlook for further important strikes in this area is, however, getting poorer every day. In other Huronian areas in Northern Manitoba prospecting has, so far, been conducted with negative results.

* * *

In regard to Quebec and the Maritime Provinces, asbestos is the only mineral except coal that figures in the millions column when it comes to yearly production. It should also be noted that asbestos is a non-metallic mineral and when it is necessary to include this mineral and also cement, drain tile, sand and red brick to make out a claim as a mineral section I think it is about time to stop bragging and realize what we are up against. These provinces contain a quarter of our population and probably about a quarter of our area; they have been settled, Labrador excepted, for hundreds of years and if there is any inconceivable mineral wealth there it is time we received a little on account.

I have not referred to the coal resources. In the last volume of the Transactions of the C. M. I. Mr. Herd says, "The Sydney coalfield undoubtedly contains a large tonnage but it has not the illimitable resources popularly supposed." On the Pacific coast the Nanaimo coal field is the most important. According to Clapp's Memoir it contains 1,340,000,000 tons. This is a tonnage worth while, but the trouble is that what a coalfield contains and what is recoverable are two widely different totals. This estimate includes seams one foot thick and assumes extraction to a depth of 4,000 ft. Present practice on the Island is to recover only about half the coal when it is over three feet thick and there are indications that a 4000-ft. depth is out of the question.

* * *

The Alberta coal reserve was delivered to the wrong address. It should have been left on the Pacific Coast or near Montreal. If we are to boast of inconceivable wealth some iron should have been left with it. A much smaller coal area would have done for Alberta even should a considerable amount of manufacturing be done there in the future. At present it is needed mainly to supply a seasonal demand for fuel.

The possession of valuable deposits of coal and iron, convenient to each other, is what has put Britain, France, Germany and the United States well up in the industrial world. We have spent millions of dollars on a hot-house iron industry and we are prepared to spend more if circumstances justify it. Last year's report, however, shows that only about 5 p. c. of the iron ore used in Canada was from our own mines. Low grade iron ores are talked about, but so is gold in sea water, and the present status is that they cannot be made to pay on their merits. A country, the size of ours, that does not possess commercial deposits of iron is very badly handicapped and anything to the contrary is a dream. Improvements in scientific methods will help not only low grade iron ores but ores of all kinds. Thanks, however, to the kaiser and our mania for railways and consequent taxation, it will call for very marked improvement in methods before even pre-war costs are reached.

* * *

A mining engineer should be an optimist, but when a deposit has its length and breadth defined, and it is found that they are not abnormally large, it is time to cease dreaming of a Rio Tinto, for the bottom is usually not far off. The same is the case with the Dominion. The accessible parts, and that includes many parts accessible only with difficulty, have been prospected. That stereotyped statement that "our mineral resources have hardly been scratched" is therefore out of date. The character of the mineral wealth in the outlying areas remaining is for the future to determine, but if this wealth does not average better than the results to date the total for the Dominion can be very easily conceived and an approximate date for its extinction arrived at.

The above represents the condition of affairs as I see it. I consider the situation serious in the extreme and I consider such language as I have referred to as particularly harmful. While I believe that the best man available should be appointed as Minister of Mines — that is unanimous—I also believe he should be a man who realizes the gravity of the situation and is prepared to see that the best use possible is made of the balance of our mineral resources, rather than one who is imbued with the extravagent ideas that I have felt it necessary to combat.

Yours,

C. M. CAMPBELL.

EDITORIAL

THE JOURNAL AND ITS READERS.

Curious, but quite understandable, misapprehensions exist concerning the functions and meaning of a technical journal. To many, perhaps to the majority, a technical publication signifies merely that some misguided person believes there is money to be made in launching such an enterprise. It may be mentioned, also, that not a few professional men, men who really should know better, have a vague idea that the technical periodical is more or less parasitical. It were well to clear away at once these wrongheaded ideas.

The properly conducted technical periodical is an organic part of the professional body politic. It is not, and never has been, a very inviting venture from the investor's point of view. Indeed, it cannot become even self-supporting without the active assistance and continued moral support of its constituents.

What, it may be asked, constitutes the value of the technical periodical? This question is easily answered.

In the first place it is (always postulating the support of its constituents) the clearing house of current technical thought. It is the forum wherein are debated and resolved the urgent problems of today, and wherein, also, is foreshadowed tomorrow's progress. It is the guardian alike of professional liberties and of professional ethics. The advance of industry and technology without such a medium is unthinkable.

It is obviously impossible for one man, or for any small group of men, to sit in editorial chairs and there distil and distribute wisdom drawn from their own intellectual reservoirs. But, apparently, this fact is only dimly apprehended by the busy member of the profession. No one, alas, is more painfully aware of these facts than is the poor and plural editor. Indeed, it is not the editorial conscience that needs awakening.

To be explicit, the Journal calls upon its readers, both those of the laity and those of the profession, to send ideas, topics for discussion, records of events, and any and all matter that may stimulate thought and inspire debate.

To achieve this high aim, the intellectual energy, professional experience, ambitions and even prejudices of editors and readers should be syndicated.

Let us devoutly pray for this desired consummation.

DUST AND VENTILATION.

The prevention of illness among miners is a matter that cannot have too much attention. A subcommittee of the American Institute of Mining and Metallurgical Engineers has been studying the subject and has recently reported on some of its investigations. Among these is a report on dust and ventilation which is of interest to gold miners.

The harmful nature of fine rock dust, such as arises from the operation of drilling machines, has long been well known. To combat this a great deal of work has been done, notably in the South Africa gold fields. The use of water has reduced the danger, but there are indications that water alone does not eliminate the danger of phthisis. Ventilation is important, and the exhaustion of air through pipes from drives and winzes is highly commended. One writer points out that in South Africa the large dust counts are found in unventilated working places.

An American investigator, Harrington, states that the most effective prevention of dust in mine air, apart from the elimination of dry drilling, is the circulation of pure air at the working face. In South Africa Orenstein and Ireland also emphasize that air in stopes should be induced to flow along the face and not back in the open waste. The efficiency and comfort of the worker are increased by air movement.

The investigating committee reports that the U. S. Bureau of Mines, the U. S. Public Health Service, the American Society of Heating and Ventilating Engineers, the National Research Council, and cooperating [illegible]

versities are now engaged in extensive laboratory studies to try to formulate definite standards of temperature, humidity and air movement to maintain health, efficiency and comfort of workers. Useful results will doubtless be obtained. It is work that will commend itself to all.

THE MISSING LINK.

To meet the needs of our continent-wide country, to provide the explorer and the prospector with geological maps, the miner with much-needed information, and to perform all the multitudinous duties that a governmental technical department is supposed to undertake, Canada possesses an absurdly undermanned Department of Mines. Neither the Geological Survey nor the Mines Branch—particularly the latter—receives one-quarter the appropriation it should.

For this state of affairs it is patently unjust to blame either the Survey or the Mines Branch. Nor is it our intention to asperse in any way the fair fame of these afflicted sisters. Far be it from so. The blighting truth—a truth long known to the generality of mining men—is that no Federal Government seems to have the dimmest sense of the degree in which Canada's future is bound up with the exploitation of her minerals.

There is a gap between the Government and the governed, a gap easily bridgeable. To this end there should be provided suitable means for presenting direct to Parliament the claims and aims of the mining community. The creation of a separate Ministry of Mines may not be necessary. At any rate the Honourable Mr. MacKenzie King does not deem it so. But there is no denying that something must be done.

If Royal Commissions have not fallen entirely into disrepute, we would suggest the expediency of the immediate appointment of one, to examine into and report upon the distressful situation indicated above. Upon the wise selection of *personnel* the success of such a Commission will depend. Our only suggestion is that it should consist of as few members as may be consonant with its necessarily representative character.

As has been frequently pointed out in these columns, the earning power of our great National railway systems will never be even approximately normal until Canada's mineral possibilities receive the attention they deserve. It is not yet commonly realized that our National railways traverse areas that embrace the greater proportion of our known mineral-bearing lands.

Since mineral deposits are discovered and developed by mining men, the mining man is the only channel through which the government can act effectively.

OUR IRON ORES AGAIN.

In a paper presented at a meeting of the Toronto branch of the Canadian Institute of Mining and Metallurgy, Mr. R. H. Flaherty, one of the best authorities on iron ore deposits in this country, commented on the fact that it has long been the habit of Canadians to view our iron ores with scant appreciation and to exert an equally scant effort upon their investigation and development. The lack of investigation is indicated by the fact that there has been less than 50,000 feet of diamond drilling done on Ontario deposits, while over eleven million feet of drilling has been done in the adjoining State of Minnesota.

We have many iron ranges in Ontario and some exploratory work has been done on them without disclosing large bodies of ore of the same grade as that which is imported from the United States, free of duty and at cheap water rates. Mr. Flaherty is of the opinion, however, that some of the deposits already discovered could be worked profitably in the face of this competition. There are apparently many who have accepted the view that we know enough about our iron ore deposits to conclude that they cannot be counted upon to supply our iron. So long as this view is generally held there will be little investigation of the facts and we will have continued repetition of pessimistic views from men who have slight knowledge of the facts. The statements made by Mr. Flaherty should help to bring about more activity in exploration of iron ore deposits.

It is well known that the search for iron ore in Ontario has resulted in discovery of very large quantities of material that has an average iron content somewhat below merchantable grade. It is also well known that some attempts have been made to establish an iron mining industry and that these attempts have not been successful. It is, however, unsafe to conclude that none of our known iron ore deposits can be profitably worked or that we have found our best ones. We need more exploration and more effort in devising methods suitable to our conditions.

Those who are satisfied that our iron deposits cannot be profitably used will never determine whether or not this is a fact. The pioneers in this as in other industries will be found among those who attack the problem and keep at it until it is no longer a problem. Exploration of known deposits, search for other deposits, investigation and improvement of processes for treating the ores, may result in the establishment of an iron mining industry here. The optimistic views of Mr. Flaherty are refreshing and, in view of his knowledge of the subject, should have a good influence on the unduly pessimistic.

EDITORIAL NOTES.

Whiskey from Peat?

According to the 'Northern Miner' the Peat Committee has received an order from a leading Ontario distiller for a large shipment of peat. Enquiry brought out the information that the peat is used to give a smoky flavor to whiskey. The "Miner" predicts that a gigantic new industry may spring up along the T. and N. O. Ry.

Potash Deposits in Oil-bearing Rocks.

In drilling for oil in Texas, operators have found potash salts in numerous beds and many localities. They are just beginning to preserve samples of the sludge in such cases. The U. S. Bureau of Mines reports the analysis of these samples periodically, with a remark upon their imperfect nature. It seems not impossible that potash beds of commercial value may be located by this means.

One wonders if this possibility is being kept in view by those who are drilling wells at present in Canada. The chance of finding important beds of potash salts would seem to offer a reward comparable to that afforded by a "gusher", and the scrutiny necessary to identify the salts in the sludge would not add materially to the cost of the well.

A Generous Geologist.

In a recent issue of "Science" there is a description of the gift made by Dr. I. C. White, since 1897 State Geologist of West Virginia and distinguished for his contributions to the geology of coal and petroleum, and Mrs. White to the University of West Virginia and the City of Morgantown. The gift consists of 1,911 acres of coal land in Marion county, and officers of the Geological Survey estimate that the tonnage of the acreage will approximate 15,000,000 and on a conservative royalty basis should yield at least $4,000,000 over a period of years, $2,000,000 to the city and $2,000,000 to the university.

By the deed of gift the university funds are to be used to equip and maintain a geological department at the State university. The city's share is to be employed for the purchase, improvement and maintenance of a public park and for securing, equipping and maintaining a public hospital.

Dr. White, the generous donor, is well known to most Canadian geologists. He is sometimes called the father of the anticlinal hypothesis, which has been of such great service in the development of petroleum and natural gas fields. A year ago, at the meeting of the Geological Society of America in Chicago, he was the retiring president. Dr. White's career illustrates the fact that a study of pure science sometimes leads to great economic results.

Mine Telephones and Gas Explosions.

That telephones used in coal mines may be the cause of mine explosions is shown by investigations carried out by the U. S. Bureau of Mines at the experiment station at Pittsburgh. The ringing of the magneto makes the telephone in gaseous atmosphere a source of danger. In the trials numerous ignitions and explosions were obtained in a gallery in which there was a mixture of natural gas and air.

The results of the investigation should lead to more care in the use of telephones in coal mines. A type of instrument that lessens the danger should be used. The ordinary mine telephone is not explosion-proof.

Map of Gowganda Silver Area.

A new map of the Gowganda Silver Area is just off the press and copies can be obtained on application to the Department of Mines, Toronto. This map was published to accompany a report on the area by Mr. A. G. Burrows of the geology staff of the Department. The surface geology has been carefully plotted and there are two sections showing the structure. The report is still in the hands of the printers, but it also will be available in a few days.

RIBBLE MINES LTD.

Ribble Mines Ltd. has been organized in Ontario with a capital of $2,000,000 to finance mining enterprises. The first business of the company will be the development of the Wasapika gold mine. The directors of the new company are Geo. R. Rogers, president; R. E. Hore, L. J. Lahay, J. E. Day, and J. C. Mahon. The head office is in Toronto.

LAMENTATIONS.

Now, woe is me that ever I
Chose Mining Engineering;
Life's zenith is distressing nigh;
Gaunt poverty is leering.

More woe is me, and woe again,
That, when I did the choosing,
I chose a life so full of pain —
The prize forever losing.

Well, lack a day! chen! alas!
Fees furnish feeble feeding;
Employers turn me out to grass;
Promoters do the leading.

I have no bailiwick, nor home;
No hearth to warm my feet at;
With growing years the more I roam;
'Tis sure enough to greet at.

Yet did I once more make my choice,
Despite my bitter sneering,
Methinks I'd give a willing voice
To Mining Engineering!

ANON

PERSONALS

Mr. W. R. Wilson of Fernie, B.C. and Mr. Norman R. Fisher of Thetford Mines, Quebec, are candidates for the presidency of the Canadian Institute of Mining and Metallurgy.

The Ontario candidates for the two vacancies on the Council of the Institute are John McLeish, W. H. Collins, James McEvoy, Geo. C. Bateman and D. E. Keeley.

Mr. A. J. Young has been elected president of the Atlas Gold Mining Co.

Trail Smelter In 1921

Metallurgical advances again keep pace with declining prices; Lead and Zinc Plants break their best records; Machinery for projected Kimberley Concentrator will be made in Tadanac Machine Shop; year ends with accumulated stocks well reduced, chiefly on foreign orders.

Metallurgical advances in the treatment of the zinc-lead ore of the great Sullivan mine at Kimberley have for the second year in succession kept full pace with the declining prices of those metals, and have enabled the Consolidated Mining and Smelting Company of Canada to keep in continuous operation the group of plants at Trail, known as the Trail smelter. These advances, with the large tonnage upon which they have been put into practice, have been the vital factors in enabling the company to maintain operation during a very difficult year, for the sake of the mining industry and of the communities dependent upon the company's activities.

In following this course, the Consolidated has been in rather conspicuous contrast to the smelting industry of the continent as a whole, many tremendous plants being absolutely cold. In copper for instance, there are idle smelters at Great Falls, Anaconda, Garfield, and Mason Valley. The Tacoma plant is down to 60 per cent of its capacity. In lead, Tooele has been shut down completely. Midvale and Murray are running on much reduced tonnage, and Bunker Hill and Helena have each only one furnace going. The Great Falls zinc plant, while shut down for the greater part of the year, is now running at about 25 per cent. The confession of these companies that use their own ore, that they cannot operate profitable at present, explains perhaps why lesser producers have also had a hard time.

Lead and Zinc Break Records.

So far as lead and zinc are concerned, Trail has broken all its records, and the smelter is operating, and has operated throughout the year, full blast. For the last six months every plant at Trail connected with either of those metals has broken its own record month by month, incident to the improvements in treatment. There is another angle to this, it being obvious that large scale operation is necessary if costs are to be at the minimum, which they must be in order to make operation reasonable. An example of this expansion of output is the test mill at Trail, built for the Sullivan ore, whose original capacity of 500 tons per day has now worked up to 1,000 tons which is probably not yet the limit. The lead and zinc ores are no longer shipped separately, but all the Sullivan ore goes the one route, being separated in the course of milling, the zinc plant producing lead concentrate as a by-product.

The essential point is that the concentrator is recovering more lead as a high-grade lead concentrate, and more zinc as a high-grade zinc concentrate, so that a ton of Sullivan ore nowadays yields more pounds of refined metal than such a ton did formerly. This is a very moderate statement of the facts. Various processes have been devised and given a trial in the test mill, but flotation is the basis of the present satisfactory recoveries. Incidentally a certain old criticism of the Trail smelter must now be revised, for it can no longer be contended that the Sullivan ore is being financed at the expense of shipments from private mines, when there is no zinc ore from private shippers to mix with the Sullivan ore.

Progress At The Sullivan.

While the metallurgical staff at Trail has been winning its victories over the Sullivan complex ore, the mines department has further developed the great property by putting through the raise from the "tunnel" below to the "hill" above, thus connecting the two mines by an air-way that in the course of time will be utilized for taking out the ore below the level of the upper workings. The "tunnel", which was driven to the ledge in 1920, is at present furnishing the bulk of the ore. The most modern methods are, of course, used in mining the ore, power scrapers being used to haul the broken-down ore into the raises, where it reaches the cars by way of chutes, or, where conditions are suitable, the cars are loaded by mechanical muckers.

Copper Output Lower.

Though the Trail smelter has operated during 1921 on a larger tonnage than ever before in its history, this record has been made in spite of a reduction of its copper tonnage. The copper market has been a strict mistress, for in this case there has not been the opportunity for compensating advances in metallurgy. During the last half of the year the Emma, the Consolidated's principal property in the Boundary, was not operated, and the company's famous Rossland mines are being asked for considerably less than their normal tonnage. Throughout the year the big property of the Canada Copper company at Copper Mountain, near Princeton, whose concentrates Trail prepared itself to handle, was not operated. In fact, from five to ten tons a day has been the output of the copper refinery during 1921.

This is not for want, however, of capacity. Early in the year the extensions and improvements were completed that enlarged the capacity of the copper refinery from 30 tons to 70 tons, the extension having been made to secure more economical operation.

Copper Rod Mill Awaits Duty.

The rod mill, with a capacity of eight tons of copper or brass rods per eight-hour shift, could be put into operation at a few days' notice. The building is of re-inforced concrete, with steel roof and cast iron floor, and the plant comprises a Hoagland mill of the very latest pattern. All the machinery is in the building, and most of it is set up, ready for use. Rods and wire bar are the only forms of copper that now come into Canada duty free, and the New Jersey and New York plants, by reason of proximity, have the market. If the duty asked by the Kootenay is placed on these forms of copper, the Trail plant will be able to add this new branch to Canadian industry.

Financial conditions have dictated practically the entire suspension of development work in the company's many minor properties and prospects, owned or under lease, and the company's mining activity has been central on the Sullivan and the Rossland group of properties, with the Emma for a portion of the year. That some large properties in the Kootenay

can successfully operate under present market conditions is gratifying, when contrasted with the fact, for example, that $40,000 is being dispensed monthly as charity in a mining center like Butte.

Development Program.

The same financial conditions have naturally shelved temporarily both the development projects that are popularly supposed to be on the Consolidated's program for the future. When the time comes when they can again be considered, it is expected that the large concentrator at Kimberley for the Sullivan ore will have the preference, for when that is built it will release the present test mill at Trail, for the use of Rossland ores. When built, this concentrator will save fortunes in freight on the carriage of the crude ore from Kimberley to Trail, and its successive units will enable the Sullivan to multiply its output.

Similarly, the proposed concentrator for the Rossland mines, at a location said to be already chosen adjacent to Trail, would result in multiplication of the Rossland tonnage.

A necessary part of the development program, when it comes, will be the further development of the big plant at Bonnington, of the West Kootenay Power and Light company, now a subsidiary of the Consolidated.

Make Own Machinery.

An interesting present development is connected with the company's machine shop at Trail, now supposed to be the finest in the province. From now on, it is proposed to construct at Trail as much of the machinery required by the company as possible. This will be more satisfactory than buying it, and it will often be more economical as well, beside the consideration of giving employment to workmen at Trail. A lathe is to be installed that will swing a cylinder 10 feet in diameter and 17 feet long, or one 20 feet in diameter and three feet long. It will be possible for the Trail shop to make all the machinery required for the Sullivan concentrator except the motors and crushers, and it is not improbable that work on this machinery may be started before long.

The Financing Problem.

A desire to push its new Sullivan ore treatment processes to completion, and the desire to hold together a highly efficient organization, added weight to the considerations against shutting down the Trail plant, and along with it a good deal of the Kootenay, at a time when other mining companies bowed to market conditions and refused to deplete their ore reserves without hope of profit. But it has been difficult going.

Not only were metal markets low, but also in many cases they were fictitious, and there was not a real demand behind published prices, the result of offering metal at current quotations being to further break prices, with perhaps no sales in the end. All over the globe, markets for the metals produced at Trail have been assiduously sought.

During the greater part of the year the store of metals at Trail has been increasing despite the best efforts of salesmanship. During the last two months, however, the lead pile has been pretty well reduced, two thirds of it being sold to foreign markets, while most of the home consumption has been from Tadanac. The zinc sales have also been picking up materially, though Canada takes very little of this product, most of it being sold abroad.

With easier financing, the Consolidated has notified the lead shippers that after January 1, settlements for their ore will be on a spot basis, changing from the 90-day notes that have been in use since September 1. Prior to that, Trail always operated on deferred settlements.

The full significance of the year's operations, taken inclusively, will not be grasped till it is recalled that zinc, which is the basis of both the year's tonnage and much of the year's income, is selling today at a cent less than the average of the 10-year period preceding the war, and that lead, its companion metal, is down to the pre-war price.

Still The Keystone.

The Trail smelter is the keystone of metal mining in British Columbia. It is a unique collection of plants that so far as known is not duplicated in the world. It comprises:

A copper smelter.
A lead smelter.
A zinc plant.
An electrolytic lead refinery.
An electrolytic copper refinery.
An electrolytic zinc refinery.
A refinery for the precious metals.
A copper rod mill, not yet operated.

A number of these plants, including all three electrolytic refineries, are the only ones of their kind in Canada. Including plants, ore, and stocks, the company's investment from year to year according to its annual reports, amounts to $17,000,000 or $18,000,000.

While the mining interests of the Consolidated increase from year to year, and its own tonnage exceeds by many times the aggregate tonnage of private shippers, its plant is, of course, at the public service, and at some stage or other is used by practically every mine in this territory, and by many beyond the provincial boundaries.

The same market conditions that made it difficult for Trail to operate, temporarily put a blanket on Kootenay mining in general; but during the last six months the list of shippers has expanded to almost its usual proportions, though for the year just ended the custom tonnage is very light. The year ends, however, with a materially better outlook for mining generally.

OIL DISTILLATION IN NOVA SCOTIA

Toronto—The proposed developments of the Anglo Persian Oil Company and allied interests of the oil and shale territory in Pictou County, N.S., will be under executive control of the Oil and Nitrate Company with head office at Chatham, Ont., according to an announcement from London. This company will have charge of the development and construction, and will have the co-operation of the Anglo Persian Oil Company's engineering staff. It is proposed to immediately establish a plant on the property capable of treating 2,000 tons of shale a day.

In addition to the shale plant to extract the crude oil and ammonium sulphate, there will be refining facilities for handling a complete line of petroleum products.

A great deal of prospecting and experimental work has already been carried on by experts associated with the Anglo Persian, and the result has been a pledge of £5,000,000, of which £1,000,000 will be immediately available.

Mineralography*

by E. THOMSON.

The microscopic study of opaque materials by reflected light is not a new subject. For some years the metallurgists have used this method for the examination of metal surfaces, more particularly to bring out the microscopic character of various grades of steel products. In its application to the study of minerals it is especially useful for the determination of the opaque minerals, as these can not be studied microscopically by transmitted light. The optical properties which are so useful in the identification of the transparent minerals depend entirely on light passing through the specimen and will not serve in the case of opaque minerals. It is true that the few ores that are encountered as accessory constituents in rock sections can be determined with fair accuracy, by reflected light it may be noted in passing, but the method fails altogether in the determination of the multitude of opaque minerals to be found in ore deposits of various kinds. This very practical phase of the application of microscopy to the study of minerals is taken care of by the examination in reflected light, and a very high degree of accuracy in the determination of these ores can be attained in the majority of cases.

The pioneer work in this subject dates as far back as 1814 when Berzelius sliced and polished a specimen of pyrrhotite. He noted that the pyrrhotite was cut by small veins of another mineral but did not examine the section under the microscope. It would be unprofitable to repeat the names of all the investigators in this field since that time. It will be sufficient to state that only within recent years has the study attained any prominence, chiefly through the efforts of such men as Campbell, Knight, Graton, Lindgren, Murdoch, Bateman, Davy, and Farnham. The first two named carried out experiments on ores from Sudbury and Cobalt, describing the characteristics of the minerals in them. Murdoch published a text-book on the subject classifying the minerals on the basis of color and microchemical properties. Davy and Farnham collaborated in another book on the subject, in which the minerals are classified chiefly on the basis of microchemical reactions and to a lesser extent on their physical properties.

For the proper examination of the opaque section by reflected light a smooth polished surface of it must first be prepared, so that as much light as possible is reflected. This process is carried out in three definite stages, the first two being grinding operations and the last one polishing. In the first stage the mineral is ground down to an even surface, progressively finer grades of abrasives being used till the abrasion pits are very minute and of uniform size. The procedure varies slightly in different cases. Where it is desired to cut the mineral specimen in a particular way, the diamond saw may be used to advantage. In cases where the specimen contains two or three minerals of widely differing hardnesses the later stages of grinding with the finer abrasives may be lengthened to give a more uniform surface. The grinding may be carried out satisfactorily on motor-driven horizontally-revolving steel plates, or more simply by hand on a stationary steel plate, the abrasives being fed on along with water. In both cases the plates must be thoroughly cleaned of the abrasive last used before starting with that of finer grade. In the second stage of polishing the specimen is carefully beveled so that no sharp corners or edges remain to catch in the cloth with which the polishing wheels are covered. This may be done quite rapidly on a motor-driven emery-wheel. As some minerals change their composition when heated, care must be exercised during this operation to keep the specimen cool by constant dipping in water. In the third stage of preparation several grades of polishing powder are used, varying from fine alundum flour to rouge or tin oxide. The polishing of the section may be done roughly by hand but is much more effectively accomplished by machine. The machines used are of two types, the one with a horizontal spindle on which revolve two vertical wheels, the other with a vertical spindle carrying one horizontal wheel, which is kept covered when not in use to protect the surface from dust. Both of these have their advantages. The first one, while a little more awkward to work on, has the advantages of providing more than one polishing surface to the one machine and also of obviating the necessity of covering the polishing surfaces when not in use. The second one has the decided advantage of being easier to work on. The polishing surfaces are covered with linen for the most part, although in the final stage of the polishing a broadcloth or velours covering has been found very effective. The length of time the specimen is held on each polishing surface varies with the mineral mixtures. The polishing powders are mixed to a fluid paste with water and fed on wet with a brush provided for that purpose. To avoid any possibility of mixing the powders, separate dishes and brushes are provided for each, and these are kept carefully covered to keep out the dust. Between the stages of this polishing it is necessary also to wash thoroughly not only the specimen but the hands of the operator as well, so that none of the powder from one stage will be carried on to the next. After the final burnishing on the last surface the specimen is ready for examination. Where the section is very brittle the same procedure as for the preparation of friable thin sections by cementing with balsam, may be adopted. In specimens too small to be held in the hand, which would include mineral powders and mill-products, the material is embedded carefully in sealing-wax before being polished. In this way powders fine enough to pass through a 200-mesh screen may be given a very satisfactory polish.

The section, being now ready for examination under the microscope, is mounted in some plastic substance, preferably artists' clay, on a small glass slide of a size to suit the microscope used. Various schemes are employed to insure the exact horizontal position of the section, the simplest way being to place an annular ring of constant height around the specimen and then squeeze the section down in the clay with a level glass plate till the plate rests evenly on the ring all the way round. Any ordinary microscope with but one extra fitting may be used for this work. This extra part is called a vertical illuminator and consists of a short tube inside of which revolves a reflecting device and with an aperture at one side for admitting the light. The reflector may be of the plane glass, half-mirror, or prism types. This illuminator is placed immediately above the objective lens of the microscope. The light enters the small aperture at one side, is reflected or refracted

* A paper presented at the Toronto meeting of the A. A. A. S.

down to the polished section and from there is reflected up the middle of the microscope tube to the eye. The prism type of illuminator is the best one for this class of work and can be fitted in the Swift, Leitz, or Bausch and Lomb microscopes. The best work is done by daylight, preferably in the morning when the light is strong. For dark days or for night work, artificial light may be used, the source of light being placed close to the aperture in the illuminator. A convenient form of lamp for this purpose is the so-called "Daylight Lamps", equipped with a light blue glass in front of the light bulb, by means of which the colors as seen in daylight may be imitated fairly closely. In certain cases it may be desired to study effects in oblique light. The Silverman illuminator is especially designed for this part of the work. It consists of a circular lamp which clamps on to the nose of the objective. This appliance is particularly useful in the determination of the transparent ores, such as sphalerite, where internal reflections may be noted. For testing the hardness of the minerals a convenient instrument is the familiar shoe-makers' awl sharpened to a point. Only three grades of hardness, low, medium, and high are attempted in this work and these can be easily determined with such a simple instrument. The minerals with low hardness are scratched with little pressure, those with medium hardness with fairly heavy pressure, and those with high hardness very little if at all with any pressure. In the microscopic examination of the polished sections certain physical properties such as the color, hardness, relief, crystal form, and cleavage are used, but the microchemical reactions are of chief importance in the identification of the mineral species. A set of six standard reagents is used and the reactions of the mineral to each one carefully noted. Bottles fitted with a combined rubber nipple, stopper, and capillary-tube, are used to hold the reagents, a drop of the liquid being placed on the section at the spot desired by squeezing the nipple. A convenient text-book has been prepared by Davy and Farnham in which the minerals are listed in tabular form depending on their reactions with these standard reagents. With these tables as a basis one can run down the majority of minerals in fairly quick time, the one regrettable feature being the dependence placed on the effervescence with dilute nitric acid. Where the section contains considerable carbonate, this part of the tables has to be used with discretion. The reagents used are dilute nitric acid, dilute hydrochloric acid, a 20 p.c. solution of potassium cyanide, a 20 p.c. solution of ferric chloride, and saturated solutions of potassium hydroxide and of mercuric chloride. Special microchemical tests may be used for the detection of various metals, as for example the familiar dimethyl glyoxime test for nickel, or the potassium ferro- and ferri-cyanides for iron. Not only may the minerals in the section be determined accurately by this method, but the genetic relationships of the one to the other may be judged with quite as much accuracy as in the case of the transparent minerals in thin sections. This is of value particularly where the question of secondary enrichment is to be studied.

So that a permanent record of the various mineral sections may be kept, it is necessary to take microphotographs with instruments especially designed for that purpose. A convenient form of apparatus is the Bausch and Lomb Metallographic Outfit, which has a camera, microscope, condensing lens, and lantern fitted up on an optical bench. The source of light commonly employed is either the ordinary arc lamp, using very small carbons to produce a fine pencil of light, or a special electric bulb with a filament which will focus the light to a point. With this equipment, which may be fitted with an oil immersion lens, magnifications of over 1000 diameters may be obtained. For ordinary microphotographic work a magnification of 100 to 150 diameters is quite sufficient to bring out the detail desired. As most of the minerals differ from one another but slightly in color, light filters of various kinds are needed to show up the different minerals in these photographs. It is interesting to note in this connection that the two minerals, bornite and chalcocite, while radically different in color to the eye, are indistinguishable in the photograph unless a color-screen is used. Each combination of minerals presents a separate problem and the length of exposure, size of aperture, and color-screen to be used must be determined experimentally. Special plates with a very rapid emulsion are used and must be developed in green light, being sensitive to the red rays. Tank development is to be recommended as giving more uniform results.

This method has numerous applications, not only in the study of solid minerals, but also for the examination of fragmental material and mill-products. Not only may the individual minerals contained in the specimen be determined with a good degree of accuracy, but also their size, shape, and relation to the minerals associated with them. The practical value of this is strikingly illustrated in the case of certain ore deposits, which contain large tonnages of valuable mineral and would appear on casual inspection to be worth development. On microscopic examination of the ores concerned however, it appears that the minerals are so intimately mixed as to make the separation of them too costly for profit. The genetic relationships of the ores may be studied by this method with very satisfactory results, the primary and secondary minerals being frequently quite easy to distinguish. The value of this determination in the case of deposits where secondary enrichment may be expected need not be emphasized here. As an aid to the various stages of milling this method should be invaluable, although this phase of the subject is still in the experimental stages. The separation of different minerals in the crushing of ores may be satisfactorily traced by microscopic observation of the particles in each stage of crushing. In very many ores, two, three, or even four minerals are intimately mixed together and it is a matter of supreme importance to the mill man to determine the size to which the particles must be crushed to separate the valuable from the valueless mineral. Not only the ore in the different stages of crushing but also the concentrates and tailings from the other milling processes may be polished and examined in this way. The importance of this from an ore separation standpoint is obvious. But the most important function of this method of microscopic determination is to serve as a control over chemical analysis. Take for example an ore which on analysis shows certain proportions of copper, iron, and sulphur. The analysis which only tells the quantities of these elements present, may be supplemented by a mineralographic determination which discloses the presence of the minerals bornite, chalcocite, and pyrite, and which shows the approximate proportions of each. I quote from an actual case where only bornite and chalcocite were visible in the hand specimen. This is a very simple illustration and the value of the control is better shown in more complicated mixtures. The

Port Arthur district, or more particularly Silver Islet, was credited for some time with a rare silver arsenide called macfarlanite which had been found nowhere else in the world. It is true the analysis looked rather peculiar, listing appreciable amounts of nickel, lead, zinc, and sulphur as well as the silver and arsenic, and many of us suspected its individuality as a true mineral species, but nevertheless it was listed in Dana's System of Mineralogy. A year ago last summer when the old Silver Islet Mine was unwatered an opportunity was afforded Professor Parsons of our department to collect some of this macfarlanite material for microscopic investigation. When polished and examined it proved to be a mixture of native silver, niccolite, and galena, with smaller amounts of sphalerite. Another illustration of the success of this method when applied in this direction was encountered in the case of the mineral dyserasite, an antimonide of silver the analysis of which varied from about Ag3 Sb to Ag6 Sb. On examination under the microscope the variation was traced to a more or less graphic intergrowth between native silver and a silver antimonide, the latter presumably corresponding to the formula Ag3 Sb.

In conclusion it would appear that this method opens up a very wide field for the microscopic investigation of the opaque minerals. For the economic geologist and the mineralogist it furnishes quite as much microscopic evidence as a thin section of the transparent minerals is rocks and will have infinitely more practical value. All determinations have so far been carried out in ordinary light, but there are possibilities in the direction of observation in polarized light that have not as yet been tested.

GOVERNMENT OWNERSHIP OF MINES.

by J. A. McRAE.

Government ownership of mines would probably retard progress and would rob the country of the great benefit of the individual enterprise that is so essential to the speculative business of mining, particularly in the early stages of exploration and development.

In regard to precious metal mines, particularly gold, it is probable that government ownership would be disastrous. The reason is this: the prospecting and exploring of mining land is extremely expensive and is carried on for the reason that when success is achieved it is usually highly lucrative. Students of mining have estimated that for the recovery of each ounce of gold produced throughout the world, which has a fixed value of $20.67 per ounce, there is between $35 and $40 spent in one way and another. That is to say that the government would sustain a loss of perhaps $15 on each ounce of gold produced. It is true that the government could take over the mines that are already established and could operate them at a substantial profit; but the business of carrying on exploration work would gradually consume these profits and the industry would develop into a liability.

Prospecting is done by men who devote a great part of their lives to the work, without wages or compensation of any kind unless they are fortunate enough to stake something saleable. These prospects are purchased by promoters who organize companies and sell stock to the public. The loss of $15 per ounce on each ounce of gold produced the world over is thereby distributed over prospectors and speculators who are gambling on the long odds. Occasionally, success is achieved and prospectors make fortunes while stockholders become millionaires. Those who lose, either quit or save up for another venture, while new speculators are created by the fortunes made by the lucky ones. The world is ever ready to forget about the failures, and to point out the courage of the successful men who have taken a chance.

By all means, let us discourage any thought of government ownership of precious metal mines. The wide expanses of Northern Canada are crying out for men of courage, initiative and enterprise to blaze new trails at some cost and personal sacrifice. Reward is offered to only a small percentage, but falls in lavish abundance in the laps of the lucky few.

In the northern parts of the provinces of Ontario, Quebec and Manitoba, especially Northern Ontario, Nature has placed a veritable storehouse of fortune. The gold-ore deposits already found in Northern Ontario offer the possibility of yielding eventually a billion dollars, while farther north lie virgin fields.

These facts are given, not with the intention of creating the impression that fortune awaits all those that are prepared to do the pioneering. Not so; for the difficulties are many, the hardships of pioneering are frequently severe, and the obstacles are manifold.

Under government control, the incentive to exploration would become minimized. Self-sacrifice, courage and the willingness to endure harship are the products of voluntary action, generally for individual gain. Out of this there arises an industry that bestows riches upon the successful, while the benefit to the government is the establishment of mining enterprises and the creation of communities that in turn are taxable, and thereby contribute their share to the maintenance of government.

The progress of the mining industry rests upon our continuing to give the individual an opportunity to succeed in a big way, if at all. The cost of paid pioneering would be so great as to definitely preclude the possibility of government ownership of precious metal mines in the Dominion.

A PERFECT MINE.

There is one perfect mine and mining town.

Every official of this mine and every man employed underground or on top always does his work well and never breaks the safety rules. There are never any accidents at this mine, nothing ever goes wrong, the working conditions are fine. Everybody is contented and happy, no one quits or gets fired. There is work every day and the pay is good.

The town is clean and sanitary; the houses are comfortable; there is a good school; there is never any sickness; all the prices are reasonable; no one ever offends his neighbor; and all is peace and contentment.

This is the Ideal Mine, located in Modeltown, Progressive County, State of Good Health.

PETROLEUM PRODUCTION.

New York.—World production of petroleum in 1921 is preliminarily estimated by the United States Geological Survey at 750,000,000 barrels, as compared with 695,000,000 barrels produced in 1920. Production of petroleum in the United States in 1921, as indicated by the quantity transported from producing companies, compiled from company reports to the survey, amounted to 469,369,000 barrels, representing an estimated value at the wells of $753, 300,000, according to announcement made today. The high record daily average production of crude oil in the United States was reached during the week ended January 14, 1922, and was 1,430,710 barrels.

Northern Ontario Letter

THE GOLD MINES.

Will Develop Sturgeon Falls Power.

Confirmation has been received by the Journal correspondent that the Northern Canada Power Company has made the necessary arrangements to develop hydro-electric energy at Sturgeon Falls on the Mattagamai River provided the litigation with the Hollinger Consolidated Gold Mines is cleared up within a reasonably short time. At the time of writing from the mining district, the decision of the court in the power dispute is expected hourly and interest is running high. Should the matter be cleared up, the work of taking in supplies for the new development would commence almost immediately. It has been learned that the Sturgeon Falls could be developed within approximately nine months from the date of commencing the work, and this tends to hold out promise of the additional 7,000 h.p. being available for use at the mines by the end of the current year.

Present Power Situation.

With regard to the present power situation at Porcupine, it has been officially learned that the mines will get through the winter without shortage. Also, that the spring freshet will result in sufficient water being stored to assure all necessary energy up to the end of this year. The new dam at Kenogamissee Lake which was completed last fall will cause the water to rise back for twenty miles and will increase the volume in storage to approximately six times the former capacity. The importance of the arrangement to carry on additional development at Sturgeon Falls is that this will assure the producing mines not only of continued requirements as at present, but will provide the additional energy required to operate the big additions which are being made to the milling plants. Also it will assure energy for the smaller and newer properties which are in a state of exploration or development.

Dome Capital Reduction.

A special general meeting has been called for February 11 by the Dome Mines Company for the purpose of passing by-laws in connection with carrying out the proposed capital reduction. It is planned to empower the director to make capital repayments when desired without having to hold special meetings prior to each payment. The first of these repayments will be made on April 20, and will amount to $1.00 per share, thereby automatically reducing the par value of Dome shares from $10.00 as at present to $9.00 per share. It is generally believed that the Dome will be able to make a second reduction of like amount during the fiscal year. In the meantime, the regular dividends of 10 p.c. annually, are being paid. Shareholders are thereby assured of 20 p.c. during the coming fiscal year with good prospects of receiving 30 p.c.

Porcupine V. N. T.

An application has been cabled from London asking for power from the Northern Canada Power Company to re-open the Porcupine V. N. T. Mines. It is understood that the company is desirous of resuming operations almost immediately. Concerning this, the power company has given assurance that the required energy can be secured at the beginning of April. It is the plan of Major Bell of the Porcupine V. N. T. to continue the main shaft from its present depth of 600 feet to a depth of 900 feet. Lateral work will be extended at the 600 ft. level where good ore is already in sight, while another development level will be opened up at a depth of 750 feet and still another at a depth of 900 feet. Following the completion of this work, the $70,000 provided from the sale of 475,000 treasury shares at 15 cents each will be pretty well exhausted and the company will then be confronted with the question of financing further work from production. As to this, should development work continue satisfactory it is believed that the present mill might be operated on a scale that would provide additional money for further construction, either that or would warrant borrowing sufficient money to finance the building of a big plant. On the other hand, should results be satisfactory only to a limited extent it is not considered improbable that the concern might figure in a consolidation with an adjoining property on which a first class mill is already available to treat the ore.

Elbow Lake.

According to advice from a director of the Hollinger Consolidated Gold Mines, the reports have recently been wrong about this company having taken over property in the Elbow Lake district in Manitoba. The truth would appear to be that certain of the directors of the Hollinger, through a private syndicate, have interested themselves in an option on the property of the Murray Brothers and that considerable exploration work is planned.

Triplex.

Duncan B. Harrison of the Triplex Gold Mines, formerly the Tommy Burns and the Pope properties, has purchased the old mill of the Casey-Cobalt and plans to have the equipment taken down and shipped to the Triplex within a short time. No arrangements appear to have been made however with the power company for electric energy to operate the mill and this has lead to the belief that the equipment is not intended for use for some time.

Paymaster.

Some weeks ago the Journal made the announcement that Dr. Walter Harvey Weed had made an examination of the Paymaster property situated south west of the Dome Mines and had recommended that the shaft be continued to a depth of 100 to 500 feet. This report of Dr. Weed's has now been submitted. In the meantime the work in connection with deepening the main shaft has been under way for some weeks. Another cross-cut will be driven at a depth of 100 feet for the purpose of determining the average gold content of the 98 ft. wide body at that horizon.

Teck-Hughes.

During the next few months the development work on the Teck Hughes Gold Mines promises to attract widespread attention particularly on account of high grade gold telluride ore having been encountered at the 600 ft. level and on account of the decision to carry work as fast as possible to a depth of 980 feet. It requires little breadth of imagination to grasp the importance of what continued favorable development to that depth would be to stockholders of the Teck Hughes. Lateral operations at these lower levels will be well under way by the middle of the current year.

Queen Lebel.

At a depth of 18 feet on the Queen Lebel property the vein is stated to have widened out considerably, being of greater width than the shaft.

Ontario Kirkland

The first gold bar from the Ontario Kirkland Gold

Mines will be shipped this month and the indications appear to be that the enterprise will experience no difficulty in showing substantial profits. A rich strike was made on the mine this week at a depth of 150 feet where the vein is about six feet in width.

The Kirkland Lake Board of Trade is now lending its support to the agitation in favor of having the Kirkland Lake highway extended eastward through the townships of Lebel and Gauthier and to Larder Lake. An effort is also being made to encourage the Ontario Government to extend the Goodfish Lake road northward to the Lightning River Gold area.

THE SILVER MINES.

Kerr Lake.

Operations have been completely suspended on the Kerr Lake mine and no effort will be made to resume work until such time as wages and the cost of material declines considerably or until the price of silver increases. The result of development work during recent months has not been very satisfactory and it has been found that the low grade ore now in sight cannot be handled profitably under existing conditions. Harry Kee, manager, left a few days ago for New York and gave the foregoing information to the Journal representative at the hour of his departure. It is understood that some of the older employees of the company may be taken to Utah where the Kerr Lake is operating a silver property on a profitable basis.

Haileybury Frontier.

A feature of the work which the Mining Corporation of Canada proposes doing on the Haileybury Frontier property in South Lorrain is that a new shaft will be put down at a point from which to carry on exploration and development along the continuation of the fracture in which the Woods vein on the adjoining Keeley Silver Mines is yielding such high grade ore. While this work is being done, the present workings of the Haileybury Frontier will be kept open and there are said to be good prospects of the present known limited shoots of high grade ore being found to continue beyond their present known limits. It is not improbable that the ore taken out may pay the cost of the general plan of exploration and development work. In the meantime, the machinery which has been taken to the Frontier from the old Cobalt Lake mine is being brought into operation.

Nipissing's Report.

It is expected that the annual report of the Nipissing Mining Company will be out about the end of the current month and will show a production of upwards of three million ounces of silver during the past year. As regards ore reserves, nothing official has been learned. It is general knowledge however, that some very rich ore was developed during the closing months of 1921, but whether or not these shoots were sufficient to offset the volume of silver extracted during the year is not officially stated as yet.

Silver Producers at Cobalt.

Silver producers in the Cobalt district now include the following mines in order of importance: Nipissing, Mining Corporation, Coniagas, O'Brien and Bailey Silver Mines. The total pay roll is now between 600 and 700 men.

In an effort to get out of financial difficulties the Cobalt town council is considering a plan to appeal to the Ontario Government for more revenue by taxation of such mines as are producing silver from property held within the corporation limits.

May Re-open in Spring.

The decision to suspend operations on the Kerr Lake mine has not discouraged the belief that the Cobalt field will experience a fairly general revival of activity in the coming spring. Such mines as the McKinley-Darragh, Beaver Consolidated and Temiskaming are expected to figure among the properties being re-opened at that time.

Castle-Trethewey.

The incorporation has been completed of the Castle-Trethewey Silver Mines Company to take over the assets and liabilities of the old Trethewey-Cobalt Silver Mines, the deal as outlined recently in these columns being ratified in detail. It is hoped to soon get operations under way on the Castle property in the Gowganda district.

Boards of Trade meet at Timmins.

A meeting of the Temiskaming and Northern Ontario Associated Boards of Trade will be held in Timmins this month, and will deal particularly with problems of interest to the mining industry. It is probable that the questions of cooperation, transportation and motive power will figure prominently in the subjects of discussion.

Maidens Mines.

At a recent meeting of the stockholders and bondholders of the old Maidens Mine in South Lorrain there were two offers made by which the property could be de-watered and sampled with a view toward resuming operations. One of these came from Hugh Sutherland of Toronto and was rejected. A second came from Arthur Ferland of Haileybury and this was also rejected. It was finally decided to double the capitalization to 2,000,000 shares of the par value of $1.00 each instead of 1,000,000 as heretofore. The holders of bonds amounting to about $12,000 agreed to take stock in settlement. It is now planned to sell a limited amount of the new treasury stock as a means of financing the work of having the mine de-watered and sampled. Some arrangement will then be undertaken to have the mine placed under general operation.

Victory Silver.

At the time of dispatching this letter to the Journal a report has just been obtained that a large vein of exceptionally good promise has been encountered on the Victory Silver Mines.

VANCOUVER MEETING C. I. M. & M.

H. Mortimer-Lamb, secretary of the British Columbia Division of the Canadian Institute of Mining & Metallurgy, reports that arangements for the annual meeting to be held at Vancouver B. C. from the 13th to the 15th of February, are well in hand. One Session is to be devoted to the topic of prospecting and its encouragement, in which connection information will be presented regarding areas in the Province as yet unprospected and papers read on such themes as "aerial photography as an aid to the prospector" and the "diamond drill is a means of prospecting ore bodies." Coal mining also is to be given special consideration while the treatment of complex ores, a problem always before the operators of British Columbia, will be dealt with by W. G. Woolf, of the Bunker Hill & Sullivan Mining & Concentrating Co. M. Y. Williams will read a paper on the "Oil Possibilities of the Mackenzie River."

Mr. Harry Kee, manager of Kerr Lake mine, is in New York.

TIN IN NEW MEXICO.

Tin is found in a rather out-of-the-way part of New Mexico, from 60 to 80 miles by road southwest of Magdalena, in a high plateau country. It occurs as the oxide, cassiterite, in small scattered veinlets in rhyolite and as nuggets and grains in the gravels of the streams. The United States Geological Survey, Department of the Interior, has just issued, as Bulletin 725 G, a report by J. M. Hill entitled the "Taylor Creek tin deposits, New Mexico," which describes the deposits in detail. There is undoubtedly considerable tin in the district, but it is so dispersed through the rocks that profitable exploitation of the deposits under existing conditions is rather doubtful.

DRILLING WITH LOW-PRESSURE GAS.

The results of the investigation made by the United States Bureau of Mines, at the Petroleum Experiment Station, Bartlesville, Okla., in cooperation with the Osage Oil and Gas Lessees Association and the Mid-Continent Oil and Gas Association, relative to the use of low-pressure gas in oil field boilers for drilling purposes, have been incorporated in a report printed by the last-named association as a part of its Year book. Copies of the report may be had by applying to the Mid-Continent Oil and Gas Association, 506 Cosden Building, Tulsa, Okla.

British Columdia Letter

To glance at the extent and the methods of taxation of operating mines in British Columbia by the Provincial Administration is interesting at this time. The claim is made by some that the industry is hampered by these taxes, but an analysis would seem to indicate that the burden is placed where it can best be borne. Properties that have come to stand firmly on their own feet are affected. It is a matter outside the scope of this article to enumerate the measures taken to encourage the development of mineral claims to the point of economic independence.

All mines are subject to a tax upon income subject to certain exemptions and allowances. In the case of mines paying an output tax this income tax is collected only if it proves greater than the output tax. The output tax then is regarded as part payment of the income tax. In addition to the ordinary working expenses metalliferous mines are permitted to deduct from their incomes charges under various other heads. These may be enumerated and explained as follows: 1.—Development, the allowance granted for such work being the proportion of the capital expenditure in the course of the year's operations which may be considered properly to have been used in this form of work. That substantial sums must be invested continually in the operation of any mine to the end that its resources may be opened up according to the best mining practice, thus assuring the maximum ultimate return and a continuous supply of ore during the life of the property, is everywhere recognized. The Provincial Government has admitted the soundness of the principle that allowance should be made for this form of expenditure in figuring annual assessments. 2.—Depreciation, an allowance under this classification being made on buildings and plant. 3.—Depletion, the amount allowed being estimated to be such proportion of the capital cost of the mine as, by reason of its being a wasting asset, may be chargeable to the year's operations. It is specified that these allowances are made at the discretion of the Minister of Finance, subject, however, to an appeal to the Lieut.-Governor in Council.

One of the oldest mining taxes in British Columbia is the Output Tax, under the terms of which all mines, other than coal or gold, are subject to a tax, payable quarterly, of 2 per cent on the gross value of ore, less cost of transportation from the mine to the reduction plant and the cost of treatment at the reduction plant. Any such mine, other than a placer mine, not realizing on ore shipments market value of $5,000 in any one year is entitled to a refund of one half the tax paid.

Iron mines, in addition to the 2 p.c. tax, are subject to a tax of 37 1-2 cents per ton on their output but, under the Bounty Act, this is more than returned by a substantial margin. This measure provides that the Provincial Treasury will pay $3.00 for every ton of pig iron manufactured in the Province from provincial ore and $1.50 for every ton of pig produced in the Province from foreign ore.

The Mineral or Output Tax does not apply to gold mines. A mine is considered a gold mine when the market value of the gold recovered from the ore is 85 per cent or more of the gross value of the metal content of such ore.

Coal is subject to a tax of 10 cents per ton of 2240 pounds, with the exception of such coke as is shipped to coke ovens within the Province. There is a tax of 10 cents per ton on coke, the only exemption being in cases where the tax has been paid on the coal used for its production. A tax, also, is levied on coal lands, that from which coal is being mined being taxed at 1 per cent on the assessed value in addition to any other ordinary tax.

With regard to taxation on unworked mining property, Crown Granted Mineral Claims, upon which $200.00 worth of development work has not been done during the preceding twelve months are subjected to a land tax of 25 cents per acre. Unworked coal lands are taxed at the rate of 1 p.c. upon the assessed value.

Premier mine.

Stewart, B. C.—Dale L. Pitt, superintendent of the Premier Mine, Salmon River, is quoted as stating that the new aerial tramway now is handling 100 tons of ore a day. Later it is planned to double the amount being delivered at the dock at Stewart, [illegible] being shipped to the smelter at Anyox. In addition to ordinary shipments the Premier is sending out 100 tons of concentrates a month, the same being the output of its stamp mill.

Homestake.

Alice Arm, B.C.—The Homestake Mining Company is planning the resumption of development work on its property on the Kitsault River. A crew will [illegible] during the month of March. A [illegible] has been shipped to the property.

Granby Consolidated

Anyox, B.C.—H. S. Munro, general manager of the Granby Consolidated Mining and Smelting Co., [illegible] returning from a visit to New York and other points in the United States, announced that the Company is planning the construction of a [illegible] at an estimated cost of [illegible]. [illegible] present power needs and [illegible]

at all seasons. There are some 930 men employed at Anyox, the Company's industrial centre, and the production per month averages 2,500,000 lbs. of copper. When copper reaches 14 cents a lb. there will be a general increase of wages averaging 60 cents a day, according to the agreement now in effect and which expires on the 1st of April. Mr. Munro denies the report that it is the intention of the Company to build a smelter at Stewart.

Kootenay Needs Ore Testing Plant..

Nelson, B. C.—L. H. Biggar, manager of the Ottawa Mine near Slocan City, speaking recently of the need for an Ore Testing Plant in the Kootenay Districts of this Province, said that he was convinced that the zinc could be eliminated from the silver-lead-zinc ores of this section and that the process worked out by the Consolidated Mining and Smelting Co., in the treatment of the product of the Sullivan Mine could be applied to small properties. The latter could be made profitable by an adaptation of this method. There was a large tonnage of silver-lead ore that could be worked with good return by the elimination of the zinc. A plant of the kind wanted could be obtained for between $30,000 and $40,000.

Ore Receipts At Trail.

Trail, B. C.—A total of 26,267 tons of ore and concentrates have been received at the Trail Smelter of the Consolidated Mining and Smelting Co., for the first three weeks of January. Of this amount 25,371 tons are from the Company Mines. There have been thirteen independent shippers since the beginning of the new year, whose aggregate shipments have reached 896 tons. Six of the latter are in the Slocan District.

Rebuilding At Britainnia.

Vancouver, B. C.—The work of re-establishing the buildings and plant of the Britainnia Mining and Smelting Company, which have been wiped out by fire and flood, is under way. Not many months will be taken in bringing back to Britannia Beach its former appearance of bustling activity and productivity. The Canadian Northwest Steel Company, of Vancouver, B. C., has the contract for the supply and the fabrication of the steel frame work of the concentrator. Messrs. Hodgson, King, and Marble, also of Vancouver, have been given the work of rebuilding a railway bridge that was destroyed. The supervision of the erection of the concentrator will be in the hands of Mr. Richard Trench, who has had experiences in similar work at Trail, B. C., and who expects to be able to start on his task early next March. The new mill site is on the slope of the mountain side, a short distance to the west of the former situation of that which was destroyed. J. L. Walsh, a construction engineer of San Francisco, Cal., has been retained by the Company, as consulting engineer in its re-building program. E. J. Donohue, general manager of the Britannia Mines, is in general charge of work at the mines as well as of the re-construction operations.

Discovery in White Water District.

The reported richness of recent discoveries in the White Water District, B.C., has directed attention to the Bridge River, Lillooet, and to the country through which it flows. Prospectors believe that it has possibilities for the placer miner. There has been mining on this waterway, both lode and placer, the latter in various forms, for many years. Those engaged have had more or less success but there have been no late reports of big returns. This is not to be taken as a slur because there are properties in the Bridge River zone that have promise and of the future of which their owners, no doubt with justification, have every confidence. But it was the find of recent months, in the White Water Country, that has caused the miners' eyes to dwell with interest upon this part of the provincial interior. A prospector named Taylor located on Iron Creek. He developed his claims, took out considerable gold, and also a quantity of what has been termed tellurides. Whether the latter term is correct has yet to be determined. There seems to be no [illegible] however, that he has a good prospect. Others already have staked next to and all around him and as soon as the season opens there will be a considerable movement through Lillooet, over the mountain passes and into the valley of promise beyond.

TWO FLOWING WELLS OPENED AT LA PAZ.

Toronto. — Col. J. F. H. Usher, of Toronto, who has recently completed a tour of inspection of the properties of the La Paz Oil Corporation, in Mexico, returns with a report which will be gratifying to a large number of Canadian stock holders. Early operations in the Tepila district have been most successful. Two flowing wells have been opened, and the output sold to the Pierce Oil Co. of New York. Col. Usher points out that at the contract price the company's annual revenue from these two wells alone should approximate $600,000 or the equivalent of 5 per cent on the par value of the capital outstanding. A contract for a new well in lot 11 in the Zacamixtle district adjoining Tepila has been let, and drilling will be commenced in the course of a few days.

As a result of the recent appointment of the English directors to the board, $1,000,000 additional capital will become available almost immediately, and will enable the company to undertake development and production on a more elaborate scale. Other drilling contracts, he added, were pending.

Representations have been made to the Mexican Government, Colonel Usher stated, during the course of the past few weeks on the part of British and American oil interests, with a view to the adjustment of certain points of difficulty to the trade, arising chiefly out of the recent heavy increase in the export tax on oil. As a result of this meeting, there was ground for hope that the tax would be either completely removed or extensively modified.

U. S. COPPER IN 1921.

The smelter production of copper in 1921 from ore mined in the United States, as shown by the actual production for the first eleven months and by estimates made by smelting companies for December, was about 461,000,000 pounds, according to a report by H. A. C. Jenison of the United States Geological Survey, Department of the Interior. The refinery production as similarly shown was about 601,000,000 pounds from domestic material and about 320,000,000 pounds from foreign material. According to the records of the Department of Commerce the total imports of copper for the first eleven months of the year in ore, concentrates, matte, blister, and refined copper were about 318, 000, 000 pounds, of which about 68, 000,000 pounds was refined copper and 157,000,000 pounds was blister copper. The exports for the first eleven months totaled about 567,000,000 pounds, of which about 538, 000,000 pounds was new refined copper and 29, 000,000 pounds was manufactured -- wire, rods, pipes, tubes, sheets, etc.

The total new supply of primary refined copper for the year was about 989,000,000 pounds, which includes refined copper produced from foreign and domestic material as well as imported refined copper. The stocks of refined copper in the hands of domestic refineries on December 31, 1921, excluding those in transit, as estimated by the refining companies, were about 496,000,000 pounds.

SALES OF IRON ORE.

Halifax. — In an interview tonight, R. M. Wolvin, president of the British Empire Steel Corporation, who returned on the Empress of Scotland on Sunday, said that while in Germany and England he had been negotiating for sales of iron ore from the Wabana Mines, and felt the negotiations would result in satisfactory business in the future. "In Britain business conditions have improved very greatly during the year, and British export trade is increasing," Mr. Wolvin said.

"In Germany there is little evidence of unemployment and the condition of the people seems reasonably satisfactory. The German steel industry is working to about 60 per cent. of capacity, and would do better if it were not that Germany has to make deliveries of coal to France. Skilled workmen in Germany now receive 100 marks per day, equivalent to fifty cents in Canadian currency."

PLACER GOLD YIELD IN YUKON.

Production of placer gold in the Yukon, Canadian territory, during 1921, was valued at roughly $1,250,-000, according to government reports based on collection of royalties in Dawson. This is larger by nearly $20,000 than the yield for 1920.

The large dredge and hydraulic plants, working the creeks within a fifty-mile radius of Dawson, are responsible for most of the output. The Highest Creek dredge in the Mayo district, and rich new pay-streaks in the old Miller Glacier districts added considerably to the year's yield.

A special issue of the Dawson News, dealing extensively with the mining situation in the Yukon, claims that the year's showing proves the Klondike the most durable of all northern placer camps, while new dredging operations assure the district of at least twenty-five more years of activity similar to that of 1921. General Manager Wheeler, of the Alaska, White Pass & Yukon Railway, recently stated that the Mayo district was likely to develop the richest silver mines on the continent.

OIL PRODUCTION IN DERBYSHIRE.

According to figures which have been furnished by the Petroleum Department, the production of crude oil for the past year at the Hardstoft well, near Chesterfield, amounted to 2,652 barrels, or 342 tons. These figures compare with 2,909 barrels, or 375 tons, for the previous year. The total output of the Hardstoft well from the time it was brought in until the end of last month amounted to 932 tons. The well was pumped from April 10th to July 24th last year, after which it was again allowed to flow under its own pressure. The operations at the D'Arcy well have been recently recommenced, the well having been shut down for a considerable time during the past summer on account of water shortage. The total depth now reached is 1,-237 ft., and much difficulty is still experienced on account of the caving of the strata, it being necessary to under-ream the hole and follow with the casing as soon as possible after the drill.— Petroleum Times.

In the course of the investigation being conducted at Pittsburgh, Pa., by the U. S. Bureau of Mines and the American Society of Heating and Ventilating Engineers with reguard to the effects of temparature and humidity on workers in both the mining and non-mining industries, an experimental room has been prepared in which the walls are insulated by about four inches of cork. Apparatus for refrigerating, heating and controlling the moisture and air movements have been installed.

EDITORIAL

EDUCATION OF PROSPECTORS.

The prospector is, to the average citizen, and even to the average mining man, rather an enigma. What is it that induces him to eschew the comforts of civilization, brave the black flies and mosquitoes, and, worst of all, try to assimilate the products of his own culinary efforts? Surely he cannot really enjoy being dirty and fly-bitten, without company or entertainment, cut off from music, books and all the amenities of life. Can hope be the well-spring of his effort? Hope has been dashed so often and deferred for so long that surely it must be gone by now. Whatever, it may be that converts a normal human being into a prospector, we may be thankful that there are still a few hear the call of the wild woods each spring, and feel the lure of discovery.

Our prospectors are, so far as is humanly possible, the creators of our mineral deposits. The whole structure of our mining industry is built upon their efforts. This statement is almost trite; but few even in the mining profession realize what it implies, sufficiently clearly to formulate the corollary. If our mining industry depends primarily upon the prospector, then it is the business of those interested in the industry to try by all possible means to make the prospector's work effective. Mr. Mandy points out, in this issue, a number of ways in which we can aid this prime mover of our mineral industry, and in which he is aided in British Columbia. Here, we will mention an educative effort that is being exerted by the Ontario Department of Mines.

Realizing that the prospectors of the province are few (all too few), and that they can be readily reached in a comparatively small number of centres on the edge of the woods during the winter season, the Department has decided to put in their way the means of elementary education in their calling. There was a precedent for this in the summer Prospectors' classes that were conducted throughout the province fifteen to twenty years ago.

During the winter of 1920-21, and again this winter, free classes in elementary mineralogy and a short course of lectures on geology, lasting for ten days, have been held at selected points, under the direction of Dr. W. L. Goodwin. To indicate the practical nature of the instruction, it may be mentioned that a set of about 75 minerals and rocks, appropriately labelled and described, is presented to each man (or woman) that attends the class. There have been found, still in use by prospectors, similar sets of minerals distributed fifteen years ago. Thus, at the expense to the public of a few thousand dollars, the prospectors of the province are provided with a chance to acquire a sound grounding in their trade.

What further can be done for the prospector? This is only a beginning. Our mining industry is second only to agriculture in magnitude and importance. The education of the tiller of the soil requires, in the estimation of the public, sums that constitute a fat slice of the provincial revenue. In fact, the farmers are almost embarrassed by the attentions of those who would educate them more highly. There are agricultural colleges, experimental farms, dairy schools, cheese inspectors, potato inspectors, bureaus for information and propaganda, public nurseries, and we know not what else beside. Against this we have a lone teacher for prospectors. We must improve upon this.

Advanced courses of instruction may be expedient, to follow the course already provided. On the other hand, instead of taking the facilities to the prospector, he may wish to come and get them. A certain proportion are sure to have sufficient initiative and general education to allow of instruction on the correspondence school plan. This will involve the writing of suitable texts and the provision of the personal supervision required. There must be numerous devices to be found for the seeking whereby the summer's grind of our average bush-whacking prospector can be made more

effective. When effective devices have been formulated, we can confidently expect from our provincial governments the wherewithal to put them into effect.

THE FEDERAL DEPARTMENT OF MINES.

The "Engineering and Mining Journal comments, in its number of Fernary 4th, upon the need for organization among miners, and states that "our continued survey of the situation reveals that the mining industry has great need of being mothered: not coddled, but given a fair chance with the rest." Our contemporary advocates the establishment of a Department of Mines. Evidently there is lacking in the United States mining industry something that is also lacking here. We have a Department of Mines, but our Governments have not endeavored to find a Minister who would give his best efforts to further the development of mineral resources. The Ministry of Mines is little more than a name and the mining industry is not properly represented at Ottawa. The men who are called Ministers of Mines, and there have been many of them in the past twenty years, are not expected to give much attention to mining; for they are loaded with other work that occupies most of their time.

It has been pointed out by the secretary of the Canadian Institute of Mining and Metallurgy, Mr. Geo. C. Mackenzie, that our Department of Mines cannot itself improve its circumstances. "It is a collection of civil servants who are not expected to express pronounced views on matters of government policy." Mr. Mackenzie suggests that the Institute should assert itself and convince our Governments that the industry is deserving of considered recognition. If the Institute were broadened out and developed so that it adequately represented the industry it would to some extent supply that element which is lacking here and which our contemporary finds need of in the United States.

The immediate need is to make the Institute really representative of the industry, rather than of any group of those connected with the industry. This matter we are pleased to see is being given serious attention by the Council of the Institute. The Institute does represent the industry at present, but not as well as it should. To make it truly representative is something worth striving for; then the needs of the industry can be more effectively brought to the attention of Governments. The Department of Mines could be materially helped by the activity of such an Institute.

CAPITAL STOCK REDUCTION FOR MINING TOWNS.

The useful life of a mining town is ordinarily limited by the life of the mines it serves. They grow, flourish and wane in proportion to the work of mineral extraction that is current. So we have booms, periods of prosperity and depression, and finally and inevitably extinction, in both cases.

Sound mining finance now includes provision for the inevitable. The latest and most striking example of this is the capital stock reduction of the Dome Mines, application for which is now before the Provincial authorities. Are those who are guiding the destinies of the corresponding mining camps equally wise? Apparently not. Dawson City, though sadly diminished from its former glory, is still the centre of a substantial mining operation; yet it is in a chronic state of indebtedness, inherited from the expenditure and expansion of boom days. The town of Cobalt, surrounded by mines past the zenith of their production, is beginning to look for outside financial aid.

Certain members of the mining fraternity, and others holding public offices, are in a position to influence the financial operations of corporate mining communities, by personal influence, propaganda, and the enactment of public or private regulations. It might be well for these to consider the advisability of inducing or enforcing the reduction of the public debt of mining communities, as a natural sequel to the reduction of the capital stock (or similar expedient) of the mines. This may not appear to be a logical part of the duties of those suggested as responsible; but as it would without doubt be to the general public benefit, and would react favourably upon the mining industry as a whole, it seems probable that a place could be found for such regulative supervision as would conserve public (and private) resources without undue restriction of personal liberties.

THE OTTAWA MEETING.

The annual meeting of the Canadian Institute of Mining and Metallurgy will be held at Ottawa March 1st, 2nd and 3rd. The business and technical sessions will be held at Victoria Museum where the facilities are better than in the ordinary places of meeting. There will be excursions through the Royal Mint, through the new Parliament Buildings and through the plant of the British America Nickel Corporation at Deschesnes, as well as an excursion to the Kingdon Mining, Smelting and Manufacturing Company's lead mine at Galetta. The various laboratories of the Department of Mines will be open for inspection by members and their friends. Among the entertainments will be a smoker and concert in the Palm Room, Chateau Laurier, on Wednesday evening. The annual dinner will be held on Thursday evening at the Chateau. A ladies' Committee is arranging a special program of entertainment for the wives and friends of visiting members.

A special effort has been made to secure deliberate discussion of papers presented at the meeting. A large number of these papers have already been published in the Institute Bulletin and members have thus an opportunity to discuss the papers intelligently, there being opportunity to read and study the papers prior

to their presentation at the meeting. The papers are of diverse character, covering a variety of subjects and it is not to be expected that all members will be interested in all the papers; but a discussion carried on by members well-informed on a subject is listened to with much interest by all. The attempt being made to bring out such discussoin will be heartily approved of.

The report of council shows that the officers of the Institute were unusually active during the year. The Secretary visited over fifty different localities and attended twenty branch meetings throughout the country. The Council advises that an annual tour of branches by the Secretary would be most valuable in strengthening the bonds between headquarters and branches, kindling active interest in the Institute and thereby increasing membership.

Among the matters in which the Institute has shown an interest during the year were: Engineering Legislation, A Dominion Mines Act and Nickel Coinage. A ballot of Ontario members is being taken to obtain an expression of opinion on the proposed Engineering Legislation. After the result of the Federal election was announced, President C. V. Corless on behalf of the Institute brought to the attention of Hon. W. L. Mackenzie King, the claim of the mining industry for representation in the Cabinet.

The report of the Finance Committee shows that the expenditures for the year exceeded the revenue by $5,441. This, the committee points out, resulted from the expressed opinion of members that the Institute should take a more active interest in the affairs of the Industry and also get in closer touch with the Branches. With this in view the salary of the secretary was increased $2,000 was allowed for travelling expenses and salaried editors were appointed. These extra expenses account for practically all the excess expenditure. This report indicates that the Institute is not able to long continue such work unless some way is found to lessen expenses and increase revenue. Consequently it is hoped that there will be at the Ottawa meeting full discussion of this report and of the secretary's paper on Institute Policy. It is to be hoped that a way will be found to permit the continuance of the activities of the Institute on the present scale. In our opinion, the view voiced by Mr. Mackenzie, that to be effective the Institute must be made more truly representative of the Industry, should be supported.

EDITORIAL NOTES

Ottawa to Hull, and Return.

It has been announced that the committee in charge of arrangements for the Annual Meeting of the C. I. M. M. in Ottawa have provided for tobogganing from the Chateau to Hull. We trust that this will not result in any casualties, and that there has been provided, for the convenience of sliders, an elevator for the return trip.

The Prospector's Notebook.

The habitual failure of the prospector to transfer his daily experience to a note book is due to two causes. One is inability, the other is indifference. It is morally obligatory upon a man who is grub-staked to render an accounting of what he has done. He should be able to do this through the medium of daily notes and continuous itinerary and local sketches. Such records are of value, whatever the results of the search for valuable minerals may happen to be.

Nota bene, readers who are prospectors, or who are responsible for prospectors.

Engineering Legislation.

In the "Northern Miner" of February 4th the proposed Engineering Legislation is discussed by Mr. Geo. R. Rogers of Toronto. Mr Rogers is quite evidently of the opinion that the proposed legislation is both unnecessary and undesirable.

The peculiar feature of the agitation for this class legislation is that most publicly expressed opinions are against it. If there are any mining engineers in favor of it, they are evidently of the opinion that arguments in favor of the proposal are unnecessary.

It is possible that the lack of interest in the legislation will result in the placing of ill considered measures on the Statutes. Aside from uneasiness due to this cause, the proposed legislation is not of concern to many mining engineers.

BUSH.

You may suffer from the pack
Sack upon your blooming back
You may hit a trail where windfalls interfere
You may curse the murd'rous flies
That close up both your eyes
But as sure as fate you'll hustle back next year.

Be it river, be it lake,
Be it muskeg, watch it shake!
It's the bite that gets us grub upon a man
So it's no use saying "No!"
You have simply got to go
Quick in answer to the bush-call of your clan!

VNON

PERSONAL AND GENERAL.

There will be a meeting of the Toronto branch of the Association of the Women of the Mining Industry, at the Royal Ontario Museum on Wednesday, February 15th. Prof. W. A. Parks will give an illustrated talk on the geology of Toronto, after which Mrs. Parks will entertain at tea.

Mr. Norman C. Hosken has been elected president of Granby-Kirkland Gold Mines, Ltd.

The 125th meeting of the American Institute of Mining and Metallurgical Engineers will be held in New York, February 20-23.

Publishers' Announcement

The publishers of the Canadian Textile Journal take pleasure in announcing that they have been fortunate enough to secure the services of Mr. JOHN THOMAS HOYLE as director of extension courses for the training and education of apprentices in all the industries served by the journals issued from the Garden City Press, Gardenvale, Que. They feel that this is an important step in the history of their organization and in its development along the lines they have planned.

Mr. Hoyle, who will enter on his duties at Gardenvale on the 1st of next month, is a Canadian. He was born in Hamilton, Ont., and started his connection with the publishing business by serving as newscarrier and "devil" on the Hamilton Evening Times. He received his education at the Collegiate Institute, Hamilton, at McMaster University, Toronto; and at the University of Rochester, Rochester, N.Y.

Mr. John Thomas Hoyle

In all departments of the publishing business, whether editorial or mechanical, Mr. Hoyle has had a singularly ample and varied experience. At the present he is professor of Editorial Studies and head of the Department of Printing and Publishing at the College of Industries, Carnegie Institute of Technology, Pittsburgh, and is on the lecture staff of the Library School, Carnegie Library, Pittsburgh. Among the other positions which he has occupied may be mentioned those of Textbook writer and chief of the editorial department, International Correspondence Schools, Scranton, Pa.; Manager Textbook Department, International Correspondence Schools, New York City; Department Editor, "The Grit", Williamsport, Pa; Managing Editor, "The Fra Magazine" and "The Philistine", East Aurora, N.Y.; Vice-President of the Royerofters and literary advisor to Elbert Hubbard.

Among the works which Mr. Hoyle has edited are the following: "The Complete Writings (in fourteen volumes) of Elbert Hubbard; A Royeroft Anthology; In Memoriam; The Liberators; In the Spotlight; The Philosophy of Elbert Hubbard; The Four Minute Essays (in ten volumes) and The Crane Classics (in ten volumes) of Dr. Frank Crane; "Good Hardware", Aspinwall, Pa; and "The Winged Head", Pittsburgh.

Mr. Hoyle is the author of numerous articles in magazines and technical journals. He is also joint author of the Complete Advertising Course, International Correspondence Schools, and Standard Apprenticeship Courses, United Typothetae of America.

It will thus be seen that, in adding Mr. Hoyle to their organization, the publishers are adding one whose almost unique qualifications cannot fail to result in a great accretion of strength and efficiency to the entire organization in practically all its branches. His wide experience in the preparation of manuscript and in the artistic translation of manuscript into type will materially assist in the publishers' efforts to build up at Gardenvale a corps of copy producers, typesetters and pressmen second to none.

ANNUAL MEETING, C. I. M. & M.

For the Annual Meeting of the Canadian Institute of Mining and Metallurgy, to be held in Ottawa on March 1st, 2nd and 3rd, a well-chosen and select programme of papers has been prepared. It is at present subject to revision.

Wednesday, March 1st.

A.M.—Presidential address, by C. V. Corless.
Mineral statistics.

P.M.—The Economic Relations of Canadian Gold Production by Dr. Adam Shortt.
The Relationships of the Mining Industry to the Canadian Railway Problem, by Chas. Camsell.
The Mining and Milling of Gold Ores, by the Hollinger Staff.

Thursday, March 2nd.

A.M.—Institute Policies, by G. C. Mackenzie.
The Probabilities of a Stable Gold Production from Northern Manitoba, by J. P. Gordon.
Some Possibilities of Placer Mining in the Cariboo District, B.C., by W. A. Johnston.

P.M.—Recovery of Precious Metals from Sudbury Nickel Ores, by R. L. Peek.
Ontario Gold Deposits: Their Character, Distribution and Productiveness, by P. E. Hopkins.
Mining and Milling McIntyre-Porcupine Gold Ore, by the McIntyre staff.
Moving Picture Films Descriptive of Gold and Talc Mining in Ontario, by Ontario Government.

Friday, March 3rd.

A.M.—Ball Paths in Tube Mills, by H. E. T. Haultain and F. C. Dyer.
Drop Shaft Sinking, by A. A. MacKay.
Prospecting Conditions in Northern Manitoba, by R. C. Wallace.
Feldspar in the Ottawa District, by N. B. Davis.

P.M.—Excursion to plant of British American Nickel Corporation at Deschenes.

Evening.—Moving Picture Films Descriptive of the Asbestos Industry, by the John-Manville Asbestos Company.

Some Thoughts About Mining Engineers, Prospectors and Legislature

By JOSEPH T. MANDY.

Have you ever heard the wilderness howl? Most people of the great outdoors have. Perhaps, though they were not aware of it, they were being unconsciously impressed by this howling of the wilderness. The wilderness seems always to be howling. It howls with its impenetrable silence and it howls like ten million demons of wrath with its storm-swept mountains, forests and seas.

The influence of the wilderness, like that of music, is impressive on any individual. In those of even lethargic imagination, dormant emotions are stirred.

Unfettered nature can be soothing in its tranquility and terrifying in its unrelenting ferocity.

Always is the emotional influence of nature elevating to man. That is why the prospector, intimate with the swaying moods of Mother Nature, is generally lofty in his thoughts.

The unfettered, overwhelming freedom of the gigantic British Columbia Cordillera is always productive of constructive thought. Even though footsore and weary, staggering upward along a goat trail, panting under the load of a heavy pack, sweating blood in the conquest of some glacier-crowned peak, thoughts sometimes bitter, sometimes sweet, but generally lofty, course through ones brain.

It was under conditions such as these, during the traverse of Goat Mountain glacier, that Scotty, who was piloting me to his claim, let drop a remark which showed that he had been thinking. Seated on two blocks of blue ice, we had paused for breath at the jagged edge of a crevasse. As the woodsman accompanies his thinking with the careful whittling of a stick, so was Scotty lost in thought whilst his icepick worked overtime chipping futuristic designs on the ice. Suddenly he dug his pick viciously into the blue glacier, wiped the sweat from his furrowed forehead, and spat with great deliberation into the depths of the yawning crevasse. Then he spoke.

"Doc" he said! you're the first engineer I've been able to get up to my property. I've had others in tow; get 'em a little way, then they get a fit of the 'pessimistice' and reneg. 'Taint right! Call 'em mining engineers? I call 'em damned 'pessimism engineers'! 'Taint right!" Again he spat viciously into the blue depths of the crevasse. The engulfing possibilities of that crevasse as some gigantic spitoon seemed to fascinate Scotty.

"Scotty", I replied, "mining engineers who are chronic pessimists are not true to their profession."

"Doc, you sure spilled a mouthful. Let's go!"

A shower of tobacco juice shot into that gigantic icy hole.

Slowly we shouldered our packs and plodded wearily upward across the jagged surface of that grimly gaunt glacier. The slowly moving and bent figure of Scotty ahead of me symbolised deep thought. I think I know what was in his mind.

Scotty was right in his reference to pessimistic mining engineers. His remark bared to me a world of thought on relative mining subjects.

I have spent many months of examination work in the mountains of British Columbia, eating, sleeping, talking and thinking with the prospector. The pessimistic mining engineer seems to be a great grievance with him.

Why are so many field mining engineers pessimists? Why is this mental condition exotic to the profession, and what is the remedy for the condition?

With the hope that the sequence of thoughts as they occured and were discussed by Scotty and myself, sometimes on the trail, sometimes in camp, may be of some constructive value, I set them down now. Although they refer to British Columbia, this is perhaps only because they were born in the mountains of this province. They could be applied, I believe, to general conditions elsewhere.

Let us commence with the attitude of the examining engineer during the course of his work.

In general work the great majority of properties available for examination are of course raw prospects. The examination of a raw prospect should be productive of a deal of satisfaction to the mining engineer. The engineer is always nursing the hope that he may be instrumental in bringing a new mine to light. This is natural. In so doing he is returning good interest to his employers on the money invested in his services, fulfilling the motive of his profession, which is the production of something constructive and beneficial for humanity, as well as advancing his own personal prestige. Previous to the examination of every prospect, this should be the mental attitude of the engineer. If it is not, then he should not examine the property; he has omitted the first essential step of his work. This is a thorough preliminary investigation from every available source and material that will lead to the conclusion that the prospect has, or has not the earmarks of making a mine. If after this preliminary investigation the engineer concludes that the probabilities are against the property making a paying mine, then he is willfully wasting his time and that of his employers in conducting an examination. He will be deliberatly setting out to examine something that in his judgment he knows his employers are not looking for. This is not honest to his employers, himself, or the motive of his profession. If he has formed the reverse conclusion from this preliminary investigation then he cannot help but undertake the examination in the hopes that he will bring a new mine to light, for that has been the incentive to make the examination. If, perhaps, the engineer conducts an examination of a prospect without having previously made any preliminary investigation, what then is his mental attitude, and what prompts the examination? Surely not the hopes that he will bring a new mine to light for the hope that he will find a mine.

In the large majority of cases the results of his examination will lead to disappointment, but if he is true to his profession this should have absolutely no bearing on his honest, technical mental attitude.

There may be of course engineers who on account of many disappointments in examinations and "wild goose chases" have become cynics or skeptics. Some people who have been disappointed in love and life in general become bitter and cynical towards humanity and the world in general; they see nothing but evil, they think nothing but evil, they live in a mental atmosphere of destruction, not construction, and they exude this atmosphere. "Ex nihilo, nihil fit."

A mining engineer is after all only human. It is consequently quite possible for some disappointed examining engineers to become "mining cynics." These people are, however, neither true to themselves nor to their profession. Mining engineering is a highly constructive profession, probably the most constructive of all professions. A destructive or cynical mental attitude is consequently foreign to the motive of the mining engineering profession. A mining engineer, in order to be true to the impelling motive of his profession, must therefore necessarily be an optimist—meaning "a hopeful person." This does not mean an "ultra-optimist." Such a person is an extremely expensive and dangerous factor to the profession, and just as foreign to it as the cynic-sceptic-pessimist. A mining engineer must just simply be a well balanced optimist, "a hopeful person."

We see however that it is possible for a "mining pessimist-cynic" to result from the following of his profession. Why should this be, and what is the remedy? Plainly the cause is something lacking in the engineer's mental equipment; something missing from his education and training. The remedy is positively therefore the introduction into the curriculum of the mining engineer's training, of a subject, the absorption of which would eradicate or aid in the eradication of the exotic attitude. The trouble is very plainly a mental one, and the remedy nothing more than PSYCHOLOGY- the science of mental phenomena- "PSYCHOLOGY APPLIED TO MINING".

Everybody should study psychology. The mental equipment of every professional man is incomplete without a knowledge of Psychology applied to his profession. The mining profession is no exception. Now, some people are natural psychologists, but some are not. Some of those who are natural psychologists do not know how to apply their psychology. Some people who are not natural psychologists might wish to become, and undoubtedly do become, mining engineers. Let us hope that the training of the mining engineer will be made more complete by the introduction of "PSYCHOLOGY APPLIED TO MINING" as a compulsory subject in the curriculum of the student.

This leads us directly to related subject, namely the prospector and his relationship to the examining engineer, and through the examining engineer to capital and the mining industry in general.

The prospector's lack of necessary knowledge and opportunity for acquiring it is responsible for much—perhaps all of the cynicism produced in some examining engineers.

Much was said at a recent mining convention, and very justifiably, in eulogy of the prospector. Every thinking man must acknowledge the primary position the prospector occupies in the mining industry. Without the men who find the potential mines, there would naturally be no mines, no mining industry and no necessity for mining engineers. It is on account of this important position occupied by the prospector in the mining industry that he is deserving of every consideration, encouragement and aid, that will tend to increase his efficiency. He offers excellent material to work on. From the comparative standpoint of humanity the real prospector is a wonderful type of man. One has only to live with him, talk with him, sleep with him, eat with him, pack with him, smoke with him, share with him, in the intimacy of mountains, snows trails tent or cabin, to find this out. The life he leads' midst the uncontaminated purity of nature, surrounded by the results of the gigantic forces of nature, elevates character. His exterior is rugged and rough as his beloved mountain crags, but his spirit is sterling. His ideals are lofty as the mountain peaks. His morals and ethics are of a high standard. He is thoughtful, and constructive as well as analytical in his thinking. He is the personification of unselfishness. He is not avaricious and is by nature very modest in his ambitions regarding material things. His urge is not, as most people imagine, the acquisition of great wealth; nor is it fame. In reality the impulse is the fascination of his undertaking, his love for the surroundings and atmosphere with which his undertakings brings him into contact, and the peace of mind produced by these surroundings. Many a prospector has remarked to the writer, "Well, if I sell this property, I suppose I will have to go and find another." Robert W. Service puts this very aptly in one of his poems, when the prospector says, "Taint the gold that I'm wanting, so much as just finding the gold." Particularly endowed with these qualities is the British Columbia prospector of the Coast, Coast Range, and Interior Plateau with whom the writer has come in very intimate contact. Those of the Gold Ranges and Rocky Mountain Range, forming the Eastern ranges of the great Cordilleran system, are possibly of the same ilk. The province of British Columbia has a valuable asset in the standard of the real Cordilleran prospector. In the qualities of character of this real prospector there is the finest material to aid in developing the mining industry of the province. The fullest advantage should be taken of this.

Much is said and in newspaper conventions reports regarding what is being done for the prospector. It is shown that the department of mines aids in the building of trails. That the services of the District Engineers are available for advnce. This is fine, excellent, a very progressive step. It is also pointed out that a course of lectures by the District Engineers has been inaugurated. In these lectures the prospectors will be taught Mineralogy, Geology, theories of ore deposition and principles of mining. This is also fine and excellent and a very progressive step. The prospector should be helped in the acquiring of this knowledge.

Besides Geology, Mineralogy and kindred subjects, the prospector should have some knowledge of the mine operator's or capitalist's business. He must be able to co-operate with the intending purchaser. This is mutually beneficial. The prospector, after he has made his discovery and partially opened up his prospect, is dependent on capital for further development, or eventual purchase of his property. It is highly important that he should have some understanding of what the operator is up against in undertaking to further investigate his property by means of development, with a view to purchase as a potential mine. To meet this end the prospector must know something about mining finance.

Knowledge of this sort will also assist the prospector in descriminating between a worthless prospect, and one of commercial importance. So many prospectors waste their time, money and energy on things that are glaringly commercially unimportant. The mineral occurence may be mineralogically and geologically interesting, but financially or commercially of no importance.

Now, something more that is in the writer's opinion extremely important. After the prospector has found something that he figures has ECONOMIC possibilities, he has to open it up, and put it in shape for exa-

mination by the engineer representing capital. The object of his work is to throw further light on the ECONOMIC possibilities of his prospect, not only for his own satisfaction, but also for that of the examining engineer. The more efficiently the prospector does this, the easier it is for the engineer to form a definite opinion. The more definite the opinion the less the speculative risk (this of course varies in proportion to the value of the opinion) not only to the capital of the intending purchaser, but to that of the prospector. In any event the chances for a "deal" are increased, or the prospector finds out that he has possibly erred in his judgement. A great fault with the British Columbia prospector in opening up his property is that he pays too much attention to underground work, at the expense of surface work. His capital is always far too limited to accomplish anything underground. The inducement sometimes is that he has a sheltered place to work in. Those who know the mountains and their rigorous climate can understand this attitude and sympathise with it. At the same time the great importance and value of surface work, the proving of surface continuity should be taught to the prospector.

It will be found that the prospector is an excellent pupil and thirting for knowledge.

Besides the aforementioned things, there are other considerations by which the prospector can and should be aided, and which, as they are at present, do not seem quite right. Take for instance his licence fee. This is a comparatively small item, but it is something, and the average prospector needs every cent he has. Why should a man who wishes to search the hills for something that will increase the prosperity of the country and everybody in it, have to pay for doing so? The work he is engaged in is absolutely constructive as far as the country is concerned. If his search is successful, the total benefit to the country and the people in it is far greater than that enjoyed by himself. True, he receives the protection afforded by the recording of his claim in a recording office, and other aids offered by the Department of Mines; but the results of his successful search are more than ample to offset the expense of these.

The recording fee is for like reasons equally unjust. Its abolition, and the working out of regulations to prevent unscrupulous and nonconstructive "blanketing" by psendo-prospectors, is too lengthy a matter to deal with here.

Now a suggestion regarding financial aid to the prospector in opening up his claim. The British Columbia Legislature has already shown excellent progressiveness in providing through the "Mineral Survey and Development Act" for aid by means of diamond drilling and boring, on recommendation by the District Engineers. Frequently, however, a prospector has not sufficient funds to do the initial work necessary to open up his discovery efficiently as a preliminary to drilling. He lets it lie without doing any, or at most, very little work, and holds it by means of periodical re-staking. If it were more efficiently opened up it would possibly be in line for drilling, and consequently a step nearer a mine. The industry would be much further ahead if aid were offered for initial work, conditional on the recommendation of the District Engineers and repayment under the same conditions as those offered for drilling and boring.

Speaking of the inadequate recognition of the work of prospectors, one cannot help but think of their co-workers, the members of the Geological Surveys. The remuneration received by these people bears no relation whatever to the potential value of their efforts. The more adequate recognition of the importance and value of the Dominion and Provincial Surveys to the prosperity of the whole Dominion cannot be too highly and urgently recommended. As an aid to the prospector the work of these departments is apparent. It increases his efficiency as a prospector, and so brings him nearer to the capital he and the industry need. To the examining engineer the work of the surveys is a tremendous help, and so through the examining engineer tends towards the introduction of capital. To operators, the value of the work is infinite.

In British Columbia, at the present time, as in other provinces, besides the more general and broad work of the Survey, the work of the various members is concentrated on the detailing of areas broadly investigated by their predecessors. This detailing or localization work is extremely important and valuable. It saves a great deal of money and time for the prospector and the operator. The localization work of Miller Knight, Burrows and Hopkins in Northern Ontario has saved and been productive of millions for the Northern Ontario prospector, operator and capitalist. Definite areas, zones and geological conditions have been emphasized, the working out of which would have necessitated expensive, laborious, and time-robbing processes of elimination on the part of the prospector, operator and capitalist.

Many areas are observed in the field that never a prospector has trodden where localization conditions, particularly tectonic, are far more favourable for the deposition of commercial orebodies, than some in which the unknowing prospector is spending his time, money and energy. Many areas are seen in which the prospector is working, and in which he has practically no chance of success. His location may be petrographically right, but tectonically wrong. He may be only on the fringe or rim of a stress or pressure zone, in which he finds more or less superficial indications of commercial orebodies. He camps there, and works there, with no chance for success.

With the mapping of Localization Zones within the sphere of the Coat Range Batholith we will be able to concentring the constructive energy of those interested in the progess and development of the mining industry of British Columbia.

As a last suggestion, but perhaps the most important, "cut out" the exorbitant and destructive taxation of the industry.

T. & N. O. ELECTRIFICATION

The T. & N. O. Commission, as announced lately decided to go ahead and make a complete investigation into electrifying the road and the power that would be required, with particular reference to the extension from Cochrane to Oil Can Portage.

It is estimated that 500,000 horsepower can be developed on the Abitibi River at four or five separate points, between Kettle Falls, 16 miles north of Cochrane, and Oil Can Portage, or New Post, 70 miles north of the present end of steel.

The commission already has its eye on various waterfalls in the Ottawa, Montreal and Sturgeon River watersheds, from which power for the southern end of the line can be developed, but to mention the names of these places would considerably increase their value.

British Columbia Letter

Oil Flotation Used to Obtain Clean Coal and to Recover Coal From Material Heretofore Wasted.

A new washery plant is being installed by the Western Fuel Corporation of Canada, Nanaimo B. C., which is said to be unique in respect of colliery equipment on the American continent. Provision is made for incorporation of some principles found to be commercially practicable as a result of experiments in oil flotations that have been carried on for months. It may be said in passing that similar experiments have been undertaken both by the Canadian Collieries (D) Ltd., and the Granby Consolidated Mining Smelting & Power Co., the latter also being Vancouver Island Companies.

Mr. John Hunt, general manager of the Western Fuel Corporation of Canada, who has authorized the construction of the new washery, has two objects in his decision to use oil flotation. One is to produce clean coal and the other to use material that heretofore has been wasted.

On Vancouver Island, coal mines have been equipped with washery plants in which Robinson cone washers were used, and it has been customary to treat the residue from the washer by passing it through jigs and over concentrating tables in order to clean the smaller sizes. No serious effort has been made to concentrate the slack and sludge, which have gone to waste dumps or into the sea.

The coming summer should see the plant in operation, as construction already has started and the machinery has been purchased. P. E. Peterson, well-known as a pioneer in oil flotation concentration, is the designer and it is said that the plant is remarkable for its simplicity, requiring at the most two men per shift to supervise its operation. It will be an addition to the present washery, in which jigs have been discarded and four Deister coal concentrating tables substituted.

Refuse from the picking tables of the present washery and outside refuse are the materials to be treated. That from the dumps is delivered by paddle conveyor to a trommel screen. The oversize passes from the trommel by gravity down a launder to an eight foot Hardinge Ball Mill while the undersize passes by gravity into a screw classifier, the oversize from which passes by gravity to two Deister coal concentrating tables. These tables produce three products, viz.: coal, middlings, and rock. The undersize or overflow from the screw classifier is carried by gravity to a battery of six Peterson flotation cells; the product from two of these cells is clean coal and from the other four middlings. The coal from the flotation cells passes by gravity into a settling tank 30 feet in diameter from which the de-watered fine coal passes to a paddle conveyor by which it is carried to railroad cars for market.

The Middlings from the flotation cells pass by gravity along a launder to a bucket elevator near the Ball Mill into which the overflow water from the settling tank is also discharged. The bucket elevator discharges into a launder, along which the material passes by gravity to the trommel screen and is subjected to the same series of treatments as have been described. The coal and middlings concentrate made on the Deister tables are carried by gravity to a second screw classifier near the settling tank, while the fine de-watered coal is carried to the paddle conveyor, which delivers it into the railroad cars. The refuse from the picking tables is carried in cars to a bin from which it goes into a Blake crusher, which discharges into the Hardinge Ball Mill.

New Ventilating Plant at Comox.

The Canadian Collieries (D) Ltd., have a modern washery plant at Union Bay, Vancouver Island, where the product of their Comox Mines is assembled for water shipment from large bunkers and wharves. The equipment consists of Robinson cone coal washers and ten Maseo coal concentrating tables. During the past year the Company have been experimenting with oil flotation, some carloads of coal having been shipped to the Mineral Separation Company of San Francisco for testing, while a small experimental laboratory has been established at Union Bay.

General improvements effected recently include the enlargement of ventilating facilities at No. 4 Mine, Comox. In October of last year the installation of a second fan was commenced and with its completion Nos. 1 and 2 slopes of this Mine will be ventilated each by a separate unit. The present unit consists of a Sullivan double inlet fan, having a capacity of 180,000 cubic feet per minute, against a six inch water guage. The fan is electrically driven, a 350 H.P Induction Motor 2,200 volts, Speed 250 R. P. M. is directly connected to the fan shaft. This fan will in future ventilate the workings of No. 2 Slope, while the new installation will take care of the workings of No. 1 Slope. The new unit is situated west of the travelling way and in order to make room for the installation, extensive changes were made in the railroad yard, which not only increased the capacity, but added much to the efficiency and appearance of the whole plant. The new fan plant consists of a 108 inch double inlet reversible Sirocco fan on concrete base with half housing in steel. The fan will be connected to the mine by a reinforced concrete tunnel fully equipped with explosion doors. The fan will run at 250 R. P. M. and will deliver 200,000 cubic feet of air per minute against a six inch guage. The primary power unit will be a 500 H. P. synchronous motor, 2,200 volts, equipped with a self-starting unit. The motor will run at 500 R. P. M., connected to the main shaft of the fan through a Jack shaft with Silent Chain Drive in two sections each 15 inches wide, the ratio between the speeds of motor and fan being 2 to1 . The distance between centres of drives will be 106 inches. In addition to the premary drive there will be carried as an emergency unit a 350 H. P. Induction Motor, speed 250 R. P. M., which can be connected by a coupling directly to the main fan shaft. This induction moter is a duplicate of the motor now in use on the present ventilation units at No. 4 Mine and also at Nos. 5 and 6 Mines, and can in emergencies be used on any one of the three units.

The power unit will be housed in a fireproof concrete building with asbestos roofing, making one of the most complete and efficient plants in the province.

Considerable exploratory work in the form of diamond drilling has been done by the Company in the Table and Cumberland fields of the Island. In 1921, 6,991.6 feet of drilling giving a two inch core was completed. In 1919 and 1920 there were 15,051 feet drilled in the same area. To permit the transport of drills and supplies, 115,220 feet of roads were build

in the year last mentioned while in 1921 12,900 feet of road work was performed. In the Cumberland District, 3,370 feet of drilling was done and 12,300 feet of road constructed. There was a total, therefore, in the Comox Field during 1921 of 25,200 feet of road work and 10,361 feet of drilling performed by this Company. No official reports are available as to the results. In some respects they are satisfactory, according to common report. It was stated recently in the Press that six and seven-foot seams of high-grade coal had been cut in the vicinity of Cumberland.

The same Company has been carrying out systematic prospecting by means of the drill in the Extension and South Wellington fields, Nanaimo Mining Division. Work on Wellington coal seam has been under way on Haslam Flat, Oyster District, three bore holes having been put down, two 1500 feet deep and a third 900 feet. Good coal of workable thickness has been determined. About 300 feet of drilling has been done near the Nanaimo River in the Cranberry District.

An outstanding feature in connection with practically on the line of the Company's railway from Extension to Ladysmith.

No Explosives at Cassidy Mine.

The Department of Mines, Victoria B. C., recently prohibited the use of explosives in the Cassidy Mine of the Granby Consolidated Mining & Smelting Co., the reason given being that it constituted a menace to the miners. The order followed reports of blowouts of methane and coal dust, a number of these occurrences taking place at intervals over a period of some months. In the opinion of the men affected, the prohibition is unduly severe, and objection is taken chiefly because it makes the work of the miner harder and, for those working on contract, less remunerative. Hon. Wm. Sloan, Minister of mines, has promised to consider the matter and in the meantime has forwarded a sample of coal from the mine in question to the U. S. Bureau of Mines, Washington D. C., in order that tests may be made to ascertain the explosive range of the coal dust.

Northern Ontario Letter

THE GOLD MINES.

every producing gold mine in Northern Ontario is that the managements are looking forward to further additions to the milling plants. In the case of the Hollinger Consolidated the plans and the specifications for adding over fifty per cent to the capacity of the plant are even now being prepared and this company is expected to be in a position to treat upwards of 6,000 tons and possibly 7,000 tons daily some time during the coming year. At the McIntyre also the work of increasing the size of the mill is actually progressing and before the close of the first half of the current year this company is expected to be treating between 700 and 800 tons of ore daily as compared with around 550 tons daily during recent years. This general desire to increase tonnage has also spread to the Dome Mines, where arrangements are being made to add from 20 to 25 per cent. to the capacity of the mill for treating the higher grade ore now being taken out.

Dome Mines.

By the time this letter gets into print, the daily papers of the country will be carrying a somewhat sensational story about results obtaining at the Dome Mines. It has been learned that mill heads have recently far exceeded the average at any other gold mine in the Porcupine field and have been a close second to even the bonanza Lake Shore at Kirkland Lake. Production for a single day has reached as high as $16,000. In connection with the remarkable achievement the Wall Street Journal carries the following news item:

"Dome Mines Co., Ltd., produced approximately $15,000 a day during January. The ore, as mined, averages at present $17.78 a ton in gold, and the recovery is $15,861. On January 26, wages were reduced 50 cents a day at both the mine and the mill.

"Although February is a short month, it is believed that gross earnings will be greater than for January, when the figures were the highest in the history of the company.

"At present rate of production, earnings are at the rate of between $4.50 and $5 a share on the 176,667 shares outstanding."

Concerning the foregoing statement in the Wall Street Journal, it is obvious that the paper is in error. For instance, if production did amount to $15,000 daily, it is a fact that tonnage has been about 1,000 tons daily and the recovery has exceeded $15 per ton. Another known fact is that costs are between $4 and $5 per ton, in the light of which the daily output of $15,000 would represent a profit of at least $10,000. Indeed, basing the analysis on this story of the Wall Street Journal, and estimating costs at one-third of the total yield, the net profit was $310,000 for January, or at the rate of $3,720,000 a year. This net profit would equal 78 p.c. annuity on the $1,766,670 of issued capital. Such an achievement is probably beyond anything that may be accomplished as yet, but the most conservative mining men in the business are expecting the Dome Mines to show net profits of from 35 to 40 p.c. annually from this date forward and with a further increase possible should the mill be again added to.

Claim Dismissed.

The dismissal of the action of the Hollinger Consolidated against the Northern Canada Power Company was announced on the 10th and is expected to signalize the commencement of work in connection with developing Sturgeon Falls on the Mattagami River. This will assure unrestricted operations at full blast at all the gold mines of the Porcupine district.

Gold Reef.

It is reported on the street that certain English interests may become involved in the Gold Reef property. This company was re-organized a couple of years or so ago in order to provide an extra million shares of stock with which to finance operations. Due to high wages and so on, nothing was done, but it would appear as though a plan of operation may now be mapped out. There are some spectacular showings of gold on the Gold Reef.

Paymaster.

A. S. Fuller of the Paymaster property, situated about one mile southwest from the Dome Mines, told the Journal correspondent that the work of continuing the shaft to a depth of 500 feet will commence this week.

Dr. Walter Harvey Wood, who visited the property recently recommended the expenditure of $100,000 on exploration and development work.

A plan is under way to re open the old Scottish-Ontario property, toward which end some English capital has been secured.

Ontario-Kirkland.

The first gold bar on the Ontario-Kirkland was poured during the past week and thereby places this promising property among the regular gold producers. The size of this first clean up has not yet been announced.

At a depth of 150 feet a new strike has just been made. The vein is about six feet in width and carries good milling values. The downward continuation of this ore body has been under development for some time at the 300 and 450 feet levels, a feature of the latest development being that it provides a third level from which to draw ore for the mill.

Bidgood.

Values at a depth of 400 feet on the Bidgood Gold Mines continue to improve and already a substantial amount of ore of good grade is in sight. At the time of writing, the gold values have increased about 25 p.c. in the drift as compared with assays at the point where the vein was first cut at this level.

Hunton-Kirkland.

Another important deal has been made in the Kirkland Lake district involving the Hunton Kirkland Gold Mines as well as two claims known as the Gibson-Duncan on the west and the Slaght-Solomon fraction on the east. The merger of these properties has already received the sanction of directors and only awaits final authorization by the stockholders of the Hunton-Kirkland.

It has been learned officially that a new company, probably known as the Hunton Consolidated Gold Mines will be incorporated to take over the entire group and will have an authorized capital of $3,000,000 made up of 3,000,000 shares of the par value of $1. each This will be allotted as follows:—1,000,000 shares to the Hunton-Kirkland. 410,000 shares to the Gibson-Duncan and 90,000 shares for the Slaght-Solomon.

This will give the new company a property approximately one mile in length from east to west, the direction in which the zone of mineralization courses through the claim. The stock remaining in the treasury, with the exception of 250,000 shares will be under option to the new company at prices ranging from 10 to 50 cents and will provide a total of $350,000 if all taken up. The 250,000 held in reserve will be available to raise money if needed for the erection of a mill in due course.

It is learned that the Minaker-Kirkland was also expected to join in the merger, but that delays due to the absence of two directors has prevented this company coming in for the time being. In the meantime, it is stated that the Minaker will still be given a chance to enter the consolidation in consideration of 500,000 shares in the new company.

The foregoing proposition carries an assurance from the holders of the option on the stock of the new company that a minimum of at least $1,500 will be spent monthly on the property. William Green has been active in negotiating the deal.

Reorganize Light Railway Co.

Cyrus D. Pinelle, liquidator, has issued notice that a meeting of the creditors of the Canadian Light Railway Construction Company, Ltd., will be held in Toronto on February 22nd.

"A meeting of the shareholders of the company recently held was of the opinion that the company was not properly organized, and unanimously passed a resolution that the company should go into voluntary liquidation for the purpose of re-organization; and at the same meeting approved of the company entering into an agreement for the sale of its undertaking to a new company known as the Canadian Light Railway Construction Company, Ltd., as a going concern, to be paid for by the allottment of a share of the new company's stock for each issued share of the capital stock of the old company and in consideration of the new company assuming the old company's liabilities." (The "old company" referred to was known as the Northern Light Railways.)

The statement continues further: "The new company has a capitalization three times as large as the old company; less than one-fifth of its capital stock will be required to replace the shares held by the shareholders of the old company, and the remaining shares will remain in the treasury of the company for the protection of the creditors and shareholders.

"The shareholders of the old company trust that its creditors will realize that the shareholders have materially altered their position in favor of the creditors, and desire that the creditors release the old company and accept the covenant of the new company to pay the creditors of the old company, so as to enable the re-organization to be consummated.

"It is important", continues the statement, "that as liquidator of the old company I should know at once if the creditors are willing to do this, and that I should know at an early date the amount of the creditors remaining unsatisfied, so that the new company will be able to provide for payment thereof."

THE SILVER MINES.

Beaver Consolidated.

Reports are current that something may be done to re-open the Beaver Consolidated Mine within the next sixty days or so. Frank L. Culver, president of the company, visited the camp recently and this strengthened the opinion that a new start may be made. It is known on good authority that the physical condition of the Beaver mine is quite good and that the prospects of mining a big tonnage of good low grade ore are excellent.

South Lorrain.

Perhaps the most outstanding feature in connection with the silver mining industry of this district is the renewal of interest in the South Lorrain district. The records in the office of the mining recorder are being searched in detail and any mining claims not in good standing are being re-staked.

During the past week the Mining Corporation of Canada took out some exceedingly rich ore from the Haileybury Frontier property, which it holds under working option. One specimen weighed upwards of eighty pounds and is said to have contained several thousand ounces of silver to the ton, having the appearance of a huge silver nugget.

Victory Silver.

The new vein on the Victory property, situated in

south-west Coleman, which was reported last week in the Journal, has maintained an average of from two to six inches in width and continues to carry high silver values.

Silver Bullion Co.

The annual meeting of the Silver Bullion Company, holding property in the Leroy Lake section of the Cowganda silver area, will be held some time during the current month at which time the question of resuming operations will be considered.

Nipissing.

The Nipissing has made no announcement as yet with respect to its intention about the Rochester property in the Porcupine district, although the general result of exploration work by diamond drilling is such as to indicate the likelihood of the Nipissing taking over the property.

Working forces at the silver mines of Cobalt now number between 600 and 700 men, or approximately the same number as are engaged in the Kirkland Lake district.

KIRKLAND LAKE.

(Special Correspondence.)

This Ontario gold mining camp now ranks next in importance to Porcupine. The centre of the camp, on the south shore of Kirkland Lake in Teck camp, is reached by a motor stage drive over a first rate road from Swastika on the T. & N. O. Ry. This road is good in summer and better in winter. This astonishing fact is due to the unusual enterprise of the people of Teck township (which includes both Swastika and Kirkland Lake) and to the skill and energy of Walter Little, who undertakes to keep the road open for motor car traffic all winter. This he does with a wonderful snow-plough drawn by from three span to seven or even nine span of horses. After that plough has passed, the road is like a paved street and a fairly wide one at that! The Kirkland Lake Hotel, just opened, offers the traveller clean, well heated rooms, and even the luxury of a hot bath. The village, growing fast, must accommodate itself to the demands of about 600 miners, and a large number of prospectors, some of whom can be seen every day passing, pack on back, for it has been found possible to continue prospecting, but particularly development work, through the winter months.

The camp is rather remarkable for the number of small surface showings which under good management and courageous investment have led to producing mines. Attention was first given in some cases to small, very rich, ore-bodies which were soon worked out, and, if the methods pursued in so many Ontario gold camps of the past had been followed, this field would have been abandoned. But, as in the case of the Tough Oakes (but without its dormant period), successful search has been made for large ore bodies of more modest gold content, and the result has been some five or six mines either producing or with production assured, and everything so far points to the continuance of the ore bodies in depth. It is a rather common experience in this camp to find somewhat insignificant outcrops of ore expanding into large ore bodies as sinking progresses. Gauthier, the second township east of Teck, has yielded promising results to the persistent prospector. A discovery was made late last fall by three prospectors, Perry, Tobicoe and Fetterly (Miss Mabel Fetterly). As is quite commonly the case in this district, the values were found in a mineralised zone which includes stringers of quartz with altered rock, the latter predominating. In the opinion of a competent mining engineer who has seen this discovery, it is of considerable importance.

It is noticeable in this district that many prospectors carry on development work throughout the winter. The ore bodies in many cases outcrop in low-lying ground, where test pits are more easily sunk in winter when water is not so bothersome.

While it may be confidently stated that the operations in those mines located on the main break running through Kirkland Lake have proved the presence of good-sized ore-bodies with paying values, judgment must be reserved as to the future of outlying properties. But on the whole there is ground for the hope that a considerable number of mines will be added to those already on the producing list.

SOUTH AFRICAN CHROMITE.

In the current Bulletin of the Imperial Institute, the chromite deposits of Rhodesia are briefly described. As Rhodesia is Canada's chief competitor in the production of this mineral, we reproduce this description.

"H. B. Maufe describes the result of a further investigation of the chromite deposits in the Umvukwe Hills. The ore is in seams, generally less than a foot thick, in the central portion of the Great Dyke, and its occurrence has been compared with that of a series of coal seams lying one above the other in a basin.

"The country rock is usually enstatile partly serpentinised, but in some cases the floor of the seam is enstatite and the roof serpentine, which appears to be derived either from a dunite or a saxonite. The synclinal structure of the dyke at this point is similar to that in other parts of the dyke described by P. A. Wagner and others. The method of depositions of chromite in the Great Dyke differs widely from that of the well-known Selukwe deposits, or indeed from any other known deposits of the mineral, and the deposit is of later geological age. The Great Dyke chromite can be hand picked to yield a product containing 50 per cent. of chromic oxide, and the quantity available probably amounts to some millions of tons."

INDUSTRIAL NOTES.

Ingersoll-Rand have issued bulletin 10102, describing their Price Rathburn oil engine. This is built in sizes from 105 to 1,000 B.H.P. Features are, smokeless exhaust, due to complete combustion of the fuel, high fuel efficiency; ignition by its own heat of compression, and rugged and single construction.

This new prime mover might prove specially suitable for mines or mills, where fuel is expensive, and where hydro-electric power is not available; or it might prove to be an economical "stand by" to guarantee electric plants against shut down in case of failure or reduction of power supply.

Hardinge Company, in catalogue No 12, describe in a general way the use of pulverised fuel, and in particular their Quigley Fuel Systems. The latter includes a flexible system of crusher dryer, pulveriser, air conveyor, storage bin and burners.

The use of pulverised fuel is of particular interest in Canada, where low grade fuels are the rule rather than the exception. The development of apparatus such as described in this bulletin in will help materially to solve our fuel problem. Of particular interest in this connection is a reference to the possibility of using economically both lignite and peat.

OLIVER FILTERS FOR THE HOLLINGER.

The Journal is reliably informed that C. E. Rodgers of Cobalt, representing the Oliver Continuous Filter Company of New York and San Francisco, last week closed a Contract with the Hollinger Consolidated Gold Mines Limited for six more 14' x 16, Oscillating Type, Oliver Filters, together with complete vacuum and solution pump equipment and all accessories.

One Oliver Filter of the same size and type was installed at the end of the Dorr Counter Current section of the Mill some months ago. This filter has been operating continuously with highly satisfactory results, having decreased the soluble loss in both gold and cyanide to a practically complete recovery. The one machine, together with the additional filters just ordered, all seven of which will be placed at the lower end of the present cyanide plant and take the underflow from the Dorr tanks (what has normally been the final tailing), will have a capacity of at least 4,000 tons of dry slime per day. The total filtering area will be about 5,000 square feet.

The exact price of the entire filtering equipment is not stated but is understood to amount to about $70,000. This sum may at first appear to be a large capital expenditure; however, when it is realized that it takes an additional recovery of even less than 5 cents per ton for one year, on 4,000 tons per day, to save $70,000, it resolves itself into merely a very profitable investment.

The residue from the filters will contain about 20 p.c. moisture and it is planned to discharge this comparatively dry cake to conveyor belts which will deliver to the final tailing disposal system.

HEMATITE IN SOUTH AFRICA.

In the transactions of the Geological Society, South Africa, (1921), are described the hematite deposits of the Rustenberg District, Transvaal. These were formerly to be sedimentary beds, representing exceptionally rich portions of banded ironstones. Now it appears that they owe their origin to a process of secondary enrichment, whereby the original layers of certain sections of the banded ironstones have been replaced by iron oxide, giving rise to solid bodies of ore made up of alternations of primary and secondary hematite layers. In this respect they are of identical origin with some Lake Superior hematite deposits.

The Rustenberg deposits overly dolomite, and are overlaid by a bed of chest-conglomerate. Many million tons probably average not less than 40 per cent. of iron, but the high silica content destroys their value as potential ores of iron. However, lenticular and irregular tabular bodies of high-grade ore occur, associated with ironstone, from a few inches up to 51 ft. in thickness, and from a few yards up to 1,000 yards in length. The two main horizons containing the hematite deposits occur near the contact in the chest-conglomerate, and also near the contact with the dolonite, and the lower portion of the former has in one place been replaced by hematite, giving rise to small irregular deposit of that ore. Analysis show the ore to be of high grade, containing from 60 to 67.75 per cent. of iron, from 0.55 to 6.32 per cent. of silica, from 0.006 to 0.05 per cent. of phosphorus, and no sulphur.

GOLD MINING REVIVAL IN NOVA SCOTIA.

Halifax — According to reports received by the Provincial Department of Lands and Mines, there will be considerable revival of gold mining in Nova Scotia this year. Many prospectors have taken out licenses, and old companies have been enlarging their plants.

Gold mining has been carried on in this province for over a century, but the production has not been large, the greatest annual output being valued at $589,000. Between 1862 and 1920 the production was 967,457 ounces, which at a valuation of $19 per ounce was worth $18,229,683. The annual production has ranged between 20,000 and 30,000 ounces.

Nova Scotia gold is derived entirely from vein workings. The auriferous quartz bearing veins occur in groups, running parallel to one another in a system of anticlinal domes. The Atlantic shore from Canso to Yarmouth is occupied by the auriferous strata. The width of this district varies from ten to forty miles and the area in which gold occurs is estimated at 3,000 square miles.

Mica In the British Empire

The Imperial Mineral Resources Bureau have added lately to their list of bulletins a clear and concise review of the mica industry of the British Empire. We in Canada are apt to take for granted our position as one of the world's chief producers; and it were well for us to bear the fact in mind, and to take pains to preserve by whatever means are possible, our present prominent place in the industry. Below is reproduced a part of this report

General.

Owing to the irregular mode of occurrence of mica, systematic mining operations are rarely possible. For the most part the mineral is mined or quarried by open-cast methods and the excavation abandoned when the visible supply is exhausted. Where true mining operations are possible, the work is carried out by hand drilling, just sufficient explosive being used to loosen the rock preparatory to removing the mica crystal by picking. The product is sorted and split into plates and roughly thumb-trimmed and graded on the mine, after which it is sent to works where the plates are further trimmed, graded, and split.

Clear sheet mica commands a high price for stove and furnace doors, for gas-lamp chimneys and shades, and other purposes. The chief use of sheet mica, however, is for electrical purposes as an insulator. During the war it was used for gas masks.

Sheet mica is used largely as follows:—

(1) For separating the commutator segments of dynamo-electric machinery. A soft mica is best for this purpose, as this ensures equal wearing of the copper segments and the mica separators. Consequently phlogopite or a soft muscovite is in greatest demand for this purpose.

(2) For electrical heaters and cookers, and for pyrometers.

(3) Electrical condensers.

(4) Sparking plugs and magnetos.

(5) Washers, and insulation of bolts and screws generally.

For all the above, as indeed for most other purposes, it is necessary that the mica should split easily. It should also be free from cracks and conducting inclusions. Sheet mica less than 2 by 4 inches is practically useless for the purposes specified.

Discs and washers punched from mica sheets are also used in arc lamps and gramophones, and smaller ones in the sockets of incandescent lamps. Flexible mica-covered cloth and tape find various uses in electrical apparatus.

Formerly only sheet mica measuring 2 by 4 inches and upwards could be readily marketed, and much material of smaller dimensions was sent to the waste dump. At the present time, owing to the method of building up mica sheets from thin plates of scrap mica suitably trimmed and cemented with shellac, the greater demand in the industry is for splittings less than 2 by 4 inches in size, which can be hydraulically compressed and cemented with shellac into sheets of any desired thickness or size, or moulded to various shapes. Such material, known as "micanite", has now largely replaced sheet mica in commutators, especially those of large machines.

An important use of micanite is for the insulation of the conductors in high-tension alternators when sheet mica cannot be used. The micanite is made in large thin sheets and is wound round the conductor by means of special machinery, the insulation being completed by heating under pressure. Alternatively, tubes are made in a similar manner, and the conductors afterwards inserted.

Micanite is largely used for marine switchboard insulators. The use of micanite is rapidly extending in the electrical industry; and consequently the chief demand is for mica splittings, which are imported in large quantities from India and Canada.

Ground mica pulverized from mica scrap is used for a variety of purposes, the principal of which is to impart a lustre to wall-paper. Only the finer grades passing 160 to 200 mesh screens are suitable for this purpose. Other uses for fine-ground mica are as a component of paints and as a lubricant.

World's Production.

At the outset of the period under review the chief mica-producing countries were the United States, India, and Canada; comparatively small quantities were obtained from German East Africa (now Tanganyika Territory), Brazil, Argentina, and Madagascar.

Throughout the war period numerous factors contributed to increased activity in the mica-mining industry, and many new producers came into the market. Germany was formely a large consumer of high-grade sheet mica suitable for electrical purposes, and the closing of this market had a depressing effect upon the mica-mining industry generally. As the war proceeded large quantities of mica were required for munition purposes, and both the Allies and the United States obtained increasing quantities of sheet mica from Argentina and Brazil. The enemy powers, being shut off from the regular sources of supply, turned to Norway and Sweden for their requirements. In the latter country a considerable industry sprang up in the manufacture of electric insulating material from mica mined in the Bohuslan district, and it is expected that this industry will be permanently established in Göteborg.

Before the war the exploitation of mica in Argentina was chiefly in German hands. Output was desultory and the industry could not be considered permanent. The high prices ruling throughout the war period for sheet-mica of good quality stimulated production, and in the latter years of the period important shipments of such mica were made to England, the United States, Italy, and Spain.

Large sheets of mica are recorded from Finland, but difficulties of transport have militated against mining operations in that country.

British Empire.

The greater part of the high-grade sheet mica consumed in industry is obtained from countries within the British Empire. India produces most of the high-grade sheet muscovite consumed, while Canada possesses almost a monopoly of the phlogopite variety. In addition to these producing countries, South Africa, Brazil, and Australia have considerable resources of high-class mica. So great is the producing capacity of India, that little effort appears to have been made to utilize scrap mica, which is at present thrown on the dumps, and an enormous tonnage of this material is now available for the manufacture of mica-board (micanite) and ground mica. In view of the great importance attained by the micanite manufacturing industry in the United States, and the large quantities of valuable sheet mica now being produced in many South American countries, the value of the Indian scrap mica for grinding and mica-board manufacture should not be overlooked.

THE EMPLOYMENT SITUATION.

The Department of Labour, Ottawa, has just published its returns for January. The following items relate to the mining industry.

Iron and steel.—Very pronounced shrinkage occurred in this group. Statements were received from 632 firms with a total payroll of 75,699 workers as compared with 102,623 employees on December 17. There was therefore a decline of 26,924 workers or 26.2 per cent. This contraction comprised fully 50 per cent of that recorded for all industries during the fortnight under review. The larger share of the loss was due to temporary shutdowns in railway car shops over Christmas and the New Year, which affected employment in practically every province although the reductions were particularly heavy in Quebec, Ontario and the Prairie Provinces. Declines on a much smaller scale occurred in the manufacture of crude, rolled and forged products, general machinery, steel ships, heating appliances, shoe metal, boilers, engines, tanks, agricultural implements and iron pipe. These contractions affected very many more persons than those recorded in the corresponding fortnight in 1920, and employment for the period under review was approximately 34 points lower than at the end of December of the preceding year.

Mining.—Further contractions though on a more moderate scale were recorded in the employment afforded in the mining industries. Returns compiled from 192 operators showed that they employed 42,260 men as compared with 42,918 workers in the preceding fortnight. There was therefore, a decline of 658 persons or 1.5 per cent. Coal mining in Nova Scotia, metal mining in Ontario and British Columbia and stone quarrying in Quebec and Ontario afforded less employment. The contractions in the coal and metallic ore branches of the industry were less pronounced than those reported at the end of December, 1920, but in non-metallic minerals they were somewhat larger. The index number for the group as a whole, however, was about 3 points lower than during the same fortnight in the previous year.

WORKING DAY IN COAL MINES.

In 1903 the United States Geological Survey began the collection of statistics of the established working day in local mines. In that year 26.5 per cent of the bituminous mine workers were employed at mines where the standard day was 10 hours; 17.1 per cent were employed at 9-hour mines, and the number of 8-hour day workers was 56.4 per cent of the total. The average working day in that year was 8.7 hours.

These figures, it will be understood, are not the average number of hours that men labor, but the average hours in the standard working day.

No great changes in the working day occurred in bituminous mines up to 1917. The average for that year showed only 8.4 per cent. employed in 10-hour mines; 12.6 per cent. in 9-hour mines, and reduced the average working day to 8.3 hours. The 8-hour day was even more generally adopted in 1918, when 90.6 per cent. of the bituminous workers were employed in 8-hour mines. The statistics for 1919, indicate that 95.5 per cent. of the mine workers now labor in mines where the 8-hour day is the rule. The number of workers in 10-hour mines was 6,127.

The anthracite mines now work an 8-hour day. Prior to March 31, 1916, the standard anthracite day was 9 hours.

MORE GOLD FROM LILLOOET?

From Lillooet comes the report that old-timers there are showing renewed activity, and already the hills are beginning to resound with shots of dynamite as prospectors continue their eternal search. The fact that there is but little snow on the ground is the reason for the early start.

Writing of the Whitewater district in 1911, Dominion Geologist Bateman reported that the formation extended from Eldorado Creek to Chilco Lake and that the gold was traceable throughout this stretch in the contact between the Coast granites and the volcanic rock, practically every creek cutting this contact panning gold.

Charles Camsell, now Dominion deputy minister of mines, who visited the district in 1918 for the purpose of inspecting the Copper mountain findings on behalf of the Dominion government, corroborated the conclusions of Mr. Bateman.

Seated around the camp fire one night, in company with several prospectors, Mr. Camsell strongly recommended the latter to prospect north-west of Copper Mountain along the contact. From his examination of the country he stated that he had reached the conclusion that along this contact great gold finds would be made. It was largely owing to this advice that E. J. Taylor, who was one of the party, and who had for many years prospected the Bridge River and surrounding country, decided to concentrate his efforts upon the Whitewater, his decision resulting in the discovery of the "Windfall" and other claims.—Resources Monthly, Prince Rupert.

COPPER IN SHETLAND.

In Special Report No. 17, on the Mineral Resources of Great Britain (1921), there is described the occurrence of copper in Shetland.

There are two wide lodes, one of which has been proved to a depth of about 300 feet. Oxidised ores, including malachite, melaconite, limonite and hematite, occur to a depth of 100 feet (water level). Below this, the filling consists of pyrite and chalcopyrite, in stringers and nests, in a white gangue of carbonates of lime, magnesia and iron.

The mine was opened about the end of the eighteenth century; shafts were sunk, and £2,000 worth of copper ore was raised, after which the workings were abandoned. The mine was reopened in 1872, and it is estimated that in the following eight years 10,000 tons of iron and copper ore were raised. An inclined shaft was sunk on the vein to a depth of 180 ft., and most of the material above the 100-ft. level was removed, but large reserves of ore were left below that level. Nothing further was done until 1920, when active development started.

Both pumping and crushing machinery have been erected, as well as an electrolytic refining plant, but it is understood that operations at the mine and works ceased in October, 1921, no doubt largely owing to the low price of copper.

Let us remember, always, that Canada offers to the prospector the most inviting and accessible partly-known territory in the world.

It is an unrivalled country for all who feel the red blood of the pioneer, the prospector, the "blazer of trails" coursing in their veins.

EDITORIAL

PROSPECTING IN OLD ONTARIO.

Old Ontario has begun to vindicate itself as a metal producer. For many years the failures and fiascos of the early promoters and miners gave the province such a bad name that no one would believe it capable of substantial and consistent mineral production. The discovery and successful operation of deposits at Sudbury and Cobalt, and then Porcupine, gave New Ontario a place as a mineral producer; but still is was commonly held that Old Ontario's day was done — and a very short and stormy day it had been. Meantime, a steady, and increasing, production of mica and feldspar, mostly on the initiative of farmers and would be miners, wrung from the public and from the accredited members of the mining profession, the concession that Old Ontario was capable of the economic production of non-metallic minerals. The successful talc industry at Madoc and the operation of pyrites mines confirmed this impression.

Today we have a demonstration that Old Ontario's mineral production has entered a new phase. The Kingdon mine and smelter produced last year three million pounds of lead. This year the amount will be doubled, and that is not the end. It has been publicly stated, on the basis of geological examination, that there are in Eastern Ontario a number of veins similar in character and prospective value to the Kingdon vein. This argues well for the production of lead in Old Ontario.

There are mining men (few and far between, to be sure) that consider South Eastern Ontario well worth serious attention as a possible source of metals. It is excellently served by railways, natural water-routes and canals, and most of it is well served by highways and lesser roads. It is settled sufficiently to provide food, shelter and labour in almost any quarter. Except for small, isolated areas, it has not been prospected since the early days of settlement, and then only in the cursory way common to the time. At present there is little prospecting being done except by local residents, whose knowledge of methods, minerals and rocks is ordinarily so fragmentary as to make their efforts of little avail. The trained prospectors of the north will not come down to a district where the mineral right is held already by farmers and by the speculators of old time. Consequently this district, at one time, and still, of such promise as a mineral producer, continues to be dormant for lack of the prospecting and initial development that must precede all productive mining.

We have a practical (and possibly practicable) suggestion. The majority of the consulting mining engineers of Eastern Canada live in or near the area under discussion. Some of these are fully occupied, others have time for additional professional work. All claim title to proficiency in at least one part of mining, and most of them have specialised in examination of prospects. Our suggestion is that, when time and circumstances permit, these members of our profession should hunt up, examine and develop promising prospects on their own initiative. There are plenty to be had awaiting such attention. In Old Ontario there are few busy at such work, and the reward of these few has been, on the average, above that of similar pioneers in New Ontario.

At times rebuke and even abuse is heaped upon the heads of trained mining engineers by those who deal more directly with Mother Nature. Perhaps it is thus the case when the "bush whacker" speaks of the consulting mining engineer. Often he must bring the results of his toil for the consideration of a white-collared, prosperous-looking individual in an armchair behind a polished desk, and there accept a decision based on — he knows not what. This is irritating, to say the least. If our consulting engineers were to make

a practice of sharing, as far as possible, in the labours of the men on whom they depend for a living, it would be better for prospector and practitioner, and the public as well.

MINING INVESTMENTS.

The "Northern Miner" on Feb. 18th asks whether Toronto is in danger of losing its control of the mining development of Northern Ontario and replies in the affirmative. According to the "Miner" there is in Toronto an adverse influence at work that is responsible for unfriendly legislation and lack of sympathy with the mining industry of the North. The "Miner" sees evidence of this in the frequent attacks on mining enterprises in some papers and in the legislation under consideration in Queen's Park. The "Miner" is evidently of the opinion that the attitude of the Drury government is hostile to the development of Northern Ontario, and that Toronto is losing its influence in the North and will lose its market for goods also, as the business will naturally be diverted to the more friendly centres that supply the money needed for developing the new country.

While much evidence can be found in support of such views, we have little doubt that Toronto will not easily be deprived of its business relations with Northern Ontario. The attitude of the Drury government is not necessarily the attitude of the people of Toronto.

The "Miner" refers to recent sales of Hollinger shares to Montreal buyers and of McIntyre shares to New York buyers. Such transactions, if very large, would make notable alterations on the list of shareholders, but would not affect operations much unless control passed into new hands. The buying of such shares does not put any money into the treasuries of the companies. It is notable that this is the type of investment that is commonly highly commended. Everybody knows that these mines are not in need of money for development, that they are being operated profitably and paying dividends and that they will likely continue to do so for some time. Under the circumstances financial editors who know little about mines can safely advise purchase of the shares. To sing the praises of these mines now is but to join the big chorus. Twelve years ago when money was needed to develop the properties and the owners could not yet demonstrate that the ore would be profitably mined, there was no chorus and many critics. It is the investments that make mines that are of interest to the North. The trading in shares is of comparatively little consequence.

The control of mining enterprises commonly remains in the hands of those in control when profitable production begins. Until that stage is reached the necessity for raising money may bring many changes; but, when operations are yielding a profit the changes are relatively few. Consequently the position of Toronto or any other centre with regard to control of northern mining enterprises will depend largely on those who make mines rather than on those who invest in shares after the mine is made.

To what extent the people engaged in mining enterprises are affected by adverse criticism from those that advise against the initial investment we cannot say. Unfair criticism has doubtless done harm, but we doubt whether it results from a studied effort to discredit mining enterprises. There are always risks to be run in the development of mineral deposits, and those that wish to keep their money until there are no risks will never help to develop mines. Those that cater to such investors magnify the known risks and introduce much unfounded adverse comment that is evidently designed to hold the reader to the view that an enterprise in need of money is dangerous and not to be engaged in honorably. The fact that those that provide the money to make mines are much more useful citizens than those that buy shares in the made mines is seldom given prominence. Luckily there are a few who realize that the making of a new mine is something worth while.

There are chances of profit in both types of investment; and advocates of either type that rest assured of criticism from those that favour the other.

SCIENTIFIC RESEARCH.

The Advisory Research Council at Ottawa has just issued a brochure of twenty pages entitled "Research and the Problems of Unemployment, Business Depression and National Finance in Canada." The title suggests something compendious; but the twenty pages are brief and to the point, as befits a dissertation on scientific facts, intended for wide-spread and popular distribution. We wish to outline here the history of the movement of which this bulletin forms a part.

Three years ago there was first presented in public by the advisory Research Council a proposal for the establishment of a National Research Institute at Ottawa. This met with a storm of opposition. Universities feared their prerogatives (and funds) might be curtailed. Students of public administration foresaw a further waste of public resources in yet another government department. Misanthropes saw our once-vigorous researchers waxing fat on soft government jobs, with initiative gone and progress long forgotten. Honest fears wereadded to vague feelings of distrust and (it was whispered) even personal envy and private spite, to bring the project into a disrepute that was widespread among the technical and general public.

The gentlemen who had formulated the idea refused to be intimidated, or even gravely concerned by the coldness with which their proposal was received. They had studied long and hard before reaching their conclusion, and were prepared to stick by it. They probably realized at this time that their seed had been sowed on ground they had failed to till suffieiently; still they were ready to prepare the ground further

and sow again, before despairing of a crop. Incidentally it may be remarked that few among our men of science realize how formidable and intricate a task is public propaganda, until enlightened by some such experience as this.

Fortunately, the innate persistence of the researcher is shared by the members of our Advisory Research Council. They have set out to educate the public to the need of research on a national scale and for national objects, and to convince it of the soundness of the scheme they have proposed. Most of, if not all, our universities are now satisfied that the National Research Institute will not duplicate their work; nor will it undertake research that should more properly be conducted within college walls. Our manufacturers now understand more clearly the service the Institute will be able to render them. It has been pointed out, too, that the researcher seems to have a kind of auto-inoculation against the energy-destroying diseases that usually attack government employees. The progress of this propaganda is well marked by the support given by the Commons in Ottawa during the last session, to the bill to create a Research Institute. Possibly it is fortunate that the Senate threw out the bill. It seems as if our House of Commons had, for once, preceded the public in its support of a progressive measure; now the public may have time to catch up.

It says much for the soundness of judgment and forbearance of the Advisory Research Council that they have refused to use the $100,000.00 voted them last autumn in the face of the ill-timed and short-sighted economy of the Senate's veto. As an expression of the Commons' faith in the judgment of their scientist advisers, this was acceptable; but as the means of erecting and equipping a Research Institute, it was hardly adequate. The vote might easily have been considered an earnest of more to come, and it would have been quite permissible to proceed with the establishment of the Institute on this basis. Wiser and more far-sighted counsel prevailed, and the education of the public proceeds apace, by means of public addresses, press notices, and now the present pamphlet.

The discussion and controversy of the past three years have no doubt modified somewhat the original ideas of the sponsors of the National Research Institute. This is salutary, and indeed necessary. We hope that the present legislature will see to it that a new bill is presented and passed, to found and maintain what has now been satisfactorily demonstrated to be a national economy and a national necessity.

EDITORIAL NOTES

Cheaper Oil from Shale.

In a recent editorial we called attention, in a purely speculative way, to the possibility of producing oil from shale without removing it from its native bed, this idea being based upon the successful recovery of sulphur by the Frarch method in Louisiana and Texas. Now comes news from Tasmania of actual trials of such a method, re-printed on another page. The commercial development of such a method will mean much to Canada.

Banking of Coal in Cape Breton.

A contributor to the Bulletin of the C. I. M. & M. says of the wage question, which is now seriously affecting the coal industry in Nova Scotia, that he would be inclined to take a chance, strive after a compromise for a twenty five per cent reduction instead of thirty-five and then give orders to work all collieries full time. Then with a million tons of coal on bank he would be ready to supply the extra demand sure to follow in the event of a strike in the bituminous mines of the United States.

This solution of the present problem is one that might have good results for both employers and employees. It is a solution of course that places the risk on the employers; but they have to take such risks at all times. The surest thing about coal mining is that the operators will pay the wages that they agree to pay.

That the production of coal in Nova Scotia should be maintained at capacity is much to be desired. Provided the operators believe they have a reasonable chance of making a profit on operations they will doubtless endeavor to produce large quantities. Faced by poor markets and high costs they are unwilling to take chances. If the costs were reduced to a considerable extent there would be some incentive to mine coal now, and take chances on future markets; but to mine coal at high cost this year is not an attractive enterprise.

Wright Hargreaves.

The report on operations at the Wright Hargreaves mine for 1921 will be pleasing to shareholders. The mill was put in operation on May 1st and by the end of the year there had been produced $468,665 in bullion from the treatment of 36,081 tons of ore. On January 2nd $137,500 was paid to shareholders.

The Wright Hargreaves is apparently nicely started on a long and profitable career. The property is an excellent one and those who have brought it to the producing stage will be well repaid for their enterprise.

OBITUARY.

HON. G. R. SMITH.

The Hon. George R. Smith died at Thetford Mines, Quebec, on Monday, Feb. 20th. Mr. Smith was for years an outstanding figure in the Canadian Mining Institute. As one of the Institute's founders, he fought its battles frankly and played no small part in preserving its existence during very tronblous times. His connection with the asbestos industry will be more fully touched upon in a later number of the Canadian Mining Journal.

The late Mr. Smith was always a man of keen and discerning public spirit. For 12 years he sat in the Quebec Legislative Assembly for Megantic, and in the year 1911 he was appointed a member of the Legislative Council. His death will be deeply mourned by scores who had learned to respect and love him.

W. A. BOSTWICK.

The sudden death of W. A. Bostwick, President of the International Nickel Company leaves a vacancy in the affections of his friends and deprives the mineral industries of Canada and the United States of one of their most unobtrusive and capable chiefs.

Not many knew "W. A. B.", so unassuming was he in all things excepting where business and personal rectitude exacted his assertion of what was right. A trained scientist in steel and its metallurgy, a master mathematician, he was another of "Carnegie's young men", who have left their indelible imprint upon the records of industrial achievements in the past thirty years. Loyal as an adjutant to the late Ambrose Monell, familiar with the economics of the Nickel industry, undeviating from his sense of duty to his company and Canada, Arthur Bostwick, as his familiars knew him, had executive abilities of the highest pre vision.

"Now It Can Be Told", as Philip Gibb's entitled one of his books", might have included a chapter on what Mr. Bostwick and his colleague, Mr. Monell, did toward winning the Great War. That work, and what has ensued, no doubt drained the vitality of the President of the International Nickel Company. Self-centered in his work, a diplomat, with a large discretion, it devolved upon him to navigate the tronbled waters during those stormy days when nickel as a metal was vitally essential to the Allies—and it was as vital that the enemy should have no supplies of it.

A silent sentinel keeping vigil, playing an open hand with the representatives of the allied nations, having every transaction of record and making it clear to authorized officials—"Now It Can Be Told" that it was Arthur Bostwick who personally went to an upper floor of the Equitable Building and charged with treachery the man who diverted a small quantity of nickel so that the Deutschland could sneak it away by the undersea route.

The recreant confessed his guilt. It was the solitary slip in the arrangements for the perfect control of the sale of nickel. Mr. Bostwick made in impossible for the conspirators to spirit away the nickel that had been taken from one warehouse to another—eventually getting to Brooklyn. The United States not having declared war, all that could be done was to notify the Canadian and Imperial authorities as to what had happened. The Secret Service saw to it that the nickel remained in the Brooklyn warehouse.

Mr. Bostwick appreciated the gravity of the matter—and it was not until the Deutschland reached the United States that all his precautions proved unavailing.

In this, as in all else, Mr. Bostwick never thought or acted obliquely. The millions expended by the International Nickel Company—to a great extent under the direct supervision of Mr. Bostwick—display his optimism, and the fruition from Copper Cliff, Spanish River and Port Colborne plants will be ample when the times are ripe. What Mr. Bostwick performed as a patriotic executive and prescient economist, inevitably leaves it to his associates and intimates to understand what a vacancy has been created by his death.—Alexander Gray.

PERSONAL AND GENERAL.

Members of the Association of Women of the Mining Industry were entertained last Wednesday at the Royal Ontario Museum by Prof. W. A. Parks and Mrs. Parks. Many friends of members were present and a most delightful afternoon was spent. The Library committee reported that they had shipped 142 books to the Kirkland Lake public school as the beginning of a library that the members of the Association have undertaken to furnish for that school.

E. J. Donohue has resigned the position of general manager of the Britannia Mining & Smelting Company after having been with the Company for about nine years. Having entered the service of this Company in the early years of its enterprise on Howe Sound, B. C., he has been closely identified with its development and expansion to one of the largest copper producers of the Empire. His duties at first were the supervision of financial and business affairs but subsequently he succeeded J. W. D. Moodie as general manager. Mr. Donohue has been subjected in the course of a few months to the strain of two disasters at Britannia Beach, one the destruction of the Company's Mill by fire and the other the wiping out of the mining community by flood with considerable loss of life. He feels that his health demands a prolonged rest and so has asked to be relieved of the responsibilities of his office. Mr. Donohue is highly respected and very popular in British Columbia and his many friends regret his determination to leave.

D. M. Drumheller Jr., formerly manager of the Tidewater Copper Company, has returned to Sidney Inlet. He will supervise the re-opening of the company's Indian Chief Mine and plant. Considerable development, including the construction of a concentraing mill and a tramway, had been completed when the slump in copper occured and a close-down was forced. A shipment of 400 tons to the Tacoma Smelter was the last of any size from this property. It is expected that the mine will be producing again within a month. Mr. Drumheller has been in private practice in Spokane for a year.

W. Haseltyne, a well-known American metallurgist, has been placed in charge of the concentrating and cyanide plants at the Premier Mine, Portland Canal.

The Wages of Colliery Workers in Nova Scotia

The following is an authoritative statement, in brief, of the events to date leading up to and following the recent "Gillen award" in the Sydney coal fields. It will serve as an authentic record of the facts of the case, as well as a source of information for those who have not followed the matter closely in the daily press. — Ed.

During the year 1921 the wages paid to the mineworkers in the Nova Scotia coalfield were governed by an agreement arrived at in November 1920 between the employees and the several managements of the coal companies now merged into the British Empire Steel Corporation, namely the Dominion Coal Company, Nova Scotia Steel & Coal Company and Acadia Coal Company. This agreement was arrived at because of a mutual refusal of the men and the coal companies to accept the recommendations of a Royal Commission which enquired into the wages and working conditions at the coal mines in the Summer of 1920. At the beginning of 1920, under the guidance of a Conciliation Board headed by Mr. Clarence Mackinnon, a wage agreement had been come to which covered the year 1920. About the time when commodity prices reached the peak in June 1920 the mineworkers applied for a further increases in wages. Their action resulted in the appointment of the Royal Commission and the eventual disagreement above referred to, and in November 1920, an agreement was made which gave the mineworkers an increase of 55 cents per day, with equivalent tonnage increase to contract workers. This agreement, since known as the Montreal Agreement, expired at the end of November 1921. Under its terms the parties thereto agreed to meet in November to negotiate a new wage understanding, but by mutual consent negotiations were deferred until the middle of December. The coal companies gave notice that business conditions compelled them to ask a reduction in wages upon the expiry of the Montreal Agreement, and the mineworkers took the ground that no reduction could be accepted. At the deferred negotiations in December the mineworkers consistently maintained refusal to accept any reduction, no matter how slight, and, for this reason, the negotiations were entirely futile. The coal companies thereupon announced a reduction in wages effective at 1st January 1922, of approximately 33 percent. from the rates current in 1921. The wording of the notices announced a reduction of 25 percent. from the rates of the Mackinnon Award, the reduction being applied in this way in order to preserve the rate differentials which were a feature of the Mackinnon Award, having been arrived at by protracted negotiations with the mineworkers.

The United Mine Workers, upon receiving the notification of reduction, immediately applied for a Board of Conciliation, which was appointed by the Minister of Labor, without the concurrence of the coal companies. The mineworkers secured a temporary injunction restraining the companies from putting a reduction into effect pending a reference to a Conciliation Board, contending that the action of the companies was a violation of Clause 57 of the Industrial Disputes Act. An appeal to the full bench of judges in Halifax resulted in suspension of the injunction, on the ground that both parties having consented to meet to negotiate a new understanding, and having failed to do so, no violation of the Industrial Disputes Act could be argued. One of the judges, in a separate judgment, expressed his grave doubt of the constitutionality of the Industrial Disputes Act insofar as it undertook to regulate private business in the Provinces, but as the injunction was suspended on separate and sufficient grounds, the constitutional point was not raised in the main judgment.

A Conciliation Board, under the chairmanship of U. E. Gillen, General Manager of the Toronto Terminals Railway, was held in Halifax, the proceedings occupying almost a fortnight, and attracting widespread public attention.

The report of the Board recommended a modification of the reduction announced by the coal companies, making the reduction of the laborers' rate 25 percent. and in the other rates of approximately 28 1-2 percent. below the wage rates of 1921.

The mineworkers have voted on an unqualified question put by their leeaders as to whether or not they should accept the award of the Board, and practically unanimous vote against acceptance was given.

The coal companies have notified the mineworkers of their willingness to negotiate an agreement with the Award as a basis, if acceptance by the men were signified by the 15th February. It is understood that, in the event of non-acceptance, now assured by the vote mentioned, the companies will put the Award into effect.

TASMANIAN SHALE OIL EXPERIMENT.

"The Industrial Australian and Mining Standard" states that Mr. John Fell's experiment of firing the mountain side in "panel" section for the extraction of oil, in contrast to the usual method of retorting, is still attracting attention from experts in the oil industry. It is worth recalling that a report on the proposed project was prepared by Mr. R. H. Cambage, the State Under-Secretary for Mines, as far back as August, 1917. Mr. Cambage then said: "Mr Fell's proposal to fire the shale mines at Wolgan, and thereby use it as a retort for the extraction of the oil, is a unique one, but within certain limits it is recommended that such proposal may receive departmental sanction. The two important questions which present themselves are those of success and danger. The success or otherwise of the venture is for Mr. Fell to consider; that of the danger, by the fire getting out of hand and destroying the shale as a whole of the locality, also the possibility of an explosion near the mouths of the tunnels, and the consequent loss of life in the vicinity, is for departmental consideration. I understand that the shale outcrop in this vicinity is not of any great extent, and is covered, in most cases, with from 50 to 100 ft. of loose earth on the talus slope of the hill, so that the chances of an internal fire reaching the workings are very much minimised. I would suggest, however, that, for the present, the permission to fire the shale be restricted and the result of operations on this area be awaited before further permission is granted. I understand from Mr. Fell that this particular area is the one he proposes to first operate upon."

Pat Daly, veteran prospector and [illegible] Stewart B. C., has left for New York with a view [illegible] is understood, to interesting capital in [illegible] properties of the Salmon Arm [illegible] Portland Canal District.

Kingdon Mine and Smelter

Ontario has a full fledged lead mine and smelter. This will be news to all but the select few who have followed the quiet and consistent progress of the Kingdon Mining, Smelting and Manufacturing Co., Ltd., since 1914.

Forty five years ago a calcite vein carrying galena was located on Chats Island, where the Mississippi river divides to flow into the Ottawa. Little was done to develop this outcrop until it came to the notice of Mr John E. Hardman, consulting engineer and Mr. A. G. Munich of the James Robertson Company, eight years ago. The steady and logical development that has been conducted since then is a credit to the pertinacity and sound judgment of those in charge.

Fig. I.— Headframe Under Construction.

The galena that provides the reason for the plant now erected, occurs with calcite in one of the regional fault-planes common in this part of Ontario. It has been described by Uglow in the Ontario Bureau of Mines report, Vol. 25 (1916), and by Wilson in the Summary Report, 1918, of the Geological Survey and a memoir now in the press. The country rock is crystalline limestone of the Grenville series, cut by occasional dykes of granite and intrusive masses of diorite. Very little zinc or other impurities are in the vein, so mining, milling, smelting and refining have all been favoured by Nature.

Within the last few months, extensive alterations and additions have been made to the hoisting and milling equipment, and now all is in process of being "tuned up" for steady production. The hoisting and crushing equipment has more than sufficient capacity to supply the mill, which is designed to handle 250 tons a day of ore. The mill building, by the way, gives evidence of its recent growing-pains, by its lumpy and patchy exterior. One can be justly suspicious of a mill building that looks as if it had been made-to-order—it is more likely than not to represent pre-conceived ideas on the part of the mill-man that usually spell ruin for the undertaking. The smelter, on the other hand is a neat unit adopted ready-made from the East St. Louis Smelting Works. It will treat 22 tons a day of concrete, and will produce 18 tons a day of refined lead.

The Mine.

The vein has been developed to date by a shaft 426 ft. deep, with levels at 85 ft., 200 ft., 300 ft. and 400 ft. Above the 200 ft. level, all ore has been stoped. The main ore reserves at present are between the 300 and 400 ft. levels. The 400 ft. level has been developed by drifts on the vein (in a northwest and southeast direction) 1350 ft. in length. A winze, now at a depth of 519 ft., will be sunk to 550 feet, and from that level, a raise made to the main shaft. In this winze the vein is 6 ft. in width, of first-class ore. The vein varies in width from 4 ft. to 16 ft., with an average of about 5½ ft.

Shaft to Mill.

The shaft has three compartments, each 4' x 4', for cage, skip, and ladder and pipes, respectively. The head-frame, 65 ft. high, was built by the Dominion Bridge Co., and houses a Ross grizzley, primary crusher and bin. The machinery is all electrically-driven, power being had from a falls on the Mississippi river at Galetta, a mile away. A small Flory hoist handles the six-man cage, and a larger Marsh (Belleville) hoist, the skip. A Canadian Ingersoll-Rand high-speed, two-stage compressor, of ten drill capacity furnishes power underground.

A feature of the ore-handling equipment outlined in the above flow-sheet is the Ross drop-bar grizzly feeder and screen. It is a rugged piece of machinery, and as its name implies, gradually feeds the skip-load of ore to the crusher and acts a screen for undersize. It is operated intermittently, at the will of the crusherman, by a small motor, and makes the feeding of the crusher steady and safe. A special description of this will be given next week.

All feeder and conveyor belts are the endless Dunlop "Samson" variety, and belt idlers are from the Elmira Machinery and Transmission Co. It is refreshing to find such a large proportion of Canadian-made machinery at a Canadian mine.

Mill.

The present mill is the result of experiment and trial extending over several years, under the guidance of Mr. Hardman, consulting engineer for the company. The flow-sheet is simple, as benefits an ore that is not

Fig. II.—Headframe, and Conveyor to Mill.

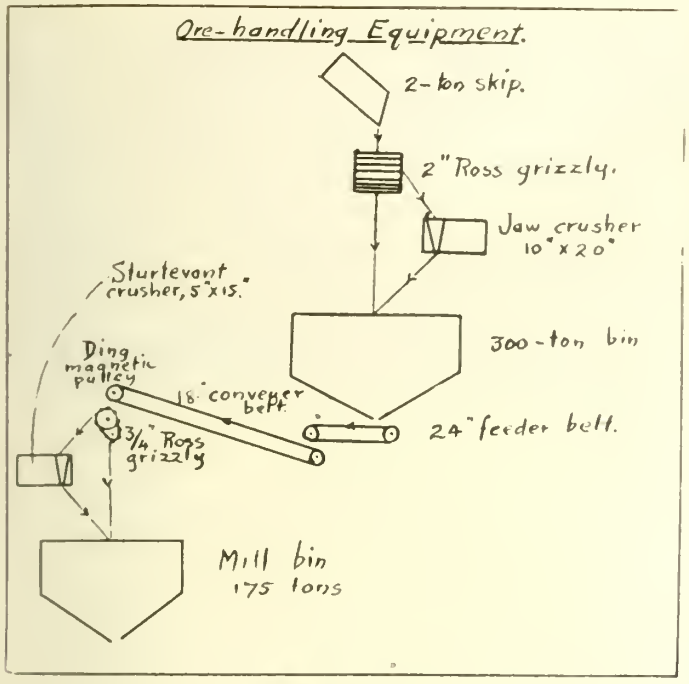

Fig. III

complex, and it is flexible, to allow of whatever adjustments may prove to be in the interests of economy. The apparatus used is, in general, of the compact type characteristic of modern metallurgical machinery. The flow-sheet is self-explanatory; but some of the items need detailed description.

A mill bin, of ample capacity, is connected by a combined feeder and weighing belt to a bucket elevator, which goes from bottom to top of the mill. This elevator also hoists re-crushed material from the rolls and the Hardinge mill, mentioned later. The ore, two inches in size and under, is fed, with water, to a ½" Mitchell Vibrating Screen. The oversize goes to rolls set at ½ inch and back to the bucket elevator. The undersize falls directly on a second vibrating screen of 3/16" mesh, whence the undersize goes to a third screen of 3/32" mesh, and the oversize to a second pair of rools set at 3/16 inch, and thence to the bucket elevator. The undersize from the third screen goes to a Richards classifier and James sand and slime tables, and the oversize to a James Automatic Jig. The jig is a multiple unit, giving from the first gate a clean lead concentrate, from the second, a lead middling, and from the third and fourth, a lead-zinc middling, the three middling products going to a small Hardinge ball mill, and thence to the bucket elevator for return to the main circuit. This jig is a comparatively recent development, and is an ingenious combination of the principles underlying both the old Hancock jig and the newer Richards pulsator jig. Like the latter, its tonnage capacity is quite out of keeping with its small size.

To return to the James tables, all sand goes first to No. 1 table, which gives a lead concentrate and a middling product. The latter is thickened in a Callow cone and then divided into sand and slime in a Richards classifier. The sand goes to Nos. 2 and 3 tables, and the slime joins that from the former Richards classifier to pass over the James slime tables, Nos. 4 and 5. Tables Nos. 2, 3, 4 and 5 each give a clean lead concen-

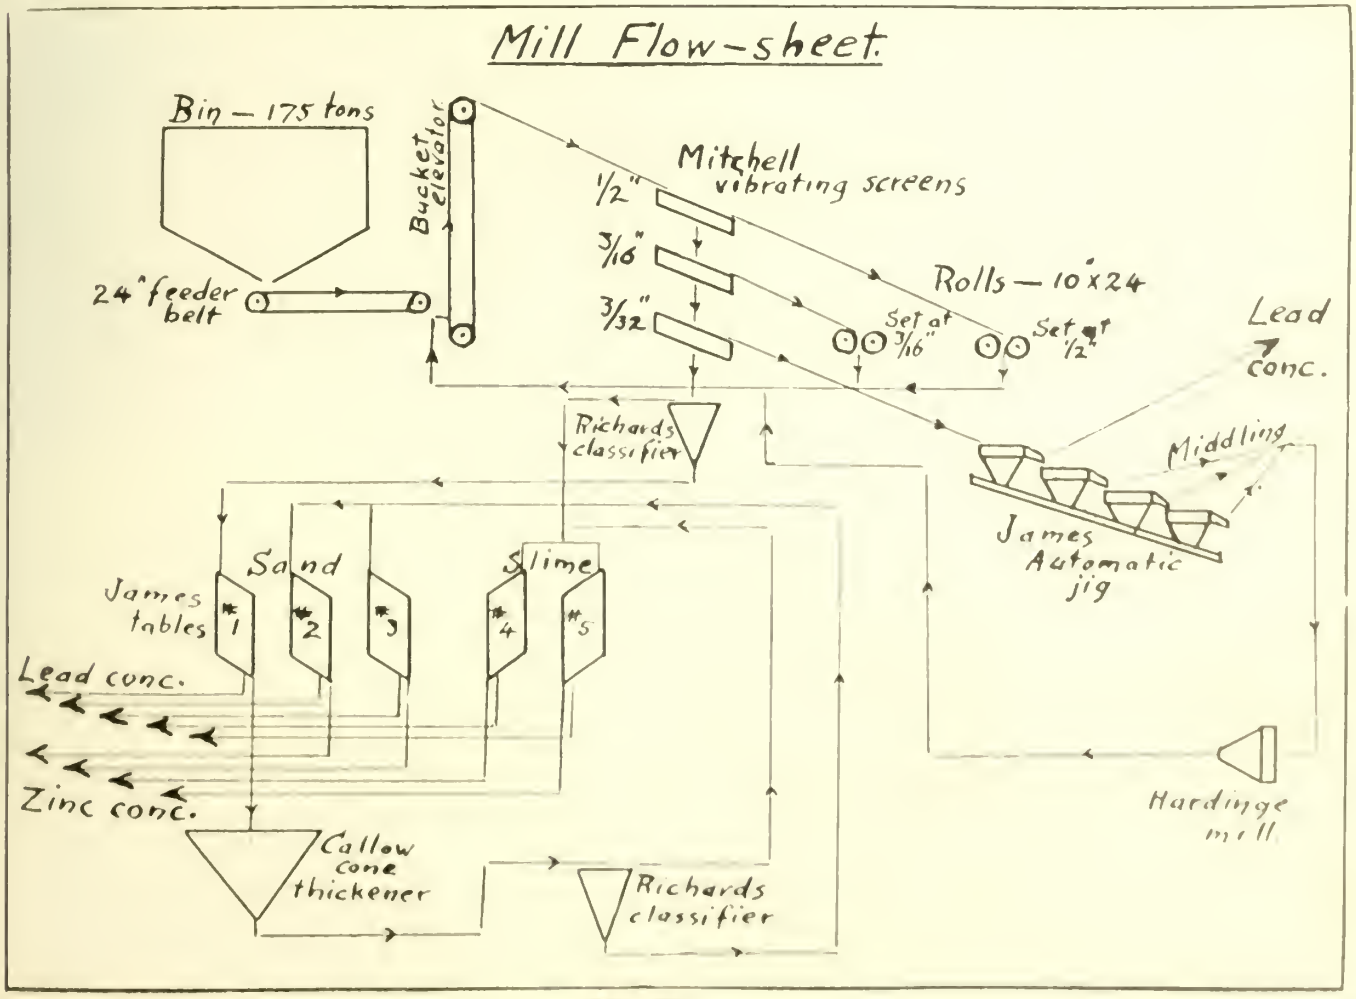

Fig. IV

trate and a clean zinc concentrate, the latter being at present stock piled. All tailings run in a flume to the Mississippi river close by, whence also the water for the mill is pumped.

A feature of this equipment worth special description, is the Mitchell Vibrating Screen. On the small area of the screen there is handled an amount of material that surprises one accustomed to stationary, or the ordinary shaking screens. A separate description with an illustration is given on another page.

Smelter.

Fig. VI gives a general view of the smelter. The reduction of galena to lead is one of the simplest of all

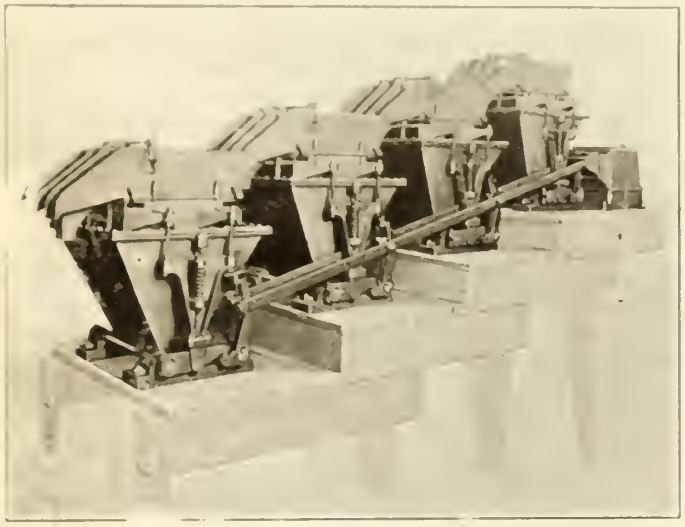

Fig. V.— James Automatic Jig.

smelting operations, and no complicated or expensive plant is necessary when the ore is clean. The Kingdon ore is so free from impurity that, without unusual precaution, an unusually pure pig lead is obtained. If a premium is to be had for pure lead, "Kingdon" brand should get it; in fact a premium of 2 cents per pound has already been paid for shipments made to the Hartt Accumulator Co. of St. Johns, Que., who require specially pure lead for their storage batteries.

The furnace is an open-hearth of the modern type developed at the East St. Louis works by Mr. W. E. Newnan. The hearth has forced draft below and induced draft above, and a mechanical rabbler that operates over a hearth eight feet long, in place of the four foot length to which the hand-rabbled hearth is restricted. The hood is so designed as to eliminate al-

Fig. VI.—Smelter.

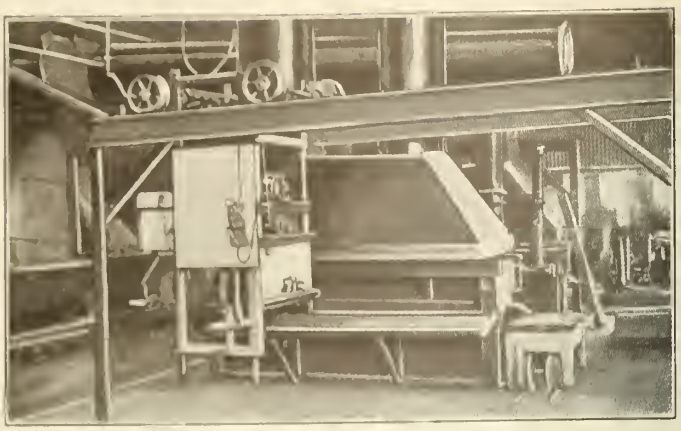

Fig. VII. St. Louis Hearth—rabble at beginning of trip.

most all danger of the lead poisoning from fumes so common with older hearths. Figs. VII and VIII show the furnace clearly.

The mill concentrate, containing from 78 to 82 per cent lead is fed by hand to the heart with a few per cent of coke breeze to assist in combustion and reduction. From 80 to 95 per cent of the head contained in the charge is reduced and tapped as crude pig lead, the remainder becoming "grey slag" (mostly oxides and sulphate of lead with some sulphide) which must be treated separately in a blast-furnace, and dust and fume, which are caught and re-treated on the hearth.

The gases, with dust and fume, from the hearth, pass first through goose-necks, to cool them, then through a flue or "trail", 700 ft. long, where the dust settles,

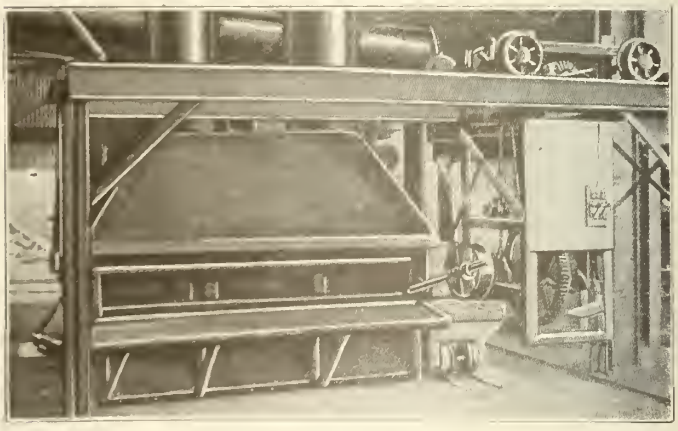

Fig. VIII.—St. Louis Hearth—rabble at end of trip.

to the bag-house, where the fume is filtered off. These bits of by-product apparatus are easily recognized in Fig. VI. So far as lead production goes, they form a closed circuit with the furnace.

The crude pig lead goes to a refining kettle, heated by a coal fire. It is "poled" with green poles, and when sufficiently freed from oxides and impurities, is siphoned to molds, and is ready for market.

At present the "grey slag" from the hearth is not treated at the plant. It is intended to erect by May of this year a small blast-furnace to reduce this material When this has been installed the metallurgical, as well as mining and milling equipment will be complete—a condition always desired and seldom attained by a mine manager.

During 1921, over three million pounds of lead was

marketed from this property. Improvements now completed will practically double the capacity of the plant, and will also reduce the cost per pound of producing the lead.

Thus we have, within thirty-five miles of our capital city, an enterprise that is a credit to those who have developed it, and to the Canadian mining profession. It is small, but it will grow, and we may rest assured that the growth will be a healthy one. Thanks are due Mr. R. R. Rose, superintendent of the mine, and his assistants and associates, for their courtesy to the writer, who can recommend heartily to brother engineers an inspection of the plant at the Kingdon Mine.

British Columbia Letter

Premier Acquires Control of B. C. Silver.

Stewart, B. C.—Particulars have been published of a deal under the terms of which the Premier Mining Company, Portland Canal District, acquires control of the holdings of the B. C. Silver Mines, Ltd. These consist of seventeen crown grants and fractions adjoining the Premier Company's property. The latter Company has obtained over half a million shares of the B. C. Silver Mines Ltd., paying for them something over $100,000. The British Canadian Silver Corporation Ltd., a British Company, controls the issued stock of the B. C. Silver Mines Ltd., and has an option on all the treasury stock, for which the consideration was 800,000 fully paid up shares in the British Canadian Silver Corporation. The latter corporation is capitalized at £400,000 sterling in 5 s. shares of which 1,000,07 shares are issued and fully paid up. The company's head office is at 19 St. Swithin's Lane, London, England. The British Columbia offices of the company are in the Pacific Building, Victoria.

Silverado.

The aerial tramway to the Silverado Group of Mineral Claims, Portland Canal, is in condition for operation. A snow trail has been constructed from the lower terminal to tidewater. With these facilities considerable high grade ore now ready will be shipped. Plans are being made for next season's development work.

Bear River..

A permanent bridge is to be constructed by the Provincial Department of Mines across the Bear River, replacing that which was washed out by recent floods. This will assure ready access to the mineral properties of the upper Bear River and its tributaries.

The Lion Group.

Alice Arm, B.C.—The Lion Group of Mineral Claims, situated a short distance from the town of Alice Arm, has been found to carry several small veins of high grade ore, which were uncovered in cross-cutting at a distance of 100 feet from the surface.—One hundred tons of high grade ore taken from the Esperanza Mine is ready for shipment.

Silver Ore on Bell Property.

Kaslo, B. C.—Improvements are to be made to the power plant of the Cork-Province Mine, with a view to permitting the Mine and Mill to be operated throughout the year. No work was done last year.—On the Bell Group of Mineral Claims, Wallace Mountain, a substantial vein of ore has been uncovered. Some samples have given returns of 6,000 ounces in silver to the ton. A shipment is being prepared for the Trail Smelter. The Bell adjoins the Sally Group which has shipped much valuable ore in past years and still is under development.

Ore Receipts at Trail.

Trail, B.C.—During the last ten days of the month of January there were shipped to the Trail Smelter of the Consolidated Mining & Smelting Co., 10,676 tons of ore and concentrates. The Company's properties were responsible for 10,469 tons. The Metallic Group, Silverton, contributed 24 tons; the Mollie Hughes, New Denver, 29 tons; the Utica, Adamant, 34 tons; and the Josie, Rossland, 120 tons.

Free re-entry of lead bullion.

Cranbrook, B. C.—An effort is being made to obtain suppor in British Columbia for the principle of a resosupport in British Columbia for the principle of a resowest Mining Association, recently held at Spokane, advocating a reciprocal agreement between Canada and the United States providing for free re-entry of lead bullion to the country of its origin. It is argued that its adoption would insure uninterrupted development and greater prosperity in all border districts. Whether there will be an enthusiastic and undivided endorsation of the proposal in this Province, however, is a moot question. There are some who take the view that it simply means smelting or refining in bond in the United States. The statement is made that it was virtually the same policy, applied by the United States to Mexican ores, which assisted in laying the foundations for flourishing industries in the former country. The tendency of Canadian legislation has been in the opposite direction. In 1901 the Canadian Government passed "An Act to provide bounties on lead refined in Canada." On the repeal of this measure the policy was approved of making straight payments to the smelters, ranging from $5 a ton (2,000 lbs.) of lead in 1902 to $3 in 1904. The British Columbia Government has offered a bounty of $3 a ton for pig iron produced in the Province from local ores and $1.50 a ton on pig iron produced in the Province from foreign ores.

Cedar Creek.

Quesnel, B. C.—Placer ground situated on Cedar Creek, which was found to contain good values last summer, has been bonded to outside interests, the intention being, it is stated, to undertake development during this year's open season. The new records are believed to be on the old channel of the Quesnel River.—The Del Ecuador Mining Co. Ltd., also has acquired holdings in the same locality and is reported to be arranging to put a dredge to work as soon as weather permits.—Hydraulicing is to be undertaken by the Cariboo Goldfields Ltd., on Roses Gulch. A recent announcement has been made that the ground and equipment are ready for operations.

Lucky Stakers at Mayo.

Victoria, B. C.—The Mayo Silver Camp, Yukon Territory, is glowingly described in the columns of a special edition of "The Dawson Daily News" just to hand. Present conditions and future prospects are dealt with in detail. Here is a sample: "Two thousand five hundred tons of silver ore from Keno in 1921 was but a starter, but, as mining camps go, a mighty big one. In 1922 it promises to be twice as large. Another year it may be ten times as large, and five years hence it may be smelters, concentrators, a railway and a camp to rival

Cobalt, Comstock, Leadville or Butte." A second of the shorter articles reads: "The most notable strike on Keno Hill, centre of the Yukon's greatest silver activity, made during 1921 was the finding of the lode on the west end or McQueston slope of the hill. The vein starts at timber line and has been traced along the hillside through the deep moss and trees pratically a mile, and ranges in width from five to fifteen feet between the walls. Numerous crosscuts have been made on the lode at frequent intervals for almost the entire length, revealing the ore in place at every point tapped. The discovery claim, the Ladue, at the north end of the lode, was found by David Cunningham and Ray Stewart, pioneer Yukon prospectors. A buckboard turned up a piece of float half a mile away and Joel Sunderland there found the vein on the Friendship claim. Other lucky stakers and owners on the lode were James Clark and Frank McNeill, while Raoul Binet and Dick Mercure were given one of the claims. All have bonded the ground for $10,000 to $65,000 a claim. A year ago one of the claims was offered in Dawson for $200 with no takers. The ore assays 200 to 500 ounces in silver to the ton."

Northern Ontario Letter

THE GOLD MINES.

To all those who have not been able to visit the Porcupine gold area during the past few months, the magnitude of the present outlook may be difficult to grasp. Ore reserves are increasing to an important extent, costs are declining a little, and there is every evidence that milling facilities in the aggregate will be increased by approximately fifty per cent within less than a year.

Hollinger.

It has been reported in usually well-informed circles that the Hollinger is now considering the question of increasing its dividend from one per cent. every four weeks as at present, to one and a half per cent. This would amount to 19½ per cent. annually, and would require the distribution of $4,689,000 a year, a record which it is believed would not be difficult for the Hollinger in view of the fact that present income is actually at the rate of over one million dollars a month. Even now the company is taking on additional staff in connection with preparing plans and specifications for increasing the capacity of the milling plant to close to 7,000 tons of ore daily. The mill has recently averaged a little over 4,000 tons per day.

Rochester.

On the Rochester property, the Nipissing continues to carry on diamond drilling operations. The question is still undecided as to whether or not the option will be exercised, but the odds appear to be in favor of this being the final result.

Schumacher.

F. W. Schumacher is reported to be asking a dollar a share for the controlling block of 1,300,000 shares in the Shumacher Gold Mines, but the negotiations have not yet taken a decisive turn.

McIntyre.

The McIntyre-Porcupine is proceeding with preliminary work in connection with enlarging its milling plant. The listing of the shares in New York and the plan to alter the par value from $1.00 to $5.00 per share serves to advertise the mine. As a consequence of this the excellent merit of the enterprise has caused the quotations for the shares to rise.

Dome.

The Dome Mines continue to occupy the centre of the stage in point of sensational results in its mill. Ore has recently been found to range from $11 to $17 per ton and net profits are accumulating at a rate never before experienced by this company. One of the assistant provincial geologists has declared that the amount of ore actually blocked out would alone keep the mill running at full capacity for three or four years.

Longyear drilling.

The Longyear Company continues to acquire mining claims under option in the area lying along the possible south-westerly continuation of the auriferous zone which passes over the Hollinger and McIntyre areas. This company it said to be taking claims under an agreement to carry on exploration work by diamond drilling and to have an option to buy the ground within a specified time on a basis of around $100 per acre. This would amount to $4,000 per each 40 acre claim taken up.

Gold Reef.

Reports continue to circulate that steps may be taken to reopen the Gold Reef property. Something definite is expected shortly.

Additional Power.

Coming quickly on the heels of the dismissal of litigation between the Hollinger Consolidated Gold Mines and the Northern Canada Power Company is the information that the work of providing additional power requirements for the Porcupine field has actually commenced.

It was learned here today that the work of clearing the way for the power transmission line has been started, while supplies will be shipped in as rapidly as required in connection with the power development itself. This means a great deal to the gold mining industry of Porcupine, the significance of which is contained in an official statement made to this paper, namely, that there is already sufficient power to keep the mines running at present capacity until the spring break-up of the ice in the lakes and rivers and that the water storage facilities will then assure a full supply of energy until the end of this year. Mr. J. H. Black state that within about nine months after commencing the development of Sturgeon Falls the new "juice" could be turned on.

For the first time in their history, therefore, the gold mines of the Porcupine district are confronted with not a single obstacle and the world is assured of results which will probably make the achievements of the past in gold mining in Ontario appear as comparatively small. In support of this belief are ore reserves which now exceed seventy-five million dollars and with every gold producing mine in the country planning mill enlargements of from twenty to one hundred per cent.

Kirkland Lake Area.

The growth of the Kirkland Lake mining field is steady and substantial and promises to occupy for many years a place of second importance only to the Porcupine district as a gold producer.

Lake Shore.

While the management of the Lake Shore has refrained from making estimates of ore reserves it is an interesting fact that in taking the available details of lengths, breaths and average gold contents of known ore bodies that conservative engineers are expressing the opinion that at least 400,000 tons of ore may be estimated which, at a value of $15 per ton would amount to $6,000,000. In making these estimates, an interest-

ing comparision may be made with the McIntyre-Porcupine mine, which shows the physical condition of the Lake Shore and the McIntyre to be on almost an equal basis. The one handicap for the Lake Shore is in having a mill of only 70 tons daily capacity as against 550 tons daily on the McIntyre and with an increase being made to the latter which will permit 800 tons daily to be handled.

Tough-Oakes.

The work of preparing the Tough-Oakes and Burnside properties of the Kirkland Lake Proprietary (1919) Ltd. for production in the early spring is proceeding satisfactorily and the mill will likely be placed in operation late in April.

At a depth of 300 feet on the Sylvanite property the result of work is favorable and it appears to be only a matter of time until this mine will take its place among the producers.

Argonaut.

Official advice to the Journal about the Argonaut Gold is reassuring. The work of continuing the shaft to a depth of 500 feet will commence at once. Diamond drilling will be done from the present depth of 300 feet. A ball mill has been purchased and lumber is being sawed for the new mill. About 75 p.c. of the material will be on the ground before the break-up.

Hunton.

A special meeting of the shareholders of the Hunton-Kirkland will be held this week for the purpose of ratifying a merger with the Gibson-Duncan claims.

Miller Independence.

At the sixth annual general meeting of the Miller Independence Mines, Ltd., held in Dayton, a report in detail was submitted by the general manager, W. E. Simpson, as well as a financial statement by John C. Schaefer, secretary and treasurer.

The $50,000 required during the past year for carrying on development operations and for diamond drilling had all been subscribed in a remarkably short time, and a satisfactory financial balance is reported to have been shown for future work.

The manager's report dealt exhaustively with the results of practical operation, and showed that early in the year some highly spectacular ore, showing both free gold and tellurides, had been developed in sinking an inclined shaft to a depth of 55 feet at which point operations were suspended pending the inauguration of a campaign of development with the diamond drill. Extensive cross-cutting was done at the 500-ft. level to within 150 feet of the northern boundary. A total of 2,974 feet of diamond drilling was done during the year and the work continued during January making a total of 3,257 feet in this campaign to date. A total of eight holes were completed, all at the 500 ft. level, three to the west to test horizontally at this depth the porphyry which at surface is asociated with the "Jumbo" vein; two holes running east to the porphyry at the "C" shaft, with one east and one west, both dipping at an angle of 45 degrees.

Mr. Simpson stated that although a large number of veins have been cut both in cross-cutting and by diamond drill no one of these is of sufficient size in itself to yet justify the erection of a large mill. The suggestion was offered by Mr. Simpson that, instead of deeper sinking as was at one time proposed and, seeing that the company had done a very large amount of development work single handed in the Boston Creek district while all other surrounding properties without exception continued to remain idle, it might be advisable to become interested in other properties of merit in other districts which might be likely, in the near future, to become centres of "co-operative activity."

The old board of directors was re-elected with Dr. Howard V. Dutrow filling the only vacancy created by the permanent absence of Mr. Vandervoort.

The meeting was adjourned pending the report of a committee which will inquire into the possibilities of securing new property as suggested by Mr. Simpson. The adjourned meeting will be held on April 6th.

THE SILVER MINES.

Continued favorable developments on the Nipissing mine, together with good results at depth on the Violet property of the La Rosa and on the Victory Silver Mines as well as on the Keeley Silver Mines and the Haileybury Frontier in South Lorrain combine to offer good promise of prosperity during the balance of this year in connection with the silver mining industry. Although no further cut has been made in wages since the reduction of one year ago yet it is a point of great importance that production costs are steadily declining.

McKinley-Darragh.

Reports have been current this week that the McKinley-Darragh Company of Cobalt is becoming interested in the Bidgood Gold Mines of Kirkland Lake. The report entirely unofficial at the time of writing. However, the Journal correspondent has secured the information that certain "individuals" who are identified with the McKinley-Darragh have for some time been interested as stockholders of the Bidgood and it is not improbable that this fact may have given rise to the current reports that the McKinley-Darragh Company itself is becoming interested.

Silver-Cliff.

In a winze at the lower level of the old Silver Cliff mine a promising vein has been encountered. Meanwhile, ore is being sent from the property regularly and fair tonnage has been found to carry about 23 ounces of silver to the ton.

Bailey.

About 60 feet of cross-cutting remains to be done at the 4th level of the Bailey Silver Mines to reach the Big Pete vein. A number of small veins have been encountered at this level but no drifting will be undertaken until such time as the cross-cut reaches its main objective.

Coniagas.

Considerable interest centres around the plan of the Coniages to diamond drill the Ruby property in the township of Bucke. There are not a few mining men who are of opinion that the geological structure peculiar to the township of Bucke might reasonably prove to be profitable ground in which to explore. Were one success to be achieved in this area it is probable that a general revival of activity would follow. The nearest approach to commercial success heretofore in this section was on the Green Meehan which property was operated by Edwards & Wright. There are promising silver showings on the Ruby.

Crown Reserve.

The Crown Reserve is attaching considerable importance to its newly acquired property in the Larder Lake district, and the interest of the stockholders will centre particularly on this new venture for the next several months. The work of equipping the Larder Lake ground with a mining plant is proceeding satisfactorily.

Keeley.

Major Bell of the Keeley Silver Mines will return from England about the end of February, at which time it is expected a general report on the mine will

be available, showing the results achieved during the past ten or twelve months.

Beaver.

Another visit by Frank L. Culver to Cobalt has strengthened the belief that the question of opening the Beaver mine this spring in under careful consideration. It is known that the Beaver is in quite satisfactory physical condition and was not allowed to run behind in development work prior to curtailment of operations. A large amount of medium grade ore is in sight and good profits appear to be assured at such time as the directorate decides to go ahead.

Nipissing.

Due to the mill being closed down for the first week of January, which is the usual custom in order to make the annual clean-up, the production of silver from the Nipissing was lower than during preceding months. Development work during the period, however, continued favorable, the following being the regular monthly statement as issued by Hugh Park, manager, to the president and directors:—

"During the month of January the company mined ore of an estimated net value of $139,622 and shipped bullion from Nipissing and custom ores of an estimated net value of $364, 579. The value of the month's silver production was estimated at 66 cents per ounce.

"The most encouraging feature of the month's work underground was the new development on vein 251. The winze put down from the second level of 63 shaft encountered Keewatin at a depth of 45 feet. The ore, however, continued for another eight feet and a level was stablished at 53 feet. The station has been completed and the west drift at the new level has been driven 25 feet, the vein over this distance having an average width of three inches and assaying 3442 ounces. The east drift is in 15 feet but all asseys have been low grade, the ore being slightly above the drift. The vein in the winze had an average assay of 7,573 ounces over a width of three inches for the 53 feet. In the level above, where the vein was first encountered, drifting developed an ore shoot 70 feet long averaging 2¾ inches and assaying 4,563 ounces.

"Other work at the 63 shaft consisted of exploration and some drifting on a few small low-grade veins. Work at 73 shaft produced no new developments during the month. At 64 shaft, operations consisted mainly in putting up a number of raises, some for developing new portions of the vein, which proved to be satisfactory, and some to facilitate future stoping.

"Exploration work is now proceeding at shaft 128 and is being done from a new level established at 75 feet. Former work had been done at a depth of 125 feet, but work in all directions was somewhat restricted due to the area of conglomerate occuring in a bowl-shaped basin.

"The low grade mill treated 6,222 tons. The mill was shut down during the first week of the month, due to the annual clean-up, which fact reduced both tonnage treated and the month's production. The high grade mill treated 109 tons. The refinery shipped 544,414 fine ounces of bullion."

Statement of Ore Shipment Over The T. & N. O. Ry. for the Month Ending January 31st, 1922.

(In tons of 2,000 lbs.)

Cobalt Proper.	Tons.	
1. Bailey	32.00	
2. Coniagas	43.89	
3. La Rose	34.08	
		109.97

The above shipments were made to the following companies:

United States.

American Smelting & Refining Co. Perth Amboy	43.89	
Pennsylvania Smelting Co. Carnegie	66.08	
		109.97

Note.

Jan. 9th. Highest price of Silver During Month	66.250
Jan. 3rd. Lowest price of Silver During Month	64.125
Average price of Silver During Month	65.450

CORRESPONDENCE.

Prospecting in Ontario.

To the Editor.
Canadian Mining Journal.

Sir,—Today I read your leading editorial: "The Journal and its readers." In answer to your suggestion, I offer this prospector's mite.

I wish to call attention to the fact that there is a general continuity of our mining camps, located along breaks or fractures, running in a general direction, E. N. E., clean across Northern Ontario, said breaks or fractures being caused by the cooling and contracting of the granite. These fractures afforded escape-ways for volcanic ejections. This prospector places himself on record as predicting a series of mining camps strung out along these breaks.

The most southerly break can be traced from Lake Temiskaming near Haileybury, through Cobalt, Timagami, Emerald Lake (Golden Rose), Wahnapitae and the Sudbury nickel area, which is right on the contact. Further to the west and south the old rocks are pretty much capped over by the sediments.

The next break can be followed from Larder Lake, near the Quebec boundary, through Kirkland Lake, Swastika, Matachewan, Gowganda, East Shining Tree, West Shining Tree, and is plainly seen crossing the track on the C.N. Ry north of Sudbury between Makeva and Gogama, flanked on both sides by the granite, continuing on into Sehist Lake, and passing to the north of Bisco on the C. P. R. it is again pretty much covered up by the sediments through the Missisauga.

The next parallel break, starting from Abitibi, crosses the T. N. O. Ry. at Kelso, on into Porcupine (where the prophyry kicks in and does the world some good) across the Matagama River, into Bristol and Whitesides, and is again plainly seen flanked by the granite crossing the Canadian National north of Sudbury at Ground Hog between Tionaga and Foleyett. It is again seen crossing the C. P. R. at Missinabi and then down into Goudreau. These are just a few of those closer to home. North of Lake Superior there are quite a bunch of them.

In following along these breaks, which is very slow work and is hard on dry goods, when we come to where the prophyries have intruded the volcanics and there are signs of shearing and schisting, we usually make camp and hunt around a while for the root of all evil —Gold.

Yours etc.

Tom Saville.

Sudbury Feb. 15, 1922.

To the Editor,
Canadian Mining Journal.

Sir,—After reading Mr. C. M. Campbell's interesting though pessimistic letter in your issue of February 3rd, in which he states the mineral resources of the Dominion are extremely limited, and the accesible parts have been already prospected, I made up my mind to pack up and go to the farm and try to forget about mining opportunities in Canada, and in grabbing the last number of the Bulletin of the Institute, which I was including in my baggage—more for sentiment than anything else—my eye caught the following words on the inside last page over the signature of the Deputy Minister of Mines for Ontario:—

"The pre-Cambrian, representing 70 per cent of the area of the Province is pre-eminently the metal-bearing formation of America. It is estimated that only about 10 per cent of this promising area in Ontario has been prospected."

While meditating over this a few pages turned and I noticed a similar statement of the Minister of Mines for Quebec to the effect that that province comprises an area of 706,834 square miles ..... 90% of which is underlain by rocks of pre-Cambrian age..... and only an insignificant proportion of this immense area has been touched by the prospector.

I did not pursue the matter further as I am hoping that we may have the pleasure of arranging for these three gentlemen to sit at the same table at the banquet of our Annual Meeting, when perhaps this seeming divergency may be satisfactorily disposed of. In the meantime I will postpone my departure to the farm for another season.

Yours,

H. H. Claudet.

Ottawa, Feb. 18th, 1922.

To the Editor,
Canadian Mining Journal.

Sir,—I have received a clipping from the issue of "The Northen Miner" of the 24th of December which contains the following:

"Look over of the men who are to represent the branch of mining engineers in the provisional council: C. R. Camsell, of Ottawa, H. E. T. Haultain, of Toronto, Jas. McEvoy, of Toronto."

The point is well taken. The selection of two geologists with a professor between them to administer an Engineers' Bill does seem ill advised. Less than this put the Canadian Mining Institute to sleep, but it will be unfortunate if personalities are allowed to interfere with proper consideration of such an important movement as is this proposed legislation for Engineers.

Yours etc.

H. E. T. Haultain.

Toronto, Feb. 14.

BLUE SKY LAWS.

A Good Substitute.

The following despatch from Toronto may serve to illustrate the fact that we have already on the statute-books the means of dealing with those that issue and sell bogus shares. Possibly we have "blue sky laws" already in force, without realize it.

P. W. McAffrey and J. C. Ryan came up today before Judge Coatsworth in the Criminal Court for sentence for conspiracy to defraud and for issuing a false prospectus in connection with the Ryan Anti-Glare Light Company, organized at $1,000,000. McAffrey goes to Kingston penitentiary for five years and Ryan for three years.

"The case is one with which the court cannot deal lightly," said His Honor, "These two men received large sums of money from nearly 175 people, and in most instances 25 per cent was handed over to the men who sold the stock. A large proportion of the people who bought the stock were poor people whose savings were sought for this investment and which they thought would realize a considerable sum of money."

THE MITCHELL SCREEN.

The No 1 Mitchell Screen is designed for coarse screening. The Vibrating Unit is held in a ball and socket joint seated in a cast iron frame and the vibrations are transmitted to the screen cloth through steel arms, over which the cloth is stretched.

The type 5 Mitchell Screen combines vibratory, sifting and rotary motions. The vibrator, screen frame and screen cloth are suspended as a unit by a ball and socket bearing, with perfect freedom of movement in any direction, communicating to the screen surface over its entire area the ideal screening action.

The Mitchell Vibrating Screen is revolutionary, yet perfectly sound and practical. The operating mechanism consists of one horse-power motor enclosed in a dust and moisture-proof housing. Each extension of the motor shaft has keyed to it a ball cage containing a number of steel balls. The balls in the two cages are 180 degrees apart. Encircling the ball cages and pressed into the housing are hardened steel ball races. When the shaft rotates, centrifugal force keeps the balls in contact with the races, resulting in an eccentric motion of the vibrator at each end.

The three motions imparted to the screen cloth are positive and powerful. There are 3600 vibrations a minute, driving the screen into the material and forcing the small particles through the mesh. There is also a sifting action in a direction at right angles to the vibration, rolling the particles toward the screen openings, and in addition a rotary motion that insures screening efficiency.

The screen is manufactured in Canada by the Engineering Equipment Co., Ltd., New Birks Bldg., Montreal.

No. 5 Mitchell Screen.

EDITORIAL

THE ANNUAL MEETING, C. I. M. & M.

The best yet, is the Annual Meeting of our miners and metallurgists now being concluded in Ottawa. There were evidently those who had doubts about the suitability of Ottawa for the meeting, as shown by the special facilities advertised beforehand, and emphasized by Mayor Plant, for short inter-provincial excursions. Actually, there has not been any general interest in these excursions, and the members have paid more than the usual attention to the business and technical sessions.

A tone of confidence and optimism has pervaded the meeting. Dr. Corless' presidential address gave the cue for what followed. This remarkably able exposition of the limitations and possibilities of our chief natural resources, and of the predominant part the miner must play in Canada's development, disproved conclusively his first remark that "it is a wide subject—so wide that there may be nothing in it!"

Dr. Corless' demonstration of the potential importance of our mining industry, and his plea for an adequate national policy bore fruit immediately. The meeting endorsed unanimously the Secretary's "forward" policy as regards membership, and likewise instructed council to carry out the full programme of printing brought up for discussion. There is no doubt that the liberal policy as regards membership in the Institute is in accord with both its tradition and the attitude of its present members, and that the powers now put in the hands of the council will not be abused through the election of members unworthy of the honour. There are many Canadians deeply interested in the development and operation of our mineral resources who up to the present have not had the warm welcome they deserve from the Institute. It was aptly pointed out at these meetings by a number of speakers that the capitalist, the business manager and the investor in mines are essential factors in mineral development. These men have yet to be adequately represented in our Institute. The present meeting may mark the change.

Rather more uncertain and less clear-cut is the Institute's financial policy. It is a "forward" policy, too; but whether there will go forward a debit or a credit remains to be seen. The discussion and the resolutions adopted showed a complete confidence in the ability of council and our secretary to make ends meet. It may be that this confidence rests upon the fact that "we have now a real, live secretary, and we hope to have a real, live council." We hope it rests upon definite plans formulated by the secretary and approved by the late council. No such plans were made public at the meeting; but this might properly be the case with a speculative or tentative programme. In the meantime, the buoyancy of a meeting that has given "carte blanche" to its executive in the way of expenditure might reasonably be called in question by those capable of acting as ballast in the Institute ship. There are sure to be head winds during the coming year; but we hope the skipper and crew will have sufficient skill to beat safely to port.

The technical papers have been of a high order, worthy of the Institute's annual meeting. The contentious subjects that are so apt to consume time, and that amuse a few and bore the rest, have been studiously avoided. Also, highly technical subjects have been subordinated to those of general interest and national importance, the numerous meetings of branches having provided a more suitable outlet for specialized information and its discussion.

Particularly commendable is the attitude of co-operation with progressive thought outside the Institute, evidenced by Dr. Shortt's return visit to the annual meeting, and by Captain Carter's expert advice on aeronautical questions. If the Institute is to play its part as a national force, it must co-ordinate itself with

the other factors in national progress. Here is tangible evidence that the Institute's leaders recognize the necessity and the expediency of such co-operation.

An important question that was not formally discussed, but was alluded to in sufficiently conclusive way, is the attitude of the Institute as a body toward restrictive legislation for engineers. Whatever may be the individual tendencies of members on the question of a trade union for engineers, it is quite clear that the Institute will not itself become exclusive, as it is intended to make the proposed corporation. The mining engineer performs a function that engineers in other branches are seldom called upon to do. It is he that must locate, develop and make immediately useful to humanity the natural resources upon which progress mainly depends. Most other engineers build upon the result of his efforts, and have functions that are capable of clear definition. The miner's functions are as diversified and as difficult of pre-determination as the ore-bodies he finds and develops. Herein lies the difference between him and his brother engineers. Here also, is the source of his pride, and his peculiar usefulness to civilization.

THE STRENGTH OF UNITED EFFORT.

In concluding his comments on operations at the Hollinger mine during the past year, Mr. A. F. Brigham said: "I take great pleasure in referring, in terms of highest appreciation, to the services rendered by the staff, although perhaps the most eloquent testimony is borne by the result of the year's work." The economical mining and treatment of over a million tons of gold ore demands the attention of a large number of skilled men. In each of the several phases of mining and milling operations many thousands of dollars are expended and each of the numerous operations is important. Under the head of mining come cross cutting, drifting, raising, sinking shafts, timbering shafts, stoping, scaling, timbering stopes and raises, backfilling, track laying, tramming, electric haulage, pipefitting, drainage, hoisting, landing and dumping, drill repairs, sharpening steel, distributing steel, mine sampling, lighting, excavation, surveying and assaying. In milling there is a similarly long list of operations: crushing, conveying, classification, tube-milling, concentration, treating concentrates, handling and thickening pulp, cyaniding, agitation, decantation, filtration, neutralizing, clarifying, precipitating, refining, sampling and assaying. Then there are a number of important items classed as general charges, including a variety of things from clearing surface and building roads to marketing the bullion. In order that the steady stream of gold may be maintained all these parts of the business must function, and in order that the whole operation may be carried on advantageously each department must be operated efficiently. There are many men who contribute to the successful operation of the mine. Many engineers, and a multitude of others, contribute their quota to the sum-total of accomplishment reported on by Mr. Brigham. The individual efforts are known to few, but the total results indicates that the big machine is working well in all its parts.

BACK TO THE LAND—AND THE BUSH.

Canada is much interessted in the "back to the land" movement. This interest is "altruistic" in the case of many Canadians, for it means that *the other fellow* is to go back to the deserted farm, or hew out a new one on the frontier. However, the idea is fundamentally sound. Though the product of one farmer's efforts is now many times what it was even a few years ago, due to the mechanical aids that multiply his capacity, still the continuous drift from country to city, accentuated during the war-time, has left us in a state of un-balance.

There is a moral in this for the mining profession, and now is the time to point it, when our rivers, lakes and mountains are about to wake from their annual sleep, ready to receive to their bosoms the sleek canoe and the sleepy burro. To understand the present necessity for pointing a moral, one needs but study Mr. Corless' Presidential address in Ottawa this week.

Hard times have driven many a man back to the old farm already, and more will go. There, food and shelter at least can be had, and a competence unless conditions are awry. Many engineers, not excluding mining engineers, have felt the pinch. Where can they go? Why, back to the bush of course!

As the farmer supplies the chief means of subsistence for the whole community, so do the prospector and the man who does initial development care for the continuance of the mining industry. A recent correspondent of the Journal argues, in pessimistic vein, that we are using up ore faster than we are finding it. A correspondent today points out the vast possibilities of our territories. We wish to point out that it is only the efforts of the prospector that can justify the optimistic view and dispel the gloom of the pessimist.

The farmer is the back-bone of our whole community. So the prospector is to the mining community. prospecting is attracting more and more, highly trainable as farming, and similarly fundamental. Both "hay-seeds" and "bush-whackers" suffer the gibes of ignorant scoffers. The prospector particularly excites the risibility and often the derision of men in more settled occupations who consider themselves much more important in the cosmic organization. But the self-important ones are wrong. Without the prospector they would revert to pegged shoes and ox-carts, and would have to farm or starve. Also, the field for prospecting is, attracting more and more, highly trained men, and the old-time prospector finds it expedient to train himself similarly in order to hold his own.

What about the investment, the works itself and the reward? It costs ridiculously little to provide for the legitimate expenses of a prospector in the field. The work of preliminary development, up to the point at

which the technical representatives of capital can safely be called in, is likewise far from costly in most cases; in fact that main investment is usually the energy behind a pick and shovel, and the power behind a hand drill.

The field for the prospector extends from the International boundary to the uttermost parts. We have pointed out lately that some parts of Canada long settled offer district opportunities. Not all trained mining engineers are versed in wood-craft; but most can find their way round partly settled regions, and so can locate a field for prospecting suited to their training.

The prospector's reward cannot be definitely gauged beforehand, and even the results in general must remain a matter of opinion. Our experience leads to the belief that, if he is at all adapted to the work, and if he applies himself discreetly and consistently, the reward of the trained prospector or mining engineer is as sure as most things are in this uncertain world. Instances could be quoted and multiplied to prove this; but the statement will suffice.

Thus there is offered to the adventurous engineer, as well as to the man willing to "take a flyer" much sounder than is to be had on the stock markets, a chance to forward his own interests, along with that of the country. Initiative, courage and a small amount of money are the pre-requisites. We can safely assume that where the first two are present, the third will be found.

MAPPING OF QUEBEC.

In a paper presented at the Ottawa meeting of the Institute of Mining and Metallurgy, Mr. A. O. Dufresne gives some account of recent progress in prospecting in Quebec. Considering that Ontario's great silver and gold producing areas are but a few miles west of the Quebec boundary, and that there are large areas in Quebec of rock formations similar to those of the Ontario mineral areas, it is to be expected that Northern Quebec may some day rival its neighbor as a mineral producer. As yet Quebec's output is chiefly from the Eastern Townships.

In the early days of prospecting at Cobalt, it was generally held that the Ontario mining laws were more favorable to the prospector than were those of Quebec. The present Quebec mining law is favorable to the prospector and enables him to secure title to property at moderate cost. Prospectors will to well to pay more attention to Northern Quebec.

The geological mapping of Northern Quebec is proceeding only slowly. The Province might well spend larger sums in learning more about its mineral resources. Prospectors should have something to guide them in their search, and Government maps and reports not only serve as guides but stimulate interest. There are, now available geological maps of parts of Northern Quebec, but the Province is in large part still unmapped.

EDITORIAL NOTES.

"Silver" Process for Gold Ores.

The treatment of gold ores containing carbonaceous matter has received much attention lately in Northern Ontario because of the occurence of gold ore in carbonaceous schists. The black rocks have been encountered at the McIntyre and Hollinger mines. Owing to the action of carbon on the cyanide, the gold occuring in such rocks is not easily recovered and much ore of this character has been left unmined pending the devising of suitable methods for treatment. Some time ago it was announced that a suitable method had been worked out at the McIntyre mine and would be used in the new plant to be built this year.

The Merrill Company of San Francisco, now announces that it has taken over the rights to the "Silver" process, named after Mr. Silver, metallurgist of the Tonopah Belmont Development Company, who discovered it. By a simple pre-treatment of the ore with an inexpensive reagent, the carbon is rendered inert and the ore may by cyanided with normal extraction and cyanide consumption.

This carbon problem has been attacked by many metallurgists and there can be little doubt that the researches consequent upon the occurrence of such ore in California and the Gold Coast will be of value at Porcupine. It would be interesting to have some account of these researches from some of those that have been recently engaged on the problem.

ANNUAL MEETINGS.

Time was when, from the East and West,
We gathered near the Ides of March
And did our utter, eager best
To see that no one felt a parch.

Years pass and jealous tempus flies;
Manners and morals suffer change,
Man may improve, but pleasure dies
If Puritans can so arrange.

* * *

Thus thinking, I adjourned to Hull
And there acquired a quart of Mull

Anon.

PORT ARTHUR NOTES.

By J. J. O'Connor

Mr. George Glendenning, of Toronto, made an examination of the McKellar Longworth, Jackson Development Company, Vimy Ridge and Pommaker Company's gold properties in the Schreiber district, in the interests of New York and Toronto parties, during the past two weeks, and left for Toronto today.

Negotiations are under way between the various interests involved, whereby it is intended that the above properties will be combined under one company and operated under one management. If this merger is consummated, it is the intention of the proposed purchasers to undertake an aggressive campaign of development on all the properties concerned. It is understood that they are now in negotiation with the Hydro-Electric Power Commission, with a view to having the necessary power delivered to the properties from the Nepigon hydro development.

The Canadian Institute of Mining And Metallurgy

Twenty-fourth Annual Meeting.

It is rather a hopeless task to attempt to compress into a few brief paragraphs proceedings so compendious and so well worth careful attention as those of the meetings now being concluded in Ottawa. If such an outline will help to stimulate a study of the papers themselves, it will have served a useful purpose.

Mineral Statistics.

The first item was, as usual, the consideration of mineral statistics. Mr. Cook's report from the Dominion Bureau of Statistics followed the same general lines as the reports formerly issued by the Department of Mines, as recommended by the Institute last year. A decided forward step is the co-operation of Provincial and Dominion authorities in the collection of statistics from operators, with the object of avoiding the useless labour involved in a duplication of returns. Mr. Gibson at this meeting formally turned over to Mr. W. R. Rogers the responsibility of presenting Ontario's statistics in future. Mr. Denis gave his report for Quebec as usual. British Columbia was represented by Mr. J. D. Mackenzie of Vancouver.

To offset the general reduction of mineral output during 1921, there are a few compensating features. The success of the Trail smelter in the treatment of Sullivan ore is of outstanding importance. The fact of the Mond Nickel Company's continued operation points to the soundness of a diversified production; Italian vineyards still need copper sulphate, and platinum jewelry is still the vogue. More and more, conditions favour the mining of gold, and Ontario's production is going up by leap and bounds. Coal production in Nova Scotia is now on a sounder basis than it has been for some years.

The Presidential Address.

Dr. Corless chose for the topic of his Presidential Address the question that is always of the utmost consequence to the mining fraternity, but seldom has the attention its importance warrants. The usual description of Canada's potential mineral wealth is adjectival and that only. Dr. Corless has not stinted the adjectives, but he describes as well the facts of nature that inspire his confidence. "Illimitable mineral resources" corresponds logically with a half-continent of mineral-bearing rocks, only a corner of which has as yet had even preliminary exploration, and of this corner, only a small fraction has been thoroughly prospected. The nickel field offers a case in point. Its posibilities will not be exhausted until many times the present amount of exploration has been done. It is obvious, when once it has been pointed out, that Canada's fifteen per cent. of agricultural land cannot lead eventually to agriculture as our chief industry. The pre-Cambrian shield and the ore-bearing mountain ranges East and West have pre-determined our main national occupation. We need the help of Dr. Corless' broad outlook to keep these things before us.

Dr. Shortt's Paper.

Dr. Shortt's exposition of "The Economic Relations of Canadian Gold Production" showed clearly the reason for facts observed by all and understood by few. The discussion that followed demonstrated mainly how indiscreet it is for a layman to question the conclusions of a learned economist. Particularly startling was it to find that in abnormal times like this a gold reserve performs a function that is mainly psychological, its proper function (that of balancing international difference of trade) having ceased when the load of difference became too heavy for it to bear. The present loss that the United States is subject to on account of its huge holdings of gold was aptly illustrated by Dr. Shortt's remark that we might as well build another transcontinental railway and let it lie as to keep the equivalent gold in our vaults, so far as the real value of either is concerned. The relative indestructibility of credit he demonstrated by pointing out that "the gold of Britain has melted away, whereas her credit is still good."

Two interesting predictions were made by Dr. Shortt; first, that within a few years gold will, relatively, be worth more than $20.67 an ounce; second, that when the gold of the United States is finally distributed throughout the world, it will be through the hands of British bankers, and with profit to Britishers.

The Mining Industy and Our Railways.

Dr. Camsell gave specific information about railways and the minerals they carry, where ordinarily only conclusions and generalisations are available. "In the United States one freight car out of every three carries coal; but excluding coal the mining industry in that country furnished in 1919 twice as much tonnage as agriculture, three times as much as forestry, and twelve times as much as the animal industry." In Canada we have not yet reached that proportion; but with only a fraction of the arable land of the United States and potentialy many times her capacity for mineral production, we will do well to lay more stress upon the relation between railways and minerals that Dr. Camsell discusses.

Mr. Price-Green of the Canadian National Railways pointed out in discussing the paper that a substantial beginning had already been made in educating possible investors to the mineral possibilities along the National lines.

Gold.

As is natural and logical, gold loomed large in this year's programme. Accomplished facts were represented in the compendious and lucid accounts of operations at the Hollinger and McIntyre mines. As records of sound and progressive engineering, and as a guide to those responsible for similar development in the future, these papers deserve a prominent place in the Institute's transactions.

Of interest in a different way and to a wider public is Mr. Hopkins' paper on "Ontario Gold Deposits." It promises well for the volume now in the press and shortly to be issued by Ontario Department of Mines. This address was made the occasion of a graceful compliment from industrial pioneer to scientist. Mr. Tom Saville, veteran prospector, resolved with unanious approval that the thanks of the Institute be tendered Mr. Hopkins and his brother geologists for the help they have given to the mineral industry in general and to prospectors in particular. One needs travel but a short while with a geologist among his friends the prospectors to know how real is the service and how warm the appreciation.

The forward view in gold mining was provided in Mr. Gordon's estimate of future gold production in Northern Manitoba, and in Dr. Wallace's account of prospecting conditions in the same region. It would

seem that it will require only the consistent and determined efforts of prospector and engineer to make Manitoba fulfil the promise of a youth that is promising indeed.

Of more than the usual interest was Dr. Johnston's description of his investigation of the old Cariboo placer field in British Columbia. The scenes of sixty years ago will never be re-enacted at Barkerville; but determining by means of a moderate amount of drilling of almost two million dollars of recoverable gold must imply renewed activity in the famous gulches.

Precious Metals at Sudbury.

Mr. Peek's resumé of the occurrence and recovery of gold, silver, platinum and palladium in the nickel ores of Sudbury gave the result of some experimental work done under his own direction, as well as the gist of what has been already published on the subject. His last remark, that the production of metals of the platinum-palladium group is commercially hazardous owing to the caprices of fashions in jewelry and the fact of actual and possible substitutes in the arts, presents a warning that is sound and not apt to occur to the average observer.

Ball Mills, and Drop Shafts.

Prof. Haultain's paper on "Ball Paths in Tube Mills" and Mr. A. A. MacKay's on "Drop Shaft Sinking" were the most highly technical presented at the meeting. The first gives the results of one of that multitude of painstaking researches that gives us, in the aggregate, the whole of our scientific knowledge. The second records an achievement in practical engineering that makes for the progress of the practical art.

The Newest Feldspar Quarry.

Ottawa is not commonly known as a centre of mining activity, but it is rapidly becoming so. Mr. N. B. Davis' paper describing the Derry quarry, north of Buckingham, Quebec, makes known to the general mining public the fact that Canada has now a worthy successor (or possibly partner) to the famous Richardson feldspar quarry. Mr. Davis omitted mention of the fact that he is himself responsible for locating this unique deposit, and that it is the result of a consistent and arduous search that he had conducted among the hills of Ontario and Quebec for many weary months.

Geologising by Seaplane.

The "canoe" geologist has been superseded. Seaplane is the latest style. Dr. E. L. Bruce's account of the actual results he got from aerial observation during the course of his experience of last summer in Northwestern Ontario is definite and conclusive. He has not merely pictured the seaplane as an aid to pioneer geological and topographic mapping; he has demonstrated it. It is to be hoped, as will as expected, that the co-operation begun by Dr. Bruce and Captain Carter will be extended through a long series of geological reconnaissances in our unmapped regions.

The moving pictures given at various times during the meetings were a blessing. It it notoriously more difficult to follow an argument by ear than by eye. The pictures provided relaxation, as well as a real source of information.

Institute Policy.

Last here, but the most prominent among the considerations before the Institute at this meeting, was the Secretary's programme for the coming year, and the policy he has formulated. After showing clearly the Institute's present position with regard to membership and funds, and having demonstrated what the future would bring if the present policy (or lack of policy) were continued, Mr. Mackenzie offered two alternatives. The Institute cannot afford to drift along as at present; either it must become a closed corporation, highly technical and exclusive, aiming to improve the status and remuneration of its members; or it must make itself really representative of the mining industry by including among its members all reputable men directly or indirectly concerned with its operation and progress. A spirited debate followed these proposals. That the Institute is already well along the road the Secretary proposed it should travel was demonstrated by two of the members that supported him. Mr. T. B. Caldwell, for long among the Institute's most active members, is a woollen manufacturer who develops mines as a hobby. Mr. J. P. McGregor is a lawyer who specialises in mining law, and is prominent in Institute affairs.

A most dignified opposition to the measure was presented by Mr. J. D. Mackenzie, representing the British Columbia memebers. He foresaw dangers in extending the membership unduly, and in incurring additional expense through the publication of both monthly bulletin and annual transactions. However, when it came to a vote, the Secretary's policy came through with flying colours, and he gracefully thanked the meeting for their vote of confidence.

The Local Committees.

That the committees in charge of the arrangements in Ottawa had spared no pains to provide for the comfort and convenience of members, was evident on all sides. The official taxi service to the Mint, Parliament Buildings and other local points of interest; the excellent office arrangements; the shepherding of the many small groups of excursionists; the entertainement for ladies; the constant care of visitors—all leave an impression of friendly courtesy that is much to the credit of our Ottawa members.

The two principal excursions, to the refinery of the British America Nickel Corporation at Deschenes, and to the Kingdon lead mine at Galetta, will provide further opportunity for acquaintance with courteous miners and metallurgists. The old days of the tobacco-spitting, loose-tongued, hard-fisted mining man are pretty well gone; his successor may be less interesting as a curiosity, but is a much saner companion and friend.

KINGDON MINE.

The article last week describing the Kingdon Mine and smelter failed to give credit to the late James Robertson for a faith that has been more than justified by the development done under the direction of his son, Mr. Charles M. Robertson, the present head of the James Robertson Company. For forty years the late Mr. Robertson held Chats Island firm in the conviction that his prospect would one day make a mine. Engineer after engineer was retained to examine the outcrop and little development pits, but not till 1911 did all attendant circumstances permit the Kingdon Mine to emerge from embryo.

A correction must be made in last week's account. There it was stated that a large premium had been paid for Kingdon lead for storage batteries. This exaggerated the premium actually paid, though it is true that lead of exceptional quality such as this does command a special market.

The Crowsnest Coal Field

(By our B. C. correspondent.)

Both in the light of the mining experience of the past and in the possibilities of the future, the Crowsnest Pass Coal Field of British Columbia and the coal measures of the districts contiguous to it are of special interest to the coal operator and to all associated with the industry.

The paper read by Robt. Strachan, senior mines inspector for British Columbia, before the Canadian Mining Institute at its recent meeting in Vancouver, was followed with close attention. He described it as the most important coal field on the Pacific slope of the continent, estimated the probable reserve at 38,378 million tons, and said the quality varied from a bituminous to almost an anthracite. Analyses were quoted to show that the coal ranks among the best in the Dominion and that "only two seams of all those tested showed greater heating value, namely, the Phalen and Harbour Seams of Cape Breton."

As to conditions he said: "The nature of the overburden differs greatly with the locality. In some places it consists merely of the surface of timber and a slight covering of coal blossom, while in other places the seams run under the mountains until the cover reaches almost 3,000 feet. The coal is easily reached along the outcrop where it is exposed by the erosion caused by the creeks that traverse the measures, and it can easily be traced along the escarpment on the east side of the Elk river, where the seams can be seen at an elevation of 1,500 to 2,000 feet above the level of the river, dipping into the mountains. Here the great dynamic forces that have caused the upheaval resulting in the formation of the Rocky mountains, have twisted and folded the measures, making the working of the coal seams along this outcrop difficult and dangerous. The points at which mining has been successfully conducted are situated where the creeks have cut through the coal measures, exposing them about three to five miles from the Elk escarpment, at Coal Creek, Michel, Morrissey, Hosmer and Corbin. At the present time collieries at the first two and the last of these localities are working."

The holding of the Crow's Nest Pass Coal Co., it was stated, amount to about 200,000 acres on which there are at present two active collieries, viz., those at Coal Creek and Michel. Considerable detail was given regarding the coal measures being worked. These comprise five seams, ranging in thickness from 5 to 30 and 40 feet. The character and quality of the coal varies, that of No. 1 seam being dark grey in colour and very friable; that of No. 2, bright black in colour and not so friable; and that of "B" seam, which is 5 feet in width, dull grey in colour and inclined to be hard. The Coal Creek coal, it was pointed out, is practically all mined by hand, the percentage extracted by machinery in 1920 amounting to 0.057 p.c. of the total output. Explosives are not used in getting down the coal.

Methods of Mining.

As to the mining methods adopted, Mr. Strachan stated that "some form of the 'Pillar and Stall' method has been adopted in every case. These pillars were generally 30 by 40 feet, while of the stalls, those intended for main roadways were driven 12 feet wide and the remainder 18 feet wide. In the early days, no doubt owing to the irregular contour of the seam, from 25 p.c. to 30 p.c. the pillars in many cases fell short of these dimensions and little attempt was made to extract any of them."

The address continued:

"Several attempts were made to work the No. 2 seam by the longwall method, but these eventually were abandoned for several reasons that combined to render the method too costly, mainly the lack of suitable material for packs, and the great thickness of the seam, which necessitated very heavy cogs.

"At Coal Creek the overburden is at its greatest thickness and partly because of this and partly because of the irregular size of the pillars considerable trouble has been experienced in working the mines on the south side of the creek. This trouble was occasioned by the strata settling down, thereby breaking the supporting timbers and, in the case of No. 2 seam, pushing the pillars into the floor, accompanying which was an outflow of explosive methane gas. In the case of No. 1 seam it caused the sides of the pillars to flow out into the roadways, which in some instances were almost filled. Disturbance of this nature, termed locally a "bump", was very pronounced in 1908, causing the loss of several lives and practically cutting off the greater portion of No. 2 Mine. Profiting by experience, W. R. Wilson, who had just previously been appointed general manager, determined in 1911 when laying out the new No. 1 east mine on the No. 1 seam, to increase the size of all the pillars and to drive his main roadways so that the greatest advantage should be taken of long and solid pillars to assist the ventilation. Following this plan three pairs of parallel levels were driven, having between each level a 50 foot pillar and between each pair a 150-foot pillar. Butt entries were set off every 600 feet so that between each pair of entries there was a pillar 380 by 140 feet, which only provided for the extraction in the first operation of about 19 per cent of the coal. The development of this mine had proceeded for more than five years and the output of coal had reached over 1,500 tons per day, when another disturbance, similar to those experienced during 1908 in the No. 2 mine occured, cutting off the greater part of the mine. This disturbance occurred in the main level district, about 4,000 feet from the mine entrance, and almost exactly over or above the ground where the trouble was encountered in No. 2 mine. The existence of the old workings may have been a contributing cause, but the principal cause no doubt was the great weight of the strata overhead, accompanied by possible weakness in the strata. Above this coal seam the mountain attains a height of over 2500 feet, which under normal conditions represents a weight of 187 tons per square foot; but the conditions here are far from normal, the coal seams being entirely unsupported on the north side, while deep gashes sides leave it practically like a lever supported at on end."

Further precautionary measures were then determined upon, the speaker asserted, it being decided that "all future work should provide for still larger pillars. These were to be increased from 150 to 200 feet, thereby reducing the percentage of coal obtained during the first operation from 19 p.c. to about 12 p.c. In other mines this system is modified to suit local requirements, the size of the pillars being increased

Gas And Ventilation.

After giving an account of the methods of mining and shipping the coal Mr. Strachan gave some interesting figures illustrative of the amount of gas given off in the various mines and the ventilation provided to meet underground conditions. The table showed the amount of air provided per unit per minute (a unit representing each man or boy while each horse or mule was estimated as three units), the amount of methane produced per ton of coal mined and the amount of methane given off every twenty-four hours, as follows:

Mine	Amount of air circulated per minute for each unit.	Methane produced per ton of coal mined.	Methane given off in 24 hrs.
	cu. ft.	cu. ft.	cu. ft.
No. 1 East	1,000	6,192	2,476,800
No. 3	624	2,697	868,320
No. 2	476	1,360	345,600
No. B. North	552	3,086	610,560
No. 1 North	331	1,867	672,480
No. 1 South	268	384	102,240
No. 9	460	.....	82,080
Total			5,158,080

It was noted that in the mines with the greatest production of methane the greatest amount of air per unit is provided and that "the new fan, which has been built for the most gaseous mine, No. 1 East, will almost double th present amount of air per unit."

Dust Prevention.

Concerning coal dust dangers it was stated that roadways, sides, roof and floor are treated with water, piped for the purpose when it cannot be obtained locally. When it can be obtained locally it is kept under pressure by means of a pump, driven by compressed air, and the water is used with a hose to wash down the roadways and also the working face. In some portions of the main roadway sprays are arranged to blow off at every 100 yards all night and in this manner the moisture permeates every portion of the roadway. In addition the dust and second burnt ashes are in use as a preventative to the propagation of an explosion. Within the past four years all oil-burning lamps (except those required by the officials, not exceeding twenty) have been eliminated from the mine in favour of the Edison electric safety lamp. Gas tests are made not only with the safety lamp but as well with the Burrell gas detector at least once in every eight hours in every mine. Records are made of these readings and a diagram kept in the manager's office shows the daily percentage of the methane given off, the barometric pressure, the amount of air passing at such times as it is measured, and the result of the analysis of the air samples taken.

Michel Colliery.

A similarly complete and interesting description was given of the Michel Colliery, opened in 1899, and situated about 17 miles north of Fernie, and 8 miles west of the summit of the Rocky Mountains. Michel Creek has cut across the coal measures leaving them exposed on either side and the seams, of which seven are enumerated, have a thickness ranging from 5 1-2 feet to 10, 12 and 14 feet. Three mines are working, two on the No. 3 upper seam and the third, No. 8, on the No. 8 seam. The coal of the former is of a brilliant dark colour and of firm texture while that of the latter is a dull grey colour. Mining methods are like those at Coal Creek, simplified through lack of "bump" trouble, the reasons being comparative lightness of cover and the greater solidity of the formation. Explosives are used at Michel to a limited extent for the blasting down of coal, and the proportion of machine-mined coal is greater than at Coal Creek although not more than 4.3 p.c. of the total output.

The amount of gas given off and the ventilation provided are detailed in the following table:

Mine.	Amount of air circulated per minute for each unit.	Methane produced per ton of coal mined.	Methane given off every 24 hours.
	cu. ft.	cu. ft.	cu. ft.
No. 8	271	211	95,040
No. 3 East	1,090	6,096	1,828,800
No. 3	551	1,732	606,240
Total			2,530,080

To dilute this amount of dangerous gas, 254,822,400 cubic feet of air is circulated every twenty four hours, and the methane percentages average just under one per cent. Similar measures to those applied at Coal Creek are used to deal with the coal dust problem, men being detailed in every mine to keep the roof, floor, sides and working face free from dust.

Huge Veins at Corbin.

An interesting account was given of the Corbin Coal & Coke Company's operations, whose holdings of about 20,000 acres, are situated about 20 miles due east of Fernie. The locality is known as Coal Mountain and the seams are almost vertical and attain great thicknesses. "This latter feature appears to be due", it was stated "to monoclinal folding of the measures, so that in a horizontal section of 2,604 feet we have 811 feet of coal. The whole of the mountain has not yet been prospected and although over a million tons of coal have been extracted since the colliery was opened, this represents no more than a scratch on the surface."

A rather novel method of mining the coal was described as consisting of "stripping off the timber, then washing away the surface of coal blossom, and loading the coal directly into railway cars with a steam shovel. But owing to complaints of the pollution of the streams this method had to be abandoned and steam shovels were then used for stripping the overburden, which was loaded into dump cars, removed some distance from the workings and dumped."

It was affirmed that "the mining of the coal by the stripping method did not prove as economical as might have been expected, the amount of coal lost being considerable", and in opening another seam the caving system was practised. In this system the pillars are first formed and then split into small portions when owing to the weight either of the surrounding ground or of the seam itself the coal runs of its own accord. In the event of the coal failing to run however, either one of the existing cross cuts is used or a new one is driven to the point and a blast set off. Owing to the friable nature of the coal here no trouble was experienced unless timber that had not been withdrawn caused a stoppage. In this manner practically the whole series of pillars can be drawn until all the coal is extracted, but unless the roof of the floor is that of a tender nature and follows up the coal, trouble is likely to be experienced with the huge cavities left behind."

In the development of a new mine another method, somewhat similar to that in use in Michigan iron mines, is to be adopted. The seam being laid off in panels, raises are driven up until the side of the panel is reached and the pillars will then be extracted in lifts. A solid floor of timber will be laid down under the tracks and this will act as the roof for the next lift, and so on.

The liability of these large seams of coal to taking fire, it was explained, had retarded their development, No. 1 seam being on fire and the upper portion of No. 4 seam burning. The latter mine has so far been saved through the vigorous efforts of officials.

The coal is described as being black and glossy in appearance, possessing a greater ratio of free carbon and less of volatile matter than the coal either of Michel or Coal Creek and as having a higher percentage of ash than the coals of those localities.

British Columbia Letter

Prince Rupert Coalfield.

The construction of a forty-five mile railroad to open up a coal field in the Morice River Region, northern British Columbia, is being asked of the Dominion Government by a deputation of residents of Prince Rupert and the districts adjacent. Such transportation facilities, according to a statement made by the Prince Rupert Coalfields Ltd., would tap a proven reserve of 54,000,000 tons of high grade bituminous coal. Diamond drilling, it is stated, has established that there are three seams on the property, measuring 4.5, 5.5 and 7.5 feet respectively. The railway also would give the operators of the Betty Mine connection with the Grand Trunk Pacific Railroad. Thus the project would assure a continuous supply of fuel to Prince Rupert and users throughout the north country. Not only this, but it would make possible the development of a substantial bunker trade at the port of Prince Rupert. It is argued that, with the unquestionable wealth of this part of British Columbia in respect of coal, those whose businesses and whose homes are there should not be dependent on coal imported from Vancouver Island and the Province of Alberta.

Chu Chua Coal.

When Professor W. L. Uglow, of the Canadian Geological Survey, gave his geological description of the Chu Chua coal deposits before members of the Canadian Mining Institute assembled in Vancouver, he raised a storm that threatened to become turbulent, but shortly subsided and died harmlessly away. The professor gave the analysis of a number of samples of Chu Chua coal that were not flattering, the ash content being rather high. This coal basin, it may be explained, is situated in the North Thompson Valley, and a comparatively short distance from the town of Kamloops. John Cunliffe questioned the propriety of the delivery of such an address before the Institute, deprecated the professor's alleged statement that the property was not likely to prove a commercial success, and said that he had inspected it and found substantial evidences of large quantities of coal. Prof. Uglow replied that he had inspected the property at the request of the director of the Canadian Geological Survey, and that no malice was intended in his remarks, which were almost entirely with reference to the geology of the field, answering further he said that he had not sampled a "seam of dirt" but a seam of coal and that he had been, in person, in the mine.

Notes on Coal Flotation.

P. E. Peterson read a short paper entitled "Notes on Coal Flotation" at the Canadian Mining Institute's recent meeting in Vancouver. He explained that he had carried on some experimental work to test the suitability of the flotation process for the cleaning of Vancouver Island coals, that samples had been taken from the product of the Douglas seam for this purpose, and that for laboratory experiments a Janney flotation test machine was used, larger tests being made with a Peterson cell, eight feet six inches in diameter, having an approximate capacity of fifty tons per twenty-four hours. "The results," he declared, "show that, on the material tested, good recoveries of clean coal can be made by the use of the process."

WHERE THE MONEY GOES.

The Hollinger report shows that in 1921 the cost of mining was $2.98 per ton, milling $1.46 per ton and general charges 42 cents per ton. There was paid for labor in the three departments, $1,979,817, $500,891 and $228,924 and for stores $1,215,026, $1,067,292 and $120,739. The employees received during the year a total of $2,709,632 and those who supplied the stores received $2,403,057. There was paid in taxes $429,889. Shareholders received in dividends $3,198,000. There was left to be added to surplus $828,927 which will be used to provide plant for increasing output.

"Hard times" seem to have brought exploration and prospecting to the fore. This illustrates once more the fact that compulsion is the great factor in progress.

Chance Finds

By Reece H. Hague.

When one looks over the notable mineral discoveries of the world it seems remarkable the large part the element of chance has played in the majority of them. Of course there are many cases where finds have been made by prospectors after a long and weary search, but a big percentage of strikes have been stumbled upon more or less by accident.

Greenhorns have been responsible for some of the most important discoveries made, and in numerous cases they have been unaware of the richness of their finds until enlightened by some sophisticated prospector or mining man. Experienced prospectors sometimes run across the mine of their dreams when least expecting it, and it is astonishing how many finds have been made by prospectors putting ashore for lunch or when held up from travel by the elements.

Northern Manitoba has been no exception in the matter of mineral finds having been made by chance and one could quote many instances of luck which has led to men running across promising mineral deposits.

Last summer a prospector named Gaspard Richard made a discovery in the Snow Lake region near Herb Lake, and a number of prospectors hastened to the spot to stake, impressed with the samples Richard displayed. Having put up their location posts, the prospectors were camped on the eve of their departure on a bank near the lake. When they retired for the night fresh logs were on the fire blazing near the tents. To the consternation of all it was discovered in the morning; that during the night a large log had rolled from the fre to the lake shore and burned the end of one of the canoes that were tied there. The charred end was removed and the canoe patched up as well as was possible with the limited means at the disposal of the men, but it was decided that it was not strong enough to carry its full quota of passengers. Consequently two of the men were elected to walk the several miles through the bush to the Herb Lake camp, one of those chosen being Jacob Cook, an Indian prospector employed by J. P. Gordon.

Cook and his companion were proceeding back to Elbow Lake when the former noticed considerable oxidization in an outcropping and stopped to investigate. Panning disclosed a good tail of gold.

Cook made all haste to acquaint Mr. Gordon of his discovery. When he arrived at Herb Lake and told his story a number of men immediately left for the spot described by Cook and several promising veins were located and staked, free gold being found in places.

Jacob Cook was the man that discovered the Red Rose mine at Copper Lake for Mr. Gordon, some two and a half years ago. Samples from this property aroused considerable interest in the mining world when they were brought in by Cook, as they were richer than anything that had previously been taken out of the district.

That Cook's luck occasionally deserted him however, was shown by the fact that he, among other prospectors, had frequently camped on the spot at Elbow Lake where the Muray Brothers made their sensational find last Spring. The water was at the time the Murray brothers stopped at this point for lunch, very low and enabled them to see big splashes of free gold at the water's edge. They subsequently traced the enrichment for some distance inland.

The Flin Flon mine, which diamond drilling sinking and drifting have proved to contain more than 16,000,000 tons of mixed sulphide ore, was discovered by prospectors paddling a canoe on Flin Flon lake, who saw the sulphides glistening under the surface of the water and thereby were enabled to locate the ore body.

The Mandy Mine, from which in the neighbourhood of $2,000,000 worth of high grade copper has already been taken, and which still contains $12,000,000 worth of low grade ore, was found by two prospectors that had picked the site where the mine now stands as a suitable place to put in for lunch, and were highly elated when they found they were sitting eating bacon and bannock on rock of great value.

Two years ago the wife of a man employed cutting cordwood for a mine at Herb Lake wandered away into the bush one morning and in her ramblings ran across a vein of quartz carrying free gold. She arrived back at her shack highly elated and with clothing torn from contact with the shrubs. Men went back with her to the scene of the discovery and staked the ground.

One could go on almost indefinitely describing the peculiar incidents connected with the discovery of mines. Time and again a prospector has stumbled across a mineral deposit of untold wealth on a spot which had previously been traversed by hundreds of people oblivious to the richess beneath their feet.

How many prospectors have spent their whole lives seeking the elusive mineral, and died in poverty, having never made a single strike of importance, while a greenhorn on his first expedition covering the same ground as the dead man has made a find that has yielded him a fortune? It is very true that in prospecting luck does not always come to the most deserving. Some strikes have been made by prospectors after many weary months of conscientious search, but many of the world's richest mines have been found accidentally by comparative greenhorns.

How many prospectors have staked properties and after doing a little work abandoned them, to have them picked up a little later by someone else, who after doing a trifle more exploration work, has uncovered a veritable Bonanza? But these things are all in the game. The unfortunate prospector gives a grunt of disgust when he learns that he has slipped up on a winner, shoulders his pack, and, pick in hand, starts out on another trip of discovery, always hoping that the next journey will reward him for all his years of toil, and always confident that he will some day find the pot of gold that lies at the foot of the rainbow.

The Merrill Company of San Francisco has issued a bulletin on "Merco" processes and products. In this are presented descriptions of apparatus used at many gold mines. The Merrill Clarifying Filter, Crowe vacuum apparatus, Merrill filter press, McKenzie-Sigstrom plug valves and merillite are described.

Nothern Ontario Letter

THE GOLD MINES.

The public at large has at last appeared to realize the importance of developments at the gold mines of Northern Ontario. Right on the eve of probable dividend increases on the shares of the leading producers, a wave of speculation and investment has set in which has caused the market value of the operating companies to advance possibly ten million dollars as compared with two months ago.

An event for which thousands of people have been waiting is the mailing of the annual statement of the Hollinger Consolidated covering operations during the past year. Also, the ending of the fiscal year of the Dome Mines on March 31st is looked forward to with extreme interest. Stockholders of record on or before the end of March will participate in the capital repayment of $1 per share that is to be made on April 20th, together with the regular dividend of 2½ p. c. The double payment, will amount to $1.25 on each share and will result in the distribution of approximately $595,000.

While the public show signs of clamoring for shares that they believe may rise to much higher quotations on the open markets, the operations at the mines continue at full capacity and with general preparations for further enlargement of mills and broadening scope of underground operations. It is already obvious that the aggregate output for the current year will exceed by a large margain any former record in the history of gold mining in Ontario. Preminminary estimates range from $21,000,000 to $23,000,000 for this year in newly produced gold from the Porcupine and Kirkland Lake fields.

The report in last week's issue of the Canadian Mining Journal that power development at Sturgeon Falls would commence in the early spring and that the work of clearing a transmission line and general preliminary preparations have commenced, has received official confirmation this week. This removes the last obstacle in the way of a full realization of the prosperity that is bound to lie behind such large and rich ore bodies as are already opened up in the Porcupine district.

Dome Mines.

If the record of the past several weeks on the Dome Mines is maintained, this enterprise promises to be one of the sensations of the year in the world of industry. For the time being, the mine has risen from the position of having the largest low-grade gold bodies in Canada to a point where its ore exceeds in richness the Hollinger Consolidated and even the McIntyre-Porcupine. The significance of the achievement will be more fully realized within the next few months, perhaps within the matter of a few weeks.

Longyear Options Claims.

The Longyear firm of contractors are securing options on properties lying to the west and south-west of the Hollinger-McIntyre area. The options usually comprise an agreement to do a certain amount of explorations by use of diamond drills and with an option to buy the properties in whole or in part for $100 per acre within a specified time. The claims secured in this way are covered with sand overburden to depths ranging from 50 to 100 feet. The drilling venture is based upon the theory that the zone of mineralization may be found to continue for some distance on its present strike and has only remained concealed owing to the heavy overburden. It will be remembered that the Longyears carried out a somewhat similar venture with success in the Sudbury district, as well as in Spitzbergen.

The Porcupine V. N. T. as well as the Porcupine Crown are expected to resume operations this spring. There are reports on the street that in view of the Porcupine V. N. T. having only $50,000 in sight with which to carry on work, it would not come as a surprise were some basis of consolidation to be arranged with the Porcupine Crown. In this way, the mill of the Porcupine Crown could be quickly brought into play on ore from the Porcupine V. N. T.

Speculators are turning their attention to such properties as the Newray, Moneta, Inspiration and Preston East Dome. The success of the leading producers of the field has led to a widerspread belief that the purchase of certain of these properties may be only a matter of time.

Hollinger Mill Enlargement.

In regard to the proposed enlargement to the mill on the Hollinger Consolidated, although definite annoumcements have not yet been made, the plan favored is undertsood to be to be to instal ball mills on a super-structure back of the present stamps. In this way, at such times as the ball mill may require repair, the stamps can be temporarily brought into play. The stamps may be discarded altogether, but, if not, by-passes will be provided to convey the crushed ore to the stamps. The question is also being considered of installing rolls ahead of the ball mills so as to further reduce the ore in size before letting it pass into the ball mills.

Wright-Hargreaves.

The annual statement of the Wright-Hargreaves has been issued, and deals with milling operations from May 1st to Dec. 31st. A feature of the statement is that while 36,081 tons of ore went through the mill, this came entirely from development work. Moreover, an additional amount of approximately 25,000 tons in broken ore was placed in reserve. Following is a general summary of the report:—

A net profit of $201,186 is shown by the Wright-Hargreaves Mines, Ltd., for the eight months ending December 31, 1921, in the first annual report of the company, since mining operations were begun, now going forward to shareholders. The report is a most satisfactory one and shows that 3,0681 tons of ore were treated during the period under review, from which they received $468,665, and this ore came almost entirely from development work.

The treasurer's report shows that the company is in good financial shape. The profit and loss statement showed an income of $486,282, of which the big item was bullion production of $468,650. Mining and development cost $127,250, and general expenses totalled $231,000. Current assets showed cash on hand and with bank amounting to $282,972, and bullion in transit $32,836. In the capital assets, mining property is valued at $1,500,000, and plant and equipment at $359,865. An allowance for depreciation on the property and equipment was made of $20,722, and there was also written off the preliminary development cost $32,477, leaving the total assets at $2,425,796. Current liabilities are given as $172,026, of which $137,500 is

for a 5 per cent. dividend, payable January 2, 1922.

Much developement was carried out during the year according to the report of General Manager A. Wende. The first four months of the 1921 season were taken up in preliminary and development work, mainly due to power shortage, and it was not until May 1 that production actually commenced. Work was confined mostly to No. 2 vein with very satisfactory results. During December preparations were made for continuing the No. 3 shaft from the 400 ft. level to the 700-ft. level. Since commencement of milling on May 1 the mill, has run 91.89 per cent. of the possible time, and the average value per ton of the ore treated was $13. The broken ore on hand December 31 amounted to 25,085 tons. The average number of men employed during the period was 103.

Argonaut.

In an official statement to the representative of the Canadian Mining Journal, John W. Morrison, manager of the Argonaut Gold stated that about 75 p. c. of the material required for the new mill at this mine would be on the ground before the snow leaves. The company has its own sawmill in operation and is hauling cement for concrete foundations. By late summer it is expected to be turning out gold bricks. Mr. Morrison also made the announcement that work would commence immediately in connection with continuing the main shaft from the 350-ft. level to a depth of 500 feet. A large tonnage of ore is already in sight and this deeper development is expected to put the mine in a very satisfactory physical condition.

Lake Shore.

During the month of January the Lake Shore mine produced $51,883.30. A feature of the achievement for the month was that 2,335 tons of ore was put through the mill, this being a daily average of 75 tons and comprising the highest tonnage record for this mine. The work of enlarging the main shaft was under way during the period. It has been learned that an electric hoist will be installed during the second quarter of this year which will be sufficiently powerful to carry operations to a depth of 1,000 feet. The question of enlarging the mill to perhaps double or three times its present capacity will not be taken up for the present.

King-Kirkland.

The machinery for the King Kirkland Gold Mines is being transported to the property over the snow roads and this property will be operated in an aggressive way during the coming summer. The outlook for the enterprise is exceptionally good

Teck-Hughes.

Work of deepening the shaft on the Teck Hughes has commenced. The work will be carried from the 600-ft. to a depth of 980 feet and will make this the deepest mine in the Kirkland Lake field for the time being. As to this, however, it is interesting to learn that the Kirkland Lake Mining Company is considering the question of extending its underground workings to 1,000 and possibly 1,200 feet in depth.

Bidgood.

A special meeting of the Bidgood Gold Mines has been called for March 1st. Among other things the question of increasing the number of directors will be considered. The balance sheet shows cash and accounts receivable of $18,059.11, against which are accounts payable and outstanding cheques of $23,039.15. The stock remaining in the treasury at the end of the year was 326,615 shares. In addition to this, the statement contains the somewhat unique announcement that 158,500 shares have been contributed by certain stockholders to further strengthen the treasury. To date $113,313,82 has been spent on the property A total of 1,077 feet of underground work has been done.

THE SILVER MINES.

At a depth of 600 feet on the Violet property of the La Rose, a substantial quantity of good milling ore is being opened up. The indications appear to be that the La Rose will enjoy another prosperous year.

The Mining Corporation is defending an action which has been brought against it by the La Rose in which the latter company is endeavoring to collect money for the value of silver contained in tailings which resulted from the treatment of its ores some years ago by the Cobalt Reduction Company and which was later taken over by the Mining Corporation.

Coniagas.

Within the next month, the Coniagas will commence the exploration of the old Ruby property in Bucke township. A diamond drill will be used to test the formations as well as to explore for veins. It is understood that the Coniagas also secured options on two other properties.

Mining Corporation.

The reports about the Mining Corporation having taken the option on the Forneri property in South Lorrain are erroneous, although it is understood the Corporation, in addition to working the Haileybury Frontier has become interested in the Haileybury Silver.

McKinley-Darragh.

Reports reaching Cobalt this week have it that the McKinley Darragh has optioned property in Northern Manitoba, although the point is not made clear whether the option is for property in The Pas or at Elbow Lake.

Tesmiskaming.

Bids are being made to the Tesmiskaming Mining Company for lease on certain sections of the underground workings. This question was previously considered by the Tesmiskaming but was held in abeyance owing to some favorable developments having been encountered about that time. In view of the improved economic situation since the mine was closed down, it is believed the property could be worked profitably under existing conditions on company account. In spite of this, the plan to grant leases is believed to be worthy of careful consideration.

Colonial.

The local press prints a report that the old Colonial mine, situated adjacent to the O'Brien has been sold to New York interests. No details as to the terms of the reported deal have been secured up to the time of writing. The Colonial is recognized as one of the more promising of the undeveloped properties in the Cobalt field

PRICES OF PORTLAND CEMENT IN 1921

Preliminary estimates made by the United States Geological Survey from reports of representative producers of portland cement show that the average factory price per barrel of portland cement, excluding cost of container, in the United States in 1921 was approximately $1.87.

The average net factory price received per barrel for the whole country in 1920, as shown by reports received from all producers was $2.02

Canadian Copper Possibilites

By ALEXANDER GRAY.

Although there is no rush about it (to avail of a familiar expression) it might be as well for those who give precedence to precious metal propositions, to bear in mind that Canadian potentialities in copper are a long way from being negligible. The immediate future particularly of undeveloped properties, may not evoke much interest and activity, but there is encouragement in the remarks of Mr. Parke Channing to the effect that "there will be a copper famine in fifteen years unless new, large deposits are found".

The popular impression has been that existing porphyries, South American producers, and those of Granby and Howe Sound, in British Columbia as well as of Alaska, suffice for the world's needs for longer than Mr Channing foresees. Chile and Utah, the largest in point of known ore reserves, were regarded as more continuous sources of the red metal, even when the mines of Arizona and Nevada shall have been dismantled. Anaconda, with its South American subsidiaries, was supposed to be immune from exhaustion for more years than Mr Channing suggests. However, he is not an engineer and executive who indulges in extravagant statements, and the very fact that he publicly admitted the likehood of a copper shortage so soon, leaves it for Canada to prepare for eventualities, notwithstanding the nonchalant view entertained by some, that a substitute for copper will be found should the necessity arise. Perhaps what may happen fifteen years hence is of less immediate moment than what has been accomplished since Jackling and his contemporaries took the cue from the late James Douglas and others in the treatment of copper ores. Without the porphyries and modern smelter practice, copper would be a semi-precious metal in price. Were it not for flotation as perfected by John Ballot and associates, the acute stage in copper would be present. That 1½ and 2 per cent. ores became economically profitable, gave a filip to production beyond the ken of pioneer metal masters when Hamilton Smith was guide, philosopher and friend to the Rothschilds in copper matters, and Rio Tinto and Butte were supposed to be the elastic limit of expectations. Matte went to Swansea because London was the metal market. Douglas, the Guggenheims, Clark, and others, including Jackling, took the leadership away from Boston and its Calumet & Hecla millionaires. Ballot and his Minerals Separation in co-operation with electrolytic practice minimized losses in recovery and thereby postponed the critical period to which Mr. Channing directs attention.

Singularly enough, it was at a Canadian copper mine, the Britannia, that the first practical test was made of the oil flotation process. Flotation admittedly is indispensable. Its added saving of copper content and consequent increase in production and profits, supports the belief that the last word has not been written about the limit of payability. Simplified treatment and low mining costs put off the evil day as fixed by the vice-president of the Miami company. Meanwhile, there is accumulating testimony that Canada is going to have large copper mines, more of its own smelters and refineries and have Canadian-made copper products.

To the Nickel-Copper Industry, is to be accredited the erection of nickel and copper refineries. The Consolidated Mining & Smelting Company have rounded out their metallurgical works at Trail. At Anyox, the Granby company are giving a demonstration deserving of more than passing mention. With a grade of ore comparable with the generality of porphyry coppers, a pruned payroll and an efficient plant, the rate of copper production in recent months has been greater than the company reported for 1920. Shipments averaging 2,5000,000 lbs. of copper per month, the precious metal output, and by-products from coke ovens and metallurgical departments, bespeak more than has been expressed by the capable management. In 1920, the Granby company mined and smelted 802,-067 tons of copper ore, containing 7615 ozs. gold, 381,-742 ozs. silver, and 25,404, 950 lbs, of copper. The Hidden Creek property, therefore, began to take precedence in the province, the Britannia mine production being adversely influenced by metal markets and a series of mishaps continuing until a month or two ago. Granby carried off the honors, although broader markets and more working capital will be welcomed.

Meanwhile, promising prospects indicate the certainty of British Columbia becoming a producer of copper on a larger scale. The Consolidated Mining & Smelting Company no doubt will take advantage of easier money markets to do substantial financing on behalf of the Sullivan Mine, West Kootenay power, the Rossland properties, and those Vancouver Island copper areas that have been accumulated in the past few years. Owing to the price of copper and high freight rates, the Canada Copper Corporation cannot operate. Apart from that, the Consolidated Mining & Smelting Company have the very comprehensive plans indicated in the annual report for 1920, as follows:

> "The increase in Property Account during the year is $799,912.82. The increase includes the purchase of additional stock in the West Kootenay Power & Light Company, Ltd.; the purchase of bonds of the Coast Copper Company, Ltd, the purchase of stock and of bonds to finance development of the Sunloch Mines, Ltd.; payments on properties under bond; and expenditures on trunk line development at Kimberley and Rossland."

The metallurgy of the Coast and Sunloch ores has received attention. Sooner or later they will be served by a mill on the spot, and thereby obviate the needless cost of hauling raw ores long distances, as has been done at Kimberley. What is expected of the Consolidated copper areas, was briefly referred to by President Warren in his last annual report, in this way:

> "Further development of the Sunloch and Coast Copper properties has been suspended until the Copper market improves. These properties promise to provide a very large tonnage of copper ore high enough in grade for profitable results under normal conditions and metal prices".

Evidently these are "discoveries" within the meaning of Mr. Parke Channing's portentous remarks. Taking Mr. Warren's statement as its worth—that the tonnage offering is "very large",—there is the further judgment of Mr. S. J. Schofield, than whom in the premises there is no higher authority:

> "The Britannia sills and the Britannia formation, which may be considered as a unit, since they were affected by the same geological processes, are surrounded and underlain at some depth by granodio-

nevertheless, in view of Mr. Campbell's position and reputation I am apprehensive that his article, particularrite of the Coast Range batholith. This great batholith extends from the International Boundary-line on the south in a north-westerly direction to Alaska. The main mass holds many inclusions of all sizes which are termed roof pendants or roof remnants and are more or less mineralized".

The absense of outcrops is noted in many instances, "only by persistent prospecting and faith", Mr. Schofield writes, have the economic worth of certain sections been disclosed. Mineralization so extensive, he points out, offers a field for enterprise. Money conditions will govern the extent of explorations; but in due course the Messrs Guggenheim, the Granby interests, and the Consolidated Mining & Smelting Company, will enter upon further capital expenditure. It is significant of the Consolidated Mining programme that more copper areas have been acquired. The company's annual report does not so specify. The 1920 annual report of the British Columbia Minister of Mines does dwell upon developments in the Sunloch Group, and says "prospecting carried on during the past season resulted in the staking of seven additional mineral claims, so that the Sunloch Mines Company, Limited, now owns thirty claims and fractions having an area of aproximately 1,300 acres. The development-work during 1920 consisted of 1,802 feet of diamond drilling and 995 feet of cross-cutting and drifting, making the total work done on the Sunloch Group of claims 3,470.-5 feet of diamond drilling and 3776.3 feet of crosscutting and drifting. Diamond-drilling demonstrated the downward continuation of the ore in that zone (the west side of the River Jordan) to a depth of 150 feet below the mine workings".

Construing that along with the comment of Mr. Warren as to the presence of a "very large tonnage of copper ore high enough in grade", there should be more conclusive information forthcoming one of these days. A mill there, another at the Sullivan Mine, and Rossland supplying ore in greater quantities, confirms the impression that the Trail metallurgical works will become more and more of a manufacturing center, specializing in copper, zinc and maybe brass products.

East from Portland Canal, through the Skeena and Omineca districts; over into northern Alberta and Manitoba, eventually will respond to better transportation facilities. While the Flin Flon occurrence may be somewhat of an isolated one, it is not a rash assumption that there are others. The Mandy Mine prompted prospectors who located the Flin Flon and its $140,000,000 or $150,000,000 worth of metals in combination. That and the Rice, Herb and Beaver lakes country gave prospectors the urge to find more, hence the Elbow Lake discoveries and their spaetaenlar features. In the Murray properties at Elbow lake there appears to be a real basis for a movement. Outcropping conditions at adjacent properties indicate the enrichments are not localized at the Murray ground. At all events, the rigors of Winter in that latitude are not deterring the adventurous from staking rather than await open weather. Responsible mining engineers qualifiedly vouch for the possibilities of the sections. So to Flin Flon copper-gold contents is added this latest field tending to inspire optimism.

The Canadian West has had only "forty winks" since the Rossland boom and is refreshed. Developments are invigorating and the capital necessary would rather come to Canada than go elsewhere—all things being equal.

CORRESPONDENCE.

The Editor.—

Sir.—In your issue of Feby. 3rd you print a letter from Mr. G. M. Campbell anent misrepresentation of our mineral resources, and in the same issue is an editorial, partially explanatory and wholly defensive.

I have, in my lengthy experience, been called many names but no one has yet considered me an optimist;

ly his concluding paragraphs, may be construed abroad as representing truly the position of the Dominion in respect to its mineral resources. Solely with that thought in my mind I have yielded to the temptation to support your editorial views rather than to endorse Mr. Campbell's policy of seeing things just as they are".

To claim at the present day any equality of mineral resources with the well-developed Republic to the south of our boundary is absurd, and purely hypothetical. We are all of us from Missouri we have to be shown; but to assert that our mineral resources are only just beginning to be discovered, that their development is in its infancy, and that our potentialities are daily increasing, is only to state the facts, in other words the **truth.**

In a paper that I had the honor to present before the Toronto meeting of the American Association for the Advancement of Science I showed that the products of the Mining Industry (apart from the products of quarries, oil wells etc.) had grown from a value of $18,000,000 in 1870 to $228,000,000 in 1920, that is in 50 years; and that Canada as a producer of ores and minerals was only about 30 or 35 years old. If our production has increased nearly 1300 per cent in the past 50 years, during which time transportation has been new, difficult and expensive and most of our country practically unknown, it is reasonable to infer that the next 50 years will show an increase which, if not equal to the past 50 years will nevertheless be extremely satisfactory.

Comparisons are usually odious, because to compare **truly**, conditions must be identical. As yet, and for many years to come, conditions in the United States and Canada are anything but identical, and ratios will be unreliable if not misleading. But on the principle that roses grown on a quarter acre may be as sweet as those grown on a quarter section we should not decry our Canadian resources.

Mr. Campbell sounds a true note in advocating a conservative optimism, and in regarding the language often used by promoters (and others) as "particularly harmful"; he has the feeling of every conscientious engineer who deprecates optimism that exceeds good judgment, that becomes untrustworthy through totally unwarranted predictions; but such an attitude must be receptive of both facts and possibilities, and the writer is one who does not believe that the possibilities of Canada can be definitely measured by the yard-stick of development during the past 40 years.

The ordinary adjective descriptive of size is purely comparative, and often depends upon the blood pressure of the writer or talker, so that Mr. Campbell's objection to "huge," "illimitable", etc. etc. is well taken. But it is not necessary to have a Rio Tinto, or a Homestake, a Mount Morgan, or a Calumet and Hecla, at every doorstep to become an optimist as to the future of Canada's mineral wealth. And, if Mr. Campbell will pardon me, it is decidedly fallacious to say a thing will never happen because it has **not yet** happened.

If Mr. Campbell is right when he prints: "There has not been one solitary discovery of ore of outstanding importance in B. C. during a quarter of a century," does the failure of discovery in B. C. militate against or overbalance the remarkable discoveries that have been made in Ontario in the last 17 years? Can any of us safely make any predictions as to what may be found in the great pre-Cambrian "shield" that covers so many thousands of square miles in the very centre of our Dominion? Clearly none of us can. In 1900 the fame of Ontario as a mineral country was based solely on the nickel ores of the Sudbury region; on what is it based today? The answer is the very large values obtainable in gold and silver found in the then wilderness of Northern Ontario.

The writer is fortunate enough to have had a very considerable and extensive acquaintance with the whole Dominion during the past 25 years; he is not, and never has been, a pessimist though often called that, and he is rash enough, or wise enough (time only will tell which) to differ from Mr. Campbell; he believes that Canada's present output of metallic wealth will be many times increased during the next quarter of a century.

While it may be true that "it does not take long to go over the outcrops in a district" and locate the large outcrops, it is equally true that it takes a very considerable length of time to **find the districts,** particularly in such inaccessible country as Canada's central basin.

There are many "outcrops" of valuable copper, gold and lead-zinc veins or deposits from the Straits of Belle Isle to Lake Winnipeg of which the writer has personal knowledge. Time, transportation and population are needed before these regions can be definitely added to positive mineral regions. No one can at present truthfully say what such regions may produce in mineral wealth. Therefore a healthy optimism should not be deprecated, rather should it be endorsed.

Yours, etc.

John E. Hardman.

Montreal, Feb. 25, 1922.

The Journal and Its Readers.

In the issue of February 10th there is an article with the above heading which is an appeal to the readers of the Journal to send ideas for discussion. The article makes it clear that it is difficult to carry out the present undertaking and we are asked to "syndicate even prejudices".

As you ask for prejudices you shall have them. It has always appeared to the writer that it was ill-advised to attempt a weekly publication, it must cause anxiety with each issue to find the material and lead to the dilution of the material available in order to spread it out and fill so many columns. Moreover it does not allow time to correct the mistakes in printing which appear at times and are very annoying to the careful reader.

The weekly issue seems to be due to listening to the propaganda of the pestilential Ad Club, as if a thing could be made valuable or desirable by copious writing and advertising. We know that the things which are intrinsically valuable and which people really want do not require advertising; no one spends money to advertise gold bullion or wheat, nor would it be necessary to advertise good liquor if one had it and could legally sell it. My suggestion is that the Journal should be issued fortnightly or 26 issues in the year—one for every letter of the alphabet, and call them A. B. C. etc.

This is a humble suggestion of your faithful reader who will sign himself under the name of the animal which is the example of patient, silent, intelligent industry.— The Beaver.

EDITORIAL

DRILLING THE PORCUPINE SAND PLAINS.

Systematic exploration of areas near the producing mines at Porcupine has hitherto been largely confined to places where outcrops occur. The heavily covered rocks are now to be explored by diamond drilling. Some such work has already been done; but according to recent announcements, work of this character is now to be pushed vigorously.

The gold discoveries that have resulted in the establishment of a mining industry at Porcupine were made in rock outcrops that narrowly escaped being covered by the glacial mud and sand which has become known as the Northern Ontario clay belt. These outcrops represent the hilltops of the rocky surface that the glacial deposits have so largely hidden from view. The lower parts of the rock surface are so well covered that even in the immediate vicinity of the Hollinger there are areas still unexplored. Here a thick bed of sand hides the rocks from view and makes ordinary surface prospecting impossible. It is not to be wondered at that an attempt is being made to determine what underlies the sand plain west of the Hollinger.

The method of attack is by the diamond drill. The cores brought up will reveal many secrets. The preliminary holes will show the character of the rock formations, and comparison with the rocks that enclose the known gold deposits will give hints as to where the chances for more intensive exploration are most worth while. It is quite probable that there are good ore bodies under the sand, and it is to be hoped that they will be found. The finding of a few ore bodies similar to those of the Hollinger would reward the drillers, and would be hailed with delight by the mining community. The nature of the venture and the cost of drilling will necessitate risking a considerable sum of money. The regular prospector will recognize in those that engage in this drilling enterprise men of kindred spirit.

HOLLINGER RESERVES.

The annual report of the Hollinger Consolidated Gold Mines has, as usual, met with general commendation, as is deserved by such a frank and full statement. Such regard for the truth, and the whole truth is not yet characteristic of the annual statements of mining companies, particularly of those where the control is held by "insiders." It is well to remember, in the case of the Hollinger, that the larger part of the capital stock is still held by the original owners, the LaRose syndicate, and that it is by their leave and under their direction that the annual statement is made. Thus we may justly be proud of the spirit that animates the directors—all Canadians— of our largest gold mine. They have in full degree the sound progressiveness of the times—a part of our democratic inheritance.

To those accustomed to the hand-to-mouth policy so often necessary in pioneer mining operations, an ore reserve of over four million tons, capable of supplying the present mill for three and one-half years, may seem something only to be dreamed about, and hardly capable of realization. Nor does this figure measure the reserves. The "probable" and "possible" ore usually included in estimates on the basis of deduction rather than on the basis of mining development is rigidly excluded from calculation. The Hollinger management can afford to be conservative in their estimates; they are under the necessity neither of persuading doubting investors, nor of bolstering up the hopes of stock holders.

While the state of the Hollinger's ore reserves is thoroughly satisfactory, it induces certain reflections. Mr Brigham states that to maintain the present reserves for further development will keep $1,750,000 tied up continuously. This represents the difference between the cost of exploration and development by diamond drill and actual mining, and the value of the gold recovered from these operations. To this must be added

the cost of breaking the stoped ore held in reserve. This sum, always invested in development works, is 17 per cent. of the annual gross income, and 34 per cent of the nett income. In the case of the Hollinger, these percentages are fortunately low; if nett profits were not so large a proportion of gross income, the interest charge on this item of capital investment would be reflected noticeably in dividends. In other words, the investment in development is a much more serious charge on the income of a low-grade than of a high-grade mine.

There are gradually being delimited in Canada large bodies of low-grade ore. A few of these are now being worked; most of them are still substantially as Nature has presented them to us. Any means that will serve to prove at less cost than at present, the value of the deposits in advance of actual mining work, will be an aid to opening up these deposits. The diamond drill has done much in this regard but its usefulness is limited. Let us be on the "qui vive" for similar and more effective means toward the same end.

Lately we commented on the Dome's policy of gradually reducing the capital stock, in accordance with the using up of the mine's supply of gold. The Hollinger has adopted a different means to the same end. Instead of repaying the capital stock to share-holders, it is being held in trust, as interest-bearing securities. The result of the two schemes, so far as it concerns stock-holders of long standing, should be the same. To those that invest temporarily, or merely speculate, the difference may be more marked. On the surface it seems as if the simple and direct expedient of reducing the capital stock would bring more clearly to the attention of the average investor the fact of dwindling ore-bodies. It will take the combined attention of a broker and a psychologist to get to the bottom of the matter.

BLUE SKY LAWS AND MINING.

In an article published in the "Financial Post" the effect of blue sky legislation on development of mineral deposits is discussed. The writer takes as an example the case of the Hollinger property. He recalls that before the present owners developed it, Senator M. J. O'Brien had an option on it and gave it up after testing it with the aid of diamond drills. Later the Timmins syndicate secured the property and developed it into a great mine. The writer of the article points out that there was here, as in all cases, difference of opinion as to whether development would prove profitable. No one can with certainly estimate the value of an undeveloped or partially developed property.

The writer of the article evidently believes that blue sky laws are unpractical so far as the development of mines is concerned. He questions whether there would be a single producing gold mine in Ontario today if blue sky laws had been in force. There are many that hold the same opinion. The intention of those that advocate the laws may be good; but the business of the men that by hard and honest work endeavor to make mines out of prospects is put in jeopardy by others that in their eagerness to devise laws that are, to their view, just, do not hesitate to support legislation that may be dangerous to the future of the mining industry.

Mines are made by men that take risks and by persistent effort turn to useful account ore deposits that appear to them to be promising. Their opinions vary with their experience and are variously regarded by others. The determinable facts can be ascertained by a competent sampler; but the indeterminate facts are in the case of a prospect of quite as much importance as those that can be determined. Consequently opinions based on experience are a prominent factor in mining enterprises. The value of a mining property cannot be determined until it is worked out. Every day's work brings out new facts.

MONEY FOR MINING OPERATIONS.

An interesting item in the week's news is the announcement that a block of treasury shares of McIntyre-Porcupine Mines Ltd., has been sold for about one million dollars. This money goes into the treasury of the company and is available for expansion of the company's business. It will facilitate the enlargement of the company's plant and will thus materially help in the growth of the mining industry at Porcupine.

The money received for this block of shares goes into the mining business. The company does not need the money to carry on operations on the present scale and therefore is now in a position to get ahead quickly with plans for larger operations. A sale of shares of this character is of vastly more importance to the industry than is the sale of private shares.

Interesting from a different standpoint is the great increase in trading in gold stocks on the mining exchanges. The daily transactions have been recently very large, and the prices of many gold stocks are now much higher than they were a few weeks ago, and much higher than a year ago. This we interpret to mean that a large number of people believe that the outlook for our gold mines is brighter than it has ever been. Trading in shares in such volume is evidence of interest t othe traders, it has an influence on the industry, just as affairs of the industry have an influence on trading. The trading does not put money into the industry as does the sale of McIntyre's treasury shares; but it directs attention to the gold-mining industry. Those that inquire into the reason for the increased

activity in trading find that it is belated recognition of the fact that our gold mines are much more valuable than has been generally believed.

EDITORIAL NOTES.

It was recently pointed out by the Hon. Mr. Mills, Minister of Mines for Ontario, that the Provincial government spent considerably more on Northern Ontario last year than was received in revenue from that region. This is as it should be. Rational development can be stimulated only by liberal expenditure, sanely directed

There is encouragement in the fact that, despite depression in other industries, mining in Canada is showing constant signs of vigor. Overseas transactions are becoming more numerous. This leads to the thought that there is needed some positive means of censoring mining "propositions" submitted by Canadians in London and elsewhere. This is quite as much to be desired as are the proposed measures to control Canadian brokers in their local activities. Canada's good name is a precious asset.

GOUDREAU GOLD CAMP

(Special Correspondence.)

In view of the anticipated activity in the Goudreau District this Spring and Summer, it might be interesting to your readers to know something definite about what has been accomplished to date by local and outside interests in preparation for development work.

Nothing much has been published about the new gold district, except some scant notes about the progress being made with development work on the Goudreau Gold Mines properties. There are, however, at least a dozen other companies with considerable money on hand that have taken over large acreages in the district and will spend a large amount of money there just as soon as the snow goes.

On the Goudreau Gold Mines property, three shafts have been sunk on the main vein, and at depths of fifty and sixty feet the very rich character of the ore continues. Engineers who have examined the workings recently state that it is one of the richest deposits of gold that they have ever examined, and that the length, strength and general conformation of the veins gives every evidence of depth and permanency. A six-mile power transmission line has been completed from Steep Hill Falls, where a power plant owned by the Algoma Steel Corporation is located, and all the necessary machinery is on the ground, including drills and compressor, and the plant is expected to be in complete working order by March 15.

There have been deals consummated in the new camp and many rumors of deals.

In general, owners have been willing to accept reasonable cash payments on account, and have retained a large interest in the properties on being assured that ample funds would be available through the sale of treasury stock to thoroughly prospect and develop their claims. In a number of cases, the initial cash payments have been substantial amounts, but the point is that the bulk of the money raised is going to be spent by these various new companies in the actual, intensive and thorough exploration and development of the Goudreau district.

Experienced mining men are not in the habit of paying fabulous sums of money for unproved prospects. They are, however, willing and anxious to provide any reasonable amount of money necessary to prove up good-looking prospects, particularly when the prospector or operator is willing to go along with him and share the risk of development. This is about what is happening in the Goudreau district at the present time, and the writer can confidently state that, as soon as the snow clears away, development work in a large and serious way will begin. There will be a rush to the Goudreau district, and undoubtedly during the Summer a number of other discoveries will be made that may equal or rival the now well-known Murphy Foster properties. This is the kind of legitimate mining business that will keep Sault Ste. Marie and the Goudreau camp in good repute.

HAVE YOU?

Have you ever had a pardner in the bush or in the town?
Have you ever had a pal that seen you through
A bird that stuck right by you when you certainly was down,
And wouldn't let you shake him—just hung to you like glue?

He might touch you for a ten-spot; he might swipe your smoking plug;
He might bone you for the last you had to chew;
But he'd do his share of totin' with a cheerful, smilin' mug
On a trip or in a trouble—why, the guy would see you through!

Well, I've found them just so often in the bush and in the mine,
From Thetford west to Rossland in the land I've laboured through;
But I've never yet found any with a sense of "mine" and "thine"!
Now although I hate to ask you—just inform me, sir, have you?

Anon.

INTERNATIONAL NICKEL CO.

The profit and loss statement of the International Co for the nine months ending Dec 31 shows a total income of $361,271, while expenses were $382,002, leaving a deficit of $14,728. There is also $228,266, to be charged against maintenance and shut-down expense, and $395,684 for depreciation and mineral exhaustion. This brings the deficit to $164,678. Dividend on preferred stock amounted to $401,067. This makes a total deficit of $1,042,745 to be subtracted from the surplus, leaving a surplus at Dec 31 of $10,843,139.

A. T. Donald and Co., consulting and chemical engineers, are now installed in their new premises at 40—42 Belmont Street, Montreal, not far from their old building. A host of friends and clients will follow with good wishes the removal of the firm to new and larger premises.

Gold And Copper In Northern Manitoba*

The outstanding event in Northern Manitoba mineral enterprise during the past year was a discovery by Murray Brothers in June last of a quartz porphyry dike containing free gold in quartz stringers of exceeding richness. The find is located at the south end of Elbow Lake near the outlet, and this lake lies about midway in the mineral belt north of The Pas, between its western extremity at the boundary of the Province and the eastern end at Wekusko Lake near the Hudson Bay Railway.

Naturally the first discoveries in this district were made at either end of the belt, those being the most accessible points; the western end being readily reached by water via the Saskatchewan River, and the eastern by the Hudson Bay Railway. However, during the last few years prospectors have penetrated farther inland, mainly by way of Grass River, and a couple of years ago notable discoveries were made at Copper Lake and at the Northern end of Elbow Lake. And now comes this new development. All these discoveries are practically along the well defined water courses, and the country back therefrom still remains a virgin field of great possibilities. The Murray claims have been visited and inspected by wellknown mining men — engineers, geologists and others — and all have come away full of enthusiasm at the prospects; and what is more to the point, have made reports which have resulted in several important deals and the beginnings of actual development work.

A very practical, and perhaps the best evidence of the importance of the discovery and the value of the property, is found in the fact that as a result of a special examination and report by Mr. Samuel Cohen the men that control the Hollinger Mine have taken an option on the claims in question, have paid a considerable amount in cash, and, what is really of greater moment, have undertaken to carry out investigation and development. These people have the essentials for an enterprise of this kind, ability, experience and money, and it is stated on good authority that they intend to prove thoroughly the claims and that they have every confidence in the outcome. Already 35 men are on the ground, erecting camps and doing necessary premilary work. A road has been cut to Mile 55, Hudson Bay Railway, giving a much shorter route into the camp than that hitherto travelled, and large quantities of freight are now being taken in preparatory to extensive summer operations.

As a result of this find and subsequent development, a miniature gold rush has recently been staged, and the whole countryside in the vicinity of the original claims has been staked, much of it in the snow. A number of Montreal financial men have become interested, and there are indications that Montreal proposes to occupy a similar position in respect to this northern mineral field that Toronto has occupied in relation to the Cobalt and Porcupine areas. Montreal men have formed a company, "The Elbow Mines Ltd.," and now own a number of claims "close in" to those belonging to the Hollinger interests. Walter DeKeyser, a New York engineer representing an important English mining company, has recently visited the district and inspected a number of claims. Consequent upon this he has obtained options on or purchased outright several of those, and the indications are that his company intends to become a real factor in development. Numerous other deals have been made or are now pending, the purchasers being in the main either Montreal capitalists or local men.

Copper Lake.

Since the discovery in 1919 of the "Big Dike" at Copper Lake by Gordon's prospectors, much work in the way of development on those and associated claims has been done, and a diamond drill was in operation on the property last year. Earlier reports of "good values in gold" have been borne out by these operations, and it is now announced that drilling will be continued during the coming season and that the outfit hitherto operating will be supplemented by one or two additional drills. This is an immense property, and with fair values in gold and a little silver should make a good producer.

Herb Lake.

At Wekusko or Herb Lake is the real pioneer gold camp of the north. The discovery of gold in 1914 on the Kiski-Wekusko claims was followed in that and succeeding years by numerous other discoveries, and there are now at this point several well-known properties in various stages of development. The Rex, Moosehorn, Bingo, Elizabeth, Syndicate and Apex are only some of these. The Rex is undoubtedly the premier property in the matter of development. From this mine $33,800 in real gold has been taken. A shaft has been sunk 270 feet and there is nearly 400 feet of drifting at the 100 and 200 feet levels. A 30 ton Lane mill with full equipment is erected on the property, and at the clean-up of all the ore taken out of the mine, realized in bullion $18.00 per ton exclusive of tailings and concentrates.

The Bingo Mine.

Nearby is the Bingo, on which a shaft has been sunk to the depth of 160 feet. Some of the ore taken out has been put through the Rex mill and realized a handsome return. A thorough examination of this property was made last year by a well-known geologist, and in his report he states that 82 samples from the vein give $145.15 per ton for width of 11.65 inches. Seventeen additional samples indicate additional values of $66.68 per ton in width of 19.5 inches.

Other promising claims, such as the Moosehorn and Syndicate (the former of which is already in the producing class), could then be worked to advantage, and their product taken care of by the Rex mill. Conditions therefore give reason for great hopefulness that mining activity at Herb Lake will be resumed in the spring on a much increased scale. This camp is easily accessible. The south end of the lake is connected with Mile 82, Hudson Bay Railway, by a provincial highway 11 miles in length.

Flin Flon and Mandy.

In the Pas Mineral Belt are found a diversity of minerals; two, however, predominate. In the eastern part the discoveries hitherto have been almost exclusively gold, while in the boundary district at the west, copper is prominent. The discoveries have been mainly along the shores of Lakes Athapapuskow, Schist and Flin Flon. Much has already been written regarding

* From a memorandum issued by the Commissioner of Northern Manitoba, The Pas.

the super high grade chalcopyrite of the Mandy and the tremendous orebody of the Flin Flon, but these camps, so recently the scene of mining activity, are now silent. The situation in many respects is similar to that at Herb Lake but the reason for inactivity is far different. The gold properties of the eastern end require capital as a condition precedent to active production, but with Flin Flon and Mandy it is otherwise; capital is available, but at present, owing to the exceedingly low price of copper, a fraction over 13 cents, production would not be profitable.

A year ago the mining fraternity were on the "qui vive" to know whether or not the Thompson interests were going to take up the Flin Flon option. There had been spent, it was authoritatively stated, by these interests, over $200,000 in extensive operations in the way of diamond drilling, sinking shafts, etc., and it was an open secret that the results of this most thorough testing were favorable; but the still lower price of copper, then around 12 cents, was a deciding factor against the deal and it was not consummated. Shortly afterwards, however, the Mining Corporation of Canada bought up all the interests concerned in this property except those of the Faskens, so that these two interests now own and control the whole property, which, with its proven tonnage of at least sixteen million tons, is entitled to rank as one of the big properties of the continent.

To properly operate this mine there will be required, besides the usual mining machinery and equipment, a power development scheme, a smelter, and a railway connecting with the Hudson Bay Railway north of The Pas. Exclusive of the railway, the other essential features would mean an expenditure variously estimated at from five million to eight million before any returns would begin to come in. The owners are prepared to proceed with the work as outlined above, but await a time when the price of copper will approximate more nearly to normal.

The erection of a smelter at Flin Flon would be of great import to the owners of other properties and claims in the district and to the copper industry generally. The Mandy would resume operations, and numerous claims on Athapapuskow and neighbouring lakes, on which to date only superficial examinations have been made, would then be further developed; for there are strong indications that some of those at least will prove up and develop into real mines.

The price of copper has been gradually rising. Capitalists are becoming more interested — not only those of Eastern Canada and the States, but, owing to the rapid rise in the exchange value of the pound sterling, those also in the Old Land, so that altogether 1922 finds a more hopeful situation than has existed for several years.

INTERNATIONAL NICKEL TUNING UP.

By ALEXANDER GRAY.

While a dolorous condition pervades nickel as well as copper markets, it is to be observed that the International Nickel Corporations of the United States and Canada are adhering to their policy of putting their ablest young men into executive positions and girding them with the sinews of industrial warfare,—a policy that the new order of things will make inevitable.

Admittedly, the immediate outlook is such that the most rigid economy is essential. Readjustments in administrative departments recently necessitated regrettable changes. Universal depression has been accentuated by the death of two Presidents and two most influential directors. Ordinarily, and were it not for the perfect organization always maintained by the International corporations, the combination of adverse circumstances would be more disconcerting, especially when metal trades are askew. However, the demise of Messrs. Monell, Bostwick, Converse and DeLamar, and the consolidation of the Canadian administration have brought about the promotion of other and younger nickel masters, and there is a consequent buoyancy among the best informed, notwithstanding the fact that the immediate prospects of trade revival are somewhat discouraging.

The election of Mr. Robert E. Stanley to the Presidency of the International Nickel Corporation of New Jersey, has the happiest augury. He is an expert in whatever pertains to the metallurgy of nickel and copper and the marketing of the metals. His attainments were demonstrated while in charge of the Bayonne Refinery, and later at the Port Colborne, Refinery, which in view of enlargements that can be readily made has a capacity sufficient to meet the world's requirements. Mr. Stanley is not only a scientist, but also an executive with "the punch," and is as popular as he is competent for his responsible duties.

If Mr. Stanley lacks anything, it will be supplied by Mr. Charles Hayden, senior partner of Hayden Stone, one of the outstanding men in the metals world. Mr. Hayden's acceptance of the Chairmanship of the International Board, his great experience and intimacy with industrial chiefs and financial leaders, will be recognized as a decisive vote of confidence. No one is better equipped to succeed the late Mr. E. C. Converse.

Supplementing Messrs. Stanley and Hayden, and admirably so, are Mr. John L. Agnew, who has been the chief executive at Copper Cliff, and in charge of all operation there, and Mr. Britton Osler, of Toronto, of whose legal qualifications nothing need be urged. As directors, these two gentlemen will contribute virility and acumen. They are "en rapport" with the administration and thoroughly comprehend the potentialities of their nickel mines and plants.

Along with these are Mr. Jaretsky, a premier in his profession, Mr. Ashley, who is "au fait" with everything in Nickeldom, and Mr. Mein, a mining engineer with a reputation for rectitude and regard for economical operation. So the International Nickel Corporations are attuned to the new order of things, although the old order changeth not.

La Rose has declared a dividend of 10 per cent. payable April 20, to shareholders of record March 21. This calls for the distribution of $150,000 or slightly more than the year's profit. There remains a very large surplus. Some shareholders are expressing dissatisfaction with the management. They evidently consider it undesirable or unnecessary to keep such a large surplus.

Mr. John Wilson Jr., who for the past fifteen years has been associated with the sales organization of the Dominion Bridge Company, and its subsidiary companies, the Dominion Engineering Works and the Structural Steel Company, has accepted the position of Sales Manager with the Walsh Plate and Structural Works Ltd., of Drummondville, Que. Mr. Wilson assumed the duties of his new position on March 1.

The Vancouver Mining Convention

(by our B. C. Correspondent.)

From the mining camps of the East, Northeast, Northwest, as well as from the centres of mining activity nearer home, came members of the Canadian Institute of Mining & Metallurgy to attend the Annual Convention of the British Columbia Division of that organization held in Vancouver on the 13th, 14th, and 15th of February.

With truth it may be said "and a good time was had by one and all." The country newspaper description of the experience of those present at the township "sociable" certainly applies to the mining men who assembled at the Vancouver Hotel for the Convention in question. These meetings are not confined to the instructive, or the educative if you will. The latter features are prominent. But if the average mining man were asked what, in his judgment, are their outstanding attraction the answer would be "the reunion, the good fellowship." And really it was the opportunity offered for the renewal of friendships, the making of new and congenial acquaintances, and the exchange of reminiscences that made the last meeting go off with a swing and an enthusiasm that makes it a very pleasant memory. Of course, the background of technical and semi-technical papers, bearing on matters of interest to those facing the problems of mining in this comparatively new country, was an indispensable and a very important part of the programme. But their instruction and their information, notwithstanding its value, will take no more permanent place in the minds of the members than the rollicking time afforded by "The Smoker" and the joviality of "The Banquet." At the former, Professor Freeman's magic translation of water to an inspiring beverage, and at the latter the Hon. Wm. Sloan's (Minister of Mines) optimistic address on mining prospects were noteworthy occurrences.

The subjects dealt with at the various Sessions ranged from a review of the past year's mining to the oil possibilities of the Mackenzie River. Dean R. W. Brock, of the University of British Columbia, struck a keynote when, at the meeting's opening, he said that mineral wealth was the basis upon which the Province must build prosperity. If the same tragedy of isolation that has befallen Kentucky was not to overtake this country, mineral resources must be developed and railways built to transport the product. Mr. Sloan struck much the same note when, in the concluding address of the occasion, he declared that no adequate conception existed in the minds of mining men, or of the general public, of the possibilities of the mineral wealth of the West. If the Hidden Creek Mine and the Anyox Smelting Plant could produce practically all British Columbia's copper for 1921 and keep the output within range of that of the previous year, and if the Sullivan Mine of Kimberley and the Plant of the Consolidated Mining & Smelting Co., could produce all the lead and zinc and establish new records in respect of the production of these metals, it was hard to exaggerate the mineral possibilities of the Province.

Lieut.-Governor W. C. Nichol opened the Convention, and an early feature was a review of mining in the Province during 1921, by Wm. Fleet Robertson, Provincial mineralogist. He placed the value of production for the year at $28,504,903, a decrease of $7,038,181. The value of metal production was given as $13,232,002, and that of coal as $13,272,903. A significant point made by Governor Nichol was that "if our mineral resources are to be of the greatest value to us we must ourselves own and operate to a far greater extent than we do and not leave it all to outside enterprise." Mayor Tisdall, of the City of Vancouver, supplemented this by expressing the hope that "hereafter more local capital will be invested in our mining prospects."

The Prospector.

Wm. M. Brewer, resident government mining engineer, summed up a discussion of the prospector and the scarcity of the type so familiar in the American West throughout the latter half of nineteenth century, by charging too much education with responsibility for this decline. "The youth of today," he say, "are educated to the point where, after graduating, they contrast unfavorably the lonely life of a prospector as he climbs mountains with a pack on his back with life in a city where in a trade or profession money can be earned with ease and certainty, and with no sacrifice of comfort or of social opportunities and excitements."

Regarding present conditions and future prospects, Mr. Brewer said:

"It would not be unnatural to assume that recently graduated students from the Universities and Schools of Mines would be well equipped, by reason of their training to become successful prospectors; and, provided they also possess the essential temperamental and physical qualities, they should be ideally fitted to take up this pursuit. To-day some of the big mining companies are putting this to the test by sending out young engineers to prospect sections where minerals are likely to occur. The results are awaited with a good deal of curiosity, because, if they are successful, it would appear as though the question of the future supply of prospectors may be definitely settled by the infusion of this fresh blood; it would also usher in a new era in prospecting, and mark the disappearance of the picturesque "old timer," with his camp-fire yarns, sourdough bread, flap-jacks, bannocks, hunches, philosophy, and dreams of the untold wealth he will eventually find.

"This brings us to a query which is ever present in the mind of the writer when considering the subject of the prospector and of prospecting. Can a prospector be made by education, in a like manner to that in which a physician, lawyer, parson, or engineer is molded? The writer, speaking in the light of his own personal observations and experience, would answer this with a decided negative. The prospector is, like the poet, born, not made; and education without temperament is of no avail. In fact, prospectors have been in the past, and can be in the present day, successful without education. Conversely, they will almost certainly fail if they depend merely on education and lack the necessary mental and physical qualities."

Taxation.

The expediency of advocating the imposition of heavier taxation on crown granted mineral claims, or of requiring a certain amount of development work to be done each year in place of the present tax of 25 cents an acre, were discussed with spirit. There was a faction headed by F. W. Guernsey, mining engineer, Vancouver, in favor of some course different to the policy now existent, to the end that crown granted mineral claims, held without development and obviously

for speculative purposes, should be so dealt with that their mineral wealth would be exploited, if not by present owners, by others willing to do so. On the other hand, while it was generally admitted that in the well-prospected areas there are many dormant crown granted claims, and that such are neither healthy or desirable, strong opposition to a change developed. C. P. Hill, of the Hillcrest Collieries, argued against the principle of adding to taxation on non-productive property, title to which had been fairly earned by prospectors who had roughed it and were responsible for the discovery and opening up of the great mining camps of the West. Others acknowledged the blight of unworked claims, but felt that a radical change in the law might do an injustice to many deserving mining men. No conclusion appeared possible, and the issue was left in suspense.

Aerial Photography.

"Aerial Photography as an Aid to Prospecting" was dealt with by Major E. MacLaurin, the claim being made that the airman, with present equipment, can render valuable assistance to the prospector. His explanation was that large tracts of territory could be photographed in strips, pieced together and the final mosaic would permit careful study and consideration before entering the country. From this mosaic the prospector could prepare his field map, showing the drainage of the country, the best route for entry, the relative locations of mountains, valleys, lakes and other important information as to cover, rock croppings, etc. Major MacLaurin stated that conditions in this Province were favorable for this kind of preliminary exploration. "In my experience,," he declared, "an efficient seaplane or flying boat may move almost anywhere in comparative safety, as the province abounds in lakes and rivers suitable for emergency landings. As far as I know, very little use has been made of aircraft by mining men. Outside of one or two photographic surveys of oil properties in the South, the Imperial Oil Company's experiment in the Peace River Country, and a flight made by Professor Bruce, of Queen's University, last summer in Northern Ontario, not very much has been done. British Columbia is exceptionally well suited to the operation of aircraft. Its physical features are exceptionally rough, offering difficulties to the ordinary means of locomotion, while its innumerable lakes and rivers provide splendid natural landing places. Straight-forward flying, with a reliable pilot and a properly cared for machine, offers a perfectly safe and sane means of travel."

Coal Measures Of Vancouver Island.

J. D. Mackenzie, of the Canadian Geological Survey, gave a talk on the coal measures of Vancouver Island, referring particularly to the Cumberland Field. Briefly he told of the badly broken and faulted nature of the veins of the locality and the consequent difficulties in their development. Thos. Graham, of the Canadian Collieries (D) Ltd., said that his Company had sunk between 150 and 175 drill holes in this section and had failed to correlate the seams. The commercial exploitation of the field always would be accompanied by serious problems. Prof. Daniels, of the University of Washington, who was on this Vancouver Island field last Summer, corroborated these statements.

Pulverized Coal.

William Calkins, of Seattle, in discussing pulverized coal and its use declared that where it had been applied in a large way the results were satisfactory. It had yet to be demonstated, however, that it was adaptable to smaller plants with success. Col. J. E. Leckie, president of the Institute, saw hope for the coal industry of the Province in its struggle with the competition of foreign fuel oil if the pulverized coal process becomes perfected. Another view was that with increasing difficulties in coal mining, pulverization and flotation are destined to play more important parts in the solution of the operators' problems. It was stated that the Pacific Coast Coal Company, of Washington State, through the installation of a coal pulverization plant, had been able to save much of its hitherto wasted production. As one speaker put it, "If we can recover coal now too high in ash content for domestic use, we are going to eliminate much of the present loss in coal mining."

The Crows Nest Field.

Robert Strachan, senior mines inspector, took for his text the Crows Nest Pass Coal Field. More than 17,000,000 tons of coal had been won from this field since 1897, and almost 4,000,000 tons of coke have been made from the coal produced. There still remained in the Crows Nest Pass Field 1500 times the amount of coal taken away. With the inclusion of the Upper Elk Crown Mountain, and the Flathead the amount of available coal was more than 2250 times what had been extracted. He dealt with the markets, showing that they had been considerably curtailed in recent years, with the result that the industry had not grown in proportion to its possibilities. On this point it was said that about 60 per cent of the product finds a ready sale in the United States in competition with the coals of Wyoming, Washington, and Montana. Existing freight rates and adverse grades accentuated the market difficulties of the operating companies.

Coal Mining Methods.

A paper on coal mining in the Nicola, Princeton District referred particularly to methods at the Coalmont Colliery, the only plant of the kind in the Province to use an aerial tramway as an important feature of its transportation system. One of the specially interesting papers of this series was by P. E. Peterson on "The Flotation of Coal." He described in detail the plant being installed under his supervision in connection with the Western Fuel Corporation, Nanaimo, B. C., and explained that, while the innovation will not revolutionize present methods of coal washing, it will serve as a useful adjunct in recovering the dust that in the past has been lost. Prof. W. L. Uglow, of the University of British Columbia, discussed an Eocene coal basin at Chu Chua, which is on the east of the Thompson River.

The Britannia Mine.

General mining and milling practice at the Britannia Mine, Howe Sound, was discussed by C. P. Browning. Of the geology of the property he said that mineralization is confined to a shear zone entirely within a belt of metamorphosed sedimentary and igneous rocks which forms an inclusion in the granodiorite batholith of the coast range. He took up the different claims and mining operations, giving exhaustive accounts of both. He concluded that having power entirely produced on the property "the whole operation of mining, transporting, and concentrating a capacity of 2,500 tons of ore daily is more or less a self contained unit, with the exception of the smelting and refining of the copper concentrates."

Mackenzie Oil Field.

"Oil Possibilities of the Mackenzie River" were described by Prof. M. Y. Williams. He recounted the results of the prospecting of the Imperial Oil Company

A gusher had been struck, capped, and later the flow had declined. It was not likely that, whatever the field developed into, it would produce what were commonly referred to as gushers. There was this to be remembered, that the Company had not to sink far before obtaining the oil of which the world knew.

Address By The Minister Of Mines.

Mr Sloan, the minister, received a very cordial welcome at the banquet of Wednesday evening, the concluding session.

He prefaced his remarks by saying that, notwithstanding the hard year in the mining industry, the cheerful enthusiasm of the convention was an inspiration. The mining man is no quitter, and there is no place in the business for the man who lives in the past. The Minister reviewed the production of the year, showing that the total value of mineral production was in the neighborhood of $28,000,000, a decline of approximately $7,000,000 in comparison with the previous year, or roughly 20 p.c. He, however, pointed out that if this matter was a matter of condolence, the production of the State of Arizona showed a decline of 77 p.c., Montana 75 p.c., Utah 55 p.c., Idaho 51 p.c., and Nevada, 50 p.c.

"The perseverance and the confidence of the independent operators, the smelter companies, and the prospectors in all sections of the province are to be commended and should be encouraged. The Provincial Government has spent substantial sums in the past years in the construction and maintenance of roads, trails and bridges to mining properties. Miners have been given the benefit of the advice of qualified mining engineers, and the Mines Department has endeavored to keep in close touch with such organizations as the Canadian Mining Institute and the Prospectors' Protective Association, in order that the needs of those indentified with the industry might be clearly understood and every thing possible done to meet requirements, always having in mind financial limitations by reason of the heavy demands on the Provincial Treasury from many other sources.

"Within the past few years there has developed in Bristish Columbia a mining district the potentialities of which we are beginning to grasp. I don't think, however, that any of us yet have an adequate conception of the possibilities of the Portland Canal and the mineral-bearing zone of that and adjacent areas. If the next decade were to give birth in this part of our Northwest to one or two more properties such as that of the Premier Gold Mining Co., we would quickly take a first place among the gold and silver producing countries. There is no reason why this should not happen. Reports indicate that it is well within the bounds of possibility. Operators and prospectors from this part tell us that there is nothing more certain. Of course they are so proverbially optimistic that their statements sometimes need amendment. In this case, however, there is support from geologists and mining engineers of repute, and there is the indisputable evidence of the production of a wonderful mine.

The Northwestern Mineral Survey District, within which is the Portland Canal Division, is estimated to have turned out 75,000 tons more ore in 1921 than in 1920. The gold output exclusive of placer, which was about the same as in 1920, showed an increase of approximately 30,000 ounces, some 60 per cent greater than the figures of the previous year. The silver yield for 1921 is reported to be about 1,500,000 oz., an improvement of about 125,000 oz. Both the gold and silver outputs are due, almost entirely, to the Premier Gold Mining Co., that company's production of silver alone aggregating over 1,000,000 oz.

The Hon. Mr. Sloan then proceeded to review the coal mining industry, which for many years past has been the leading producer in point of value in the province.

"With coal fields of great extend awaiting exploitation, it does not seem right that development, as indicated by annual production, should be stationary. We should be making more rapid strides in this industry. Our material prosperity as a Province and as individuals depends more than we appreciate upon realizing in greater degree these great and practically untouched natural resources.

"This brings us, in natural sequence, to the question of markets. Our coal seeks the points of greatest demand. That is the inexorable law of trade. In the summer months it is absorbed chiefly by vessels plying the North Pacific, by foreign consumers, and those within the Province who use it industrially. In the winter season the domestic trade becomes substantial. Under these conditions it is easy to understand that the market fluctuates violently. Experience has been that in summer the collieries to a large extent have worked only part time, while in the winter on occasion they have had difficulty in supplying the demand. Such a condition is most unsatisfactory. To have plenty of coal available at the minimum price, there must be a steady and a healthy market, so that the mines may be kept working at full capacity. The manufacturers, businessmen, and citizens generally of the Province can help in bringing about this change, and no doubt will do more when more clearly understanding what it means to themselves and to the country."

The Minister then drew a very happy comparison between the results of the State of Arizona and that of British Columbia. In this connection he said:

"The mining history of the State of Arizona makes an interesting study in considering the situation in British Columbia. That State has an area of 113,953 square miles as compared to this Province's 402,660 square miles. The value of the State's mineral output in 1918 was $202,134,880 and British Columbia's $41,782,474. There is a wide gap here. I may be thought unduly optimistic, but the time is coming when the gap will be bridged. Arizona, scarcely more than one-fourth the size of British Columbia, produces enough mineral wealth in any one normal year to pay our total debt, to buy the P. G. E. several times over, to furnish freight for our transportation lines that will forever silence the argument sometimes heard that we cannot feed the railroad sufficiently to warrant treatment on an equality with other Provinces in point of rates, and to relieve our government and our people of all their financial problems.

"It may be said that Arizona is exceptionally endowed in mineral resources. That it true. To become the biggest metal-producing State of the Union, responsible for 40 p.c. of the copper mined in the United States, it must have unusual wealth. The same happy condition, however, exists in British Columbia. Such is my conviction. It is justified, I maintain, when we find a single mine in British Columbia producing almost 34,280,000 lb. of copper, the total of last year's output. Further confirmation is supplied by the fact that a single mine provides the bulk of the 45,000,000 lb. of zinc that we produced in 1921. When we consider these facts and then reflect upon the vast ex-

tent of British Columbia's undeveloped and unprospected mineral-bearing zones, it is possible to realize something of the possibilities. British Columbia has roughly 268,600 square miles of mineral-bearing territory, as against Arizona's total area of 113,953 square miles. In British Columbia, 44,225 square miles may be said to be producing. Of the possibilities of the remaining 224,375 square miles we have no more than general geological knowledge. Under the circumstances can it be said to be an extravagant prediction that the future holds as much in store for British Columbia as has been bestowed upon the State of Arizona?

"If we take the adjoining States of Washington, Oregon and Idaho, the comparisons are interesting and favorable. The three could be fitted into British Columbia, and our Province would be scarcely more than half covered. Add California, with her area of 158,297 square miles, and the sum for the four States comes to 408,011 square miles, a few thousand more than the area of this Province. These facts will serve to drive home the extent of our heritage."

He then paid a tribute to the department of Geology and Mining at the University of British Columbia, paying especial attention to the eminent qualifications of each member of the staff and showing the opportunities afforded of studying under these men. He thought that the University of British Columbia must soon be recognized as the principal center for geological research in Canada. In conclusion, the Hon. Mr. Sloan said:

"The twentieth century, it has been said, will be Canada's century. Never was there a truer prophecy. But I feel that it has a peculiar significance in its application to British Columbia. We are facing unprecedented development of trade and commerce on the Pacific. The signs of this are clear. The effect of the opening of the Panama Canal is being made apparent The industrial advance of Japan likewise is reacting on the Pacific Coast of the American continent. We, a naturally rich and little developed country, stand at the gateway. It will be our own fault if we fail to take the fullest advantage of our opportunity that presents itself not only in connection with the mining industry, but in respect of all those industrial activities that are the life blood of our civilization."

HYDRO ELECTRIC DEVELOPMENT IN U.S.

The U. S. Geological Survey has just published data regarding water-powers up to the end of 1921

At present there are in the United States 3,116 water power plants of 100 horsepower or more, with a total capacity of installed water wheels of 7,852,918 horsepower. Of this total 79 per cent is in public utility plants and 21 per cent in manufacturing plants. New York still maintains its position as the leading State in the amount of developed water power, with 1,291,857 horsepower, California is a close second, with 1,119,099 horsepower; Washington it third, with 151 356 horsepower, Maine closely follows in fourth place, with 449,614 horsepower; and Montana is fifth with 344,420 horsepower.

The latest survey of the potential water power that is capable of commercial development shows a total of 28,000,000 horsepower minimum, and 51,000,000 horsepower maximum The minimum is based on the average flow of the two seven day periods of lowest flow in each year of record

OIL FROM SHALE.

There is the possibility, after years of bitter disappointment, and the loss of a million and a half of British capital, of the Commonwealth Oil Corporation yet making good. The company was formed in 1905, under favourable auspices; a new plant was laid down at Wolgan Valley, and a line of railway built from Newnes, on the main western line, to the works, a distance of 32 miles. An immense area of oil shale has been proved to exist, some of the seams being narrow, but on the Capertee side a width of 3 to 4 ft. has been exposed by tunnel for a distance of 4000 ft., which will yield from 100 to 150 gallons of crude oil per ton. Disastrous strikes and unreasonable demands by the men ruined the whole business, making the cost of production so high that even a small margin of profit was out of the question, and resulting in the closing down of what, under fair working conditions, would have developed into a paying concern of immense magnitude employing thousands of hands. Over two years ago Mr. John Fell entered into an agreement with the company, which provided for him to work the concern, on behalf of himself and the company, the further capital required to be equally provided by the parties to the agreement. Mr. Fell thereupon set about to try to determine a cheaper mode of working, and he now appears to have solved the problem.

The scheme is a bold one, and on the face of it looks somewhat risky, as it involves the setting alight of the shale body **in situ**, and converting the mountain into a series of retorts. The sections treated are blocked out, and bricked in, and air is carried in to regulate the fire and keep it under proper control. So far much success is attending the system, and from a "kiln" recently opened, the oil was flowing in such quantities that it was difficult to provide sufficient containers to receive the outflow. Out of the burning shale a large quantity of gas is issuing, and it is intended to utilise this gas to drive engines for the generation of electricity. This, apart from oil production, opens up a wide field for the cheap supply of electric energy to the whole of the Lithgow district, including the railways. "As the crow flies," Newcastle is distant only about 70 miles, and a cable could provide electric power to that centre also. So far as matters have advanced under Mr Fell's direction, the prospects for the company appear bright, and provided no untoward catastrophe occurs, such as the igniting of miles of shale seams, so causing the biggest roaring inferno ever known there may be millions of money in it for shareholders.

The "Sydney Morning Herald" of October 29, referring to this apparently venturesome scheme, says that the "experiment has been under consideration for some years and permission was granted by the Mines Department about four years ago to enable the method of attacking the shale deposits to be put in operation."

The conservation of opinion amongst the officers of the Mines Department when permission was sought was that it involved absolutely no danger. From the Wolgan to the Carpertee side the seam dips slightly and the firing is being done with the dip. In this way the fire needs coaxing. Air has to be introduced to keep it going. This affords the necessary means of control which eliminates any source of danger. The Industrial Australian and Mining Standard

Northern Ontario Letter

THE GOLD MINES.

Hollinger.

The Hollinger annual statement, for which mining men had been waiting, brought no surprises. Ore reserves were maintained, while net profits amounted to 16½ p.c. In addition to paying 13 p.c. in dividends, upwards of $800,000 was added to surplus. In view of this achievement, which was accomplished in spite of extremely adverse conditions during the first three or four months of the year, the Hollinger is expected to encounter no difficulty in showing a net profit of approximately 20 p.c. for the current year.

Dome.

A party of directors of the Dome Mines visited the property this week. The company will end its fiscal year on March 31. From unofficial figures published in leading newspapers throughout the country, it would appear as though the profits are exceptionally large. Certain papers go so far as to state that the net profits during January and February were at the rate of 75 p.c. annually on the company's issued capital, and that the net profits for the first two months of the year would alone be sufficient to cover the regular dividends for the whole of the year. A feature is that the Dome has risen from the largest low-grade gold mine in Canada to one with ore so rich that the mill is being operated on a grade of ore which is even richer than the average at the Hollinger Consolidated and the McIntyre-Porcupine. In view of the current net profits being so large, the capital repayment of $1 per share which will be made to stockholders of record March 31 will not be seriously felt, and may be paid out of profits accumulated since the beginning of January.

Power from Sturgeon Falls.

In connection with power development in the Porcupine district, the Northern Canada Power Company will utilize electric energy from Sandy Falls with which to provide motive power in connection with the work of harnessing Sturgeon Falls. This will expedite the work and is expected to make it possible to provide an additional 6,000 to 7,000 horsepower by the end of the year.

Thompson-Krist.

According to information available here, the Thompson-Krist interests have only this week to make good on their liabilities in connection with the Northerown Mines, of which they hold a minority of shares. The obligations are said to amount to approximately $40,000. Failure to comply with this is believed to point to the danger of foreclosure.

McIntyre.

The proposed sale of treasury shares in the McIntyre Porcupine is stated on the street to involve a price at the rate of $3 for each of the old shares, or at the rate of $15 per share for the new. It is intimated that, in addition to providing over $1,000,000 in cash, a plan has been under consideration among insiders to operate a pool and possibly turn attention to the market for a time. In the meantime, the work of enlarging the mill is proceeding, and the production during the last half of the current year will register an increase of upwards of 40 p.c., or close to a total of $3,000,000 per year. It is also considered probable that, in addition to having an eye on the Plenaurum and the Newray properties, the McIntyre is casting covetous glances toward the Shumacher. The acquisition of these three properties would give the McIntyre a big acreage and might place the enterprise in a position to make a bid for a leading place in the business of gold mining.

Keora.

Plans have been made to endeavor to raise money with which to reopen the Keora property. The outcome of the effort may be known within the next sixty days.

Porcupine V. N. T.

Arrangements have been made to commence work on the Porcupine V.N.T. early in April. Work for the beginning will consist of continuing the shaft from its present depth of 600 feet to a depth of 900 feet. Levels will be opened up at 600, 750 and 900 feet deep.

It is also planned to resume operations on the property of the Porcupine Crown this spring.

Night Hawk.

The Night Hawk Lake Mining Company, which holds property on the east side of Night Hawk Lake, and which has met with encouraging results during the course of diamond drilling is negotiating for the sale of its property. Good reports are coming from both the Night Hawk Lake and the Peninsular, which adjoins.

Ontario-Kirkland.

A merger of the Ontario-Kirkland Gold Mines with the Montreal-Kirkland is being negotiated. The directors have already agreed upon terms, and the stockholders of the Ontario-Kirkland are to vote on the question on March 9th and on the Montreal-Kirkland on the 15th. A new company with $5,000,000 capitalization, made up of 5,000,000 shares of the par value of $1 each, will be incorporated. Of this, the Ontario-Kirkland will be given 1,500,000 shares with 1,725,000 shares to the Montreal-Kirkland. The new company will assume the present liabilities of about $125,000 against the Ontario-Kirkland. The large allotment of stock to the Montreal-Kirkland has occasioned considerable surprise.

Tough-Oakes.

At the annual meeting of the Tough-Oakes Gold Mines, according to official advice to the Journal, the announcement was made that milling operations would be resumed early in April. The mine is now in good physical condition, due to the favorable developments at depth on the main break which dips onto the Burnside. The mill has a capacity for handling 120 tons of ore daily and is expected to produce about $12 per ton.

Atlas.

A contract is being let to explore the Atlas property by diamond drill. Following the recent friction between certain of the interested parties, the following board of directors was elected: President, I. Singer; 1st Vice-President, Mr. Nesbitt; 2d Vice-President, Mr. Mathieu; Sec.-Treas., R. Davis, with M.P. McDonald managing director.

Lightning River.

An enthusiastic meeting was held in Guelph by the Lightning River Gold Mines. About 70 stockholders were present. John W. Morrison pointed out that the physical condition of the company's property in the Lightning River district warrants aggressive work. The vein had a width of 30 inches at surface and has widened to 69 inches at a depth of 40 feet. Mr. Morrison stated that the indications were that considerable commercial ore could be developed. He advised the stockholders not to consider the question of putting in

a small mill at present, but to find means of carrying out extensive development work, with a view to determining the extent of the mineralization, and possibly proceeding at a later date with the construction of a large mill. It is understood that this plan will be followed. A by-law was passed, changing the head office from Haileybury to Guelph. It was also announced that two more mining claims had been purchased. Following are the officers and directors: President and general manager, W.J. Lucy; 1st vice-president, John W. Morrison; 2nd vice-president, W. Cochenour; Sec.-treas., Udney Richardson; directors, Dr. Robt. Lucy, Mr. Hewer and Mr. Treleavan. An endeavor will be made to raise a substantial treasury fund for carrying out work commensurate with the merit of the property.

Locating Placer Claims.

Considerable excitement has developed in connection with the reported discovery of placer gold in that area lying east of Matheson on the T. and N. O. Railway, which was recently announced in these columns. Mining claims are being staked out for placer in the townships of Munro, Michand, McCool and Guibord, and already between 75 and 80 have been recorded. These are distributed with 42 in Munro, 22 in McCool and 12 in Michand.

Reports tell about the discovery of gravel and sand in which fine nuggets of gold occur. Other reports are less optimistic, but the discovery has been sufficient to send a host of prospectors to the district, and interest is running high.

It is pointed out that geologists are at one in believing that hundreds of feet of the gold-bearing formations of Northern Ontario have been eroded during past centuries, and that, as in the case of Porcupine, this erosion may have ground down rock which yielded possibly hundreds of millions in gold, all of which may either be lying at some point of concentration or be scattered far and wide in too small quantities to be found or mined profitably.

Just what further work in the Matheson and Munro township area will reveal is a matter which may only be decided as exploration work proceeds, and, in the meantime, prospectors who are "loath to overlook any reasonable bet" are found staking out mining claims in this new prospective field.

A point of interest is that the placer discovery lies in the vicinity of the Croesus mine, which yielded such fabulously rich specimens of gold quartz some years ago.

THE SILVER MINES.

Silver Production.

A feature in connection with silver mining in this field is that the O'Brien Mine has won its way to the position of being the second largest silver producer, ranking second only to the Nipissing. The official figures for 1921 now available, show the following:

Company	Ounces Silver Produced
Nipissing	3,012,611
O'Brien	1,408,890
Conagas	1,301,860
Mining Corporation	896,627
La Rose	658,123
Keeley Silver Mines	281,659
Miller Lake-O'Brien	223,168

Figures for the Bailey Silver Mines are not available at the time of writing.

A total of 8,279,320 ounces of silver was produced from Cobalt, South Lorrain and Gowganda in 1921, another feature being that, although the Keeley commenced production only in the early summer, the output by the end of the year exceeded that of Gowganda.

Interest is keen in South Lorrain. One leading mining concern in the Cobalt district offered $50,000 in cash for a property in that area. The offer was refused, although possibly a year ago the owners of the property would have jumped at it.

Nipissing.

It is stated in Cobalt that the Nipissing Mining Company has optioned the Jordan group of claims in Northern Manitoba.

Claims Thrown Open.

A repetition of last year's clean-up of claims in arrears with dues to the Provincial government has been made in the Temagami Forest Reserve. An Order-in-Council, signed by Hon. Harry Mills, cancels the leases under which such claims were held.

As no provision is made for reinstatement of the former owner's rights, restaking by outsiders will hit hard some of the syndicates and companies, particularly in James township of the Elk Lake field, that have done a large amount of development work on their claims.

CANADIAN MINERAL PRODUCTION LESS IN 1921

The Dominion Bureau of Statistics has published a Preliminary Report on the Mineral Production of Canada which shows that the economic minerals produced during the calendar year 1921 reached a total value of $172,327,580, as compared with $237,422,857 for the preceding year. The report was prepared under the direction of Mr. S. J. Cook, Chief of the Mining, Metallurgical and Chemical Branch of the Bureau.

By classes the value of the mineral production during the year comprised: metallics $52,580,000, non-metallics $89,405,000, and structural materials and clay products $30,342,000.

The principal mineral-producing province, according to the returns for 1921, was Ontario, the mineral output from this province being valued at $54,505,770. British Columbia came second with a mineral production worth nearly $35,000,000. Nova Scotia was a close third with $32,5000,000; Alberta ranked fourth with $29,000,000. Quebec was fifth with $11,600,000, and Manitoba, Yukon Territory, New Brunswick and Saskatchewan followed in the order named, with productions between one and two million dollars each.

The ten principal products of the mineral industries of Canada in 1921, arranged in order of value, were coal, $74,273,000; gold, $21,327,000; silver, $9,185,000; copper, $7,459,000; nickel, $6,752,000; natural gas, $4,902,000; asbestos, $4,807,000; lead, $3,855,000; zinc, $2,758,000, and gypsum $1,726,000.

The report contains forty three pages of reading matter and tables, giving in detail the statistics relating to the production of Canadian minerals during 1921. Copies may be had on application.

One-third the electric power produced by public utility plants in the United States is hydro-electric. The remaining two-thirds requires the annual consumption of forty million tons of coal, twelve million barrels of fuel oil, and twenty billion cubic feet of natural gas.

BOOK REVIEWS.

A Coal Manual for Salesmen, Buyers and Users, by F. R. Wadleigh. Published by National Coal Mining News, 831 Union Trust Building, Cincinnati, Ohio, 184 pages. Price, $2.50.

The ordinary user of coal is wonderfully and fearfully ignorant of the limitations and idiosyncrasies of that mineral. For instance, the difference between "fixed" (or "inherent") ash and "extraneous" ash is without meaning to him. The Coal Manual throws light upon this very practical phase of coal consumption, and upon many other such phases. In short, it is designed to lighten the darkness of the head of the family who continually wonders why his furnace is so reprehensibly unsatisfactory.

This, however, indicates only a part of the scope of the volume.

The industrial use of coal is clearly dealt with. Particularly interesting are references to "Alcohol from Coal" (Ware, Volstead Act!) and "Low Temperature Carburization." Instructions as to the storage of coal are sane and practical.

It is a pity that the little volume before us has not been more carefully prepared typographically. The material is excellent; it deserves a better "corpus".

Mineral Land Surveying, by James Underhill, Ph.D. Third Edition Revised. Published by John Wiley and Sons, Inc., and the Renouf Publishing Co., Montreal, Que. Price, $3.50.

Earlier editions of this useful treatise will be familiar to many of our readers. To the mining engineer who may at any time be called upon to follow his calling in the United States, "Mineral Land Surveying" will be a competent guide. It is a pity that a similar volume, written from a Canadian point of view, has not been published.

Burning Liquid Fuel, by Dr. William Newton Best, F.R.S.A., etc. Published by the U.P.C. Company, 234 W. 39th St., New York. Price, $5.00 net.

There can be no doubt as to Dr. Best's qualifications for the task of writing a book on Burning Liquid Fuel. Neither can there be any doubt that most of us are ill-informed upon the subject, if not entirely ignorant.

Describing his early experiences in burning crude oil, Dr. Best alludes to the devices then used as being "even more crude than the oil we were attempting to burn." However, the first locomotive equipped for oil burning by Dr. Best showed a 15 per cent. better performance than when burning coal.

During a long career in his chosen field, Dr. Best has installed oil burners in a great variety of furnaces used in many diverse industries — bread baking, brick making, glass furnaces, and so on. He emphasizes the especial need of expert guidance in the use of oil fuel, and very strongly deprecates the unwise practice of approaching the subject from a purely theoretical stand point.

Right and wrong oil systems are fully described, and illustrated diagrammatically. Foundry practice, copper industry practice, cement, lime glass, and many other uses of oil burners are adequately touched upon.

To Canadian engineers, metallurgists and manufacturers, this book should appeal strongly. Canada is only at the beginning of her metallurgical career. A record of practical experience and achievement, such as is outlined in the volume before us, should not be overlooked.

ASBESTOS.

In his report to shareholders of Asbestos Corporation of Canada, President W. G. Ross states that shipments of raw asbestos during 1921 were about 45 per cent of that made the previous year. The orders on the company's books, though less than a year ago, are still considerable. The looked-for revival in trade should increase demand by manufacturers. The years profit was $543,258. Dividends amounted to $460,000. Surplus is $2,136,090.

Zirconium and its alloys or compounds are finding increasing uses as an acid resistive metal, for electrodes, for armor and automobile steels, abrasives, pigments, mordants, insulators, fire brick, and other products.

THE NIGHT HAWK LAKE DISTRICT.

(Special Correspondence.)

At Connaught Station the Porcupine branch of the Temiskaming and Northern Ontario Railway crosses the Frederickhouse River near its entrance into Frederickhouse Lake, or rather the flat which was once the bottom of that lake. The story of its drainage is worth telling. Up to 1909 the level of the lake was maintained by a natural dam a few miles below the outlet of the lake, where the river flowed over a ledge of rock with a drop of 46ft. To enable him to further explore an outcrop on the bank of the river, Father Paradis cut a pilot ditch around the rocky ledge and through the higher part of the natural dam, which happened to be clay. The river did the rest, wearing its channal down through the clay, draining the greater part of the lake, and spoiling the potential water power. This lake-bottom may be of use as farming lands, although attempts to use it so far have been discouraging. Some interesting finds on the lake bottom have been made. Your correspondent was shown a copper skinning-knife picked up by a Connaught resident, George David, apparently of primitive manufacture. The copper may have come from Lake Superior, although there is a possibility that it may have been brought from the far north, the Coppermine River region. A later implement used by Indians was found by David, a hand made iron tomahawk which, I suppose, dates sometime since the arrival of the white men.

Another expansion of the Frederickhouse River is Night Hawk Lake, which begins up the river about seven miles south of Connaught. Discoveries of gold have been made about this lake, the shores of which are largely rocky, although the surrounding country is mostly drift-covered. A promising prospect is being developed under the management of Mr. A. R. Globe. The shaft is down 200 feet, and about 600 feet of drifting has been done. Here, as in the Abitibi Lake area, the gold has been found in association with basic lava flows. This greatly enlarges the possibilities of discovery of gold; and, taken with recent finds in the Goudreau area, so close to the iron formation, it should lead to careful prospecting of rocks which have hitherto been looked upon as very unpromising.

Other minerals that have been found in paying quantities in this district are barite and pyrite in Langmuir Township. The latter is said to be in large quantities and within easy reach of transportation. If quality and situation are right it should be easy to induce the Iroquois Falls people to use it instead of the native sulphur they are importing from Louisiana for the sulphite pulp process. A little native silver is found in the barite, and curiously enough this rather spoils it for grinding.

The considerable areas of serpentine in this district are receiving attention. The notice of prospectors has been called to the possibility of finding asbestos in this rock. Good asbestos has been found in considerable quantities farther west in Deloro Township.

The search for platinum in serpentine, olivine diabase, and peridotite might yield results if it were made systematic. While the discovery of placer platinum is not very likely in a country that has been so extensively glaciated, that it is possible is shown by the placer gold of Quebec province and of New Zealand. There is always the chance, too, of finding a paying quantity of this valuable metal in place. At $105 an ounce, very little would make a paying proposition.

THE "ANGLE SYSTEM"

In a paper on "Coal Mining in Alberta" presented at the Toronto meeting of the A. A. A. Sc., Mr. Jas McEvoy called attention to the rapid and steady increase in coal production in Alberta, which is equivalent to the addition of one new colliery producing 1000 tons a day each year for the past 18 years.

Mr. McEvoy in his paper gave an account of the mining of coal by the "angle system".

This system was developed in that portion of the bituminous area lying west of Edmonton, Alberta and was suitable only to thick seams which were high pitching, 60° or over from the horizontal being preferable, and which were free from or comparatively free from impurities.

The system cannot be adequately described in a short note but roughly outlined it is as follows:—

Driving a main and return entry in the ordinary way, then after leaving a sufficient protection near the front, driving up pairs of inclines or angles at 800 or 900 foot intervals on a slope of 30° from the horizontal. These are called "main angles".

From these main angles back angles are driven at regular intervals also in 30° slope, with cross-cuts between, all of which are driven on the floor of the seam, so as to block out all the coal above the return entry into pillars 40 to 50 feet square. Main angles and back angles are narrow ways, 7' x 9' or less.

In the main and back angles a chute is built at one side of strong boards or 2 inch plank lined with sheet iron and the coal is drawn out commencing at the bottom of the top row of pillars and allowed to slide down the chutes to the main entry.

For safety purposes and to control ventilation the mine is laid out in panels of 1200 feet or more running length, and a block of coal is left standing between the panels, whence there has been no extraction except what is taken out in driving a pair of upraises to the surface.

Mr. W. T. Rolfe, superintendent of the Creighton mine of the International Nickel Co., has been appointed superintendent of the Canadia Associated Goldfields mine at Larder Lake, succeeding Mr. Geo. Gray.

EDITORIAL

COURAGEOUS LEADERSHIP.

In the current issue of "United Empire," the journal of the Royal Colonial Institute, Mr. J. S. Little says:

> "The ball is at our feet. Huge territories await our sons and daughters to people them. Limitless resources ask for their brains and sinews to develop them. The English race, here in these islands, has increased from ten to forty-seven million souls in less than a century. What is to prevent its increase in the Overseas Dominions to proportions as undreamt of today as the increase of the English in these isles was undreamt of in the days of George III?"

The Hon. Wm. Sloan, Minister of Mines for British Columbia, said recently in addressing the Vancouver meeting of the Canadian Institute of Mining and Metallurgy:

> "It [optimism] is justified, I maintain, when we find a single mine producing 31,280,000 pounds of copper, the total of last year's output. Further confirmation is supplied by the fact that a single mine provided the 15,000,000 pounds of zinc that we produced in 1921. When we consider these facts and then reflect upon the vast extent of British Columbia's undeveloped and unprospected mineral-bearing zones, it is possible to realize something of the possibilities."

The mature judgment of Dr. C. A. Corless was given in his Presidential Address in Ottawa on March 1st. After mentioning that in the little corner of the pre-Cambrian shield that projects into Michigan and Minnesota there have been found the world famous copper and iron deposits, he continues:

> "On the Canadian side of Lake Superior, real prospecting in this vast pre-Cambrian area is scarcely begun. . . . And not only this, but continual discoveries in the partly prospected region are convincing evidence that even in this restricted area a mere fraction of the valuable metalliferous deposits has so far been discovered. Only rough prospecting has so far been carried out over a part of this smaller [explored] area. Scientific prospecting is not really begun. . . . . I have lived eighteen years in this great mineral region . . . . . In stating these gradually formed convictions, I am expressing what was at first merely a hope; what grew with study, observation and experience to become a probability; and what has finally grown with me to be a practical certainty."

On the same occasion, Dr. Charles Camsell, Deputy Minister of Mines at Ottawa, said:

> "Twenty-five years of exploring leaves me with a firm belief in the future of Canada's mineral industry. . . . As a people we have not shown the faith in the future of our mining industry that the conditions warrant."

These statements are not the ordinary opinions of the average writer or publicist; they represent the authoritative judgment of men in high position, each speaking about a field to which he has devoted special study, and in the case of the three Canadians, each basing his conclusions essentially upon personally observed facts. These now join their voices with those of Dr. W. G. Miller and kindred spirits—students for decades of the fundamental problems of our [illegible] and long convinced of what [illegible] Nova Scotia could hold in store for us.

That these utterances come [illegible] when Canada, the Empire and the world are in the depths of a business depression, [illegible] In times of stress that leaders come to the fore. Our mineral industry has been tried [illegible] and men of character feel a [illegible] to exert directly in the public interest [illegible]

that is ordinarily directed into other channels. In good times, optimists can be safely looked upon with suspicion, they are being carried along upon the wave of prosperity, and will very easily slip behind into the trough. The optimist in hard times is more likely to be a true prophet, as it takes the courage born of well-founded knowledge and firm conviction to oppose the tendency of the times.

When we are convinced that Canada's undeveloped mineral resources are worthy of the best efforts we can put forward to develop them, it still remains to put our resolution into effect. Action, not words, will be the final test of our conviction and of our good faith. It will devolve upon a multiple of prospectors, engineers, investors and miners to do each his part in making more tangible Canada's heritage of mineral wealth. When we analyze the situation, we find that it is essentially upon the man of initiative that the burden rests. There be many to follow, but who will lead? To the prospector that risks his time and effort; to the engineer that hunts out a good prospect and then stakes his reputation upon it; to the man of small means who "grub-stakes" a friend; to the capitalist that will chance failure in turning a prospect into a mine; to these men will Canadians of a future generation point as the pioneers in one of the world's great mining centres.

THE JOURNAL-PRESS.

The "Engineering and Mining Journal" of New York and the "Mining and Scientific Press" of San Francisco have joined forces. The combined journals will be published under the name "Engineering and Mining Journal-Press," with Mr. J. E. Spurr as editor. Mr. T. A. Rickard will be contributing editor, representing particularly the West.

These two journals are well known wherever mining is carried on. Each has served well the mining industry. There can be no doubt that the joining of forces will make possible the publication of a greater journal; but it was nevertheless with mixed feelings that we read the announcement. One new friend is poor compensation for two old ones, even though the new friend is known to combine the good qualities of both the old. On the other hand, there can be little doubt that the consolidation will permit the giving of a much improved service to the mining industry.

Mr. McGraw aims to make the Journal-Press the one great mining journal of the world. He indicates his plan for expansion with the object of keeping ahead of progress in the industry. He points out that both the Journal and the Press have international interests and that neither represents a section. The union will make possible the carrying out of plans that cannot be safely embarked on by either publication separately. A really great mining journal should result from the carrying out of these plans.

SILVER IN YUKON.

The mining history of the Yukon has been largely a history of placer gold mining. The Klondyke poured out its riches at an astonishing rate and brought to Canada's far northwest thousands of adventurous men. The flood has long since subsided, but a constant stream of gold continues to flow from the camps of the Yukon. Many of the men that were attracted to the country by the sensational discoveries of the early days have remained in the Yukon, and among them are many who believe that gold mining will continue for a great many years. During the last fifteen years production has been largely from deposits that were too low in grade for operations on a small scale. Huge dredges and hydraulic plants are at work on the creeks of the Klondyke. The two companies operating dredges near Dawson have already handled forty million cubic yards of gravel; but there is such a large area to be worked that the operations on these properties are expected to continue for at least twenty-five years longer. These dredge operations give the Dawson district a steady production. New discoveries in other districts help to swell the output. It is evident that placer gold mining will continue in the Yukon for many years yet.

That the Yukon has mineral riches other than gold is to be expected. Some of these have been discovered in recent years and during the past two years there have been developments indicating that silver mining is to be a big industry there. Silver ore of high grade will be shiped out this year from Keno Hill; one company has about 5,000 tons ready now. Two well-known gold-mining companies, Yukon Gold and Alaska Treadwell, are developing silver mines. Another Alaska company, Slate Creek Mining Company, has options on several properties. Notable discoveries were made during 1921 and several hundred claims staked. It is expected that there will be much activity in this new silver camp during the coming summer.

The most notable discovery on Keno Hill during 1921 was the location of the lode along the western slope of the hill. According to an account published in the "Dawson Daily News," the vein has been traced for nearly a mile and is five to fifteen feet in width. The shipping ore assays 200 to 500 ounces silver per ton. At four shafts there is about two feet of such ore, with lower grade on either side.

Development is steadily proceeding and it appears probable that production will be large and continuous. For some time the output will be limited, but a considerable quantity of the high-grade ore taken out in the development work will find its way to the smelters this year. The people of the Yukon may well be pleased with the prospect.

EDITORIAL NOTES.

The futile, useless and lamentable disturbances in South Africa have brought to the fore once again that signally efficient statesman, General Jan Smuts. General Smuts is a practical hero, a practical patriot, and a man as clear in thought as he is prompt in action. He recognizes the meaning of stable government. He sees that the British Empire is now a congeries of republics—in all but name. The name, he knows, is good for all time.

The announcement of the newly-appointed president of the Canadian International Nickel Company, Mr. J. L. Agnew, to the effect that all refining of nickel will be done hereafter in Canada, is one of the effects of post-bellum industrial readjustment.. It signifies more to our country than would appear on the surface. Statistically, it will greatly enlarge the money value of our mine products. As a demonstration of smelting economies, it marks one step toward the goal of a self-supporting Canada. There is much food for thought in this.

It is with vast relief that we feel ourselves justified in assuring our readers that our valued correspondent and mentor, Mr. Alexander Gray, is not guilty of a grave charge recently preferred against him. Very respectable verses (but still verses) appeared lately in a Montreal daily, signed "Alexander Gray." Our suspicions were aroused. We were bold enough to put the question direct to Mr. Gray. His denial of paternity was a trifle more than emphatic. The phrases used do not lend themselves readily to type in any country where even a casual censorship of the press is maintained. However, we have no remaining shadow of a doubt that Mr. Gray is *not* guilty.

PROSPECTS AND PROSPECTORS.

Elbow Lake, Manitoba.

An engineer fresh from the Elbow Lake discoveries gives a glowing account of the gold veins to be seen. He says the outcrop is both very rich and large. Its solid "chunks" of gold completely put in the shade the Dome's famous "Golden Stairway." It seems quite certain that the Hollinger syndicate, who have men at work on the Murray claims, will take up their option.

A New Copper Prospect

In Halifax township, Megantic county, Quebec there has been recently opened up a promising copper prospect. Stringers of copper oxides intersect a zone impregnated with the same oxides. A prospect shaft is being sunk in this mineralized zone. A small amount of stripping has been done, which indicates that the lode will continue for a length of several hundred feet at least.

To provide funds to prove and develop the property, the Quebec Megantic Copper Company, Limited, has been incorporated, and stock is being offered to the public. Senator Pope has been made president of the company. Competent technical advice has been obtained, and will be put into effect when funds are available.

The raising of funds for speculative development is at present extremely difficult. One consequence of this is that only a disproportionately small fraction of any sum raised is available for actual work on the ground. This is apt to impose on a prospect an undue burden, sufficient to nip in the bud a career of usefulness. It is a pity that the prevalent attitude of men with large capital makes it necessary for impecunious prospectors to adopt such means.

A Novel Grub-stake.

To provide funds for prospecting and for developing his prospects, Mr. Tom Saville of Sudbury, has organized the Mines Service Corporation, Limited, and invites subscriptions (at par) from the public. This veteran prospector (much older in experience than in years) has a reputation for square dealing that has lasted since the days of the Cobalt boom.

The gambling spirit affects us all more or less. Cards and dice are probably the least offensive of gambling devices, though they provoke the most censure. Race tracks cost the country a pretty penny each year and support a host of employees and hanger-on, with nothing much to show for the expenditure. "Flyers" on the stock exchanges provide, no doubt, pleasurable excitement for many thousands of honest citizens; but they might get a better return at less risk in a poker game.

If we must take a chance, why not take it in a way that involves a constructive effort? If money is made in the ways enumerated above, it involves a transfer from someone else's pocket. If money is made from the shares of the Mines Service Corporation, it will come out of the ground.

Mr. Saville deserves the support of the public in his effort to find and develop mines.

MUCK.

You take a shovel in your hand
And go up to the face;
The shift boss swears to beat the band,
You strike a hellish pace.

You lift, and bar, and load away
Until your back is broke,
Until your back is broke to stay
And then you take a smoke.

And this goes on for half a shift
Until it's time to eat,
And then again you load and lift
And once again repeat.

And so it goes for months and years
And get some geezer'll growl
Or weep most hypocritic tears
Or try to get us foul.

Because we like to hit it up
To drown our sodden sorrows—
Forgetting (sanctimonious pup)
The prospect of *our* morrows.

IVOY

The Modern Column Hoist

Its Construction And Use In Mine And Quarry Operation.

By F. A. McLEAN, Assoc. M. C. I. M. & M.

In proportion as men have applied machinery to their tasks, conserved their minds and nervous energies for constructive thinking and planning, and then applied their plans and ideas to the utilization of this machinery, have they made real progress.

Skilled labor is an asset only when its time is spent in doing the work which it alone can do; thus, not labor economy, but a proper distribution of labor turns losses into profit. The substitution of machines for men on temporary work and the odd hauling, skidding and hoisting jobs which are so often met in mine or quarrying operations, is therefore, highly desirable, as each time that an employee calls a fellow workman away from his allotted task, the firm that employs them is losing money. Furthermore, the use of manual labor for this kind of work is not only too expensive but often increases the danger of accident, since the men of one shift will have a tendency to shirk or leave the hoisting and hauling of the necessary timbers to the shift that follows.

Of the various methods of solving light hoisting, hauling and skidding problems that have been made available to the mine or quarry operator within recent years, none has done more toward the curing of these evils than the air-operated column hoist. Within the last few years these little machines have been introduced in coal and metal mines, quarries and industrial plants all over the world with remarkable success—and to any one who is not familiar with them, their versatility and number of possible applications is often surprising.

Description of a Modern Portable Column Hoist.

One of the best known hoists of this type, is the "Little Tugger" illustrated in Figure 1. The motive power of this hoist is provided by a simple engine using air or steam expansively and giving four power impulses per revolution, thus securing smooth operation; and as there are no dead centers it may be started in any position. The engine is readily reversed and is controlled by a small lever on one end of the drum housing. Pushing this lever forward raises the load and when it is thrown backward the load is lowered. The reverse can also be used as an auxiliary to the regular brake if desired. When the throttle lever is released, it is automatically returned to the central position cutting off the supply of air or steam and stopping the hoist. The control is very sensitive and the hoisting speed may be varied at will. Power is transmitted to the drum by means of a clutch and gears which are controlled by a clutch lever located on the end of drum housing opposite the throttle; cords may be attached to the control lever if desired, and the hoist controlled from a point some distance away. The gears are machined from steel and run in an oil bath which also lubricates the various bearings. The engine is lubricated by oil from a reservoir in the cylinder casting, and the drum bearings are supplied from a large oil cavity—in the centre of the drum—which has sufficient capacity to do away with frequent refilling. A "Raybestos" lined brake of the band type is actuated by a long lever attached to the base of the hoist and operates through the medium of a double-screw on which are cut both right and left hand threads. This arrangement permits the brake to stay in any position in which it is put either on or off without the use of ratchets, toggles or other complicated parts. The brake is adjustable for wear and the brake lever may be placed in the position most convenient for use in cramped or close quarters, for which this hoist is particularly well adapted, owing to the entire absence of all exposed moving parts or projections which might interfere with the operator in the dim or uncertain light underground. As the drum is mounted independently of the engine shaft, wear and friction from the brake band load are eliminated.

A very useful feature of these hoists is the clutch

Fig. 1. — Column Hoist.

mechanism, which enables one man to successfully operate the hoist on haulage work, as he can leave the hoist and carry the rope to the desired point, whereas, in hoists not fitted with this clutch, it is necessary to employ two men and pay the rope out under power—one man being required to run the hoist and the other to carry the rope.

These hoists are furnished in two sizes known as the 1-H and 5-H models. The smaller or 1-H model is furnished for use either with wire or manila rope and when equipped for the latter, is termed an 11-H hoist. Both sizes are built to operate either on air or steam. Machines intended for operation on steam are called Class 1-HS, 11-HS and 5-HS hoists respectively, have larger valve clearances than the Class H hoists and are fitted with lubricators and drain cocks. In all other respects, however, the Class H and HS, are practically identical.

The 5-H hoist develops 5 Horse Power and the 1-H machine 2½ Horse Power. The drum capacity of the largest hoist is 645 feet of ⅜" wire rope or 1,025 feet of 5/16" wire rope, that of the 1-H and 1-HS hoists 700 feet of ¼" wire rope or 450 feet of 5/16" wire rope and that of the 11-H or 11-HS hoists, 300 feet of ⅞" manila rope.

The 5-H and 5-HS hoists have a lifting capacity of 1,500 pounds at a rope speed of 110 feet per minute, the 1-H and 1-HS, 1,000 lbs. at 85 feet per minute, and the 11 H and 11-HS style 600 pounds at a rope speed of 85' per minute, or smaller loads at higher speeds, on a steam or air pressure of 80 pounds.

The hauling capacity of the 1-H and 1-HS "Little Tugger" on various grades is shown in the table in Figure 2. The haulage capacity of the 5-H and 5-HS hoist is about 50 per cent. more and that of the 11-H and 11-HS hoists about 40 per cent. less. The air consumption of the 5-H "Little Tugger" is about 300 ft. and that of the 1-H and 11-H Little Tuggers averages about 165 feet a minute when they are lifting their full loads at maximum rope speed.

Rise per 100	Angle of incline	Load including car
5 ft	2 deg. 52 Min	14,290 lbs.
10 ft	5 deg. 43 Min	8,330 lbs.
15 ft	8 deg. 32 Min	5,950 lbs.
20 ft	11 deg. 18 Min	4,630 lbs.
25 ft	14 deg. 03 Min	3,780 lbs.
30 ft	16 deg. 42 Min	3,260 lbs.
35 ft	19 deg. 18 Min	2,850 lbs.
40 ft	21 deg. 49 Min	2,550 lbs.
45 ft	24 deg. 14 Min	2,320 lbs.
50 ft	26 deg. 34 Min	2,140 lbs.
55 ft	28 deg. 49 Min	1,990 lbs.
60 ft	30 deg. 58 Min	1,870 lbs.
65 ft	33 deg. 02 Min	1,770 lbs.
70 ft	35 deg. 00 Min	1,681 lbs.
75 ft	36 deg. 53 Min	1,610 lbs.
80 ft	38 deg. 40 Min	1,550 lbs.
85 ft	40 deg. 22 Min	1,500 lbs.
90 ft	42 deg. 00 Min	1,450 lbs.
95 ft	43 deg. 32 Min	1,410 lbs.
100 ft	45 deg. 00 Min	1,370 lbs.
110 ft	47 deg. 44 Min	1,320 lbs.
120 ft	50 deg. 12 Min	1,270 lbs.
130 ft	52 deg. 26 Min	1,230 lbs.
140 ft	54 deg. 28 Min	1,200 lbs.
150 ft	56 deg. 19 Min	1,170 lbs.
160 ft	58 deg. 00 Min	1,150 lbs.
170 ft	59 deg. 33 Min	1,130 lbs.
180 ft	60 deg. 57 Min	1,120 lbs.
190 ft	62 deg. 15 Min	1,100 lbs.
200 ft	63 deg. 27 Min	1,090 lbs.

Fig. 2. — Haulage capacity of 1-H and 1-HS Little Tugger Hoists on various inclines.

The 5-H and 5-HS models weigh 475 lbs. the 1-H and 1-HS models 285 lbs. and the 11-H and 11-HS models 358 pounds. All types of these hoists require very little attention and can be quickly bolted to a column, pipe, timber, flooring, or any other convenient support that will hold the load, without the use of special tools or fittings. The 11-H hoist can also be obtained with a divided drum for balanced haulage, when so desired.

Column Hoists Speed Up Mine Timbering.

Pulling timbers from old workings is one of the fields in which one man with a column hoist can do as much as from two to six workmen by hand. At the Negaunee Mine in Minnesota, the system is top slicing and the ore is won in drifts running from a raise to footwall. The raise is driven upward from a main haulage level on an incline of about 20 degrees from the vertical and is sufficiently large to be divided into two sections, one an ore chute and the other a ladder road.

Timbers are hoisted up the ladder road for timbering drifts in the sub-levels, which must be closely and strongly timbered. The timber cannot be lowered from above as all of the area directly above the sub level is a mass of debris and caved material. The timber, in the face of these conditions, must be hoisted from the haulage level.

The old system required four men to hoist timber with a windlass; thus, two working partners were obliged to call two other men from their work to assist them with their timber. This provided an incentive for the men to work ahead of the timbering, so as to throw the job of timber hoisting on to the next shift. This was a dangerous procedure, owing to the necessity for strong timbering in this mine, as mentioned above, and the problem was finally solved by the use of a "Little Tugger" Hoist in the following way:

The hoist was clamped to mine timber posts placed back 10 to 12 ft. from the raise, the rope being passed through an iron pulley-block over the top of the raise and then dropped to the bottom to receive the load. One man now makes up the load at the haulage level and the other stays at the hoist.

Fig. 3. — Skidding Mine Timber

This makes a two man job, does the work much quicker and makes less work for two men than there formerly was for four, and in fact, so reduces the work of hauling timber that each shift now takes care of all of its timbering with added safety and satisfaction to all concerned. Thirteen of these little hoists are now used in the mine and the miners swear by them.

In many sections of the anthracite district, particularly where the coal beds are steep pitch, the rapid and economical movement of mine timbers into the upper workings presents a real problem. In such places the Little Tugger Column Hoist serves a double purpose—supplying the needed tractive power and furnishing air for ventilation.

In one section of the Catherine Colliery, the vein pitches 15½ degs. and the steady movement of timbers up such a steep slope seriously taxed the endurance of the men formerly employed on the job. A slope of 250 feet long connected two levels. Up this the timber was moved, and down it was discharged the coal extracted in the development of the upper level. The development of four rooms and two gangways required six mine car loads of timbers per day, and for carrying up these timbers by hand six men were constantly employed.

A 1-H Little Tugger Hoist was installed in rather close quarters at the head of the sheet iron lined timber chute (See Fig. 3.) Its 5/16 in. wire rope is pulled down into the lower level where one man attaches it

to the timbers on the cars. On signal to the hoisterman, the hoist pulls up from three to four timbers 14 ft. long with an average diameter of 8 to 10 inches. The ropeman rides the timbers to the upper level and returns with the slacked off rope. The timber is thus hoisted with the services of only two men, and these two men do in half a day the work which formerly required six men all day. The other four men are thus available where badly needed for getting out coal—so that the hoist really performs the equivalent of eight men's work per day.

As previously stated, the 1-H Little Tugger Hoist has a speed of 85 feet per minute in lifting a maximum weight of 1,000 lbs. vertically, but in hauling these heavy timbers 250 ft. up the slope it is a little slower, so that 5 to 6 minutes are required for the round trip by the ropeman.

When not employed for timber hauling, the hoist is used to haul coal in a one-ton buggy from the face of the level along a slight grade to the rocker dump at the head of the chute. Scores of these hoists have been installed in the mines of the anthracite district and are used for a wide variety of purposes besides timber haul-

Fig. 4. — Hoisting muck in a winze with hoist clamped to stretcher bar.

ing, such as, for instance, the hoisting of rock in buckets from shallow shafts, the hoisting of tools and men into raises, and even pulling 40-ton capacity empty coal cars up a slight grade to a loading position beneath the discharge chutes of a breaker.

Column Hoists Solve Many Haulage Problems.

In driving a rock tunnel to connect with a shaft, at another large colliery, it was desired to use the 108-cu. ft. capacity cars which were used about the mine to carry the rock mucked from the working face. The tunnel was about 300 ft. long and had only a slight grade, except at one point where for about 50 ft. the track was given a grade of 10 per cent. The cars when loaded with rock weighed about 12,000 lbs. and to pull them up the 10 per cent. grade, three 1-H hoists were installed.

The concentration of three separate hoists pulling three ropes attached to one heavy car, is of course, un-

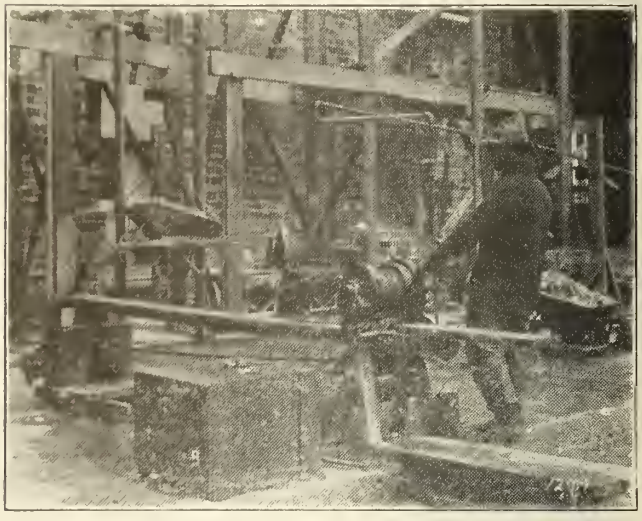

Fig. 5. — Hoisting brick with a Little Tugger Hoist.

usual and would not often happen except in emergency cases or for temporary work. This installation serves to illustrate, however, the wide adaptability of these machines, and the possibility of using them to tide over a situation where the delivery of a larger and more powerful single hoist would seriously delay urgently needed production or development.

Column Hoists a Convenient Source of Portable Power Underground.

Many needs for portable power have been met by these little hoists on account of their compactness, ease of installation and operation. Hauling cars in and out of small drifts is a common application, and in sinking prospect shafts these hoists have been used to handle nearly everything, as the little two-drill compressor commonly used supplies plenty of power for hoisting when the drills are not working. In the larger sinking operations these hoists have been used to handle sinking pumps; for hoisting the drilling machines before shooting, and to put piping, conduits, etc., in the

Fig. 6. — Hauling Rails through a rail bender with a Little Tugger Hoist.

shaft. In winzes and raises they handle drills, steels, powder, timbers and muck. (See Fig. 4.).

As auxiliaries to the regular mine hoists needed in the larger winzes, column hoists have proved labor savers in bringing the rope back to the bottom which, when done by hand requires the work of several men.

The Alabama red o e mines employ column hoists in drifts where the grade is too steep to push an empty car by hand or to haul it with a mule, and where the

Fig. 6a. — Hoist arranged for hauling rails through benden.

down grade is not sufficient to keep the cars moving by gravity. In some of the Michigan Mines where it is necessary to move the tram cars on 30 degree slopes between levels, hauling up empties and lowering loaded cars is efficiently done by these small machines which handle some remarkable loads.

To prevent the flow of water into an Arizona mine, holes were drilled to bed rock and slime was pumped in under pressure. This slime "set" like cement and it was found that a portion of the faults could be filled up and the pumping costs consequently reduced. A drilling rig similar to a churn drill, was used, the actuating power being a Little Tugger Hoist. The string of 3-in. tools was raised by the hoist and allowed to drop of its own weight and by this method 30-ft. holes were sunk at a fair rate of speed.

Fig. 7. — Changing stamp mill shoes with a column hoist mounted on a small truck.

Column Hoists Have Numerous Uses on the Surface.

The uses of column hoists above ground are, if anything, even more varied than underground, and range all the way from removing dirt from a foundation excavation or raising brick and mortar, (See Fig. 5) to driving a tumbling barrel by belt from the rope drum. In the latter case, drill steel is tumbled to clean it for electric welding. At an Alaskan mine, a Little Tugger Hoist is used for hauling large logs from the water up the beach to the lumber pile, and then to pull the logs along in front of a saw, and at another mine, all the fuel oil and supplies are hauled up an incline tram with a column hoist, as labor is too expensive.

Rail bending is not an infrequent requirement in mine track work, and the usual method of cranking the rails through a rail-bending machine, is generally a slow, back-breaking job. At one of the Juneau (Alas-

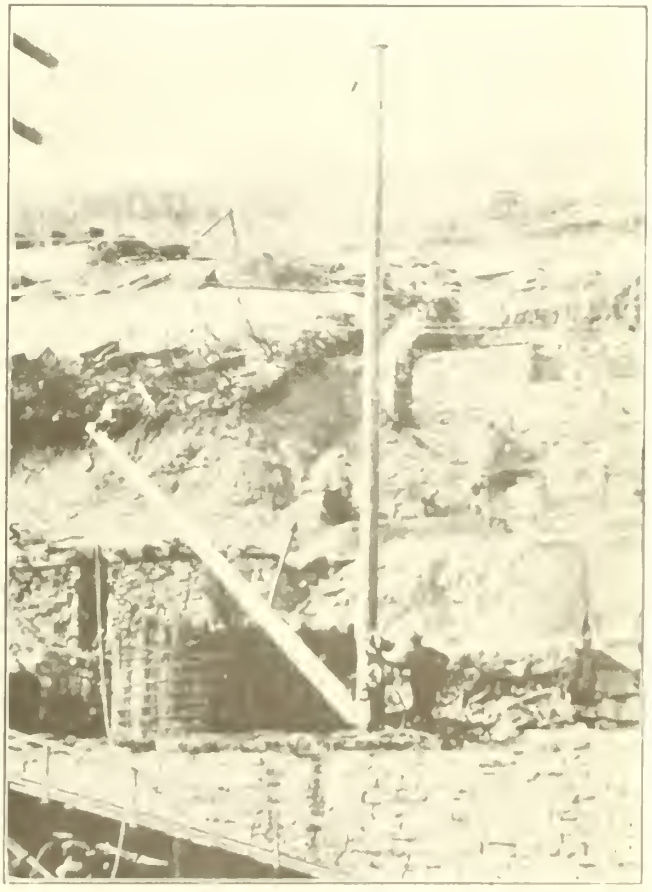

Fig. 8. — Tugger Hoists used for "powerizing" a derrick, one hoist is used for hoisting, and the other for swinging.

kan) mines, fifty pound steel rails were being bent by hand with a three wheel hand power bender when the idea of using an air operated Little Tugger Hoist to pull them through occurred to the Superintendent. The rail bender was therefore, fastened on the truck at a point where the curvature was approximately the same as that of the rails to be bent and the hoist placed a little over a rail's length away. The rails were then started through the bender and the hoist pulled them the rest of the way. The power required

was, of course, considerable and when a curvature of short radius was required a block and tackle was sometimes employed to increase or multiply the pulling power of the hoist.

When cranking the bending machine by hand, eight men were able to bend but eight rails a day. With the assistance of the "Little Tugger" two men bent six rails per hour, the other six being kept busy carrying them to and from the machine. As shown in figure 6, the hoist is bolted to a timber skid which enables it to be quickly anchored in any place desired.

At a mine in Cuba, two of the hoists were placed on a locomotive and used to haul cars in and out of sidings to save switching the locomotive itself. This, however, would not be practicable in many cases. A 1-H Little Tugger Hoist bolted to a small flat car is used by a Western mine for all sorts of odd jobs, such as erecting and repairing machinery, changing stamp mill shoes, etc., (Fig. 7,) and at a mine on the Great Lakes, a Column Hoist bolted to a post is used for shifting heavy boxes and parts of machinery in the store room, unloading cars, etc.

These hoists are also used quite extensively for "powerizing" hand derricks. In the installation shown in Fig. 8, two hoists are used, one for the hook and the other actuating the boom, although, as a rule, only one hoist is used.

(To be continue.)

The Mining Outlook In Northern Manitoba.

By REECE H. HAGUE.

Never since Northern Manitoba first attracted attention as a potential mineral producer has the outlook of the industry in the district been so bright as it is at present. The past twelve months have seen more large mining corporations become interested in the district than ever before, and indications would point to considerable activity in the mineral belt during the coming summer. The hopes of residents are high that their long period of waiting is at an end, and that Northern Manitoba will soon take its place among the big producers of the country.

A year ago the Mining Corporation of Canada took over the Flin Flon property in the Schist Lake area, making a substantial payment to the owners. It is now understood that this company intends to carry on further exploration work during the summer. The exact nature of the work to be done has not been stated, but it is understood that it will include the diamond drilling of claims recently acquired, adjacent to the proven ore body.

Approximately $750,000 has been spent on the Flin Flon property in diamond drilling, sinking and drifting since its discovery, and an ore body of tremendous size has been proved. Values have been found to be consistent, and sufficient ore is in sight to enable a smelter with a 2,000 ton daily capacity to operate for more than 30 years.

At the time the Canadian Mining Corporation took over the Flin Flon, copper was at an almost unprecedentedly low figure, and mines were closing down all over the continent; so this powerful corporation must have felt great confidence in the property to purchase at such a time.

Work is in progress on the Murray claims at Elbow Lake, and sufficient supplies have been taken in by freight teams this winter to provide for a large force of men all summer.

Numerous sales of claims are reported in the Elbow Lake and Claw Lake districts, and it is anticipated that the spring will see a large influx of prospectors and mining men into that area.

Walter A. Rukeyser, a mining engineer from New York, who recently visited Elbow Lake, spoke highly of the district in the course of a recent article in the Mining and Engineering Journal, New York. The district was described as another Porcupine. Mr. Rukeyser optioned a number of claims for the British Exploration Company, not only at Elbow Lake but in the Lake Athapapuskow region, where he secured two large sulphide bodies.

The advent of the Nipissing Mining Company of Cobalt into the district has attracted wide-spread interest. This organization secured 14 claims at Copper Lake from J. P. Gordon and intends to spend $100,000 on exploration work on the property next summer. Mr. Gordon's claims were staked two and a half years ago and are situated some eight miles from the scene of the Murray find at Elbow Lake. During the winter following the discovery Mr. Gordon spent $50,000 in diamond drilling a huge quartz dike that occurs on the property, and got favorable assays in gold.

W. Lee Heidenreich, engineer for the Nipissing group, arrived in The Pas recently and will take charge of operations at Copper Lake. Supplies are at present being sent out by freight teams, and a diamond drill belonging to Smith and Travers of Sudbury is on the way to the property. An assay laboratory will be established on the ground in order that drill core may be tested without delay. It is the intention of the Nipissing Company to drill a large sulphide body that occurs on the Gordon claim, and also to employ a number of men in general exploration work.

With such companies as the Nipissing, the British Exploration, the Mining Corporation of Canada and interests associated with the Hollinger, all displaying interest in Northern Manitoba, and intending to do considerable development work, it seems safe to assume that the critical stage in the development of the district has passed. Lack of transportation facilities is the principal difficulty under which the district is laboring at present, but there is every ground for belief that railway communication will soon be established between The Pas and the mineral belt.

Eighteen months ago the Manitoba Provincial Government conducted a preliminary survey of a proposed railway route to Flin Flon, which will connect up many of the important properties in the district and will provide direct water communication with Elbow and Copper Lakes. It is hoped locally that construction of this line will be commenced within the next few months, when a great impetus will be given to mining generally in the locality and intensified prospecting of outlying portions of the mineral belt will be hastened.

British Columbia Letter

Stewart, B.C.—The newly installed tramway of the Premier Mining Company has been operating satisfactorily, 120 tons of ore being brought to the seaboard every eight hours. The ore is graded at the bunkers, that containing the lesser values being deposited in an ore bunker for shipment to the smelter at Anyox, while the higher grade is shipped direct to the Tacoma Smelter. There are yet some details to be completed in connection with the tramway system, but these are of minor importance.

The Company intends to construct this summer a number of houses for the use of married men in their employ. An assay office is being built next the cyanide plant, and in this will be installed a plant for the conversion of precipitates into bullion. This will not be pure gold bullion, as it will contain all the minerals that are in the Premier ores. As soon as this equipment is complete, the shipment of the product will commence and it will be the first bullion ever sent from the Portland Canal Mining District.

Reports from Bitter Creek are to the effect that the L. L. and H. claims are showing up well on development. A tunnel has been driven about 15 feet and still is in ore. New work on what is known as the second lead has proven it to be at least 60 feet wide, carrying gold and silver values.

Granby.

Anyox, B. C. — Operations of the Granby Consolidated Mining & Smelting Company's smelter have been impeded for a week or more owing to lack of water, which of course has reduced the power available. The water shortage was caused by excessively cold weather resulting in the freezing of the creeks of the district. Only one furnace was in operation for a period. It is with a view to avoiding the possibility of the smelter being affected by cold weather in the future that the Company has decided to construct a 25,000 foot-acre reservoir during the coming summer. More than 900,000 tons of ore were smelted last year by the Granby Company.

Drilling for Oil at Kitsumgallum.

Hazelton, B. C. — Considerable activity is expected in the way of oil drilling in the vicinity of Kitsumgallum Lake as soon as weather conditions permit. Arrangements have been made by the Imperial Oil Company, it is reported, as well as all other interested concerns, for the sinking of bore holes in this District.

While on the subject of oil prospecting it is interesting to note that three carloads of casing and drilling supplies have arrived at Spirit River from the Imperial Oil Company and are being transported over the snow to Ponce Coupe.

Increasing Lead Refinery Capacity.

Trail, B. C. — That the lead surplus of the Canadian Consolidated Mining & Smelting Company has been sold out, that the smelting costs of the treatment of eastern British Columbia silver-zinc ores now are so low that the Company can fearlessly compete with the world in the production and sale of lead and zinc, and that the lead refinery at Trail is to be enlarged from a capacity of 90 tons to 150 tons a day, were statements made by Mr. J. J. Warren, President of the Company, at the recent annual meeting of the Associated Boards of Trade of Eastern British Columbia.

This meeting took place at Nelson. It was attended by many of the mining operators of the Kootenay Districts, as well as by business men representing those sections of the Province. Mr. Warren, who has just returned from the East, could not have made announcements more enthusiastically acceptable. The opinion was expressed on all sides that this indication of a new and progressive policy on the part of the Company would have an immediate and a beneficial effect on the mining industry of the Canadian West. Mr. L. H. Biggar, Manager of the Ottawa Mine, was one who gave expression to the general feeling of gratification. As a small operator, he appreciated what had been done and what was projected, and predicted that there would be important results.

Mr. Warren's Address.

Mr. Warren's address opened with some generalities. Amid laughter he observed that he was just back "from the centres of intelligence." Getting back to the Kootenay was indeed getting back home, for he had the kindliest feelings for the people of the Kootenay and the Okanagan, notwithstanding certain criticisms that were raised against the smelter, some merited perhaps, some unmerited, and some mischievious. The smelter had been smelting ores for a long time, and doubtless it would smelt them for a long time in the future, and such esteem as the smelter would ultimately obtain would be what in the long run it would deserve. After referring to conditions in Eastern Canada and on the Prairies, Mr. Warren said that the selling price of British Columbia's products was not so important as the production costs. The thing to be done was to keep production costs down. British Columbia did not fabricate in the sense that the Eastern Provinces did. Its products were more in the nature of raw materials—metals, lumber, fish and agricultural products. There was not sufficient population locally to absorb its output, so that the Province must export and the cost must be kept down. Anything that would reduce costs would aid. It was no secret, Mr. Warren said, that a year ago the Consolidated was in a very anxious position, like many other concerns. Its bank credit was poor. It had large stocks of metals on hand, the market was low, and there was a very small demand. It was in a position of anxiety, and had to consider whether it should close down, or should carry on.

He would have the people of Kootenay believe that what influenced the decision most was not whether the shareholders should make money or lose it, but what would be of effect on the district if the smelter carried on or closed down. The decision was made to carry on for another three months, even though it meant piling up more stocks.

Following this decision, Mr. Warren said he himself made a journey to China and Japan, perspiring in July and enduring all the perfumes of the oriental cities, to see if those countries could be induced to buy more lead. He arranged agencies to handle the company's products, and largely as a result of this, not only was it a case of the Consolidated not having much metal on hand, but it was completely sold out of lead, and was now in a position to carry on its operations in competition with the whole world.

This accomplishment was a credit to the company's operating staff, he said, which staff had done the greatest metallurgical work of a year ever known.

Admitting that he preached cutting [illegible] Mr. Warren said the Consolidated had first practised what

be now preached, for it had cut the costs of production of lead and zinc to such a point that it did not fear any competition whatever. Lead and zinc were down in price, but in spite of that, owing to the progress made in treatment, the company would be able to sell them at enough to keep going.

On account of the large production of lead ore by the company, and of what would be forthcoming from private shippers, the lead refinery, now of a capacity of 90 tons a day, was insufficient, and the directors had authorized an increase to 150 tons a day. The company would then produce about 15,000 tons of refined lead per annum.

An Epoch in B. C. Mining.

Mr. Warren said the Consolidated had found a way by which it could accept shipments of zinc-silver lead ores, paying shippers a reasonable sum for the metal contents of all three ores. Formerly the zinc operated as a penalty. In a short time the company would be able to take care of the zinc, and give full value for it.

"This marks an epoch in British Columbia Mining," he declared. Some criticized the company for not having done this before, but as a matter of fact, the Consolidated had spent $3,000,000 in developing its zinc process, and it was too dangerous to vary the feed even slightly until the process was better under control. What the company was now preparing to do for the shippers of zinc ores was only the start. As the process improved, as it certainly would do, the company would give the shippers further benefits.

If the operators would stop talking about what the government should do for them, and rely on themselves, the Kootenay would have a prosperous mining industry. Any assistance that the smelter could give to the shipper or the prospector would be cheerfully given, he declared, provided that no paternalism was expected.

Duties on Minerals and Metals.

A number of questions relating to the mining industry of the Province were discussed at the recent annual Convention of the Associated Boards of Trade held at Nelson, B. C. Resolutions were passed asking for "adequate duties on all base metals entering Canada up to the point where metals can be supplied by Canadian products"; and advocating adequate duties on "copper rods, copper wire bars, zinc sheeting, sulphate of lead and fluorspar." Regarding fluorspar Mr. F. W. Bingay of the Consolidated said that Canada imported that article both from England and Kentucky, that Eastern manufacturers using that product have plentiful supplies in Ontario to draw from and would not be injured. It also was urged by resolutions that "The same duties on scrap copper, zinc and brass be imposed, as upon the virgin metal." The Colliery Companies, it was decided, would be petitioned to take steps to reduce the prices of coal and coke by every possible means at the earliest possible date.

All told, Trail sold only 350 tons of lead in Canada in December, and about 360 tons in January, while in each of those months it produced 2,700 tons. This showed how much of a market there was here for lead. So far as lead bullion went, the only Canadian purchaser was the Consolidated company, and it would be a funny proposition for a shipper to send his ore south to be smelted and then bring the bullion back to sell to Trail. What he would make by this traveling would not be very much.

Mr. Warren stated that Trail was increasing the capacity of its lead refinery and was reducing its rates. It has been accused of shutting down the Slocan, whereas the fact was it had never refused a ton of ore. When the company arrived at the stage where it could secure no more credit, it notified the shippers that it would advance the freight, and would stand the smelting charge, but that the shipper would have to pool his ore with that of the company and receive payment when it was realized on.

As soon as credit got easier, the company met the shippers in conference and arranged to pay them cash for their ore.

A couple of years ago an inquiry was asked for and granted and after the auditors went over the company's books they gave it a certificate of character that one would think would be appreciated.

Referring to criticisms of the smelter from a certain source, Mr. Warren said the Consolidated had to find $500,000 a month for its operations, and did not have time to chase every dog that barked at it.

L. H. Biggar said he wanted to be recorded as against the proposal, which he believed detrimental to the interests of Canada. On the matter of the treatment of shippers by the smelter, Mr. Biggar said the small shippers fully realized that it had been a matter of bank credit, and not of a desire to close them out.

The resolution was laid on the table.

A resolution from the Northwest Mining Association in convention at Spokane, asking support for reciprocal free re-entry of lead bullion to the country of its origin, was almost unanimously opposed. This was offered by the Nelson Board of Trade, although not endorsed by that Board.

F. A. Starkey of Nelson thought that the proposal was intended chiefly to benefit the smelter at Kellogg, Idaho. There were as good facilities at Trail as at Kellogg for smelting. J. K. Hunter did not think that there was much chance of the United States sending ore here to be treated.

Receipts At Trail.

Ore receipts at the Trail Smelter of the Consolidated Mining & Smelting Company for the third week in February totaled 6,395 tons. Of this, 6,276 tons came from the Company's mines, 37 from the Ruth, 43 from the Silversmith, 13 from the Trail Mining Company, and 26 from the Wind Pas, Chu Chua. This brings the total for the year to date to 61,690 tons.

Although Mr. J. J. Warren, President of the Consolidated, did not so state before the Associated Boards of Trade, it has been authoritatively announced that the Company will construct a small plant for the handling of the silver-lead-zinc ores of the Slocan and other districts. This will be entirely distinct from the plant now in use chiefly in the treatment of ores of the Sullivan Mine. It is expected that the Company will be able to accept zinc-silver concentrates from the custom shippers on or about the first of June. This equipment will be of special benefit to the operators of the Slocan. The Slocan Mines, it may be explained, produce two classes of concentrates: lead-silver, containing some zinc and known as lead concentrates, and zinc-silver, known as zinc concentrates. The lead-silver concentrates have been shipped to Trail, but there has been no outlet for the zinc concentrates. The latter, therefore, have been piling up and it has been a problem of concern to all interested in mining to find an economic method for their treatment. That this is to be taken in hand by the Company is gratifying news to all those affected.

Florence Silver.

Nelson, B. C.—A contract has been entered into by the Florence Silver Mining Company to supply the Pacific Color Company at Chilliwack with a supply of concentrate containing not less than 60 per cent lead. The first shipment the Color Company received contained 67 per cent lead, 8 per cent of iron and 3 per cent zinc. The Color Company expects to consume about five tons of concentrates from which it will produce a variety of pigments.

Silversmith.

The gravity section of the Silversmith Company's Ivanhoe mill is now running at full capacity, and the flotation section will soon be in operation. During January the company shipped 350 tons of concentrate to the Bunker Hill and Sullivan smelter, at Kellogg, and in future it is expected that not less than 400 tons will be shipped monthly. The average tenor of the concentrate was 67 per cent lead and 106 ounces of silver per ton. When the flotation plant is completed, it is expected that the grade of the concentrate will be markedly improved. An immense body of ore has been developed in the mine. The oreshoot has an average width of 7 feet and a length of 450 feet, and it is being mined on three levels.

High-Grade Silver Ore.

Grand Forks, B. C.—Some high-grade silver ore has been opened up on the Bell Mine and the Sally Group of claims, both of which are situated on Wallace Mountain near Beaverdell. The Bell is owned by Duncan MacIntosh, and the Sally by a Penticton syndicate. Mr. P. B. Freeland, Resident Mining Engineer, has been over the showings and his report is very favorable. Samples of the ore show as high as 6,000 ounces silver to the ton.

Cedar Creek.

Lillooet, B. C.—The freighting of machinery and supplies to Cedar Creek, where considerable placer mining activity is expected to develop this year, has been interfered with by heavy snowfalls in the Cariboo District. Much freight has been housed temporarily at 150-mile house. Freighting will be resumed as soon as weather conditions permit.

Vancouver, B. C.—The new claim which the Britannia Mining Company began to operate after the flood of a month or more ago is reported to be producing some extremely high grade copper ore. Assay returns run as high as 22 per cent. No shipments of this ore have yet been made, owing to the fact that the company's plant has not yet been restored. The claim in question is the Victoria, and it lies two miles farther east than any property yet worked by the company. It is on the east side of the mountain, and is approached by a tunnel from the older workings.

Arrangements are being made by the Tatlayoco Lake Gold Mines, Ltd., to ship a concentrator to their mining property, which is situated at the south end of Tatlayoco Lake. It will be transported over the Pacific Great Eastern Railway, and thence by Government wagon road for 150 miles. Considerable development work with satisfactory results has already been done on these claims, it being estimated that $75,000 has been so invested. An equal amount is to be expended on the mine plant and other necessary equipment.

Testing Iron Ore.

Victoria, B. C.—S. P. Silverman, President of the Tidewater Copper Company, Sidney Inlet, Vancouver Island, is quoted as stating that a Sheffield steel firm and the Krupp interests of Germany are testing samples of magnetic iron ore from his company's property, in order to ascertain whether the quality of the product would warrant its shipment to Europe for use in the manufacture of steel. He says that this ore contains a large percentage of molybdenum, nickel and manganese. At present the iron ore is being cast aside, but if markets can be found for it in Europe, shipment can be made at the rate of 3,000 tons per month.

KENO HILL SILVER.

The most notable strike on Keno Hill, center of the Yukon's greatest silver activity, made during 1921 was the finding of the lode on the west end or McQuesten slope of the hill. The vein starts at timber line and has been traced along the hillside through the deep moss and trees practically a mile, and ranges in width from five to fifteen feet between the walls. Numerous crosscuts have been made on the lode at frequent intervals for almost the entire length, revealing the ore in place at every point tapped. The discovery claim, the Ladue, at the north end of the lode, was found by David Cunningham and Ray Stewart, pioneer Yukon prospectors. A buckboard turned up a piece of float half a mile away and Joel Sunderland there found the vein on the Friendship claim. Other lucky stakers and owners on the lode were James Clark and Frank McNeill, while Raoul Binet and Dick McGuire were given one of the claims. All have bonded the ground for $40,000 to $65,000 a claim. A year ago one of the claims was offered in Dawson for weeks for $200, with no takers. The ore assays 200 to 500 ounces in silver to the ton. The claims crossed by the lode are the Ladue, the Bluestone, the Friendship and the Sadie. They were staked in the spring of 1920. Several adjoining claims also have been bonded to same companies.—Dawson Daily News.

A NOVEL CANADIAN INDUSTRY.

The Pacific Color Manufacturing Co. which was organized a year ago to develop the patents of H. D. Swartout, has brought the first unit of its plant at Chilliwack, 70 miles east of Vancouver, B. C., to the producing stage. The process that the company employs for making pigments consists of dissolving galena in dilute nitric acid contained in cast iron retorts, of special design heated by steam. The resulting nitrate of lead is drawn off into vats, where the lead is precipitated in different forms by various reagents, giving the desired pigments, while the oxides of nitrogen and any nitric acid that distills over are recovered. The insoluble residue is drawn off from time to time through valves at the bottom of the retorts. The patents cover reagents, temperatures and retort design.

The galena is obtained in the form of concentrate from the Florence Silver Mining Co., which is operating a silver lead mine at Ainsworth, in West Kootenay. The contract with the mining company calls for a concentrate containing not less than 60 per cent of lead. The first carload delivered contained 67.8 per cent of lead, 8 per cent of iron, and 3 per cent of zinc. The company is using 5 tons of concentrate daily, but expects during the next few months to install another battery of five retorts, which will double its output. Nitrate solution after the precipitation of the lead sulfate will be evaporated and sold for fertilizing purposes.—Chem. & Met. Eng.

News and Comments.

By Alexander Gray.

MINING ROYALTIES HIT PRAIRIE PROVINCES.

Regulations by Order-in-Council at Ottawa fix the royalty collectable by the Dominion Government "on the sales of the products from quartz mining locations on Dominion lands" on the basis of 2½ per cent. on such sales.

Accompanying this announcement is the explanation that "in order that investors may be aware of the extent of their liability in this connection, a scale of values has been laid down as follows: Gold is valued at $15 an ounce, royalty 37½ cents an ounce; silver valued at 60 cents an ounce, royalty 15 mills an ounce; copper valued at 12 cents a pound, royalty 30 cents a hundredweight; zinc valued at 4 cents a pound, royalty 10 cents a hundredweight; lead valued at 4 cents a pound; royalty 10 cents a hundredweight."

Presumably this is the forerunner of the transfer of mineral resources to the Prairie Provinces. No doubt the Dominion Government has exercised forethought; yet it is characteristic of the merely casual nature of public interest in such matters that the action has evoked little or no comment. It is not of public record that anyone identified with mineral industries was consulted. The sales tax imposed would not be burdensome were it the only levy. Considering that there are Provincial and Dominion income taxes, and in view of the fact that Alberta and other northwestern sections are deeply concerned with new and promising prospects, the regret is that such orders are formulated without discussion with investors and mining authorities. Manifestly the tax is invidious, in that it affects only Dominion lands located in areas where mines like the Flin Flon, and properties like those at Elbow Lake and vicinity, are undergoing development.

A NATIONAL ASSET.

What a large gold mine means to merchants, manufacturers, wage-earners and governments, to say nothing of shareholders, was illustrated by President Noah A. Timmins of Hollinger Consolidated at the annual meeting. To date Hollinger shareholders have received over $17,000,000. Mr. Timmins pointed out that to the end of 1921 the company had paid $27,420,185 to the people of the Dominion and Ontario, other than shareholders, in order to develop and equip their properties. This, of course, includes power, labor and supplies. Moreover, all but about $1,000,000 of the total was spent in behalf of Canadian labor and products. Mr. Timmins emphasized the possession of $6,042,794 in government securities, cash and materials. Taking the total of dividends and adding what is really cash in the treasury, the company dividends and money in hand are equivalent to $23,042,794, compared with the issued capital of $24,600,000. Therefore, Mr. Timmins was very much in order when he discussed the relationship of the gold industry to the public purse. Last year it cost the Hollinger Company $4.87 to mine and market the gold produced from each of the 1,072,493 tons milled. That was the dividend accruing to those supplying labor, power, machinery, and supplies, and to the governments. The shareholders received $2.98 per ton in dividends, and the speculative investment underground was maintained to the satisfaction of all concerned, the solitary dissentient holder being the late general manager, Mr. P. A. Robbins, who demurred at the policy of producing so much gold when costs and taxes were so high. That Mr. Robbins did not voice the Canadian view, and that his economics got twisted when departures from his policy were made, goes without saying. President Timmins made the admirable rejoinder that the company recognized the greater worth of their gold when out of the ground than when in place. Besides, it was more patriotic to mine and mill to the maximum possible in the circumstances while the country needed the money, and labor the employment.

INTERNATIONAL NICKEL OF CANADA.

John L. Agnew has been elected President of the International Nickel Company of Canada. As such he will coordinate the work of the Canadian organization with that of the New Jersey corporation, presided over by Mr. Stanley. Treasurer James L. Ashley also becomes a Director of the Canadian corporation, and Mr. Fred. S. Jordan is a new vice-President. Those veterans, in conjunction with Mr. Britton Osler, Wm. Wallace Mein and their colleagues, sustain the confident expectation that Canada will have the fullest measure of activity and efficiency in bringing the nickel industry to restored prosperity. The selection of Mr. Agnew to be chief executive at Copper Cliff, with jurisdiction over the Port Colborne Refinery, is specially acceptable to all who appreciate the magnitude and importance of International enterprises. He can be "hard-boiled" or "bonhomme" at will. These are the pre-requisites to the superintendence of the largest factor in the nickel industry.

Northern Ontario Letter

THE GOLD MINES.

The new hydro-electric development is being pushed rapidly by the Northern Canada Power Company. In spite of this, it has been stated here this week that the Hollinger Consolidated Gold Mines has appealed its case against the power company for damages of almost two million dollars. It has also been stated officially by Mr. Noah Timmins, president of the Hollinger, that the company is still endeavoring to secure the right to develop hydro-electric energy on the Abitibi River. This threatened continuation of litigation and this endeavor of the Hollinger to secure a power site of its own cannot be interpreted in any way as being detrimental to general progress, unless it should result in discouraging the Northern Canada Power from going ahead with further power development pending the outcome of the litigation. As to this, the recent decision appeared to be so completely in favor of the power company that this concern has seemed to feel secure, hence the present rapid progress being made in con-

nection with harnessing Sturgeon Falls on the Mattagami River.

Will Reopen V. N. T. Mine.

Major J. Mackintosh Bell, in an interview with the Journal made the announcement that the work in connection with re-opening the Porcupine V. N. T. would commence within the next three weeks. It is planned to carry development work to a depth of 900 feet, with a view to conducting lateral operations at the present depth of 600 feet as well as at depth of 750 and 900 feet.

Dome.

Directors of the Dome Mines who visited the property over the past week-end were greatly impressed with the favorable developments of recent months, and particularly with achievements in the mill.

The Production Record.

Official figures showing that the gold mines of Northern Ontario produced approximately 30 tons of gold bullion during the past year, and that the Dome ranks second only to the Hollinger among the producers, are facts that have left a deep impression upon the official visitors.

Great as has been the achievement during the past year, it is reasonably certain that the results accomplished during the current year will mark another increase of about 25% over 1921. This will be brought about by an enlarged plant on the Hollinger, as well as a big addition to the McIntyre-Porcupine and a considerably increased tonnage on the Dome.

While these three big mines are setting the pace, the Wright-Hargreaves, Lake Shore, Teck-Hughes, and Kirkland are all grinding out their fair share of bullion, while the Tough-Oakes mill will go into operation within the next three weeks. There are good prospects that this year will witness the Porcupine Crown, Porcupine V. N. T. and Schumacher mills all in operation, as well as the Argonaut some time during the last quarter of the year.

These facts tend to show that the output of gold from the end of March forward will reach at least a ton and a half monthly, or upwards of twenty million dollars a year, with probabilities of this reaching a ton of bullion per week during the coming year.

Gold Reef.

Reports continue to circulate that there are good prospects of English capital becoming involved in the development of the Gold Reef mine, situated in the northern part of the Porcupine field.

McIntyre.

Within the next three months the addition to the mill on the McIntyre-Porcupine will be completed. This consists of a 250-ton unit which has been constructed for the purpose of treating carbonaceous ores encountered in one section of the mine. This will bring the total capacity of the plant up to 800 tons daily and should result in a production of approximately $3,000,000 per year.

Wright-Hargreaves.

The Wright-Hargreaves Mine has declared a dividend of 2½ p.c. payable April 1st to stockholders of record March 17th. This will call for the distribution of $68,750 and compares with $137,500 disbursed on January 2nd. The mill is now treating close to 200 tons of ore daily, and is producing approximately $70,000 monthly. The work of carrying the main shaft to deeper levels is progressing rapidly, and before the end of the current year the Wright-Hargreaves will probably be operating at a depth of 800 feet.

King-Kirkland.

The mining plant of the King-Kirkland is being assembled and will be completely installed within the next six weeks. The company is now preparing a report which will show results up to the end of 1921. The small amount of drifting at a depth of 100 feet showed an ore shoot 70 feet long and containing about $8 per ton across a stoping width. Once the new plant is installed, the underground work will be pushed forward vigorously.

Goodfish Gold.

At a depth of 80 feet on the Goodfish Gold Mines, the vein carries high-grade ore across a width of about six feet.

Hunton-Minaker.

The merger between the Hunton-Kirkland and Minaker-Kirkland is practically assured according to information circulating here. The terms of the merger have not been announced, but are understood to be mutually satisfactory. This information comes as an agreeable surprise following the rejection of the recent plan to merge the Hunton with the Gibson-Duncan..

Among other things, the understanding is that fifty thousand dollars will be provided to carry on deep work through the present Hunton shaft.

Ontario-Montreal-Kirkland.

At the special meeting of the Ontario-Kirkland held on March 9th, the plan to merge with the Montreal Kirkland was ratified.

The agreement provides for the formation of a new Company with a capital of $5,000,000, divided into 5,000,000 shares of the par value of $1.00 each. The Ontario-Kirkland, with a capitalization of $1,500,000, owning about 88½ acres, equipped with a complete plant, including a 100-ton mill, are to receive 1,500,000 shares of the stock of the new Company with the agreement that the new Company will assume to the exoneration of the Ontario-Kirkland Company its current liabilities amounting to not more than $120,000 as of the 15th of February, 1922, and in addition the new Company agrees to issue 481,250 shares of stock to provide for the payment of the present outstanding notes of the Ontario-Kirkland Company amounting to $173,250., and further agrees to issue additional shares at forty cents to cover the 6 per cent interest on the said notes.

After providing for the payment of all liabilities of the Ontario-Kirkland Company, and the issue of share for share of stock in the new Company, the present shareholders of the Ontario-Kirkland Company are to be given the privilege of subscribing to additional stock of the new Company before same is offered to the public.

The Montreal-Kirkland Mines, Limited, capital $2,500,000, owing about 200 acres, equipped with buildings, plant, and free of liabilities, are to receive 1,725,000 shares of the stock of the new Company.

Thus when the deal is finally consumated, the combined holdings will consist of about 280 acres, fully equipped with mining plants and mill capable of treating 140 tons of ore per day, which capacity can be readily increased when conditions warrant. Several veins have been opened on the Montreal-Kirkland showing high gold values, and the large acreage of the amalgamated Companies offers big possibilities.

The Directors of the Ontario Kirkland have fought stubbornly against the extraordinary conditions of money, labor, and delays, the aftermath of the Great War, which are only too familiar to all of us, and have evidenced their confidence and good will toward the stockholders by personally advancing and procuring from time to time the funds necessary for additional costs, development and operation. Unpreventable delays in delivery of machinery, accidents and other causes held up production considerably beyond the time estimated by conservative engineers. This with the heavy current expenses piling up in the interim has left the Company in a condition where new capital is necessary and a welcome aid to continue in a safe, business-like, and profitable way.

In an interview with the Journal at the close of the meeting, Walter Hurd, promoter of the Ontario-Kirkland, stated that the cost of developing and equipping the property had been under-estimated, while unforeseen delays in securing equipment and commencing production had been the cause of the heavy debts.

Elston-Dunkin.

Surface work on the Elston-Dunkin property in the township of Ganthier has resulted in opening up some exceedingly rich gold ore. Further work is being carried on, and this enterprise promises to be one of the more interesting new developments of the current year.

Staking In Munro Township.

The staking of mining claims in the Munro township area on the strength of the discovery of placer gold has continued and a total of about 300 claims already been recorded. The staking rush is one of the largest since the discovery at Fort Matachewan.

Prospectors Active.

Larder Lake is said to be alive with prospectors, and there are general signs of increasing activity in the prospective fields all over Northern Ontario during the coming summer.

THE SILVER MINES.

Nipissing.

Another dividend of 3 p.c. is expected on the Nipissing, this being the regular quarterly disbursement which falls in April. Production continues to be heavy, while the treasury is in an exceptionally strong condition.

Keeley.

The recent paper by Mr. J. Mackintosh Bell before the Institution of Mining and Metallurgy in London gives a good general summary of conditions at the Keeley Silver Mines. These developments have been such as to offer promise that the South Lorrain district will replace to some extent the gradual decline in Silver production from Cobalt proper.

Colonial.

Reports are current that a diamond drilling campaign may be undertaken on the Colonial property for the purpose of determining the formation underground as well as established the location of the contact zone.

Victory.

The vein that was encountered in the shaft at about 300 feet on the Victory Silver Mines, dripped out at about 330 feet. It is planned to carry on cross-cutting operations at a depth of either 400 or 500 feet with a view to opening up this vein as well as others at a point in close proximity to the contact of the Keewatin with the underlying diabase.

Bailey.

Another vein has been opened up at the 4th level on the Bailey Silver Mines. Good mill rock has been encountered over the 18 feet of drifting so far done along the new vein.

Golden Rose.

W. R. Sweeney of New York has purchased the Golden Rose Mines, situated in the Temagami Forest Reserve, northwest of Temagami Lake. The price paid is stated to have been quite large and was paid in cash. This includes the purchase of a stamp-mill on the property as well as some other mining machinery. This property has been reported on several times recently, among those making reports being Mr. Hitchcock of the International Nickel Company. On being asked about the deal, Mr. Sweeney said: "Yes, I have bought the Golden Rose and have paid for it. Several offers have been made to me already for its purchase, I have not decided what I shall do with it yet."

The Golden Rose is one of the oldest known gold prospects in this part of Northern Ontario and has been idle for a good many years.

According to the official returns as compiled from the records of the Bureau of Foreign and Domestic Commerce of the United States, America imported during 1921 no less than 125,306,841 barrels of crude oil, as compared with a total of 106,175,289 barrels for the previous twelve months. With the exception of 122,000 barrels, the whole of the imports came from Mexico. During the year the total exports amounted to 8,939,634 barrels, as against 8,757,092 barrels for the preceding year. Of the total, 7,166,874 barrels were last year shipped to Canada. The excess of imports over exports last year was 116,367,207 barrels.

EDITORIAL

RATIONAL MINING INVESTMENT.

GOLD mining has of late become so well-established in Ontario, and some of the mines have had such spectacular success, that world wide attention is being drawn to the new and promising field. We have recently reached the depths of a depression, and are now, by common consent, on the up-grade. With the revival of legitimate business will come also a revival of certain practices, often called business, that are more properly called by less dignified and more unsavory names. Gold mining is sure to suffer its full share of attention from the "get-rich-quick" and their kind; it is incumbent upon those vitally concerned in the welfare of our mining industry to see that the useless and senseless activities of these gentry are kept at a minimum. "Fore-warned is fore-armed." The public must be told of what is coming, that all susceptible to protection may have whatever help can be accorded by legitimate mining men. This is merely what is due the public from the professional miner.

From the press and from personal information, we gather that a campaign of irresponsible and illicit stock flotation is to be begun in London, using the good name of Northern Ontario's gold mines as the bait. It has already begun in Montreal. This sort of gamble appeals irresistibly to certain people, who are bound to be parted from their money, whatever precautions are exerted to guard them. But it is on behalf of another class of investor that we wish to make a suggestion.

Those that have accumulated capital to the extent of becoming investors in measurable degree, have usually a moderate amount of caution and discretion, as a prerequisite. We may assume that most investors will inquire to the full of their ability as to representations made them by promoters or vendors of stock, and will require some evidence of their "bona fides". That many investors fail to learn the truth about the mines (or near mines) represented by their stock, and that often the good faith of the promoter is demonstrated chiefly by the large proportion of good money he keeps in his own pocket, is a matter of record. The obvious means of avoiding this preventable waste of capital that would otherwise be available for legitimate mining development, is to put within the reach of people who wish it, the truth. The present means for circulating the truth are not so hard worked as the means for circulating falsehood. Yet the truth should be widely known, and can be if certain simple devices are put in operation.

The Canadian Institute of Mining and Metallurgy is profoundly interested in the progress of mining in Canada, and in the adequate provision of funds for its rapid development. While the membership of the Institute is comprehensive, it has in its Professional Members an exclusive class of well-qualified mining engineers. The requirements for admission as a Professional Member are strict, and the credentials submitted by an applicant are now subjected to so close a scrutiny that admission to professional membership in the Institute's guarantee of good character and professional experience and ability. Upon these men, singly and collectively, rests chiefly the responsibility of protecting the good name of the industry upon which they depend for a livelihood.

Our suggestion is that the officials of our Institute should make it known, publicly and broadcast, that its services are at the disposal of intending investors, who may wish authoritative information about specific Canadian mining properties, or the financial structures built upon such properties. The chief means to this end will be a printed list of the Professional Members of the Institute, setting forth in brief their qualifications, experience, and special knowledge. If the public is informed officially where to look for sound professional advice, many investors will avail themselves of the assistance they need. The Canadian Institute of Mining and Metallurgy can now, if it will, exert upon behalf of the profession and the public the good offices performed by the bar and medical associations.

BROADENING OUT, AND SPECIALIZING

FORMAL education of engineers is so recent a venture, compared with that of other professions, that its requirements still need definite formulation, and expedients to meet these requirements are still subject to pronounced, if not radical change. Members of the old established professions are hardly yet ready to receive the engineer in the fold of the learned. His credentials are still imperfect. His manners are out of accord with his pretentions. His function is not yet understood, the ideals of his profession have still to be clearly defined and generally accepted. He has not yet developed the exclusiveness and sense of superiority that is the sure mark of the self respecting member of the bar, the army, the medical profession or the clergy.

The newness and often vagueness, of present-day engineering education is particularly marked in the mining branch. Mining was recognized as a distinct specialty of

engineering at a time when all other engineering was left to the Army and Navy, and to church-building enthusiasts of the clergy and laity. Yet the education of mining engineers today is so various throughout even the English-speaking world, that an outsider might be excused the wonder aroused by the diversified result. Graduates from certain British institutions have little but a thorough grounding in the fundamental sciences, and a history of their profession. On the other hand, certain colleges in the United States emphasize present-day practice to the virtual exclusion of more fundamental considerations. There has not yet been clearly formulated and generally adopted a scheme of education for mining engineers that will provide both a firm grasp of principles and a wide adaptability to existing conditions. We may well study the lawyer's term of pupilage with this point in view.

The Canadian colleges where mining is taught seem to have found the middle way. A solid grounding in the fundamental sciences has been followed by a finishing-up year or so in present-day practice. There is no doubt that much room for improvement exists; but the record of our graduates, at home and abroad, is evidence that their education has not been completely off the mark. Toronto University is offering more and more facilities to graduate engineers for research, and so is paving the way for highly-specialized technologists. Queen's University offers to graduate engineers a special course in economics, with a view to training them in the responsibilities of executive office. On the other hand, all our colleges tend to lay more emphasis upon a good English course and a comprehension of the elements of economic science, both of them essential to a good education, and too often neglected in a technical curriculum.

Special conditions require special education. This axiom has become an obsession with some educationists, notably extreme proponents of technical education. Others, such as those over-enthusiastic for the classical education, deny the validity of the axiom. Without under-rating in any way the value of, and the necessity for, a firm grounding in the fundamentals of mining engineering, we wish to point out here a need, peculiar to a new country like Canada, that has not been adequately met in our case.

Canada is just entering upon a career of mining activity that promises to be long and useful. The promise of her youth is hard to visualise, it is so comprehensive and extends so far into the future. If she is to fulfil this promise, it will be mainly through the agency of the graduates of our mining schools. What a charge, then, rests upon the shoulders of those responsible for the guidance of the next generation of mining engineers! These mentors must forecast with certainty the conditions their pupils will be called upon to meet, and prepare them well to fulfil their tasks.

In mining, more than in any other industry, Canada is still in the pioneer stage. Moreover, the nature of mining is such that pioneer effort will always be essential to its progress, to provide the succession of new deposits necessary to replace vanishing reserves. So the Canadian mining industry requires at present, and will require for a generation or more, an abnormal proportion of pioneers among its technical men.

Are our colleges filling this need? We fear not. For some reason, our graduate mining engineers appear to fight shy of pioneering effort, choosing rather the comfortable existence of a follower-up in the advance of progress. We need leaders, men for the van-guard of progress—the position of honour in an advance. The natural instinct of our young men is toward pioneering and adventure, as evidence the annals of the Great War. It must be that the ideas inculcated during their college days deter them from following this instinct, rather than encouraging them to pursue it.

This point is of prime importance to our growing mining industry. It is not clearly before the minds of our educationists and administrators. We invite discussion in the Journal's columns.

POTASH FROM FELDSPAR.

THE Imperial Institute, London, has just published a monograph on potash. This was prepared under the direction of the Mineral Resources committee and gives a very good account of the sources of potash.

Soluble potash minerals, mined on a large scale in Germany and France, supply most of the world's needs. Numerous other sources have, however, been drawn upon on occasion, and of these the feldspars have attracted most attention in Canada. It is of interest to note that while the problem of extracting potash from feldspar economically has not yet been solved, this possible source of supply is still attracting attention. Our abundant supply of feldspar and our present lack of soluble potash minerals; our need of potash for agriculture and our dependence on Europe for the supply are factors that stimulate investigation. It is nevertheless a problem that has so far defied solution. No potash in commercial quantities has yet been derived from feldspar, even the stimulus of war-time shortage having failed to give the expected results.

EDITORIAL NOTES.

HON. JAMES MURDOCK, Minister of Labour for Ontario, appears once more as a fearless exponent of the truth. This time he protests the action of J. B. McLachlan, secretary-treasurer of the United Mine Workers of America, at Sydney, Nova Scotia. Failing to attain his ends by fair means, McLachlan has resorted to foul. His influence, and that of others of radical tendency in Cape Breton, was exerted successfully to persuade the miners to reject last week the compromise effected by their own executive (McLachlan excluded, with the officers of the Dominion Coal Company. The

result is that, instead of receiving the enhanced wages agreed to in this compromise, the men still receive the lower wages set by the official Gillen Conciliation Board.

McLachlan has now counselled an un-British, undemocratic and un-sportsmanlike method of attempting to force his views on the Dominion Coal Company and upon the public. We are sure his "sabotage" and "striking on the job" will prove unsuccessful. It is unworthy of Canadians (McLachlan is not indigenous to Canada), and deserves the censure now accorded similar "Red" methods in Russia by the larger part of the thinking public, and by that sane and fearless labour leader, now a Minister of the Crown.

The old Laurentian Mine, in Northwest Ontario, prominent in the gold boom of twenty years ago, is being opened up. It is one among many such properties, most of them the victims of stock manipulation and mismanagement during the years just preceding and succeeding the turn of the century, that are now well worth careful re-examination. In many cases, it is known that only a perfunctory examination of the ore-bodies has ever been made, in spite of imposing mills and surface equipment.

The Journal is not at present satisfied that the new attempt to open up the Laurentian Mine has been organized in such a way as a present-day mining engineer can thoroughly approve. The raising of money promiscuously at this time is liable to cost more than it is worth, and consequently is likely to impose an undue burden of debt upon the natural resource whose development is attempted. We hope that the promoters of the new Laurentian venture have given more regard to this fundamental consideration than rumour has given them credit for. Only on a sound basis can such a mining development be successful.

Sales of copper from New York, the world's chief centre of distribution, are going up by leaps and bounds. Britain is the chief buyer. This speaks well, not only for the revival of industry in Britain, but for a revival of activity in copper mining. Copper sales on a large scale will lead rapidly to higher prices. The large copper deposits of Northern Manitoba will benefit ultimately, if not soon, from this movement.

A despatch from Calgary quotes Mr. S. E. Slipper of the Geological Survey in optimistic vein. Mr. Slipper has had a thorough experience in oil geology, and has a reputation for acumen and discretion. He is quoted as saying that a new oil well at Kevin, Montana, sixteen miles south of the international boundary, indicates possibilities on the Alberta side that surpass any known area in Western Canada. Unless Mr. Slipper has been misquoted, we have here a professional opinion to which serious attention can be accorded.

The value to a steel producer of a diversified production is well illustrated by the fortunes of the Steel Company of Canada during this trying time. Though rails and large sections are in small demand, the housewife cannot get along without tacks, nor the farmer without fence-wire; and there are several million such consumers of steel products throughout the Dominion. Probably the iron and steel works in Cape Breton (the nearest thing we have to an indigenous Canadian iron industry), which is now on the verge of closing down for lack of orders, will have provided for fabricating more of their raw product before the next stretch of hard times comes upon us.

W. Jett Lauck, one of the leaders of the United Mine Workers of America, is quoted as saying, "The United Mine Workers defy the country that wants deflation of wages!" Mr. Lauck seems to have the heart of a lion, and the confidence of a born leader. We wonder which battalion he headed in the great fight at Chateau Thierry.

The Port Arthur, Board of Trade have recently memorialised the Department of Mines, Ottawa, requesting that the unfinished magnetometric surveys of the iron ranges in that district be completed. This is both fitting and timely. For the sake of the slight amount of expense involved, we might well afford to learn more about these bodies of ore, of such immense potential value, and of special interest at present in view of the experiment at Babbitt, Minnesota.

Time was when a library was not a necessity—or seemingly not—to the mining man. That time has long passed away. A compact library of handbooks can be carried now without inconvenience. It is a painful mistake to be without these aids to proper work.

TO THE TUMP LINE.

O! Tump Line! Emblem of base servitude!
Symbol of suffering in the Northern wilds!
How oft hast thou upon my tortured frame
Inflicted pains and penance more than death.
How oft have I, weak victim, in thy toils
Felt all the anguish of the criminal hanged
Hanging were better—for a moment's pang
Ends all. Thy service is an endless chain
Of horrid hangings, pangs and frightful toil
How oft, I say, in stepping high and wide
To clear a cursed windfall in the trail,
Hast thou betrayed me, Tump Line, badly tied
And left me helpless as a split canoe?
Too often! Now do I forswear, abjure
The northern Wilds and all that they imply.

* * *

I've cursed thee, Tump Line and (what profits to repeat)
I've cursed thee in the blankest of blank verse.

VNON

A Five-Foot Shelf of Books for Mining Men.

(Written specially for the *Canadian Mining Journal.*)

THE fact that the mining engineer is called upon to travel a great deal and is often marooned for months at a time, far from libraries and bookshops, should not prevent him from keeping his mind in training. It does not debar him from using his tooth brush and razor. His mental requirements mean quite as much to him as the use of his toilet accessories.

No two persons can be counted upon to concur wholly in the choice of a "travelling" library. But the majority of those who have really used books will agree on at least five or ten. For this reason, I shall begin the list of what I consider an easily portable library with the titles of a few volumes that can be had in uniformly small size, and that appeal to all whose training has been based upon a knowledge—wide or limited—of geology. I purposely omit mention of certain invaluable modern engineering hand books, first, because they may be too bulky to carry; or, second, because the mining engineer would not be found dead without them.

The Geological Foot.

Turning to geology, then, I believe that for mental profit, the older authors are the best to read. My choice would be Sir Archibald Geikie—in one volume. In Geikie one gets pure diction, concise statement, logical arrangement—a very pithy and readable whole. Of course, the reader will see that I am not recommending Geikie as a book of reference, but as a stimulating volume that will furnish many an hour of pleasant thought, and will promote one's intellectual digestive processes.

In reading (not *studying*), and re-reading Geikie I suggest the use (at first very casually) of a note book, so that, at a later date in civilization, certain allusions may be looked up, and certain of Geikie's highly condensed paragraphs expanded into modern re-statements.

Naturally, there are a dozen—well, no, not a dozen, but perhaps four—other authors who might take Geikie's place. However, having chosen him, I would certainly choose Hugh Miller as his companion. "The Old Red Sandstone" will never lose its charm. Not alone is the reader refreshed, but he is also given the privilege of reading the simplest and best of English. So much, then, for geology.

As to Chemistry.

To the reading man who reads for both pleasure and profit, I would, five years ago, have commended Mendelejeff's "Principles of Chemistry,"—wonderfully original and complete volumes. Today, however, I would advise him to choose Molinari's "Inorganic Industrial Chemistry," a book that contains a wealth of reading, is modern, and most ably prepared. In Molinari one gets suggestive side-lights on mining and metallurgy and on the world's trade in products of mine and quarry. Both authors review the principles of chemistry in a way that only masters can attempt.

What of Mineralogy?

I know that Dana's "Text-book of Mineralogy" has no rival (although it has many supplements and complements) and that, for me, it never will have. But new phases of the study of mineralogy are being developed. Mineralography, the practical field determination of mineral entities by means of microchemical tests and the microscope, is one of these new phases. This may be taken as a suggestion worthy the attention of the searcher after more definitive methods than the unreliable (though honoured) blowpipe.

Prospecting.

From the time of Georgius Agricola downward, there have been published swarms of books and booklets on prospecting. Only the most recent have practical value. Many of these are convenient and suggestive pocket-books. One bulky and popular "Handbook" has a really invaluable section on prospecting. However, it is truer of prospecting than of any other part of mining, that the only way to learn is to prospect. I do not, therefore, make any specific recommendations in this department. What time is not devoted to our suppositious book-shelf can well be spent in compiling one's own notes. A mild hint I may throw out. Either Darwin's "Voyage of the Beagle" or an English mining engineer's record, "A Naturalist in Nicaragua", is an almost ideal model of records of daily observations.

Mining and What-not.

The literature of mining is too vast, and increases too rapidly to choose any of the hundred of good books available, as being more meritorious than others. Let me direct the reader to the catalogues of well-known publishing houses on both sides of the Atlantic.

* * *

There is yet much empty space on our five-foot shelf. Since it were invidious to pick and choose amongst the multitude of modern writers, let me draw attention to two volumes that will be a never-failing source of instruction, sheer joy, amusement, and edification.

One is a translation from Oriental writers and compilers, done into wonderful English at the express command of James the First of England. The other is a group of jewel-clusters, the handiwork of a simple English playwright who charmed the ear of the Virgin Queen of England in her declining years. Both works can be had cheaply and in convenient size. Neither is quite as popular as it deserves.

* * *

After all this talk about it and about, our shelf is not yet half filled.

Do not attribute it to indolence or indifference if I refuse to name another book until I am assured that you have read those mentioned above. And so, adieu.

CAPRICORN.

PERSONAL.

Major Gwyn Williams of London has returned to Toronto after visiting mining districts in Northern Ontario. He leaves this week for England.

Premier Norris of Manitoba is urging on Hon. Mr. King the return of the Province's natural resources and asking compensation for that part already alienated.

Mr. W. R. Wilson of Fernie, B.C., has been elected president of the Canadian Institute of Mining and Metallurgy.

The Modern Column Hoist

Its Construction and Use in Mine and Quarry Operation.

By F. A. McLEAN, Assoc. M. C. I. M. & M.

(Continued from page 152)

Some Applications of Column Hoists in Quarries.

At the Wetmore and Morse Granite Quarries in Vermont, two hoists of the Little Tugger type are used. One handles drill steel, powder, tools, etc., and the other is used for hauling the heavy cable from one of the derricks, across the quarry pit. (See Fig. 10.)

On one occasion, the swinging gear on one of the big derricks broke, and these little hoists were bolted to 2 inch planks and chained to a large rock, as shown in Fig. 9. Lines from the hoists were led to opposite sides of the bull wheel, one swinging the boom and the other bringing it back. This rig worked quite satisfactorily while the swinging engine was under repair and illustrates the value of these machines for emergency work.

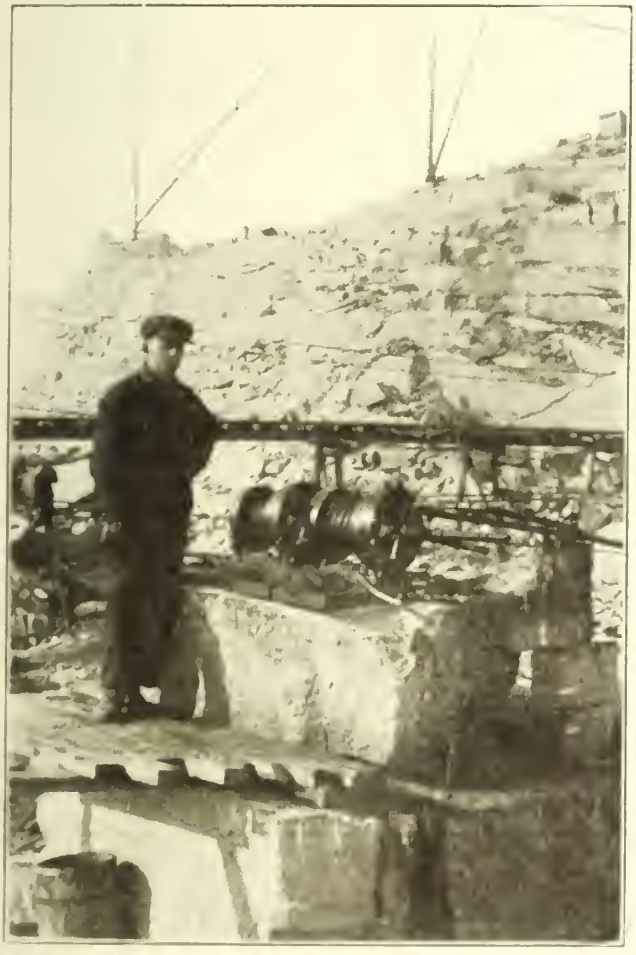

Fig. 9. — Two Hoists of the Little Tugger Type used for swinging a large derrick.

At the Rockland Lake Quarries, loaded cars are delivered by the locomotives to an inclined cableway, where they are hauled up into the crusher house and dumped directly into the crusher. From here they coast down an incline and up a slight grade toward the upper end of the quarry, where they are switched over and run by gravity, back parallel with the quarry face. It frequently happened that a car, or two cars would not carry past the switch, and to keep the cars in motion, a 1 H Little Tugger Hoist was bolted to a timber at the extreme end of the track and hauls two 6½ ton cars up this 6 per cent. grade without any trouble.

Tugger Slushing in Metal and Coal Mines.

Time studies show that one of the most promising fields for labor saving in the mine is in "mucking" which in metal mines is estimated to consume 35 to 45 per cent. of the total working time. For handling dirt on the surface in making excavations for buildings, roads, etc., the drag scraper or slusher is a very old arrangement, and various modifications of it have been

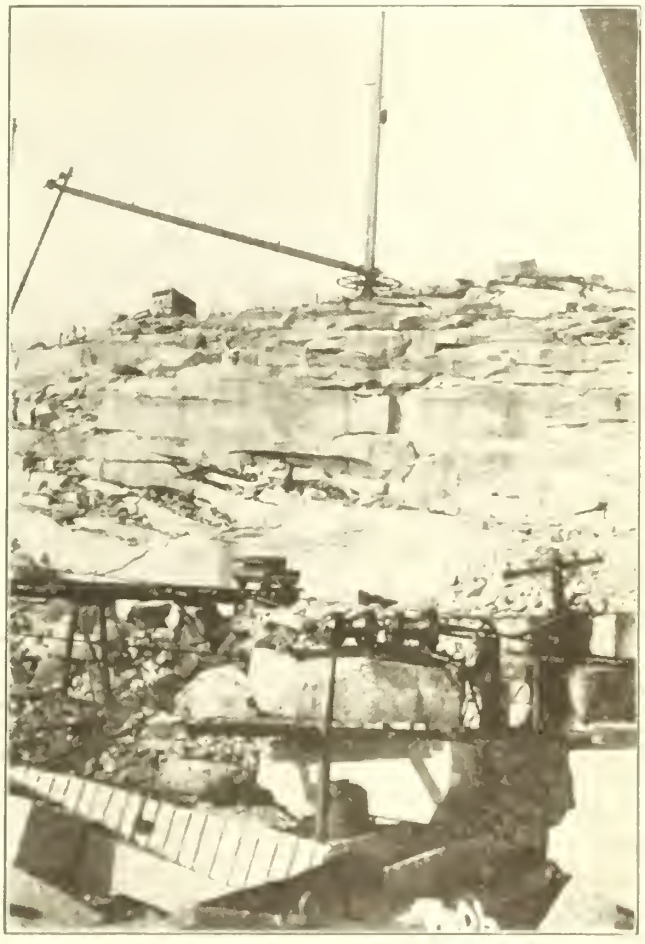

Fig. 10. — Tugger Hoists used for hoisting supplies and carrying derrick cable across quarry.

used underground for several years. The first requisite of a simple, underground scraper system in metal mines, is a small, portable, powerful, reversible and reasonably inexpensive hoist that can be set up anywhere, on a post, drill column, or sled and operated by anyone under all sorts of conditions.

Hoists of the Little Tugger type appear to have met these conditions satisfactorily and have led to the introduction of what may be termed "Tugger Slushing Systems", into coal and metal mines in various parts of the country.

Type of Scraper.

Some mines use a scraper similar to the ordinary road scraper—which is quite all right if the ground is broken finely or is of a sandy nature. Where the ground is chunky, a scraper made more nearly vertical

and with fingers of 20 pound rail on the bottom so that it will more easily dig into the broken rock, is better. In one mine in which the ore was very wet, a scraper formed of slats or bars to form a sort of rake, was used. It is a simple matter to make the scraper of such size and construction as will best suit the character of the material to be handled. As a rule two men—one on the hoist and the other on the scraper—are employed and change jobs at intervals.

The most common arrangement where there is no tail rope for hauling back the empty scraper, is to use a single hoist bolted to skids, as shown in Figures 11 and 12. In Figure 13 it will be noted that the hoist is mounted on a horizontal column bar, to permit the ore car being loaded to go underneath it. It is only the work of a few moments to alter the height of the hoist or move it from one location to another with this arrangement. In some mines, two hoists mounted on a single column are used so that the scraper can be hauled back by a tail rope; (Figs. 14 and 15) although it is questionable whether the use of a tail rope is of much

Fig. 11. — Mucking ore in a drift with a Little Tugger Hoist.

advantage where the haul is less than 50 feet, as the clutch on the hoist makes pulling the scraper back by hand a comparatively easy job on short hauls. When a straight pull from the breast to the raise in which the ore is dumped, or to the car to be loaded cannot be secured, a snatch block is used to make the turn, but should be avoided whenever possible.

Another slushing method used in a large Michigan Iron Mine, consists of a light channel iron supported by legs or drill columns and located near the top of the drift. This channel carries a sheave on its front end, an 1-H Little Tugger Hoist on its rear end, and a trolley between. Winding up the rope on the hoist drags the scraper into and up the pile of dirt, and when filled, it is run backward to a point over the tram car and dumped. It is then drawn back by hand to the digging position. In using this arrangement in hard ground, however, it was found that in case the nose of the scraper got under an immovable chunk the man on the handles was likely to go over the top and head into the breast. This particular method is therefore, only applicable to use with dirt that will break easily and without large chunks.

Fig. 12. — Mucking ore in a chute.

Tugger Slushing at the Spruce Mine.

The Spruce Mine at Eveleth, Minn., is a typical "soft ore" mine worked by the top slicing method and in places where the ground is strong enough to permit of putting in raises at fifty feet intervals or less, mucking is done by Tugger slushing—a 1-H Tugger is set convenient to a raise and a slusher attached to the rope. This slusher is a small edition of the ordinary contractor's drag scraper, 24" x 30" x 9" deep at the back and has a capacity of about 3 cu. ft. One man operates the Tugger, the other carries the scraper to the pile of broken ore, fills it and returns with it, easing the scraper around the timbers, corners, etc., and dumps the ore at the raise or car. At present cars are loaded by this means only on the level; in those sections where the mining has progressed down to the point where haulage level has become the sub or slice level; and where the timbers allow sufficient head room to dump the scraper.

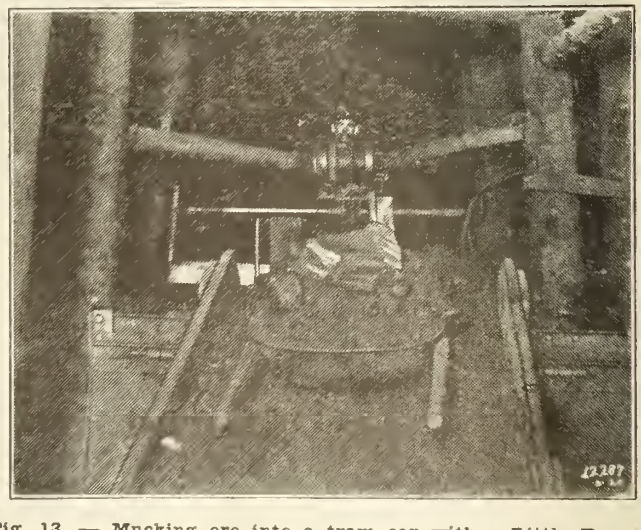

Fig. 13. — Mucking ore into a tram car with a Little Tugger Hoist.

Where they are mucking in the slices, about half of the work is straight hauling. The right angles are eased by blasting off the corners of the pillars but the man who operates the scraper has considerable work to do in keeping it from catching, and in places where it is necessary to turn a right angle a snatch block is placed at the corner and the scraper either hauled to the corner and dumped and the ore relayed in two operations or the rope removed from the snatch block and the haul continued. This depends on the men, and on the amount of ore to be handled. Beyond this no provision is made to protect the rope in the curving hauls, it being permitted to ride against the timbers, etc.

The cars are loaded by hauling the scraper up an inclined slide made of plank about ten feet long, one end of which is elevated slightly higher than the side of the car, the height of the timbers on the hauling

Fig. 14. — Two Tuggers mounted on one column for tail-rope slushing.

level permitting the dumping of the scraper. All car loading is straight hauling, the cars being brought to the opening from the crosscut and the Tugger set on a cross bar on the side opposite the chute. The Tugger is usually set directly behind the raise to which the ore is handled and generally remains in the same place for a week or more. In the haulage level where cars are filled, the machine must be moved as fast as the pillar is cut back and generally is shifted every three or four days. Where the mining is carried on under the rock capping it is not necessary to use so much timber and the machine may not be shifted for two weeks.

Mucking by hand ordinarily takes about 10 per cent. of the total working time. The slusher is in use about 25 per cent. of the total working time and is operating continuously for from 1½ to 5 hours depending entirely on the amount of ore broken. At times under the rock where there is little timbering to do, enough ore is blasted to keep the slusher at work the full shift. Depending on material (fine or chunky) and distance the men will handle from 8 to 12 tons an hour with the slusher, each trip of which brings about 500 lbs. of ore to the chute.

The Tuggers are mounted on a home made turn table arrangement which is fastened to a skidder truck and blocked down from the roof of the opening. In places where they are loading cars an auxiliary cone is bolted to the Tugger base and the Tugger placed on a stretcher bar on which is placed a regular column arm clamp, the whole arrangement being elevated high enough so that the rope clears the top of the car.

Air conditions are not very good in this mine due to use of under-size pipelines. Pressure at compressor is around 70 lbs. but not more than 58 to 62 lbs. at the hoist and running pressure ordinarily is 45 to 50 lbs. and sometimes as low as 36 lbs.

Hoist operating troubles are practically nil, it being estimated that the Tuggers used in this work average a year's service before going to the shop. If the machine is lubricated properly there is no trouble. In fact instances have occurred where the hoists have been buried under tons of rock and when dug out, started again without any repairs.

Cost of operation is rather hard to estimate, no figures being available, but electricity costs about 3.5 cts. per K.W.H. and considering that the machine is operating but half the time slushing and as the slusher is only hauled loaded by the hoist, it would appear that the cost for air is in the neighborhood of 25 cts. an hour. Contracts are set from 5 to 10 per cent. lower in Tugger than in shovel places.

When this work was first started it was rather hard to convert the men to the use of the slusher, but now they will ask for one whenever conditions warrant same.

Fig. 15. — Tugger slushing with tail-rope showing scraper and arrangement of snatch block.

The following figures show relative production in car and Tugger places:

Comparative Car and Shovel Operation—Spruce Mines Sept. and Oct. 1920.

	No. Contracts	Tons Mined	Shifts Worked.	Tons per man per day.
Tugger Slusher	11	17,092	1371	12.13
Shovelling by hand . .	21	783	2257	10.09
Increase Tugger over hand			2.31 or 13.10 p.c.	

Comparative Shovel and Incline Plane—Spruce Mine—August, 1920.

	No. Contracts	Tons Mined	Tons per Man per day
Tugger on Inclined Plane.	3	3555	12.65
Shovelling by hand . . .	3	2610	11.60
Increase Tugger over hand		1.05 or 9.05 p.c.	

In analyzing the above figures, it will be seen that they cover production of enough ore to make them worth something. The first statement covers handling ore to raises and adding to the increase in production the saving in track laying, and spreading the fixed overhead, the final cost figures would undoubtedly be more than 23 p.c. in favor of the Tugger method. The second comparison in the operation of loading cars does not show up so well for the reason that the air pressure was insufficient to haul the slusher up the incline with any speed and also that the first two sets of ground off the crossent had to be hand shoveled and the slusher really handled only about 60 per cent. of the production. However, taking the saving in track and timbering into consideration, there is certainly much more than 9 per cent difference in favor of the Tugger system.

Tugger Slushing in Buggy Mining.

At the Hollenbeck Colliery of the D. L. & W. at Wilkesbarre, Pa., they use buggies in a vein of coal about 1 to 5 ft. thick on a slope of some 18 per cent. and use 2 "Little Tuggers" to lower the buggy to the dump and return it to the breast, one hoist being mounted in "a break through" and serving two chambers. The buggy in dumping runs into an automatic dump provided with a trip which opens the front of the buggy, the coal then drops on to the floor of the entry and is loaded by hand into the mine cars.

The principal advantage of the Column Hoist and Scraper rig in places where buggies are now in use, is the elimination of the track and buggies in the chambers and the fact that the scraper can handle more than can be handled with shovel and car. The portability and low comparative cost of this method makes it possible to arrange the work so as to allow one machine to one or two chambers, sometimes giving three men two places to work and making the work more efficient by cutting out a lot of work changing rigging, etc., from one chamber to another.

Advantages of Tugger Slushing in General.

Obviously, the Tugger method can be used in places where it would be impossible to use a large loading machine and is more flexible. It simplifies the replacing of loaded cars with empties and in the sub-levels it dispenses with track laying entirely, if the raises are properly placed with reference to the slices. It can be worked in seams of any height, although more favorable to low-seam operations than high and is not affected by seams of moderate inclination.

The entire system is simple and economical to operate, easily shifted from place to place, and—in the event of falls of roof, little or no injury to the hoist can occur—as it is free from small exposed parts which might be bent or broken off.

AN OLD FRIEND REVIVING.

Once more the Lake of the Woods seems destined to hear stamps dropping, and, in addition, the roar of the ball mill. The old Laurentian, at Gold Rock, after being closed for almost a generation, is being unwatered. It has now become the property of the Kenbrooke Gold Reserve, Limited, whose head office is at Sherbrooke, Que. The mill buildings are said to be yet available, and the machinery in better case than had been anticipated.

It is understood that the company proposes to sink the main shaft another 500 feet; ball mills and cyanide vats are to be installed, and the whole mill modernised. A superintendent and crew of men are now working. The property consists of 216 acres, and the average value of ore blocked out in the mine is estimated at over $16 a ton. There is said to be a large tonnage.

When the Laurentian was running it was thought to have a future, and with modern milling methods and a more complete recovery than was possible by mere amalgamation the outlook should be better today.

Even more important, perhaps, than the re-opening of the Laurentian is the resumption of work on the Mikado, a mine that all Kenora believes to be without a peer in this region. There is thought to be a very large amount, perhaps $4 a ton, in the tailings heap, which would indicate that the recovery by amalgamation was not good. At any rate, the present summer will tell the tale, because so soon as the ice goes the workings will be de-watered and exploratory developmen begun. Provided ample capital is forthcoming and the best technical talent retained, the Mikado may quite possibly prove itself to be what so many claim it to be—an exceptionally good gold mine—Chas. A. Bramble.

INTERNATIONAL COAL AND COKE.

The annual report for 1921 of the International Coal and Coke Co., Limited, of Coleman, Alberta, just received, records a satisfactory year, in spite of hard times. A dividend of 4 per cent has been paid on the capital stock of $3,000,000, and the reserves are unimpaired. The report concludes thus:

"The policies adopted by your Company, after careful consideration, with a view to protecting it against the evil effects of such a period as at present, have proved effective, enabling us to look forward to the future with confidence.

"The physical condition of the mine is good, and the financial position of the Company sound."

Mr. O. E. S. Whiteside, the man in direct charge of the Company's mines, is to be congratulated on having successfully met a trying time.

News and Comments

By ALEXANDER GRAY.

PAKOWKI RESERVATION OIL CONCESSION.

P. Chester Thompson, erstwhile of Butte, Columbia, Venezuela, Wyoming, and meanwhile of Porcupine, is a lively bird of passage; so it is not surprising to hear that the Ottawa Government by Order-In-Council granted to him and his associates the rights over about 28,000 acres in the Pakowki Bird Reservation. It is unusual to have it so, and it is a reversal of Government policy to have it thus; but Mr. Thompson has the documents signed, sealed and delivered, and preparations are being made for an immediate test of the Sweet Grass Arch, as it is termed, in Southern Alberta. Nominally the acreage is held by the Sanctuary Oil Company, Mr. Thompson taking his cue from Pakowki Lake, the Bird Sanctuary. Actually, title is vested in the Royal Canadian Oil Syndicate, which will conduct operations. If the gas done in evidence, and other structural features confirm the optimism of the organizations interested then the Prairie Provinces will have made a real start in bulk production. This Pakowki Bird Reserve has possibilities. What drilling was done to the northwest of it—the Foremost Well for example—was disappointing. Because the area dealt with by the Hon. Mr. Stewart and the Government was a preserve, or had been, previous governments were loath to grant concessions. Mr. Stewart, unlike his predecessor, took the position that the ground is worth proving, and his stipulation is that drilling must proceed promptly, a bond of $15,000 being exacted for performance under the agreement. The 44½ sections are sufficient for extensive exploration, provided a measure of success is met with in the initial drilling. Each section has to be tested. If the first section yields oil, the Royal Sanctuary people take it at 50c an acre and the usual royalty of 2½ per cent. for the first five years, 5 and 10 per cent. thereafter. When the first well is finished, two others have to be drilled, and then, if the venture succeeds, the Government and Thompson interests share fifty fifty. P. Chester Thompson and Jack Reynolds have placed the bet. Now let them roll.

MANDY MINE RETURNS INVESTMENT.

It is to be noted that the Tonopah Mining Company did not fare so ill from its Mandy Mine venture. The mine, it is announced, has been "stripped of it's profitable commercial ore." What remains that might be disposed of were transportation facilities otherwise, is not stated. However, liquidation of the various assets, principally Canadian bonds, enabled the parent company that financed the Mandy enterprise to the extent of $248,938, to recover the amount and a "plus" worth $89,000. The details of Mandy operations are

	1921	1920
Working capital	$536,513	$188,581
78.6 p.c. to Tonopah Mining Co	121,500	118,000
Mine owes Tonopah Mining Co		248,938

GOLDALE AND HOLTYREX

Contact conditions in the Pearl Lake Section of Porcupine are receiving more attention since the Nipissing Company drilled the Rochester Veteran claim and got what pioneer holders of the ground did not find because the geological features had not been accurately defined. Location of the contact and the subsequent drilling seem to have started another mine where it was to be had for thirteen years.

The Pearl Lake Company ground merged in the McIntyre was the victim of mismanagement. It had a contact, and a lot of drilling and development work were done; there was a lively speculation in the shares, but claims of tonnage and values were not sustained; hence liquidation. Presence of the contact of the greenstone schist and porphyry was not conceded due importance.

What happened in this immediate vicinity, the gold output of the McIntyre Company has placed beyond dispute. Not only in the McIntyre ground but also in the Jupiter, the "Pearly Schist" bugaboo lost its significance. For years it was assumed by the Jupiter management of the time, that the contact ran through the centre of the property, or thereabout. The Jupiter management fatuously avoided the western end of the property, notwithstanding which it has transpired that ore bodies exist there, which now are yielding a considerable tonnage.

In connection with this, the latest McIntyre report had a map showing a plan of the lower levels and contacts which lend speculative interest to properties to the immediate east and northeast, notably the Plenaurum and Holtyrex. Though the McIntyre map is presumed to correctly represent the underground contact conditions down to the lowest levels as they were a year ago, it has occasioned no public comment that the contact swings around to the northeast toward the Holtyrex. This gives a status unthought of heretofore, to a section that has lain fallow. If, as is declared, they have located outcrops of prophyry-schist there, it may mean the existence of the coveted contact. Mineralized schist over a width of about 96 feet is reported, consequently the diamond drill core obtained by Captain Anchor about 300 feet East of the Holtyrex boundary may have more significance than was attributed to it at the time. At any rate the area has come under careful consideration.

More immediately important is the alignment of the Kerr Lake Lewisohn interests with the Goldale Company areas formerly held by Bewick Moreing. Some of these areas are close to the McIntyre Holtyrex on the northwest, and the Plenaurum-Platt on the east. General Manager Kee, it is understood, will have charge of the Goldale work, which means that it will be thorough. The Goldale property on the eastern axis of Pearl Lake was drilled a year or two ago and the results were said to be encouraging.

"A MINE" BUT!

"While this is a mine, and therefore not what we would consider the highest class of investment," writes a reputable Montreal private banking firm, yet the Asbestos Corporation balance sheet "is well worth while," and investors should "look into it."

Mining scientists and capitalists acknowledge this as among the "small favors thankfully received." Asbestos Corporation, with all due respect to the bankers, is not "a mine." It is the chief factor in the [illegible]

tee industry and possesses a series of mines. At those mines there are known assets, just as there are timber limits and pulpwood assets, and fields that ensure the operations of our flour mills. Neither is inexhaustible. All are dependent upon markets. Enough drilling has been done by the Asbestos Corporation, and enough ore was been disclosed to provide a stronger Rest Account than some banks have had of late.

MINING "BOOMS" BEING GROOMED.

Montreal, like the familiar infant that "won't be happy" until it has a certain brand of soap, has clamored for the revival of the local Mining Exchange, which will at least give the unemployed of the previous organization of this sort a livelihood, even if it leaves the venturesome section of the public without their petty cash. Formerly the Montreal Exchange traded in whatever came along, "and no questions asked". A list of the "securities" of those days looks like a deserted graveyard. My fyles contain what resembles a roster of slain. So keen was the competition, the crudest of bucket shops could not exist unless it went "into the mining game." When there was nothing to be gained by sending the bucket to the public well, mining brokers had to devise other means. If it was not oil, it was anything that could be dressed up. The example set by international curbsters was availed of, and the recent crusade in the States and here induced a goodly number (though not quite enough) to emulate the Arab and quietly fold their tents.

Nor are Montreal, New York and Toronto to have a monopoly of the mining business. London is not overlooking developments, hence this gratuitous gibe appearing in The Daily Mail:

"While there is hope for the employment of British capital in developing Canada's mineral resources, it cannot be said that British investors have fared at all well with Canadian mining ventures in the past, and caution is as necessary as ever. Several Canadian gold mining flotations are being prepared for submission to British investors, and we hear of people being circularized in vague terms to arouse interest."

There is a large and unpalatable mouthful of truth in this comment. London is receptive toward Canadian mineral resources, but London has yet to convince those deeply concerned with constructive Canadian enterprises that it is any more circumspect than other centres. Of late there has been abundant evidence of this. Propositions have been entertained over there that the fully-informed on this side would not accept. Of all the London undertakings at Cobalt, but one, the Trethewey, brought any satisfaction, and it was managed by long-distance until the Watsons pulled it out of the mire. Further back, London took on the Lorrain and other sad ventures. When Porcupine was discovered, the experience with London was not flattering to its honesty of purpose or to its technical efficiency. It is better to be frank about this. Overseas mining financiers shagged their shoulders or sought a quick profit. London's failure to participate in Hollinger was excused hurriedly. London took a bit of Rea, and an eruption. London had the Scottish-Ontario, and was nauseated next morning. The McIntyre was proffered and rejected. London compromised on The North Thompson. Dr. Simon was commissioned to come all the way to inspect the work on the Feldon ground in the "lemon belt." "England's Premier," located in the Moose Mountain locality on the Montreal river, was really "England's Dernier," in that quarter.

No one on this side was deceived by these happenings. London can be incorrigible, without any assistance from Canada. Now that Kirkland Lake is showing its real values, it would be positively unkind to revert in detail to London's acquiescence in an unfortunate episode. Nor was the Daily Mail exempt from culpability in that case.

By all means, let there be caution. That will encourage the real capital Canada seeks, not for "turnover," but rather for the potential mines, which deserve more than transient interest.

CANADIAN OIL OUTLOOK.

Elder Statesmen at Ottawa have extended leave in the matter of their investigation of the New Brunswick Oil Shales. Like Tennyson's brook they are going on forever, though why those shales should be in suspense when the Anglo-Persian people have been testing them for years and others have held a blanket concession over them for ever so long, is unexplained. At present there is an over-production of oil, and by-products are hard to sell. Perhaps this explains the senate's action. Maybe a special consideration for those that will work the shales, will be in order. The area certainly has been fully proven and the terms of the grants are not at all onerous; but if it takes so long for the Honorable Senators to report on the shale, how long long will it be until a thought is given to the situation in the Canadian West and Northwest?

International oil corporations are contesting for a slice of Persia and Mesopotamia. They have acquired millions of acres in Columbia and Peru. Venezuela is being investigated. Rumania has been parcelled out. Only the Imperial Oil Company and one other, a stray lot of capital, have made earnest efforts to find productive wells in Canada. Although the daily average production in the United States is greater than ever, as well as the imports and although the price of crude makes the existence of the small fry precarious, American oil interests are taking on territory wherever there are prospects. The only manifestation of activity in the Dominion is that of the Imperial company and the Senate's Commission referred to, unless it be by the promoters of the Lake Pakowki concession in Southern Alberta. These latter contract to drill wells on a partnership basis, after a first section has yielded oil. To that extent there is a possibility of something being done to supplement the extensive work patriotically prosecuted by the Imperial company. Beyond that, Ottawa has not moved, and the years are passing since the Fort Norman prodigy came in. The Pakowki arrangement is a precedent indicating an intelligent attempt on the part of the Minister of the Interior to remove restrictions and give speculative capital a chance to make some money for both parties. A similar plan two years ago, entered into by the Government and influential, oil-operating corporations, would have cleared the atmosphere instead of leaving it more beclouded.

Asbestos mining is considered to be one of the coming industries of South Africa. The asbestos occurs in a belt of hills, known as the Asbestos Mountains, extending roughly from Prieska to a little north of Kurumon. Little development work has been done as yet, due to lack of cheap power.

British Columbia Letter

MINING men in the West are on their toes in anticipation of the early opening of navigation in the Yukon and Alaska, as well as in the active camps of northern British Columbia. The annual flow of prospectors and operators who have been wintering in Vancouver, Victoria, and Seattle, has started northward. Outbound steamers are crowded already and the bookings on Canadian, as well as on American ships scheduled to leave during the next few weeks have been so brisk as to put accommodation at a premium.

While Atlin, Dease Lake, Alice Arm and other well-known and long popular districts are attracting their quotas, most of the travelers are *en route* either to the Portland Canal region or to the Mayo Camp. Up to the present the majority favor the latter section. The rush to that famous silver producing camp close to Dawson City has started early through a desire to get in over the snow, for when the break comes it will be some time before the roads or trails are in good condition.

Good Reports from Mayo.

Meanwhile the reports from Mayo continue to be favorable. It is said that new strikes have been made on Keno Hill and that high grade veins have been opened on the Croesus, Crystal Gulch, Gambler Gulch, Slate Creek and Stone Claims. The Slate Creek company is opening up a vein five feet wide of steel galena at a depth of sixty-five feet. The Yukon Gold Company is shipping three thousand tons of ore from vein number nine on the Rico Claim. At a depth of three hundred feet the ore is reported to be richer than nearer the surface. On the Sadie claim the Treadwell people have two shafts down about a hundred feet. This company has several million tons of ore blocked out on the McQuest—Cenelop Group. The vein on this property is said to measure three feet in width and to carry ore averaging from two to five hundred ounces of silver to the ton.

Construction of a new steamer at Mayo has been started by the White Pass & Yukon Railway Company to handle the business of the Camp.

The judicial committee of the Privy Council has refused the application of Anna Theresa Boyle to two placer mining claims on the Klondike River, thus sustaining the decision of a Dawson Mining Recorder. This ends litigation that has been carried from court to court for several years. Some valuable gold property, as a result of the judgment will go to the Canadian Klondike Company Ltd.

The Del Ecuador Mines Company, with a considerable block of leases in the Cedar Creek Section of the Cariboo, is reported to be making arrangements for putting a dredge on the ground this year.

Joseph Tretheway, who recently bonded the discovery claims, Iron Creek, Taseko (Whitewater) River Lillooet District, is reported to have shipped a diamond drill outfit to Williams Lake by the Pacific Great Eastern Ry. Thence it will be taken across ice and snow by way of Hanceville into the Whitewater and set up ready for work as soon as weather permits. With this equipment it is proposed to thoroughly prospect the telluride formation reported to be rich in gold. It is as a result of the accounts of recoveries made from this property by a miner named Taylor last summer that so much interest is being taken by prospectors in this region.

On Cherry Creek, a placer and quartz gold mining district near Kamloops, a Seattle syndicate has staked a number of claims and already has a crew of men on the ground. Placer ground, it is said, is to be opened up by means of hydraulicking while some lode prospects are to be explored by diamond drill.

There is activity of a similar character on Shorts Creek, west shore of Okanagan Lake. In this case, however, interest is being manifested exclusively in the placer possibilities.

It is reported that a Keystone Drill will be put to work on the Prince of Wales Mining Company's leases, Horsefly Creek, this summer.

The Indian Mines Ltd. and adjacent claims, situated in the Salmon River Valley, Portland Canal, have been acquired by G. D. B. Turner and associates. This property is northwest of the Premier Mining Company. The work so far done shows a vein from 6 to 11 ft. wide with fair gold and silver values, and in places considerable galena. The latter is uniformly low in silver. The camp is well established and development will start as soon as the season opens.

H. S. Munroe, general manager of the Granby Consolidated Mining, Smelting & Power Co. Ltd., has returned to Anyox after a trip to California. He announces that it is the intention to build a short railway to the site of the dam which the Company is to construct in order to assure a constant and ample supply of water for purposes of operation. Recent heavy rains have improved the situation in the district of the Hidden Creek Mine and the Anyox smelter. For a week the work was seriously interfered with because of lack of water.

Shipments to the Trail Smelter of the Canadian Consolidated Mining & Smelting Co. totalled 10,131 tons during the first week of March. Of this 3,805 came from the Arlington, 21 from the Ottawa, 10 from the Paradise, 33 from the Lucky Jim and the remainder from mines of the company. The year's receipts total at about 71,824 tons.

Col. R. H. Palmer, chief forest [illegible] in southern Alberta, recently made some observations concerning present conditions at Crowsnest Gold [illegible] prospected for oil. It [illegible] commercial oil [illegible] and will spread north to the Fort Norman field. At present there are [illegible] at Pine Coulee and the possibilities are great but whether the results to date can be considered satisfactory or otherwise cannot be ascertained. The [illegible] little, although it is established that there has been a strong outflow of oil at the [illegible] done is sufficient encouragement to warrant the continuance of operations by the company. Col. Palmer said that a new [illegible]

some have been drilled in the Pouce Coupe district. It was found that several parties have been holding leases, paying taxes on them, but not developing. As this was to no real purpose "community" wells were drilled, the cost to be paid by the various leaseholders in lieu of taxes and each possessing a proportionate interest in the well. The plan seemed to be working satisfactorily.

Pacific Coal Trade Light.

The coal business of Vancouver Island has been suffering by season of the strike of Chinese seamen at Hong Kong. Most of the Canadian Pacific Steamship Company's ocean liners were tied up at Oriental ports for weeks unable to get away because of the refusal of these men to go to work. Consequentely there has been little or no bunker trade. In fact it is stated that during February not one large ship took on coal at the bunkers of the Canadian Collieries (D) Ltd. and that the same condition continued until within a few days ago, the 14th March.

The slackness of this branch of the coal business, however, is not altogether accounted for by the strike. It is noted that recently vessels bound from the Orient to America have not carried full cargoes. In order to fill unoccupied space, and for the purpose of so trimming the ship as to secure the most satisfactory sea-going qualities, coal has been taken on in the East. This has happened more than once and again the Canadian operators have found their usual market cut from under their feet.

The domestic trade has been steady. The winter in the Pacific Northwest has been longer and colder than is customary and the demand for fuel has been well sustained. Consequently the mines, although not working to capacity by any means, have been kept in operation.

Labor Dispute in Western Coalfields.

Unless something intervenes, of which there is no present indication, the operators and the coal miners of District 18 (Province of Alberta and Eastern British Columbia) will be joined in industrial battle on the 1st of April next. On that date the existing agreement expires. The employers are asking the men to accept substantial reductions in wages and a general rearrangement of the understanding that now exists. The United Mine Workers of America have refused to consider the proposals. The Western Canada Coal Operators' Association a few days ago made the announcement that all negotiations have been broken off. Robert Livett, international board member of the U. M. W. of A. has said that "everything now is up in the air." From the Crow's Nest Pass the word received is to the effect that nothing is being done to bring together the two parties to the issue. The operators of District 18 appear to be prepared to close down the mines and the miners seem determined to strike rather than to accept the changes. A bitter struggle is anticipated.

Dr. J. D. MacKenzie, head of the British Columbia Branch of the Canadian Geological Survey, is in Ottawa, to confer with Dr. Charles Camsell, Deputy Minister of Mines, Ottawa, and other officials regarding the plans of the Canadian Geological Survey for field work in this Province during the coming summer. He has also attended the annual meeting of the Canadian Institute of Mining & Metallurgy.

H. S. Munroe, General Manager of the Granby Consolidated Mining & Smelting Company, Ltd., has left on a visit to California.

A. M. Haor of Seattle, Wash, who bonded the Bear and Wolf groups on Maroon Mountain near Kitsumgallum Lake is adding two more Ross Mills to the one installed last year, the one mill being found insufficient to deal with the quantity of ore that has been developed.

Fred A. Starkey, a leading British Columbia delegate to the International Mining Convention at Spokane, states that the meeting was very successful, that its educational features were noteworthy and that it afforded the opportunity to renew acquaintanee with representatives of the mining industry of the Northwest. The mineral exhibit from the Kootenays attraeted much attention.

DELORO SMELTING AND REFINING CO.

The branch office of the Deloro Smelting and Refining Company, Ltd., of Deloro, Ontario, which has been in Toronto since the inception of the enterprise in charge of Mr. Thomas Southworth, Managing Director of the company, has been removed to Ottawa, and is now located in the Bank of Nova Scotia Building, 114 Wellington Street. Hon. M. J. O'Brien is President and Mr. J. A. O'Brien, Vice-President of the Deloro Company, and the removal of the Managing Director and branch office from Toronto to Ottawa consolidates control with the head office of M. J. O'Brien, Limited.

OBITUARY.

Henry Cecil.

The tragic death of Mr. Henry Cecil, who for some years has been a well-known figure in Northern Ontario mining, is announced in the Toronto papers. Mr. Cecil was killed in a hotel-elevator accident at the King Edward Hotel, Toronto. The operator of the elevator is being held under heavy bail. Mr. Ceeil, formerly an Australian mine operator, was one of the most active and picturesque of all Northern Ontario's mining promoters. He possessed, in rare degree, the initiative and courage of the older type of mining adventurer. Long experience in Australia and other countries had qualified him for the part he played in Ontario. Of late years he had made Barrie, Ont., his home. The Canadian Mining Journal proffers its sympathy to Mr. Cecil's widow.

Philip Argall.

The death occured in Denver on March 19th., of Philip Argall, mining engineer and metallurgist.

The late Philip Argall was a native of Belfast, Ireland. Coming to the United States in the year 1887, he established the firm of Philip Argall and Sons. His contributions to technical literature were numerous and greatly valued. He was a member of the leading professional bodies of Great Britain and America. As a keen analyst of metallurgical processes, he attained a great deal of prominence.

The News of Mining

The situation as regards labour in Canada is improving steadily. Official reports issued by the Department of Labour, Ottawa, show that amelioration set in as early as February of this year.

The work of Mineral Separation, Limited, England, in adapting froth flotation to the cleaning of coal has met with considerable success. Granular coals seem more amenable to this treatment than do coals in a finely ground condition.

Ducktown, Georgia, farmers within the area affected by fumes from the plant of the Ducktown Sulphur, Copper and Iron Co., have come to an agreement with that company whereby the latter agrees to permit the escape of gases containing not more than 40 tons of sulphur per day.

In the year 1915 the Government of New Brunswick introduced a portable limestone pulverizer to demonstrate to their farmer constituents the use of limestone as a fertilizer. Last year, working in conjunction with the railway authorities, the Government was instrumental in installing at Brookville, a modern crushing, pulverizing, screening and sacking mill. The machinery was supplied by the Sturtevant Mill Company, Boston. During the year, pulverized limestone to the amount of 6,666 tons was supplied to farmers at very moderate cost.

The Canadian coal miner is not a hardly-used worker. Last year the average daily (8-hour) earnings of contract miners in Nova Scotia were $6.66. Twenty-one years ago the corresponding figure was $2.27 per day. In Alberta and British Columbia the figures last year were higher than in the east, being respectively $9.57 and $8.34 per day.

Occupation of the Baku oil region by Bolshevik forces occurred a second time during April, 1920. The oil industry was then nationalized. Since then production per employee and drilling average per man have steadily fallen. At last reports monthly production amounted to about half of that reported five years ago. Labour efficiency has lessened to from one-third to one-quarter its former standard.

The Norwegian Government is seeking to introduce legislation establishing compulsory arbitration in labour disputes.

The Johannesburg strikers (or insurgents) have cost the citizens of the Union more per capita than the great coal strike cost the citizens of Great Britain per capita. Wages were higher on the Rand before the strike than in any other part of the world.

The president of the United Mine Workers announced on March 20th that approximately 600,000 bituminous and anthracite coal miners would be called out on strike in the United States and Canada on April 1st. It is not yet known if the coal miners of Nova Scotia will join the strikers. U.M.W. officials assert that 600,000 miners will respond, and that 1,500,000 workers in other industries will be affected by the shut-down.

To prepare for the strike of coal miners, which is announced for April 1st., Canadian consumers are negotiating for supplies from Great Britain.

In the coal mining regions of North Wales, there are still large numbers of unemployed. In South Wales conditions are favourable, especially in the steam coal trade.

Sir John Cadman, president of the Institution of Mining Engineers of Great Britain, recently emphatically denied that the British Government is engaged in the oil business, or that it is discriminating against United States citizens, or that it is attempting to monopolize the petroleum resources of the world. This should "lay" a number of ghosts.

Competent authorities agree that the market for copper is gaining strength constantly and will become normal sooner than might have been expected a short time ago. Domestic consumption in the United States now exceeds 90 per cent of the maximum pre-war years.

Recent official estimates state that of the iron ore resources of Europe, France controls 35.2 per cent.; the United Kingdom, 18.2 per cent.; Sweden, 12.5 per cent.; and Germany, 11.1 per cent. The estimates include "known," "probable" and "possible" ore. Of the "known" ore, France now possesses nearly 50 per cent. The present situation marks one of the most radical changes wrought by the war.

The output of iron ore, per man per year, is extraordinarily high in the United States, reaching the figure of 590 tons. In Europe, the Swedish miner holds highest position, with 395 tons per year to his credit; whilst Germany is lowest, with only 92 tons per year as the miner's average production.

The Government of Western Australia has for a number of years operated "State Batteries" for the benefit of deserving mine owners. During the year 1920, the gold ore milled amounted to nearly 40,000 tons. The loss in milling (including rebates allowed to owners under the Development of Mining Vote) averaged somewhat more than $1.00 per ton of ore. Including slimes, tin ore, and scheelite, 73,300 tons were handled at a cost of less than $3.00 per ton.

In Germany there has been developed a method of producing crude sulphur from gypsum and anhydrite. The first step is the reduction of these minerals to calcium sulphide. The sulphide is then disintegrated with magnesium chloride lye to form sulphuretted hydrogen, which, in turn, is converted into sulphur by burning. About 60 per cent. of the available sulphur is recovered. It is expected that this recovery will soon be materially increased.

Under French administration, the collieries of the Saar valley have been brought up almost to the pre-war maximum production.

Great Britain supplied Holland with 1,767,000 tons of coal during 1921. Germany and Belgium supplied, each, about 1,275,000 tons; the United States, 497,000; and Canada, 56,473 tons. From far South Africa came 10,800 tons.

Coal miners' working hours are gradually being standardized throughout Europe. In Spain a 7-hour shift obtains. In Poland the working shift is 8 hours, bank to bank. Here, however, the law was suspended by mutual agreement between employers and men, and a 10-hour shift was adopted for two years.

CONTRACT PRICES AT HOLLINGER.

At the Hollinger mine all development work is contracted. The price paid ranges from $10.50 per foot in the main drifts to $8.50 per foot in some of the crosscuts. All crosscuts are 8 ft. 6 in. high and 7 ft. wide. The contract price covers drilling, mucking and explosives. Explosives are charged at a fixed price of 16 cents for 1¼ in. stick 50 per cent and 14 cents for 40 per cent. The powder used on each drift by the blasting crew is posted each day so that the miners can check their expenses. A development crew consists of four men — two men drill a round in the afternoon shift and two clean out the drift in the morning shift.

Drifting is also done on contract at $9 per foot of advance of 6 ft. wide and $1.10 per ton for extra slashing. The taking down of backs to 17 ft. height is contracted at 85 cents per ton.

Diamond drilling is done by contract at prices from 80 cents to $1.10 per foot depending upon nature of the rock and percentage of core recovered. During 1921 the average paid was $1.04 per foot, and core recovery was 88 per cent.

JUDICIAL SALE OF MINING PROPERTIES, PLANT AND EQUIPMENT.

IN THE SUPREME COURT OF ONTARIO.

IN THE MATTER OF PREMIER LANGMUIR MINES, LIMITED; AND IN THE MATTER OF THE WINDING-UP ACT AND THE AMENDMENTS THERETO.

Pursuant to the order for sale made herein, dated the 28th day of February 1922, there will be sold by public auction by the Liquidator, with the approbation of H. S. Blackburn, Esquire, Local Master of this Court at London, at his Chambers at the County Buildings, Dundas and Ridout Streets, London, Ontario, on Monday the 1st day of May 1922, at the hour of 3 o'clock in the afternoon, the following lands, buildings, mining plant and equipment, namely: those certain parcels of land situate in the Township of Langmuir in the District of Temiskaming (Ontario) and numbered 39, 40, 41, 42, 43, 44, and 4373 in the Register for the District of Temiskaming, containing two hundred and fifty-five acres more or less and being the mining properties formerly owned and operated by Premier Langmuir Mines Limited as a barytes property; together with the buildings, mining plant and equipment now on the said mining properties and heretofore used in connection therewith.

On the said lands are situate the following buildings: Mill Building, Engine House and Boiler House, Blacksmith's Shop, Superintendent's Office, Shaft House — all of which are protected by asbestos sheeting — Office, Storage Building, Bunk Houses with beds and bedding, Dining Camp with ordinary equipment and a stable. The Mill Building is equipped with the following machinery: Crusher, Dryer, Jiggs, Pulverizer and necessary shafting and pulleys. The Engine House is equipped with a Goldie-McCulloch Engine, 150 h.p. and the Boiler House contains a boiler of 125 h.p., a hoist and other equipment. There is an electric light and power plant, a tramway from the mine to the water, two horses and harness.

There are on the property about 125 feet of shaft work and about 250 feet of tunnelling and drifting.

The Liquidator has a letter from the Provincial Geologist, Ontario Department of Mines, stating that "the veins are strong and well defined and there is a large quantity of barytes in the deposits". There are showings of native silver and argentite in some of the veins. Photographs and descriptions are contained in some of the Government mining reports.

The lands are situate in the Township of Langmuir in the Porcupine Mining Division and are on the Night Hawk River about 30 miles from Connaught Station on the T. & N. O. Ry. and about 30 miles south east of Porcupine.

The property will be sold in one parcel.

Ten per cent. of the purchase money is to be paid down on the day of sale and the balance, over and above the amount which may be found to be secured by a mortgage on the said lands to secure a bond issue (which mortgage the purchaser is to assume), to be paid within thirty days after the sale or as soon thereafter as the amount of the mortgage is ascertained.

In the event of the amount of the mortgage not being ascertained within thirty days after the sale the purchaser shall, if required, pay such additional sum on account of the purchase money as may be fixed by the said local Master, having regard to the probable amount which may be found to be secured by the said mortgage, and upon such payment the purchaser shall be entitled to possession. Any balance remaining unpaid after the amount of the said mortgage is ascertained shall be paid forthwith thereafter.

The purchaser is to search the title at his own expense and fifteen days from the day of sale shall be allowed for that purpose and if any objection to or requisition on title is made within that time which the vendor is unable or unwilling to answer or remove the contract shall cease and the deposit money will be returned to the purchaser without interest. The vendor is not to be bound to furnish or produce any abstract of title or any proof or evidence of title other than those in his own possession.

In all other respects the terms and conditions of sale will be the standing conditions of The Supreme Court of Ontario.

Further particulars can be had from F. W. Raymond, Esquire, Liquidator of Premier Langmuir Mines, Limited, London, Ontario, and from Ivey, Elliott & Ivey, Esquires, London, Ontario, Solicitors, for the Liquidator.

Dated at London this 13th day of March, 1922.

H. S. BLACKBURN, Local Master, Middlesex.

EDITORIAL

CANADA'S COAL

THE modern colliery is the embodiment of a closely-run commercial enterprise. Net profits per ton of coal sold are small. Labour is the chief item of cost. Administration and other overload charges are relatively and absolutely small. Payment of interest on capital investment and of reasonable dividends is necessary to the continuance of all industries. Coal must be marketed in the face of strong competition.

Strange as it may seem, coal miners do not grasp the fact that, when they stop producing, they are piling up liabilities against the colliery, and thereby automatically reducing the chance of bettering their own condition. Every dollar of debt loaded on the back of the mine by this, as well as by other means, must be paid back through the agency of coal brought up from the mine.

Trite and axiomatic this proposition may be; yet it has not yet been borne in on the consciousness of the coal miners, whose lot, by the same token, is rather to be envied than pitied.

It is pitiful, it is amazing, that in these days when the machinery of the law will give him the fairest of fair play (for there is always a preponderance of sympathy for the employee as compared with the employer), the miner should deliberately choose to impose suffering, loss and privation upon the whole community. He seems to think—or to believe that he thinks—that by dislocating trade, causing large losses directly and huge losses indirectly to his own fellows and to the country at large, he can advance his personal interests.

We sincerely hope that the coal miners of Canada will **not** join hands with the strikers on the other side of the international boundary. There is, at date of writing, some reason to believe that they will not. By remaining at work they will do themselves infinitely more good than they could by any other means. The only disappointed persons will be those parasites that depend for their livelihood upon their ability to arouse class hatred.

PERSISTENCE OF ORE AT DEPTH

PRESIDENT TIMMINS' statement that the Hollinger plans have been made "in the belief that we should have ore at 3,000 ft." and that "after nine and a half years of operations we have seen no reason to change our opinion," should help the people of Ontario to appreciate more fully what opportunities there are for building up a great gold mining industry in the Province. When the Timmins-McMartin-Dunlap syndicate agreed to pay $330,000 to Ben Hollinger and his associates for the properties, they had no means of determining definitely the value of the property. There was some good ore exposed at the surface, but most of it was not rich, and there was no chance of shipping out a few carloads of high grade ore to pay for the property as was done at Cobalt. There were those who were convinced that the ore would not persist with depth. It was no place for pessimists. The men that made the Hollinger ventured a large sum of money, and the results show that the optimistic view was the correct one.

We are of the opinion that the possibility of making deep mines in Ontario has long been underestimated, and that even now, it is not yet sufficiently well-recognized. The success of Mr. Timmins and his associates was largely due to the fact that they would not believe that the chance section of the veins exposed by weathering and glacial action belied the character of the ore deposit. So much rot has been circulated about surface enrichment of ore deposits that there has been for years in Ontario an unwillingness to believe that the ore at surface has not been enriched in some way. This belief doubtless delayed development of many ore deposits, for where there is lack of faith there is lack of funds to develop mines. The results at Porcupine and Kirkland Lake have been enlightening and will have their effect on future operations.

In our view there is just as good a chance of Ontario gold deposits continuing to great depths as there is in the case of the Michigan copper and iron deposits, in spite of the sedimentary origin of the latter ore bearing beds. Individual ore shoots will terminate, and unfavourable geological conditions will in some cases reduce the value of the gold bearing zone to unprofitable dimensions; but the old fiction about surface enrichment can be safely discarded. It arose from close study by able men in districts that are quite different geologically from those of Northern Ontario. It is a safe guide in certain mining areas, but it has no place here. Such a belief in it is not in accordance with the facts disclosed by mining operations in Ontario, and can only result in underestimation of our mineral resources. We need more optimists like the members of the Timmins syndicate, not because they are optimists, but because their confidence in the persistence of such ore deposits in depth is a logical deduction from observed facts.

ENERGY.

NATURE has been rather indiscriminate in scattering her blessings over Central Canada. Particularly is this so in her provision of energy available for man's uses. Economists, practical and theoretical, are now hard at work studying the means of making our surplus of electric energy, available from waterpowers, supply the deficiency of heat energy, due to the lack of coal deposits. This is a highly important problem; but we must not let it overshadow related problems of similar importance.

Throughout the country at large, the form of energy most in use and most prized and appreciated, is heat, as used in furnace, open grate and cook-stove. We may wish to have the convenience of railways, tapwater and electric toasters; but we *must* have heat for cooking and for warming our houses. The former are perquisites of civilization; the latter are pre-requisites.

The larger part of the dwellers in Ontario and Quebec still use Canadian fuel. The wood-lot is still an institution in our rural communities, and there is still sufficient wild land within reach of some of our towns and cities to provide a fraction of their needs. Properly conserved and regulated, the wood-lot will continue to fulfil its function indefinitely.

The urban communities, even those in the North country, draw their fuel supply mainly from the coalfields of the United States. It is expensive fuel, but it is convenient, and cheaper than anything at present available from within our own borders. But the fact of dependence upon a foreign source of supply is unsatisfactory in different ways, and has lately caused a good deal of hard thinking and heart-searching. One result has been a renewal of the attempt to use peat.

The public have been ill-informed about the facts of the recent experimental work on peat; even technical men have failed to follow developments with the care the matter warrants. The result—the inevitable result—is that misconception has taken the place of truth; the forty devils have come in when they found the place unoccupied. The Journal deplores this result, and will do its bit to help mend the case.

We print today a resumé of what appears to us to be the present situation. We hope to keep the Journal's readers supplied, from time to time, with information on this important question. Those interested in the commercial supplying of fuel in Central Canada will do well to keep a shrewd eye on developments.

"PLAIN GEOLOGY."

OUR compliments to Dr. George Otis Smith Director of the United States Geological Survey. Our hat is off to him. Geology can be made so occult a science that only the elect can penetrate its arcana. The geologist can, and, to our grief, sometimes does, clothe himself with all the mystery and circumstance of the Delphic Oracle His polysyllabics are his protective armour, his weapons of offence, and the instrument with which he smites the Philistines.

Dr. Smith has rent the veil. Let us quote him, for we are ourselves becoming distended with words:—

"I am convinced that, at its best," says Dr. Smith in a current contemporary, "science is simple,—that the simplest arrangement of facts that sets forth the truth best deserves the term scientific. So the geology I plead for is that which states facts in plain words — *in language understood by the many rather than by the few.*"

We have taken the liberty of italicizing the last phrase because it is kernel of the nut. The hard-shelled geologist wishes to give to the public only his conclusions. He does not think the average citizen capable of following his reasoning. Further, he takes extremely good care, by using a terminology that is a fearful and wonderful complex of Latin and Greek derivatives, that none but the initiate *can* follow him. This may titivate the geologist's pride, but it pleases no one else.

Dr. Smith is a geologist himself, and this is what experience has taught him:—"It takes years for some "geologists to break the fetters of their scholastic "habit of using big words for small ideas."

We remember that in our early adolescence we were forced to learn by rote at definition of the term "word". The definition we shall never forget, flagellation having stereotyped it on the tablets of our memory. It ran thus:—"A word is a significant com-"bination of articulate sounds capable of being re-"presented by written characters." To our then untrained ears these sounds were significant of nothing. Other parts of our anatomy were appealed to.

Quite seriously, Dr. Smith has pricked a bubble, lanced a boil, and laid a ghost. We are thankful that in the matter of turpid terminology (we beg Dr. Smith's pardon,—we shall have said "long words"!) Canadian geologists are not as blameful as are their brethren in a mighty republic that shall be nameless.

FINE GRINDING OF GOLD ORE.

ALL interested in the treatment of gold ore will find a fund of information, well worth the closest study, in the papers presented at the recent annual meeting of the Canadian Institute of Mining and Metallurgy. Particularly instructive are the figures giving the comparative efficiencies of stamps and ball mills.

At the Hollinger, six ball mills followed by twelve tube mills do more work than 200 stamps and twenty tube mills, and consume less power. The cost in the former case is 26 cents per ton, and in the latter, 41 cents per ton. There is, therefore, little doubt as to

the character of the additional plant for fine grinding, shortly to be installed in the enlarged Hollinger mill. The ball mill has again proved itself eminently suitable for the gold ores of Northern Ontario.

As the main factor under consideration at the Hollinger just now is the provision of facilities for the treatment of more ore, it may safely be assumed that ball mills will, for some time to come, be used to supplement, and not to replace, the present batteries. Soon, however, the roar of the stamps will split the ears of visitors no more. Gold milling will have lost something of the picturesque, but the mill-man will appreciate the added comfort.

Thanks are due the managements of the companies that have made public, information that will assist materially in the rational design and economical operation of other and newer milling units in the growing gold-fields of Northern Ontario.

EDITORIAL NOTES

MCINTYRE-PORCUPINE shares are now selling at a figure that indicates a capital valuation of $16,000,000 for the mine. Those that buy the stock at the present figure (and hold it) will have to see the mine produce approximately $32,000,000 of bullion in order to realize a reasonable return on their investment. The last annual report of the notably capable General Manager placed the gross value of the ore reserves at about $6,000,000.

We refrain from pointing the moral.

A wonderfully interesting thing is the history of the stamp-mill. Originally, if records are to be believed, it was used for laundry purposes. The development of the device is one of the romances of ore-dressing. Yet, in essence, the stamp-mill is wasteful of power and ponderous in performance; and frankly mediaeval in design. The Journal invites comments from any of its readers that may think this statement too radical.

Time and time again the phenomenon recurs—the phenomenon of the investor buying an interest in a metallurgical process that has nothing to recommend it save the fantastic claims of its inventor. Processes, like all other expressions of human endeavour, are accretionary growths, evolutionary indeed, but rarely (if ever) revolutionary.

In mining, the corresponding phenomenon is commonly evident on the stock markets. Fancy, properly seasoned with the sauce of over-optimism, is made into a seemingly palatable dish by certain clever cooks. Some refuse to accept the poisoned delicacy; others eat, are nauseated, and clear their systems only after violent effort.

Until comparatively recently, it was considered that the potash-bearing salt beds of Alsace and of Stassfurt were unique, and were destined to supply the world's needs indefinitely. Now it appears that beds of similar geological occurrence, similarly rich and extensive, have been located and are under development in Spain.

The Malagash salt beds in Nova Scotia created quite a "furore" for a time when their content of potash become known. When drilling and similar exploratory work have been done, Canada may find herself similarly fortunate to Spain. Elsewhere in Canada, the possibility of finding high-grade potash salts can hardly yet be gauged.

Our friend, Professor H. E. T. Haultain, in an address, the text of which appears on another page, presents in his happiest and most whimsical style a topic that is of deep import. He invokes women's aid in developing a "tribal soul" in the engineering profession. For an alleged misogynist, this is going pretty strong. We commend the address to our readers' attention.

At last there is definite and decided action towards improving the salaries of technologists in government employ at Ottawa. For some time it has been generally recognized that the present scale of salaries to our highly trained scientists particularly in the Department of Mines, constitutes both a disgrace to the public service, and a danger to its efficiency.

The Hon. Mr. Stewart is to be heartily congratulated upon having spoken in an unequivocal way in favour of paying to our scientists in the public service a larger fraction of what they earn.

THE STRIKER

(Press despatches announce that 600,000 coal miners will go on strike on April 1st. It is expected that 1,500,000 workers will be thrown out of employment.

'Tis not enough that poverty and death
Stalk through the land. 'Tis not enough that war
Still hovers hateful in the West and East.
The STRIKER'S greed, his pride of power, his lust
For full dominion of our State and Realm,
These are insatiate. He must test his strength
It matters not who suffer or who die.
He must impose his will upon the whole
Distracted body politic. Who cares
How many little children lack for bread?
How many homes destroyed, or broken hearts,
To blaze the progress of the glorious STRIKE?

* * *

Methinks that God reserves a special curse
For those inciting simple men to strike.

—ANON

The Romance of Engineering

By H. E. T. HAULTAIN*

Mr. Chairman, Ladies and Gentleman,
more particularly the Ladies:—

This is a meeting of more than ordinary interest. In the first place, it is part of an Annual Meeting being held at Headquarters. I am aware that Montreal draws a distinction between "Montreal Branch" and "Headquarters," and today we are are guests of the Montreal Branch, but they have interlocking directorates. Montreal has been Headquarters of the Canadian Society of Civil Engineers and the Engineering Institute of Canada ever since its inception thirty-five years ago, and it has been an autocratic Headquarters. Sometimes it has been considered an arrogant autocracy. It is well that it has been so, because we have been through our times of difficulty and trial when strength and persistence were needed. But it has been an autocracy of leadership rather than of domination. It has been an autocracy by virtue of influence rather than by virtue of jurisdiction.

Another reason why this is an important meeting lies in the fact that this is the only function of this Annual Meeting in which the ladies take part. Before I go any further, let me explain that I have persistently on every occasion possible opposed the idea of the ladies taking any part whatsoever in any of our meetings. I have used my best endeavour, and to be quite candid, I have considered that I had some ability in matters of this kind, but I have failed to have any influence on the course of events. I am quite sure that many members have entirely agreed with me, but hardly any of them, in fact none of them, have stood up openly and supported me. The only explanation that I can find for this is that they have been married twelve years, and apparently have still much to learn.

I have been making enquiries as to the advent of the ladies into our affairs and I find that the first occasion was in Ottawa four years ago, when there was a dance and a reception and an afternoon tea for the ladies. Those of you who have experience of official "Ottawa" know that there is a strange atmosphere at Ottawa and they do queer things. The next occasion was at the summer meeting at Niagara Falls when every meeting and function was open to the ladies. The Engineers, of course, have found some use for Niagara, but apart from that Niagara has only two functions, honeymoons and picnics, and this summer meeting was a picnic, and of course no picnic would be complete without the ladies. (Nor honeymoons either for that matter.) The next occasion was in Toronto last year when I put in my special efforts to keep them out, but I was a minority of one, nevertheless a solid minority. At this meeting the ladies or their friends butted and horned into everything they could and when this did not work they sat on the doorstep until they were invited in. There was a dance and a musicale, and a reception at Government House, and an afternoon tea, and this was not enough; they found their way into our Smoker, and some of them even into the holy of holies, the President's dinner. I think they thought this last was the unholy of unholies. It is perhaps note worthy that, though many meetings and functions were arranged for the ladies, at none of them were they welcomed. (Notice the "d" at the end of that word.) I mean, there was no official word of welcome, and as far as I was personally concerned, let me say it again, they were never welcome. Now we come down to this meeting and Headquarters has only invited the ladies to this one luncheon, and the amusement that they provide is a dry old professor from the dry town of Toronto. I am afraid they have rather put one over you. Probably they are putting one over me too, and have put me here to do penance in full public view for my attitude in this matter. Why is it that you ladies, or some of you at least, have been so anxious to mix in at our affairs? Is it that you think we are having too good a time and that you are entitled to your share, or is it that you know that we are having a smoke too much and perhaps a drink too much, and need looking after? Probably both of these, and also because the women of the present age have found great satisfaction in doing just those things they have been told they must not do. Having succeeded so well as far as you have gone, why not go to a lot further? There are all kinds of opportunity for you. You can form committees; you can be elected to office with all kinds of distinguishing names; you can hold meetings and have addresses and get your names into the social column to your hearts' desire. The road is all clear for you. The reputation of the Engineering Institute is at your disposal to play to the limit. You say that is not what you are after; that you would not seek social eminence in such a manner. You say that is not characteristic of Engineers' women-folk. I believe you. In fact, it is only because I believe that, that I have dared to take the extraordinary venture of appearing here to-day.

To be more serious (though I have been much more serious during the last few minutes than you have been inclined to believe), within the last few years I have seen miracles. I have seen a new phase of womanhood. I have seen women force their way into places and organizations where they were very much less welcome than you have been here. I have seen them force their way quietly into circumstances where they were openly damned and less openly, but just as severely, shown they were not wanted by the more subtle means of the cold shoulder and the sneer. I have seen them persist and in a very short time, a matter of only a few weeks, I have seen these same women welcomed with language of the very opposite extreme. I have seen language fail completely to express the feelings of blessings towards these women, and this not in isolated cases, but in hundred of cases throughout Canada. I am referring to the "Girls in Green." Some of you may have worn the green uniform in the hospitals, or some of your relatives or friends have I am sure, and you will know what I am referring to. I have seen what these girls accomplished, and I am prepared to believe anything possible, either as to the manner in which a woman gets into the game, or as to what she does after she has arrived there. What did these girls do? Well, they saved men's souls, thousands of them. I am not referring to the salvation of souls from the hell-fires of the future, but from the hell-fires of today. They saved that part of man which saves him from despondency and despair, which makes him feel a man, and makes him hold up his head, and makes him something in the com-

* A Luncheon Address at the Annual Meeting, Engineering Institute of Canada, Montreal.

munity. To most of these girls, this work and its results was true romance of a very deep kind, in many cases, I firmly believe, a truer and richer romance than the personal affairs of their own hearts.

What is it all about? Is it just simply to have a good time? Why are we here today? Why the Engineering Institute of Canada? Why these Annual Meetings with their serious scientific papers and serious discussions and their dinners and their smokers and their drinks?

All this effort and fuss is just for one purpose. It is for the purpose of developing a tribal spirit. It is for the purpose of developing the manifestation of a tribal soul. You don't like that use of the word soul; neither do I. Give me a better word. What do I mean by it? What is it that makes the McGill man hold his head up when he says "I am a McGill man"? It is the spirit of old McGill. The word spirit it not strong enough. I want something deeper. I want something with more deference attached to it. The soul of McGill is a magnificent asset. McGill has a magnificent principal. McGill has a magnificent staff. But a greater asset than either of these is this tribal soul which binds McGill men together. We go down to New York and we say "I am a Canadian," quietly, unostentatiously, and what is the result? We get deference. That illustrates what I mean by the tribal soul. We have a splendid Queen's spirit at Kingston and we have a splendid "School" spirit in Toronto. But the strange thing is, that we have nothing like the same spirit in the engineering profession as a whole, or at least we have not the same manifestation. There is no particular pride or uplifting when a man says "I am an Engineer," but unfortunately there is the feeling that the other chap is saying "He is only an Engineer." Now, this is what we have to remedy. With a proper development of the tribal soul we can become anything in the community. Without it, we are very little indeed, the majority of us are but hewers of wood and drawers of water — some possibly nothing but sounding brass.

Now there is your romance. Help us find our tribal soul. There is where you may play the game on a fine broad scale. That may be the real romance of engineering as far as Canada is concerned. How are you to go about it? I have not the remostest idea. I still have some shreds of wisdom hanging to me and I am not foolisr enough to attempt to tell a woman how to handle a man. Your chairman gave me just before I rose a very happy French proverb: "Ce que femme vent Dieu le vent," which he translates: "What woman wishes God wills." I am inclined to put it, "What woman wishes these days she gets." But I am inclined to place much more weight upon her thoughts; her serious thoughts; let us say, her heart thoughts. I think her wishes as far as we have been concerned were just simply to see what was going on. If she will think more seriously about the true romance, she may accomplish wonders; I have no doubt she will accomplish wonders.

Just one word more, not a word of advice, simply a suggestion, or rather a statement of fact. There are in this city about 200 young men graduating each year from the University into the profession at the most susceptible period of their lives, not conscious that there is such a thing as an Engineering Soul. Women could do anything with them.

AN INVITATION.

Here are words of wisdom from the modern prospector. "One lesson that Porcupine has taught us, is not to worry so much about locating spectacular gold showings, but to watch these contacts (porphyry intrusions in Keewatin greenstones, basalt, etc) for mineralized schist, and pan and keep on panning. Then, if the condition looks right, strip across the mineralized zones, and channel samples and get them assayed."

This is from Tom Saville, of Sudbury, who continues, "Just now I am working on a piece of geology that suits me fine—a long strip of volcanics flanked by the granite, with several intrusions and lots of life, movement, and sheared zones, and just enough gold to keep a fellow scratching. This particular place lies between Makawa and Gogama on the C. N. Railway, eighty miles north of Sudbury, and extends nearly east and west on both sides the track. I am scouting this country alone, and would be glad to see more prospectors here, who might help to reduce the deficit of the C. N. R. on this section."

PLACER GOLD IN NORTHERN ONTARIO

(Special Correspondence.)

A prospector just returned from the region south of Abitibi Lake where there has recently been a rush to stake for placer gold, describes the country where the gold has been found as a gravelly ridge running nearly north and south from the Township of Milligan on the north, then between Munro and McCool, and ending between Guibord and Michand. The ridge stands high above the sandy plain through which it runs. An old Westerner pronounces it "exactly like the gravelly bed of an old river," but the description tallies rather with that of a very long and large esker. "Ruby" sand (garnet) has been observed where the panning shows good values. Small round lakes are frequent (kettle lakes?), and clear springs flowing winter and summer are characteristic features. One prospector has run a tunnel into the ridge for seventy five feet and gets values varying from forty-five cents to twenty dollars a yard. Whereas only very fine gold is got by panning the sandy plain, the gravel of the ridge gives nuggets of considerable size. The direction of the ridge indicates its origin as glacial drift rather than pre glacial gravel left as in the cases of Quebec and British Columbia by the glacier riding over a narrow river-gorge transverse to its direction. There is a chance, however, that the subglacial river has done extensive sorting of drift moved a relatively short distance. The district in question is a few miles east of the Croesus Mine, which produced such phenomenally rich ore.

Two weeks ago, on page 152 there appeared a cut with the description "Little Tugger Hoist." The hoist illustrated is actually a Waugh hoist, the cuts having been inadvertently interchanged. To the average observer, the two pictures are indistinguishable, though of course the manufacturer of each sees special points in his own.

The shortage of supplies of gold in London owing to the Rand strike has caused a shipment of gold — worth $800,000 — to be arranged from the United States to Bombay. This is the first consignment of gold to be exported from the U. S. A. for some months.

Peat

A SURVEY of the status of peat as a fuel in central Canada is pertinent at any time. With the threatened cessation of our imports of coal, the present situation directs our attention with added force to an anomalous condition. We have a native fuel at our doors, yet have failed to use it. Attempts made by private enterprises having resulted unfortunately, public funds have been allotted and spent in an endeavour to solve the peat problem. For one reason and another, we (the public) have failed to follow the case closely, and have allowed misconception to take the place of fact in our minds.

There are now, within a radius of two hundred miles of the peat bog at Alfred, a good number of well-satisfied users of peat fuel, with an unsatisfied inward sensation like that of Oliver Twist—they want some more, please. Alfred is on the Canadian Pacific Railway, between Ottawa and Montreal; yet from as far away as Peterborough there is a demand for more peat, and still more, from people that have experimented with trial carloads. A complete statement of the facts of the case is not possible in the present instance; an illustration will have to suffice in the meantime.

Caledonia Springs, whence comes our main support and solace in these dry (or near-dry) days, is on the border of the Alfred peat bog. The bottling works is in Montreal. The Canadian Pacific Railway are the owners; as usual, they have not lost any chance for turning to account a natural resource. So we see "Caledonia Water" from coast to coast on the company's dining-cars, and find the healing waters broadcast throughout numerous parched provinces, in various guises and under various names.

The Canadian Pacific Railway employs, and has the hearty co-operation of a host of progressive Canadians.

One of these noticed that the recent experiments next door to Caledonia Springs seemed logical and well-conducted, and that the blocks of peat had an attractive appearance. He tried a little bit in his stove and fire-place, and it burned beautifully. On inquiring about the cost, he found it to be reasonable, and consequently the Company shipped a trial lot to the bottling works in Montreal. The peat burned well under the boilers, was convenient to handle, cost less than coal, and appeared to be a good investment. Some of the workmen tried it in their stoves and fire-places, and they and their wives asked for more. The management experimented on a number of their friends in the same way, with the same pleasing result.

It began to look as if there were here a real "find". The management brought two carloads of peat to Montreal last summer, conducted some simple and conclusive tests in comparison with coal, and now are convinced that Nature has not treated us so badly in the way of fuel in Ontario and Quebec as we have been accustomed to believe.

Air-dried machine peat can be cut, macerated, spread and harvested, and sold profitably at a rate not exceeding $5.00 per ton, f.o.b. cars—probably for less, eventually. It stands transportation well, is convenient to handle, is smokeless, leaves hardly any ash, and has a calorific value a little more than half that of good bituminous coal. It kindles easily, and burns freely. On account of its bulk, (somewhat less than that of dry beech or oak), and the speed of its burning, it is not suited for furnaces or fire-boxes required for heating purposes in severe weather. These have been designed for a more compact fuel, and will not hold enough peat to last over-night. But for use in mild weather, or in a grate or kitchen stove at any time peat is "hard to beat."

The facts of the case are, briefly, as follows. During the decade before the war a number of serious attempts were made to develop a commercial process for making peat fuel from the raw material, obviously so abundant. These attempts, while by no means barren of results, for one reason and another all fell short of commercial success, and a lot of money was lost. Meantime the federal Department of Mines had conducted a demonstration on a small scale, which was promising but inconclusive.

The general impulse to endeavour, born of war conditions, stimulated a further attempt to solve the peat problem, and since four years ago, public funds have been appropriated annually by the Ontario and Federal governments for the use of the Joint Peat Committee. This committee investigated first the fundamental conditions involved, and found that previous efforts, mainly concerned with the artificial drying and briquetting of peat, were fore-doomed to failure; it takes more calories of heat to effect this end than are contained in the resulting briquettes. This narrowed the field to air-dried peat, and the Committee have consistently and persistently worked at the development of mechanisms suitable for this purpose. They have now, after three seasons of experiment (the season is short—only 100 days,) succeeded in developing machines that give promise of producing an excellent fuel, saleable at a cost considerably less than that of imported coal.

The experiments of the last three years have, incidentally, resulted in the production of several thousand tons of peat, and its sale to those interested. Not all the peat made during the experiments has been of the first quality; that would be impossible from the very nature of experimental work. Nor was it practicable to segregate these poor lots of peat. As a consequence, a small amount of poor peat has been distributed with the good material, and there has been an occasional discord in the general song of approval from peat users.

The importance of the solution of the peat problem to all and sundry in Ontario and Quebec is well illustrated by a map of these two provinces showing the peat bogs that have been already examined. We have all had a vague idea that there is plenty of peat to be had; we have not all realized how well-distributed and accessible it is from our main centres of population and of fuel consumption. The huge bog at Alfred, 70 miles from Montreal and 40 miles from Ottawa, is capable of supplying the domestic hearths of these two cities almost indefinitely; and even their industrial requirements may be partly met by peat, as research and experiment extend its uses. Montreal, St Johns, Cornwall, Brockville, Ottawa, Kingston, St. Catherines, London and Kenora have their future fuel supply almost at their doors. The citizens of Toronto will have to pay freight on their peat for about a 40-mile haul. The North country is so well-blessed with peat-bogs, still unexplored by the official surveyors, that their future fuel supply is assured.

The News of Mining

The Commercial Intelligence Service, of the Department of Trade and Commerce, Ottawa, issue every Saturday the *Commercial Intelligence Journal*. Trade Commissioner Norman D. Johnston, whose headquarters are in Rotterdam, contributes to current numbers a very informing series of articles on the Scandinavian iron and steel trade, with special reference to the possibility of developing a market for Canadian products.

In a memorandum submitted to the Right Hon. Winston S. Churchill, M. P., by a deputation of the Royal Colonial Institute, it was pointed out that there is room in Canada for a 19,000,000 increase in population before this country would attain the density settlement that obtains in New Zealand. The expansion of the mining industry will account for much of the wished-for immigration.

On account of the severe depression in the Australian iron and steel industry, the Broken Hill Proprietary Company, which, with its plant at Newcastle N.S.W., is the largest producer, estimates that a reduction of 33 per cent in the price of coal, labor and supplies will be necessary before overseas competition can be met.

There are more than 130 blast furnaces in Sweden, most of them using charcoal as fuel, and 25 electric steel furnaces.

The American Smelting and Refining Company announces a marked increase in the output per man per day among its employees. The following figures represent a comparison of outputs seven years ago and at the present time:—

Plants	Operation	1911	Oct. 1921
Durango	Crushing	3.18	52.2
Murray	Unloading	9.2	25.3
Arkansas Valley	Roasting	6.4	13.6
El Paso	Bricking	2.0	4.1

The president, Mr. Simon Guggenheim, states that by means of various economies, their enterprises are on a sound basis, and that the Company will be able to take advantage in every way of the coming turn in the tide.

According to figures recently published by the Dominion Government, the developed water power in Canada now totals 2,756,000 h.p. There are roughly still about 50,000,000 h.p. available. As compared with the United States, Canada has installed 280 h.p. per 1000 of population, against 93 h.p. per 1000 of population in the former country. The vast untouched reserves of water power in British Columbia, Ontario and Quebec indicate that these three provinces have in store a wonderful future as centres of metallurgical industry.

Forty five United States potash producers have appealed to Congress for relief from German competition. They assert that German agents are conducting a campaign of misrepresentation to prevent the United States producers from securing moderate protection.

Present standard wages in the chemical and metallurgical industries of the United States range from 50c. to 75c. per hour; in England, 30c. to 45c. per hour; in Germany, about 10c. per hour at current exchange, or the equivalent of 20c. to 25c. terms of retail purchasing power.

Employment in the iron and steel industries of Canada shows a decided improvement. In copper industries there is a falling off, as there is, also, in coal mining in Alberta; whilst metal mining in general is holding its own.

The Premier Diamond Mining Company, Limited, South Africa, reports a revenue of only £439,636 from diamonds for the year 1921, as compared with £2,098,482 for the year 1920.

Because of the decreased cost of living and the need of reduced mining costs, the Rhodesia Mine Owners' Association has decided for a reduction in wages to take effect on April 1st. For the more highly paid employees, the reduction is to be 12.8 per cent. This is the maximum. The minimum is a 6 per cent. cut.

The London Daily Mail has issued a warning to investors in mining shares in Great Britain. The Mail referred especially to three Canadian flotations, sponsored respectively by Col. Grant Morden, F. C. Sutherland and Co. (Toronto,) and the Bingo Mining Company (Winnipeg). The two former flotations have to do with Porcupine, Ont., properties, the last with properties near Herb Lake, Northern Manitoba.

A newly organized company, the Dominion Alloy Steel Corporation, Limited, authorized capitalization $15,000,000, proposes to establish a plant at Sarnia, Ont. The reported annual capacity of the plant is 50,000 tons of alloy and high-carbon steels. Despatches state that Sir William MacKenzie is on the board of directors.

The United States Government has issued an official warning that no violence will be tolerated in the event of a coal miners' strike becoming an accomplished fact on April 1st.

The Hon. Mr. Stewart, Minister of Mines, Ottawa, last week submitted to Parliament a report upon the condition of his Department. Following is an extract therefrom:—

"The difference between Government salaries and those obtaining in commercial work and even in the universities at present is too great, and unless this is rectified there are bound to be frequent and recurrent changes of personnel resulting in a general lowering of standard in men employed and work done.

"This state of affairs should be avoided if possible, since the work of the department is such that only the most highly trained men should be employed, for anything short of the best is worse than none at all."

Within a few months the experimental work of the Joint Peat Committee will have been completed. All evidence up to the present points to the complete success of their experiments. Their success will add one more item to the long list of man's aids to his own civilization.

On March 23rd, the executive board of the United Mine Workers at Sydney, N. S., voted 4 to 3 to adopt J.B. MacLachlan's plan of instructing all Nova Scotian coal miners to cut coal production down to a point where there would be no possibility of profit for the operators. Already 18 men, employed by the Dominion Coal Company, have been discharged for loafing. The output to date to date has diminished somewhat, and the number of workers handling the coal from the face to the surface has been reduced in proportion.

In his paper read recently before the Institution of Mining and Metallurgy, London, Dr. J. MacIntosh Bell states that at the Keeley Mine, South Lorrain, Ont., the oxidized zone in the northern part of the vein goes down only a few feet, and immediately gives place to rich ore. On the southern working on the vein, the oxidized zone attains greater depth, passing through the contact and into the diabase.

A special feature in recent United States coke-oven practice is the exclusive use of silica bricks. The resistant character of silica brick is illustrated by the fact that one battery of evens has been shut down 15 times in five years, without requiring rebuilding or relining.

The Secretary of Mines for Great Britain has announced that certain types of breathing (rescue apparatus have passed official tests, and that the Board of Trade has approved them for use at mines and reserve stations. The approved types are:—

The Paul Mine Rescue Apparatus, made by the American Atmos Corporation, Pittsburgh, Pa.

The Mecco-Briggs Rescue Apparatus, made by the Mining Engineering Company, Sheffield, England.

Mining concessions in Spain are granted only to Spanish citizens, or to companies domiciled in Spain. In all such companies, directors and officials must be Spaniards.

The Ontario Department of Mines has issued its annual report on mining accidents in the Province during the year 1921. On that period there were 24 fatal accidents, of which 11 occured underground, one on the mine surface, 4 in metallurgical works, 5 in quarries, and 3 in sand and gravel pits. Of the mine fatalities, 8 were due to falls of rock. The non-fatal accidents numbered 1,262, including mines, quarries, etc. Accidents at underground ore-chutes were the most numerous in the classified list. The report shows a great diminution since the year 1908 in fatalities per thousand men employed.

A magnificent laboratory is being built at Minneapolis for the University of Minnesota and the U. S. Bureau of Mines. It is to be equipped for research work on iron and manganese ores.

OBITUARY.

William Thomlinson.

William Thomlinson, a well-known British Columbia mining man, died recently at his home, New Denver, Colorado. He came to British Columbia thirty years ago and became interested in mining. After completing a course in mineralogy at Queen's University, Kingston, Ontario, he was employed on several occasions by the Provincial Government in the collection of mineral specimens for exhibition purposes. In 1914 he was commissioned by the Dominion Government to assemble a representative collection of minerals of British Columbia for display at the Panama Pacific International Exposition, at San Francisco, California. He served as the British Columbia representative on the mineralogical staff of the Canadian Government Commission at that Exposition as well as the Panama International Exposition at San Diego, California. Later on he became identified with the Munition Resources Commission, in which connection he was especially interested in the platinum resources of the Province. Following the war he was commissioned by the Geological Survey to make a collection of the minerals of Southern British Columbia. An ardent worker in the interests of the mining industry of the Canadian West, and possessing a personality of force and charm, his death is very much regretted by all associated with mining in this Province.

Kent Archibald.

The sudden death of Kent Archibald at Truro, Nova Scotia, on March 21st, marks the passing of one of the very few successful operators of gold mines in the province. The late Mr. Archibald, along with Charles Mott, opened and sold the famous Dufferin mine. The Dufferin, after many vicissitudes, died a natural death. During the time that Mr. Archibald operated it, the mine paid handsomely. He also mined profitably in Hants and Guysboro Counties.

Mr. Archibald was of that admirable old type of Bluenose pioneer that never admitted defeat.

PERSONAL.

Dr. A. O. Hayes, late of the Geological Survey of Canada, and now field geologist with the Whitehall Petroleum Company, left Canada last week for California, where he will spend some months with his family at 505 W. Washington St., San Diego.

Mr. Alexander Gray last week paid a visit to Mr. J. L. Agnew, President of the Canadian International Nickel Corporation, in Copper Cliff.

The Toronto Branch of the Association of the Women of the Mining Industry of Canada held a meeting at the home of Mrs D. A. Dunlap on Tuesday March 28.

The Toronto Branch of the Canadian Institute of Mining and Metallurgy will hold a meeting on Saturday April 1st. Mr R. Home Smith will address the meeting.

Mr. E. P. Mathewson has returned from Burma via San Francisco.

Mr. F. W. Schumacher of Columbus, Ohio, president of Schumacher Gold Mines, is in Toronto for the annual meeting of his company.

M.J. M. Cohen is at Elbow Lake, Manitoba.

Mr. Geo. Hoehn of Waco, Texas and Mr. F. W. Hoehn of Pittsburgh have joined the board of directors of Schumacher Gold Mines.

News and Comments

By ALEXANDER GRAY.

The Basic Industries.

WHILE it is satisfactory to note the progress of precious metal mining in Canada, it would be a mistake to ignore the present unsatisfactory state of what is much more important — the coal and iron industries. There is now substantial evidence that these basic industries are, in the United States, on the up-grade. The United States Steel Corporation is now operating at 60 per cent. of normal capacity, which is about twice what it was last year. Agencies in Canada representing American steel producers report a satisfactory increase in the volume of orders.

In Nova Scotia, orders from abroad for iron ore brighten a prospect that is otherwise dull. The labour disputes prevent the resumption of coal mining on a large scale.

It cannot be said that Canadian steel fabricating plants have a cheerful outlook just at present; but the tide is on the turn, and when the banks feel at liberty to release funds, there will be enough business in construction work and in providing equipment to make our steel men smile once more.

The Prospector in the Alps.

A gold mine on top of the Alps where shipments may or may not have to be made by aeroplane, rawhiding being too laborious, is a cabled announcement. The intrepid prospector is undaunted by either space or diffienlty. Canadians of this species would rather stake in the snow and "mush it" anywhere. It is their intrepidity that provides silver linings for the clouds.

George Gray.

A word of commendation is due to Mr. George Gray, late Manager of the Associated Goldfields of Larder Lake, for declining to subordinate his personal and professional integrity, when proposed operations on the properties demanded the abandonment of both. If his report on those properties was in existence when the last annual meeting of Associated shareholders was held, why was it intimated that it would not be ready for about three months?

The Immature Banking View.

A glib Montreal branch bank manager the other day oracularly exclaimed: "Mining is not a sound business!"

What unsoundness prevails in real mining and development of mineral resources, it might in verity be urged, is somewhat attributable to such as he, who classify meretricious claims with actual returns expressed in bullion. However, it is dawning upon other bankers, and not a few business men, that the motive power provided by the Mining Industry is becoming formidable. A payroll of about $20,000,000 and the quantity of stores purchased entitle the Mineral Industries of Ontario to speak above a whisper. In wages and for stores the Transvaal mines annually expend approximately $150,000,000. A recent survey brought out the statement that 1,750 industrial establishements are centred on the Rand with its gold mines, Pretoria with its diamond mines, and Vereenigin with its coal mines and power. These subsidiary industries have a total capital of about $80,000,000. This represents a quarter of the registered capital employed in industrial undertakings for the entire South African Union. That is why those that disturb the industrial serenity of the mines out there are given short shrift. The business of mining is the mainstay of Africa south of the Zambesi. Without it the banks would not require so many branches. Branch managers, however admirable in daily intercourse, as a rule have no discretion other than what is prescribed by head offices. If more of them studied mining data, clients might get salutary advice rather than malediction for legitimate mining.

Ringing the Changes.

Oblique reasoning will have it that as a certain mining stock is at a premium of 150 per cent, above the gross value of the estimated ore reserves, then, another stock might as well duplicate the market performance. Both companies would then be capitalized in the market at $18,000,000 and $100,000,000, respectively, and there would be nothing but the absorptive power of the public to prevent endless others from volunteering for the over-the-top movement. The trouble with this is, however, that the pyramid would become inverted, and "great would be the fall thereof." Gravity has inflexible limitations. There must be a broad base for market movements of the sort on exhibit. Dizzy height induces vertigo. Manipulation will make a mine no more valuable than it really is and overplayed markets have but one result. So the safest course is to avoid markets with an undertow from which the best swimmers cannot escape. The definite factors of ore reserves, plus certain allowances for indicated ore, are all that should be considered by those that would avoid danger. Getting in at the steeple in order to reach the basement suits no one but sellers. So why indulge in sophistry about what this, that or the other stock ought to sell at, because some other stock has a blackboard valuation out of line with its ore reserves and prospects?

On to Quebec!

The staking of areas around Larder Lake, in Gauthier and surrounding townships in Ontario, is giving Quebec an overflow of snow birds that may be helpful. It is long since Opasatica and Obier and Reneault Lake sections were favorably considered. Ten years ago Dr. W. G. Miller noted that some of the Huronian rocks in Quebec corresponded with those of Porcupine. Harvie dealt with the geology and mineralogy, gold occurring both free and in combination with the silver telluride, petzite. Staking in winter, though, is not always worth while.

Putting it Over.

A cellulose Colonel, an Earl, a Sir Knight, and a staff officer of the "C. P. R." are sponsoring three mining issues in London. Under such patronage, the public naturally will place the responsibility where it belongs.

Further the deponent saith not! Canadians will keep their ears to the ground and await detonations.

Maintaining Our Status.

With the German mark quoted at 2.100 of a cent

it is to be truthfully maintained by unprejudiced Canadians that there is no lack of mining script worth infinitely more than the mark, although there is a considerable tonnage that will not stand the cost of cartage.

Hollinger Tonnage in Millerton Area

When the Hollinger mill is ready to dispose of six or seven thousand tons a day, it is taken for granted the average grade of the ore as given in the latest annual report will be diluted with some of the Millerton ore, of which nothing has been said since the former General Manager in discussing the basis of the merger wrote: "There is ample justification for assuming a high potential value" for the property. Never since then has reference been made to the Millerton mineralized section, which showed "an average value of $4.80 over a width of 126 feet," two portions of which showed "a value of $6.30 over a width of forty feet, and $6.50 over a width of 22 feet." It was intimated six years ago that "future development will show a comparatively large tonnage of ore averaging in the neighborhood of $6.50 per ton."

What further determinations have been made in this Millerton area is apt to be one of the surprises when Mr. Brigham has in operation his bench system of working the section. It may not be 126 feet wide all they way from the surface to the contact—and then, again, "It may continue through the contact." At any rate, 300' X 700' or so need not be a full 126 feet wide to great depth in order to provide a few million tons of useful ore. That is another reason why the Hollinger Company must have power a' plenty—and why they will have it, whatever the source. The province will see to it that this potential wealth is made real. Mining scientists are eager to have General Manager Brigham introduce the bench system of mining, with its low costs. Until the average cost of milling is established, the management discreetly has refrained from estimates as to how many million dollars now in low grade ore may be added to the fully proven reserves of higher grade.

Dome Reserves

One of the results of the recent visit of Directors is the semi-official statement that Dome mill heads are running $9.50 to the ton, and have been doing so for about two months. This is the highest average attained by the management in the history of the company, and it is expected to maintain it, if developments at the 1,100-ft. level prove the downward extension of the area of enrichment. While it may be that this grade of ore cannot be accepted as the average of the whole tonnage in reserve, the improvement is regarded as an endorsation of the policy of selective mining and will permit of the dilution of some of the higher with lower grade, thereby providing a satisfactory profit from a larger tonnage. No statement of Dome ore reserves of recent years has been incorporated in Dome reports, but if the conservative management feels at liberty to feed the current grade to the mill it is thought there is justification for so doing, for the time being. No doubt Mr. DePencier will safeguard his milling requirements sufficiently far ahead to exclude those errors of estimation which rather detracted from the otherwise efficient preceding management. Now that the Dome has been established upon a more substantial basis, it might be expedent to make more definite detailed pronouncements in the annual report. President Bache and General Manager DePencier in all probability will meet this suggestion when the report is published.

Hollinger Dividend Policy

Compared with others the market action of Hollinger shares is unsatisfactory to speculative holders and those that are not holders. They prefer livelier movements, and it is a frequent contention that Hollinger dividends are out of line with the market price, or vice versa. Whatever be the merits of the latter contention, there is no misunderstanding of the policy of the chief owners—the Directors. They have a great gold factory that has paid its original shareholders 353.7 per cent. on their speculative investment—there is another 171 per cent. in what is practically cash-on-hand and the proved ore reserves at the moment assure a further return of ot least 100 per cent. on the shares at parity, without considering the potentialities of the properties beyond present workings. Counting the cash assets, and assuming that one-half the gold in the reserves will be profit, there is more than $5.50 for every share issued. This leaves as the speculative factor the ore contents undetermined below the 550-ft levels and to depths unknown. So the Hollinger administration is not catering to those with a momentary interest, however willing it may be to reward the faithful and satisfy recent arrivals. As it has been with the great mines elsewhere, so it is with such as the Hollinger; those that continued steadfast from the beginning have several birds in the hand, and more in the bush.

Hollinger Makes Crushing Record

While it is definitely stated that the Dome Mines are contributing ore averaging $9.50 per ton, it is an open secret that Hollinger Mines are making the mill hit the high spots. In the week ended March 4th., Hollinger is said to have earned a profit of $138,000 or at the rate of $7,176,000 per annum. On one day a milling record of between 4,300 and 4,400 tons was achieved. That, if maintained, would mean a crushing of 1,400,000 or 1,500,000 tons in 1922. The management is making no such predictions, and the fact that a weekly profit of more than twice the dividend requirements was earned, is not being publicly purveyed. Since the beginning of this year, Hollinger Mines have travelled through a first quarter that lays the foundation for the world's milling record. Mr. Robbins, late General Manager, questioned the economy of this milling expansion; but the millions available are to be put in circulation, if the directorate can carry out their policy. Costs are nearer to normal and the greater tonnage being treated also increases the percentage of profits. General Manager Brigham has his economies well in hand. His mines have 46 miles of underground development; his mill is doing more per day than any other mill on earth; by shaft and diamond drill it has been demonstrated there is no change of formation or disconcerting feature that he knows of to a depth of 1,500 feet, and that is why he wears a who-should-worry smile. In his reckoning, it makes a decided difference when mines appeal to mills to take more ore. And yet Hollinger Directors continue in a bide-a-wee mood about increased dividends. In all of which, as majority shareholders, they hold they are conserving what will reward those who are patient.

British Columbia Letter

The Zinc Custom Plant at Trail.

Some weeks ago Mr. J. J. Warren, President of the Consolidated Mining & Smelting Company, was quoted as stating that arrangements had been made for the installation at Trail of a zinc Custom plant, and that with its completion the minerals of the Kootenay carrying this element would not be subject to penalty as heretofore. Wide publicity was given this declaration in the Province, is being rightly stated that the inauguration of such a policy would mean everything to the mine operators of eastern British Columbia. While Mr. Warren's offieial explanation is not yet available, it is understood that too broad a construction has been plaeed upon his words. It is true that a zinc custom plant is to be constructed, that zinc concentrate will find a market at Trail, and that the latest metallurgical methods will be applied to the treatment of the complex ores of the Kootenay. There is no doubt that this is an important advance, but it has not yet been indieated that the problem of economically handling these ores has yet been completely solved.

Another Dividend from Premier.

The Portland Canal Mining Distriet is beginning to stir, although the snow has not yet left and the open season must be considered some distance away. A new bridge is being thrown across Bear River by the Provincial Government. This will make the Marmot and Bitter Creek Section, where there will be much prospecting this summer, easy of access. The Premier Gold Mining Company has been at work all winter and with the opening of its new aerial tramway has begun making regular shipment. The country adjacent to this Company's property has been widely staked and substantial investments will be made in its prospecting and exploring.

It is interesting to note here that the Premier Company is reported to have prepared for the declaration of a dividend of $500,000 for the quarter ending March 31st, on its capitalization of 5,000,000 shares of a par value of $1.00 each. Following as this does the payment of a dividend of $400,000 for the quarter ending December 31st last, the Premier Mine appears to be realizing very rapidly the anticipations of the most sanguine.

The Independent Group of mineral claims, situated on the north side of Goose Creek, and at an elevation of 600 feet, is being extensively developed by the Fitzgerald Brothers. Supplies have been taken in over the snow on hand sleighs and work will continue all summer. They say that there are three large parallel mineralized zones on the property, which run east and west and are traceable on the surface for a considerable distance. Each has been stripped and tunneled to an extent with satisfactory results. On Bitter Creek the L. L. & H. Group is reported to be looking well. A large tonnage of ore has been proven. While it is not expected that it will develop into a high grade proposition, the ore is of a good grade for milling, its values showing gold and silver. J. Harkley, the owner, is proceeding with work in order to clearly demonstrate the possibilities of the property. This done, it is hoped that capital will be induced to take up the enterprise in a large way.

George Clothier, the resident mining engineer, has not yet got into the field, but will make inspections of a number of promising prospects as soon as the weather permits. He still advocates the opening up of the Unuk Country, situated just north of the Portland Canal Zone, by the construction of a trail, either altogether through Canadian territory or from the Coast first through American and then Canadian territory. It is his opinion that in this hitherto unexplored zone there are good prospects of important mineral discoveries.

Excitement at Cedar Creek.

Interest continues in the reported gold discoveries of the Cedar Creek section of the Cariboo. The excitement, for it already has reached that point, has been accentuated by the optimistic reports credited to several persons, who recently arrived on the Coast from this placer field. R. D. Featherstonhaugh, a mining engineer, declares that the Cedar Creek ground he examined is the best prospect he has ever seen. He stated that it was diffienlt for him to go over all the claims because of the depth of snow, but he had opened up the old workings and tested the values. He is quoted as saying that panning tests gave returns of from twenty to three hundred dollars per square yard, and that the gold is coarse, of glacial origin, and nuggets frequently found. A. Gilfillan, a claim owner, is equally enthusiastic. He makes the statement that after removing about four feet of snow from the surface and, by means of steel, loosening some of the frozen ground, he was able to obtain several ounces of coarse gold. Mr. Gilfillan thinks that Cedar Creek and the district immediately adjacent will be found to compare with some of the richest of the water ways of the Klondike.

Making all proper allowances for the natural optimism of those directly interested it would appear that good placer ground has been found at the point in question. It is noteworthy that the situation of this discovery is not far from the old Bullion workings, out of which the late Mr. J. B. Hobson took a considerable quantity of gold. The location is in direct line with the so-called "gold run", the sweep of which is from the Alaskan Coast in a south-eastern direction through the Yukon, the Omineca and the Cariboo. The only strange feature is that such ground should have been overlooked by the miners of 1862 in their operations in that district. The old-timers, as records show, were very thorough in their exploration and usually worked out their claims completely. They were operating all round the Cedar Creek district, some of the most productive properties of that time being situated not far away. However, more unusual things have happened than the oversight that this seems to indicate.

There is no doubt that there will be stampede to the discoveries as soon as the snow leaves. Inquiries for information are being received by the Mines Department from many sources. Most of the prospectors will enter the country by means of the Pacific Great Eastern Railway, leaving the train at Williams Lake and thence by stage to their destination. The accessibility of the ground no doubt will induce many to make the trip through curiosity rather than with any serious intention of actively engaging in mining.

Drumlummon Mine.

The Drumlummon Mine, situated at Hartley Bay,

northern British Columbia, is likely to be extensively developed, it having been announced that New York funds to the extent of $275,000 have been secured for that purpose. The building of a new camp, a dock, railroad and the installation of a new compressor plant are some of the improvements contemplated. There are three large veins on this property, and it is the intention to open them up at depth. Some very high grade copper gold ore has been taken from the vein to which development thus far has been confined.

Maroon Mountain.

The Kitsumgallum Lake district northern British Columbia will see some mining development this summer. There are a number of properties situated on Maroon Mountain, among which are groups known is the "Bear" and the "Black Wolf". A Ross mill was taken in last year to handle the ore of these claims, but it was too late in the season to start operations. A test run, however, will be made as soon as conditions permit and it is the intention of the owners, if the results warrant it, to bring in two more mills, either of the Ross or of another type.

Ore Receipts at Trail.

Ore receipts at the Trail smelter, Consolidated Mining & Smelting Company, from March 8th to 14th inclusive totalled 9153 tons, making the aggregate for the year up-to-date 89,212 tons. Of the week's returns the Mountain Chief, North Denver contributed 9 tons; the Paradise, Windermere, 36 tons; the Rosebury Surprise, 143 tons; and the Silversmith, Sandon, 666 tons; and the remainder came from the Company's mines.

Tyee Company to be Wound Up.

Advices from London, England are to the effect that the Tyee Lumber Company, Ltd. is to be wound up. This company was organized in 1900 to develop the Tyee Mine on Mount Sicker, Vancouver Island. The mine was equipped with an aerial tramway, three and a half miles long, connecting with the E. & N. Railway, and a smelter was built at Ladysmith. The Property was purchased for $400,000,, this being made up of fully paid-up shares. The mine was operated from 1902 to 1907, when the ore was exhausted. During the time it operated the Company paid dividends of from 5 p.c. to 20 p.c. per annum, and accumulated a reserve of $400,000. The ore body was 2,500 feet long and varied in width from 5 to 50 feet with a depth of 50 feet. The values averaged $3.00 in gold, 25 ounces of silver per ton and 4 p.c. copper. The shaft was 1,000 feet deep, but it encountered no ore below the 300 foot level. Considerable diamond drilling was done on the exhaustion of the ore body, but without success. Since then an effort has been made to keep the Ladysmith smelter in operation on custom ores, but this has not worked out satisfactorily. It is suggested as a possibility that the plant might be taken over by the Consolidated Mining & Smelting Company. This Corporation has a number of properties on Vancouver Island under development, notably the "Old Sport," "Quatsino" and the "Sunloch", Jordan River. With a continuous supply of ore assured from these properties,perhaps supplemented by the contributions of other Coast producers there is every reason to believe that the smelter could be kept in operation continuously.

Vancouver Island Prospectors Association.

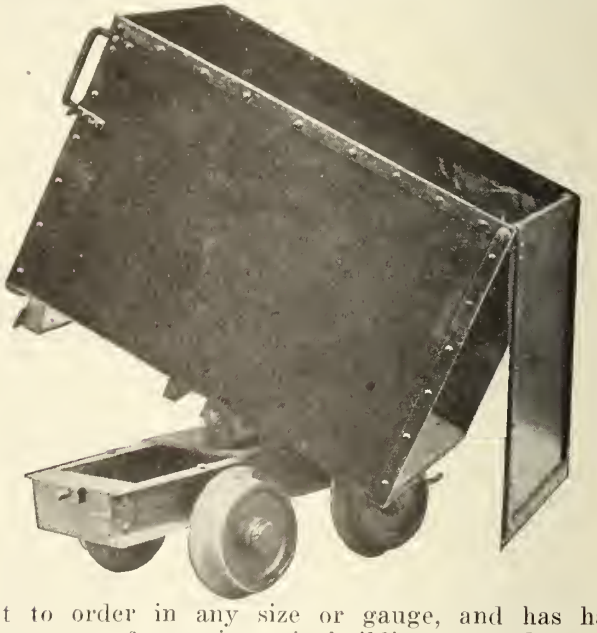
Much interest has been taken this winter in the Lectures delivered by Government mining engineers to mining men. They have been largely attended on the Coast and reports from the interior indicate similar appreciation. One of the results has been the organization of a Vancouver Island Prospectors Association, Thomas Golby being appointed chairman and G. E. Winkler secretary. It is proposed to call prospectors and others interested in mining together frequently for the purpose of discussing matters of common interest.

Shipping Ore from Mayo

Reports from Dawson, Yukon Territory are to the effect that when navigation opens on the Yukon rivers there will be shipments of ore, mined in the Mayo district, of record size. The Yukon Gold Company alone will have 31,000 tons of silver ore ready to be carried to the smelter.

CANADIAN MADE MINE CARS

The illustration, showing a side and end Mining Dump Car on a turn-table base, is one of the several designs of this type of car manufactured by the Phillip Gies Foundry of Kitchener, Ont. This firm, which has been established for upwards of twenty years, specializes in the manufacture of mine cars



built to order in any size or gauge, and has had many years of experience in building cars adaptable to Canadian conditions.

The car shown is 18 inches gauge, with a capacity of 20 cubic feet. With the equipment and facilities this company control at Kitchener they are in a position to turn out these cars in any quantity that may be required by our Canadian mines.

In addition to this line they also manufacture the "Superior" Shaking and Dumping Grate, as well as a line of vises and other equipment useful to the Mining Industry.

The Standard Steel Construction Co. Limited of Welland, Ontario, have received the contract for the structural steel work of the new mill building being put up at Schumacher by the McIntyre-Porcupine Mines Co., Ltd. The work on this building will be proceeded with at once and will make quite an addition to the already extensive plant at this Company's mines.

It is reported that gold has been discovered near Bontddu, Merionethshire, Wales, whilst men were preparing to plant trees. It will be interesting to see whether the "Axe" of economy will now fall less heavily on the Department concerned with afforestation.

Northern Ontario Letter

THE GOLD MINES.

A steady stream of gold bars, pouring out from the big producing gold mines in the districts of Porcupine and Kirkland Lake, is drawing widespread attention to the mining fields of Northern Ontario. Everywhere, there seem to be signs of prospecting activity on a scale heretofore unequalled in these districts. In some instances, the attention of speculators is found turning to the stock market where quick fortunes are being made through the spectacular rise of prices on the open market. Interest of a more lasting variety, however, has turned to new properties where exploration work holds out promise of new and profitable mines being developed.

Porcupine Peninsula.

As a result of the exploration work going on, some good results have been encountered in that part of the Porcupine mining division lying on the north-east shore of Night Hawk Lake. Lateral work has been under way on the Porcupine Peninsula property, under the management of A. R. Globe, a former superintendent of the Hollinger Consolidated Gold Mines. The vein has a width of between 18 and 20 feet and is being opened up by a drift at the 200-feet level. Cross-cuts are being run at intervals of every 50 feet along the vein. Visible gold is present in the quartz and the assays are reported to be promising.

A. Lewisohn in Goldale.

According to official advice both from the Goldale Mines, Ltd., and the Kerr Lake Mining Company, it is learned that Messrs Adolph Lewisohn & Sons of New York have entered into a contract to purchase a considerable block of stock in the Goldale property at Porcupine.

The Lewisohns made an outstanding success of the Kerr Lake mine at Cobalt and are rated among the first-class mine operators of this continent. Their entry into Porcupine is therefore regarded as being extremely important.

A feature of the deal is that it involves fifty mining claims made up of fifteen groups, and that a considerable part of the property lies at the north-east end of Pearl Lake in direct line with the strike of the big deposits of the Hollinger and McIntyre mines. Also, a considerable acreage lies adjacent to the Dome Mines on the north-east.

It is understood that the work will be done by the staff of the Kerr Lake Mines, with Harry Kee in charge of operations.

South Keora.

The promoters of the South Keora property have succeeded in raising about $40,000 and are endeavoring to increase this amount preparatory to resuming operations by early summer.

Dome.

According to late information, the output from the Dome Mines for the first quarter of the current year will exceed $900,000, and, with the premium on United States funds, may realize a gross income of not far under $1,000,000 for the three months. This achievement is far ahead of anything formerly recorded on the Dome.

Increased Efficiency.

Much higher working efficiency is being established at the gold mines and the cost of producing the metal in Porcupine promises to undergo a subtantial decline this year. It is noted particularly at the McIntyre that a substantially reduced force of men are doing more work than did the larger force not long ago. This is pointed to as being extremely important from the point of view of the stockholders.

V. N. T. to Reopen.

It is now practically assured that the Porcupine V. N. T. will be in full operation some time during April. The controlling interests of this mine are also in control of the Keeley Silver Mines where outstanding success is being achieved, which fact is said to assure funds for carrying out an extensive plan of operation on the Porcupine V. N. T. No attempt will be made to operate the mill before several months of development work.

Kirkland Lake.

The Journal representative made a general tour this week through the central part of the Kirkland Lake district and is in a position to record some interesting facts. One of these is that the Kirkland Lake Mining Company, which is controlled by the Beaver Consolidated, has encountered a change, or, rather, repetition of the geological condition at the lower levels as compared with that found at the upper levels. The porphyry intrusion in the upper workings appears to have petered out, but work at the 7th and 9th levels seems to be on the apex of an ore shoot distinct from that worked closer to the surface. The ore at a depth of 900 feet is high grade and the work of connecting the central shaft to this level will be completed within the next week or so. The opening up of the 8th level will be undertaken, while arrangements will be made to carry the main shaft down to a depth of 1,150 feet, thus providing working levels at 900, 1025 and 1150 feet deep. The probability is that this zone of enrichment may be the continuation of what was recently developed at the 600 feet level of the Teck-Hughes, which comes close to surface on the Lake Shore.

Teck-Hughes.

During February the Teck-Hughes handled an average of 149 tons of ore daily, the mill having reached as high as between 170 and 180 tons per day on certain dates. Meanwhile, the work of continuing the winze from the 600 feet level to a depth of 980 feet is proceeding at a good rate. Some early delays occurred, but the winze is now down about 700 feet and is proceeding at the rate of approximately five feet per day. After this work of sinking is completed, attention will then be turned to the development of levels at depths of 605, 730, 805 and 980 feet. The work recently done at the 605 ft. level will be remembered as having opened up a considerable quantity of high-grade ore.

Wright-Hargreaves.

At the Wright-Hargreaves, the mill during February handled an average of upwards of 200 tons of ore daily. This was a new high record and is in excess of the capacity for which the mill was originally designed. Gold bars are poured twice monthly, each clean-up being made up of two or three bars of an aggregate value of $30,000 to $40,000, or at the rate

of not far under $70,000 monthly. The work of sinking toward the 1000 feet level of the mine is proceeding. Production is coming from the 200 and 400 feet levels, while the shaft has been carried to 550 feet, where a station has been cut.

Tough-Oakes.

Within the next two or three weeks the mill on the Tough-Oakes mine will be in shape for operation. All is now in readiness to place the cable and buckets on the aerial tramway, while the crushing station at the central shaft (formerly the Burnside No. 3) is also nearing completion. The new ore at the 400 feet level has been made accessible from the central shaft by a cross-cut, while another cross-cut is being driven north to the No. 11 vein. The main shaft, three-compartment, will be at the 550 feet level by the end of March, at which point another cross-cut will be driven to open up the downward continuation of the new ore body.

Lake Shore.

During the month of February, according to the regular monthly statement of R. C. Coffey, manager, the Lake Shore mill reduced 1,961 tons of ore and produced $44,082.20. The mill ran 97-17 per cent. of the possible running time and treated an average of 70 tons of ore daily. The grade of the ore continued high, at $22.48 from each ton treated.

THE SILVER MINES.

McKinley-Darragh.

The expectations of a general revival this spring in the Cobalt district has not been justified as yet. The announcement that the McKinley-Darragh would not be re-opened this spring came as a disappointment to the community in its vicinity.

Nipissing.

On April 20th, the Nipissing Mining Company will disburse a regular quarterly dividend of 3 p.c., to stockholders of record March 31st. The financial statement shows liquid assets of $4,287,933.55. The physical condition of the mine continues to be favorable and the production is being well maintained.

Sanderson.

A deal is being arranged where by the Sanderson property in the Gowganda district may be operated. A Montreal syndicate is interested and the necessary arrangements are being made to finance work.

Elk Lake prospectors have re-staked a large number of claims that were numbered among the recent forfeitures. Among these were such proprties as the Tee Arr, Crown Jewel, McKenzie, McCrea and so on.

La Rose.

Information just obtained would tend to indicate that the voting at the forthcoming meeting of the La Rose Mines will result in a return of the present management by a large majority.

It would appear as though the shareholders' committee that seems to make its headquarters in a Toronto brokerage office, is meeting with widespread opposition, and that the uneasiness created by the sudden attempt to discredit the management is rapidly being allayed in the light of the real facts of the situation.

There seems to be no doubt entertained but that the directorate headed by Lorne McGibbon will be returned and that the management of the mill will continue under G. C. Bateman.

JUDICIAL SALE OF MINING PROPERTIES, PLANT AND EQUIPMENT.

IN THE SUPREME COURT OF ONTARIO.

IN THE MATTER OF PREMIER LANGMUIR MINES, LIMITED; AND IN THE MATTER OF THE WINDING-UP ACT AND THE AMENDMENTS THERETO.

Pursuant to the order for sale made herein, dated the 28th day of February 1922, there will be sold by public auction by the Liquidator, with the approbation of H. S. Blackburn, Esquire, Local Master of this Court at London, at his Chambers at the County Buildings, Dundas and Ridout Streets, London, Ontario, on Monday the 1st day of May 1922, at the hour of 3 o'clock in the afternoon, the following lands, buildings, mining plant and equipment, namely: those certain parcels of land situate in the Township of Langmuir in the District of Temiskaming (Ontario) and numbered 39, 40, 41, 42, 43, 44, and 4373 in the Register for the District of Temiskaming, containing two hundred and fifty-five acres more or less and being the mining properties formerly owned and operated by Premier Langmuir Mines Limited as a barytes property; together with the buildings, mining plant and equipment now on the said mining properties and heretofore used in connection therewith.

On the said lands are situate the following buildings: Mill Building, Engine House and Boiler House, Blacksmith's Shop, Superintendent's Office, Shaft House — all of which are protected by asbestos sheeting — Office, Storage Building, Bunk Houses with beds and bedding, Dining Camp with ordinary equipment and a stable. The Mill Building is equipped with the following machinery: Crusher, Dryer, Jiggs, Pulverizer and necessary shafting and pulleys. The Engine House is equipped with a Goldie-McCulloch Engine, 150 h.p. and the Boiler House contains a boiler of 125 h.p., a hoist and other equipment. There is an electric light and power plant, a tramway from the mine to the water, two horses and harness.

There are on the property about 125 feet of shaft work and about 250 feet of tunnelling and drifting.

The Liquidator has a letter from the Provincial Geologist, Ontario Department of Mines, stating that "the veins are strong and well defined and there is a large quantity of barytes in the deposits". There are showings of native silver and argentite in some of the veins. Photographs and descriptions are contained in some of the Government mining reports.

The lands are situate in the Township of Langmuir in the Porcupine Mining Division and are on the Night Hawk River about 30 miles from Connaught Station on the T. & N. O. Ry. and about 30 miles south east of Porcupine.

The property will be sold in one parcel.

Ten per cent. of the purchase money is to be paid down on the day of sale and the balance, over and above the amount which may be found to be secured by a mortgage on the said lands to secure a bond issue (which mortgage the purchaser is to assume), to be paid within thirty days after the sale or as soon thereafter as the amount of the mortgage is ascertained.

In the event of the amount of the mortgage not being ascertained within thirty days after the sale the purchaser shall, if required, pay such additional sum on account of the purchase money as may be fixed by the said local Master, having regard to the probable amount which may be found to be secured by the said mortgage, and upon such payment the purchaser shall be entitled to possession. Any balance remaining unpaid after the amount of the said mortgage is ascertained shall be paid forthwith thereafter.

The purchaser is to search the title at his own expense and fifteen days from the day of sale shall be allowed for that purpose and if any objection to or requisition on title is made within that time which the vendor is unable or unwilling to answer or remove the contract shall cease and the deposit money will be returned to the purchaser without interest. The vendor is not to be bound to furnish or produce any abstract of title or any proof or evidence of title other than those in his own possession.

In all other respects the terms and conditions of sale will be the standing conditions of The Supreme Court of Ontario.

Further particulars can be had from F. W. Raymond, Esquire, Liquidator of Premier Langmuir Mines, Limited, London, Ontario, and from Ivey, Elliott & Ivey, Esquires, London, Ontario, Solicitors, for the Liquidator.

Dated at London this 13th day of March, 1922.

H. S. BLACKBURN, Local Master, Middlesex.

EDITORIAL

T. A. RICKARD

OUR old friend and new conjoint contemporary Engineering and Mining Journal-Press, made its first appearance on April 1st. We observe with approval that the front outside cover is adorned with a characteristic portrait of Mr. T. A. Rickard, who, since the merger, has become contributing editor to the consolidated publication.

That Mr. Rickard's services have been retained is a matter of most sincere congratulation. His absence from the field of technical literature — particularly from the quarter-section of polemics — would leave a distressing gap. Mr. Rickard's writing has been variously characterized. We have heard it described as "mordaunt", "vitriolic," "incisive," "polished," "splenetic," "clarent," "lucid," "forceful", and in numerous other ways. To some of these adjectives, Mr. Rickard himself would take strong exception, quite apart from any question of their applicability. To us they seem either inadequate or inept. As a matter of fact, Mr. Rickard is first a trained, honest, and capable observer, a fearless recorder of his observations, and a careful user of the English language. Add to these qualifications the divine spark, a touch of knight errantry and the habit of writing only when he has something to write about, and you get a fair mental picture of the *doyen* of English technical writers.

We wonder if Mr. Rickard will resent the epithet!

DISPUTE AND STRIKE.

THE introduction of the policy of "striking on the job" in Nova Scotian collieries is in essence a criminal act. The moral responsibility for this overt misdeed rests primarily with Organizer McLachlan. In lesser degree the miners themselves must bear the onus. By no perversion of logic can the stand thus taken be condoned. The policy is short-sighted, stupid and unequivocally dishonest. That any of the miners have been led into it is deeply to be regretted.

Miners are citizens, normally the very best of citizens. All large aggregations of men following the same industrial calling may, under stress, become foolishly responsive to the demagogue. In doing so, they lose sight of their inescapable duty as citizens, of their obligation to the community and to the nation, to the association of fellow-beings that makes existence possible for them and their families.

If the Western miners' demands are as represented in the daily press, then it is out of the question for the operators to accede to them. If the operators are guilty of a breach of faith, then it is incumbent on the Governments of the United States and Canada to see that faith is kept.

But there are far too many "ifs" involved. What the consumers must have is a judicial presentation of both sides. Meantime both sides will lose face if wrong methods are tried. The public is judge and jury.

EDUCATING THE PUBLIC.

AT a meeting last week of the Associated Boards of Trade of Northern Ontario, a resolution was passed asking the Provincial Government to give more publicity to Ontario's mineral resources. Resolutions were also passed asking for better transportation facilities, and the enlargement of the activities of the geological department.

The communities of Northern Ontario exist mainly by reason of the mining industry, and realize the fact. Throughout the older parts of the province, the facts of the mining industry are known only vaguely, if at all. The present effort of the newer community to educate the older is commendable, and worthy of being continued.

The advertising at present enjoyed by the mining industry is not altogether of a savory sort. Our newspapers publish the current prices of shares, sensational movements in shares, and news items, mainly calculated to influence the market. Occasionally items of more substantial interest creep into the columns, but this is more by accident than by design. One result of this condition is that some of the more reputable of our newspapes refuse to publish any mining news or notes unless these have undergone a severe censorship — and few items survive. But the main result is, and a deplorable result it is, that the public has been educated to the belief that mining consist mainly of trading in shares, and that mining is a business of dubious character, highly speculative, and radically different from any of the more substantial and better known phases of our national activity.

Nor does the trading in shares itself give any substantial return to the mining industry. It is true that, when a spectacular "boom" in gold shares is in progress, the public learns more about our gold mines. But truth is so inextricably mixed with falsehood that it is difficult, if not impossible, for any but the initiate to separate the wheat from the chaff. The results, on the whole, of trading in mining stocks are probably such that no trading at all would be better for the industry. The real issues are usually obscured

in the trading, and it gives justification to the idea, almost universally held at present by the public, that mining shares exist primarily as a means for stock gambling.

What our mining industry needs, and needs badly just now, is disinterested publicity of a general sort, such as will help the public to consider mining as an industry, and of our undeveloped mineral resources as sound and safe bases for the establishment of new enterprises. Unfortunately, the men that labour hard and long to make mines are not organized as are those whose business it is to trade in shares. Consequently the united voices of those calling from the stock markets on behalf of the mining industry almost drown the calls for aid from the operators of mines and prospects. The public pays attention to the loudest shouting, rather than to the relative merits of the causes advocated. It reminds one of the nomination of a President in the United States!

Every means must be adopted whereby the average citizen may become more fully cognizant of the facts of the mining industry. Only by this means will mining get its full share of public support, and take the place in our national economy that it must and will occupy. We must tell the public the true story of the prospector, working year in and year out, despite discouragement that would deter all but a genuine enthusiast, and the reward often all too meagre, that attends his effort. We must let it be known how the engineer takes over the find from the prospector, and develops it to the point where Nature's store is available for human use. We must warn the public of the tendency their funds have to shrink, and even evaporate completely, on the devious way from their pockets to the new mines and mills. In short, we must lose no opportunity of introducing to the public the man who has made mining his business, and is today doing more than any other to make Canada and Canadian prosperous.

MINING INVESTIGATIONS.

THE United States Bureau of Mines, of which Mr. H. Foster Bain is director, has issued a summary report of the principal investigations it is conducting. This report shows that a large number of technically trained men are carrying on work for the Bureau. Over three hundred investigations are under way. A great variety of subjects is covered, including such diverse ones as analytical distillation of petroleum, causes of death among coal miners, effect of furnace lines on blast furnace operation, methods of extracting pillars in coal seams, precipitating copper from sulphate solutions, ventilation in deep gold mines, application of military explosives to commercial purposes, prevention of losses in sluicing placer gravels, handling rock drill steel in mines, preparation of iron sponge, iron mining methods, shooting of oil wells, and air currents in metal mines.

The Bureau is evidently finding a great deal of useful work to do in the mines of the United States and in allied industries. The contributions of these investigators are quickly made available to the industry. Much work is done that is a benefit not only to the industry in the United States but to mining everywhere. The Bureau is doing good work and we have little doubt that its efforts are appreciated by United States mine operators. Many of the investigations are of importance to men in the mining industry in Canada, and the reports of progress are welcomed here. In the distribution of information, Americans and Canadians fare alike. We, working under pioneer conditions, cannot afford to undertake such extensive work of investigation as is centred in Washington; and we appreciate the friendliness of our neighbor.

THE GOVERNMENT GEOLOGISTS.

THE request for enlargement of the work of the geological department of the Ontario Department of Mines has been frequently made. The department does good work, and more is wanted. The staff is, however, too small to permit of its doing half the work that is asked for, work ranging from preliminary examination of new areas to detailed underground geologizing at mines. Most attention is paid to the geological mapping of new and promising mineral-bearing areas. A few areas have been mapped in some detail, and with these as keys, larger tracts are rapidly run over in an effort to guide the prospectors.

The results of this areal mapping have been very satisfactory. Criticism is often heard of inaccurate plotting or of rash statements made after brief examination; but on the whole the work is very well done and most of the criticism is based on the assumption that the mapping has been detailed. Only in a few areas has detailed work been attempted. The inaccuracies of the areal maps are for the most part the natural result of an effort to sketch boldly the outlines as a guide in exploration.

With its very limited staff the Department has evidently sought to assist prospectors rather than operating mines. This policy is generally commended, and the prospectors have made good use of the maps prepared for them. Tangible evidence of appreciation was given at the Ottawa meeting of the Canadian Institute of Mining and Metallurgy, when a well known prospector moved that a vote of thanks be tendered a well known geologist of the staff of the Department.

If the Department had a large staff it might be possible to do a greater variety of work, all of which would be useful to the industry. At the operating mines there is always something to be learned about

the character of ore deposits, and structural features are better understood as mining progresses. A good record should be kept of the geological information gained as mining proceeds, and to this end studies such as have been recently made at Cobalt should be carried on in all our important mining districts. If, however, such studies can only be carried on to the neglect of the areal survey, we believe that the latter should have the preference, now and for many years to come. Our geologists are mere humans; they cannot be underground and placing claim lines at one and the same time.

EDITORIAL NOTES.

According to figures just made public by the Dominion Bureau of Statistics, the total deficits for the past year on railways owned by the Dominion Government is $68,000,000. It is obvious that radically constructive measures must be taken to increase the earning-powers of these railways. The chief undeveloped source of non-seasonal freight lies in the mineral deposits in territory tributary to the railways. Facts and figures relating to this have appeared in these columns a score of times. It is surely the bounden duty of our Government systematically to investigate these possibilities. Not vivid imagination, but clear business vision is called for in formulating a policy that will put our vast systems of steam transportation on a paying basis.

A contributor in this issue suggests that prospectors and those directly interested in them should band themselves into an Association for mutual benefit and protection. It is not so generally known as it should be that there are already throughout Canada, local Prospectors' Associations. The latest addition, announced in last week's Journal, is on Vancouver Island.

The functions of these Associations have still to be clearly defined, and they need co-ordination. But here is the beginning of a movement that may work wonders in helping the genuine prospector and his financial backer.

The Journal wishes to add its congratulations to those of Mr. W. H. C. Mussen's host of friends. The removal of Mussen's Limited from the voluntary liquidation into which it entered in 1915 marks the accomplishment of an undertaking only too rarely entered into by men of business in Canada. Mr. Mussen has publicly vindicated his probity, which no one that knew him ever doubted, and his business ability, on which only the irrational and panicky conditions of 1915 threw any shadow.

PULVERIZED FUEL.

An Inexpensive Plant.

In this country, where metallurgical installations are liable to be small, it is of interest to have plants that are comparatively simple and inexpensive. The ordinary plant for pulverized fuel is rather complicated, and includes machinery for drying, crushing, pulverizing, conveying and storage. In the Foundry Trade Journal of January 12 is described a simple apparatus, built by Stein and Atkinson Limited, Victoria Street, London, S. W. It is in use with heating furnaces and steam boilers.

The unit is a pulverizing mill and fan combined, and consists essentially of a single steel casing containing three compartments, two with blades for crushing and pulverizing the coal, and the third with a fan. Part of the air required for combustion is admitted with the coal, and it is the speed of this stream, carrying away the fine particles, that regulates their size. The remainder of the air serves to convey the coal to the burners. The moisture, if not abnormally high, is vapourised by the heat generated in the pulvering chambers.

The particular installation described is a heating furnace for small ingots, ten feet by six feet. Slack coal is used, containing 23 p.c. ash and 10p.c. moisture. With the hand firing previously used, the furnace consumed 12 cwt. of the best coal per ton of ingots heated; only 3½ cwt. of the pulverised slack is needed now. The cost of power for the unit is 8s. 8d. per shift of eight hours.

COAL DUST EXPLOSIONS

Sir William Garforth, who died near Pontefraal, England, last October, as early as 1891 suggested the use of "stone-dust" for the prevention of coal dust explosions. Seventeen years later Sir William proved that coal-dust is explosive without the presence of gas. Next he proved that stone-dust would extinguish the flame of an explosion. He was also a leading pioneer in introduction of deep underenting machines. His experimental gallery, erected to test breathing-apparatus, was the first ever constructed.

CONCERNING CHEESES

Prospectors, they may toast a bit
The engineer may crow,
The mill man may with pride be lit
But did you ever know
The plain geologist to brag
Or claim to be the cheese
Or chew the metaphoric rag
No, Sir! And, if you please,
Don't snicker, and pray do not laugh,
For what I say is true—
Geologists must stand the gaff
For me and them, and you!

ANON

The Prospector and the Grubstake

(Written specially for the Canadian Mining Journal.)

IF prospectors could be organized into an incorporated body, there is little doubt that they could bring suit successfully against the general public and against novelists and magazine writers in particular. The magnificent types of supermen, Galahads, parfait pinks of chivalry, indomitable two-six-gun men (that phrase doesn't sound quite right), knights errant, suffering and abused lovers, are some I have never seen or heard of in real life. They exist only in fermented imaginations and on the printed page. Action for libel would be sustained by any judge in Christendom—or should be.

Added to this, the general public, or that part of it that is interested in mineral deposits, thinks that the prospector has only to wander casually through bosky glades, encounter a vein, corrall it, and make the fortunes of all concerned.

Neither point of view is sane, and each is unprofitable.

Defining the Prospector.

The work of prospecting is as arduous, calls for as much constructive thought, as that of any other vocation or profession. It demands an unusual amount of initiative.

The good prospector plans carefully his season's campaign. His work is consecutive and cumulative. Gradually and painstakingly he delimits the areas that he intends to go over intensively. He depends not upon luck, but upon sound reasoning. He must be a practical geologist; but this does not imply that he is able clearly to put his geological thoughts into words, although often he can.

It is essential of course, that he be an efficient bushman.

Granting these qualifications, (and only too few men of this generation possess them), it will be admitted that the prospector is worthy of his hire, and of something more.

The Prospector and the Grubstaker.

We are enjoined in Holy Writ not to muzzle the ox that treadeth out the corn. Yet the man behind the prospector is only rarely willing to give him half a chance. This is a fact. One reason for it is partly indicated above. Another reason is that the grubstaker is often careless in the selection of his man, and thus fails to get a *bona fide* prospector. Perhaps he ties up with a man who intends only to have a pleasant summer at the expense of his partner, and who will loaf on the job without shame. The grubstaker is wholly to blame for this, but the *bona fide* prospector is the goat in the long run.

I believe that, except in extraordinary circumstances, no prospecting party should be sent out unless ample provision is made for keeping it in the field for at least two years, if not three. Provision should also be made for preliminary testing of the more promising claims that may be staked. In other words, a prospecting party should be organized and managed on business lines, and with an eye on possible future needs.

The qualified prospector puts into his work the experience of years of hard training. His proper occupation covers only part of the year. He is not a wage-earner. His object is to make a stake, and more often than not, to spend that stake in finding other saleable claims. Disappointment hit him harder than it hits the grubstaker. He must start all over again against the same chances of failure.

The Prospector's Guerdon.

It is my conviction, therefore, that there should be created a guild, or Protective Association, or something of the kind (so long as it has no kinship with a labour union), whereby recognized prospectors may be safeguarded. Legislation does not protect, because all such legislation can be evaded. But the prospector and the grubstaker can afford each other mutual protection.

Briefly, then, the grubstaker risks only his money. The prospector risks everything that he has and is. Fair play demands that he should be a partner to, let us say, the extent of from 25 per cent. to 50 per cent. in all valuable discoveries made. Circumstances may modify this arrangement. Yet I think it a good basis to work from.

I suppose that not more than one prospector in a hundred makes even a moderate stake. Yet good men are willing and anxious to take on the ungrateful task of making other men rich.

Coming To The Prospector's Help.

Information has come to me from reliable sources to the effect that the Dominion Geological Survey and the Quebec and Ontario Departments of Mines are this year making a special effort to delimit certain mineral-bearing districts for the express benefit of prospectors, to save them needless work and to give them sound guidance. This is good hearing.

I, along with my fellow mining men, devoutly pray for the time when governments, investors, mining engineers, and prospectors will realize that their interests are indissolubly linked together.

CAPRICORN.

NOTES FROM GOWGANDA

(Special correspondence.)

Things are looking up a bit in this district. The Miller Lake-O'Brien is producing steadily, although working with only one shift on account of power shortage. This could be avoided if available storage basins were not withheld from use on account of some departmental technicality.

The Castle property has been re-opened under the management of Mr. Murray Kennedy, brother of H. G. Kennedy, manager of the Miller Lake-O'Brien.

The Sanderson discovery at Wigwam is under examination by a well-known Montreal engineer.

A prospect at Silverado, about twelve miles south of Gowganda, has been under development for some time.

The re-staking of claims, following the recent cancellation of leases for non-payment of taxes, has been pretty extensive. It is understood that the development of some of the properties will be carried on promptly and vigorously by the stakers.

Sequel to Sinclair's "Jungle" Book

by "ARGUS."

SUDDENLY, and for reasons quite obvious (if unexplained), the "Standard" of Montreal (owned by the "Star") has begun to loosen depth bombs at the steel and coal companies of the Maritime Provinces. A special "investigator," actuated no doubt by humanitarian as well as economic purposes, asserts and insinuates that there is a new theme for a second Upton Sinclair in the jungle of Nova Scotia. There are "ugly, sinister stories" afloat about the "miseries," "gouge-games," "tyrannies" and other varieties of frightfulness involved in the management of mines and miners by the constituent companies of the British Empire Steel Corporation.

According to the preamble, "romantic history" and tragedy are so interwoven that the serial from the pen of the "Standard's Special Commissioner" is going to be interesting. He has undertaken to purge an Augean stable, and his river of words is gathering force and speed for the task.

The scene opens with the efforts of the poor-but-honest pioneers. The "Standard" generously concedes that Graham Fraser, Forrest McKay and James D. MacGregor were well-intentioned men,—but their like has not since been in that community. Heroes there were in those day, fit for the hard struggles they encountered. To quote the "Standard" without censorship, here is what happened:

"The real savior of the whole concern was Mr. R. E. Chambers, the gentleman who discovered and located the vast ore bodies at Wabana, Belle Isle. This saved the company at a critical period, although Mr. Chambers, at the present time, is not much in the limelight. The officials of the company never were burdened with much technical knowledge of steel making. During the years of Moxham's regime there was lavish expenditure and much waste. It is probable that the company's properties never really had the services of first-class technical experts. In the coal department there has been waste, and there is waste today in the methods of production. As a matter of fact, there is not a mine in Nova Scotia being properly mined, or properly equipped for mining. This is one of the things that the Government should thoroughly investigate. When Mark Workman took hold, his management was not popular in Nova Scotia, but it showed result and there was never any charge of mismanagement. The retirement of many Canadian business men of first-rate ability from the Board at the time of the merger has undoubtedly proved a great weakness. Some of those acting in Great Britain in an advisory capacity form another weakness. . . . . .

"Since the big strike of twelve years ago, Glace Bay has never been normal. At that time, and since, the suppressive power of certain factions, exercised over liberty of thought and speech, has now grown into a habit of mind. In Glace Bay today, you will find men unable to express their thoughts above a whisper—men cautious to the verge of timidity—men too frightened to declare their convictions. To these men, heedless outspokeness would seem the height of folly, to these men, prudent silence would seem the only way to avoid innumerable risks, **mysterious hidden dangers.**"

There are many counts in this indictment—and more to follow. Following the line of departed heroes there has been a succession of lesser administrators—Cantley, Plummer, Crockard, Fergie, Workman and others still within the jurisdiction of terrestrial courts. Among all these, only the "Knight of the Goose" has won the "Standard's" approval. The "Standard" will not accept the contemporary judgment of their peers as to the professional qualifications of these leaders in industry; the "Standard" deems them unworthy successors of men of "integrity and considerable business ability." So be it!

It is rather startling to find that "first-class technical experts" were never retained to advise the several companies. A number of the most eminent engineers have been bought for consultation from Britain and the United States, where their reputation has been of the best. It is a certain satisfaction to discover, through the columns of the "Standard," that these engineers have fooled not only Nova Scotians, but their own countrymen as to their attainments.

The "Standard" brings an additional charge against the "many Canadian business men of first-rate ability "who" retired from the board at the time of the merger" a few months ago. It professes to admire these men; but actually it points out that "the miserable condition of present-day Glace Bay," a town of "mysterious hidden dangers" where "you will find men unable to express their thoughts above a whisper," was brought about during the years when these men *were* on the respective boards, and responsible for the alleged mal-administration. The "Standard" has launched a javelin that turns out to be a boomerang!

Seriously, such stuff as is offered to the public from the pen of this "Special Commissioner" impugnes the intelligence of the average reader. It is calculated to excite the imagination of "Reds" and others of unbalanced temperament. It is a deliberate attempt to excite class jealousy and [illegible]. It shows an ignorance of the facts of the case, [illegible] nearly the engineering facts, that would make a [illegible] merely smile were its influence not likely to mislead the uninformed.

Ex parte accusations anonymously made are not decent propaganda, and should not be taken too seriously. But in the present disturbed state of industry and of men's minds, stuff of this sort is intolerable even in the pages of the "Standard."

In the Katanga region of the Belgian Congo a tremendously large copper field was located by one George Gray, twenty years ago. A group of British and Belgian investors, operating under the name of Union Miniere Tanganyika, has opened up and equipped the property, made connection with ocean ports and prepared for production on an immense scale. Work has proceeded for years, despite the decided adverse report of a prominent mining engineer some time ago. In the year 1914 a consulting engineer was engaged whose duties consisted largely of following progress made in treating copper ores, particularly in the United States. It has been decided that a leaching process is most suitable for the treatment of the Katanga ores. The Company, therefore, is developing large water powers and preparing for an output of 50,000 tons of copper per year. It seems highly probable that this enterprise will rival in importance the largest of the Western United States porphyries.

Tinkering With The Wages Dispute

By our Nova Scotia Correspondent

The struggle over the wage question in the coal industry of Nova Scotia seems to have entered upon a new phase and the industry itself is to become a political football during the coming weeks. It was just beginning to break in on the minds of the mine workers that the laws of trade cannot be side-stepped and the peak wages of war could not be maintained, when a new factor appeared to keep the trade in turmoil and the colliery districts in continuous ferment. The result promises to be an almost idle summer at the collieries and undue advertising and exaggerating of alleged bad conditions existing at every colliery town in the Province. The whole nation will be asked to shed tears over the miners of Nova Scotia, who, as a class, are much better off than most elsewhere.

Had the miners been left to fight out their own battle without government interference, the stability of the coal trade of the Province would have been assured for years to come, and miners would have settled down as good citizens whose occupation is to mine coal rather than agitate to lower production by "striking on the job."

Not satisfied with the award of a Conciliation Board, the senate of Canada resolves to appoint a commission of enquiry into the wage question, and the Government offers to reconstitute the Gillen Board. It will take weeks to get the machinery in operation and the end of the whole business may be just as unsatisfactory as was the first award of the Gillen Board.

Meantime Nova Scotia will have had a lot of free advertising as the land of the slave, while the whole country waits patiently for lowered coal prices and cheaper fuel. How this is to be brought about is puzzling to the minds of those who have an expert knowledge of the coal trade. Markets which all along have been claimed by Nova Scotia have been invaded, and it appears only a matter of time when these will be lost for good. Foreign coal is being landed in St. John, N. B. and in Halifax. Large unloading plants are being erected at St. John; storage ground has been bought and preparations made for conducting a permanent business. That a part of the coal market can be filched from Nova Scotia at a time when collieries are only working half time, and some of these attempting (though not succeeding) in carrying out a "striking on the job" policy, is an unmistakable warning of danger. The difficult conditions of coal mining in Nova Scotia place it at a disadvantage with American coal, but we should expect to hold our own against American and British coal in ports close to our mines. If we cannot do this, how can we capture territory further afield? It cannot be done so long as the coal industry is made a bone of contention to further the interests of some political party. "Hands off" shuld be the policy of all Governments at a time when the revival of trade depends largely on cheap coal and lower railway freight charges.

Looking back over the past three months, one sees two large, well-organized bodies coming together to try to find common ground for a wage agreement. Pubic sympathy strongly favored the United Mine Workers because it was generally thought that the wage reduction was too great.

The Empire Steel Corporation, like all hugh concerns, was feared, and we do not love the thing we fear. Public sympathy was against it. The parties failed to find common ground for an agreement, and the dispute was placed before a Conciliation Board. The findings of the Board favored the men, but even then they would not accept the award. The public still clamored for a further conference between the company and the men. Both parties were agreeable and a new offer was made by the company, which brought the wages up to a higher level. A wage agreement was signed. This was subject to a referendum of the Union and was defeated. On none of these occasions had the union made the move that brought on the conference.

This unbending attitude on the part of the workmen alienated public sympathy, which shifted to the side of the Company. The Secretary of the district openly advocated "striking on the job" and publicly insulted the Premier of the Province and the Minister of Labor. This outrage of moral feeling disgusted all good citizens and changed the question at issue from the material one of wages to one of public morals.

The first question now to be settled is whether any man is to be permitted to openly advocate the destruction of an industry because it cannot pay the wages demanded by an unreasoning and ill-advised labour union. The question of good citizenship is before all other questions, the first one to be settled, and any attempt to pass it over will leave the mining towns of Nova Scotia a prey to every ambitious and selfish agitator that comes along.

To the credit of the International Union in the United States, it is opposed to the pernicious practice of "striking on the job." The Sherman Act is aginst restricting production, by either monopolies or labor unions. We, in Canada, seem to have no such law and rely on public sentiment to frown upon conspiracy to restrict output. But public sentiment has failed on this occasion and as general sentiment is the basis of law, why not crystalize it into life and action? This gain alone might mean much for our country in future labor struggles.

With our knowledge of labor conditions in Nova Scotia we are safe in saying that interference by any party at this time will establish a precedent of which labor unions in the future will take advantage. No dispute will be considered settled until it has passed before Conciliation Boards and Royal Commissions and been reopened and reviewed until the public becomes weary and disgusted with the whole procedure. Then competent men will refuse to serve on Boards or Commissions to adjust labor disputes in Nova Scotia.

We are more than three-forths of the way through the dispute. Why not let us finish it and be done and let each party take what is coming to it?

The principal market for the iron ore of Scandinavia is in Germany. The financial disabilities of Germany since 1914 are well illustrated by her imports of iron ore from Norway. These dropped from over 300,000 tons in 1914 to 25,000 tons in 1919. In 1920, though, German iron-masters were evidently once again able to satisfy the Norwegian exporters as to their ability to make payments, as the imports of ore jumped suddenly to over 200,000 tons.

The Late John Ballot of Minerals Separation

By ALEXANDER GRAY.

JOHN BALLOT under whose direction Minerals Separation by Oil Flotation wrought a revolution in modern recoveries, died in New York City on April 1st., after a lingering illness. Associating with him was Claude Vantin, and it was they who financed and perfected the processes that made practicable those economies without which the metal industries would to-day be infinitely less prosperous. His charming personality, business acumen and scientific precision, and Vautin's genius as a metallurgist, brought success where recurring disappointments would have discouraged the less resourceful. Mr. Ballot lived to see only partial fruition of this work, though flotation has been adopted by nearly all the greatest copper producers and by numerous producers of other base metals. Mr. Ballot was further rewarded by seeing it applied to coal, and now as he dies, its application to precious metal ores appears to be assured.

Twenty years ago John Ballot was urbane but lonesome. A native of Cape Colony, closely identified with South African mining developments, his smile was a benediction. His silk hat, round and neatly-groomed figure were to be seen everywhere in "the City." Flotation was his theme in and out of London Wall, Cornhill, and Throgmorton street. As usual, London was somewhat incredulous and wedded to its idols. It mattered not what others had indicated in the Elmore and other contemporaneous results, or what Vantin's research had determined.

Mr. Ballot's money went with his confidence. Loyal friends co-operated; yet the main factors in metropolitan mining circles kept aloof. Dusseldorf was observant; Swansea indifferent. Inevitably Mr. Ballot had to "plow the lonely furrow." His optimistic equable temperament was tested. Eventually he confounded his friendly and unfriendly critics, and Minerals Separation was accepted without cavil from Broken Hill to the Britannia Mine in British Columbia.

No metallurgical development (unless it be the adaptation of the cyanide process) involved more bitter controvery and persistent litigation. Throughout it all, Mr. Ballot preserved his characteristic serenity, without surrendering any of the rights of himself and his associates. Where Elmore failed at Broken Hill, Minerals Separation succeeded. That is another story, it brought animosities. Concentration of mind and money upon the flotation and concentration of minerals left no room in Mr Ballot for resentment. When he was forced to fight, he fought, though his suavity continued unperturbed.

Millions have been expended in contesting the Minerals Separation patents, and in defending them. Hundreds of millions hinged upon court decisions. Courts of all degrees have looked into the antecedents of the Mineral Separation Processes, and have tried out the claims of rivals. Mr Ballot steadfastly maintained the integrity of his position. Vindictiveness could not exist in him. When he could, he played a magnanimous role. When he was struck fouly he left nothing undone to send his opponents to the corner for the count—and he got the count.

During the Great War, Minerals Separation was assailed at Washington and in the press with a venom that rankled in Mr. Ballot—ever the most patriotic of Britishers. It was charged that Minerals Separation, was under alien enemy control. Nothing could be more libelous. Germany, it is true, had foreseen the results of the Ballot-Vantin research, and had taken over from England the mastery of metal markets (through default on the part of England) but there was never a minute when Mr. Ballot was not 100 per cent. true. He opened his books to Ottawa. On one memorable occasion, with which the writer is very familiar, Director Van Manning at Washington had opportunity to bear testimony to the splendid loyalty of Mr. Ballot, who tendered to the United States Government "every facility owned and controlled" by Minerals Separation, for War Metal purposes, leaving it for the Goverment to fix the remmneration. Thereafter, Minerals Separation could not be traduced.

Perhaps it is too early for the revelation of state secrets, and the discussion of delicate subjects. Mr. Ballot was generous in compromise and unrelenting in a fight. Minerals Separation was his life work. It made him more than a millionaire—an unpretentious, lovable millionaire. To have had his confidence in times of stress was a priceless trust. He detested obliquity; but when put upon, he exacted the penalty in full. That is why Minerals Separation fought it out rather than acquiesce in what he considered unsportsmanlike conduct. When he was asked if he would let by-gones be by-gones, and give his opponents the same terms as the Anaconda, Inspiration, Phelps-Dodge Clark interests, he recorded a vigorous negative. John D. Ryan, Ex-Senator Clark, and the Phelps Dodge people had been graceful in their recognition of the rights of Mineral Separation.

Toward Canada, Mr. Ballot preserved an affection, for it was at the Britannia Mine in British Columbia that his flotation methods were first applied on this continent. Latterly he was specially concerned with the solution of Canadian Mining and Smelting problems at Trail, and to that end Minerals Separation technical staff devoted itself. Concentration and flotation at Trail having made the Trail metallurgical works an international institution, Mr. Ballot took pride in the result and was unstinted in his commendation of the enterprise of the management. Withal, Mr. Ballot was as modest as he was masterly. He was quietly great.

At one of the oldest glass factories in Bohemia, after many years of experiments, a glass has been produced which, it is claimed, is absolutely unbreakable, says the London "Times Trade Supplement."

Receptacles made from the material, it is said, can be thrown about, made red hot and then put into cold water and yet do not break. It is claimed that hammers made from the material can be used for ordinary purposes. It is difficult to cut even with a diamond, while the ordinary carborundum stones are useless for the purpose.

The original founder of the factory whence this invention emanates was an ordinary glass worker who rose to fame by his production of [illegible] glass. It is important to note, however, that this invention can only be placed upon a commercial basis when a special kind of sand has been found and is available in large quantities. At the present time the sand is said to exist only in the neighbourhood of Dresden in comparatively small quantities.

Dog Days in the Nickel Industry

By ALEXANDER GRAY

DURING the twenty years since the International Nickel Corporation was incorporated in New Jersey, the graphic curve of Nickel Copper production, has all the acute angles the most ardent cubist could wish. No switchback has ever had more thrills and chills.

Starting with a metallurgical Ishmaelite, full of the "Old Nick," the special industry centered in the Sudbury District of Ontario has been a stormy petrel to its chief patrons and to politicians. Nickel has always, until now, been associated with the War spirit. That nickel alloyed with steel kept the ensign at the peak and sent enemies to perdition, seems to have been the greater reason for changing with every crime in criminal code those that developed the mines and perfected processes for its industrial application. If nickel had not been identified with armor-plate; had it not been a martial metal; were it clear to the popular mind that nickel always was destined to become a prime factor in widespread industrial economies, about twenty years would not have elapsed between Howie's discovery in the Canadian Pacific Railway cutting and the incorporation of the International Nickel Company, and it would not have required a further twenty years to convince all parties that the industry cannot be subjected to perversity, adversity, and recurring manifestations of resentment of its existence. Notwithstanding all of which to the end of last year it had produced:

Nickel	$169,675,494
Copper	58,721,361
Total	228,396,855

A minor fraction of those totals is to be credited to spasmodic production of copper in districts other than Sudbury. Metallic nickel, oxides and other compounds, have been recovered in incidental quantities from silver-cobalt-nickel ores, and from the Alexo and a few outside properties. The great bulk of the metals, however, came from the Sudbury norites, and as the grand aggregate represents government valuation rather than the selling price, we can gauge conservatively what it is we owe to those that fostered the ugly duckling because they could not get rid of it and recover their capital. The spending power of the industry is eloquently indicated in this partial presentation of the wage bill since the panic of 1907:

Years.	Wages	Number Employed.
1908	$2,159,055	2414
1909	2,605,128	3251
1910	2,973,172	3317
1911	1,830,526	2439
1912	3,543,419	3746
1913	3,291,956	3512
1914	3,424,352	3859
1915	3,835,179	4538
1916	4,920,720	5306
1917	6,113,572	3747
1918	7,983,526	4378
1919	4,139,523	3004
1920	6,704,883	4007
Total	$53,525,011	

There are pages in history that might as well continue turned down. Excepting as a harrowing chapter, events of the first two decades need not be recalled. There were no ecstacies. For years after the organization of the International Nickel Corporation there were no dividends upon preferred and common stock issues. So the records of the thirteen best years and what they meant in wages should not be used as an argument why the industry should be pilloried and penalized, misjudged or subjected to animadversions. In 1903, 1904 and 1905, the International company earned 6.3 p.c., 3.8 p.c. and 7.4 p.c. respectively on the preferred stock. In 1906, 8.4 p.c. was earned on the common. Just as it seemed that the organization was about to give some return, and 1907 showed 14.2 per cent. on the common, the panic upset calculations; consequently we have the foregoing table of wages paid as a reflection of later progress. Including the lean and fat years, though, between September 1902 and December 31st, 1920, this is what went out in behalf of mining and smelting operations exclusively in the Sudbury district:

Outlay on Mining and Smelting.

Labor and salaries	$35,913,755.32
Mine supplies	13,915,453.36
Coke	6,485,869.68
Coal	2,439,408.24
Wood	685,578.31
Freights	11,736,230.97
Contractors	2,014,233.77
Total	$73,190,529.65

As applied to those items and their grand total (for mining and smelting purposes solely, without reference to refining, marketing and administration) it is worth noting that 10,500,000 tons were mined while that money was being expended; so it follows that each ton meant an expenditure of $6.96, irrespective of all else. The present day inventory of $19,000,000 of which $1,600,000 is in dwellings, the hospital, schools, churches etc.; the pure water system, costing $170,000 (for life of five communities) bespeak some of the achievements resulting from the advent of those married-in-haste Ohioans who thought they had unalloyed copper fields and discovered they had the Devil's Own complication to deal with. No better epitome of the benefits accruing from the nickel-copper industry can be offered than the foregoing table and this statement by the recent Royal Ontario Commission appointed to consider the whole subject:

"It should be pointed out that the mining industry is one of the most effectual agencies in the settlement of our northern and northwestern districts. It affords employment to labor, frequently on a large scale, and provides the best kind of market for farm produce and manufactured goods. Not only the tillers of the soil, but the artisans and merchants of the older parts of the province derive a benefit from the increase arising out of the mining industry. That this benefit is large, may be judged from the fact that on a close estimate it takes ten million dollars to pay the wages and provide the supplies for the Sudbury nickel mines for

twelve months. The railway companies also feel the effects in a larger volume of business."

Through the courtesy of the International Nickel Company of Canada, in furnishing the figures quoted, we are enabled to verify the generalizations of the Royal Ontario Commission. How much more has gone and is going toward the Port Colborne Refinery that cost $6,000,000, need not be surmised. Recent developments on dams and a water storage system cost another $3,200,000. The plant at which Monel metal will be rolled is being constructed and will cost a further impressive amount. Probably that will be the last large capital expenditure; but in this connection it is as well to state that the International Nickel corporations are not borrowers. Red ink there has been in the books. However, all construction has been and is being paid for out of surplus, and what profit there is in current operations. How thorough-going are the methods of conducting International affairs, is evidenced in the following:

Disposition of Finances 1903-1920 Inclusive

Total income after charging manufacturing, selling expenses and repairs	$112,713,256.41
Administrative, head office expenses, and capital stock, corporation, United States and foreign taxes	14,937,508.46
Depreciation of plants and mineral exhaustion	16,939,726.16
Bond sinking fund and interest on bonded debt	6,440,243.31
Net profit	74,302,314.72
Preferred stock dividends	7,753,847.99
Common stock dividends	48,892,180.11
Balance to profit and loss	19,874,367.78
Expended on additional property, construction, equipment, less recoveries	25,746,547.92
Current assets	12,600,540.34
Cash, loans on call, certificates of deposit, government securities, at end of year	5,289,537.45

All bonds were retired in 1913.

It is a coincidence that the net profit of $74,302,314.72 to the International corporations, closely approximates the amount expended by the producing organization in the Sudbury District, $73,190,529.65. Not until 1906, a fifth of a century after the Howie discovery in 1885, was a dividend paid on the preferred shares of the International. The first dividend was paid in 1910 on the common shares. The latter, to the end of 1920 had brought their holders $29.22 per share and it took eighteen years to do that.

Present Position and the Future.

It is not necessary to become doleful over what is now happening. The past record of the International and Mond companies does not call for sentimentalities or "sob stuff". The International, has mined 10,500,000 tons, paid for whatever there is in plants and equipment, is in ample funds, the unparalled Creighton Mine has an estimated ore reserve of about 10,000,000 tons, and there is no doubt a further supply awaiting determination. At the Frood Mine section there is said to be another substantial asset of a probable 70,000,000 tons of disseminated ore that will average around 4 per cent. combined metals. It is this knowledge that lends an element of under-valuation to formal announcements of Messrs Hayden, Stone & Co., the senior member of which firm is the chairman of the board of the International Nickel Company of New Jersey, such as the following:

"The proven ore of the Sudbury district can be conservatively estimated at 70,000,000 tons. Of this amount the Creighton, Frood and Cream Hill mines belonging to the International Nickel Company, contain ore reserves of approximately 57,000,000 tons.

"The Creighton is the greatest nickel mine in the world and it is supplying the bulk of the world's output of nickel, which aggregates about 70,000,000 pounds per annum. The average grade of the ore extracted from this mine from 1903 to 1915 was 4.43 p.c. nickel and 1.56 p.c. copper."

Messrs. Hayden, Stone could have added that the Creighton contributed more than 5,000,000 tons of ore since the outbreak of the war. In that time well on toward $1,500,000 was expended upon the Creighton plant, —a plant that caused the late Governor General while on a visit, to squint at the headframe, shaft houses and the surface establishment in general, and to exclaim, "Well, someone must have a lot of confidence in this property." His Excellency was not far wrong. Between 300,000,000 and 400,000,000 pounds of nickel have had the Creighton hall-mark upon them. Without the Creighton—well, the tale might have a different telling, as other producers will attest. Here the graphic curve may be availed of. In 1902, the total tonnage treated from all sources in the province, was 233,388 tons; 1903, 220,537 tons; 1904, 102,844 tons; 1905, 257,745 tons; 1906, 340,059 tons; 1907, 359,076 tons. Starting with 1907, the International company treated 303,000 tons on individual account. Then the panic disturbed the trade. In 1910, 508,000 tons went through. Brightening skies were beclouded by the War; only 199,000 tons was smelted in 1914. Two years after, the Allied demands necessitated the treatment of 1,100,000 tons; 1,168,000 tons in 1917, even in 1919 the total was 1,093,000 tons.

Amid the Encircling Gloom.

Whereupon the nickel industry fell upon evil days. It was taxed a plenty and to spare, and surtaxed, notwithstanding it had consistently declined to raise the price of nickel during the war. Dominion, Provincial, Municipal taxes, pressure for plant expansions, provision of the refinery at Port Colborne that can supply the world's requirements in any emergency, costs and continuely from where encomiums should have emanated, sent the serenities to the demnition bow wows.

Yet Hayden, Stone, presumably speaking [illegible] *dia*, wrote a year ago of the nickel outlook:

"The future of industry can often be forecasted fairly accurately by a study of its past record."

Not so long ago the possession of a nickel mine was considered the doorway to wealth. Areas supposed to rival any or all of the producing mine were tentatively held. Prominent Canadians enlisted the help of overseas capitalists, including Norwegians who are producers in nickel, the Imperial Government lent their patronage, and what was considered a rival to the International and Mond companies was launched upon a tidal wave of prosperity in the British American [illegible] seeming abundant acreage, including the Murray Mine. The plea in extenuation was that the British American would safeguard the Empire in all events. Conse-

quently the enterprise was greeted with approval, regardless of cost and despite a doubt as to the grade of its ore, unless improved processes and continued prosperity attended the whole nickel business. Before it had been demonstrated that the mines and plant were ready to operate profitably, financial difficulties necessitated reorganization, and then the suspension of operation. This was due to the fact that governments and the other large producers had more nickel on hand that the world required, or would take during the coming period of depression. If there was anything the nations were not short of after the Armistice, it was nickel. The International refinery at Port Colborne was temporarily, like Potash & Perlmutter's two cylinder Cadillac "liability—not an asset." Nickel ingots were piled up there and at the Constable Hook refinery of the International, the Allied nations were jettisoning their over-supply of the metal. Mond and Brunner-Mond specialties have softened somewhat the asperities of the situation, but the former company still has a quantity of metallic nickel awaiting markets. As the International people have an aggressive organization, their surplus stocks on hand have begun to move. The stocks in Canada have been augmented by the dismantling of the Constable Hook refinery, and it will be some time before any of the producers are in a position to give the "all clear" signal. Only the Mond plant at Coniston has a furnace going. The all-round readjustment cannot be hurried. What the demand for the metal is going to be when the pendulum is swinging the other way, is something about which none of the parties interested are venturing prophecies.

Monel Metal To Arrive.

One certainty is obvious: The International will not stand on ceremony when the log jam breaks. It is selling nickel, and its objective is to occupy its field, the high-grade character of its ores and its modern metallurgy leaving no misgivings as to the adequacy of profits from the output, when that output is as large as it should be. There is at present a feeling among the producers of nickel that their continued operation is handicapped by undue taxation, at a time when the nickel industry is harder hit than any other branch of production or trade. As a matter of fact, the use of nickel and its alloys calls for an intensive and expensive campaign. Sudbury and surrounding communities, including farmers, are in hearty accord with nickel producers, because they find their markets at zero and their customers without the wherewithal to buy. The most obstreperous who raved about fumes are as impatient to have roast heaps in action and smoke stacks belching, as they were about the destruction of vegetation. Executive officers are grim. Staffs are depleted, dwellings are unoccupied, or their occupants have to be leniently dealt with. Copper Cliff is a model residential town with a decimated population, part of which cannot go elsewhere lest the change be "out of the frying pan into the fire."

International Nickel organizations cater to wide and diversified markets. They are anticipating the popularizing of their Monel metal, a natural alloy of which Hayden, Stone write:

"It contains about 67 p.c. nickel, 28 p.c. copper and 5 p.c. other metals. It is as strong as steel, non-corrodible as bronze and more durable than either. It is manufactured in the form of rods, castings, forgings wire, strip stock, sheets, etc., and is used for permanent roofing, propeller blades, valves, bolts and nuts, shaftings, pumping rods, etc."

To meet the market anticipated for this alloy, a large rolling plant is nearing completion. Besides, the intention is to press the consumption of nickel-silver alloys for tableware and for electro-plating. At the same time it is recognized that nickel-steel is a prominent factor in modern construction. It combines strength and ductility, and has proved its usefulness in bridges, locomotive forgings, automobile parts, electric rotary gears, marine engine works, stationary engines, and a host of diversified product. A recent list of the uses for which Monel metal is applicable, includes in part; turbines, refrigerators, filtration equipment, perforators, milling machinery, welding equipment, wire rope, rolled anodes, cast anodes, crucibles, wire cloth, castings, hot rolled sheets, chains and fly screens. Considering that it was a very few years ago that Monel metal was first drawn, the infinite variety of its uses to-day sustains the confidence expressed in its future.

What Research Is Doing.

Research departments have proved the quality of Monel in amalgamating apparatus where metals come in contact with mercury. Filter presses handling corrosive liquids, in the beet sugar industry for example, have made the metal a favorite. Likewise with filter cloth. Wherever acids are present, as where diamond dies are used for wire drawing, in sugar pumps subjected to the cutting action of sugar crystals, for "doctor plates" in pulp mills, or in the manufacture of "white gold," nickel and monel metal are given preference. Nickel cast iron pistons have become a feature of the automobile trade. It has been found that nickel provides greater hardness and resistance to oxidation at high temperature, which has opened up a possibly large market for stove iron and similar services. Nickel for annealing and carbonizing boxes and cyanide pots is being tried out with most favorable results. It may be that "white gold" will be in greater demand from jewelers. It includes 20 p.c. of nickel. Sheet Monel suggests a broader field in the washing, dairy and dyeing industries.

The Wilson Welding Company recently discovered a heretofore unknown property in Monel. It seems Monel can be used in welding cast iron with very much better results that any other welding wire, for it acts as a scavenger in absorbing the carbon from the iron and prevents the hard spots and brittleness so often found in electric welding of cast iron. Perhaps the latest development is that of a high tensile Monel in the form of rods, which has a tensile strength of around 150,000 with a yield point around 100,000, together with an elongation in two inches of 25 p.c. This, it is said, can be machined and forged readily, is non-corrosive, and can be specially adapted for turbine blades. Iron-nickel alloys with from 25 to 75 p.c. nickel, are represented as having rather remarkable electrical mechanical and thermal properties. Developments long this line of research are looked for in the near future.

It is not the intention to catalogue the potentialities and practiced adaptions of nickel and Monel metal. The idea actuating this review is that the Nickel Industry is showing renewed and continued initiative, without which the scrapping of navies would also involve the scrapping of the industry.

Nickel, nickel-steel, Monel metal, malleable nickel, in the form evolved at the Mond or International works or elsewhere, will surely find markets, when the world has ceased to worry and the wicked are at rest, (which latter includes overtax overlords). There are strenuous times ahead in Nickeldom.

The News of Mining

Great Britain supplied 15 per cent of Switzerland's coal imports in 1920, and 19 per cent. in 1921. The returns for 1921 show that 202,553 tons come from Great Britain, 259,343 tons from the United States, and 265,691 tons from Germany.

Austrian production of coal amounted to 2,600,000 tons during the year 1921, an increase of 170,000 tons over 1920.

Egypt imported about 900,000 tons of coal in 1921. The greater part of this came from Great Britain and the United States.

In the coal mining districts of Lanarkshire, Scotland, the cost of living is still 88 per cent. above pre-war level, according to local authorities.

Approximately one-sixth of all coal used in Great Britain is consumed in private dwellings, of which there are about ten million.

Total accidents in the collieries of Great Britain numbered 1.26 per 1,000 persons employed. In the year 1920, they numbered only 0.88 per 1,000 persons employed.

A suit brought by the Cape Explosive Works (South Africa) against Lever Bros. and the South African Oil and Fat Industries, failed in the Supreme Court, at Capetown recently. The point at issue was the fact that the defendants had agreed to deliver crude glycerine for use in the manufacture of explosives, at a fixed price. When, later, the British Government raised the controlled price of glycerine, the defendants raised their prices correspondingly. It was held by the court that as there had been no misrepresentation, the defendants were not liable.

The Ontario Government is planning to provide facilities for the sale of small lots of ore by prospectors. Small lots of ore will be accurately sampled as they arrive and will be stored at the Temiskaming Testing Laboratories until one or more carloads have accumulated. The ore will then be sent to a suitable mill for treatment. This will assist in sampling properties and in helping the prospector defray expenses.

The only producing oil well in Great Britain is situated at Hardstoft, in Derbyshire. It was put down for the British Government. During the latter half of last year, it produced 78 tons of oil.

German contracts have been placed for 800,000 tons of Wabana (Newfoundland) iron ore. It is reported that contracts for 1,000,000 tons yearly are being arranged.

The United States Steel Corporation expended $1,061,685 on safety work during the year 1921, and in the same year paid out $1,109,211 in accident insurance.

Colonel Grenfell, chairman of the Messina Copper Mine, South Africa, in an official statement, states that high working costs and taxation have made the mine unremunerative. He asserted that the Messina can be run with a complement of fifty white and eighteen hundred natives, but before the mine was closed the company had been forced to employ 170 white men at wages 50 per cent. above those current in 1914. This was too high a proportion of white labour.

Hon. James Murdock, Dominion Minister of Labour, severely arraigned organizer McLachlan, the advocate of the "loafing on the job" policy amongst Nova Scotian coal miners. Speaking in the House of Commons on March 30, the minister urged the need of combating any such policy without reserve or equivocation. He charged that the same tactics are now being used in the Nova Scotia strike as were used during the war by the I. W. W.

Seven years ago, Mussen's Limited, a prominent firm in Montreal, dealing in mining and contractors' supplies, went into voluntary liquidation. At that time their assets exceeded their liabilities by $250,000. But business was stagnant and the firm's assets could not be quickly turned to cash. On March 31st, Mr. W. H. C. Mussen discharged the last of the firm's outstanding obligations, according to promise. This is a rare and creditable example of business honour.

In a hearing under the British Safeguarding of Industries Act, some interesting data are presented in connection with the manufacture in Britain and in Germany of domestic aluminium ware.

There are now thirty manufacturers of aluminium hollow ware in Britain, compared with twelve before the war. Their product is characteristically of heavy gauge, highly-polished, and of thorough workmanship. There is a popular demand for lighter and cheaper utensils, and this is being supplied from Germany. That the possibility of competition from Germany is due to the depreciation of the German mark, seems to be indicated by the fact that the price of Canadian and American aluminum is higher even than in Britain. In spite of this, American manufacturers of aluminum ware are under-selling all their competitors in India and the Eastern market—presumably part of a determined effort to capture this market for the United States.

Canada is now one of the world's chief producers of ingot aluminium, and has an increasingly large interest in the world's aluminium trade.

In the same way that the discovery of [illegible] in Sheffield reinvigorated the Sheffield cutlery trades, so the discovery of a new non-ferrous alloy of nickel that does not readily stain or tarnish has caused activity in sections of the electro plate [illegible]. So great has been the demand from shippers, retailers and the general public for spoons and forks and hollow ware of the new product that stocks have been exhausted at some of the works, and the makers of the product are installing additional plant to cope with the demand.

British Columbia Letter

Will Explore Coal Lands

Coal lands situated in the Copper River District, northern British Columbia, are to be subjected to systematic exploration by the National Finance Company Ltd., who are acting as liquidators of the Yorkshire and Canadian Trust Ltd. This announcement was made recently in the course of an application before Mr. Justice Murphy of the Supreme Court of the Province for permission to proceed with diamond drilling. That there are 15,000,000 tons of coal actually proven and that in the region in question and that adjacent there are estimated to be reserves running between 300,000,000 and 500,000,000 tons of coal were statements made by counsel. It was shown that creditors representing a considerable block of the liabilities against the defunct company were in favor of the proposed work, the cost of which is placed at $18,000. While the judge could not see his way clear to granting the application until all creditors were notified of the proposal it is not thought that any difficulty will be met with as the purpose is to keep the holdings in good standing as to government requirements and to so demonstrate their value as to make it possible to effect a sale on terms commensurate with their possibilities.

Northern Coal Areas

Activity in the development of coal areas of northern British Columbia has become more marked in the past two years, chiefly for the reason that with the growth of Prince Rupert, and of settlements along the line of the Grand Trunk Pacific Ry., the local domestic market has materially expanded. Although the mines are being worked in a small way as yet, and notwithstanding the lack of good transportation, the fuel can be produced and sold much cheaper than that imported from the collieries of Vancouver Island. In time there is no doubt that this coal, which is a high grade bituminous with first class steaming qualities, will find a considerable mercantile market. The citizens of Prince Rupert have been agitating for the construction of bunkers at that port to permit the development of such a trade.

The Betty Mine, known as the Aveling property, and situated about six miles west of the town of Telkwa on the G. T. P., is the only mine actually in operation at present. Within the past year there have been shipped, chiefly to Prince Rupert, from this source some 20,000 tons of coal. Only five miners are employed and the hauling to the railway, a few miles distant, has been done by horse and wagon.

The Telkwa Collieries Ltd., whose coal seams are found on Goat and Mud Creeks not far from Telkwa, was the first property to be opened up in the district. Already development represents an investment of about $20,000 and 75,000 tons of coal has been shipped. Work has been suspended pending the building of a spur track to the mine.

There also is the property of the Prince Rupert Collieries, whose holdings are 37 miles west of Telkwa. In this connection it is the desire of the owners to obtain the contruction of a branch line of railway to the measures. The field is an extensive one and, if the mission of those now engaged in representing the situation to Dominion Government officials is successful, the opening up of the coal resources of the north country in a large way is assured.

Coal Industry Problems

Problems connected with the coal mining industry of Vancouver Island, such as the effect of fuel oil competition, the possibility of popularizing pulverized coal, and the utility of improved methods of flotation and hydrogenation of coal, were discussed at a recent meeting of the Vancouver Island Division of the Canadian Institute of Mining & Metallurgy held at Ladysmith.

Thos. A. Spruston, superintendent of the Wellington-Extension Colliery of the Canadian Collieries (D) Ltd., presided and among those who gave addresses were Col. J. E. Leckie, Dean Brock, Dr. Hanson, Messrs H. Mortimer Lamb, N. Thompson, and E. A. Haggen, representing the Vancouver Branch of the Institute; and Kenneth Duncan M. L. A., Duncan; Mayor Walkem, Ladysmith; and C. M. Campbell, manager of the Cassidy Collieries, Granby Consolidated Mining & Smelting Co.

Recent developments in connection with the coal mining industry of Vancouver Island are encouraging. New deposits of coal have been opened up in the Reserve Mine, Western Fuel Corporation of Canada, and the Farm Mine, Comox, Canadian Collieries (D) Ltd. The collieries have been working steadily and the output is being well maintained. The domestic business has been good but the bunker sales weak, this because of the holding up of trans-Pacific shipping in Oriental ports. It is not anticipated that the mines of the island will be affected by the strike of bituminous miners ordered for the 1st of April, the wages being regulated still by the Dominion Fair Wage Officers.

The production of British Columbia coal mines for February follows:

Output of Coal for B. C. for the Month of February, 1921

Vancouver Island District

Mine	Tons.	
Western Fuel Corporation of Canada Ltd., Nanaimo	56,313	
Canadian Collieries (D) Ltd., Comox	30,360	
Extension	18,962	
South Wellington	7,630	
Granby Consolidated M.S. & Co. Cassidy	23,987	
Nanoose Wellington Collieries, Wellington	8,624	
Old Wellington (King & Foster)	536	
Total	146,412	146,412

Nicola-Princeton District

Northern Ontario Letter

THE GOLD MINES.

Exploring Goldale.

This week finds the Kerr Lake interests actively engaged in making preparations for an extensive exploration and development campaign on the Goldale property. Harry Kee, manager of the Kerr Lake is in charge of the undertaking, while, as stated last week in the Journal, Messrs. Rudolph L. Wilson & Sons are financing the enterprise. In addition to the excellent possibilities of that part of the property lying east of Pearl Lake, it would appear that special merit also attaches to that part of the holdings which lies adjacent to the Dome Extension side of the Dome Mines.

Porphyry Hill.

An interesting case was taken before Mining Commissioner T. E. Godson, K.C., when the Porphyry Hill property figured in a trial whereby the original owners endeavored to re-establish their title, following forfeiture under a recent Order in Council in regard to non-payment of acreage taxes. At the time of writing no decision has been rendered.

Dome's Income.

The work of preparing the annual statement on the Dome Mines is now in hand, covering the fiscal year ended March 31st. It is understood the report will show an income of something like $2,750,000, during the period under review. Of this total, the income for the last three months is understood to have exceeded $900,000. In view of the ore being exceptionally high grade, it is believed the net profit will amount to at least fifty per cent. of the gross yield, the recent achievement indicating a big surplus over the 10 p.c. dividend requirements and 10 p.c. capital repayment.

Dome Lake.

In regard to the outlook for the Dome Lake and West Dome properties, it has been learned by the Journal correspondent that certain of the principals believe these properties may be successfully operated on the present known ore-bodies. It has been a popular belief that these ore-bodies were too narrow and that the possibilities of making good in a substantial way would rest on the outcome of developments at deeper levels. However, it has been pointed out by officials that the former mining policy was at fault, and that by taking proper precautions against diluting the ore by breaking too wide it will be possible to place the enterprise on a profitable basis.

Schumacher.

At the annual meeting of the Schumacher it was announced that negotiations were pending with regard to either the sale of the controlling block of stock or for raising money with which to resume work. The financial statement contained no surprises, it being shown that the company is without any money, but is not saddled with any serious debts. The outcome of present negotiations will be of importance to the stockholders. There is a general feeling that either the Hollinger or the McIntyre would be justified in acquiring the Schumacher provided the terms were reasonable.

V. N. T.

Arrangements have been completed to resume work on the Porcupine V. N. T. Cold weather has deferred the date of the spring break-up which is to signalize an abundant supply of hydro-electric energy and thus make it possible to get under way at full blast. By the middle of April, the various plants in the Porcupine field will be fully supplied with energy.

Platinum from McArthur.

Assays as high as $41 per ton in platinum are reported to have been obtained from samples brought out by prospectors from the township of McArthur, about 20 miles south of Porcupine. The find was reported last week in the Journal, it being pointed out that the precious metal occurs in pyrrhotite and that the Clifton-Porcupine interests are identified with those who made the discovery.

Blue Quartz Mine.

About 300 feet of lateral work has been done at the 300-ft. level of the Blue Quartz Gold Mines at Painkiller Lake in the Matheson district. This is a consolidation of the former Cartwright Goldfields and La Santa Lucia Mines. The company holds about 500 acres and there are eleven veins which show visible gold at outcrop. At the 100-ft. level the main vein is said to have widened out and carries good values. High grade ore was encountered in the drift last week.

Wright-Hargreaves.

Application has been made to list the Wright-Hargreaves Mines on the Standard Stock Exchange. It will probably be listed before this statement is in print. This company has 2,750,000 issued shares of the par value of $1 each. The mine has operated as practically a closed corporation. The few shares changing hands have recently commanded a price of about $2 each. The company commenced production in May, 1921, and has produced an average of from $60,000 to $70,000 per month since that time. A dividend of 5 p.c. was paid in January and another of 2½ p.c. is to be paid in April.

Kirkland Lake Proprietary.

Once the Kirkland Lake Proprietary completes the present building-up process, the question of carrying on deep exploration by use of a diamond drill will be taken under consideration. This announcement is important for the reason that the Kirkland Lake field has never yet had the advantage of exploration at depth by core drilling.

Lake Shore.

Newspaper estimates of $18,000,000 have been placed on the ore reserves of the Lake Shore "above the 600-ft. level". Such guesses are contrary to the general policy of the Lake Shore and are an exaggeration of the truth. The physical condition of the Lake Shore is exceptionally favorable and there are possibilities of this enterprise being a close second to the McIntyre-Porcupine, which in its last annual statement showed an ore reserve of $6,300,000. It is a pity that exaggerated estimates get into circulation when the management is opposed to such guesses and has adopted a sound and conservative policy.

Highland-Kirkland.

A diamond-drill outfit is now on the Highland-Kirkland property and an extensive campaign of exploration work has been laid out.

King-Kirkland.

The plant on the King-Kirkland will be ready for operation before the end of the current month, according to present progress.

EDITORIAL

Many of us have an abiding faith in the great lone Northland, with its apparently barren and waste stretches of rock and water. The call for its successful development is as compelling as the missionaries' cry which came over from Macedonia. *- A. E. Barlow, 1913.*

WATER POWER, MINING AND METALLURGY

TRUE conservation of our water power resources, which are inexhaustible through use, lies, not in withholding them from development, but in their efficient utilization in the public interest for the economic exploitation of our other natural resources, and for the conservation of our exhaustible fuel supplies." So states, and states truly, the Dominion Water Power Branch in a recent report.

The importance of hydro-electric power in the utilizing of Canada's mineral deposits is not easy to gauge at first glance. It is conceivable that, by virtue of cheap coal, the mining and metallurgical plants of the coast and the interior of British Columbia could be operated economically, though certainly at a disadvantage. But the case of the mines throughout the great Northland of Central Canada, and even in the southern parts of Ontario and Quebec, would be almost hopeless, were it not for hydro electric power. Mining activity in the present centre of Canada's mineral industry would diminish almost to extinction if the water turbines should be permanently disconnected from compressors, stamp batteries, and cyclone mills.

No world progress in metallurgy have a fair chance in Canada without the aid of the electric current. The very big electrolytic plants at Trail, the production of aluminum and of calcium carbide at Shawinigan Falls, and scores of lesser undertakings are directly dependent upon large supplies of electricity at a cheaper rate than can ever be provided by the use of coal. In all our metallurgical plants, cheap hydro electric power is going to emerge, even though in some cases it is not an essential.

How much the development of our Northland depends upon the adequate provision of hydro-electric power, can be gauged from the present difficulties in the Porcupine and Kirkland Lake gold districts of Northern Ontario. Either through mismanagement (which is inexcusable) or through some unavoidable complication as yet unannounced (for which it will be hard to find adequate excuse), the development of unharnessed power on the Abitibi River has been delayed for months. This has already cost the Province a lot of money, through the deferred production of gold that would otherwise have been extracted from the ore, and through the lack of employment to miners and others that would have been available with more power. This refers only to operating mines and mills; how many prospects would have been developed to the producing stage had power been ready for them, it is difficult to say.

It is encouraging to know that at long last, the three claimants to the water-power on the Abitibi River have been brought together in conference. If this results in agreement, well and good; if the three fail to agree, then it is incumbent upon the final authority, the Provincial government, to adjudicate immediately, and relieve the uncertainty of all concerned.

A VIRGIN FIELD FOR PROSPECTORS

The field geologists of the Dominion Geological Survey are pioneers, and their number is all too small to cover the field for which they are responsible. The areal geologists particularly have before them a task, the magnitude of which seems to reduce the human effort to midget dimensions. Still, the work of this handful of pioneers has astonishing results, results that we often fail to recognize or to hold at their true value.

Dr. E. M. Kindle contributes to this issue of the Journal a short description of his journeys last summer in Labrador. It is full of suggestion to the prospector. The Journal is glad to be the medium of such contacts between the pioneer geologist and the pioneer of mining industry.

As Dr. Kindle speaks of Labrador is almost [illegible] to the world. A few [illegible] of the east peninsula have been made hurriedly, by canoe or dog team. None of these routes [illegible] conducive to the discovery of mineral deposits. None have the [illegible] surveys of our government geologists afford of more than a glance at the rock formations. Prospecting routes have been [illegible] knowledge acquired [illegible] prospectors.

The present day field geologist in Canada [illegible] of privacy and [illegible] the features of economic

geology as well as pure geology. Constantly we have instances of the value to prospectors of "tips" from geologists. The chances of a geologist locating an ore deposit are slim; his eyes are concentrated on other features, and he has no time to follow up favourable indications. But his judgment as to the likelihood of finding ore deposits and his advice to the prospector are worth the most serious attention. That Dr. Kindle is ready to recommend Labrador to the attention of prospectors, means more than would appear to the casual reader.

Parts of the Labrador coast are at present rather difficult of access on account of the long intervals between the calls of boats at the scattered fishing villages. But there are regions served regularly by steamers, where supplies are readily available. Given adequate supplies at any one of a hundred points on the coast, the interior is readily accessible by canoe. If mineral deposits of first-class importance were once located, development would be comparatively an easy matter, the present seeming inaccessibility would be wondered at, and the coasts of the peninsula would soon be travelled by prospectors.

A PERFECT BLAST

ON Saturday, April the eighth, there was a demonstration at the trap-rock quarry at Havelock, Peterborough County, Ontario, of a perfect piece of engineering work. Thirty tons of dynamite, distributed in tunnels over the area of an acre, broke 260,000 tons of rock. Not a bit of rock flew over a hundred feet away, and the whole mass was so shattered that only a small fraction of it will need secondary blasting in order to enter a 48 inch by 60 inch crusher.

An instance of engineering work so near perfection as this is worthy of record, and of unqualified commendation. It not only shows the application of professional skill, but is an admirable demonstration of temerity. Few engineers care to risk their reputations on the turn of a switch. If this thirty tons of dynamite had not been skilfully placed, the blast would have been a failure, and a large part of the $35,000 it cost to place the charge would have been wasted. If ten per cent. more dynamite had been used a large part of the rock would have been buried in a swamp, and scattered over fertile fields. If the charge had been ten per cent. smaller, the rock would hardly have been moved, and the blast would have been a failure.

To Mr. George W. Rayner, of Toronto, and to Mr. W. W. Wallace, who assisted him in the field, are due the congratulations of the mining fraternity for a fine bit of work. Both are "hard-rock" men, old in experience, though young in years. It is skill and confidence born of constant and long-continued use that have, in their hands, resulted so fortunately.

La ROSE

THE contest for control of La Rose Consolidated Mines Ltd., Cobalt, is now over and the old board continues in control. A large majority of the shares were voted in favor of President McGibbon's board. Mr. G. C. Bateman, who has been manager since 1916, continues in charge of the mine operations. It may therefore be assumed that exploration will be carried on vigorously.

The contest for control brought out some interesting facts, chief of which was the satisfactory progress made under the present management. Six years ago the old La Rose mine was reported nearly worked out, and the other mines owned by the company were not highly regarded. To explore and develop the ore-bodies necessitated heavy expenditures; but the result of the exploration was to give the mines a new lease of life. A large production has been made, and while costs were necessarily high owing to the smallness of reserves, the company has continued to be profitably operated. Criticism of the management therefore was really criticism of the policy of spending money to find ore. If that policy had not been adopted, La Rose would doubtless have been closed down long ago.

Known ore reserves at Cobalt silver mines have always been small as compared with the annual output. Time and again the life of the mines has been protracted by exploration work. One of the notable successes has been the La Rose since 1916. It is true that La Rose is but a shadow of its former self; but compared with expectations of six years ago, it has since done very well.

There is always room for difference of opinion as to how much a mining company should spend in efforts to find ore. It has been demonstrated however in the case of La Rose that large expenditures were justified. It is pleasing to see that the efforts of Mr. Bateman to keep La Rose on the list of producers are appreciated by the larger part of the shareholders.

"LEST WE FORGET."

In the thick of the Passchendael fight, an Anglo-Canadian and a Canadian were discussing the merits of the Britisher. The conversion wound up with the remark, by the former, that the Englishman is the most merciful man in the world. It is true. The sight to be seen any day there was a "push" showed that it is true also of Canadians. When German prisoners were busy carrying in wounded on stretchers, they joined the long lines of Canadians waiting their turn at the coffee-stalls, and were treated without discrimination by soldiers, padres, and Y. M. C. A. workers.

There is a moral in this.

We Britishers are apt to forget, and to let by-gones be by-gones. This is, for the most part, an admirable characteristic, and bound to stand us in good stead in

the long run. But, in the meantime, it may lead us into doing less than justice to our neighbors.

As in the war, so in the peace, Canadians are far removed from the scene of action. During the wartime we had plentiful reminders of what was going on in France and Flanders, and were inspired to do our bit. The French are still hard pressed, now by economic forces rather than by armed foes; in fact they still bear the brunt, as they did when under arms. We, suffering under no such economic pressure, are more than likely to forget their struggle, and to blame them unduly for their seeming laack of democratic spirit and Christian forbearance. It is easy for us to moralize.

We print today a little reminder of the difficulties under which the French iron miners are working today, as the result of deliberate and well-calculated destruction by the Germans. By a strange coincidence, we received, after this was ready for the press, a request from an eminent French metallurgist that we give publicity in Canada to a book he forwarded giving a full account of the German work of destruction. The French realize the British tendency; let us not forget to remain sympathetic allies.

EDITORIAL NOTES

WE print today, at the top of the editorial page, the prophetic words of a Canadian leader in geological and mining development. He is no longer with us in the flesh, but his spirit and his words remain to help us along in the pioneer work our country needs so urgently.

Each week the Journal will quote the words of some eminent Canadian scientist. We have had a succession of outstanding figures whose memory may well be kept green by this means. A number of our contemporaries have similar attainments, and the Journal will draw upon their inspiration for the benefit of its readers.

The appeal of potential iron ore producers in Ontario for a bounty is still before the public. The public and their official representatives have so far proved apathetic, or even hostile to the proposed bounty. We believe that the end fully justifies the means in this case.

It is a pity that there has been no concerted action in bringing this important question to the notice of the public and of our legislators. There are a considerable number of furnace operators, owners of iron ore deposits and others that will benefit directly from the efforts of the Algoma Steel Corporation, if they are successful. The officers of this company have always been pioneers and they deserve more support than the public at present accords them. There are some items of information on the case on another page.

In the issue of March 24th, we expressed some doubt as to the "financing" upon which is based the new attempt to open up the old Laurentian Mine in Northwestern Ontario. Col. H. A. C. Mackin, of Kenora, who has undertaken the venture, has set this doubt at rest. Col. Mackin has raised money for the new work on terms that are very reasonable at this time. This money, wisely expended, will, we hope, act as beefsteak to the "black eye" from which Northwestern Ontario at present suffers.

An interesting feature of recent operations at the Nipissing mine is the result of exploration at shaft 63. A drift at the second level along a new vein opened up 70 ft. of ore averaging 3,500 ounces silver per ton. This sort of thing was common enough at Cobalt ten or fifteen years ago, but it is a notable discovery now.

Commenting recently on proposed Blue Sky legislation, Mr. R. Home Smith contends that there is no need of it. He considers as unfair the adverse statements made about mining enterprises, and contends that there is no more fraud in mining in Ontario than in other business enterprises. He believes that Toronto business men will be pleased if the attempts to saddle business with Blue Sky legislation fail. Honest enterprise, real endeavor to make mines, should not be handicapped by experimental legislation.

OLD TIMER

(Twenty-odd odd years ago there happened an incident in North-western Ontario on which is based this otherwise inexcusable rhyme.)

The Boss, he put it over me;
  He knows I ain't so limber
As what before I used to be
  But I can handle timber!

I'll cut a hitch with any man
  I'll set my stulls, or laggin
As well as any youngster can
  But I can't stand no naggin'.

The Boss, he heard some talk of me
  How I'd been never tired
So he just up he sez, sez he:
  Have you done as required?

I don't let no man talk to me
  And I don't care a dime,
So I just sez, quite carelessly
  Boss, please give me my time.

So I ain't got my sackin' yet,
  And I don't need it either
Because I know my job [illegible]
  And I'm not jokin' neither.

ANON.

Some Labrador Possibilities*

By E. M. KINDLE

THE mission which took the writer to Labrador last summer gave relatively little opportunity to investigate the economic possibilities of the country. But it is not easy for any geologists who has for a season felt the spell of this vast and very slightly explored land to avoid suggesting to mining geologists that there are reasons for believing Labrador will eventually contribute to the world's supply of mineral wealth.

The Labrador peninsula is nearly as big as Alaska and it is in about the same stage of economic development which had been reached by that other great peninsula when Russia sold it to the United States, as a supposedly worthless possession, for seven and one-half million dollars. Until very recently Canada has taken little more interest in Labrador than Russia took in Alaska. This is indicated by the fact that the boundary between Newfoundland Labrador and Canadian Labrador has never been even approximately agreed upon. The maps published by standard atlases differ as much as 300 miles as to the location of the boundary between Newfoundland and Canadian Labrador in the Lake Melville region. Labrador still belongs exclusively to the cod fishermen and the fur-traders.

John Cabot's announcement on his return to Europe from the Labrador coast in 1497 in that the shoals of were so numerous that "they sumtymes stayed his ships" resulted in all the countries of western Europe sending fishermen to the new fishing grounds which have been exploited with abundant success to the present day.

Neither the fishermen nor the fur-traders who followed them have ever sought to develop any other wealth in Labrador beyond that furnished by the cod and the pelts. They have, however, given a few hints to the prospector which have thus far remained unheeded.

Copper

As early as 1840 a chunk of native copper was found on the shore of Hamilton Inlet not far from the point from which the writer's recent expedition into the interior set out. The first hints of the existence of the famous Michigan copper district came from the farmers of the Central State who picked up pieces of native copper in their fields long before the location of their source was known. In the Lake Melville district there are various half-breed trappers (the Liveyers) who have specimens of calcocite and other copper ores which they found near trap lines. In one or two cases known to the writer patents on mining property have been taken out by these trapper-prospectors from the Newfoundland Government where the finds lie almost certainly in territory which will eventually be shown to belong to Canada. Bell was shown specimens of these copper ores in 1882 (Can. Geol. Survey, 1882-1884, pp. 12-13D), but no serious attempt to investigate their comercial possibilities appears to have been made.

Gold

Placer gold of commercial value may never be discovered in Labrador but if it should be found in the sand and gravel terraces which run inland for hundreds of miles along the lakes and rivers west of Hamilton Inlet the water supply furnished by hanging valleys would afford numerous opportunities for hydraulicking on a mammoth scale.

Keewatin (?) Rocks

The discovery by Coleman in Northeastern Labrador of rocks provisionally reported as Keewatin in Mem. 124 of the Geol. Surv. Can., is another hint which the mining geologist may do well to take note of. If a series of rocks which has proven so richly productive in minerals in Ontario is present in Labrador their careful prospecting in this region would seem to be fully justified.

Water Power

The writer has recorded elsewhere his impressions regarding the forest resources of the Lake Melville district(1). When the pulp wood industry is developed in eastern Labrador as it certainly will be eventually some of the abundant water power of the country will no doubt begin to be utilized. The Hamilton river, a stream at least the size of the Ottawa river at Ottawa, has two falls with a combined drop of 70 feet within twenty-five miles of Lake Melville, which is navigable by sea-going vessels. A half dozen other streams entering this lake descend in the comrse of a few miles 1000 feet or more and offer water power possibilities which would be utilized immediately if they were on the opposite side of the Atlantic.

Grand Falls, which is one of the great waterfalls of Canada, is located about 250 miles above the mouth of the Hamilton river. The river here makes a total descent of 760 feet in twelve miles, terminating wtih a singe plunge of 302 feet. Acecording to Low the roar of this fall can be heard for more than ten miles and the "cloud of mist is visible from any eminence within a radius of twenty miles."

Interior Explorations

The exploratory surveys of the Canadian Geological Survey conducted by Low in the peninsula show that iron ore exists in various parts. The two traverses carried across the great peninsula by Low demonstrated also the possibility of exploring and mapping a great part of the interior with the aid of canoes,—the only means by which the interior could then be reached.

The use of the aeroplane should soon inaugurate a new era in the exploration of the interior. The thousands of lakes which are scattered throughout the peninsula furnish peculiarly favourable conditions for the use of the hydroplane in Labrador.

Prospecting

The mining engineer may be reminded that while the Labrador coast line was the first part of North America to be seen by Europeans most of the interior is still practically an undiscovered country. It is a country which can be recommended to the prospector who has the skill to combine trapping with prospecting. The men who can do this have the certainty of a living from their traps and a fair chance of proving that old Jacques Cartier was slandering the country when he called it the "Land that God gave to Cain."

What One Iron Mine Means to Canada

By GEORGE S. COWIE.

(Abstracted.)

No nation has made much progress industrially until it has mastered its iron and steel problem. Canada in the past decade has to a great extent improved its situation as regards its iron and steel products, but the supply of the base raw material (iron ore) entering into the production of iron and steel products has today fallen to the point where not a pound of iron ore is being mined at any point in Canada.

High Cost of Beneficiation

Now that the known merchantable iron ore bodies are exhausted, the next step naturally would be to undertake the problem of supplying to the furnaces Canadian ore from our known low grade deposits, thus opening up our natural resources. It has been proven after very costly experiments that our low grade ores can be successfully treated and made an ideal ore for blast furnace users, but the cost of treating, or beneficiation, is so great that foreign ores can be laid down cheaper, and for that reason the Magpie mine in the Michipicoten district and the Moose Mountain mine in the Sudbury district are both shut down with no prospects of reopening.

What Magpie Closing Meant

Now what does it mean to have a mine the size of the Magpie shut down? We find that during the years 1916 to 1920 almost $2,000,000 was spent for supplies. About $500,000 of this was spent in the Soo and the balance in old Ontario, Quebec and the United States. In addition $633,000, was paid for freight on the movement of the ore produced, $217,000 for freight charges on coal. Other items were sundry freight $140,000, duty $60,000, power $19,000, while wages amounted to $1,650,000, or a total for supplies, freight and labor of $5,000,000, an average of $1,000,000 per year. If the Magpie Mine were in operation this year see what relief it would have afforded to the unemployment prevailing not to take into account the benefit of the circulation of the $1,000,000.

Expenditure for Farm Products

During the five year period mentioned before, we find there was spent in the Soo for farm products for the Magpie Mine, the following amounts:

Vegetables and fruits	$ 38,000
Meats	152,000
Flour and feed	54,000
Butter and eggs	48,000
Total	$292,000

If the iron ore mines in the Michipicoten district were opened up on a large scale the amount of such purchases would be trebled.

Every year you find in the government estimates large sums for the direct benefit of the farming and other industries, but you do not see any amounts set aside to encourage or assist the iron ore industry. I think the government should very carefully consider this very important phase of mining and this year grant such assistance as is necessary to allow the mines to reopen.

Request for Government Aid

The Federal government at Ottawa and the Provincial government at Toronto are going to be asked to jointly bear the expense of the necessary temporary assistance asked for, this assistance to extend over a period of 15 years. Such assistance would have the almost immediate effect of developing ore properties in various parts of the country and especially in the Province of Ontario which possesses probably 80 per cent. of the known low grade ore deposits. Those seeking the assistance show their good faith and are content that such assistance should be payable only after the ore has been actually treated and ready for the market. Further, that private capital takes all the risk of success or failure, establishes the industry and produces its product before calling upon the governments for any payments.

Why should the request for assistance be granted?

1. Every dollar is spent for labor. There is no natural increase as on a farm. Every dollar is paid out to Canadian workmen.

2. The rapid development of natural resources is the only means of meeting the financial obligations of the war.

3. The nationalized railways must be made to pay their way. Mine products are the largest single source of railway traffic and iron ore produces a larger volume of this traffic than any other mine product.

4. Established raw material supply of any commodity is a vital national necessity.

5. Abundant deposits of low grade ores are accessible to existing railway lines.

6. The granting of assistance would involve a small annual outlay but the large returns and impetus to industrial activity would be immeasurable.

7. As no iron ore mines are now in operation the payments to mine owners during the first two years would be very small. The amount payable thereafter, depending as it does on iron ore actually mined and beneficiated, will simply be a measure of the growth of the industry; the larger the growth and expansion the larger will be the benefit to the country generally.

8. The retention in Canada of large amounts of money now being sent out for the purchase of foreign ores, and on the other hand the employment and investment of foreign capital to help the mines.

9. Expansion of the agricultural industry on lands tributary to the mining and smelting centres, larger markets for the farmer and increased consumption of manufactured articles.

10. Last, but not least the production of Canadian iron ores will complete the national equipment for the production of iron and steel as wholly a Canadian product, with the exception of the coal used, place Canada in a position of greater independence and assure the blast furnace and steel works a home product which, at any future time of stress, will enable Canada to carry on, within the confines of her own country, the complete production of iron and steel.

Iron Mines in the Briey Region, France, Damaged during German occupation, and their Reconstruction

Abstract of paper by A. Guillain (Paris), in Journal of the Iron and Steel Institute

At the time of the declaration of war by Germany, eighteen mines were in operation and a new one was being opened in the Briey field. In the Longwy field fifteen mines and three quarries were working. In 1913 the production of Briey was 15 million tons and that of Longwy three million tons. The mines gave employment to about 15,000 workmen, mostly Italians. The total population dependent upon the mining industry was about 40,000. These people were housed in workmen's colonies built by the mine owners.

The distance from Briey to Metz is 20 kilometres. The town of Briey and all the mines between Briey and the frontier were under the guns of Metz. Within a few days after the declaration of war the whole of the Briey region was effectively occupied by the Germans. In the course of brief fighting three mines were drowned out. Otherwise no further fighting occured in the mining region, and the Germans could work the mines at their leisure or destroy them.

The German government then proceeded to demolish completely or to transport to Germany all the steel plants. The majority of the blast-furnaces were preserved and shut down. Most of the mines were kept working, and the ore was sent to Germany until, the fortunes of war having changed, they were closed down, and most of the material and stocks carried off.

That the destruction of the iron mines was not completed, as it was in the case of the coal mines of the North, was due only to the fact that the precipitate retreat left them no time.

German Organization for Working the Mines

German organization began in October, 1914. The first care of the central administration established at Metz was to transport to Germany all stocks of iron ore from both fields. These amounted to 1,400,000 tons. Prisoners of war were drafted for work in the mines. They were harshly treated and badly fed.

During the first year, 1914-15, only a few mines were worked, the production amounting to about 1,000,000 tons. From other mines much surface and underground equipment was carried off. From 1916 onwards, the working of the Briey mines was intensified, and some mines already partly stripped were re-equipped. In that year ten mines yielded about 2,600,000 tons. In 1917, the output reached 5,200,000 tons, but, owing to scarcity of labour, the tonnage in 1918 was only 4,400,000 tons.

Pillaging of the mines was continued. During the whole of the four years of war operation the output amounted to only 13,300,000 tons, although it had exceeded 18,000,000 tons per year before the war. Because the only object of the Germans was to intensify production, the mines were found to be in a deplorable condition when the French owners returned in November, 1918.

Estimation of Damages

The estimates of damages were made under the control of the Ministry of Mines of the State.

The sum total of the damage at the mines of Briey and Longwy, agreed on by the Ministry of Mines and the owners, amounted to 429,465,000 francs as direct loss and 120,000,000 francs as damages for reconstruction and loss of revenue throughout the period of resumption of work.

Results Achieved in Repairing the Mines

The work of repair was begun immediately after

Steel Plant at Longwy.

Shaft and Shaft-house Destroyed.

Rolling Mill of the Longwy Steel Plant.

the Armistice, under extraordinary difficulties. The orginal mine staffs were totally disorganized. The country was occupied by American troops until April, 1919, and the railway capacity was entirely absorbed by military transport. In spite of this the dwellings were gradually put in order and equipment and machinery repaired and replaced. All plans, drawings and correspondence had been removed or destroyed, and all haulage and transmission lines removed. To remedy this, the mining and smelting companies formed a joint purchasing association, which was, through another central body, commissioned to buy all necessary material.

Owing to the bad faith of the Germans, however, the sums necessary for reparation had to be advanced by the mining companies from loans contracted in France. Government assistance had been checked by want of cash, and the work of reparation to some extent stopped.

However, the actual expenditure of the companies on the mines, partly met by the French State, amounted at July 1st., 1921, to about 150 million francs. On account of the increase in cost of working and the extra pumping necessary, it is certain that the mines will never be completely indemnified. Moreover, the companies find themselves obliged to seek new workmen in France and particularly in Italy, and to train these afresh.

Nevertheless, within a year of the recovery of the mines by their owners, about 5,000 workmen had been recruited as compared with 15,000 before the war. At the end of 1920 the workmen numbered about one-half the pre-war establishment, and the houses were by this time almost entirely rebuilt or repaired.

Progress made is indicated by the fact that the output for December, 1918, was nil; for January, 1919, 14,000 tons; and for January, 1921, 500,000 tons. This is slightly greater than one-third of the pre-war tonnage.

This tonnage has been mined and marketed in spite of the destruction of plants, dispersal of labour and the cessation of all relations with clients for four years. Amongst other new trade developments, without doubt important quantities of ore will be exported to England.

The following is of historic interest. It is an exact translation of an official German document found at the Anderv mine after the German retreat:—

TRANSLATION OF A GERMAN DOCUMENT

July 4, 1917.

Destruction of the Anderny Mine in case of a break-through on the front.

To the Imperial Administrator of Mines, Homécourt. Division A

Attached hereto we submit to you a statement showing the time and number of workmen necessary for the destruction of the mine of Anderny in case of a break-through on the front.

Directorate of the Anderny Mine
(Sined) Joesten

SECRET

Anderny Mine, July 4, 1917.

Statement of the work necessary for the destruction of the mine of Anderny in the case of a break-through on the front, and the wagons required for the removal of the more important material.

1.—Destruction requiring three-quarters of a year to make good.

Removal of pumps.

Blocking of shafts Nos. 1 and 2 by throwing in the cages and tubs after cutting the cables.

Destruction of the pulleys and the winding engines.

2.—Destruction requiring one and one-half years to make good.

As above.

In addition, to blow up the whole winding plant, engine house, foundations of the winding engine, and the stock bins.

3.—Permanent destruction.

As in No. 2. In addition, destruction by dynamite of the shaft lining. To blow up completely the head-gear, stock-bins, to burn the wood tower at shaft No. 2.

For the first case 10 men are required, time 24 hours.

For the second case 20 men are required, time 36 hours

For the third case 32 men are required, time 60 hours.

Twenty-five wagons will be required for the transport of the material, without counting those which would be necessary to remove the coal and ore, of which the quantity will be fixed according to the demands.

Anderny Mine. Director (Sgd.) Jessten.

CANADIAN GEOLOGIST HONOURED

Dr. Charles Camsell, Deputy Minister of Mines, has been honoured by the Royal Geographical Society of Great Britain, which has awarded him the Murchison grant. The Murchison grant, which is valued at £40, is given for distinguished service in exploration. Dr. Camsell has been selected to receive the grant for his explorations and surveys in northern Canada. The award will be presented at the anniversary meeting of the Royal Geographical Society in London in May. Before being appointed Deputy Minister of Mines in 1920, Dr. Camsell was geologist on the staff of the Geological Survey and carried out most valuable surveys in the unexplored north and in British Columbia. He was born in the Mackenzie basin, being the son of a Hudson Bay factor. He is a vice-president of the Canadian Institute of Mining and Metallurgy.

TITANIUM PAINTS

Of considerable interest to Canadians is the announcement by the National Lead Co., made some time ago, and quoted by Frank L. Hess in his annual summary of "Mineral Resources of the United States," that titanium paints are now a commodity on the market. We have huge deposits of ores of titanium in Canada, which have never been of much use, and are not even explored on the surface. Following is the statement:

"The National Lead Co., after a year's investigation, in January, 1921, exercised its option to acquire one-half of the outstanding capital stock of the Titanium Pigment Co. (Inc.), having a plant at Niagara Falls, N. Y., engaged in the manufacture of titanium oxide pigment, which it sells under the registered trade name 'titanox'.

"Titanium is a metal widely distributed throughout the earth, but is found in a form relatively easy of treatment in mines controlled by the company near Jacksonville, Fla. This is a new white pigment. It is very interesting in that it has twice the hiding power of pure white lead. Before the National Lead Co. exercised its option it assisted in negotiating a settlement of conflicting patent claims, by the terms of which the Titanium Pigment Co. became the owner of all patent rights in the United States previously owned by the Titan Co., of Norway. Where great hiding power without increase in weight is desired, this pigment should prove to be very valuable. Its cost of manufacture is still high, but it is hoped that, with increased tonnage and improved manufacturing methods, this pigment will soon take its place amongst the best and most marketable white pigments."

News and Comments

By ALEXANDER GRAY

"Are We Downhearted?"

AT this writing it looks as if the Nipissing company will pass up the Rochester Veteran Claim at Porcupine. That will be disappointing to those who appreciate what it would mean to have the premier silver mining corporation of Canada take part in the premier gold-field of Canada. It is not to be understood, however, that the decision of Nipissing engineers, if in the negative, is equivalent to a condemnation of the property. Drilling results were encouraging. For an ordinary undertaking they might be considered satisfactory; but they do not appear to have sufficed for Nipissing purposes. Nipissing has had another try for something suitable for the reinvestment of part of its surplus capital. Previous efforts of the sort had been made. No doubt, as Mr. Earle intimated, the quest will be continued, for Nipissing methods are worth a permanent place in Canada.

For an individual deposit of adequate size, Nipissing has all the working capital necessary. It is stronger in this respect than La Rose company was when President McGibbon took an interest in the Canadian Mining and Exploration Company. On that venture and his experiences while awaiting the finding of mines or properties that would be likely to become mines, Mr. McGibbon last week addressed La Rose shareholders, according to the daily press reports:

"The president told how a Canadian Mining and Exploration Company with five millions capital of which two and a half had been subscribed with the shares at $5,000 each had been formed to examine properties and mines and had examined over 2,000 looking for something in which they would put in their capital and in which La Rose Company could invest its surplus, but they had decided that it was almost hopeless to find any thing and the company was wound up. The company then engaged G. C. Bateman, who was the engineer of that company as their general manager and he had absolute unbounded 100 per cent confidence in his intergrity and ability as an engineer."

To most mining men there is a meaning in this, and a moral which Mr. McGibbon did not point out. He explained that La Rose management continues to be diligent in "looking round for properties", consequently there must be conservation of the cash surplus "for the purpose of investment rather than to pay dividends". Had the occasion been opportune, though, there might have been discussion as to why 2,000 examinations had resulted in wholesale rejections. Mr. McGibbon certainly is a Canadian Mining & Exploration shareholder, and the understanding was that La Rose Company would have a call upon any desirable underwriting. But neither the Nipissing nor the Canadian Mining & Exploration Company could find anything "big enough," ready made mines and imposing prospects not being plentiful.

Probably the mining and exploration venture referred to by Mr. McGibbon had more capital behind it than any other organization of the sort in ancient or modern times. Its foster parent, the late Ambrose Monell, enlisted Canadian and American capitalists who could underwrite a large slice of the universe. No idealistic optimist could have been more buoyant than he on that morning when, over a cup of coffee he babbled enthusiasm and declaimed about the likelihood of finding "another Utah, or Inspiration, or Creighton Mine". Exhibiting a telegram from a close friend asking that he and his father be "put down for a million dollars", Mr. Monell was serene.

The Consulting Engineer retained was, and is, an imperturbable, hard and fast rule man with a sense of responsibility to capital, not averse to taking a chance, but indisposed to entertain what would not defray the cost of a week-end house party to most of his principals. It was the combination of capitalists, in reality, the formidable character of it, that precluded the exploration company from taking on practically every one of the two thousand or so propositions examined. Therefore, Mr. McGibbon inadvertently erred when he inferred that not one of the two thousand was worth taking up—for that would be a reflection on Canadian mineral areas. The Surf Inlet property was subsequently purchased and brought to the producing stage by the Tonopah Belmont people. The Premier property in the Portland Canal district was abandoned before the war, and subsequently proved by the Messrs Guggenheim to be the greatest precious metal mine thus far discovered in the Pacific Coastal region. Complications prevented the acquisition of the Engineer Mine. It is unnecessary to detail the properties which the exploration company might have tested and invested in; but no ordinary mine would suffice for super-capitalists to whom petty cash dividends would not pay for the cigars. The exploration company was so strong, it was weak when it came to the commonplace property. This was not the fault of the technical staff, nor is the country to blame.

Since the exploration company surrendered its charter, and while other influential mining corporations have been in the market for properties, as Mr. McGibbon stated, producing mines of those pre war days are larger producers; Porcupine, Kirkland Lake, Portland Canal and other fields have asserted themselves. So, if the opulent are hard to please well, there are others! Instead of being down hearted, there is a surplus of optimism. Mr McGibbon and his deservedly "100 per cent" General Manager can hitch a portion of their surplus to some star proposition and bring more cheer to La Rose shareholders.

Canada has had its bumps, but there are more fish in the sea than ever were caught and some of them are whales.

"C.P.R." Interests in Mineral Industries

Modesty! Thy name should be Beatty Ogden.

No other conclusion is possible by those that read "Exhibit D" in the Annual Report of the Canadian Pacific Railway and Appendices. It is so captivating it must be hyphenated, as it combines the retiring dispositions of the President and the veteran Financier whose habitual understatements are so [illegible] ment" only in amorous language can we express it. Biographers or obituary writers could not ignore the characteristics of Messrs. Beatty and Ogden for the proof is matter of public record in the [illegible] hibit D". There, also, is partial [illegible]

George's sophism that there is such a thing as unearned increment.

The Canadian Pacific Coal Lands situated in Alberta are taken into the statistical glossary at $1. Another parcel of land (46,933 acres) in British Columbia is valued at $10 per acre. This is a concession to optimists. Natural gas rights in 1,000,000 acres sold and rented are estimated at $1, notwithstanding the revenue therefrom for the year ended December 31st, last, was $254,524.49. Besides, there are 50,000 Alberta acres in which the petroleum rights have been retained, the surface rights being sold or unsold, the petroleum rights to be developed on a royalty basis. This 50,000 acres is valued at $1. Is it any wonder the sum of $12,719.89 was "applied in reduction of the cost of mining and other property?" All things mining-wise have to be prudently handled. But in one particular the Beatty-Ogden modesty erred. They carried the 177,025 shares of Canadian Consolidated Mining & Smelting stock, at $4,425,625, or $25 per share, which is above the market. Canadian Pacific, however, owns 42 per cent of the total stock issue, as well as $2,698,400 of the $3,000,000, 7 per cent Convertible Bonds. Thus it is evident that the railway company has $7,124,025 in "Smelters" that is not valued at $1.

Mr. Tyrrell Admonishes London.

Being the Archdeacon of his profession, as it were, Mr. J. B. Tyrrell wrote to a London newspaper that migratory persons might go over there and offer "new discoveries" that are not such. In the absence of perjury as to *bona fide* discoveries having been required at this end, (the Ontario Mining Law no longer requiring this) it is not incredible that Mr. Tyrrell is an apostle preparing the way for a fuller appreciation by London that it should not "entertain angels unawares", without their being properly introduced. Unfortunately London does not always give heed to representative Canadian spokesmen.

Asbestos Industry and Fordney Tariff.

Quebec Asbestos producers and the Canadian Manufacturers Association are not going to submit tamely to the Fordney Tariff restrictions in the form of a duty of 3½ cents per square foot, plus 10 per cent. ad valorum on colored asbestos shingles, the Canadian make selling at $5 per hundred feet. Nor will they forego reprisals if other Fordney bill features are enacted. Whether a retaliatory export tax on raw asbestos will be imposed has yet to be determined; but Canada is a 'weary of what Washington thinks about appropriating Canadian natural resources. Fordney schedules may disconcert the Asbestos Industry in Canada; there is some Asbestos in the States — but there will be more asbestos manufacturing concerns on this side of the border when the controversy is further along.

Real Forward Movement Under Way.

Opportunity to obtain an insight into business developments in the States was availed of last week. The [illegible] was in such striking contrast of the blue ruin atmosphere in which metropolitan offices have been enshrouded, that a reason for it was sought. It was provided in private reports by keen observers in close contact with the largest steel and equipment plants. Almost without exception the reports bespoke the elimination of pessimism and restoration of confidence. Railroad buying, purchasing of structural materials, doings of rolling mills, reflect such a decided change of front that some of the more conservative leaders almost doubt whether the movement is not too aggressive. But business is being booked, and that is concrete evidence. Automobile plants are at or almost at capacity. The National Tube works have joined the procession. It is noteworthy that in various instances concerns that did not intend or expect to start during this year are going to open in the near future. Prices may have to be reduced, but the percentage of production is on the ascending scale, and the optimist is having his innings. Export business, it is admitted, is nothing to boast of. That awaits international equilibrium, that may be hastened by the Genoa Conference. Internal troubles like the present coal strike are secondary, because foresight was exercised and plants are supplied for months ahead.

Money for Kirkland Lake Country.

Capitalists and Mining Engineers representing very influential New York interests are examining carefully the Kirkland Lake district areas immediately east of the Tough Oakes and further along into Gauthier Township. They are doing what their training dictates; basing their plans upon underground developments at the producing properties, and the geological conditions wherever favorable. If values are found on the surface, so much the better. The men and their methods are a guarantee that they know their way about and are not "bearing" Lebel Township.

American Zinc Producers.

Periodically Canadian producers of zinc flatter themselves that they can produce the metal as cheap as their competitors. The Consolidated Mining & Smelting Company proved it could make and market zinc at a profit when others remained shut down or slowed down. So far, so good. But should the proposed Washington tariff be enacted and India and Australia return to zinc production on a large scale, what is Canada doing to maintain and increase its zinc output, apart from Trail operations? Either Canada must accept restrictions, or producers must supply more finished products. For some time, American Zinc Producers through organizations created for the purpose have been working to extend the uses of the metal. It is calculated that two-thirds of their zinc goes into galvanized iron. The present consumption for this purpose is about 50 per cent. Automobile tires are taking more and more zinc oxide. A new line has been developed in zinc shingles; really galvanized shingles. Are we to be content with sheets, discourage research, retain our scientists on a starvation wage, and await results from Washington, Pittsburg, and St. Louis?

Enterprise in Lignite

While Ottawa is debating whether or not its official scientists are so many unnecessary evils, a combination of St. Paul, Minneapolis and Des Moines capitalists has undertaken to exploit "immense lignite fields in North Dakota". A St. Paul chemist, Carl Jaeger, is heading the project, and eight thousand square miles of lignites will be "utilized", the idea being to provide "fuel in the form of pressed briquettes, lubricating oils, dyes, benzine, perfumes, carbolic acid, paraffine and various other chemicals". The prospectus and diversity of products is attractive, and the more interesting because Canada has so many square miles of lignites. It is possible we Canadians may get beyond the experimental stage and avoid the importation of what North Dakota expects to offer.

WHERE IS J. N. T. GRAY?

A letter to J. N. T. Gray, addressed c/o Humboldt Smelting Co., Humboldt, Arizona, from South Africa, has been forwarded to the Canadian Mining Journal by request of the writer. We shall be glad to hear of Mr. Gray, in order to forward the letter.

Notes From Nova Scotia

The "Strike on the Job" Finished

With the reconvening of the Gillen Conciliation Board the United Mine Workers called off the policy of "striking on the job." They justified their action by stating that they had accomplished what they had aimed at. If they have succeeded in doing any one thing, it is to show their weakness with their members, for only a very few collieries were affected and those few not seriously, by the lowered production orders sent out to the different locals. Absolutely no response was made by the miners of Cumberland County, and the output remained normal.

In the meantime the miners of Springhill went on with the recommendation of the Gillen Board and settled the machine rates. Springhill collieries since the seventies have been worked by hand picks, but the Empire Steel Company decided to put in the "Radial" cutting machines. These were found to be successful but it was found difficult to fix a rate for undercutting and the matter went over to the Gillen Board with the above-reported success.

The Pictou Collieries like Springhill took no notice of the orders from the U. M. W. of A. headquarters to reduce outputs, and went on as usual. Indeed one of the Locals refused to discuss the matter, and although a whirl-wind campaign was put on by the fiery secretary, all wheels turned as usual.

Record Output at Sydney Mines

The March output of 63,000 tons at Sydney Mines was the largest in the history of these collieries. In spite of all the efforts of U. M. W. of A. officers, local contract rates were renewed in all collieries with the exception of Florence, where the roadmakers failed to come to any settlement. The policy of the Empire Steel Company has been to place as many of the different classes of datal men on contract work as they possibly can. These men are offered favorable rates, which are an incentive to maximum efficiency and high wages. The result at Sydney Mines up to the present has been highly pleasing both to the Company and the men, and in addition to good wages, a better feeling has been created, which means much for the progress and welfare of the town. That such agreements on local contract rates can take place at a time when the whole district is thought by outsiders to be seething with ferment bordering on revolution, speaks most highly for the management in charge at the collieries.

Glace Bay Output

In the Glace Bay District the output for March was well over 200,000 tons. As there was much broken time due to adverse trade conditions, it will be seen that the "Strike on the job" policy was a failure. Very little effort was made by the Company to meet this pernicious method until all negociations looking to a settlement with their employees, broke down. It did not take long however to bring some of the worst mines into line when a definite line of action was agreed upon. Men were requested by the mine officials to send up a normal day's output and were warned that failure to do this would result in their being sent out of the mine or transferred to sections giving low outputs. Day men employed in the sections found idle were sent out of the mine. In this way the cost of operating was kept down, the tonnage of bad sections was kept up and the output of the mines made to correspond to the number of men employed. Probably no weapon of retaliation was ever used by an organized body with less success, and we are certain that none was ever so much hated and despised by miners and their wives. It is said that "Soldiers swore in Flanders" but there were more than soldiers using fierce oaths on Saturday when empty pay envelopes were opened and silly miners had to admit they could earn more but that they were afraid to be "bawled out" by their fellow-workmen. But fear fled before the crying need of families, and one after another of the Miners' Committees met and agreed with the Management that they would do a full day's work. And when the order went forth revoking the low production policy there were few to hear it for it had been fully demonstrated that the weapon used was two edged and more dangerous to the user than to the opponent.

New Development Work Awaiting Stable Conditions

A large program of development awaits a settlement of the wage dispute at the collieries of Nova Scotia. In the Cape Breton district alone many hundreds of men would be able to find employment. New slopes would be put down and new collieries equipped with up-to-date plants.

At some of the older colliery centres which have long leases of life ahead, electrification of power would be made and all other departments modernized. The Dominion collieries are kept well to the front and all mechanical devices and machinery which make for efficiency and safety are sought out and installed.

Eminent Engineers Employed

Eminent mining engineers expert in under sea mining have been brought from Britain to advise in working the extensive submarine areas of Cape Breton. Their knowledge and experience as applied to all undersea collieries of the Island has been of immense value. From the result of an inspection by one of these last fall, No. 9 colliery Glace Bay has been [illegible] seam, known as the "Harbor" seam, the Phalen seam, which is operated by No. 2 Mine. As the coal faces of both collieries were almost one above the other, it was decided that the [illegible] be advanced. This being done and No. 2 colliery has been placed on double shift to [illegible] of No. 9 Colliery.

About the time that the Empire Steel Company are taking shape expert Mechanical Engineers were brought in from the United States to advise as to changes in machinery. The future had great things in store for Nova Scotia collieries.

Undercutting machines are used [illegible] They are adapted to the different coal seams. Large [illegible] low coals and safety are all factors governing the kind of machine used.

British Columbia Letter

THE SPELTER CONTRACT

A recent debate in the Imperial House of Commons, disclosing that Great Britain is under contract up to 1930 to purchase large quantities of spelter from Australian producers at a price ranging from £1 to £10 per ton, transport extra, has created much comment in British Columbia.

Within the past few years the Consolidated Mining & Smelting Company of Canada has become a very substantial producer of spelter, its Sullivan Mine ore carrying zinc values and the plant at Trail B. C. having been brought to the point metallurgically that permits an economical reduction of the ore and the shipment of the spelter at a cost that gives assurance of at least a fair chance of successful competition in the open market.

The electrolytic plant of the Trail Smelter was installed during the war. It then was an experiment to a large extent. The cost of the undertaking was heavy. The need of the product at that time was imperative and the Company did not hesitate in taking the chances involved. The result was a considerable output of zinc which was sold at prices below those obtaining elsewhere. There is no doubt that the Company did the country a service in the bold adoption of this policy and in fearlessly carrying it to an issue at that time. Research work has been going on constantly which only recently has had its reward in bringing methods of treatment, particularly with regard to the ores of the Sullivan Mine, to that stage of perfection beyond which it can scarcely be expected to go. Coincident with this announcement comes the statement that an additional plant is to be provided for the handling of custom zinc-bearing ore of the Kootenays. The benefits, therefore, are to accrue not to the Company alone but to many of the independent operators of eastern British Columbia. With local conditions brighter than they have been for many months the realization that the market of Great Britain, and through Britain possibly a considerable part of that of continental Europe, is tied up, is viewed with some alarm in mining circles of this Province.

Criticism is met with, not only from officials of the Company affected, nor alone from mining interests directly and indirectly concerned, but from the general public. One of the Vancouver City daily papers "The Daily World", after referring to the British Government's undertaking to purchase 45,000 tons of refined spelter annually for ten years from the Electrolytic Zinc Company of Australia at a considerable premium above the present price of the metal, asks: "How is the purchase of this huge quantity of zinc—nearly double the amount that Trail turned out last year—going to affect the zinc market? It is hardly conceivable that it will have other than an injurious effect. If so the further question arises is it quite fair to the Trail plant, that has borne the burden of developing the electrolytic zinc process during the stress of war, and that sold zinc to the British government during the war at a price that sometimes was as much as ten cents per pound below the price that was being paid for the metal in the United States? If the British Government is disposed to confer favors to zinc producers surely the British Columbia plant has as good, if not a better, claim than the Australian one.

Portland Canal District

G. B. Turner and associates, who recently acquired the Indian Group of Mineral Claims, Portland Canal District, are having supplies packed in over the snow so that an early start may be made on development work.—Three crown granted mineral claims owned by the Portland Canal Mining Co. Ltd., of Vancouver B. C., have been bonded by C. S. Baker and associates. The claims are situated on American Creek and there is a good trail from the Bear River Trail to the property. Considerable work already has been done on the ore showing, a tunnel having been driven 100 feet in addition to numerous open cuts. Samples have run as high as 700 ounces silver to the ton.—The Premier Mine from the first of the year has shipped 11,800 tons of ore and concentrates. In the week prior to the present writing 2,400 tons were shipped.

Dolly Varden

No announcement has yet been made as to the plans of the Taylor Engineering Company for 1922 with reference to the Dolly Varden Mine and railroad. The assumption is that, if development is not continued on the former, the railroad will operate at least to the extent necessary to handle the ore offering from properties of the district. There is a probability that work will be done on the Wolf Group, north of the Dolly Varden, with a view to the proving of ore bodies believed to belong to the same formations as those of the Dolly.— The Consolidated Homestake Mining and Developing Company proposes placing a 150-ton concentrating mill on its property in the Kitsault River section of the Alice Arm District. The installation of a hydro-electric plant on Clearwater Creek, one and a half miles away, also is planned. Tunnelling is in progress on two veins, one of which is fifty feet wide. Conservative estimates it is said indicate that the ore carries about $25 a ton in gold, silver and copper values.

New Lead Schedule

A new lead schedule has been issued by the Consolidated Mining and Smelting Company which, it is said, will have the effect of adding about $4 a ton to the value of the average Slocan District lead ore. Both the deductions and the zinc penalties are reduced and a larger proportion of the New York exchange is allowed shippers. The changes in detail follow:

1: A larger proportion of the exchange on gold and silver will be allowed to the shipper, especially when the exchange is at a low rate.

2: Instead of a deduction of 1½ cents from the London lead quotation, the deduction will be 1¼ cents.

3: There will be a charge of only 30 cents a unit for zinc, instead of 50 cents a unit as recently.

American Boy Mine

E. T. Davey, of Mullen, Idaho, president and managing director of the West Hunter Mining Co., Idaho, was visiting Kaslo B. C. recently after an inspection of the American Boy Mine, situated near Sandon B. C. Mr. Davey thinks this property has possibilities and work will be resumed on it. Approximately half a million dollars in mineral values has been taken out of the American Boy and Mr. Davey believes that there is a large tonnage of carbonates remaining which will average 30 oz. silver, 20 per cent. lead and 15 per cent. zinc as well as some small bodies of high grade ore. Only 15 per cent. of the vein showing has been opened up, it is said, while of the latter only 35 per cent has been developed, so that there is much to be done and the prospects are good. In No. 5

tunnel there is a large deposit of zinc ore, carrying high gold values of silver. Further development will start during the summer, probably in June, and Wm. J. J. Smith, at present superintendent of the Tamarack and Lucky Jim Mine, will be in charge.

Britannia Mine

N. J. Quigley, vice-president of the Britannia Mining & Smelting Co., arrived in British Columbia recently from El Paso, Texas, and has been inspecting the Company's properties on Howe Sound, near Vancouver B. C. Rebuilding operations now are in progress at Britannia Beach. A new concentrator is under way and the town, which was wiped out by flood, is being reconstructed on a different site. The concentrator will be of a modern type and is expected to cost, when completed and ready for work, about $800,000. It will be capable of producing 2,500 tons a day of copper concentrate and preparations already are in progress at the mine for operation on a larger scale. The old plant worked at the rate of about 1,000 tons a day. The old town consisted of some 182 homes. This number is to be considerably increased. H. F. Browning, general manager of the plant, states that the new equipment should all be in place and ready for use by the fall of the year. Mr. Quigley has left to visit Mexico properties in which he and his associates are interested.

Rush to Cedar Creek

Excitement grows over the gold discoveries in the Cariboo District. There already is a rush to the Cedar Creek section near Quesnelle Forks and not from the old Bullion Workings where the first claims were staked last year. When the snow disappears in May a stampede may be looked for if reports of the richness of the ground continue. It now is said that gold has been found on Spanish Creek, which is in the same locality. These finds are on high ground back from the waterways. This is the explanation of how the gold was overlooked by the miners of '62. Some four or five feet of snow still covers the country so that little will be done of a definite nature for some weeks. Meantime supplies are going in in large quantities, the road houses are crowded, and Williams Lake, the jumping-off point on the Pacific Great Eastern Ry., already is said to resemble to an extent the gold-frenzied communities that grew up like mushrooms in the Yukon during the Klondyke rush of '98.

Radium Ore On Valdez Island

The report of the finding of radium-bearing mineral on Valdez Island, Queen Charlotte Group, has resulted in the staking of numerous claims in that part of the Province. Exploration and development on a considerable scale will take place during the summer.

Prospectors Returning To Portland Canal

C. A. Mackenzie, one of the principal owners of the "M. C." Group of Mineral Claims, situated in the Portland Canal District and said to adjoin the property of the Premier Mining Company, has returned after a visit to Stewart. He says that prospectors and miners are beginning to return to the district after spending the winter outside. With the Premier working to capacity and in view of the established richness of that Mine he was assured that there will be many engineers over the Portland Canal region this summer inspecting claims under development. Mr. Mackenzie is on his way to California whence he will go to New York.

Victoria Prospectors' Association

A prospectors' association has been formed in Victoria the officers of which are Hon. President, George H. Ayland; President, G. E. Winkler; vice president, Thos. Colby; secretary-treasurer, G. B. Kitto; Executive, F. P. Slavin, C. W. Frank, P. B. Pinnett, and James Miller.

TURBINAIR HOIST

On page 152 of our issue of March 17th there appeared an illustration of a column hoist, which had inadvertently been intercharged for another, and credited to the wrong manufacturer. In correcting this mistake, on page 185 of the issue of March 31th, the cut used was again wrongly ascribed to a third company. It never rains but it pours!

We reproduce herewith the illustration of the Turbinair Hoist, manufactured by the Sullivan Machinery Company, of Chicago and Toronto. The Journal offers its apologies for having made this double mistake.

The Congo has become a factor in the world's production of gold, though its production is less than $2,500,000 a year. An extensive mineralized area has been discovered by prospectors of the Nile-Congo Syndicate, which belongs to the Tanganyika Concessions group. The discovery is described as of alluvial gold, which is said to have been traced in several rivers. What is believed to be the source of this gold has also been discovered in the form of an auriferous belt of rocks extending several miles. An old working carrying copper and gold has also been discovered, with evidence of an ancient copper-smelting industry in the vicinity.

Jones & Glassco Reg'd., of Montreal and Toronto, have been appointed the Sole Canadian Agents for the Unchokeable Pump Limited of London, England.

The Unchokeable Pump is constructed on the Centrifugal principle but so designed that fibrous solids, skins, sacking, etc., will pass through it without diffienlty. It is specially constructed to withstand the hard grinding work inseparable from the constant pumping of all kinds of fibres, semi-solids and solid matter. No screens are necessary for large objects, and practically anything capable of passing through the suction, the pump will discharge.

Northern Ontario Letter

THE GOLD MINES

Power Shortage Over

At the time of writing this letter, the weather is mild and warm, rain is falling. The great stacks of snow are settling fast and already the water is flowing rapidly into the lakes and rivers. This has completely relieved the power shortage for the present and will now permit all mines to operate at maximum capacity.

Dome.

An official statement of achievements at the Dome Mines for the eleven months ended February 28th shows earnings of over one million dollars. The financial reserve in bonds, cash and call loans amounts to about two and a quarter million and thereby reflects the outstanding success of the past year's operations. The indications are that no difficulty will be experienced in making net earnings of from $3 to $4 per share annually.

West Dome—Dome Lake Merger.

The directors of West Dome Consolidated and Dome Lake have ratified the proposed merger of the two properties. The management are confident that the combined properties can be operated profitably.

Power Conference

An important conference relating to the industrial progress of this part of Northern Ontario was held last Thursday in Toronto.

The T. and N. O. Railway Commission is in conference with the Hollinger Consolidated Gold Mines and the Abitibi Power and Paper Company in connection with arriving at some mutually advantageous plan whereby the big water powers on the Abitibi River may be turned to early industrial use.

Heretofore the Abitibi has claimed priority rights while the Ontario Government has hinted at reservation of further development for the electrification of the T. and N. O. Railway. In addition to this, the Hollinger Consolidated Gold Mines have endeavored to secure rights to develop energy. These organizations may be correctly referred to as "The Big Three" of this part of Northern Ontario. The T. and N. O. occupies a place of great importance and influence, the Hollinger Consolidated is now rated as the leading gold mine of the world, and the Abitibi Company is one of the world's greatest newsprint producers.

The main point is that there is ample hydro-electric energy potentially available for every industrial concern in this part of the country. This round table conference has been necessary for some time, and has been long deferred.

In an interview with the Journal, A. F. Brigham, general manager of the Hollinger Consolidated, pointed out that his company has the money and the desire to go ahead with the development of power. He referred to the fact that the present situation could scarcely be excused, in that all that was required to assure development is authority form the Ontario Government to go ahead. As to this, of course, the Government has hesitated between the desire to yield to the request of the Hollinger and the duty it may owe to the Abitibi as well as the interests of the T. and N. O. Railway.

This conference is said to be a preliminary to another discussion, to take place on April eleventh. Although the Northern Canada Power Company is fortified behind established hydro-electric plants and carefully drafted contracts to supply the leading mines of Porcupine with energy, yet this company is not mentioned in connection with the conference. This fact has occasioned considerable wonder and surprise.

Wright-Hargreaves

Following the completion of the station at the 550-ft. level of the Wright-Hargreaves Mine, the work of sinking is being continued and should reach the 700 ft. level by the second week in May. In the meantime, in addition to continuing operations at the upper levels, particularly at the 400-ft. level, the opening up of the 550-ft. level is also under way. There is already evidence that the ore is as good if not actually better at the 550-ft. level than on the upper levels. The drifting operations at the new level are already supplying a substantial tonnage of ore for the mill.

During the month of March, the mill treated an average of approximately 180 tons daily, this being a little lower than during the preceding month, for the reason that a break in one of the crushers caused a delay. Production, however, continued about normal and will approximate $65,000 for the month.

A favorable recent development has occurred in the east cross-cut at the 400-ft. level where the downward continuation of a rich ore shoot, has been cut, formerly worked at a depth of 300 feet through the No. 1 shaft.

Queen Lebel

Arrangements have been made to instal a mining plant on the property of the Queen Lebel. The equipment is now on the way to the mine, and will be installed as rapidly as possible. This new property lies immediately to the east of the Kirkland Lake Proprietary and is regarded as being one of the more attractive prospects in this area. T. J. Flynn is consulting engineer for the company, and the financing is being done largely in Kitchener, Ont.

Rich ore at Sylvanite

A rich strike has been made on the Sylvanite Mine, at a depth of 390 feet. The ore has a width of from seven to nine feet and is typical of the rich shoots on the Lake Shore, Wright-Hargreaves and Kirkland Lake Proprietary. The values closer to surface had been found to be scattered in a number of stringers, but these have now coalesced and form an excellent orebody. In the meantime, a working station having been cut at this depth, the work of sinking to a depth of 520 feet is to be continued. Effort will centre largely on this sinking, and lateral operations will not be undertaken until the 520-ft. level is reached. Great importance may be attached to this rich strike on the Sylvanite, in that it occurs in the main break along which the adjoining Wright-Hargreaves on the west is getting its ore, and in which the adjoining Kirkland Lake Proprietary on the east is developing high grade ore. The property is about 1,500 feet in width between these two adjoining mines.

Wisconsin-Skead

After being idle for over two years, the Wisconsin-Skead Gold Mines will again be operated, the question of transportation facilities being now considered. It is believed a gasoline tractor will be used for hauling in supplies, and that this method will remove the serious handicap under which the property was formerly operated. It is stated that $280,000 have been spent heretofore in opening up the property.

EDITORIAL

Alaska, Northern British Columbia and the Yukon were considered worthless, because the farmer denounced them as unfit for agriculture, till the prospector and the miner cultivated their mineral crops. And the same will probably prove true of that vast, forbidding, forested country, the Labrador Peninsula, including the whole ridge between the St. Lawrence water system and Hudson Bay.--Dr. James Douglas--1909.

A PICTURE WITH TWO SIDES

In reckoning our national resources in the way of minerals asbestos bulks large. The mines of the Thetford district in Quebec provide 85 per cent. of the world's annual supply of asbestos, and constitute the bulk of the Province's mineral production. Almost all this asbestos is exported to the United States, to be re-exported or manufactured. As the value of the manufactured material is many times what it is worth when it leaves Canada, it can logically be said that the United States has a larger interest in our asbestos mines than have we Canadians.

How can Canada reap more benefit from the silky fibre that Nature has provided so bountifully? This question is now current, as it is periodically. Some believe that sufficient co-operation among the principal producers would result in an enhanced value for all grades of fibre; but the interests of these producers are so divergent that there seems little hope of such agreement. The latest proposal, not new, but re-iterated, is that an export duty should be imposed. The effect of this, as seen by a former Canadian, now resident in New York and a miner and seller of Canadian asbestos, is well set forth in a recent letter to the Montreal "Gazette" by Mr. B. Marcuse.

The fiscal policy of the United States, which has been fairly consistent for years past and will remain for years to come, precludes the possibility of importing manufactured materials from Canada, where a similar tariff results in high manufacturing costs. The only object of an export tax on asbestos would be to stimulate its manufacture in Canada. The United States is the chief market, and from it Canada's manufactured asbestos would be virtually excluded.

Canada's asbestos deposits are unique only in that they are large, accessible, and capable of economical operation. Many other asbestos districts, particularly that in Rhodesia, need only a fillip such as the Quebec legislature proposes to give them, in order to seize the world's principal markets.

There are two sides to this question, and we are confident there will be at Quebec no hasty action in the matter. To make the most out of our raw materials is a worthy object, and one that we must pursue always. But we must regulate our actions in accord with economic principles, else we will repeat on this side of the border the tariff comedy now being staged by our neighbors.

INVENTORY

The deficit of the Canadian National Railways for the past year is estimated at $72,000,000.

Cutting down expenditure and operating costs may for a time reduce this amount in slight degree. Economies, *per se*, are needed. Economies at the risk of lessening efficiency are to be strongly deprecated. Insufficient expenditure on maintenance over a short period means doubled outlay in the future.

The Canadian Mining Journal was first in drawing attention to the unquestionable fact that permanent improvement in the freight earnings of our railways can be brought about only by the expansion of the mineral industries. On August 15th, 1909, the Journal printed an outstanding article from the pen of that great Canadian, Dr. James Douglas. Dr. Douglas, always a pregnant source of ideas and of inspiration, had turned dry statistics into living fact. Since that time the journal has not ceased to urge the importance of mineral development to our railways.

In this position the Journal has been sustained and confirmed by none more ably than by Dr. Charles Camsell, Deputy Minister of Mines, in his recent calm statement of facts.

"The mining industry, therefore, is bound to be an important factor in assisting to place our National Railways on a paying basis, and the point that I wish to emphasize is that the part that this industry can and will play in this connection is far greater than the people of this country, and perhaps even our railway administrations, realize. A study of this question has fully convinced me of the great value of the mining industry to railways, and has led to the consideration of some plans whereby the Department of Mines might co-operate with the National railways to bring about a development of the mineral resources tributary to these railways, and I trust that this co-operation will become a fruitful one."

But Dr. Camsell and his colleagues will not be

energy and good-will that mortal men can muster, cannot overtake the work in hand, much less make the progress the occasion demands. Our new administration in Ottawa must face this fact squarely. Let us illustrate.

The Geological Survey and Mines Branch have, through field and laboratory examinations, made a valuable survey of Canada's commercially useful rocks. Yet annually we are wasting millions of money by using inferior wayside road-metal, instead of good trap rock. The public is ignorant; the public awaits instruction. The railroads need the freight.

Limestone is a valuable fertilizer. There is plenty of limestone available throughout the Dominion at strategic points. The public do not realize its usefulness, and need instruction and demonstration. The railroads need the freight.

Throughout Canada there are huge deposits of low-grade iron ore. In two places methods for commercial "beneficiation" are on the verge of success. An effort of national dimensions is required to make success complete. The public is, in the main, ignorant of the problem. The railroads need the freight.

Our resources in feldspar, gypsum, barite, talc, china-clay, are far beyond the present demand. Their production needs thorough-going organization, based on lines that the officers of our Department of Mines can best point out. The railroads need the freight.

If the work of the Mines Branch and of the Geological survey can be co-ordinated with the potential effort of the public, the way will be clear for a rapid development of our mineral resources. How can this be effected?

At present there is a technical officer of the Department of Mines whose special function it is to give to the public the information it wishes. He is doing the work of two men. If he could divide himself into six parts, and each part do a day's work, all would be over-worked. There is no money to provide him with assistants. Consequently the public does not get the aid it should, and progress within the department is stifled under a staggering load of routine. This is typical of the conditions under which our hard-worked and poorly-paid scientists are working.

The Hon. Mr. Stewart has recently recommended that appropriations be made sufficient to pay our technical officers in the Department of Mines decent salaries. This is the first step. The next step is to increase the numbers of the staff up to the point where education of, and collaboration with, the public can take its proper place alongside the technical work. Then the two branches of the Department of Mines will bring results that will wipe out our railway deficits within a short space of years.

PORPHYRY CONTACT ZONES

At Porcupine, Kirkland Lake, Matachewan and Shiningtree, there are masses of porphyry near the gold deposits. In some cases the gold deposits are partly enclosed by porphyry, in others they skirt it. In some cases the porphyry is merely waste rock, while elsewhere it constitutes a part of the ore. Some veins showing good ore a short distance away from the masses of porphyry, decrease in value near or in it. The variety of occurrences gives no conclusive idea of the actual connection between the porphyry and the gold deposits; but enough has been observed to make it advisable to search closely for gold in the neighborhood of porphyry intrusions in Northern Ontario.

At Cobalt there has long been significance attached to the fact that diabase intrusions occur near the silver deposits. Comparatively little silver has been mined from the diabase itself, but most of the silver has come from within a few thousand feet of the intrusive rock. The gold deposits are on a larger scale than the silver veins, and a somewhat wider zone should be prospected for gold. There is really very little known about the origin of the gold deposits, and there are few safe guides for prospectors; but the suggestion of Mr. Tom Saville that prospectors watch these contacts for mineralized schist and "pan and keep on panning," seems a good one. By the way it might be profitable for prospectors to make more use of mortar and pan than has been the case in recent years.

The special brand of porphyry that is associated with gold deposits in one area may be in many respects different from that in another area. Some are red while others are gray or white. The intruded rocks are grey and dark-gray basalts and other volcanics, conglomerates, slates and other sediments. The gold deposits are not what are called contact deposits in a technical sense. They are, however, for some reason yet unknown, associated with intrusions of porphyry. Prospectors would be well advised to examine the areas near masses of porphyry with special care and to work away from the porphyry into the basalt and schist as far as there is evidence of mineralization. This may be for miles or only a few thousand feet. Mr. Saville has "hit the nail on the head" in this case as well. We have little doubt that exploration will result in discovery of gold deposits in Northern Ontario where there are no porphyry masses; but those who would make use of observed facts will give the porphyry contact zones close scrutiny.

OPPORTUNITIES IN ROCKS

Since history began, we have records of the interest of the human race in the production of the precious metals. The inhabitants of this globe to-day are no exception. "Gold" is still a magic word, and the mention of "silver" is sure to attract attention. Yet these two metals play a comparatively unimportant part in the daily life of the average man. Our interest to-day in the precious metals is a cumulative inheritance from predecessors who, through centuries of troublous times, have found them to be attractive ornaments, useful mediums of exchange, and wealth easily hoarded, conceal-

ed and transported. Their intrinsic value today is more apparent than real; yet the habits of ten thousand years are not to be easily overcome, and gold and silver will for many a year continue to retain their preeminence in the minds of men.

Of far greater importance to our civilization are the non-metallic minerals, usually lumped under that term, and considered in a very sketchy way by the average citizen, or even by the average engineer. That these prosaic minerals are of the utmost importance may be gauged by the fact that without clay, we would have no bricks, no cement, no pottery-ware or china of any kind. Without gypsum, we would still wait months for our plaster walls to dry. Unless limestone were abundant, we could have no walls of stone except dry walls. If Nature had provided no beds of salt, the sea would yield us the table variety only at great cost, and for potash we would still be dependent upon the ashes of trees and kepy. Unless there were hard trap-rock available, our road-builders would continue to waste millions of money annually on soft rock surfaces, as at present.

Our non-metallic minerals deserve more attention than they receive. In some cases, such as the manufacture of cement, opportunities are quickly grasped. The cement industry is well-organized—too well-organized just at present, some people think. The exploitation of some other non-metallic minerals has still to be organized in a thorough-going way. Two such instances are suggested in our columns today. The gypsum trade and the feldspar trade need broad-gauge organization, particularly the latter. The exploitation of our feldspar resources has, until lately, been relegated largely to amateur miners and to mine foremen. Its organization along the lines of modern engineering and business (but not "finance"!) should yield a handsome return on the initiative expended.

The most important of all non-metallic materials in Canada just now, and the least considered, is road metal. The Provinces have embarked upon a large and extended programme of road-building; yet the roads already built have, in general, a cheap surface, made of limestone, soft mine rock, or what-not, which wears out completely in three or four years. This is poor engineering, and a worse investment. When the public come to realize that a few dollars more per mile would have given them roads surfaces that would last two, three or four times as long as the present soft surfaces, they will blame both engineers and administrators. Shoddy work seldom pays. The responsibility for shoddy road surfaces will, presently, bear heavily upon the builders.

EDITORIAL NOTES

The Canadian Mining Journal is pleased to announce that it has secured the services of a correspondent eminently suited to represent it in Nova Scotia. The trenchant criticism in the last two issues, dealing with the coal mining situation, speaks an intimate acquaintance with Nova Scotian affairs that augurs well for the success of our new coadjutor.

The Journal's recent unkind words about the stamp-mill have brought a rather touching rejoinder in the form of the song sung by this giant in the prime of his strength, when as yet his might was unchallenged. This song is not mere versification: it is the nearest approach to true poetry that we have published for some time. Its quality will be best appreciated if read aloud.

Less than a year ago the coal industry of Britain was in the throes of a strike. Today it is prosperous and progressive. The miners are working hard, and are earning good wages. The reason is that the miners are, collectively, responsible for the rates of wages they obtain, which will drop with a lessened production.

The same case is up for decision in Nova Scotia. The outrageous policy of "striking on the job" has failed. It is possible that a "collective labour contract" may prove the solution of the difficulty there, as in Britain.

PERSONALS

Mr. Percy E. Hopkins of the staff of the Department of Mines, Ontario, will leave shortly for the field. He will examine and map gold areas east of Kirkland Lake. Later in the season he will visit the Schreiber gold area.

Mr. A. G. Burrows will revisit the Porcupine gold area this season. Mr. Burrows mapped the area some years ago for the Department of Mines.

THE SONG OF THE STAMP-MILL

This is the song that the stamp-mill
Thunders all night and all day;
The song that it sings to the watchers
Watchers, working for pay
Thumpetty — strumpetty thump
Strumpetty — thumpetty thump
A strumpet is gold,
Let all men be told!
But I am so made
That I capture the jade
Tries she to 'scape'
Ha! that is a jape!
I chase her, embrace her,
Till, wanton no longer,
She finds me the stronger
Thumpetty — strumpetty — thump
Strumpetty — thumpetty — thump
This is the song that the stamp mill
Thunders all day and all night.
The song of the chase and the capture,
The song of predominant might!

ANON

Honourable Charles Stewart

To those engaged in the mining industry throughout Canada, interest in the new federal ministry centres upon Hon. Chas. Stewart, who holds the portfolio of Minister of Mines. As Mr. Stewart is, in addition, Minister of the Interior, Minister of Immigration and Colonization, and Superintendent-General of Indian Affairs, he carries an exceptionally heavy share of administrative responsibility.

The functions of Mr. Stewart's departments, and the problems with which they are concerned, are chiefly developmental. To these departments, perhaps more than to any other governmental agencies, the Canadian people are looking for the initiation of policies which will hasten business recovery and the return to substantial national growth.

HON. CHARLES STEWART

To his new posts Mr. Stewart brings personal and public experience of singularly practical value. Born at Strabane, Ontario in 1868, he removed to the west in 1905, homesteading near Killam, Alberta. As a pioneer western farmer Mr. Stewart acquired, first hand, the intimate knowledge of settlement conditions which is essential to a clear understanding of immigration and colonization problems. He appreciates, as only a successful pioneer farmer can appreciate, the difficulties that face the individual settler and the lines along which public policies in regard to land settlement must be directed to ensure sound development.

Above all, Mr. Stewart's grasp of public problems is not restricted to land settlement and agriculture. He has been one of Western Canada's outstanding advocates of diversified growth to bring into effective use not only new farming areas but minerals and all other natural resources which will build up industrial population, offer agriculture a large and dependable home market, and give the Dominion, as a whole, much better-balanced development.

Mr. Stewart entered the Alberta legislature in 1909, being elected by acclamation in that year and again in 1913. In 1917 he became Premier of Alberta succeeding the late Hon. A. L. Sifton. At various periods during his provincial career Mr. Stewart held the portfolios of Minister of Municipal Affairs, Minister of Public Works and Minister of Railways and Telephones. He has, therefore, enjoyed an exceptionally broad administrative experience and is, in addition, credited with much progressive legislation designed to meet the peculiar needs of Western Canada.

Honourable Mr. Stewart has assumed office at a period when the public mind has fastened the greatest hopes and expectations upon his post as a factor in solving the Dominion's most pressing problems. The character of his private and public experience will be a source of public assurance that the policies of his departments will be shaped by a thorough practical understanding of the services they must render.

CORRESPONDENCE

Brooklyn, N. Y.
April 10, 1922

One Grubstaker

Editor, **Canadian Mining Journal,**

Sir:— My attention has been drawn to your editorials and articles on the prospector.

Although I agree with much that you say in praise of the prospector, I wish to state that my own experience in employing prospectors has been extremely disappointing.

For 25 years I have been actively interested in mining. Of more than 20 prospectors that I have grubstaked at least 18 have caused me loss. With one I broke square, and with another I shared the proceeds of the sale of a Nevada property. This very nearly but not quite, reimbursed me for my total outlay (with interest). But I had nothing to make up for long years of mental anguish.

Perhaps prospectors in Canada are more reliable than they are in our country. I do not know. But I do know that it is a very hard thing to judge your man correctly.

For this reason I would go further than you suggest in your columns—I would have every prospector examined and certified by official authorities. This would save many a fruitless chase after *Anser Americanus* (I have forgotten my botany so, please, see if this is correct.)

Twice I have crossed the continent to look at "mountains" of ore that did not exist. Of course I should have known better. Anyway my grubstaking days are over and done with. But as I say the same thing every Spring, I may have something more to write you on the subject next Winter after the snow falls.

Yours etc.

Grubstaker.

Conditions in the Feldspar Industry of the United States

Abstracted by N. B. Davis.

THE U. S. Bureau of Mines recently issued a Mineral Technology Bulletin (Serial No. 2311), describing conditions in the United States Feldspar Industry, as reported on by Mr. Raymond B. Ladoo.

Some of the principal points set out by Mr. Ladoo are as follow:

(1) Many grinding companies do not own or control all or even a major part of their sources of crude material, but buy in job lots from many sources.

(2) There is great need of more adequate engineering and chemical control over mines and mills.

(3) Out of date, inefficient methods and equipment for mining and grinding are in common use.

(4) Little or no cooperation exists between feldspar producers, but on the contrary many feldspar companies are exceedingly secretive; this tends towards (a) preservation of obsolete methods (b) want of knowledge of the essential features of production, market requirements, and the relation between total milling and consuming capacities of the country; (c) inefficient and often mistaken trade practice; (d) unprofitable and even ruinous competition in dull periods.

(5) The small size of many feldspar deposits precludes maintenance of an efficient organization at each individual mine.

(6) Many of the best deposits of feldspar situated close to railroads are becoming depleted, which results in gradual lowering of grades and increase in cost for better grades.

(7) There is a lack of exact knowledge of the ceramic properties and behaviour of feldspar by some consumers, which results in (a) purchase of feldspar on the basis of price alone, thus encouraging low production costs at the expense of quality and (b) inefficient and expensive cross-hauling of both crude and ground feldspar.

(8) The grinding capacity of the country greatly exceeds the consuming capacity. There are more than 25 mills with a total capacity in excess of 300,000 tons per year, for a normal consumption of not more than 150,000 tons per year.

(9) There is a lack of uniform tests, specifications and standards of quality and fineness for different uses; and lack of standard definitions of grades.

Inefficient Methods and Equipment:

Inefficient methods of mining or quarrying, and out of date mills are in many cases responsible for undue waste, high costs and poor quality of product.

In the quarries visited, the proportion of good feldspar recovered to total material moved varies from 30 per cent to about 80 per cent and averages not more than 50 per cent, but a large part of the material wasted is good feldspar in small pieces or mixed with small amounts of objectionable impurities. The purer the feldspar the greater is its friability, and consequently the greater are the losses in fine sizes from blasting. In order to obviate this difficulty lighter blasts are used, which result in large blocks of feldspar. These blocks are sledged by hand, sorted and hand cobbed to remove impurities, but hand cobbing is slow and expensive. If very careful cobbing and sorting are attempted the costs may be unduly high, so the only alternative under this method is less careful work which results either in wasting large amounts of good feldspar or lowering the grade of product. At many quarries there are large dumps containing 50 to 80 per cent good feldspar either in fine sizes or in lumps mixed with impurities.

Many quarries are very poorly laid out. This is due to a lack of careful prospecting to determine the limits of the ore body before opening the quarries, and to lack of systematic planning. Several quarries were noted where large waste dumps have been allowed to accumulate on top of valuable parts of the feldspar deposits. The subsequent removal of this waste is expensive and the cost may be prohibitive. Some deposits have been opened by a series of small irregular scattered workings in such a way that efficient operation is impossible. While it is recognized that many feldspar deposits are so irregular in outline that no standard methods of quarrying may be used, still, many quarries would profit greatly if a definite scheme of development were determined and followed. Small scattered workings cause waste of ore, and are more difficult of supervision, require more equipment, and complicate systems of haulage and waste disposal.

In the milling of feldspar, inefficient methods and machines are even more prevalent than in quarrying operations. As at the quarries many needless re-handlings of ore by labor are common. At one plant the ore is unloaded by hand from the cars into wagons, hauled to the mill, unloaded by hand to the mill floor, sledged into small pieces, shoveled into wheelbarrows, wheeled and dumped into "chaser mills". In this type of mill so commonly used in feldspar grinding, the rock is crushed by heavy stone wheels revolving about a common axis on a bed. After being coarse ground, it is trammed by hand and dumped into pebble mills of the intermittent type. When the grinding is finished the feldspar is dumped on the floor, and shovelled by hand into storage bins. From the bins it is loaded by hand into motor trucks, hauled to the railroad and transferred by shovel and wheelbarrow into box cars. This method involves at least six changes by hand, while efficient methods should involve but one or two rehandlings at most.

Most of the feldspar grinding mills still use the old, inefficient types of grinding machinery which have been common for many years, although it is encouraging to note that a few mills have begun to install more modern equipment. For primary grinding the six foot "chaser mill" and for final grinding the intermittent pebble mill, or dump cylinder, are still so common as to be almost standard equipment. At most mills the crude ore is first crushed in a jaw crusher with manganese steel jaws, but in some mills the chaser mill feed is prepared only by sledging. The chaser mill should have little or no place in modern milling methods. It requires too much room and too much power for the work it does. The intermittent pebble mill is now of value mainly for grinding small batches where a small output of relatively coarse material is required. It is inefficient because it is intermittent and not continuous, because it requires much manual labor, because it occupies too much room in proportion to its capacity and because its principle of operation is incorrect for fine grinding. In this mill the grinding action is most effective in the first few hours and becomes progressively less efficient, because the cushioning effect of the fine material prevents free grinding by the pebbles. It has been aptly stated that fine grinding under these conditions is like trying to pulverize sea sand by striking the [illegible] Thousand

Small Size of Felspar Deposits

Inefficiency in feldspar mining cannot always be easily remedied. Unfortunately, as already stated, most feldspar deposits are not large. In many districts the deposits are small, irregular, scattered bodies situated in rugged areas distant from a railway or river, and with steep, sometimes impassable roads. Under such conditions, the owners of a deposit often cannot afford to maintain an efficient technical or business organization, or to install expensive machinery, and "ground hogging" methods may really be the most economical. There is, however, a possible solution to this problem. If the owners of a number of small deposits in a rather limited area, such as in some of the North Carolina districts, would get together and consolidate their holdings into one company, a unit might be formed strong enough to justify the investment of capital ample for economic operation. Work could then be concentrated on the best deposits, modern machinery installed and a competent manager and technical force employed. A few such units could easily supply the total feldspar demand of the country more cheaply and efficiently than is done today.

Exhaustion of Best Deposits.

Many of the best deposits of feldspar close to lines of transportation have been exhausted, with the result that poorer grades of feldspar near the railroads are being mined and the mining of the higher grades has become more expensive. As a matter of fact large deposits of strictly number one grade in the East are scarce, although by the use of proper methods and equipment, number one feldspar can be produced from some of the lower grade deposits. However, number one feldspar must inevitably command a higher price than it has in the past. As the most easily accessible deposits of number two feldspar become exhausted the consumers must be prepared to pay higher for this grade also.

It has been stated by some that number one feldspar cannot now be had in commercial quantities and that even number two grade, free from objectionable impurities, will not be available in the near future. This is not true, for our available supplies of feldspar, even in the East, are still very large; but better and more expensive methods of mining and preparation must be used and longer hauls will be necessary. When prices attain a certain level, it will be possible to mine and ship feldspar from regions now comparatively inaccessible in Canada and the western States.

Lack of Specifications and Standards

Comparatively few consumers buy their feldspar on specification, and no uniform specifications exist, although from time to time such a system has been suggested. Most consumers make use of a few simple practical tests, but these are not uniform and their value, as far as giving accurate dependable information is concerned, has been seriously questioned. Also, no clear definitions of feldspar grades exist. Number one grade to one potter means practically pure feldspar of the grade known as dental spar, while to another it means a material reasonably free from objectionable impurities such as tourmaline and garnet, but containing as high as 25 per cent of free quartz. Grade names or number, therefore, mean little and consequently price quotations based on such grading are not comparable. Since the feldspar producers have no uniform standards to meet, they cannot be held entirely responsible for unsatisfactory grades of product.

In order to improve this situation producers and consumers should cooperate in setting up uniform specifications and definitions of grades, and in devising simple standard tests, so that the producer can keep an accurate check on his products.

GYPSUM TRADE SPECIFICATIONS

(Editor's Note:— The following specifications are condensed from the Proceedings of the Twenty-Fourth Annual Meeting of the American Society for Testing Materials. They are therein denominated "Tentative Specifications", and, as such, are subject to revision. All of our readers who are interested in gypsum production will find these specifications exceedingly useful.)

I. Materials and Standards

Pure gypsum is calcium sulphate combined in crystalline form with two molecules of water.

No material may be considered gypsum within the meaning of these specifications which contains more than 35.5 per cent. by weight of impurities.

Gypsum may be marketed in any of the following forms and sizes:—

(a) **Run-of-Mine.**— The form in which it comes from mine or quarry.

(b) **Crushed.**— Run-of-mine gypsum reduced to sizes suitable for specific uses. It may be marketed in keted in any of the following sizes:—

No. 1.— Material all passing through a 3-inch ring; not **more** than 30 per cent. passing through a 100-mesh screen, and not **less** than 40 per cent. remaining on a 3/16-inch or equal mesh screen.

No. 2.— Material passing through a 2-inch ring; not **more** than 30 per cent. passing a 100-mesh screen, and not **less** than 10 per cent. remaining on a 3/16-inch or equal mesh screen.

(c) **Ground Gypsum.**— Ground gypsum may be marketted in any of following sizes:—

No. 1.— Material all passing through a 14-mesh sieve, and not **less** than 85 per cent. passing through a 100-mesh sieve.

No. 2.— Material all passing through a 14-mesh sieve, and not **less** than 60 per cent. nor **more** than 85 per cent. passing a 100-mesh sieve.

No. 3.—Material all passing through an 8-inch-mesh sieve, and not **less** than 40 per cent. nor **more** than 60 per cent. passing through a 100-mesh sieve.

II. Sampling

When gypsum is shipped in bulk, samples of about 5 lb. each shall be taken at regular intervals during the complete loading or unloading the carrier, in such a way as to accumulate at least 200 lb. of material. This shall be broken so that **all** will pass a 1-inch ring, thoroughly mixed, and reduced by quartering to provide not less than a one-pound sample for the laboratory.

When gypsum is shipped in packages, at least 3 per cent. of the packages shall be sampled both from the surface and the centre. These samples shall be broken, mixed, and quartered as directed above.

All samples shall be placed immediately in an air-tight container and shipped to the laboratory for test.

The British Empire Steel Corporation, controlling the Dominion Iron & Steel Company, Dominion Coal Company, Nova Scotia Steel & Coal Company and Halifax Shipyards, will move on May 1st to the sixth floor of the new Canada Cement Building on Phillips Square, Montreal.

News of Mining

Platinum deposits have been discovered in Albania, according to official reports. No details are available. The discoveries were made by Professor Sadetholm, University of Helsingfors.

An encouraging symptom as regards the copper market is the fact that the Calumet and Hecla Mining Company, re-starting operations on April 1st, will mine and mill 2000 tons of ore daily.

Mr. Edgar Rhodes, ex-speaker of the Dominion House of Commons, now president of the British American Nickel Corporation, has returned from a visit to Christiania, Norway. While in Christiania Mr. Rhodes met the Norwegian investors in the Corporation. In a printed interview he spoke optimistically of the results expected from research into possible new uses of nickel. He made no reference to the much-debated recent re-organization.

Late cables from London bring the information that both the Daily Mail and the Daily Express (Lord Beaverbrook's organ) advise their readers against investing in the Porcupine Davidson gold mine. The Mail expresses the opinion that the vendors should have been satisfied with much smaller share of capital.

During an investigation before a committee of the United States Senate Brigadier-General Amos A. Fries, chief of Chemical Warfare Service, stated that from his experience in France he was convinced that an organic chemical industry is essential to the country's well-fare and that it should be protected during development.

The world's production of coal during the year 1921 is estimated at 1,100,000,000 metric tons (2,204 lbs.) as compared with 1,305,000,000 metric tons for the year 1920.

Throughout the majority of United States coal mining districts and those of Western Canada, the miners' strike became affective on April 1st. On the preceding day the first murder due to the strike was committed near Bloomsburg, Pa. There a non union miner was shot from ambush while he was on his way to work.

At eight of the leading gold mines on the Far East Rand, South Africa, the width of stopes averages 67.5 inches. The waste rock mined ranges from 43.6 per cent to 61.4 per cent, averaging 55.7 per cent. Vein matter varies in thickness from 14 to 41 inches, averaging 30 inches. The reasons adduced for this high proportion of waste are the flat character of many deposits, the lack of hand drill labour, and the occurrence of natural bedding planes.

European Russia is credited with an output of 1,976,000 tons of petroleum during the first half of 1921. This is less than half the production of the corresponding period of 1915. Production is steadily declining under Soviet control.

The United States Bureau of Statistics, in its monthly report, notes that the February average of metal prices was 23.8 per cent under the average of all other commodities. For only one month in the last two years has any group of commodities been lower in price than metals.

The subject of a duty on imported magnesite is still being debated by a United States Senate Committee. Steel producers are stated to have urged maximum duties of $5 and $3.75 per ton on grain and crude magnesite respectively, whereas the Fordney bill provides duties of $15 to $7.50 per ton.

Before the war there was some slight activity in gold mining in France, more particularly in the Limousin and Plateau Central districts. At present all active operations have ceased.

Graphite production during the year 1921 was less than at any time since 1902, the world's estimated total being 85,000 metric tons as against 100,000 metric tons during 1920. Canada's output was almost negligible. Ceylon's exports (4,422 metric tons) were only a fraction of pre-war tonnages. Korea held its own with exports of 11,000 tons. Mexico exports 3,088 tons, almost a normal amount. Germany, alone, forged ahead with a production of 30,000 tons or 50 per cent more than unofficial returns for 1920. Shipments of 15,000 tons on consignment from Madagascar during 1920, helped to bring on the present slump.

Fluorspar production in the United States during the year 1921, fell 85 per cent in value and 81 per cent. in quantity. Shipments amounted to 35,600 tons, valued at $708,000. Imports amounted to only 6,229 tons.

During the year 1921 there were 715 fatalities in coal mines in the United Kingdom, 12 fatalities in metalliferous mines and 46 in quarries. All of these figures were lower than the corresponding totals for the year 1920, which were, respectively, 1,103, 27, and 51. Of the 715 deaths in colliery accidents, 378 were attributed to falls of ground, 250 to miscellaneous underground, 72 to surface accidents, 26 to shaft accidents, and 19 to explosions of fire damp or coaldust. In the underground deaths 116 were caused by trams or tubs.

The disastrous effects of the strike habit are illustrated in the recent history of the Sulphide Corporation, Broken Hill, New South Wales. Before the war the normal output was 200,000 tons per year. Strikes during 1916 brought the output down to 182,000 tons, in 1917 to 167,000, in 1918 to 123,000 tons, in 1919 to 113,000 tons, in 1920 to nothing, and in 1921 to only 62,119 tons. Since the year 1916 costs per ton of lead concentrates produced have risen from 26 19s. to 242 [illegible]

English buyers of tungsten ores base their contracts upon 65 per cent. tungsten trioxide (WO$_3$) as a minimum and base the content up to 1 per cent. Higher prices are paid for 70 per cent. tungsten trioxide ore with not over 0.25 per cent. [illegible] not over [illegible] per cent. and phosphorus not over 0.01 per cent. Molybdenum ores are bought on a basis of 85 per cent. molybdenum sulphide (MoS$_2$) [illegible]

per cent. Some Chinese ore runs as high as 96 per cent. molybdenum sulphide.

The New York Journal of Commerce estimates that the United Mine Workers receive about $25,000,000 a year of dues deducted from the pay envelopes of miners; and suggests that if Congress investigate the coal mining situation it should enact legislation against involuntary membership in unions and should compel all unions to account for the money they spend.

United States coke production figures for the year 1921 show the strong position occupied by by-product ovens as compared with bee-hive ovens. By product ovens produced 19,918,000 tons of coke, bee-hive ovens only 5,501,000 tons. The figures for 1920 were, respectively, 30,000,000 tons and 20,000,000 tons. Bee-hive outputs were less than in any year since 1885, while by product output was greater than that of any year preceding 1917. The full annual capacity of present by-product installations is 44,275,000 tons. 85 per cent. to 90 per cent. of the figure represents actual working maximum.

A campaign for the reorganization of the Sicilian sulphur-mine industry is well under way. Two-thirds of the mines are owned by the Anglo-Sicilian Company. At these there is noticeable improvement. Large reserve stocks, low prices and indifferent labour are the prime causes of the present slump.

The Chile Copper Company, Chuquicamata, Chile, possesses larger ore reserves than any other copper mining company in the world. Its estimated and probable ore is repoted as follows: 326,300,000 tons of oxidized ore, 1.91 per cent. copper; 151,000,000 tons of mixed ore, 2.98 per cent. copper; and 210,000,000 tons of sulphide ore, 1.84 per cent. copper. Its monthly output is about 4,000,000 lbs. of copper.

Making the Labour Union Responsible for Production

(Abstract specially prepared for Canadian Mining Journal.)

In the March 18th number of "The Industrial Digest", Mr. T. M. Ave-Lallemant discusses very lucidly the question of the relation between employers and trade unions. The issue of collective bargaining, he states, must be settled on the basis of principles acceptable to society generally.

In their attitude towards unions, employers have the choice of four alternatives. They may discourage the unions, and, if possible, destroy them; they may disregard them; they may deal with them as they are; they may co-operate with them to bring about needed reforms.

Even if, as in England, labor unions were recognized, legally-constituted bodies, their position would still be dubious. American employers do not recognize the working men's right to bargain collectively. Labour is still regarded as a commodity. To many employers the so-called "open-shop movement" aims not only at a refusal to deal with labour organizations, but also at purely individual bargains. Other employers prefer to deal with their employees through shop committees or works councils.

But destruction of the union has not been achieved. It probably never will. So long as they remain they cannot be successfully disregarded. Their partieipation in wage settlements is, therefoe, essential to industrial peace and economical production.

The Open Shop Issue

Dropping all cant, let us see what the open or closed-shop issue really amounts to. Employers say that the unions, by insisting upon a "closed" shop, limit the freedom of workers as well as of employers to make such contracts as they please to make. The answer is that collective agreements necessarily limit freedom of contract; for the collective agreement stipulates that individual contracts made thereafter shall conform to certain terms defined in the agreement. If the agreement provides that the employer shall pay not less than the union scale of wages, then the "open shop" can mean only one of two things:— Either that the employer has no dealings with the unions, though some of his employees may be union men; or, that the employer makes an agreement with the union that does not bind him to apply given terms to all employees of a certain trade, but leaves him free to employ as many workers as he sees fit to whom the terms of the agreement shall not apply.

But a trade agreement that does not apply to non-union and union workers alike is of no value to the union or to its members. The union contends that since all benefit by its agreements, all should bear its burdens by becoming members.

"Soldiering" a Common Practice

The second major objection to the union, the charge that they instruct their members to limit their individual outputs, is made even by those employers that deal with them. The charge cannot be denied; but we have no present means of knowing how generally such restriction is practiced. Only better economic organization will do away with this custom.

Most trade agreements are, in the main, wage settlements, and do not generally fix definite standards as to the quantity and quality of work to be done. It is still left to the employer or to his foreman to get as much and as good work as be can out of the men. It is a question open to debate who has done more to break down the standards of quality in workmanship—the careless and poorly trained workmen, or the manufacturers of the "just as good" product.

If an agreement stipulates a time-wage, the faster workman has no inducement to do better than the average, the manufacturer's income is reduced, and the unions themselves are reacted against. Employers, therefore, have demanded agreements that stipulate payment by results. But the piece-rate system is the crudest of all methods of paymnt by results. It cannot fix either quantity or quality. It is unsatisfactory to both unions and employers.

The Real Solution

The step now holding real promise of progress toward a peaceful settlement, is the collective labour contract. This does not mean a trade agreement. Trade agreements are not enforceable contracts. They merely imply as many individual contracts as there are workmen employed. The collective contract is an enforceable contract between an employer and a group of workmen who undertake to produce a quantity of a finished product within a certain time and for a fixed amount of money. The price to be paid for a given quantity of work within a fixed period is agreed upon. Results only are paid for, and there is no motive to limit production.

This has been done in a sufficient number of instances and on a sufficient scale to prove that the plan is practicable.

News and Comments

By ALEXANDER GRAY

The Story of Minerals Separation

One of those mental lapses which are inevitable, even if inexcusable, made me state that the late John Ballot was associated with Claude Vautin in the earlier stages of the Minerals Separation development. Vautin and his work were in my mind at the time, so I would correct my error and in doing so tell the story of who was John Ballot and how he accomplished his great work in the metals world.

Mr. John Ballot was born in Cape Colony, British South Africa, in 1861. Before leaving South Africa for England in 1895 he engaged in various mining and metallurgical ventures.

The Elmore oil-rafting process became known in England about 1899, and Mr. Ballot in 1900–1901 carefully studied this process, and in association with Mr. W. W. Webster and others took an option on the Australian rights, which option expired in October, 1902, without being exercised.

About this time, Mr. A. E. Cattermole discovered his agglutinating or granulation process. Mr. Ballot became interested in this latest development of oil concentration, and organized the Cattermole Ore Concentrating Syndicate in London in 1903.

It was during the investigation for the cheapening of this process that in March, 1905, he was associated with Messrs. H. L. Sulman and H. F. K. Picard in the invention of the air-froth flotation process of ore concentration which has since revolutionized ore-dressing methods in all parts of the world.

This process was patented in England in 1905 and in the United States of America in November 1906, and has been the foundation for world wide litigation between Minerals Separation, Limited, of London, Minerals Separation American Syndicate (1913) Limited, the Sulphide Corporation (Australia), and Minerals Separation North America Corporation, on the one hand, and the Ore Concentration Company, Limited (holders of the Elmore process patent rights), James M. Hyde, the Butte & Superior Mining Company, Miami Copper Company, Utah Copper Company, Nevada Consolidated Copper Company, Chino Copper Company, Ray Consolidated Copper Company, Magma Copper Company, and others on the other hand.

Mr. Ballot, as Chairman of the Board of Directors of Minerals Separation, Limited, was largely instrumental in defending their interests in long and expensive litigation in the British and Australian courts. This litigation was decided in favor of Minerals Separation, Limited, in the House of Lords (the final Court of Appeal of England) and the Privy Council (the final Court of Appeal for British Dominions Across the Seas).

Mr. Ballot was President of Minerals Separation North American Corporation from the day of its incorporation in 1916 until his death on April 1, 1922. He largely directed the American litigation and the Minerals Separation companies received sweeping decisions in the opinions rendered by the United States Supreme Court in both the Hyde and the Butte & Superior cases. These decisions are considered by the metallurgical profession to the most important since the famous McArthur Forrest cases. In the first suit his patent was declared valid and infringed, and in the second the limit of the patent was defined. This patent was again considered in the Miami case in the Federal District Court for the District of Delaware and the United States Circuit Court of Appeals for the Third Circuit, together with two later patents (U. S. 962678 and 1099699). Decisions in these cases were in favor of Mineral Separation and were not appealed to the United States Supreme Court.

Litigation in the various other cases is progressing.

Mr. Ballot's efforts in inventing, applying and introducing the flotation process to the metallurgical industry in all parts of the world conferred an inestimable boon to mankind, which will be remembered for many generations.

The Oil Complex

One half the Oil World wishes it did not know how the other half is over-producing. Speculators and large vested interests are perfervid in their desire for curtailment, or for confirmation of their expectations that Mexico cannot maintain its pace. General Director Deterding of the Royal Dutch Company protests against insensate over-production when the demand for enormous quantities does not exist. As a consequence of this, the price situation cannot be rectified. Producers find themselves in a position from which refiners will not extricate them. In the long run the race will be to the strong who are protecting their production by acquiring great areas. Meanwhile the small fry cannot agree with the Deterding view. They have to sell oil, even if dividends are paid out of capital. Yet Sir Henry W. A. Deterding is not a factor to be lightly disregarded.

Newfoundland-Labrador Enterprises

It is said the Armstrong Whitworth plans for developing Newfoundland water powers, forests, and mineral areas, have undergone a change, if they have not been altogether abandoned, owing to the ends large enough to meet their requirements. There was to be lumbering, pulp and paper making, diversification of the government to make concessions for coal mining, on a broad front, but the aid sought from the Government, it is alleged, is not forthcoming. Meanwhile the British Metals people are said to be drilling in Labrador in the vicinity of Gull Pond, about fourteen miles inland from Little Bay. Already two holes were put down at Little Bay, to a depth of about 1600 feet. Then the drill was moved to Gull Pond.

Washington's Affection for Canada

The so-called Fordney tariff, fearfully and wonderfully contrived, is convincing proof of the determination to exclude what will compel [illegible] essential crude materials and minerals. Senator Lafollette has the temerity to intimate that Fordney Bill (there is doubt as to its parentage) [illegible]. No doubt it is untamed. [illegible] speed limits in its amending schedules. [illegible] that copper ore from our coal-[illegible] and

precious metals bullion will be admitted free. A levy of 2½ cents a lb. on copper and 3 cents to 25 per cent. on nickel, are exhibitions of "love spats" seemingly on the assumption that the cats of Kilkenny had the right idea—the more "spats", the more cats. But they must be American cats!

Gold and silver bullion is not going to be outlawed in any degree. Refined copper and nickel are prejudiced, along with the products of Canadian iron ores. With the imposts upon farm staples and cattle, certain pulps, aluminum, etc., even the occupants of the tombs of the Pharaohs will see that Brotherly Love is rampant across the border. Advocates of Reciprocity will appreciate the more how Washington dissembles its love and throws us down stairs.

Not much has been overlooked by the tariff-smiths on behalf of professedly decrepit industries and interests of a country that has the overwhelming portion of the world's liquid capital, and a paltry $1,000,000,000 in gold. However, as "commerce is war", Canada will have to shape its course accordingly, and stop being too submissive—or is "supine" a better word? Of course asbestos is unmolested, and mattes may be exempt. Maybe the last has not been heard of the changes; for the graphite producers of Alabama are perturbed and tearful about competition from Mexico, Madagascar, Ceylon and Canada. First on the alphabetical roll of States, Alabama considers itself last in the line of preferment. Its iron and coal are shielded, but its graphite is positively solar-plexused unless it receives the first-aid sought. Without a tariff the industry cannot evade sleeping sickness or locomotor ataxia, though a rude person named Schnell publicly asserts that what Alabama most needs is quality production. To that end Mr. Schnell proposes that Alabama producers "get down to hard work and study to make it possible to compete with the foreign product".

Kirkland Lake Gold Mines

The surplus on operations of $13,015 reported by Kirkland Lake Gold Mining Company for 1921, is nothing to cherish as an heirloom. Evidently the grade of the 25,715 tons treated for a production of $147,654, made the $5.73 average recovery per ton. While latest developments are represented to be very encouraging and extensive development is planned, the explanation that "much ore is tied up on account of a possible rock slide", hardly suffices, without details. However, the fact that a great deal of money belonging to parent organizations has gone into this property makes it necessary to have the hopes of the management sustained. President Culver hung up a picture of what is below the 700 foot level; a shaft is going down to 1,900 feet, and Kirkland Lake Gold may be more prosperous than it has been.

Fooling With Our Feldspars

That the feldspars constitute the most important of rock-forming minerals is not fully realized by even the scientifically initiated. That Canadian feldspars are going to mean more and more in our national economy is less thought of than is at all wholesome or profitable. Hence the comment of the **Engineering and Mining Journal-Press** upon the latest Canadian figures on the production of those minerals is useful to emphasize our prevalent disregard of their potentialities.

The Journal-Press is complimentary to Canadian producers for the "creditable" showing made, the tonnage mined being 33,597. But agony enters when it is stated that "slightly more than 2,000 tons was milled", although "shipments, all from Ontario and Quebec, totalled 30,540 tons, valued at $223,000, an average of $7.31 a ton. Of this all but 200 tons was sold in the crude form".

The sting is in the tail of the comment. The remedy and the reason therefor is set forth in this way: "Canadian feldspar has been in considerable demand in the United States in recent years, and the erection of further grinding plants in Canada will permit of the export of Canadian feldspar at a much higher price than is now obtainable for the crude product. One new grinding plant has been opened during the year (1921), and "**Canadian producers are apparently fully alive to the desirability of preparing the Canadian product in its most valuable form**".

Under the circumstances, the words are worth the italics. It is a bit dubious to have it said we are "apparently fully alive"; but we should be grateful for the suggestion that the feldspars are amenable to more "valuable" exploitation. The trouble is "one new grinding plant" savors of the "one swallow" that "does not make a summer".

How About Lead?

What was the idea the other day when it was proposed at Spokane that Canadian lead be accorded certain privileges of entry into the States? Those present endorsed the position taken by one of the United States Senators against penalizing Canadian lead in pending tariff legislation. They want lead, and British Columbia has it. But, "in the twinkling of an eye", there is jubilation among American zinc producers, to the accompaniment of "rag time", owing to the announcement that a duty of 2 cents a lb. is to be imposed upon imported zinc. The historic game of "what's-yours-is-mine-and-what's-mine-is-my-own" must be applied both ways, unless Washington's philanthropic policy of assimilation is made fully reciprocal at Ottawa.

Bancroft Redivivus

Unmixed pleasure—downright merriment—accompanies the announcement of THE MONTREAL GAZETTE that Professor Joseph Austen Bancroft, A. M., F. R. S. C., F. G. S. A, "used to be a well-known and popular figure at McGill University", and that the veteran geologist will soon resume his work. As a "past tense" Professor who went into strenous "retreat" nearly a whole year ago, those who recall him will have no regrets at his return. To his attainments as Dawson professor of Geology he has added the knowledge acquired as Assistant General Manager of the Granby Consolidated Mining, Smelting & Power Company, at Anyox. So the hiatus of almost twelve months could not have permanently impaired his former popularity and scholastic ability.

Cobalt Magnet Steel

Sheffield put nickel on the metals market. Now it is taking a hand with cobalt. The discovery of "cobalt magnet steel" is hailed with great éclat in London. "The construction of telephones and the making of motor car and aeroplane engines is likely to be revolutionized."

This will provide Canada with another chance to export raw materials. We are specialists in exporting raw material. Now we may be able to ship our superabundant smaltite. Yet our exports are not confined to raw materials; we export finished scientists, because they are encumbrances hereabout. **(vide Mr. Meighen).**

British Columbia Letter

Activity in Yukon

Much development and general activity is expected this year in the Mayo Camp, near Dawson Y. T. The silver fields of this section of the Yukon have been looking better every year since their discovery. The results of last year's operations, satisfactory in every respect, led to the prediction that hundreds, if not thousands, of newcomers would pass through Dawson en route to the new mining Mecca of the North during the summer of 1922. These prophesies promise to be realized. Every northbound steamer from Seattle, Vancouver and Victoria in recent weeks has taken many passengers and much freight destined for Mayo. It would seem that Keno City, and perhaps other "cities" of the locality, are destined to grow, that they have an assured future, and that the former at least may become as famed and widely known as is Dawson, the centre of the golden Yukon.

Operations have been in progress on the established properties of Mayo during the winter, hundreds of tons of ore have been transported over the snow to the riverside ready for shipment south, and, with the promise of early opening of navigation, vessels are beginning to take in supplies for the miners already on the ground and those who are going there. The freight is being rushed in over the winter trail as, for a time after the thaw commences, the roads and trails, such as they are, are very soft and difficult.

In point of authoritative information regarding mining conditions generally in the Yukon an article appearing recently in the "Dawson News" by George P. Mackenzie, Gold Commissioner for the Yukon, is of interest. He says in part:

"During the war and for some time after, mining supplies, especially dredging parts, were practically out of the market, and, when procurable, the prices were so high as to be prohibitive. There is now a marked improvement in this connection which is being reflected in increased activity in dredging operations.

"The cold water thawing process referred to in my last review has proved a complete success. The substantial reduction in the cost of thawing operations by this method brings within the field of profitable operation very large areas of gravels which will not pay to dredge if thawed by steam.

"The summer of 1921 was an exceptionally dry season. The consequent shortage of water appreciably reduced the normal output from hydraulic mining operations. Notwithstanding this, however, the gold output for the year was in excess of that for 1920.

"At least three new placer gold discoveries of importance were made during 1921. The result of Keystone drilling operations on Russell creek, a tributary of the McMillan river, has been so satisfactory that the parties interested have arranged for further development work to be done in 1922, and feel confident that they have valuable dredging ground in that district. A new line of high grade and possibly extensive pay also has been opened on Miller creek. Rich pay also has been discovered on Allgold creek, on a portion of the creek not formerly prospected, and it is confidently expected that this creek will now become a substantial producer.

"Extensive development work was done during 1921 on the silver-lead properties in the Mayo district. The results of this work, I believe, justify the statements now made by competent mining men, that Yukon has in this district one of the richest and most extensive mining areas in the world.

"During the winter of 1920-1921, the Keno Hill, Limited, mined and hauled to Mayo over 2,300 tons of high grade ore, which was shipped to the smelter during the summer. This company has increased its holdings, has kept employed a large force of men during the summer in development work.

"F. W. Bradley, one of the best and most favorably known mining men in American, has acquired extensive holdings in the district, has erected permanent and substantial buildings, and has a large force of men at work developing his property which shows great promise.

"The Slate Creek Mining Co. also has acquired a large group of claims, and is doing extensive development work.

"Smaller concerns and individuals also are busy opening up their properties.

"Some of the pressing needs of this promising district referred to in my last review have been met. A free government assay office was provided in the heart of the district and has been much patronized and appreciated by the prospectors. With the very substantial and generous assistance of the Keno Hill Limited, and the F. W. Bradley interests, a good wagon road has been completed by the government from Mayo to Keno Hill, approximately forty miles. However, additional roads are needed.

"Perhaps the most pressing requirement of the Mayo district at the present time is telephone or telegraph communication with Dawson or some other point that has communication with Dawson and the outside world by telegraph. Every effort is being made to secure this communication, and it is confidently hoped that arrangements to this end will be perfected during the coming summer.

"In the south end of the territory there is increased activity in lode mining, especially in the Wheaton district. There is every reason to believe that this part of the terriory is about to experience an unprecedented development of its rich and extensive mineral resources.

"Present conditions surrounding the industry are in the main satisfactory. At no time in the history of the territory have the people generally been so optimistic for the future, and in my own opinion this optimism is justified by the facts."

The Cedar Creek Rush

It is estimated that 2,000 prospectors will pass through Williams Lake Station en route to the new Cariboo gold fields this spring. There is considerable excitement in Vancouver, Victoria and other coast cities. Blue prints of the Cedar Creek and Quesnelle sections are finding a ready sale at substantial prices. The hardware stores have run out of their supplies of gold pans and the management of the Pacific Great Eastern Ry. is figuring on the additional transportation facilities necessary to handle the men and supplies that will have to be taken to the interior during the next few months. A considerable number already have started for the hills, but the rush will not commence before the middle of May or early in June, when the snow will have gone as to permit work. At Williams Lake, Quesnelle

Forks and other centres, temporary buildings are being erected to take care of the living requirements of the stakers for gold, in fact all through that part of the country there are signs of an incipient boom. Cedar Creek is a small turbulent stream draining into Quesnelle Lake and "Discovery" is a little north of the 52nd parallel of latitude, and about fifteen miles by road and trail from the settlement of Quesnelle Forks. The strike was made about 250 yards from the creek bed in an old channel and the deposit is supposed to be due to glacial action and to be very rich in spots. Whether it will prove to be a case of "many are called and few chosen" remains to be seen, but even if the field is badly spotted the entire district will be carefully prospected.

Washing Gold on Fraser River.

Gold is being washed out along the bars of the Fraser River this spring, the water being lower by two feet than it has been for many years. A number of Indians operating near Pavilion B. C. are reported to have cleaned up over $100 a day over a period of some weeks. This practice of panning gold from the river banks in the spring time has been in vogue since the early days. The season for work as a rule is short as the river rises rapidly with the melting of the snow on the benches above, the bars are submerged and further placer work is impossible.

North Star

The North Star Consolidated Group of Claims, situated on the British Columbia coast 105 miles from Vancouver ,has been purchased from J. D. Black by J. D. Hancock, who expects to be shipping ore to the Anyox smelter within a month. There is a 10 ft. vein on the property carrying argentiferous galena the lead and silver of which is said to average $175 a ton.

Pat Daly, mine owner and operator of the Portland Canal District, who has been spending the winter in Seattle and Spokane, has returned to Stewart, B.C.

S. P. Fitzgerald, one of the owners of the Independence Group, Bear River Section, Portland Canal, is making good progress in development. He recently brought to Stewart some good samples assaying $26.50 in values (gold, silver and lead.)

The reconstruction of the Bear River bridge has started and a wharf is being built at Hyder, Alaska.

Frederick Keffer, mining engineer of Spokane, Wn., has been engaged recently in the inspection of the Riverside Mine, situated a few miles north of Rock Creek, B.C. This is the property of the Jack Paul Mining Co., of Spokane Wn. Paul Nelson has had charge of operations for some time and it is the Company's intention to do considerable development this year.

High grade ore has been opened up on the St. Paul Group, east of Vernon B.C. Gold and silver values are said to run better than $50 a ton. A 300 foot tunnel has been driven parallel to the vein. There is a stream near the property capable of developing 300 horse power. It is reported that the company is figuring on an electric plant for the treatment of the ore. It is being perfected in Spokane and, if it proves to be practical, will effect considerable economy in the handling of the product of the mine.

The Vendela, Hidden Load, and Silva Claims, situated about a mile southwest of Greenwood, B.C., have been bonded to H. McGillvray, H. M. Stramberg and associates. A tunnel will be driven to test the ore at depth. Showings as far as developed run high in copper and carry gold and silver values.

Ore shipments received at the Trail Smelter of the Consolidated Mining and Smelting Co. for the week from the 8th to the 14th of March inclusive totalled 13,168 tons, making the aggregate for the year 123,442 tons. Of the week's receipts 13,151 tons came from the company mines and 11 tons from the Ottawa Mine,Sloean.

New Development Company

The Inter-Provincial Mines Development Company has been organized in Vancouver, B.C. with a capitalization of $500,000. The managing director is T. H. Kerruish, a well-known British Columbia mine operator and prospector, with whom is associated, among others, Mr. John Pedersen, a prospector and mining man with a large circle of acquaintances. The Company has taken over the old Tecumseh Mine, now known as the Nip and Tuck and Silver Tip, on which there is silver lead ore of good grade, several shipments having been made which netted over $70 a ton. There are several veins as yet practically unexplored which show high grade ore on the surface, one shoot giving average values of over $150 a ton in silver and lead. Mr. Kerruish states that it is the intention to take over properties that may appeal to the directors as being good business propositions from the standpoint of the practical miner. He thinks that there are many such offerings in British Columbia and that all that is necessary for their selection is a knowledge of the business.

Geological Survey Parties

Dr. M. Y. Williams professor of palaeontology and stratigraphy in the University of British Columbia, has been appointed to take charge of a Dominion Geological Survey Party which will start from Edmonton, Alberta, in a few weeks to work along the Mackenzie River from Wrigley to Fort Norman. He will enter the Mackenzie River valley by a route that has never before been traveled by a geologist. Dr. Williams will set out from Edmonton in the company of Dr. G. S. Hume, who is heading another Dominion Geological Survey Party. Together they will journey to Fort St. John by rail and power boat, thence by pack train and canoes to the headwaters of the Nelson river, and thence to the Liard River and the Mackenzie. This will take them to Wrigley. The route was thoroughly explored last year by Inspector Marraway of the Topographical Survey of the Department of the Interior, caches of supplies and general necessities being left along the trail. With headquarters at Wrigley, geological explorations will be carried on, special attention being given to the country along the east side of the Mackenzie, which is comparatively little known. Dr. Hume's party will be one of the first to make Fort Norman after the river opens, and his season's work will be confined to the district adjoining Fort Norman to the north. Dr. Williams, who is one of the foremost Canadian authorities on oil geology, joined the faculty of the University of B. C. a little more than a year ago after two years' experience as professor at Yale. He is a Fellow of the Geological Society of America.

Preparing for Rush to Cedar Creek.

The Provincial Government, recognizing that a rush to the Cedar Creek section of the Cariboo District, will take place as soon as the snow disappears, is taking steps to provide adequate facilities for the recording of placer or mineral claims. There now is a Recorder at the 150 Mile House, Cariboo Road. This is some ten or fifteen miles out of the line of travel from Williams

Lake to Cedar Creek and, also, is not on the route to the Whitewater Country where gold has been discovered and to which there will be a moderate stampede, judging from present indications. For these reasons the boundary of the present Quesnelle Mining Division has been extended a short distance southward to take in Williams Lake Station, Pacific Great Eastern Railway. The Mining Recorder will be transferred from the 150 Mile House to this Station. The change will permit him to carry out his duties of Recorder for the Quesnelle Division, wherein is Cedar Creek, and Sub-Recorder for Clinton Division, in which is located the Whitewater, with the maximum of convenience to the prospectors and mining men.

Williams Lake Station is the "jumping off" point for both the new placer fields. Westerly trails lead into the Taseko (Whitewater) basin where excitement has been created by the reported richness of claims situated on Iron Creek. This route perhaps is circuitous but is likely to be opened sooner than Warner and other passes. It is understood that it has been surveyed by engineers of the Public Works Department and that, if developments warrant the expenditure, a road will be constructed into the Whitewater which, aside from its mineral possibilities, is known to be a magnificent stretch of open park-like country offering wonderful possibilities agriculturally. Northerly the trails lead into the Quesnelle Lake and Cedar Creek District. The country here, too, is open, the roads and trails under normal conditions good, and there should be no difficulty for the type of man who will be tempted by the adventure of a "gold rush" to reach "the diggings." Neither of the two "fields" that are attracting attention in British Columbia are hard to get at, there will be none of the hardship that attended the stampede to the Klondyke, although there may be some inconvenience, if the influx develops into a flood as now seems possible, because of delay in getting in sufficient supplies. It would appear, however, that the requirements of the miners will be well taken care of as to Mining Recorders. They will have, in addition to the official at Williams Lake, a sub recorder at Quesnelle Forks, only a few miles from Cedar Creek, and the Gold Commissioner at Barkerville.

The British Alaskan Mines Ltd. has been incorporated to develop the Benson Claims situated on Fish Creek on the Alaskan side of the boundary in the Portland Canal District.

The Esperanza Mine, Alice Arm, has shipped 90 tons of ore to the Anyox Smelter, Granby Consolidated Mining and Smelting Co. High grade ore is to be sent to the Tacoma Smelter for treatment.

Considerable work has been done on the Black Diamond Group of Mineral Claims, Clearwater Creek, upper Kitsault River, Alice Arm. A 32 foot vein has been under development and assay returns have shown satisfactory values in gold and silver.

The first shipment of concentrate from the Tidewater Copper Company, Sidney Inlet, to the Tacoma Smelter since the resumption of work was made a few days ago. It consisted of about 100 tons running about 10 per cent copper. About 250 tons will be shipped every 20 days hereafter. Up to the present the Mill has been operated at only about half capacity because of lack of power, cold weather holding the snow in the hills and thus causing a water shortage.

E.H. Parsons, smelter superintendent of the Granby Consolidated Mining & Smelting Co., has been studying conditions at the Trail, Anaconda and other large smelting centres.

C. S. Baker and associates have taken a three year lease on the Kansas Group, American Creek, and will start development at once.

Harrison E. Moore, of San Francisco, has been inspecting placer ground on Goldstream, Big Bend District, near Revelstoke. He is reported to have secured extensive leases in this district and to propose operating on an extensive scale during the 1922 season.

A tremendous snow slide has cut off the Queen Bess Mine, at which seven persons are employed. Telephone connection with Alamo, where J. Cunningham, the owner, resides, has been established and it is found that there are six months' supplies at the Mine. The slide, one of the greatest known to old timers in that part of the Province, carried away four towers and a mile of heavy cable.

J. T. Smith, of New York, is organizing a party to prospect the upper waters of the Peace River for gold next summer. Mr. Smith thinks that the Company which is placing a large suction dredge on the Peace has one of the best propositions in Canada. Operation of a similar plant on the Erie Canal in the United States cost less than 15 cents per yard and the same work on the Peace should be done for seven or eight cents. That there is pay ground on the river he feels confident. Miners working on the river bars near Hudson's Hope made at much as $20 a day when the river was low.

The Standard Silver-Lead Mining Company, in its report for the quarter ending December 31 last, shows a surplus of $111,710. In addition the Company has paid dividends amounting to $2,700,000 and invested substantial sums in the development of the property. The property now has passed into other hands on a bond and lease.

The Board of Directors of the Cork Province Mines, at a meeting held recently at Kaslo, B.C., decided that active mining would be resumed as soon as the snow leaves.

Reports are in circulation that a newly incorporated Company, known as the Consolidated Bullion Hydraulic Mining Co., proposes reopening the old Bullion Workings, Cariboo in the near future. This is the property that was exploited on a considerable scale by the late J. B. Hobson and over which there has since been much litigation, the right to title as between Ward and Hopp being carried to the Privy Council whose the former was successful. The investment of Mr. Hobson and his associates in plant and general equipment was substantial and their operations resulted in some good clean-ups. The new owners it is understood believe that there is scope for profitable work in these parts of the ground that remain untouched.

GOLDFIELD

At the Porter property at Goldfield, Ontario, a mining plant has been installed and mine development [illegible] expected this year. Owing to the promising [illegible] of the property there is considerable interest [illegible] prospecting in the area and considerable activity [illegible] doubtless be carried on [illegible]

Northern Ontario Letter

The Power Situation

While officials of the Northern Canada Power Company claim that the power development now under way will provide for the requirements for the gold mines from now on, officials of the Hollinger Consolidated have expressed the opinion that this will not be the case. The Hollinger is accordingly negotiating with the Ontario Government for the right to develop energy on the Abitibi River. The T. and N. O. Railway Commission is taking every precaution to retain control of the power rights that will eventually be necessary to electrify the line. At the same time, the Commissioners have gone on record as stating that there is sufficient energy on the Abitibi for all three concerns, namely, the T. and N. O. Railway, the Hollinger Mine and the Abitibi Power and Paper Company. It is believed, therefore, that whatever steps the Hollinger considers necessary will be undertaken at the convenience of that company.

Dome's New Record

Production from the Dome Mines reached a new high record in March, when upwards of $311,000 in bullion was turned out. This makes a total of over $918,000 for the first three months of the year. After adding interest on bonds and loans, plus premium on gold sold at par with United States currency, it is obvious that the total income for the three months was between $950,000 and $1,000,000. The amount of ore being handled averages about 1,000 tons daily and the average recovery is about $10 per ton. No statement of costs has been made, but on this grade of ore it may be estimated at over $4 per ton. However, allowing liberal margin, it is probable that the net profits for the three months ended March 31st amounted to about $500,000, or actually at the rate of $2,000,000 a year. This net profit is at the rate of 42 p.c. on the company's issued capital.

McIntyre

A rich strike is reported to have been made at depth on the McIntyre-Porcupine, although no official statement could be secured up to the time of writing. The McIntyre is working at the deepest level so far reached by any gold mine in Northern Ontario and the report of high-grade ore carries great importance. The General Manager, R. J. Ennis, stated to the Journal correspondent some weeks ago that the geological structure at a depth of 1,875 feet was such as to encourage the belief that the favorable results obtained at from 1000 to 1375 feet would be found to continue to greater depth.

Porcupine V. N. T.

Power is now available, and the Porcupine V. N. T. will proceed at once with an extensive development program. The present 600-ft. shaft will be continued to 900 feet deep. A cross cut will be made to the vein at 750 and 900 ft. at which points lateral operations will be undertaken. With evidence at the leading mines that the mineralization increases with depth, the operators of the Porcupine V. N. T are optimistic in regard to the result of work planned on this mine. The question of placing the mill in shape for operation will be considered when the development work is well advanced.

Gold and Platinum in McArthur Tp.

Assays from claims staked in McArthur township, about twenty miles south from Porcupine, show a gold content of from $3 to $41 and from $2 to$7 in platinum. These samples were "picked", it is understood, but the result is much as to direct attention to that promissing area.

Sinking on Goldale

The Lewisohn interests are proceeding with their plans to develop the Goldale properties in the Porcupine district. Harry Kee, manager of the Kerr Lake mine of Cobalt, is in charge of the work, and an aggressive scheme of exploration has been mapped out. Sinking operations will be undertaken on that part of the property lying at the east end of Pearl Lake, while diamond drilling operations will be undertaken at a later date, from these underground workings.

Hollinger Output

It has been learned officially by the Journal correspondent that an error got through the press some weeks ago in which the Hollinger was shown to have treated 4,700 tons of ore daily. This was due to a a stenographer at the Hollinger making a typographical error, making the statement show 4,700 instead of 3,700. The error was quickly found and corrected at the mine, but a press representative who was hot on the trail for information, secured the figures before they were corrected, hence the widespread error through the press.

Many Claims Recorded

As a result of the staking in the eastern part of the Kirkland Lake gold area well as in the "placer" district south of Abitibi Lake, the recorder for the Larder Lake Mining Division has recorded 854 mining claims during the first three months of the current year. This compares with a total of about 850 during the whole of 1921 and goes to show the extent of the growing interest in the mining areas. This information was secured officially from Mr. Watson, Department of Mines representative at the Department's North Bay branch.

Tough-Oakes

The Tough-Oakes mill of the Kirkland Lake Proprietary, which went into operation on Monday is giving good satisfaction. The whole of the plant, including the new rock-breaking installation, is running smoothly according to official advice to the Journal.

This makes a total of five regular gold producers in the Kirkland Lake district, where an aggregate of approximately 650 tons of ore is being treated daily, with a gross production of close to a quarter of a million dollars a month.

Orr and Teck-Hughes

Officials of hte Orr Gold Mines held a recent conference in New York with official of the Teck-Hughes Gold Mines. The inference taken from this in local mining circles is that either the sale of the Orr mine, or a consolidation is under consideration. The Orr property would be a valuable addition to the Teck-Hughes for the reason that the dip of the ore bodies is to the south and into the Orr property.

Lebel Lode

Directors of the Lebel Lode authorized the purchase of the adjoining La Presle claims. This will give the company about three quarters of a mile of the vein system in evidence on the Lebel Lode.

Argonaut

The shaft on the Argonaut Gold having reached a depth of 500 feet, and the work of equipping the mine with a mill being well under way, this enterprise is on a fair road to occupying a place with the producing gold mines.

Blue Quartz

At the 100-ft. level of the Blue Quartz property in the Painkiller Lake district, the vein has widened to over two feet and contains considerable visible gold. The vein material is being bagged preparatory to making a shipment at an early date.

Beaver

In the annual statement of the Beaver Consolidated, a credit balance of $944,493.66 is shown. This is made up largely of investment in the Kirkland Lake Mining Company as well as cash advances made to that concern.

Bonsall

Reports that shares in the Bonsall property in Gowganda were being quietly acquired last week, are out of date, according to authentic information to the Journal correspondent. The O'Brien has not only held control, but has held practically all of the shares of this company for some time. Any work done will consist of extensions underground of the Miller Lake-O'Brien Mine itself.

Coniagas

Official confirmation has been received in regard to last week's report that the Coniagas has dropped its options on Lande Lake properties and is taking out its exploration equipment.

THE SILVER MINES

Nipissing

According to the regular monthly report by Hugh Park, manager, to the president and directors of the Nipissing Mining Company, the result of work continues to be extremely favorable. Mr. Park says:—

"During the month of March the company mined ore of an estimated net value of $172,747 and shipped bullion of an estimated net value of $362,441. The value of the month's silver production was estimated at 65 cents per ounce. The amount of cobalt produced was 24,936 pounds.

"Most of the month's underground development continued to be favorable. No new veins were found, but development work on several small veins was encouraging.

"The low grade mill treated 7,369 tons. The high grade plant treated 152 tons. The refinery shipped 554,715 fine ounces of bullion."

Consolidated Mining and Smelting Demonstration

By ALEXANDER GRAY

The annual financial report of the Canadian Consolidated Mining and Smelting Company is a refutation of what "can't be-did" contented, as it is the only "can be-did" organization of its kind on this or any other continent during 1921, it follows that the demonstration in force accomplished the purposes of the administration and management, even though the profit was paltry. On a turnover of 110,000,000 lbs. of zinc and lead, 1,173,890 ozs. of silver, and 51,037 ozs. of gold, the net profit was $338,447, or 3.21 per cent. on the outstanding stock, after charging off $232,693 for development and allowing the usual amount for depreciation, this being the status of the profit and loss account:

	1921.	1920.
Sales	$ 7,516,865	$ 7,227,611
On hand, etc.	2,779,131	3,336,163
Other rev.	8,575	31,287
Pow. Co. div.	256,960	241,844
Total income	$10,561,834	$10,837,205
Ore prev. year	3,336,163	2,987,297
Custom ore	385,998	1,717,102
Freight	634,873	517,029
Gen. exp.	5,270,372	1,971,003
Development	232,693	203,278
Depreciation	105,357	105,116
Directors' fees	3,300	8,800
Write-off	22,736	10,928
Net profit	$ 570,043	$ 291,319
Bond int.	321,596	251,023
Net earnings	$ 338,117	$ 10,326
Dividends		790,020
Balance	$ 338,117	$ 719,701
Taxes		99,618
Prev. bal.	$ 338,117	
	809,011	1,068,333
P. & L. B.	$ 1,147,461	$ 809,011

Temerity of Directors and Management.

To do that involved more than oriental philosophy. The item credited to custom ore when compared with that for 1920, clearly establishes the fact that the Consolidated company almost monopolized the field, other producers being negligible. Universal metal market conditions excluded the generality of properties from extensive operations. Not until the latter half of the year, too, did it look as if the Consolidated would win a profit. That makes the results the more exceptional. It could not be expected, under the circumstances, to materially alter this banking position.

Liabilities.

Bonds	$ 3,000,000	$ 3,000,000
Stock	10,533,700	10,533,700
Accrued int.	112,721	121,875
Spl. loan	1,992,000	1,750,000
Other loans, etc.	3,171,957	3,601,201
Accounts pay.	1,121,356	1,777,163
Tax reserve	67,725	87,865
Surplus	1,147,161	809,011
Total	$21,317,171	$21,681,122

Ordinarily, and were the potentialities of this enterprise in all of its ramifications open to debate, those loans and accounts payable would warrant elevation of banking eyebrows. But the company has a profit and loss surplus of $1,147,161,161 and this away

Assets.

	1921	1920
Properties	$10,381,620	$10,400,166
Plants, net	6,173,873	6,241,480
Ores, metals, etc.	2,779,131	3,336,163
Stores, etc.	1,312,350	1,180,920
Accounts pay.	1,121,356	1,777,163
Prepaid chgs.	27,277	29,345
Cash	101,131	66,750
Total asset	$21,317,171	$21,681,122

Advances in Metallurgy

When it is understood that operations at the December 31st last have been cleared up to date as to metals on hand or in process the compliments be-

showed upon the staff by President Warren express the sentiments of those who hold that Canada is capable of securing a larger participation in metal markets. By perfecting metallurgy and obtaining greater efficiency throughout, General Manager Blaylock is enabled to put it on record that the company succeeded in smelting a mixture higher in zinc than any other plant in existence is treating. New standards in recoveries and costs, the grade and quantities of the ores accessible (the Sullivan Mine alone is a guaranteed fund) permit Mr. Blaylock to go further and to represent that the year in review was in many ways the most successful in the history of the company; adversity in the earlier months in contrast with what was accomplish in the last half convinced him that operations can be conducted at a profit under the most trying conditions. Mr. Blaylock pays tribute to the "spectacular" work accomplished at Trail, by selective flotation in separating the finely disseminated sulphides of iron, zinc and lead in the Sullivan ores, (something that Can't-be-dids" claimed was impossible), so, having seconded the General Manager, who courteously awards credit where credit is due, the President, Mr. Warren, subscribes to this peroration:

"There has been such an improvement in the extraction of lead and siver from the Sullivan Mine ore that the capacity of your lead and silver refineries is no longer sufficient to treat the lead bullion produced by the blast furnaces. Your directors have therefore authorized extensions to enable 150 tons of lead bullion to be treated daily.

"Metallurgical processes in the zinc plant having reached the point where it is safe to undertake the treatment of customs zinc concentrates in addition to the zinc concentrates from your own mines, your directors have authorized the installation of the plant necessary for this purpose. It is hoped that shipments from independent producers can be accepted about June 1 next.

"A very effective selling organization has been built up. It covers Asia and Europe as well as the domestic market. Its operations are being extended so that ultimately the "Tadanac" brand of lead, zinc and copper will be purchasable in all quarters of the globe.

"Generally speaking, you may look forward with confidence that your products, with the possible exception of copper, will be marketed with a fair margin of profit."

Future Development

Commanding the situation by right of enterprise and the investment of capital, the Consolidated Company have earned a goodwill that will be highly remunerative in the long run. The prices obtained for their metals were abnormally low. But the policy is one of production and more production. Besides, relief is to be given to smaller producers by the treatment of custom ores, the idea being to afford an outlet for zinc-lead-gold-siver ores. Extensions to the smelting plant are being constructed. It is the announced intention to pay from 60 to 85 per cent. of the zinc for 80 per cent. of the gold and silver in the zinc ore, and for 80 per cent. of the lead, less five units. The gold, silver and lead recoveries will be in the smelting of the residues after the leaching out of the zinc and the smelting charge will be less as the zinc ore increases.

Possibly, for the time being, the customs department will not be fruitful as to profits. The company wish to promote general mining in a Province that possesses mineral wealth comparable with the most productive sections elsewhere. Sooner or later a saving in freight bills will be effected by the erection of a concentrator at the Sullivan Mine. When the copper market improves and export business can be settled, plants for the treatment of Consolidated ores wil be forthcoming. In reality, the 1921 operations are to be regarded as preliminary, and when the money market relaxes it is not unlikely those who have doubted the ability of Trail to sustain the optimism of the administration, will regret their rash judgment.

Sullivan Mine Increasing in Magnitude.

However the Trail Metallurgical Works may have met company requirements, it is the Sullivan Mine that supplied almost 300,000 of the 400,000 tons treated. The Sullivan grade averages so high in zinc and lead contents, it was imperative that an end should come to the low recoveries of previous years. So great a mine with a tonnage and gross value worth very much more than the company's capital commitments, made it incumbent upon the administration and management to better the extraction. Having accomplished this, abandoned selective mining, and solved ore-handing problems in stopes of low dip, only the laity need to have been informed in the annual report that working costs were materially reduced. Already THE CANADIAN MINING JOURNAL readers have been told of the progress made by development and by diamond drilling, indicating further extensions of the ore zones. At the upper and lower tunnel levels, not only have lateral continuity, widths and grade been maintained beyond points intersected by drills, but an agreeable surprise was furnished. In reference to this the report says:

"An interesting, and what may prove to be an important development in the Sulivan ore bodies, was the discovery by diamond drilling of apparently a parallel ore body in the footwall of the main vein, at the north end of the South ore zone.

"The work to date is insufficient to determine the relationship or to prove that it is not a faulted portion of the original vein. Assays of drill cores, however, which showed a width of vein of approximately 20 feet, gave better silver values than the average in the main vein, being about one-half ounce to the unit of lead. Zinc values, on the other hand, were rather lower than the run of mine ore."

When power and concentrating facilities are provided, and are "more in line with the capabilities" of the property, as the report naively puts it, the millions of tons in the known ore reserves and "prospects of continued satisfactory development" will sustain every claim put forward by the Board, and leave no alternative other than to keep on equipping such a mine with whatever it requires. In a year of stressful markets, the Sulivan maintained two thriving communities, contributed remunerative freight to the Canadian Pacific Railway, established markets in two hemispheres and probably convinced "doubting Thomases" that the few bright spots should not be overlooked.

WHITE ROCK

Mr. Wm. McVittie of Sudbury, Ontario, president of the White Rock Mining Co., whose property is at Shiningtree reports that high grade ore has been encountered in the drift at the second level. The vein is much wider at this level than at surface.

Notes From Nova Scotia

Production at Wabana

Wabana Iron Ore Mines, Newfoundland, have been giving a daily output of from 28,000 to 30,000 tons during the winter months. This represents half the capacity of the four mines, which are equipped for an output of 60,000 tons. Less than half the working force of 2,200 men are employed, but when the shipping season opens this number will be increased.

Most of the ore output is being delivered by the Empire Steel Company vessels at European ports. The quality of the ore has been found excellent for steel-making in Germany, and 800,000 tons were contracted for this year with the option of taking 200,000 tons additional if needed. In normal times the Empire Steel Company's plants use 750,000 tons.

The supply of ore, so far as known, is unlimited and cannot be determined because most of it lies under the sea, but it is far beyond the amount of fifty million tons, which was the calculation of the New Glasgow men who first owned it. To say that there are billions of tons might not be incorrect; but it must not be forgotten that the mining of all under-sea minerals, whatever their quantity, has limitations set either by the cost of haulage or by the pressure on the seams. Thus coal lying at great depths sometimes cannot be won. In this case, with no change in the dip, haulage would be the limiting factor.

Wabana measures have three iron-ore seams. The general impression is that Wabana mines are simply of mountainous bulk lying underground. This is far from the truth, for Wabana ore is laid down in well-defined seams, just as we find coal. Britain has stratified iron-ore seams, but they are usually thin and are designated according to color, being known as black and clay bands.

Mining Methods at Wabana

The ore seams of Wabana have a dip of 9½ degrees, and except where faults are met with, the grade is fairly uniform. Faults are occasionally met, the majority of the heaviest being down throws, the up throws being light. In approaching these, great care has to be taken, for the fault planes are sometimes filled with a soft clay substance, which, under pressure, would, if permitted to run, quickly fill up a large section of the mine. In all development work, diamond drills are used and boreholes are kept well ahead to locate water pockets and faults or any other unknown condition. Owing to the many faults such mine plans must be carefully kept.

In all ground that is known to be faulty, a grouting machine, capable of working against a pressure of 1000 tons, is kept ready for use, and when fault planes are reached the sides are quickly and carefully concreted. The slopes are driven of sufficient width to permit of double tracks, with plenty of space between passing trips. Levels are driven at distances of 500 feet and rooms driven with 50 foot centres, with crosscuts 22 feet wide at a distance of 40 feet. To protect the slope, pillars 50 feet square are left, but from this on the pillars left for support are small and fully 85 per cent of ore is mined from the rooms.

All blasting is done by night after the men have left the mine. No mine gas has ever been met with in these mines.

In No. 2 mine considerable ore is loaded by hand, but in No. 3 there is nothing but mechanical loaders. These shovels handle 250 tons of ore per day, and in thick seams one room will keep a loader busy all day. To see this machine at work down in a mine reminds one of a steam shovel on the surface. In thin seams the Myers-Whaley loading machines are used.

The single trip system of haulage is used on the slopes, while on all levels the tail rope system is in use. Mine cars are transported from the rooms to the levels by means of electric hoist of 30 h.p.

Crushing, Cleaning and Storing the Ore

The bankheads are very simple in design. The full boxes after reaching the run in on the bankhead, pass by gravity through single tipples, and continue to the back switch and then to the empty track.

From the tipple the ore is passed on to a steel picking belt where rock partings are picked out. After going through No. 8 Gates breakers set to 3 inches, the ore is passed to a second picking belt where it is again cleaned and delivered into a bin from which it is either loaded into tram cars for shipping to the piers in the open season of navigation, or loaded into stock pile cars to be stocked.

A unique system of stocking ore without any trestle is used. Beginning from the ground and gradually increasing from an angle of 15 degrees to 45 degrees by the use of an outrigger the ore pile is built up to the desired height. An outrigger is a simple device made of two pieces of hard pine 2 ft by 30 ft, on which rails set to gauge are placed, the ends being turned up to prevent an overrun. One half the outrigger projects over the apex of the pile. As the ore piles is built up the outrigger is moved forward until the [illegible]

Ore Pockets and Loading Piers

The ore is carried from the [illegible] to the shipping piers in cars by an endless haulage system, consisting of a speed of five or six miles per hour. The cars are of steel with a capacity of [illegible] tons. The mechanisms are interchangeable and can be used on the upper for removing the rope grips with which all cars are equipped. At the pier terminals the cars pass over the cribb trestles, where the ore drops from [illegible] into the ore pockets. These pockets hold [illegible] tons each, and were excavated from the solid rock to the elevation of trestle at discharge above [illegible]

feet. Under the pocket at an elevation of 87 feet, a conveyor tunnel was driven from which raises (or chutes) were driven to tap the ore in the pockets. These raises are steel-lined and equipped with doors to control the flow of ore as it passes to a conveyor operating on a steel trestle pier. The drop from the conveyor to the vessel is 82 feet. This gives sufficient velocity when deflecting hoods are used to send the ore to any part of the vessel.

When ore is loaded from the stock piles, steam shovels are used. These load into portable hoppers, which in turn fill the cars, the shovel being too large for this work. The distance by tram line to the pier pockets is 11,000 feet. Six thousand tons of ore have passed over this line in one day. This means 400 cars per hr. or more than one car per second. The leading conveyor has a capacity of 2,500 tons per hr., when loading ore into vessels.

A humorous story is told in this connection of a Norwegian sea captain, who was in the ore trade from Narvik to Emden in the year 1913. Having had a tempestuous voyage of twelve days, he felt like taking in the sights when he reached Wabana. As soon as he docked he went to his cabin, shaved, bathed, dressed up and went on deck, only to be handed his clearance from the pier Superintendent. This surprise was too much for the Captain who was in a holiday mood, and immediately the atmosphere became charged with something very much akin to burning sulphur. The vessel had actually been loaded within three hours from the time that it was docked.

Prospecting the Seams

No. 3 mine is prospecting the outer under-sea areas and is kept well ahead of all the others. The vertical depth at the mine faces is 1600 feet. The workings are reached through a slope driven in the strata under what is known as the Dominion bed for a distance of 12,000 ft. This seam is 26 ft. high, and large electric loaders with arms of ten foot spread are used. The ore is loaded into specially designed drop-bottom steel hopper cars, drawn by electric locomotives and emptied into a pocket directly over the main slope, from which it passes into a 20-ton steel hopper car or skip in which it is drawn to the surface. Here the assorting and cleaning of the ore as already described takes place.

Up-to-date wash houses with shower baths and lockers for clothes are built at all mines. The motive power of the plant is electricity, generated from coal.

The amalgamation of the Dominion and Scotia companies reduced the over-head charges by more than 30 per cent. The power plant of the Dominion Steel Company was found sufficient to do the work of both companies, the Scotia power plant acting as an auxillary in case of a break-down. Officers in charge in Wabana are C. B. Archibald, superintendent of operation; Angus MacDonald, mining superintendent; J.B. Petrie, mechanical and electrical engineer; A. R. Chambers, consulting engineer. H. B. Gillis is general superintendent over all mines, quarries, piers etc. in connection with the iron-ore department.

EDITORIAL

The very first step of all in any well-founded scheme of conservation is to know what we have, not only in those portions of our Dominion that are settled and partially developed, but also in that vast northern land, of which too little is known at the present time.--R.L.Borden--1913.

PROSPECTORS TO THE RESCUE

On both sides of the Atlantic the migration (as it is now properly called) of British people is engaging serious attention. In Canada, those responsible for immigration policies have decided that what our country needs most is settlers on the land. This is undoubtedly true. The natural drift from country to city will always provide sufficient industrial workers, and to add to their numbers by immigration is merely to reduce the opportunities of all for earning a competency.

There is one feature connected indirectly with immigration policies that is seldom given due weight, and indeed is often disregarded entirely by authorities that should know better. The importance of mining in our national economy is habitually underrated, and is often ignored. The Canadian Mining Journal has often drawn attention to this fact, and will now approach the question once more, from a different angle.

Our farmers must have markets for their produce. At present a considerable fraction of the total agricultural production is exported, and so helps to pay our international debt and to reduce our national debt. To stand best the cost of shipment to far-distant markets, agricultural products must have the greatest possible value per unit of weight, hence the tendency to ship beef and pork, instead of the grain and fodder that are used to feed the animals. This suggests two points of interest to the miner and to the country at large.

If markets can be found close at hand for agricultural products, the farmer will of course get better prices. If the home market can be expanded, settlement on the land will be given an impetus that the opportunity for export trade cannot equally provide. The home market can be expanded only through the growth of the other basic industries or of the industrial population. Ruling out the latter as essentially dependent upon an increase in the basic industries, we can safely conclude that the development of the home market rests principally upon the development of the mining industry.

Not only do mining communities provide profitable markets for farmers, but the roads and railways built to serve the mines open up agricultural land that would otherwise be inaccessible. Thus the development of mineral deposits proves a double boon to the settler; it gives him access to his homestead and it provides him with the best of markets.

It may be argued that we must build up an export trade if we are to meet our external obligations and leave sufficient balance to make the country prosperous. Quite so. But why not export what will bring the maximum of profit? If it pays better to export bacon than to export corn and shorts, why not sell gold, silver, copper and lead instead of either?

All this presupposes the possibility of finding and developing more mineral deposits within our borders. There is plenty of evidence that potential mines are to be had for the searching; our problem is to find persons competent and willing to conduct the search.

Thus, once again, we come to the prospector. Upon him rests in large degree responsibility for the prosperity of our agricultural population. Without him, the mineral industry would decline and die. With increasing mineral production come increased industrial activity, better home markets for farmer and manufacturer alike, and an export trade of the most lucrative kind.

The prospector deserves, from all and sundry, more serious attention than has ever yet been accorded him. One successful prospector can provide employment for a thousand miners, scores of farmers, and dozens of industrial workers.

"MODERATES" IN CONTROL

In these dark days of industrial depression and labour disputes, it is encouraging to find that throughout the British Empire leaders of "moderate" tendency have regained control. This augurs well, not only for the solidarity of the Empire, but for the prosperity and industrial well being of its component parts.

The [illegible] of the series of struggles [illegible] Mother-land. The [illegible] concessions wrung by [illegible] from the mine owners and from the public during the critical war years culminated in the demand for nationalization of the mines. The public judged the [illegible] the labour leaders their immoderate [illegible]

dical demands, and secured to the miners a high rate of pay in return for a good day's work.

In South Africa, where the strikers on the Rand resorted to force, the conclusion has been summary and decided, as befits military action. That a revolution, brought about by armed force, was intended by the agitators that precipitated the trouble, is attested by the official statement issued after the rebels had been dispersed. "People of all political convictions came forward to help the Government to put down what there is no doubt to have been a social revolution by Bolshevists, International Socialists and Communists." That the miners have returned to work pending an investigation of their grievances, speaks well for moderation of a large majority amongst them. That the burghers turned out almost "en masse" in support of their Government, demonstrates their appreciation of settled rule and the ideals of British justice. Premier Smuts has promised the miners that in spite of the revolution engineered in their name, their complaints will be considered impartially by the commission of enquiry now to be instituted. His word is his bond.

For years the political struggle in Australian has been between labourites of moderate views and those with a radical tendency. In New South Wales the latter have until lately been in control. Some attribute to this the fact that the productiveness of labour in New South Wales has lately fallen to such a low mark that industry there is now virtually paralyzed. New South Wales is blessed with many natural advantages; but these will be useless until the unnatural disadvantage due to the artificial restriction of output is removed. That the late Government under Premier Dooley is partly responsible for this state of affairs is demonstrated by the fact that he offered what was virtually a wholesale bribe to railway employees in his pre-election promises regarding wages and hours of labour. Happily, his regime is ended, and New South Wales may look for a return to prosperity under a leader whose principles are more in accord with true British tradition.

The recent attempt to traduce the morality of Nova Scotian miners has been an utter failure. That the living conditions in the colliery villages are far from ideal, is an undoubted fact, and the public should know more about these conditions, in order that they may judge fairly the miners' demands. That the miners have now unequivocally refused to accede to Organizer MacLachlan's "sabotage" advice, should give them a place in the regard of the public that will ensure fair treatment at the hands of their employers.

We print today a letter from Mr. Robert Baxter, once again the recognized leader of all the Nova Scotian mine workers. The moderation expressed in this letter, and the justice and frankness of the views he states, command the respect of the public. We wish that more of our labour leaders were like Mr. Baxter.

GLACIATION OF MINERAL AREAS

The fact that most of Central Canada was at one time subjected to erosion by a moving blanket of ice, and that now the rock surface shows no noteworthy amount of weathering, is of prime importance to our mineral industry. To the glaciers may properly be attributed the removal of the products of ages of weathering. It is remarkable how little the rocks have been distintegrated since the glaciers retreated. Here and there is found some weathered material at surface, and occasionally oxidized material is found underground; but the really amazing fact is that minerals so easily oxidized have been altered so little. At Cobalt the trenching often disclosed smaltite that had been protected from weathering since glacial times by a thin covering of clay. After exposure the smaltite would rapidly be oxidized to "bloom"; yet the blanket of soil had protected it for ages. Similar indications of the inconsequential dimensions of weathering since glacial times are everywhere evident in the mineral areas. Under the circumstances it may be accepted as a general rule that weathering since glacial times has had little effect on most minerals deposits in the mining areas of the pre-Cambrian shield.

But in the ages before the glaciers crept Southward there was a tremendous amount of weathering and erosion. The pre-Cambrian mountains had been worn down almost to the level of the plains. Over all, or nearly all, was a layer of decomposed rock, including the weathered upper portions of ore-deposits. Then came the ice age, and advancing masses of ice scraped this loose material from off the solid rocks, and in places doubtless wore down the bed rock to some extent. It is improbable, however, that the glaciers wore down solid rock very much; and the constantly recurring statement that it was by glaciers that the rock hills were reduced is now archaic. Glaciers are powerful agents of erosion but they should not be credited with more than their due. They were more efficient than steam shovels in cleaning away loose or soft materials, but like the best of shovels they have their limitations. The mountains were not planed down by the ice-sheet, as was formerly claimed, but the surface was cleaned and polished by glaciation after long ages of weathering.

The important fact to the miner is that the weathered products have been removed and that the mineral deposits exposed at surface have characteristics not dependent on weathering since glacial times. The chance section exposed at the present surface is more likely than not to be an average section.

THE SALE OF SECURITIES IN ONTARIO

The Ontario Government is evidently satisfied that Blue-Sky legislation is not wanted in Ontario. The bill concerning the sale of securities, now before the Ontario Legislature, will not prevent men venturing if they want to. The purchaser himself will have to decide whether or not the chances of success warrant in-

vestment on the terms offered. No attempt will be made by the Government to determine what the chances of success are. There will be no governmental examination of properties for the purpose of determining their merits. Some of the most objectionable features of Blue-sky legislation are therefore being avoided.

There has been a strong feeling in Ontario against proposed protective legislation, because of fear that an ill-considered measure would create new difficulties for those that endeavour to make mines out of prospects. Apparently it has been recognized that no one person or group of persons is competent to judge the merits of all mining ventures. So long as this is realized, the efforts to protect investors are more likely to meet with some success without impeding the progress of the industry. The provisions of the proposed bill indicate that the Government is avoiding responsibility of determining the merits of enterprises, and consequently a good deal of the opposition to the bill will disappear. It was feared that governmental supervision of mining ventures would be interfering and harmful, and it is a relief to see that it is not to be attempted.

The provisions of the proposed bill call for the filing of full information with a Commissioner of Securities. An adequate prospectus must be given to the investor to make the transaction binding. The aim is to provide the investor with information; after that it is up to him to use his own judgment. These seem reasonable provisions; in fact they are the recognized methods now governing the sale of shares. The new feature is the Commissioner of Securities, who will have authority to see that promoters comply with the law.

As the proposed bill does not forecast objectionable governmental supervision of business ventures, the men who endeavor to make mines can continue to use their own judgment, instead of waiting for some public official to tell them whether they may do so or not. The fear of impending experimental legislation has now been removed. Well-tried British measures have been adopted, to the exclusion of measures such as have lately hampered mining development in some other countries.

EDITORIAL NOTES

A press despatch announces "miners doing housework – spring cleaning this year has no horrors for the housewife in the anthracite coal fields." Presumably the strike is a blessing in disguise.

Birds are singing, buds are bursting. The lakes are free and the rivers are in flood. The prospector's season has begun. Reports from the winter rendez-vous of bush-whackers indicate that the old-timers are all ready for the jumping off, and that a host of novices will join them. We wish them good luck, and a quick return on their investment of honest toil.

The Lord helps them that help themselves. This being so, all three nickel companies are qualifying for divine aid. Staffs no longer hard-pressed by the duties of operation have turned to research, and now new ventures, involving new processes, new plants and further investment, are to recoup the failing fortunes of Nickeldom. Such initiative brings its own reward, though it is seldom understood or appreciated by outsiders.

The reports of the commercial use of lignite and peat in numerous countries where cheap coal is not available lend interest to the attempts in Canada to use these low-grade fuels. The researches at Alfred, Ontario, and near Estevan, Saskatchewan, are being carefully and logically conducted, and merit close attention.

TO THE RECENT GRADUATE

Acumen, vigour, both combined
With supermind omniscient,
Is what we're taught that we shall find
In graduates efficient.

I shall not say I've ever known
I do not speak unkindly
A graduate so god-like grown
That I'd admire him blindly

I've met a few in knocking round,
And I've been disappointed
They might be safe, they might be sound
They *weren't* the Lord's anointed.

No genius rare anointed them,
No spark divine inspired them
For if it had, alas, ahem,
Employers would have fired them!

They prospered only if they worked
And toiled *sans* intermission,
No graduate that ever shirked
Achieved a high position.

Envoy

This highly moral verse I think
Exactly what it *should* be,
I wrote it with a solemn wink
As wise a wink as *could* be

In glancing over bank accounts
Of graduates I've *worked* with
I see some very fat amounts
Are owned by those I've *shirked* with

XNOX

A Labour Leader's View

Glace Bay, Nova Scotia,
April 21, 1922.

Editor Canadian Mining Journal,
Sir:

You ask me to give you the men's side of the controversy between the British Empire Steel Corporation and the workmen. I suspect it would be superfluous to describe all the negotiations in detail, as most of that has been published over and over again in the press. You also state that I am considered a conservative leader, and people would appreciate an explanation of the situation from myself. I do not know what is meant by conservative; if it means that I would not ask or take so much as others, then I want to disabuse your mind on that, as I am like Oliver Twist in wanting more, or in other words I am out for all we can get. I look on this as the philosophy of both capital and labor that is the contentious part of our trouble. However, I take it that the public are more concerned as to the differences amongst ourselves.

When in Montreal from Feb. 27th to March 1st inclusive, we had an offer from the Company, of an additional 15c a day for day's wage men. The offer was made with the provision that we (the Executive Board) would make the recommendation to the men for acceptance. The Company had told us forcefully and solemnly that this was their final offer; consequently it appeared to us as a choice between two evils, strike, or acceptance. When all the complicated factors were considered, five of us decided to make the recommendation, the other three agreeing to remain neutral. But we had no sooner reached home than one of the five withdrew his support, and the others went out on the campaign against the offer. The result was a vote that gave a 7 to 1 majority against acceptance.

All dealings between company and men are conducted by a valuation of force. We make an analysis of the company's position, and no doubt the company does the same with ourselves. One of the executive officers found the men were much discouraged by the severity of the cut in wages, and were not doing so much work as usual; also the officials of the company were annoyed because of the increasing cost. This prompted the idea of pursuing a policy of irritation, namely "cutting down production", "strike on the job", "loafing on the job", "ca'-canny" or "sabotage". I could not agree with McLachlan on this policy, claiming that if we had not a chance by strike, then the Company would recognize our weakness and lock the men out, which would create circumstances equal to strike, and this would put us in a position recognized by all to be weak. This is only one of the many methods by which the policy could be attacked, and because of its many weaknesses I could not subscribe to it. On the whole it is a vicious policy; to quote Gladstone, "I don't want to use hard words, which are easily employed and as easily retorted, a game that two can play at". That quotation explains my position. If we play a vicious game what can we complain of if the company plays vicious too? We could have "crossed the Rubicon", the war would be on, there would be no retreat, it would be a matter of crush or be crushed. As we are situated, the Province of Nova Scotia cannot afford to have the company crushed; it is a source of livelihood to a large percentage of her people. We (the coal miners) will not be wise in our own interests, if we pursue a policy wherein a break is very probable. There is much good that can result from having an opportunity to meet the Company officials in negotiations for wages, working conditions, and a hundred and one small matters that are constantly cropping up amongst the 12,000 miners whom we represent.

The cut that was put into effect was very severe; some of our highly skilled contract miners would lose over $2.00 per day. I had secured a favor from the International officials excluding Nova Scotia from the strike of April 1st, because of our not being much of an economic factor amongst the rest of the coal miners of the continent, in the struggle now taking place, and also, that our negotiations were seemingly nearly complete. This arrangement was made months before the big strike took place, with such advantage for the company and ourselves that it should have been the care of the company not to have asked for such a sweeping reduction. A contract for ten months, as is proposed, would allow them, if it were found our wages were out of proportion after the final settlement is reached in the United States, to have further adjustments.

Our hopes are now centred on the Conciliation Board about to be established. The findings of the same will go a long way to bring about the desired peace, which is necessary if the best returns are to be achieved for all concerned,—public, workmen, and companies. My aim has always been efficiency; to get such in mining, the co-operation of the men is essential. What the men want is an open game, where all the cards are on the table, where there are prospects of returns, and the knowledge that others, such as the consumers, are not being made to pay more than a fair price for the commodity we produce. With open arrangements such as outlined, better results could be obtained. There is just another grievance. Mining villages are most often built cheaply, companies possibly fearing that the life of the mine would not be of sufficient duration to warrant putting up expensive buildings. This in my opinion is a great mistake. It most often happens that the mine outlasts the houses. In this advanced age there should be no communities of any size without modern conveniences. The coal miner (that is the contract worker) is highly skilled; he works at a high speed, especially when young and vigourous. His average earnings, when everything is favorable, are much better than many other workmen, and the result is, that he is ashamed of the ancient methods of sanitary accomodation, and degenerate-looking buildings. Much could be done in this direction to give peace and comfort to those who produce that valuable material, coal which is of such great service to our present industrial system.

Yours, etc.

Robert Baxter.

Lammers and Maase, Ltd., of Montreal, have issued Brochure Te 4, describing the "Polar" Diesel engine. These are made in sizes ranging from 100 to 3000 B. H. P. Smaller units, from 12½ to 75 horsepower are also made. Special features claimed for the "Polar" engine are high speed, strength of design and simplicity of construction, and low fuel consumption is guaranteed.

Though most of our mines and mills are normally operated by hydro-electric power, it is often necessary to have additional power either as an auxiliary or as a stand-by. A crude oil engine should serve this purpose excellently well.

Holding The Sapphire Diggings

By DONALD C. SIMPSON.

THE following narrative is a true account of an experience I had over thirty years ago on the banks of the Missouri River at a place called El Dorado Bar. Here, after a summer's prospecting, I had secured a job under a big strapping Scotchman who was in charge of operations for a mining Company engaged in mining for sapphires.

El Dorado Bar had been worked for gold in 1860 and for several years after that by the overflow of the Argonauts of '49 who had spread north, through Oregon, Washington, Idaho, and Montana, and up through British Columbia and Alaska as well. The Bar itself was a huge bench of gravel, perhaps half a mile wide by two miles long, and of varying depths. The gravel lay on a slate bed-rock, and at the joint where operations were proceeding when I worked there, the gravel and surface soil were only about six feet deep. It seems that the attention of the Company had been drawn to the ground, from legendary reports of certain glassy looking pebbles that had been observed by the early miners when cleaning up their sluice boxes to recover the gold accumulated between the riffles. The early placer miners had no idea of the possible value of the bluish pebbles that they had thrown away so freely with the rest of the gravel on their dumps. Years afterwards, Macaulay, the Scotchman already referred to, had some of them examined by a competent authority, who pronounced them sapphires of very good grade, so the excitement was on. Macaulay kept his information to himself until he had organized a company and had secured in some way or other all the ground comprising El Dorado Bar. His next step was to mine some of the stones and find a market for them. That market appeared to be in England and Scotland, and it was reported that the Baroness Burdett-Coutts had bought some of them, besides other members of the aristocracy; also that the then Prince Of Wales, (afterwards King Edward), the Duke of Fife, and other notables had formed themselves into a company to purchase the sapphire mines of El Dorado Bar, and work them on a big scale, à la Kimberley.

In the meantime, we miners were kept on digging away, prospecting virgin ground, and producing sapphires. The "modus operandi" was very simple, and consisted in stripping off the surface soil and the first three or four feet of gravel with picks and shovels, leaving the lower eighteen inches or two feet of gravel on bed rock as it always contained the bulk of, as well as the best of the gems. Of course the gravel, clear from the surface, carried more or less gold, but that was only a secondary consideration with the company. After stripping a small area, the next move was to clean up the eighteen inches to two feet of gravel left on bed rock, shovel it into sacks, and haul it with a horse and cart down to the river, less than half a mile away. Here it was put through a crude apparatus called a "Jigger," which was simply a wooden box with small holes bored through its sides, and suspended from the small end of a pole. The "Jigger," filled with gravel, was worked up and down in the water, thus washing away the fine sand and gravel. It was kept going until there was nothing left in the hopper but fairly coarse gravel, which was spread out on a long table, and the sapphires, with occasional red stones said to be rubies, picked out by hand and preserved.

We were working away peacefully and enjoyably in this way, for the weather was fine, and the air sweet and bracing during the day, after the sharp frosts prevailing at nights, when trouble broke over the camp.

It appears that the report already in circulation, that the sapphire fields had attracted the attention of British capital, was well founded, for it now transpired that a British company had not only become interested, but had actually signed an agreement to purchase the El Dorado sapphire mines for several millions of dollars, provided the property was reported on favorably by an expert already on his way from England with power to definitely close the deal. Of course here was a fine opportunity for members of the "easy-money" fraternity, then and now quite numerous in the West, always ready to "butt in", to make as many dollars as possible without exchanging anything in the shape of vulgar sweat therefor, either mental or physical, and not at all particular as to the methods adopted.

One day, just after our mid-day meal, Macaulay arrived at the camp from Helena full of excitement and imparted to us the astonishing news that General W—, a speculator from Butte, had been in Helena the day before, making the rounds of all the popular places of resort and boasting that he and a crowd of his friends, all handy gun-men, were going out to El Dorado Bar to "jump" the sapphire ground. It had come to their knowledge, he claimed, that most, or all the titles of Macaulay's company to the ground were defective. Macaulay assured us that the titles of his company were perfect, and that this threatened claim-jumping on the part of General W— and his associates was only a blackmailing scheme, got up to extort some money from the company on the eve of closing a deal involving millions of dollars. The British company of course would be shy about investing their money in a property, the ownership of which was in question, either rightly or wrongly. Macaulay said he had taken the best legal counsel in Helena, and had been informed that in the case of unpatented mining claims, the easiest way to avoid lengthy and tedious litigation was for the owners of the claims to retain possession, and prevent trespassers from stepping on the ground, and if they did get on the ground to eject them, by force, if necessary.

This certainly seemed a pretty kettle of fish, so Macaulay interviewed the peace officers of the county in order to find out what action they would take towards protecting his property from trespassers, and was blandly informed that they could take no action until hostilities had actually begun, when they would have to intervene in order to preserve the peace. This was still more interesting, and it began to dawn on us that the law was truly a fearful and wonderful thing, and as somebody has said considerable of a "hass". As no mention was made of the *exact time* of intervention by the peace officers whether they should undertake to "preserve" the peace *after* it had been smashed to smithereens, and everybody more or less shot up, or step in at the psychological moment to *prevent* a breach of the peace was an open question. In any case, as they were at least seventeen miles from the scene of expected hostilities and refused to take cognizance of trouble until trouble actually happened, it is difficult to see how they could possibly "preserve" the peace, although they might act as gatherers-up of the peace among the survivors, if any, afterwards.

At any rate Macaulay stated that his company had decided to defend the ground at all costs, and that Detective Y— with about a dozen other good men, well

arrest, had been employed to assist in patrolling the ground, and might be expected to arrive at the camp that night. As we had a short cut to Helena from the mine by crossing the Missouri river in our boat and then climbing a fairly steep trail to the top of the bench, where the stage road which went round by Canyon Ferry was met, our re-enforcements had a considerable advantage over General W—, and his gang. These would be obliged to follow the road to Canyon Ferry, cross the river there, and then proceed down the north bank for a distance of fifteen miles. There the road entered a very deep, narrow canyon, which it traversed for half a mile before debouching on the gravel bench of El Dorado Bar. It was therefore certain that the claim-jumpers could not arrive on the ground until the following day at the earliest, which gave us an opportunity to prepare for them, and if possible stop their progress at the strategic point, in the canyon, where a bridge carried the road across a small stream. We laid our plans accordingly.

It was compulsory for General W— and his reported cohorts of "bad" men to traverse the road through the canyon, as it was impossible to get to the sapphire grounds of El Dorado Bar with any appreciable quantity of supplies in any other way. An abundance of supplies was necessary so that if they did succeed in establishing themselves on the coveted ground, they would be able to camp there, either until the Macaulay Company paid them what they wanted, or until they had had time to put up monuments, and do the required loyal amount of development.

Macaulay found that most of his gang of miners, who were all Swedes, with the exception of myself and a middle-aged Welshman, had no fancy for "military" adventure, probably having had more than enough military service in their own country before they left. They preferred to go on peacefully manipulating a muck-stick rather than to strut round with their chests stuck out, with rifles on their shoulders, doing "sentry go," or any other military manoeuvre. Therefore, as I had expressed willingness to assist in defending the claims, being at just the right age to relish such goings on, Macaulay gave me a heavy revolver, with holster and belt well filled with cartridges, and ordered me to take the Welshman along, and to go into the canyon and tear down the bridge across the creek, and to use the timbers taken from the bridge in building a barricade or breastwork across the road. This we proceeded to do that afternoon, and I must say that the job suited me fine, much better than shoeing gravel, even if said gravel did contain gold, quite a few sapphires, and an odd ruby. Of course I was only twenty, and the glamour of romance was over everything. I felt that I was a "military" man, and embarked on a real honest-to-goodness adventure at last, whether it wound up in bloodshed or not, and it certainly looked serious enough then.

After tearing out the bridge and building a breastwork across the road to the best of our ability, we went home to supper and found the camp simmering with excitement, some men being busy cleaning out, and fixing up a spare building, long out of use, as sleeping quarters for our re-enforcements. Others helped the cook prepare vast quantities of "grub," for the amount of provender that twenty-five or thirty husky men, leading an active, out-of-doors life, and breathing the keen dry air of Montana in December, can consume, would certainly surprise, if it would not break the heart of the average city boarding house keeper.

After supper the camp settled down to await the arrival of Detective Y— and his men, but it was not until nearly ten o'clock that the night was made hideous by wild hallooing across the river, and we knew they had at last arrived. Two men were despatched across the broad Missouri with the boat and soon brought back a load of men and rifles, and whiskey too, I am compelled to say for everybody appeared to have a pocket flask, and seemed jolly, though not in the slightest degree intoxicated. As the boat could only carry four men at a time besides the crew, it had to make four trips before all hands were safely across, when a lunch, with hot coffee was served to the new arrivals by the cook and his assistant, and after a smoke they were escorted to their sleeping quarters, where they bedded down in their blankets on the floor almost as tightly as sardines in a box. They certainly were a jovial good-natured crowd and all of them had "roughed it", while some of them had campaigned before, there being one or two ex-members of the Northwest Mounted Police, as well as several ex-soldiers from the British and U. S. armies, in the bunch. Of course, as always in a body of men, there were one or two humorists present. One of these assured some grumblers that "there was no occasion for grumbling about lack of room, for there would be lots of room by that time to-morrow-night."

After breakfast next morning and just as daylight was beginning to appear Detective Y—'s "army" with Macaulay and myself fell in, and marched up the road for about a mile to the canyon turn to await the approach of the "enemy". A scout on horseback had been dispatched some time before daylight, with orders to ride along the road for a couple of miles beyond the canyon, and to keep his eyes open for the appearance of General W—, and his force (which had been reported large), and to immediately gallop in, and warn us, if he saw them. So, we at the barricade had nothing to do but wait, and amuse ourselves, which we did by collecting a lot of firewood and building a huge bon-fire. Around this we sat and smoked and talked, each man holding on to his rifle with the exception of our commander Detective Y—, who had no rifle, only a revolver, and a five-gallon demi-john of whisky, which I observed he held pretty closely.

Along about noon, when we were all getting tired and beginning to think about lunch, we heard the drumming of galloping hoofs coming down the road, and our scout, a young Swede, soon appeared with a pale face and shouted to Macaulay, "they are coming" and rode round the end of the barricade and kept on his way to camp, without stopping, I presume in order to put the horse away safely.

"Come on boys, grab your guns and line up across the road behind the breast work", shouted Detective Y—, and as soon as the manoeuvre was executed and we were all set, I found out what the demi-john of whisky that our leader had cuddled so tenderly under his arm all day was for. He pulled a tin cup out of his coat pocket, and starting at one end of the line, he poured a brimming cupful of that "forty-rod" whisky, which he gave to every man with a curt invitation to "down it". I notice that the invitation had never to be repeated. I declined myself, at the time, as I never had much use for the stuff anyway; besides I wanted to satisfy myself that I was able to go through with what we all believed lay immediately in front of us, without any assistance from courageous John Barleycorn. The rest of the men accepted, I have no doubt, because it was against their principles to *ever* refuse a drink, and they saw no occasion for refusing then. I must explain to the unenlightened that "forty-rod whisky", is whisky so powerful, that it is guaranteed to bring down, or bowl over a man at a distance of forty rods, or 220 yards.

The head of the "enemy column", or what we supposed

was the head of the party, soon appeared, and to our surprise consisted only of three white-whiskered old men, one of whom was General W—, sitting in a spring-wagon drawn by a smart looking pair of ponies. So far as we could see, they had no rifles or revolvers. I don't believe the old boys really had anything more deadly than a flask or two of "forty-rod". Of course we did not yet know if the formidable array of desperate thugs and bloody-minded "bad" men that rumour had said General W—had in his train, was coming behind or not. As soon as the wrecked bridge had brought General W's team to a stop, Macaulay and Detective Y—jumped over the barricade and advanced, one on each side of the team, grabbing a rein apiece, and held a parley with the "enemy".

We could not hear what was said, but the gestures were eloquent, and I observed General W— attempting a display of great coolness. He took a cigar out of his pocket, bit off the end, put it in his mouth and lit it, but I noticed the hand that held the lighted match doing a lively jig. All through the affair, his aides-de-camp placidly smoked their corn cob pipes and looked so benevolent, with their long grey whiskers, that one had to laugh inwardly at the contrast between them and the deadly desperadoes that Dame Rumour had so freely and positively promised us. Truly, if these gentle-looking old men were all of General W—'s reported army of toughs, the anti-climax was ridiculous. I noticed the grey-whiskered amiable old Rip Van Winkles, as well as the doughty General himself, casting rather longing and affectionate glances towards the demi-john of whisky that Detective Y—had left on top of the barricade. Presently Y—eased the situation by pouring out a cupful and handing it to the General, who knew what to do with it, and promptly did it. Each of the other old boys also graciously accepted a cupful of the "forty-rod" and benignly stroked his whiskers, afterwards. Macaulay then let go the the reins on his side of the team, General W—swung the horses and wagon around, and the whole "army" ambled off up the road.

It looked as if our "military" careers were about over, and every man looked at his neighbour and grinned, but we were not immediately disbanded, as Macaulay did not appear to have any too much faith in the "bona fides" of General W—, and kept us all there for a week longer doing "sentry-go" in our turns all day and night. But nothing happened, and about a week later we heard definitely that General W—, had gone across the mountains to his home in Butte. The supply of "Forty-rod" having run low by that time, our "army" was ready to go home too, while I went back to my interrupted labour of shovelling gravel and washing sapphires.

THE COMSTOCK LODE.

At certain periods in the long and diversified history of mining on the famous Comstock lode, at Virginia City, Nev., the engineering problems of handling the treacherous floods of hot mine waters and the problems involved in the struggle for the financial control of the mines have seemed to outweigh all others in determining whether the workings should be carried still deeper, but even more fundamental has been the geologic problem of the persistence of the ores with increase in depth. If the rich silver ores were deposited wholly or largely from solutions that ascended from sources far below the surface deeper exploration is fully warranted. If they owed their richness to the action of descending surface waters on ores that originally contained relatively little gold and silver, then there is little to encourage deeper mining. The steady progress in metallurgy, by which more and more metal is recovered from low-grade gold and silver ores, has given large practical importance to the question of the persistence in depth or ores of this class. No thoughtful observer expects a revival of the golden and silver age of Comstock, mining for the tremendous fracturing which created the channels that made ore deposition possible was more extensive near the surface than at great depths. Nevertheless, the "roots" of an ore deposit so immense are by no means small, and the Comstock operators have in recent years shown their confidence in the existence of deep lying bodies of workable ore by draining a large part of the lode to and below the 2,900-foot level.

In spite of the detailed studies that have been made of the geology of the Comstock lode very little concrete, tangible evidence has been presented to show the variations in tenor or composition of the ores far below the surface, and little information has been available for comparing the results of primary deposition with those of downward enrichment in the formation of the richer bodies of ore. Yet as downward enrichment has evidently been effective in many silver deposits a tacit belief in its potency at the Comstock lode seems to have become current among many geologists and mining engineers.

The early geologic work of King and Becker on the Comstock lode was done before the development of the theory of enrichment of ores through the agency of descending surface waters. Later observers have made only brief examinations of the lode, under conditions that were most trying because of the high temperatures in the mines. Finally, as most of the ores are fine grained, it has been impossible to determine the relations of their constituent minerals by observation with the unaided eye.

Recently E. S. Bastin, of the United States Geological Survey, Department of the Interior, has made a microscopic study of the Comstock ores and in his report published as the Geological Survey's Bulletin 735 entitled "Bonanza ores of the Comstock Lode," concludes that in the ores from depths greater than 500 feet, which include most of the bonanza ores of the lode, the silver is practically all in primary minerals. Descending solutions of surface origin produced a large increase in the silver content of certain ores obtained within 500 feet or less of the surface, yet even at these depths a part of the silver is contained in primary minerals, and some rich ores taken from slight depths showed no secondary silver minerals. Gold, so far as observed, is primary in all the ores.

Although the deeper parts of the lode probably contain no ore bodies comparable in size and richness to the great bonanzas of the past, yet the primary origin of some of the rich ores encourages deeper development.

The Wellman Seaver Morgan Company, of Cleveland, Ohio, have issued a bulletin No. 71 describing installations of car dumpers, excavators, coal and ore for handling a large tonnage of ore. Such equipment they have installed at the large plants of the [illegible] copper mines of both North and South America. Where large amounts of ore must be handled cheaply, and where ore reserves warrant permanent installations, machinery such as this is a necessity.

A New Explosives Plant

NORTHERN EXPLOSIVES LIMITED, DRAGON, QUE.

The success of the Disarmament Commission at Washington will, we presume, force us to "scrap" the trite but nevertheless true old saying, "In times of peace prepare for war." However, the underlying idea,—to take advantage of periods of depression to prepare for happier and busier times—is just as sound to day as ever, and fortunately for the country there are those who not only realise this truth, but have the courage of their convictions.

The present activity at Dragon, Que., is therefore of more than usual interest to Canadians, because at this place some of the more courageous and far-seeing leaders of our basic industries are giving outward and visible sign of their faith and belief in the better times in store for themselves and for Canada generally, by having completed the most modern High Explosives plant on the Continent. This plant is of peculiar interest to Canadians, as it is the first built and designed by Canadians, for Canadian trade and conditions, under the new Canadian Explosives Act just in force.

The Northern Explosives plant is now operating, and has a capacity of approximately 5,000,000 pounds of commercial (disruptive) explosives per year. It has been so designed and built that this output can be largely increased without major alterations being necessary. The growing importance of our coal mining industry has not been overlooked, and provision has been made for the manufacture of "Permitted Explosives" when desired.

The recent visit which the writer paid to Dragon recalled old memories of the War,—memories of great difficulties overcome,—whole-hearted work and feverish activity to make refined TNT., which is one of the most destructive war explosives known. The whole atmosphere had, however, changed, and a plant devoted to peaceful industry had already risen, Phoenix-like, from out of the ashes of the old buildings. The number of returned men contentedly at work added not a little to the effectiveness of the picture.

Location

Practically everyone at some time has travelled between Montreal and Ottawa via the Canadian Pacific, but few realise the extent of the Company's site. The property (of about 500 acres) extends from the Ottawa river southward to the lower edge of that geologically interesting old worn-down ridge known as Rigaud Mountain. It would take a Washington Irving to do justice to the "Devil's Garden", and practically every McGill Science graduate has at some time listened in silent rapture to the words of wisdom of the lecturing professor, who, however, differed from local authority as to how the stones grew so abundantly there.

The property is naturally divided into three portions by the main Montreal-Ottawa road, as well as the C. P. R. short line. South of the road is an attractive industrial village, complete with hospital, store, school, inn, and about thirty houses, with good roads, sewerage, electric light, and pure spring water. In addition to the well laid out houses, ball grounds and other facilities for amusement are provided. Golf course and movie theatre are also being considered.

Between the main Montreal-Ottawa Highway and the railway are the administrative building, chemical laboratory, change, lunch and rest houses, while north of the track are the factory buildings proper. This section of the property is again naturally divided by a rise in the ground or a "Petit Cote" or hill running approximately east and west. Full advantage has been taken of this feature to separate the actual explosive manufacturing buildings or "Red Area" from the balance of the plant, known as the "Green Area".

Another feature of importance is that, being between the Rigaud Mountain and the Ottawa River, a plentiful supply of cold spring water is constantly available. The purity and low temperature of this water are particularly valuable to a Nitro Glycerine plant.

Lay-out and Construction of Building

The "Red Area" consists of the following units or departments:—Nitrator, Expense Magazine, Wet Gun Cotton Store, and three complete Powder lines running at right angles to the other units. The Powder line buildings are completely equipped with the most modern machines for the corporation, mixing and cartridging of all the different kinds of explosives used by mines and quarries. The railroad blasting explosives are manufactured in a separate unit. Full advantage has been taken of the experience gained during the war in the handling of explosives, and all machinery has been specially built for this plant.

The following brief description of a typical building will, it is thought, be of interest here. The official license from Ottawa calls for:—

"Red Area" buildings being lightly constructed of wood lined throughout with closely joined tongue and grooved square edged wood. Floor,—closely joined wood covered with Rubberoid up to about 18in. inside walls. Roof,—lightly constructed of wood covered with metal shingles. Track shed,—lightly constructed of wood studding covered with corrugated iron.

Among the more noticeable safety features are:—

Wooden rails by each building;

Doors opening outward;

No steel locks, catches, window fasteners, etc.;

Rubberoid covered floors, with this material coming well up the walls;

All corners rounded, to prevent any collection of dust.

Another interesting feature is that each working building is provided with semi-clean area, or change platform, through which everyone must pass when entering or leaving the building. Ample provision has been made for safety shoes, clothing, etc. Each building is devoted to one operation, and all the buildings are separated one from the other as called for by the "Table of Distances" as authorized by the British and Canadian Governments. They are further protected each from the other by the wooded nature of the land. In short it is thought that every precaution has been taken to render this area as safe as possible. Nothing known to modern science has been omitted to attain this result.

The Heating Problem

Heating is a big problem for every factory,—especially so for Canadians, and more particularly so for an Explosive building where indirect heating is of course absolutely essential. Every other system has far too many serious and obvious faults to permit of their use. The almost irreconcilable factors are,—

Greatest possible degree of safety;

High efficiency;

Low capital and maintenance costs.

Much work was done on hot air furnaces with thermostatic control, but there are still many difficulties to be overcome before this system is sufficiently safe. It has many good points, however, and deserves further study. Eventually an independent heating unit was worked out which did away with all metal in the working buildings, as well as all connecting pipe lines. Each unit is housed in a building of its own close to the working room to be heated. It consists of a water-jacketted heater contained in a room by itself. The radiators are in another room, and consist of a stack of "Vento" coils. These coils are jacketted, and the air intake end screened. The air is sucked through these coils, and gently blown into the working room by a fan directly coupled to a 1/2 h.p. single phase motor. The air ducts in the working room are so designed as to prevent any dust being raised or to allow any particles of what might become explosive matter to get into the air chamber. Glass windows are provided in the air ducts, for inspection and cleaning. An additional advantage of this system is that the working building is both heated and ventilated, ensuring the most healthful working conditions possible.

Nitrating and De-nitrating

One of the most important buildings in an Explosive plant is the Nitrator building, while the Nitrator itself may be said to be the heart of the works. Sobrero, Professor of Chemistry at Turin, discovered Nitro Glycerine in 1846, but the nitrating of even a few ounces of glycerine was attended with much danger.

Constant work during all these years (and more particularly during the years of the war) has done much to overcome the initial difficulties and dangers. It is thought one can safely say that modern methods have now almost if not entirely removed this element of danger.

The Nitrator is of the "Hough" type, taking a charge of 1600 lbs. of glycerine and approximately from 8 to ten thousand pounds of mixed acids. The characteristics of this apparatus are the mechanical agitator, large cooling surfaces and safety devices whereby the supply of glycerine is automatically cut off in case the agitation ceases or becomes sluggish from any cause. These and other features, while of intense interest to powder men, are of too technical a nature for further comment in an article of this character.

The Nitrator building itself is built in stone set in to the far, or north side of the hill already mentioned. In addition to the protection thus afforded it is still further safeguarded by a barricade of substantial design.

The separation of the Nitro Glycerine from the used acids, its washing, purification, filtration, etc., are all of great interest. The most modern practice is followed, and will be the subject of a second article at a later date.

An unusual feature is the inclusion of the Denitrating unit in the "Red Area". This is regarded as a distinct innovation, and was not considered necessary in the past. The policy of the Company throughout, however, has been to put safety of operation first, and to work in the closest possible way with the Explosives Division at Ottawa. In view of the fact that explosions have occurred in Denitrating units handling spent acids from glycerine, it was therefore thought best to include this unit in the "Red Area".

The Denitrator consists of a tower of special acid-resisting metal with suitable spiral packing, together with the necessary condensers, pumps, pulsometers, etc. The spent acids containing traces of Nitro Glycerine enter the tower about one-third of the distance from the top. The temperature is so controlled that practically the moment the acid enters the tower the N. G. is decomposed, doing away with any possibility whatsoever of even the most minute trace of this dangerous compound getting into any pipes or condensers. The Powder Specialty Company of New York supplied the specially designed Superheater which raises to the proper temperature the steam which enters the bottom of the tower. Ample surface and capacity are provided in a battery of six oxidising towers. Suitable acids and low operating costs are confidently expected by this system. The recovered acids are returned to the Acid Plant in the "Green Area".

The Expense Magazine and Gun Cotton store are also built into the side of the Hill, and were very interesting in themselves, but are not suitable for comment.

Every building in the "Red Area", and in fact every part of the plant, is served by a narrow gauge light railway which connects with the main C. P. R. line. An electric locomotive equipped with Edison storage batteries is used, and the track is laid out with easy curves and the grades so handled that a runaway truck is a practical impossibility along the line. Board walks are provided connecting all the buildings so that the minimum of dust or dirt is encountered.

Vacuum Acid Plant

The Acid Department is the centre of interest in the "Green Area", and the advancement in the science of the making and concentrating of acids in recent years has been particularly noticeable. The Nitric and Sulphuric Acid units are the most modern in Canada, and were designed and built under the supervision of Arthur Hough, Esq., the well-known consulting chemical engineer of New York. [illegible] in Canada. [illegible] and [illegible] Glauber, the [illegible] Albertus Magnus (who in 1225 A.D. [illegible]) and Lavoisier, who in 1780 [illegible] known [illegible] and one would like to imagine their amazement [illegible] and most up-to-date type of vacuum plant in operation.

While there are several in the United States this is the first of its kind in Canada and being the most recently constructed is therefore the last word in the manufacture of Nitric acid. [illegible] and the vacuum is maintained by a special pump which is itself a development of the war. The still is of special cast-iron encased in brick, with a [illegible] system of [illegible] control. As is usual with the "Hough" type of stills an [illegible] are so designed as to [illegible] is required. Agitation and the [illegible] perature not only reduce [illegible] and [illegible] by a

minimum, but enable the operator to get a high yield of strong acid with practically none of the lower oxides. From the still, the vapours pass through suitable condensers having a total length of approximately 300 ft. Remaining gases then pass through absorption towers, where they are collected. The final exhaust gases show only the slightest trace of nitrogen oxides. By reason of the reduced pressure the temperature at which the sodium nitrate is decomposed is unusually low. The efficiency of plant is estimated at or near 99 per cent of theoretical,—75 per cent of the acid should average about 96 per cent, and four charges per 24 hours can be run.

In order to economise in labor, the Sulphuric Acid concentrator is contained in the same building as the nitric plant. The whole recovery system is very compact, consisting as it does of a tower filled with spiral packing connected to a concentrating pot of special design. The pot is set in brick and so designed as to be heated on all sides from a Dutch oven which is part of the brick work. The incoming dilute acid passes down the tower where it meets the ascending hot sulphuric acid and other vapours from the pot, absorbing them, and at the same time being partiallly concentrated. This acid then passes into the pot. The highest thermal efficiency is obttained by making use of heat transfer apparatus. 72 hour Solvay coke is used, and the fuel consumption is low when the capacity of the plant is taken into consideration.

This whole system is intensely interesting, but is of such a technical nature that for further particulars the advanced text books on American sulphuric acid practice should be consulted.

The other buildings and departmenta in the "Green Area," namely the Dope House (where the sodium nitrate, ammonium nitrate, wood meal, etc. are dried and mixed), shell making house, &c., do not call for particular mention.

Power, (3 phase, 60 cycle, 2200 volts,) is being taken from the Western Quebec Company, and is stepped down to 550 and 110 volts,—in addition to which an auxiliary steam-driven electrical plant is connected to all motors. A special and independent line is run to the Nitrator. It is thought in this way to absolutely guarantee continuous power when nitrating.

The President and Directors of the Company are all prominent in mining, quarrying and contracting circles. The Managing Director is George C. Riley, Esqr., who has been actively engaged in the explosives business for many years. It will be remembered that previous to the war Major Riley was a director and sales manager for Messrs. Curtis's & Harvey, and he has succeeded in surrounding himself with a great number of his old men who have been making explosives on this same spot for the past 15 years.

The completed plant is of exceptional interest, and reflects the greatest credit on the management and Lt. Col. G. Ogilvie, C. M. G., the Chief Inspector of Explosives at Ottawa, who has kept continually in touch with the work. In fact the closest possible co-operation and harmony have existed between the Department and the works.

The writer desires to express his thanks to the President and Directors of the Company who are permitting the publication of this article,—also to Mr. Hough, the well known consulting engineer, and to Mr. Riley and Mr. V. P. Row, the Company's Engineer, for the information and courtesies extended him by them while at Dragon.

NOTES FROM SAULT STE MARIE

The Soo is full of prospectors and potential prospectors. There has been extensive staking in the Goudreau gold district. Developments on the Murphy claims under C. A. Foster have shown up some spectacular ore, with the usual consequent wave of excitement. There seems to be in this case, however, something more solid to build upon than a small bunch of very rich ore. It looks as if there were in addition a large body of ore of fair gold content. Capital is coming in pretty fully and in some cases at least on the sound basis of actual development work as a first-hand expenditure, without the too common expedient of company flotation and stock peddling.

Exploration for iron ore has been going on during the last year. There are properties along the Algoma Central Ry., north of the Soo, known for a good many years, but not sufficiently investigated. An attempt is being made to try out some of these, so as to settle the question as to the existence of ore in quantity.

REVISION IN BASE PRICES OF MONEL METAL

The International Nickel Company of Canada announce a revision in base prices, to be effective from April 1st, 1922. Schedules showing size and quantity differentials will be sent upon request.

(Note—All prices .O.B. Port Colborne, Ontario.)

Sheets Hot Rolled.—Lots of 1000 lbs. and over of a gauge, 48c per lb. Lots of less than 1000 lbs., of a gauge, add 1c per lb.

(Superseding base price of 58c per lb.) (No crating charges on sheets.)

Rods, Hot Rolled—42c per lb. (Superseding base price of 44c per lb.)

Rods, Cold Drawn, 53c per lb. (Superseding base price of 59c per lb.)

Rods Machined, 50c per lb. (Superseding base price of 55c per lb.)

Shot, (Foundry Metal), 34c per lb. (Superseding base price of 37c per lb.)

Blocks, 34c per lb. (Superseding base price of 37c. per lb.)

Ingots, 40c per lb.

The McCumber Tariff Bill, presented before the United States Senate on April 11, contains items that will affect Canadian mineral exports. There are distinct differences between the Underwood tariff, which became law in 1915, the proposed new tariff, and the Fordney Tariff which is still before the Senate. Some items follow:—

	McCumber Bill 1922	Fordney Bill 1921	Underwood Law 1913
Molybdenum (lb.) . .	.75	.75	free
Tungsten ore (lb.) . .	.45	.45	free
Zinc ore, over 25% zinc (lb.)	.01½	.01½	10%
Crude magnesite (lb.)	5-16	½	free
Calcined magnesite lb.	⅝	¾	free
China clay (ton)	$2.50	$2.50	$1.25
Fluorspar (ton) . . .	$5.60	$5.00	$1.50
Talc (Soapstone) lb. .	¼	¼	free
Graphite, amorphous %	10%	10%	free
Graphite lump % . .	20%	10%	free
Graphite, flake (lb.)	.02	10%	free

News and Comments

By ALEXANDER GRAY

Tough-Oakes Resumption

The mine that can withstand what the Tough Oakes was subjected to, and survive, deserves the respect and good-will of all. No one, therefore, will begrudge to the company a measure of prosperity, now that milling has been resumed and the properties have re-asserted themselves. No doubt the experience gained will be an added source of profit. The present management has shown it could meet a complicated situation, and Mr. Goodchild, a geologist of note, has pointed the way toward a sound development.

> "In the two-mile stretch there is a continuous line of prosperous mines. These mines are in their first youth, for at present they are only opened up to quite shallow depths. The character of the lode formation, to give it a common but not strictly accurate name, is such as to give confidence that the gold will live down to great depths. Further developments in the lower levels are in distinctly higher grade ore than those at the higher horizons. The Kirkland Lake field has always been noted for the high grade of its ore deposits, and, with lower horizons yielding even higher grade averages than the upper, it is impossible to forecast at present whether the limit of enrichment in grade has yet been reached. One thing is certain, namely, that in this field there is a tendency for the ore bodies not to disclose their best values on the outcrop, as is commonly the case in most mining fields"

By direct statement, and by inference, Mr. Goodchild furnishes inducements for capital expenditure under expert direction. The risk may be taken by those who can afford to lose and who deserve to win.

Mr. Raney's Stock-Selling Regulations

Solomon in all his glory had nothing on the Commissioner to be created under the Raney Act for the regulation of stock selling. The Commissioner is to pass on the regularity of the incorporation, the prospectus, but not the prospects. Pedigreed Mining Engineers clothed with Provincial Certificates that they are such, no doubt will guide aright promoters and capitalists in order to obtain the requisite sanction to sell shares. It is not the intention to restrict capitalizations. Where the letter of the law is complied with, the duties of the Commissioner will be obligingly ministerial. Anyhow, perverse human nature understands a coach and four can be driven through most statutory enactments.

Consolidating "Domes"

Barnato used to prescribe as a formula "reorganization, amalgamation, liquidation". That may or may not have a bearing in the matter of the consolidation of the Dome Lake Milling & Mining Company and the West Dome Consolidated. It is too early to formulate an opinion in the premises. How much capital will be written down or whether the dollars shares will be made \$5 shares, and what the public will be required to pay, will govern popular estimate of the "consolidation". Were it not that "certain of the directors" were "sick" last month, the launching might have been under way and a trial run given interested "bidders".

Ali Baba Literature

A Montreal firm of "specialists in Canadian mining shares" appears to be aspiring to a sudden departure, according to this "special bulletin" announcement:

"Hollinger is to-day undoubtedly the premier Canadian Gold Mine, and should before many months become the leading gold producer of the world. Expert engineers have reported that the company has practically *forty years'* supply of gold at *present* rate of production *blocked out*, which should run equal to if not higher than the present millheads of \$9.00 per ton".

On what meat do these "mining Caesars" feed?

Is Burma Out Of It In Zinc?

The metallurgy of Burma Corporation has been reported on by Mr. E. P. Mathewson with a frankness that makes it look very promising for Trail zinc output. For ever so many years the brightest mining and metallurgical intellects have been devoted to those Indian ores, so high-grade that regular processes are intolerably wasteful. Not being amenable to known processes, current practice repeatedly had to be changed in order to better recoveries. Separations, special arrangements for silver and lead smelting and zinc retorting, have left the latter where Mr. Mathewson says, in effect: "Forget it". The influential administration will not stop there, because it cannot. Too much is at stake, and too much money is involved. Meanwhile Burma is not apt to bother Consolidated Mining & Smelting markets for zinc to the extent anticipated. Broken Hill, of course, has to be reckoned with.

The Aching Void

Not a thought is given by daily newspapers to the weakest link in Canada's industrial chain as exhibited in this partial list of natural mineral products in 1921 showing a value more than \$1,000,000.

Coal	\$71,273,000
Gold	21,324,000
Silver	9,185,000
Copper	7,159,000
Nickel	6,759,000
Natural gas	6,[illegible]2,000
Asbestos	1,807,000
Lead	3,[illegible]0,000
Zinc	2,[illegible]8,000
Gypsum	1,[illegible]5,000
Salt	1,[illegible]1,000

Is Iron Mining among the lost arts forecasted? If not, it is not far removed from the vanishing point outside the Wabana section. Why not annex Newfoundland, if for no other reason than to enable it to have iron ore in the national column? Or should we rather remain somewhat overelevated? [illegible] per cent. of the total of mineral products represented by coal, and iron data freezing the [illegible] makes it imperative that Canada become an Industrial Nation, and lose no time in doing it. [illegible] the tail of the bird, but we really need [illegible]

Northern Ontario Letter

THE GOLD MINES

Hollinger

One of the more important incidents of the past week in connection with mining in the Porcupine district is an action by the Northern Canada Power Company, which constitutes formal notice that the power company will endeavor to enforce a contract to supply the Hollinger Consolidated with its power requirements for the life of the mine. It will be recalled that the Hollinger took action some months ago against the power company for alleged damages of about $1,800,000 but the decision of the court was against the Hollinger. The latter company appealed the cease, and this appeal is now pending. In the meantime, the Hollinger has been negotiating for rights to develop energy on its own account on the Abitibi River and this is believed to be the cause for the action now being launched by the Northern Canada Power Company.

Goldale

During the third week of April, the Lewisohn interests commenced the work of pumping out the shaft on the Goldale property at Porcupine. It is planned to continue the shaft from its present depth of 150 feet and to also employ diamond drills for the purpose of locating, if possible, the easterly continuation of the mineralized zone which runs in that direction across the McIntyre-Porcupine.

Porcupine V. N. T.

Work of de-watering the Porcupine V. N. T. is progressing satisfactorily, and by the middle of May the entire North Thompson side should be in shape to resume mining. The mining plant is in first class condition and will serve to carry work to a depth of at least 1,000 feet. The enterprise gets its new start under exceptionally favorable circumstances. The management has the advantage of having this mining plant immediately available, as well as having a mine which is even now estimated to have over half a million dollars worth of ore in sight, and developed to a depth of 600 feet. In addition to this there is a mill on the property which is good for 100 tons of ore daily and could easily handle 150 tons daily with an expenditure of approximately $40,000 on alterations and additions. We may expect the addition of another profitable mine in the Porcupine V. N. T.

Good One at Peninsula Mine

Among the more favorable reports coming from the newer sections of the gold districts of Northern Ontario, is advice obtained officially by the Journal from A. R. Globe, manager of the Peninsula property, situated at the north-east side of Night Hawk Lake. This is within the Porcupine Mining Division, although fifteen miles straight east of the older developed area. Mr. Globe who was formerly assistant manager of the Hollinger made the announcement to the Journal representative that at a depth of 200 feet, a drift has been driven for 150 feet, and carefully channelled samples show an average gold content of over $14 per ton across a width of 20 feet. In addition to this, the diamond drilling formerly done has indicated a body of ore assaying $5.70 across a width of 30 feet, and over a length of 500 feet as so far tapped by diamond drills at intervals of every 50 feet. Another body has a width of approximately 27 feet and assays $4.80 per ton. Up to the present, this property has been quietly operated, not a great deal being said apart from the brief official announcements in these columns. However, a total of about 1000 feet of underground work has been done, in addition to 2,800 feet of diamond drilling. It is a point of importance that the geological structure is entirely favorable, there being basalt and porphyry formation, and the structure being of the right sort. These facts, coming from a thoroughly reliable mining man such as Mr. Globe, would tend to show that the enterprise is an important gold mine in the making. It is also announced that the consolidation of the Peninsula property and the Night Hawk Lake Mining Company is being completed and that the consolidation will be known as the Peninsula Consolidated Night Hawk Mines, and the company will hold approximately two miles in length of this gold belt.

Dome Mines

Dome Mines will pay dividends at the rate of 25 cents per share quarterly instead of 2½ p.c. quarterly. This means that as the par value is reduced with each capital repayment, the current dividend rate from a viewpoint of percentage return will gradually increase. By the time the stock is reduced to $1.00 par value as against the present par value of $9.00, the dividend of 25 cents quarterly will be at the rate of 100 p.c. The president of the Dome, Mr. Baehe, made the statment this week to the Journal representative that this policy of capital repayment will probably be continued until the par value is reduced to nil. This will leave the shareholders with stock of no par value, and the profits will be distributed on a basis of so many dollars per share annually. The company has recently been making net profits at the rate of $2,000,000 a year, the indicated income for the first three months of the year having been around $950,000, with an indicated profit of $500,000 for the quarter. This indicated net profit is actually at the rate of about $4.20 per share annually.

Gold Reef

Reports are current that the control of the Gold Reef may be so placed as to assure operations being commenced within a reasonably short time. The company is said to have sufficient money in the treasury to finance a considerable amount of work, as well as having around 1,000,000 shares in the treasury.

Holtyrex

A diamond drilling machine is being taken in to explore the property of the Holtyrex, situated to the north of the Plenaurum. The promoters of the company believe they can locate the continuation of part of the mineralized area that passes over the McIntyre.

Allied Porcupine

A deal for the Allied Porcupine property is said to be under negotiation and would provide the company with working capital of about $75,000. Nothing definite has been ascertained at the time of writing.

South Keora

The work of raising finances for the South Keora is proceeding satisfactorily and it is expected the resumption of work will take place this spring.

Harnessing Sturgeon Falls

Construction work in connection with the harnessing of Sturgeon Falls by the Northern Canada Power

Company is proceeding at a good rate and the indications appear to be that this additional 6000 or 7000 horsepower will be available for the Porcupine mines by the end of th current year, as planned.

Power on Abitibi

The power situation with respect to the distribution of the right to develop energy on the Abitibi River for industrial use in the Porcupine gold area, the Abitibi Power and Paper Company's operations and the T. and N. O. Railway has been practically settled.

The Hollinger Consolidated will in all probability be given the right to proceed with hydro-electric development at a point below the Long Sault Rapids where it is estimated a total of approximately forty thousand horsepower may be developed. The one remaining point to be decided has to do with regulations in connection with the control of the storage at the head of the river. This is now controlled by the Abitibi Power and Paper Company and has been brought about at considerable expense, which fact has led the Abitibi interests to demand compensation. At the same time, those who are to develop below the Long Sault are negotiating for a voice in the manner in which the storage will be controlled. This request has been occasioned by the fact that it is the present policy of the Abitibi to conserve the flow of water on Sundays, a policy that would not fit in with the generation of power at points lower down where a steady current would be required every day of the week for the purpose of keeping milling operations going at normal rate.

Satisfactory precautions and reservations have been made for the electrification of the T. and N. O. Railway at some future date, and the indications appear to be that any further delay in the commencement of actual construction will be short. It is understood that Premier Drury has suggested that a committee of engineers should get together and bring in a report. These engineers are to be representative of the Hollinger Consolidated, the Abitibi Power and Paper Company and the T. and N. O. Railway and there is every reasonable assurance that the findings of the committee will be such as to bring about a condition under which the Hollinger may proceed with whatever development plans the company has in mind.

Hunton-Kirkland

The proposed merger of the Hunton Kirkland with the Munnaker Kirkland was ratified at a meeting on April 19th at which a vote of the Hunton stockholders was taken.

Teck-Hughes

Rumors are current that the Teck Hughes and the Orr Gold Mines are negotiating with a view to forming a consolidation by selling the Orr to the Teck Hughes. Some doubt is thrown on the suggestion for the reason that Hamilton B. Wills, one of the leading interests in the Orr, is still absent in Europe and will not return to Canada until some time in May. However, it is generally conceded that a consolidation of these two properties would be the logical procedure.

Argonaut

From end to end of the Kirkland Lake field the reports from the producing mines are exceptionally favorable. In addition to this, the outlook for a number of the properties in the development stage continues to improve. This condition exists all the way east as far as the Argonaut Gold, where a contract for the construction of a mill is just being let. This property is developed now to a depth of 500 feet.

Lightning River

A plan is under negotiation whereby the Lightning River Gold Mines Company hopes to sell about 800,000 treasury shares, which sale would place the company in shape to carry out a development campaign on its promising properties.

Bourkes

Arrangements have been made to operate the Bourke's Mines. The preliminary work is under way and the plan includes lateral work at the 400 ft. level as well as considerable diamond drilling.

THE SILVER MINES

McKinley-Darragh

Reports reaching Cobalt this week bring the information that the McKinley Darragh is considering the question of resuming operations in May. No official statement has been issued as yet, however.

The increase in the price of silver to over 69 cents an ounce is an important factor in relation to the possibilities of certain of the idle Cobalt mines resuming work.

Beaver

At the annual meeting of the Beaver Consolidated it was announced that the mine would not be reopened at present. It was also stated that the Beaver had sold a limited number of shares in the Kirkland Lake Mining Company, for the purpose of providing working capital.

A sustained high price for silver might reasonably cause the Beaver Consolidated as well as the Temiskaming mine and the Kerr Lake to reconsider their decisions to remain closed.

Nipissing and Rochester

Guesses are being made in Cobalt as to what the Nipissing will do within the next two months, when its option on the Rochester property at Porcupine must be exercised or dropped. The officials remain reticent.

Victory Silver

Some time during the last half of May the shaft on the Victory Silver Mines should be completed to a depth of about 175 feet. This will be closed to the underlying diabase which is estimated to be at a depth of about 525 feet. After cutting a station at the 175 ft. level, lateral work will be commenced for the purpose of tapping the downward continuation of the veins opened up at a depth of 150 feet as well as a vein which passed through the shaft at a depth of about 300 feet. The feature of this new work is that the vein will be opened up at a point within less than 100 feet of the underlying contact. It is important to keep in mind that on the nearby Temiskaming mine it was in that area lying within 100 feet of the contact that upwards of 70 per cent of the silver was encountered.

Bonsall

An official has been made by authority of [illegible] report about the Bonsall property to [illegible] O'Brien Company into a controversy. The O'Briens having refused to be drawn in directly [illegible] continue to stand their reports to be correct. The facts are however that the details given [illegible] in the Journal are authoritative and correct. The O'Briens has controlled the Bonsall for [illegible]

News of Mining

In what seemed to be defective zinc oxide from a United States paint works, germanium sulphide has been identified. The pharmaceutical qualities of germanium oxide are reported to be superior to those of arsenic trioxide. The germanium sulphide was at first mistaken for sulphur. It was identified by Professor Taggart of the University of Pennsylvania.

From by-product coke ovens in the United States the estimated recoveries per ton of coal charged during 1920 and 1921 were:—Ammonia (sulphate or equivalent) 21.4 lb.; tar, 8.2 gallons; crude light oil, 2.7 gallons, and gas, 10.8 thousand cubic feet. Gas production during 1920 amounted to 308,000,000 thousand cubic feet, of which about 10 per cent. was used in steel or affiliated plants, 20 per cent. distributed through city mains and 10 per cent. used under boilers, etc. Motor fuel production exceeded 55 million gallons, and benzine exceeded 16 million gallons. Other products were crude light oil, toluene, solvent naphtha, and naphthalene. About 7 per cent. of all coke made was sold for domestic and kindred uses.

A proposal to tax imported silver and place a corresponding bounty on exported silver was rejected recently by the Legislative Assembly, Delhi, India.

The unfavorable exchange situation, increased cost of labour and higher prices of coal have led to the very serious development of vast peat deposits in the Lago District, Italy. The deposits are situated at an elevation of 4,000 feet above sea-level. Italy's domestic production of lignite amounts to about 1,125,000 tons annually, whilst the outputs of bituminous and anthracite are almost negligible.

Railway freight rates in Germany were increased by 40 per cent. on April 1st by the German Ministry of Transport.

In South, Middle and East Germany the development of electrical power is based upon the utilization of brown coal and lignite. In Saxony a State owned 200,000 horse-power electric station is in course of erection. Only brown coal will be used in generating this power. At another plant near Bonn, 8,000 tons of lignite are burned daily under 24 boilers. In most cases power from brown coal is cheaper than hydro-electric current.

It has long been known that iridium occurs in the banket reefs of the Rand. In the mill concentrates the presence of the platinum-group metals has sometimes caused inconvenient errors in assay results. Lately pure specimens of iridium, osmium, ruthenium, rhodium and platinum have been prepared and steps are being taken to provide for their regular recovery.

The Tata Iron and Steel Company, Jamshedpur, India, possesses 25 square miles of territory. Its pay-roll contains no less than 35,000 names and involves a monthly disbursement of approximately $250,000. When numerous projected and organized subsidiary companies shall have begun operations the population of Jamshedpur will reach the figure of a quarter of a million. The last census returns gave the population at 71,000.

The recovery of coal and coke from ashes and cinders is engaging much attention in Great Britain and the United States. In one recent test of the ashes from a large industrial plant it was found that they contained 57.8 per cent. combustible matter. Treatment by oil-flotation showed a recovery of 47 tons of coal (containing 15.2 per cent of ash) from every 100 tons of ashes.

The world's output of tin is estimated at 93,813 tons for the year 1921, as against 118,111 tons for 1920. Cornwall's production fell off to only 700 tons as compared with 2,900 for the preceding year. A large falling off is also reported from Bolivia, the figures for 1921 being 17,698 tons as against 29,540 tons for the previous year. F. M. S. tonnage was the highest item 34,446 tons, which was practically identical with the 1920 output.

The latest investigations of the bonanza ores of the famous Comstock Lode, Virginia City, Nevada, have brought out some interesting facts. Microscopic study of specimens obtained at depths of from a few hundred feet down to 2,900 feet, show that below 500 feet in most of the bonanza ore the silver is contained by primary minerals. Above 500 feet descending solutions have increased the silver content of certain ores, yet part of the silver at those shallow depths is still primary. Gold, so far, as is known, is wholly primary in all cases. The primary origin of the metals encourages the idea of deep development. The heated ascending solutions of the Comstock system are chiefly calcium and sodium sulphate solutions.

Reports indicate that, owing to lower prices of coal, the use of oil fuel in the United Kingdom is growing less. At many plants where a change from coal to oil was contemplated, the change is not being made. On the other hand, the owners of oil-tankers are complaining of ruinously low freight rates.

Whereas by-product coke outputs in the United States declined 35 per cent. during the year 1921 (as compared with the year 1920), beehive coke outputs receded 73 per cent.

According to a report on the Laws and Regulations relating to Lead Poisoning, prepared for the Governors of the Imperial Mineral Resources Bureau, London, Eng., special restrictions are imposed by law on employers of labour in lead smelting, etc. in most mining countries. These restrictions relate to the prevention, removal, and laying of dust and to the cleanliness and medical examination of workers. In Canada, for the most part, prevention of lead-poisoning is left to employers, no special regulations being in force. The Consolidated Mining and Smelting Company, Trail, B. C., it is noted, enforces rigid sanitary rules.

Hydraulic Sand Packing for Mine Workings

By E. SCOTT RIVETT,

(Member of The Junior Institution of Engineers, London, England.)

The news that the Hollinger Consolidated is proceeding with the construction and installation of equipment for sand-packing is causing a good deal of interest among the mining-engineers of Canada, where the hydraulic method of stowing has not hitherto been greatly used.

The Hollinger scheme, as reported in the daily press, is to deposit sand from milling operations back in the mine, thereby replacing the ore taken out, and thus partially relieving the necessity of finding place on the surface to deposit some thousands of tons of sand daily. The advantage of the scheme, underground, is that in filling up the present excavations the closely adjacent ore deposits may then be safely taken out, whereas at present such could be accomplished only with considerable danger to the miners.

The idea of packing old mine workings is not, of course, a novelty, as many mines, notably coal-mines, have been forced to use this practice, sometimes owing to the thickness of the coal seams, in other cases in order to prevent surface subsidence, which may be a matter of first-class importance in some districts. For these reasons hand packing or stowing has been resorted to, and various materials, such as crushed rock and gravel, washer refuse, ashes, clinker, broken furnace slag, etc., have been used for this purpose. It has been discovered, however, there are advantages in flushing this filling-in material through pipes into the mine by means of water. On leaving the pipes the solid material settles out, and when this reaches the roof it forms a packing capable of supporting the overlying strata. The best material for such hydraulic packing is sand, and in localities where a large quantity of suitable sand is available, such as in parts of the Saar Coalfields in Germany and the central Coalfields of India, the hydraulic method is now in use in a number of collieries.

The cost of working on this method is not appreciably higher than with hand stowing, while the saving of timber is considerable and there is less danger of mine fires. The Coalfields Committee have recommended the Government of India to make hydraulic sand stowing compulsory in certain cases.

The general plan—a gravity system—as used in the Indian coal mines, was recently described in a paper read by Mr. R. H. Squire before the Junior Institution of Engineers in London. Dry sand is handled on the surface. It is transported, either by tramway haulage or ropeway, from the river bed to the point at which it is to be flushed into the mine, and then discharged into a storage bunker. On leaving the bunker the sand is mixed with water and flushed down into the mine. The flow of sand from the bunker is controlled by a hand-operated slide, and falls into an inclined mixing trough. The water supply, controlled by a valve, is led into the upper end of the trough and the mixture of sand and water discharges into a small feed hopper fixed to the pipe which leads down to the workings to be stowed. Telephone communication is usually provided between the man in charge of the sand and water supplies and the workmen in the area to be packed. The chief difficulty in India is to ensure a regular and sufficient supply of sand, but this trouble should not be experienced at the Hollinger.

In designing the flushing system the first consideration is the minimum average gradient at which stowing must be done. If the pipes are well laid, in long straight runs, with only two or three easy bends, this may be taken approximately as:

$$\text{Average slope, } S = \frac{H}{L}$$

where H = total available head, and L = total length of pipe. If, however, H is small, or if there are a number of short bends on the pipe line, then H must be taken as the difference in level between inlet and discharge, less the sum of head lost (as determined by Hagan's formula) at the inlet, at the bends, and on the discharge. In every case L must be taken as the total length of piping from the feed hopper to the point of discharge. As a general rule it may be said that if S is less than .12 for small plants or .105 for large plants the gravity system is impracticable, and unless these figures are considerably exceeded, the efficiency will be low, as an excessive amount of water will be required.

Another point, to be considered in conjunction with the minimum average gradient, is the amount of sand required and the rate at which it is to be fed into the workings. These two points will determine both the size of the pipe required and the percentage of solids that can be allowed in the mixture.

Mr. Squire remarked on the scantiness of data bearing on the percentage of solids which may be put down on any given grade without risk of choking the pipe, and made several experiments with clean river sand, of which 80 per cent passed a 30 mesh sieve. The results of these experiments are embodied in diagrams which show solids allowable on various slopes, and also show what size pipe line will be required to deliver a specified quantity of sand per hour in any given case, and also how much water will be required for flushing. It may be noted that the quantity of water should allow for [illegible] per cent voids in the volume of the dry solids, and if this is not allowed for it will be found that, measured by volume, a more [illegible] results than that intended.

The mixing trough [illegible] provides a means of regulating the percentage of solids and making the system fairly [illegible]. The trough must not be made too short and [illegible] [illegible] it at [illegible]. It should be fixed at the [illegible] [illegible] for the [illegible] and it will be clear that any increase in [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible]. One point emphasized by Mr. Squire is the [illegible] for [illegible] the lines [illegible].

The following figures [illegible] [illegible] [illegible] [illegible] as an illustration of the [illegible] of the diagrams referred to above. [illegible] [illegible] [illegible] flushed down a [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] and the length of [illegible]

to 700 feet. The proportion of water to sand improved to 1.16 to 1 (46.4 per cent. solids), and the velocity of the flushing material in this case was 24.3 feet per second. The angle of dip is small, and if we take this as averaging 1 in 25, we find the average gradient of the pipe line in the first case works out at about 6 per cent. and in the second case nearly 28 per cent. Turning to the diagrams, it will be seen that the first case comes below the safe limit, and that stowing was possible at all is probably explained by the fact that clay was mixed with the sand. The second case comes well above the safe limit, and it would appear that more water is being put into the mine than is necessary.

It is highly probable that a small proportion of slimes, in gold mining, would have the same effect upon the flushing mixture as clay, and it will be interesting to have figures from such mines where hydraulic packing is carried on as to the minimum percentage of water required when slimes are present in the mixture.

BOOK REVIEWS

General Economic Geology—A Textbook—By William Harvey Emmons, Ph. D. —First Edition—Published by McGraw-Hill Book Company, Inc., 370 Seventh Avenue, New York 1922. —price $4.00

The standard, thread-bare phrase "fills a long-felt want" can be applied without apology to Dr. Emmons' book. The author's treatment of his subject is clearer and more suggestive than that of any of his predecessors. Also it is more comprehensive. His introductory definition of economic geology is to be commended. It reads: "Economic geology is the application of geology to economic problems."

The chapters on coal and petroleum are, in effect, geological handbooks in themselves. The reviewer has read nothing more lucid than Dr. Emmons' concise summary of the geology of petroleum and oilshales. He touches upon the highly disputations subject of the origin of petroleum and natural gas with skill and judgment. His classification of mineral deposits is given greater value and interest by the lists of important minerals appended to the description of each class of deposit.

To the student possessing an elementary knowledge of geology, this new volume will prove an invaluable guide. This is really Dr. Emmons' purpose in writing the book. This, however, does not imply that it will not be of pronounced service to all classes of mining men.

It is the first approximately adequate text-book on economic geology. No doubt of its merits will remain after the reader shall have spent an hour or two in giving it a preliminary reconnaissance.

We recommend it without reservation to teachers, students, and practising engineers alike. The English-speaking technical world has waited only too long for just such a manual. The hastily compiled makeshifts that have heretofore been foisted upon us may now be thrown into the waste pile.

The Province of Quebec: Geographical and Social Studies, by J. C. Sutherland, B. A. Inspector-General of the Protestant Schools of the Province. —Renouf Publishing Co., Montreal.—Price $1.25 post paid.

The volume under review is, incidentally, an implicit rebuke to those that speak loosely about religious intolerance in the administration of the Province of Quebec. Mr Sutherland, in a concise summary of Quebec's educational system, demonstrates the fact that Protestants are very fairly treated. No doubt, religious bigotry exists in Quebec, as it certainly does in other Provinces that the reviewer knowns intimately. Yet it is not permitted to obtrude itself (a highly objectionable self in any guise) in matters educational.

It is worthy of note that four of the six illustrations embellishing Mr. Sutherland's text are connected with mineral industries. Probably the choice was made unconsciously. Whether this be the case or not, it is really significant.

A quotation will give our readers a colourable idea of the character of the book. "This book," says the author in his introduction, "can fairly claim to be a "pioneering work in one essential way, because it is the "first that has made any connected attempt to describe "a Canadian Province in accordanee with the scien-"tific principles of modern regional geography."

This excerpt, however, does not sufficiently indicate the ground covered by Mr. Sutherland. In nine chapters he carries the reader though this little-understood Province, giving him a creditably good, though necessarily sketchy, view of its geography, geology, government and culture—"culture" being applied to both its physical and sociological aspects.

"The Province of Quebec" needs none of the reviewer's overused adjectives to recommend it. Even if it were not worthy of praise **per se** (which it is), it would deserve attention as the production of a member of the Protestant minority in a Province where Catholics are in an overwhelming majority.

Reading a book for the purpose of reviewing it is seldom pleasant. The probabilities are always in favour of the reviewer getting mentally bilious, and then someone is bound to be treated badly. However, this review will conclude with the judicial asservation that Mr. Sutherland has turned out a book that is much above the average of semi-official publications, in that it is accurate and readable. To do full justice to his subject he would have to produce a series of tomes rivalling the **Encyclopedia Britannica** in word- content.

As a postscript it may be added that the author makes graceful acknowledgment to Messrs. Theo. C. Denis and J. A. Dresser for their advice as to the geological portions of his book. Mr. Sutherland could not have had more competent counsel.

The Economics of Petroleum, by Joseph E. Pogue, 375 pp., illustrated—published by John Wiley & Sons, Inc., New York.

The mining engineer is, so to speak, at sea when he has to deal with oil-bearing lands unless be makes a very special study of every phase of a very complicated branch of the mineral industry.

Those who witnessed the Calgary boom at close range know that oil experts were created overnight. Given a geological patter, a lack of conscience, and an opportunity, the tonsorial artist of yestesday became the oil specialist of today. All that was required was a favourable report on territory owned by ambitions vendors.

The other side of the shield is displayed in Mr. Pogue's admirable volume, which is a competent review of the economics and technology of petroleum. Organization, development, production, transportation, refining, marketing, utilization, and so on, are discussed lucidly. The volume is compendious. Textually and typographically it is a book to which both author and publishers can point with pardonable pride, and one, also, that the engineer and invested alike will do well to procure.

Notes From Nova Scotia

"Sabotage" Condemned by Miners

Mr. Hiram Donkin, Deputy Commissioner of Mines, N.S. and District Inspector S. B. McNeil, recently conducted an investigation into the spragging open of a door in No. 4 Mine, Glace Bay. A number of witnesses gave evidence, among them the mine official who had found the door open. The blame could not, however, be attached to any individual but the enquiry was not without effect. The workmen were represented by counsel, who stated that it was their anxious desire to have the culprit found and brought to justice.

The common opinion is that this act arose from the violent language of labor leaders and others who have been busy fermenting strife and sowing the seeds of discord and sedition among the colliery workers. Whatever the cause, it was a dastardly act which was fortunately discovered in time to save the lives of 300 miners from death by a mine explosion.

As it was the lives of these men were imperiled while the door was open, as it short-circuited the air currents, shut off the air supply and left the workmen to either die of suffocation or perish by more sudden disaster.

Safety Work — a Good Investment

The efforts of the Safety Department of the Dominion Coal Company on the human side of the coal industry have not been sufficiently advertised by the Company to attract the attention of the public and inform them of what has been accomplished by means of organization and education. This lack of publicity on the part of the Company may be entirely due to a realization of the fact that prevention of accidents is considered part of the day's work, which effects the efficiency of the business and has therefore been organized into a separate department.

While this is no doubt true, it should be borne in mind that publicity and education are large factors in the work of the Safety Department, and through these same means the general public should get to know what is being done in the way of prevention of accidents and of the aid rendered when these do occur.

Experience has taught that the majority of accidents are preventable; that they occur either through the carelessness of the workman himself or of some other fellow workman, or even of an official. Therefore it is necessary that the fundamental principles of caring for his own safety and that of others should be inculcated, and habits of carefulness and forethought be formed. Safety Supervisors see that workmen are instructed and that during working hours safety bulletins, safety posters and safety literature are ever before them, and their minds so filled with safety ideas that it is scarcely possible to forget that their own welfare is after all the first thing.

Safety and Insurance

A few facts and the principles of prevention of accidents having been imparted, these beget others, and so the training and the education of the workmen grows and spreads through all the works, and the industry becomes more noted for its low accident rate than for its great dangers. In this way the status of industries has been changed, and workmen who have been placed by Insurance Companies in the list of hazardous occupations have found themselves on an equality with men of the more favoured and less dangerous occupations.

The primary object of First Aid and Rescue work is to have sufficient specially trained men to take immediate charge of the situation, where life is imperiled through some serious accident, to give prompt and proper attention to injured men and to provide clean and aseptic dressings that will prevent infection in the wound.

When it is considered that infected cases require three times as long to recover as non-infected cases, there can be no doubt that the work of rescuing men is of the greatest value to the employer and employees alike.

The welfare, the comfort, the health and safety of the workingmen is being cared for by the Empire Steel Company. Much money has been expended in placing safeguards on machinery, in erecting new and up-to-date wash houses at the collieries in modernizing the old ones, in establishing first aid stations at convenient places on the works, and on insisting that workmen who live in Company houses, shall keep the premises clean.

Safety Organization

The Safety Department is well organized, and is under the control of a Central Committee composed of the Executive heads of the Steel and Coal Companies. These men have had large experiences and meet periodically to consider and review all phases of Accident Prevention, to discuss and determine on all safety devices, to study the causes of serious accidents and to make recommendations which will tend to prevent a recurrence of these in future. Being in constant communication with other employers of labour and in close touch with bureaus of information, they are in a position to procure valuable information on the latest and best methods of accident prevention. This knowledge is passed on by way of instructions to the Safety Engineer and Safety Inspector.

A Sub Committee composed of Colliery Superintendents receives and reviews all reports passing through the safety office and coming from colliery committees and make their recommendations to the Executive Committee. Each colliery official is member of the colliery committee which meets twice each month to discuss safety matters affecting the individual collieries.

The head of the Safety Department of the Steel Corporation is J. N. Morgan, Safety Engineer.

Alexander MacEachern is Chief Inspector of Mines. He is an experienced, capable and energetic official who fully realizes that the safety of the collieries is in his hands. Under him are a number of trained men whose duty it is to travel and inspect all workings and machinery of the collieries and make a daily report.

The Rescue Department is under the Chief Inspector of Mines who sees that weekly instruction in use of the Draeger or oxygen helmets is carried on by competent instructors. A visit to the Draeger House at No. 2 Colliery, New Aberdeen, under the care of A. MacMahon, a man most proficient in both rescue and first aid work, is a revelation to the uninitiated of

what is being done along the lines of rescue and first aid work. The Dräger house at No. 2 Colliery is one of the best equipped stations in Canada, and every thing necessary for rescue work at the Colliery is to be found there, even to the merry little singing canary, so susceptable to the influence of mine gas, but rarely used except when mine explosions occur.

Hector A. MacDonald is Surface Inspector, having charge of the collieries, the railways, the machine shops and the piers. Mr. MacDonald is a young man, who has entered upon his duties with an enthusiasm that is contagious. Since his advent upon this work, safeguards of many kinds have been placed on machinery over the entire plant.

The Accident Report for the year 1921, is in some respects very encouraging. The number of fatal accidents in 1920 in the Glace Bay District was fourteen. The number in 1921 was eight, a decrease of six, or forty-three per cent. The fatal accident rate has fallen steadily since 1917. If the Glace Bay District were cut off from other parts of Nova Scotia and a comparison made with other mining countries, it would stand in the fourth place, taking rank after Britain, Belgium and France. It is a good showing, and proves that much progress has been made. No fatal accident occurred to workmen on the surface during the last year.

The non-fatal accidents in 1921 show a decrease of 5.4 per cent. over 1920. This is not as satisfactory as might be expected considering the outlay on organization and machinery. Unfortunately the system of checking up and investigating all but the more serious of the non-fatal accidents is not and cannot be an effective one until such time as the Government takes steps to improve it by legislation. Fatal and non-fatal accidents of serious nature are, because of their very seriousness, reported at the First Aid Stations where they have been treated. Minor accidents, such as cuts and bruises, are ofttimes not reported until the person applies for compensation. Investigation of all such cases after that is a mere matter of form, which may or may not find the facts as they really are. The attention of the Compensation Board has been called to such cases, but they say "that it is a matter for the Government." Herein no doubt lies one of the greatest handicaps of the safety department in its efforts to ascertain and eliminate the cause of accidents. Until such time as all accidents are treated at the Safety Stations, much of the work of the Safety Department must remain unseen, and the statistics of accidents will fail to give the reliable information so much needed.

"Bumps" Overcome by New Method

During the last few years a number of miners were killed in No. 2 Colliery, Springhill, Nova Scotia, by "Bumps" of the working faces. Sometimes, however, these occurred on main roadways, throwing down a large amount of coal, and interfering with work generally. The depth of mine cover is 2,200 feet. The floor coal rock roof is hard and smooth. Such conditions were ideal for bumping under the methods of mining usually followed in that district. The suddenness with which these bumps occurred, with their ofttimes fatal results, created a dread in the minds of experienced miners who had been accustomed to note the warnings of impending danger. Here was a new enemy without warning, against which no one could guard and no precaution could be taken.

A new mining problem had arisen and the Coal Company attacked it with courage and understanding. The old method of mining was modified and made to meet the new conditions, and has so far been successful in preventing bumps.

The work of winning the coal was concentrated on smaller sections, and pushed forward rapidly until all the rooms and pillars coal was withdrawn. This allowed the roof to fall in, and thus relieved the pressure that would be otherwise thrown down on the other workings, thereby creating the very conditions that tend to cause bumps. The method usually followed was to open a double balance with eight or ten rooms on each side and drive all rooms forward at the same time. When the boundary of 300 feet was reached, the pillars were then drawn, care being taken to have the upper pillars in advance of the lower ones. This led to great roof pressure, to bumps, and sometimes to a considerable loss of coal.

Under the improved method, balances are driven to the rise as former, but only the three top rooms on each side are advanced, and that only to a distance of 150 feet. The pillars are then drawn, allowing the roof to fall in, which relieves the pressure and prevents bumps or other loss of coal.

A singular feature of this method is "that instead of very thick pillars being left to meet the conditions of deep mining, the pillar is only 24 ft. thick." The with of the room is 12 ft. This improvement in the method of mining has not only tended to make the work much safer for the miner, but has resulted in giving a large percentage of coal, leaving little behind.

Mr. W. Herd is the Mining Engineer of the Company. He has had a large experience in British mines and naturally feels jubilant over the results gained in the Springhill collieries.

EDITORIAL

In a true democracy, we are all masters in respect to the interests of the community as a whole, and servants in respect to our special abilities. Our greatest mistake so far has been in considering industry as somehow outside of democracy.--C.V. Corless--1917.

NEON IN EVERY-DAY LIFE

IT has often been stated, and almost as often disbelieved, that pure science is at the bottom of most of our present-day material progress. It is, ordinarily, hard to conceive how the abstractions of physics and chemistry, astronomy and zoölogy, can be applied to every-day human affairs. We have seen recently a perfect demonstration of the seemingly impossible.

Who would believe that the rare gas, neon has a practical use in operating an automobile? It is inert, incombustible, difficult to isolate, and until lately has been regarded mainly as a scientific curiosity. For a decade or more it has been used experimentally as a source of light; but research has only lately made it undoubtedly useful.

The manufacturers of electric lamps are among the most progressive of all modern men of business, though they are among the latest arrivals in the industrial world. Each of the huge plants throughout this continent has a research department, where highly-trained physicts and chemists search out Natures secrets. At one of these plants, in Pittsburgh, a young physicist was examining the properties of neon. He was impressed with the readiness with which a glass tube containing the gas glows when brought near a wire connected to an induction coil.

In Pittsburgh everybody has an auto, and everybody is, likewise, bothered at times with ignition troubles. After the day's work comes a spin, and occasionally a stalled car. Our physicist naturally joined together the two parts of his day. Why not use a little tube of neon to indicate leaks and breaks in the ignition system? A trial in the laboratory showed that the idea was practicable. The idea survived passage through the development and manufacturing departments, and now the tubes are on the market, and the factory is turning them out the rate of four or five thousand a day.

There is an unending succession of such ideas, awaiting discovery by researchers. Some will lead to neat little devices, others will be epoch-making in their respective fields. Especially in metallurgy, the latest of man's major fields of industrial activity to become organized along modern scientific lines, lie opportunities for the researcher.

The handful of metallurgical researchers in Canada have had remarkable success. The production of electrolytic copper, lead and zinc at Trail and the successful treatment of complex ores; the separation of the conglomeration of useful elements in the ore of Cobalt; the solving of nickel problems, one after another; the economical treatment of rock containing three or four per cent. asbestos fibre—these attest a quality among our practical metallurgists that is worthy of emulation. But we must not forget that it is mastery of pure science that is, directly or indirectly, the foundation upon which all this progress is built.

INSTITUTE AND INDUSTRY

In the last two issues of "Engineering and Mining Journal Press," Mr. T. A. Rickard has presented a clear analysis and pungent criticism of "the functions of Institutes." Mr. Rickard's intimate and personal acquaintance with the various Institutes, British, American and Canadian, gives him a vantage point from which he may view, judicially and impartially, the merits and de merits of each case. His conclusions are worth close attention, whether they can be accepted as they stand or not.

In discussing the policy of expansion recently adopted by the Canadian Institute of Mining and Metallurgy on the recommendation of their Secretary, Mr. Rickards concludes that "the result is a club, not a technical society. Mere expansion is worse than futile unless it is in the right direction. If the Canadian Institute will become, as the American Institute has become, a model of organization of all those connected with the mining industry, in short, a Mining Congress.

This may all be true, as regards matters of fact and possibilities for the future. We are glad to have Mr. Rickard's pronouncement of the elements the [illegible] holds in store for the Canadian Institute, but to

decline to accept the fate he predicts, as inevitable. There is an alternative.

The present policy of the Canadian Institute of Mining and Metallurgy is to enlist to co-operation and support of all those that have a legitimate interest in the mining industry of Canada. The Institute has a place among its members for the man that puts his money into the development of a mine alongside the engineer that spends it. Such intimate contact is necessary outside the Institute—why not in it? It is true that the introduction of financial and trade interests into the councils of the Institute bring in at the same time a tendency to disruption; but the mining industry is a unit, and in no other way than by means of such a common meeting place can the internally-diversified interests be brought together in an adequate way. Call it Mining Congress if you will; it is a necessity for a well-organized mining industry.

How is the solidarity (and possibly the professional exclusiveness) of the technical members of the Institute to be maintained? This is the question that in the main directs Mr. Rickard's criticism, as it should direct our constructive measures. Unless prompt and effective measures are taken, it is certain that the fate predicted for us will overtake us. We have at hand the means of avoiding the disruption of our technical body and the perversion of its high ideals.

Ideals are of restricted use until put into practice. The ideals of our Institute, as stated in its charter and re-iterated on occasion, are worthy of close and constant attention. But they have remained largely nebulous and useless because we have failed to bring them to earth. One of the Institute's principal concerns is, or should be, to keep its members in the strait and narrow path, and to ensure, so far as is humanly possible, that those in the industry, outside the institute, shall do likewise. In other words, the Institute, to put in practice its ideals, must scrutinize closely the conduct of its members, and must, outside its membership, act as "watch-dog" for the industry.

As pointed out in these columns some weeks ago, it it is entirely feasible to put into operation the simple measures that will ensure much action. We already have in our Institute a carefully selected professional membership, whose first duty, individually, is to see that the best traditions of our profession are maintained. Why not guard these traditions collectively? By so doing we shall create a bond of union among the mining and metallurgical engineers of Canada that will not only serve to maintain the present admirable qualities of the Institute, but will foster the growth of an essential quality that the Institute has heretofore lacked—the "esprit de corps" ("tribal spirit," if you will!) that can come only when men work together, seriously and consistently, in pursuit of a high ideal. Canada needs, and is awaiting anxiously, the good offices of such a body.

THE MINING INDUSTRY AND INSURANCE COMPANIES

That there should be a closer understanding between mine operators and insurance companies is easily demonstrable from present inequalities in premium rates. It is not our present intention to discuss specific instances. The broad statement may be made, however, and made without fear or contradiction, that the insurance companies are not awake to the opportunities the field of mining offers.

The past decade has witnessed sweeping changes and improvements in the management of metal mines and in the prevention of accidents. Some of these improvements have been brought about by legislation, but the most vital are to be attributed to the voluntary efforts of enlightened operators. The "safety engineer" is a more or less recent innovation. His function is not merely to see to it that prohibitions and inhibitions are respected; upon him devolves as well the duty of inculcating into employees the spirit of co-operation which is the only safe and sane foundation on which to build.

Without danger of being invidious, he may cite the Ontario Department of Mines as a notable example of efficient administration in respect of mine accident prevention. Fatalities in the metal mines and quarries of Ontario are lower for each thousand men employed than in most other mining regions. Investigation of accidents is prompt and searching, and full publicity is given in every instance. This is not altogether the case, we regret to say, with other Provinces.

In our opinion, insurance companies would do well to recognize in a very practical sense, the excellent and sustained efforts of governments, corporations and individuals in the direction of the conservation of human life. Such recognition would be in keeping with the spirit of the age and would without doubt bring its own reward to the companies themselves.

SUDBURY MINING DIVISION

The Sudbury district is known throughout the world as the source of the world's nickel. The story of the locating of the first deposit during the construction of the Canadian Pacific Railway; the accidental discovery of the nickel content of the ore; the struggle to separate nickel and copper and then to find a market for the nickel; the use of the metal by navies and armies, culminating in the Great War; all these form parts of an epic that is still in the writing. Nickel producers are "up against it" once more, and are tackling these new problems with the vigour and discrimination that has brought them through hard times before. They have large and well-developed mines, ore that is without rival, smelters that have paid for themselves already, and last but not least, an invincible determination to find a market for the metals they can produce.

Meantime the people of Sudbury are suffering. They have had all their eggs in one basket, and there has been a spill. Their dependence upon the nickel industry is now painfully obvious. But they, too, are taking hard times with a grin, and are looking round for new fields wherein to expend their energies profitably. They have not far to look.

Sudbury is the natural outlet of a promising mineral area, until recently dwarfed by the greatness of the nickel mines. The Canadian National Railway to the north traverses a promising stretch of rocky ground that has yet received little attention. Business men in Sudbury are now making some attempt to determine its possibilities and to turn its potential mines into revenue producers for their town. Meetings are being held to consider ways and means of aiding mining development. Truly, hard times are good for the expansion of the mining industry!

The Sudbury Board of Trade is now asking the Provincial government for revision of the Tax Act, aid for roads, and a railway through the mineral area lying between the Canadian National and the Ontario Government Railways. It is obvious that the nickel companies, now struggling under disabilities it will take all their energies to remove, should not be taxed at the rate imposed when their profits were undoubtedly large. Justice demands this, and justice will be done. The building of the proposed railway also merits the most careful consideration.

There are already along the line of proposed railway two mineral areas that would help materially to pay its cost. The extension of the Elk Lake branch of the Ontario Government Railway to Gowganda has been long deferred because it would benefit only one silver producer. If it were continued westward through the Shiningtree area to the Canadian National Railway, this disability would be removed, as it would then serve several mines, and would stimulate the development of numerous others.

It might be argued that a branch line of railway as suggested, built as part of the Ontario government's system, would tend to bring to the Canadian National line revenue that should accrue to the builders. This is undoubtedly so; but no such consideration would we are sure, unduly obscure the vision or sway the judgment of the men to whom Ontario has entrusted her provincial railway policy. Ontario's railway may be provincial in point of geography, but no restrictive or provincial outlook should direct the policy of its operation and extension. There is already valuable co-operation between the managements of National and Ontario railways, and this can logically be continued in the case in point.

In the past, Sudbury Mining Division has suffered from its very prosperity. The "bonanza" days of the nickel field are now over, or at least in abeyance. Sudburians are to be commended in their efforts to stimulate and aid the development of the other mineral resources of their district.

EDITORIAL NOTES

"Gold, Gold in Cariboo", is the title of a hectic story relished in our youth. There promises to be a repetition of the scenes of the sixties and seventies in the famous old placer camp of British Columbia. It is more than likely that here, as in other mineral-bearing regions of our Dominion, the pioneers merely skimmed over the ground; the areas are so vast that not much else was possible. We may logically hope for numerous "finds" from the stampede now in progress.

We have every day fresh evidence of the world-wide attention being drawn to Ontario's gold fields. Among the more recent arrivals in Canada is the South African company mentioned on another page. That capital from the gold-fields of South Africa should seek investment in the development of gold mines in Canada, suggests a possible shifting of the present centre of the world's gold production. The production of the Rand is diminishing; that of Ontario is correspondingly increasing.

PROSPECTORS' SPRING SONG

Come, pardner — come; the golden Spring is here,
The mountains send their call to you and me.
The mountain streams are running swift and clear;
The sunny slopes from snow will soon be free.

All winter, we've been longing to be there;
We felt our souls imprisoned in a town.
We longed to breathe the fragrant, piney air,
And smell the camp fire when the sun goes down.

We longed to watch the morning sun arise,
And tint the mountain-peaks with rosy red,
While underneath, the sleeping valley lies,
With cloudy billows curtaining its bed.

We longed to climb the mountain's rocky breast;
To hunt for ore, and watch all Nature play.
And, when the sun was sinking in the west,
Hike back to camp, to end a perfect day.

Come, pardner — come, I hear the wild birds sing,
Their joyful love-songs ring o'er hill and vale.
A wakened world is welcoming the Spring.
Let's load our horses, pard, and hit the trail.

Ontario's Gold Deposits

THEIR CHARACTER, DISTRIBUTION AND PRODUCTIVENESS

The impatiently awaited report on Ontario's gold deposits by Mr. P. E. Hopkins of the Ontario Department of Mines, has at last passed through the printers' hands, and has been distributed. It is available on application to the Department in Toronto. Its sixty pages of text are packed full of information, and as a bibliography alone it will serve a useful purpose.

Mr. Hopkins is specially qualified to write a comprehensible report on the gold mines of Ontario. For more than a decade he has been actively and intimately associated with the development of the gold fields discovered during that period. To know how complete his interest, one needs only talk with any of the numerous prospectors to whom he has given advice and direction. He is, in fact, known to the bush-whacking fraternity in Ontario as the prospectors' friend—a term applied to his brother geologists in the Department as well.

MR. PERCY E. HOPKINS

A good prospector was spoiled when Mr. Hopkins became a geologist. His instinct for searching things out has led him to many an old mine and abandoned prospect, where he has dug out debris and twenty years' accumulation of leaves to examine the veins, much in the way he had "dug out" his original information about them from dusty tomes in the library. Thus Mr. Hopkins is more than usually well-qualified to write about the attempts to develop gold mines that preceded his experience as a geologist.

After a short summary of the history of gold mining in the Province, the geological occurrence of the precious metal is briefly discussed. This discussion is necessarily sketchy, both for lack of space and for lack of definite information and well-founded theory. Next follows a description of the gold-mining districts, in geographical rotation from east to west. Of the 48 pages of this section, 18 are devoted to the active and producing areas in and adjoining Temiskaming District.

It is a significant fact that this report devotes 60 per cent. of its available space to the gold areas at present inactive or abandoned. These parts usually receive unqualified condemnation and curt dismissal, whenever mentioned at all. This summary treatment is ordinarily based upon hearsay evidence of the most hazy sort. This is what Mr. Hopkins says about one of these much-maligned districts. "The gold boom of nortwestern Ontario reached its peak in 1897, resulting in many unwarranted stamp-mills being erected. Inefficient management and stock-jobbing operators caused the loss of much capital; nevertheless certain mines—the Sultana, Mikado and Regina—produced from about one-half to three-quarters of a million dollars each." If stories of eye-witnesses are true, "high-grading" in these mines was so prevalent that the official returns of production represent only a fraction of the gold actually taken from these mines.

"Hollinger" is now a household word, and connotes gold, just as "Rand" does. Its success and that of several lesser (though large) mines has been a genuine stimulus to gold mining in the Province. As usual, many parasites have found nourishment in the purses of heedless investigators and speculators: but the ill effects of this diminution of funds for legitimate development and mining has not "killed" the infant industry, as it had invariably done in former cases.

This report has been written for the non-miner, and will be particularly useful to the investor, resident or non-resident. The wide distribution of a publication of this sort will prove a good investment of the public funds administered by the Ontario Department of Mines.

NEW MAPS READY

The following maps are now printed and ready for distribution by the Ontario Department of Mines, Toronto. They have been published in advance of the reports they are to accompany, as a convenience to prospectors and others that wish to use them.

Gowganda Silver Area—Scale 1 mile=1 inch—to accompany report by A. G. Burrows, Vol. 30, 1921.

Schreiber - Duck Lake Area—Scale, 1 mile=1 inch—to accompany report by P. E. Hopkins, Vol. 30, 1921.

Black River Area, Dist. of Temiskaming—Scale 1 mile=1 inch—to accompany report by D. G. H. Wright, Vol. 30, 1921.

Prospectors of the Cariboo

By ROBERT DUNN,
Mines Department, Victoria, B. C.

PROSPECTORS of British Columbia are asking when and from where the next great placer gold find is to be announced. They argue that these events come in cycles and that the pendulum has about swung to where it was when stories of the hardships of the Chilcot Trail were in all mouths. The free, almost wild, life of the Cariboo and of the Yukon, with the reward that gold bearing ground offers to the lucky, creates an environment that gets into the blood, and once there can never be removed. Robert Service, the poet of the Northland, has given the best existing conception, in his immortal verses "Songs of a Sourdough" and "Songs of a Chechako", of the conditions and the atmosphere in which the Yukon miner lived. Never has the epoch of the rush of '98 and the years of stirring incident and adventures that followed been so forcefully depicted.

The spirit of the "sourdough" is not dead. It burns still in the old-timers and younger men, waiting only the word of a "strike" to be fanned into flame. There will be modest stampedes next Summer into Cedar Creek, Cariboo, and to the Taseko Lake (Whitewater) country and, while the excitement in these cases is not yet great, let there be important discoveries and in a few months there will be in these new fields communities, no doubt closely resembling, in their hustle and bustle, their raw newness, and the variety of their amusement offerings to the miner "off duty", the Barkerville and the Dawson of the early days.

The "sourdoughs'" bull-dog perseverance and optimism are well illustrated in a recently published account of the death of a pioneer of the Yukon. This man was in the "rush" of '98. He staked on the Eldorado before the stragglers arrived, but was disappointed. Trading his claim for that of another miner who took from it the gold that formed the foundation for the fortune of a millionaire now resident in Seattle Wn., he again failed to find the precious metal. Again on Hunker Creek he missed and in all his subsequent ventures the cards seemed to be stacked against him by that fickle jade, Fate. Only a few months ago this prospector, now an old man, wandered from Dawson into the wilderness, searching as ever for the placer camp that

The Picturesque Cariboo Road, above Yale, B. C. in 1868.

On the Road to the Cariboo in 1868.

would make him as rich as Croesus. He has not come back.

As I have said there are many men of this calibre in the West. Those who went through the Yukon stampede, while the years have reduced their numbers, are as indomitable as ever. That was made evident when volunteers were asked for service with the Canadian Military Forces in the Great War. Their ranks are thinner if we are considering only the genuine old "sourdough." If permitted to count comparatively recent acquisitions, however, the muster roll would be substantial; for the call of the frontier, of the silent places, and the lure of hidden treasure, is as potent to red-blooded men as it was half a century ago. Large numbers of stalwart young men are to be found in mining and other outdoor occupations in British Columbia. A new "rush" would find them first in line. They are listening to the prospector's prophecy of a new placer gold camp, impatiently waiting for the news that will set their footsteps in the right path.

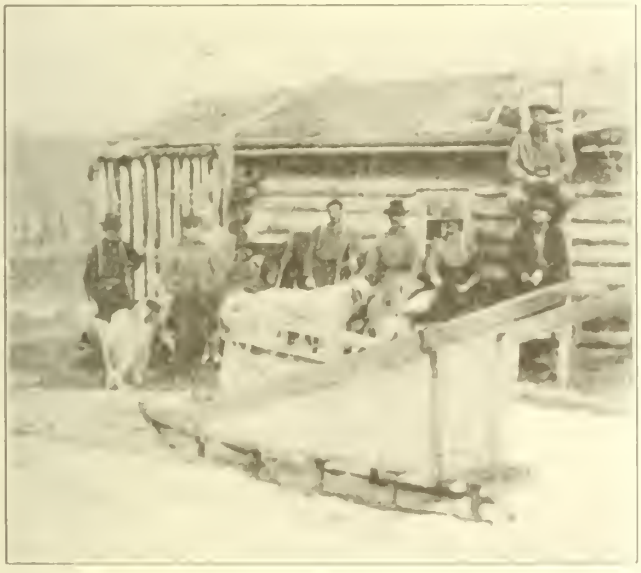
"Gold is where you find it" a prospector of the old school told me with impressive earnestness. He snorted with scorn when it was suggested that the geologist or the mining engineer might help. "We don't need no yellow-legged scientist," he exclaimed. "Them fellows never did do any good around an honest injun placer camp. They were not the first to put stakes in any of the big camps of the Pacific Coast and we don't want 'em. Put this in your pipe and smoke it; the prospector was on the job in Californee; he did the work and got out the stuff in Cariboo; and it was the prospector and a few Indians that started the Yukon stampede. And I don't mind tell'n you, kid, he'll do the trick again.

"Now this is my idee", the old fellow went on dreamily. "Leastwise it ain't my notion altogether, you'll understand. It was pretty generally thought in the old days that there was a 'gold run' from Alaska south. I suppose some of your engineer friends could give you a fancy story about that. You get the gold in Californee, in the flat country between the Cascades and Rockies of B. C., in the Omineca, the Yukon, and Alaska. Funny thing, trace it out on a map and you get a nicely balanced semi-circle. Kind of a quarter wheel with spokes pointing to discovered diggin's. But, young man, "—this in a portentous and mysteriously hushed

* Since this article was written excitement has developed in British Columbia over the Cedar Creek District of the Cariboo. Rich diggings were reported by prospectors in this locality late last season. Since then there have been reports from time to time of a favorable character. One of the last statements was that after removing four feet of snow and panning a little of the frozen surface ground several ounces of gold were obtained. Another prospector is said to have made good recoveries from an excavation started with a view to the building of a cabin. Already much of the district has been staked and is held either as leases or as ordinary placer claims. The Spring rush has commenced and there is no doubt that the disappearance of the snow will find hundreds of "Sourdoughs" and "Chechakos" on the ground.

voice— "there is a missing spoke. What does it mean?" and he leaned forward eagerly confidential. "It means that there is another, an undiscovered placer field, ground probably richer than all the others. It is in the Omineca, somewhere east of the Cassiar Mountains. I got it all figgered out. Goin to hit the trail soon's the days lengthen and maybe next winter you'll be wavin' your hand to My Royal Highness as I roll past in my limousine.

"Don't think me foolish, me lad. Take that 'gold run' stuff. It's the real dope. Don't go much on these geologist 'bugs'; but ain't it strange how it's worked out from Nome to Californee? And then a miss. Then there's that 'Heighth of Land' south-east of the Yukon, supposed to have been thrown up before the Rockies. Anyway that's what those college minin' professors say and you got to give them credit for knowin' somethin', don't you? So me and my cronies got to thinkin' about it, and doin' some reading, too. No doubt about it, the glacial drift of centuries has been hammerin' against that high land somewhere near Thutage Lake, or the headwaters of the Finlay, or the Ingenika River. Remember it's a big country, there's been hardly any prospecting, and we may not find it in a season. But it's there and the world some day, even if we don't find the treasure, will say the old prospector knew what he was talkin' about."



Government Telegraph Station, between Atlin and Dease Lake

The wind droned and whistled outside the log cabin. One of the severe storms of mid winter in the North had the land in its grip. The Yukon heater, fed frequently on jack-pine, kept the small interior cosily comfortable. The old man 'bit up' again, shifted in his chair, ad resumed: "Don't suppose you know Monte Clair. Fine fellow. Regular woodsman prospector. Blew in last fall with some great samples and fine stories. He'd been over the divide, along the Finlay, and through the Gun-a-noot Country. That's where Gun-a-noot, the Indian who was hunted for murder for years, and finally gave himself up and was let off, spent his exile. No policeman could catch a good man in there, and he'd be roaming still if it weren't for his notion of selling the skins he'd cached to give his children a white man's education. But about Clair, his samples of copper and silver sure looked good. Said there was a ledge of copper he'd traced for miles. But it was his talk about the gold he'd panned that got me because, you see, it just jibed in with what me and my partner had been thinkin' and talkin' about. Course he wouldn't tell exactly where it is 'cept that it's somewhere in the 'Indian bad land'. That's the other side of the Cassiar Range and they've given it that name because the natives won't go near. It's kind o' neutral territory, a 'no man's land.' Footprints of giants were found there years ago, so the story goes, and the Indians believe it is haunted by fearsome creatures—'supermen' I suppose you'd call 'em. The boys of these days laugh, but don't like to go near all the same. So we've fixed up a party to go up the Kispiox and Skeena rivers and over to Thutage Lake this year. We're going to find something and if it's big, why, for friendship's sake, I'll stake a claim for you, son."

"Hope springs eternal" says one of the poets. What I've told of one prospector's theories and plans is actually true. Moreover, his is lucid reasoning, whether well founded or not, and may luck be with him! Many others might be quoted. There's that pioneer of pioneers, "Bill" Sherlock, of the Cariboo. Over eighty years, if he's a day, and as spry as a man of sixty; still living on his claims; spending the summer pottering around sampling and, in a small way, working his property and the winter in studying the Placer Act, which he knows backward, which is useful in keeping a watchful and critical eye on its administration. He'll tell you about fortunes lost and fortunes made in the early days of Cariboo; about "Cariboo Cameron" and his brother and their wins and losses; the "Lost Mine" of the Cariboo, fabulously rich legend says, and for which the old 'timers are searching to this day; Judge Begbie and his stern administration of British justice in a rough-and ready camp, and how he awed some troublesome miners who approached him during his evening stroll under spreading pine trees by explaining that he was picking out the best limbs for the hanging of those to be convicted on the morrow—all these yarns "Bill" will spin and more. If his history could be written it would make a book of more compelling interest than any novel. "Bill" is wedded to his Cariboo, but he, too, will whisper in moments of confidence that he can take you to a stream "where gold nugget's gleam on the river bottom like jewels in a royal diadem."

(To be continued.)

The Dominion Bureau of Statistics has made an excellent beginning in the prompt distribution of statistical information for public use. It has still a long way to go to make its service comprehensive, a good deal of time is necessary to effect the external and internal organization (particularly the former) upon which the prompt collection and compilation of information depends. The work is well begun and under the able direction of Messrs. Coats and Cook is sure to continue until we have a service worthy of the times and our country.

It is estimated that now that the strike is over the Rand production during April will be 90 per cent. and that for May about 100 per cent. of the normal output.

Brazil, like Central Canada, has no coal, but an abundance of water power. Unlike Canada, Brazil has plenty of high grade iron ore. This combination of natural resources has induced the construction of [illegible] blast furnaces for making pig iron with charcoal as reducing agent. One company has [illegible] already in operation, and two others are preparing plants.

The Shebandowan Nickel-Copper Deposits

A Unique Mineral Occurrence

By J. G. CROSS

There has recently been discovered near Shebandowan Lake, an interesting occurrence of nickel, copper, cobalt, and an unidentified mineral, carrying comparatively high values in the precious metals, particularly those of the platinum group. In this connection we are reminded of the Vermillion Mine, in the Sudbury District which is well known.

The Shebandowan ore is essentially pyrites, but carries subordinate amounts of pyrrhotite. Nickel, in the form of polydymite, and copper as chalcopyrite, occur abundantly in the ore. Cobalt is present in much lesser amounts, the ore averaging about 0.3 per cent. Nickel and copper occur in about equal amounts, although there are zones extraordinarily rich in each of these metals, with little admixture, (see analyses further on). The rare arsenides Skutterudite, and Gersdorffite, have been identified. Niccolite, and possibly other minerals occur also.

Location

This property is situated at the southwest end of Lower Shebandowan Lake, about 70 miles west of Port Arthur, Ontario. The property is about five miles from the Canadian National Railway; but as the lake lies between, it is better to go by way of Rossmere, a small station in the vicinity. From Rossmere a canoe trip of eleven miles takes you to the property.

There are eight claims located altogether, all along the strike of the ore body. Ore occures on five of these claims.

Geology

Keewatin rocks are exposed everywhere along the shore of the lake, except on part of the South side of the middle lake, and on the North side of the lower lake, where granite, probably of Algoman age, occurs.

The Keewatin in the vicinity of the nickel-copper deposit is a dark-green basic schist, dipping at a steep angle, the strike following approximately the contact with the granite. Dikes of serpentine, granite, and porphyry also follow the contact. The ore occurs in the vicinity of these dikes.

There is a large area of serpentine to the south about a mile. It is possible that the ore is in some way connected with this serpentine, as is the case at the Alexo Mine and elsewhere.

Nature and Extent of Ore-Body

The ore occurs as a series of lenses, more or less parallel, and connected by vein-like occurrences of ore. The lenses vary from two to twenty feet or more in width, and the length is proportional to the width. The ore as a whole is rocky, but in places is massive. The massive ore is rich, and carries from eight to twelve per cent. nickel. Massive chalcopyrite is of less common occurrence. Three feet of the ore carries 15 per cent copper in a pit near the lake shore. The average of the rocky material would be about six per cent nickel, copper, and cobalt, without hand sorting.

The nickel-bearing mineral is polydymite, no pentlandite having as yet been identified. In this respect also the ore differs from well-known occurrences elsewhere.

At pit ten near the lake shore, the ore has a width of about twenty feet, and is quite rocky; about four feet will probably prove to be fairly massive, but the gossan capping has not been penetrated, although a pit ten feet deep was sunk here. The lenner portions of the outcrop contain bunches and veinlets of almost solid polydymite and chalcopyrite, occuring separately for the most part, but intermixed between these rich pockets. These rich pockets are sometimes soft and granular, and can be removed with a pick and shovel without blasting. The ore oxidizes rapidly on being exposed to the air, and soon falls to a whitish powder.

Cutting across the ore body at right angles approximately, is a series of veinlets carrying various arsenides. The following have been identified: Niccolite, Skutterudite, Gersdorffite, with possibly another whose composition has not been definitely established. The Gersdorffite is beautifully crystallized in places. Native copper occurs in considerable quantity in the partly weathered outcrop, and probably resulted from the reduction of the sulphate by organic matter.

At a considerable distance from the main ore-body there is a small vein of pyrrhotite about a foot wide. This is the only occurence of pyrrhotite on the property. It is rich in nickel, carrying about 7 per cent. This occurence is very similar to the ore from the old Vermillion mine, in the Sudbury District. Elsewhere the similarity is not so noticeable. No sperrylite could be panned from the gossan, however.

The rare metal content of the ore is especially noticeable. This is not surprising, as the ore is associated with much serpentine, and ultra-basic rocks. The precious metals, gold and silver occur only sparingly, however, —about $1.00 to the ton.

A sample was submitted to the Geological Survey for examination. They report as follows:

"The material from Shebandowan Lake submitted by you on Dec. 8th last, has received mineragraphic examination, an assay for platinum, and partial analysis.

"The platinum assay of sample 1 showed that the platinum group of metals were present at the rate of 0.16 oz. per ton. The same material on partial analysis was found to contain,

Iron	24.80%
Nickel	3.30%
Copper	5.50%
Sulphur	20.60%
Arsenic	.00%

"The microscopic examination of the polished surface shows that a complex association of fine-grained metallic minerals occur as a replacement deposit in chloritic schist. The minerals in order of their development are: Pyrites in scattered grains 1 mm. or more in diameter; massive pyrite, and finely chrystallized magnetite; chalcopyrite, pyrrhotite, and an undetermined grey mineral, with a rim of different composition from the kernel; polydymite.

"The nickel mineral is usually microscopic, and occurs in patches throughout the other ores."

Analyses

The following table shows the grade of the ore from some of the pits on the property. The width across which the samples were taken is given.

Sample.	Pit.	Width of ore, Inches.	Ni. %	Cu. %	Co. %
1	4	34	.99	3.43	.33
2	4	13	.29	.76	.17
3	4	24	1.97	3.30	.36
4	4	24	5.44	2.09	.25
5	4	25	1.85	1.91	.19

* Rocky ore.

Two selected samples of the rich ore from pit No. 3 were taken by C. W. Knight of the Ontario Bureau of Mines and submitted to W. K. McNeill, Provincial Assayer, for analysis. The following results were obtained:

	No. 1 p.c.	No. 2 p.c.
Copper	1.88	0.68
Nickel	10.54	6.73
Cobalt	0.44	....
Arsenic	.....	....
Sulphur	37.00	38.47
Platinum	.....	..
Iron	.....	31.58
Insoluble	.....	9.54

Economic Possibilities

The ore bodies occur for the most part in low land and are difficult to follow on this account. The work last summer consisted of trenching at various points to establish the size and continuity of the ore-body, and to collect samples for analyses.

Practically all the work was confined to the westerly outcropping, although a little stripping was done on the other extremity of the property, about a mile distant, on the shore of the lake. The result of the exploration work was highly satisfactory and much good ore was uncovered. The ore bodies were found to occur as a series of parallel lenses, and to be fairly continuous for a distance of over five hundred feet, with no diminution at either end. There was evidence of considerable faulting and dislocation.

A mile distant, near the other extremity of the property, the outcropping that resembled the Vermilion mine, spoken of before, was trenched. This outcropping was traced for several hundred feet westward, where it disappeared under a swamp. To the eastward the ore was sharply cut off by a fault, to appear again, however, about a thousand feet along the strike at the water's edge.

In this distance of over a mile, three outcroppings of ore have been explored only very superficially. The ore was of excellent quality, and a considerable quantity was of the "bonanza" variety. It is highly probable that in the low ground between these outcroppings future exploration will disclose a large tonnage of commercial ore. This is further suggested by finding boulders of ore along the strike on the low ground, not differing materially in physical character from any ore so far discovered. Furthermore where this low land comes to the water's edge much gossan, mixed with a few boulders of ore, are to be found under about a foot of water.

Considerable exploration work will have to be carried on, however, before the commercial possibilities of this deposit can be established. While there will probably be no large ore-bodies discovered, as ore goes in the Sudbury District, nevertheless the aggregate of these lenses of ore (if the ore proves to be only fairly continuous over such a length) will be a large tonnage.

The mining costs will be higher than at Sudbury, but this is more than compensated for by the pyritic nature of the ore, which will permit of pyritic smelting, and by the various by-products (cobalt, the precious and rare metals).

The pyritic nature of the ore should permit of pyritic smelting, and thus save a considerable fuel expense. The recovery of the cobalt adds an additional problem. However, as most of the cobalt is slagged off in the bessemerizing process, it might be possible by this means to separate the cobalt from the nickel and copper and afterwards recover the cobalt.

In the early days of the Sudbury camp some cobalt was recovered. The practice was not continued, however, so it is inferred that it was not profitable. The Shebandowan ores contain a much higher percentage of this metal than the Sudbury ores. But it remains to be proven if it will be a profitable undertaking to recover this cobalt or not.

Probably the best way to treat an ore of this kind would be to smelt to a low-grade matte containing the cobalt, precious and rare metals. This should be a comparatively simple and inexpensive operation, as little fuel would be required. The low grade matte could be further treated at one of the nickel refineries or smelters for further concentration and recovery of the various metals contained.

There is an abundance of developed water power within a reasonable distance of the property, so that the power problem would not be serious. In fact some form of electrical treatment might be worked out for this type of ore.

This property might have a very interesting future, when the nickel industry recovers from the slump.

PERSONALS

Mr. W. E. S[illegible] is [illegible] to London next week. He sails April 28th.

Dr. W. G. Miller and Mr. J. B. T[illegible] to London, England.

Prof. J. C. M[illegible] to give [illegible] Metric System in Toronto on April 28th. It is proposed to form a Metric Association in Canada.

Mr. M. W. S[illegible] to Toronto [illegible] to Mexico.

Mr. L. T. C[illegible] Copper Cliff [illegible] week.

Mr. Percy Hopkins leaves for Lake Gowganda next week, where he will [illegible] geological reports on the area.

The Southern Rhodesian gold output for February 1922 amounted to 51,422 ounces [illegible] 511 ounces for January 1922 and [illegible] ruary 1921.

British Columbia's Mines In 1921

By Robert Dunn

Official figures just available through the issuance of the 1921 Annual Report of the Minister of Mines place the value of the mineral production of the Province for last year at $28,066,641. This is $7,176,443 less than the 1920 returns, or a decrease of about 21.06 per cent.

While there has been a decline, these statistics are considered most satisfactory. They show that British Columbia's mining industry, under adverse conditions the effect of which have been manifested the world over, held its own better than did the same industry in most of those of the United States that are engaged in mining. The drop in the mining returns of the State of Arizona for 1921 as compared to 1920 was approximately 77 per cent; of Montana, 75 per cent; Utah, 55 per cent; Nevada, 50 per cent; New Mexico, 77 per cent; Oregon, 43 per cent; Washington, 70 per cent. Hon. Wm. Sloan, the Minister of Mines, consequently feels that his report not only is gratifying in the story it tells, but is full of promise of what may be expected when world economic conditions become more nearly normal.

A comparative table, showing quantities and value of the mineral production for 1920 and 1921 follows:—

	1920		1921	
	Quantity	Value	Quantity	Value
Gold Placer, oz...	11,080	221,600	11,660	233,200
Gold Lode, oz ...	120,048	2,481,392	135,663	2,804,154
Silver, oz	3,377,849	3,235,980	2,673,389	1,591,201
Copper, pounds..	44,887,676	7,832,899	39,036,993	4,879,624
Lead, pounds....	39,331,218	2,816,115	11,402,288	1,689,354
Zinc, pounds ..	47,208,268	3,077,979	49,419,372	1,952,066
Coal, T (2,240)..	2,595,125	12,975,625	2,483,995	12,419,975
Coke, T (2,240)..	67,792	474,544	59,434	416,038
Miscellaneous products..		2,426,950	.....	2,077,030
		$35,543,084		$28,066,641

Metal Prices

Comment is made upon the marked drop in metal prices in 1921. As this has an illuminating bearing on what the mining industry accomplished in the past year, it is of special interest. In this connection charts are published showing that silver started in January of last year at 65.95c per ounce; that it dropped to 56.02c per ounce in March and from that low level climbed to 70.97c per ounce in October and then began a gradual decline until it reached 65.76c per ounce in the month of December. Copper was not as violent in its fluctuations, being quoted at 12.59c per pound in January and showing a disposition to strengthen towards the close of the year, being quoted as 13.03c per pound in November. Zinc and lead too are shown to have maintained a fairly even price of somewhere about .04 per pound up to a little over .05. If these prices are compared with those obtained in 1920, it will be found that on an average, miners then received nearly 50 per cent more than for a similar quantity of metals in 1921. Mining companies, therefore, deserve great credit for the manner in which the output has been sustained. Of course it is to be remembered that throughout the year, and particularly towards its close, the costs of mining, including wages and supplies, materially decreased.

Referring to the copper market situation, the report explains that last year all the large copper producers of the continent reduced their output to about 25 per cent. of normal, or shut down entirely, so as to reduce the stocks of copper on hand, but that now some of these companies are beginning to start up again, and that the outlook is promising. Whether the metal will go beyond $0.14 a pound for some time, however, is a moot question. While lead and zinc were not in great demand, the accumulated stock of these metals at the Trail Smelter has now been reduced, a market for the same having been found in the Orient. Thus many Slocan mines that were compelled to cease operations are expected soon to be working on a normal basis, as the smelter company again is able to make prompt cash payments for ores of these metals.

Production of Northern Mines

It is noted that the Northern Coast district produced nearly 70 per cent of the tonnage of ore mined in British Columbia last year, carrying about 55 per cent of the total value of the metalliferous output. For an explanation of this it is only necessary to turn to the statistics relating to the gold and silver production of the Premier Mining Company, Portland Canal District, and to the copper production of the Granby Consolidated Mining and Smelting Company at Anyox. On the point of copper, it may be said that while the production of 1921 was nearly 6,000,000 pounds less than in the previous year, the figures would have been different if the Britannia Mill, Howe Sound, had not been burnt down late in the fall of 1920. This property ordinarily can be counted on for from 15,000,000 to 20,000,000 pounds of copper. If this, or only a portion of this, had been available, the copper output for the year would have shown an increase.

The Collieries

British Columbia's coal industry has just about been holding its own. In 1921 the collieries of the Province made a net production of 2,483,995 tons (2,240 lbs.), as against 2,595,125 tons in 1920, a decrease of 111,130 tons, or about 4.3 per cent. With the exception of the year 1920, the net coal output for 1921 is larger than that of any other year since 1912, or of any previous year excepting 1910. The Coast District Collieries produced no coke last year, but the Anyox smelter plant converted coal into coke for the use of that industry. The Crow's Nest District produced 59,434 long tons of coke, of which about two-thirds was used in Canada and one-third exported to the United States. The aggregate of the values of British Columbia colliery products in 1921 was $12,836,013.00, this very nearly equalling the gross value of the year's metalliferous products, $13,153,598.00.

Gold

There was a slight increase in the placer gold output, amounting to $11,600 or about 5.2 per cent. The total aggregate value of the same was $233,200. Practically all this came from the Cariboo and Cassiar Districts. The steady decline in placer gold production during the past four years is attributed chiefly to such economic conditions as high prices, both for labour and supplies. A shortage of labour is also given as a contributing factor.

The value of the lode gold produced in 1921, was $2,804,154.00, as compared with $2,481,392.00 in 1920, an increase of $322,762.00, or about 13 per cent. The Boundary-Yale District made no production, the Granby Company having closed down its mines and smelter there. Nor was any production made by the Nickel Plate mine, which was closed down in the month of September. The Rossland mines, too, failed to reach

the production for which they were responsible prior to 1917, but showed somewhat of an improvement over 1920. With these facts in mind, it would seem rather curious that the lode gold production for the year should show a gain. Investigation however, indicates that the output of the Cassiar District, in which is situated the famous Premier Mine, is largely responsible. No less than 85,185 ounces are credited to this section. The Surf Inlet mine also made material contributions.

On the question of gold production, the report observes that during each of the last four years, British Columbia's output has only been about one-half of what it was annually immediately preceding the war, and shows "that gold mining in this Province, as elsewhere in the world, has been adversely affected by the condition of high cost and a standard price for the metal. Nevertheless from the development now in progress, it would seem then in a short time the annual production of gold in British Columbia should increase considerably".

Silver

With reference to silver production, it is stated that the greatest increase was made in the Skeena District, and is accounted for by new shippers, the chief of which were the Premier and Alice Arm Mines. The most marked decline was in the Slocan District, where mining was retarded because of the reduced market value of silver and its associated metals. There was a considerable output, however, in the Boundary-Yale District, despite the cutting off of the production of the Granby and the Canada Copper Corporation, which formerly produced 50 per cent of the silver of the district. The silver output of this district last year was chiefly derived from the Providence, Horn Silver, Sally and Bell Mines.

Copper

Under the head of "Copper" is published a table that strikingly illustrates 1921 conditions. The Cassier District produced 34,841,767 lbs. and the total for the Providence was 39,036,993 lbs. This brings home the splendid achivement of the Granby Consolidated. The Coast District output was about a million and a half pounds, a negligible showing as compared with the usual sixteen and seventeen million pounds. The Trail Division, however, gave a little better returns than for some years, 2,277,392 lbs. as against 1,113,085 lbs. for 1920.

Lead and Zinc

Tables dealing specifically with the Lead and Zinc productions also noteworthy. It is worthy of comment, for instance, that all but about three million of a total of nearly forty one and a half million pounds of lead came from the Fort Steele Division. This means, of course, the Sullivan Mine of the Consolidated Company, Trail. There has been a gradual decline throughout 1919 and 1920 of the quantity of this metal derived from ores having their sources outside the Fort Steele section. In 1919, twelve odd million pounds of lead came from Slocan ores, in 1920 it fell to six odd million pounds, and in 1921 the total runs to a little over a million and a half pounds. Conditions as to Zinc are similar, but considerably more so. It may be said that all the 1921 production of this metal came from the Sullivan Mine, so small is the quantity that came from others ores. Fort Steel's output was 49,319,198 lbs. and that from all other sources 100,171 lbs.

Other Minerals

Dealing with other minerals the Report states that there has been no metallic iron produced in British Columbia, "but it has been strongly advocated in many quarters that the conditions are favorable for the establishment of an iron smelting plant somewhere on the British Columbia coast. So far nothing definite has materialized although there is apparently a prospect of such a plant being established. As is well-known, there is on the Coast, in the aggregate, an adequate supply of magnetite iron ore, quite sufficiently free from impurities as to be within the 'Bessemer limit' to supply ore for such a plant."

The wide occurrence of platinum in connection with placer gold deposits gives reasonable hope that it may be found in payable quantities and justifies further investigation. Last year official reports show only $100 worth produced in the Similkameen District.

For the rest the Report is made up of detailed accounts of the activities of the years in the several Mineral Survey Districts by the Mining Engineers of those Districts, together with statements by the Gold Commissioners, Mining Recorders and the report of the Chief Inspector of Mines. The former are admirable descriptions of the properties they visited in 1921 and furnish the usual valuable source of information to those interested in mining. While recognizing the depression through which the industry has been passing, these engineers all look to the future with confident optimism. The reports of the Chief Inspector of Mines and the members of his staff deal with Coal Mining and, generally speaking, are very satisfactory. One important point the former official makes is that "the ratio of accidents per 1,000 persons employed in and around coal mines during the year was 1.45, compared with 2.67 in 1920; 2.103 in 1919; 5.159 in 1918; and 8.51 in 1917."

BUREAU OF STATISTICS ISSUES COAL BULLETIN

The first number of a new monthly series of bulletin on coal statistics for Canada has just been issued by the Dominion Bureau of Statistics. The report, prepared in the Mining, Metallurgical and Chemical Branch of the Bureau, shows in detail the output of coal from Canadian mines by kinds and by districts, exports of Canadian coal by ports of exit, imports of coal from the United States by kinds and by ports of entry. Comparative figures are given for preceding years.

The report shows that the net quantity of coal made available for consumption in Canada during January, 1922, comprising all coal imported, or mined in Canada, but excepting the tonnage of Canadian coal exported during the month, amounted to 1,919,000 short tons or 613,000 tons less than the corresponding figure for December.

The output of coal from Canadian mines during January, 1922 declined to 1,208,000 short tons or 130,000 tons less than in December, 1921. Of the 14 coal mining districts for which output data are given, 3 show a gain in production, 22 of these being in Alberta, and 21 reported a lower output than in December. Alberta was the only province in which more coal was mined than in the preceding month. The [illegible] in production by provinces in January, as compared with December was as follows: Nova Scotia, [illegible] tons, British Columbia, 6,000 tons; Saskatchewan, 13,000 tons; New Brunswick, 8,000 tons.

As stated above the report is the first of a series of Monthly Reports on Coal Statistics for Canada, copies of which will be mailed regularly to those interested. Applications for this report should be made to the Dominion Bureau of Statistics, [illegible]

News of Mining

The announcement is made of a payment of a quarterly dividend of $500,000 by the Premier Gold Mining Co. (Salmon River, B. C.). The company's capital is $5,000,000. A previous dividend of $400,000 was paid on Dec. 31, 1921. The Premier mine was turned down in 1915 by engineers representing Mr. W. B. Thompson of New York. It is now partly controlled by the Guggenheims. One lot of ore 286 tons, yielded $96,000. Of this yield 60 per cent. was silver and 40 per cent. was gold.

Bolivia supplies much of the world's bismuth. The Bolivian ores, containing native bismuth and the sulphide, are associated with tin or with silver and copper.

Carbon black production from the combustion of natural gas has assumed important dimensions in the Southern United States. The value of the output for the year 1921 was $5,350,000. Louisiana contributes more than half the output. In that state it is being made imperative for the operators to extract all gasoline before the gas is burned.

The Norwegian Government, on March 8, appointed a Committee to investigate the financing of the British America Nickel Corporation and that Corporation's relations with the Kristianssand Nikkel Raffinerings Verk.

Exports of ore from New Caledonia, the French penal colony, amounted during 1921 to 29,458 tons of chrome ore, 3,364 tons of nickel ore, and 3,273 tons of manganese ore.

As compared with wages current in the year 1913, German coal miners are now receiving from 1000 per cent. to 1500 per cent. more.

The oil-shale deposits of the Ermelo district, Natal, are estimated to contain 93,000,000 tons of shale yielding from 18 to 28 gallons of oil per ton. The development of these deposits is being projected at present.

Japanese Import duties on copper plates, sheets, ingots, etc., have been increased by from 60 per cent. to 170 per cent. by recent enactment.

In the proposed McCumber import tariff, all cyanide imported into the United States will be dutiable at 10 per cent. ad valorem.

The California State Mining Bureau reports that oil drilling experience has proved the economy of using diamond drills to a depth of one thousand feet. Beyond that depth difficulty of manipulation increases costs to a point that does not compare favourably with percussion-drill operation.

British Columbian coal operators are urging the imposition of an import duty on foreign fuel oil. It is claimed that an adequate duty would not only serve to retain $12,000,000 annually in the Province, but also add $5,000,000 to industrial payrolls. Fuel oil imports in British Columbia now amount to about 350,000 barrels monthly.

The Province of Alberta, in negotiations with the Dominion Government for control of her mineral and other natural resources, has expressed willingness to give up the annual cash subsidy now paid into Alberta's Treasury from Ottawa. An early settlement of the question seems probable.

In an address before the Toronto Branch of the Canadian Institute of Mining and Metallurgy, Mr. R. Home Smith emphasized the fact that capital for mining is drawn from every country in the world. He spoke warmly of the honest effort put into Canadian mining and deprecated the "sniffing" spirit of Canadian financial men. His advice to Canadian business men was that they visit and re-visit the North and do what they can to establish connection there.

The French Government has appointed a Commission to devise or recommend methods and schemes for the carbonization of lignites in France and her colonies. Deposits of lignite, peat, and bituminous shales are to be intensively surveyed. Particular attention is being paid to the utilization of peat bogs.

In Nottinghamshire, England, last month in the course of an inquest into the death of a coal miner, due to a fall of roof, one of the expert witnesses stated that the fatalities from this cause would in future be reduced. By a new device, used with the auger and chain, timber can be withdrawn in such a way as to obviate the use of the hammer and without weakening the timber.

Despatches announce that the German Government will presently issue aluminium coins to replace the paper mark. All except the one-mark coin will have an internal layer of copper.

A special report by Mr. A. J. M. Sharpe, submitted to the American Zinc Institute, well summarizes the present condition of the Zinc industry. Mr. Sharpe stated that new arrangements entered into between the British Board of Trade and representatives of British Smelters, whereby large tonnages of Australian Zinc were made available at a contract price, had given the smelters the cheapest obtainable supply of concentrates. As in Broken Hill concentrates the silver and lead contents are of commercial value, it is deemed essential that the zinc retort residues be washed at tabling plants. The installation of such plants, in Mr. Sharpe's opinion, will tide several of the British smelters over periods of low prices. The reserve stock of zinc in Belgium is now down to normal. Belgium still must pay for many thousands of tons of Australian concentrates contracted for at high prices. The situation is governed by the fact that the cost of producing a ton of zinc is to day £22 in Germany as compared with £26 in Belgium, France, and Britain. French smelters are producing just enough for domestic consumption. The same is true of Germany, and practically true of Norway and Sweden. The unsold stock of zinc in the United States is the primary reason for the London price being £1 to £2 lower than it would otherwise be. European stocks are disappearing much faster than those in the United States which amount to nearly 60 per cent. of the world's unsold accumulation.

News and Comments

by Alexander Gray

Germany's Merry-go-Round "Money"

The German money factories are outstripping all outputting records; even script manufacturers will have to look to their laurels. Of what earthly use is it for mining share producers to try to compete with a government that can run off 7,767,000,000 marks in six working days? The printers strike in Canada has a lot to answer for.

Smelter's Financing

It is proposed to issue $6,000,000 of 7 per cent. twenty-year bonds to refund certain Consolidated Mining & Smelting obligations and in exchange for the other bonded indebtedness of the company. This, with accumulating funds, will provide a more liquid position to extend the present concentrating plant at Trail, erect a new mill at the Sullivan Mine, and generally equip the latter with more efficient operating facilities. When a concentrator is built at the Sullivan, the freight charge on ore now shipped to Trail will be largely eliminated, and the concentrator at Trail can be used for the generality of Rossland ores. Apart from these announcements made at the annual meeting, the promise to return to dividend distributions during the latter half of this year, bespeaks further optimism on the part of the administration. The expectation is the bond issue will be disposed of at parity. Zinc and lead prices are better now and should do better still; consequently the Consolidated is heading for speed limits.

Nickeled Tinplate

Rustless tinplate to be made so by means of a nickel bath, is aimed at by a Swansea Steel-Nickel Syndicate in which Henry Mond, son of Sir Alfred Mond, is interested. The added cost should be insignificant, and that should commend the invention briefly referred to in cables. It is the comparative cheapness of tinplate that made its market. Packing and canning people always were sensitive about tinplate tariffs that might influence the first cost and popularity of products in universal use. If nickel tinplate is as represented, producers of nickel in the forms required will welcome another outlet, to speed sales that have been moving too slowly to be comfortable.

The Mitchelson Promotion

Private advices to the effect that Sir. Arthur Mitchelson, Ltd., were left with 80 per cent. of their Porcupine issue, rather indicates, if reports be true, that London is not so easily inveighled. Worse things could have happened to the British public, and to Canada. When members of the issuing firm came all the way from the world's metropolis to Porcupine, and seriously announced "it was not convenient to go below the 300 ft. level of the mine", which evidently had not been dewatered for their inspection, laxity was feared and it was thought another discredit mark was being framed for Canada. However, according to cables, 20 per cent. of the share-offering was taken by the public and that is something to be thankful for. If it was so soon to be done for, what was it begun for?

The Deadly Parallel

"A report on Ontario's gold deposits, written by the Percy E. Hopkins, and published by the provincial Department of Mines became available to the public today. The first copies are being rushed to the province's agent-general in England to meet the many inquiries in that country regarding the gold mining in Ontario. With the unsatisfactory conditions of mining in South Africa and the spectacular rise in Hollinger among the great gold mines of the world, British speculators are inquiring into possibilities in the province and both the daily and the technical papers in the Old Country have laid considerable emphasis on this swing of Ontario's mines into public favor."

"Negotiations which are likely to prove favorable for Hattie Gold Mines are to be commenced on Monday, when directors of the company will meet Mr Wilson, the representative of two English financial houses, who has come to Toronto with an offer to purchase a block of treasury stock of the company.

"Mr. Wilson represents the British Security Trust Company and Stanley P. Dunlevy and Company, of London, England, who have had an examination of the Hattie Mines made for them, and have received a favorable report. It is understood that he will undertake to buy 500,000 shares of treasury stocks at 25 cents a share."

How much of a treasury will Hattie have? The Security Trust, as a title, sounds better than twenty-five cents' worth of Hattie.

Tonopah Belmont Canadian Profit.

As one of the American mining companies consistently endeavoring to develop Canadian mineral areas, Tonopah Belmont has more than the interest of goodwill. From the Mandy Mine in Manitoba, the Tonopah people realized profit out of keeping with their strenuous efforts. Then they took over Surf Inlet properties, which they developed and equipped, at a cost that would have deterred the less experienced. Now, it appears, Surf Inlet had a set back last year, as these figures show:

	1921.	1920.
"Other Income", including Surf Inlet dividends	$56,119	$201,532

In reality, Surf Inlet showed an operating profit of only $62,759 in 1921, compared with $195,259 in 1920. Of that, $62,500 went toward dividends to the parent Tonopah as against $250,000 in 1920. The grade of ore, it is explained, fell from $10.62 to 6.89. As the ore reserves, including those of the Pugsley mines are placed at 175,173 tons (values not stated), it is hoped the mining position will improve or that the company will find something better.

Yukon Gold Keno Hill Results

The first authoritative statement concerning Keno Hill, Yukon Territory, results are those of the Yukon Gold Company. During the winter of 1921-22 Keno Hill operations yielded 2,110 tons of ore containing [illegible] ozs. silver and 62 per cent. lead to the [illegible] gross value. Up to December 31, 1921 [illegible]

1,347 tons ad been mined, and a total of 3,000 tons was hoped for from the 1921-22 winter's work. As shipments are expected to begin in June, when the break-up occurs on the Yukon River, it should soon be possible to have further evidence of what the two seasons brought to the Yukon Gold Company.

Power Problems Partly Solved

Award of Three Carrying Places power rights on the Abitibi River to Hollinger Consolidated Gold Mines, is a welcome developement. It is a step toward the solution of the vexing power problem. The understanding is the privilege granted to Hollinger will be promptly availed of. Although further removed than the power originally applied for by the Company, the locality, it is said, lends itself to more economical development. Hollinger has the money to go ahead; but what is to become of the numerous other enterprises awaiting cheap and efficient power? Admittedly the Northern Power people cannot do it all. If Northern Ontario is to become the center of Canadian gold production, the power situation will require broader treatment.

Imperial Oil to a Finish

Authoritative announcement is made that the Imperial Oil Company will prosecute explorations for oil in the west and north-west until failure or fruition is assured. In this, the Imperial is consistent with what it declared to be a sense of National Duty. It is incredible that the Prairie Provinces and Northwest Territory do not contain oil. The mission of the greatest Canadian producing and refining organization is to find it. More of this sort of reproductive capital is what Canada needs.

Nighthawk Lake Peninsular Mines

Because of its prolonged probationary period and repeated reverses (for which the properties were not to blame), Nigthhawk Lake Peinsular Mines are the most interesting undergoing development, under the management of A. R. Globe, and the direction of Messrs Thaw, Dodworthy, Callinan and others, mostly of Pittsburg. Private funds (and no fuss) have acquired over 1,800 acres and presented an underground and surface situation that proves the unwisdom of precipitate judgment before thorough testing. An ore-body of width and excellent grade, another awaiting development, and a large section from which much is expected even though the average value be low, have prompted the influentieal directors to provide more plant. They prefer to define their mines before seeking public support. If progress this summer is up to schedule, these Nigthawk properties may establish a new gold area.

Relief From Nickel Taxation

When mistakes are made and they are realized, it is the part of wisdom to correct the errors, and sin no more. That is why it would be a display of better judgment (second thoughts being best) if the petition of Sudburians for a reduction on nickel production were granted. Special taxation is deliberately prejudicial, at all times. The nickel industry was singled out for surtaxes, just when it needed official help. "What is sauce for the goose, is sauce for the gander" being an aphorism applicable in the premises, all taxation should be equably apportioned. Premier Drury has promised to give the matter prompt consideration in order to encourage those who are rehabilitating the nickel industry. Consequently, there may soon be a more contented Sudbury, and its pre-requisite, a larger payroll. The burden of the complaint is—

> Whereas gold and silver mines pay a tax of only 3 per cent. on profits between $1,000,000 and$5,000,000, nickel mines pay 5 per cent., but the even greater difference is that the tax in the case of silver and gold is on basis of the value of the ore at the pit mouth, and therefore applies only to the profits of actual mining operations, while with nickel the profits taxed not only include the profits in mining, put in roasting, smelting, refining and selling as well."

Asbestos Industry Complications

The annual meeting of the Asbestos Corporation enabled President W. G. Ross, at all times a prudent business man, to point out the perplexities attending the Asbestos Industry. So accustomed are we to hear that the Quebec deposits are supreme, unparalleled in their excellence and great quantity, it is more than admonitory to have Mr. Ross declaim against any embargo upon crude products. Limited domestic markets, international exchange, competition from South Africa and possibly Russia (not overlooking the United States), according to Mr. Ross make inadvisable any legislation that would invite reprisals that might prove disastrous. While there are those who will not altogether concur in the conclusions of Mr. Ross (it is desirable that we export more of the finished articles) it seems as though the whole situation should be carefully gone into before there are heroic departures that might prove foolhardly. Undoubtedly Washington is not showing much consideration for outside industries or foreigners. But Mr. Ross invites attention when he says:

"To the ordinary reader of articles that have appeared lately advocating an embargo, it appears to them that the province's raw material should be manufactured here, but the facts of the case are, that if any such foolish policy were adopted it would sound the death knell of the asbestos mining industry of the province, for the reasons that, if such a policy were adopted, the world's supply of raw asbestos would come from Rhodesia, Russia and the United States itself, and Canada would mine only sufficient to supply such small proportion for her own needs that no mine could operate profitably. At present, approximately 1 per cent. of what is mined would supply the Canadian consumption, nor could she sell, if she did manufacture, practically anything outside of her own territory.

"No matter how well dressed up it may appear to the public generally, and how well it may appeal to those ignorant of economic conditions, it is sufficient to say that if the manufacturing concerns of Great Britain, Germany, Belgium and France, who have the finest manufacturing plants in the world, are unable, with a large and favorable rate of exchange in their favor, to sell in the United States, how hopeless it would be to expect that Canada could sell any manufactured goods outside her own territory, the demand for which is insignificant."

Canadian Iron Ore For Germany

Contracts with three German steel companies for Wabana iron ore signalize the resumption of an export trade that is expected to assume large proportions. Germany is short of iron ores, and the British Empire Steel Corporation is in a position to make prompt deliveries. It is reported between 400,000 and 500,000 tons are to be shipped. This, and the re-starting of the nail plant, provide a morsel of cheer for Sydney officials and workers.

Northern Ontario Letter

THE GOLD MINES

Hollinger

The month of April found the Hollinger Consolidated with a record of over $44,000,000 in gold produced, thereby exceeding for the first time the aggregate value produced up to this time from the Nipissing Mines at Cobalt. The Nipissing was first operated in 1903-4 and was not long in taking the lead as the greatest producer of precious metal among companies operating in Canada. The indications are that the Hollinger, which commenced to operate in 1910, will now move far ahead of any other company in point of aggregate precious metal produced in Canada.

Dome

After allowing for all costs and expenditure during the year, the Dome Mines realized $1, 250,000 profit on the twelve months period of operation ended March 31st. After making liberal allwance for depreciation and exhaustion, a profit of $633, 309.22 was shown.

Recent information shows that diamond drilling operations have indicated additional bodies of high-grade ore. Assays are stated to run all the way from a few dollars to upwards of a thousand dollars per ton, all of which holds out good promise of the continued operation of the mill on ore which carries an average of about $10 in gold per ton. In the meantime, a very large tonnage of medium grade and low grade ore is being placed in sight and assures a long life for the Dome.

Preston-East Dome

Arrangements have been made to operate the property of the Preston-East Dome. Details of the arrangement are not available at the time of writing, but it is understood the necessary details have been arranged. Wm. Gowans, who was some years ago engaged at the Dome Mines as mine captain, will be in charge of the work. The property lies directly south of and adjoins the Dome Mines.

Porcupine-Davidson

Apart from the operation of one diamond drill, no work of any consequence is being done on the Porcupine-Davidson Gold Mines. This is the name of the company that succeeds the Davidson Consolidated and in which an effort is being made to arrange finances in England.

Porcupine V. N. T.

Considerable attention is centering on the Porcupine V. N. T. and the prospects of another paying mine being established at Porcupine. The former records are being looked into. Among other things these show that over $800,000 was produced. This came largely from the Vipond claims which are now known to contain lower grade ore than that occurring on the North Thompson. The Vipond and the North Thompson having been consolidated into the Porcupine V. N. T., it is now the intention of the management to concentrate effort on the North Thompson side, where high grade ore has been found to occur. The outlook for the enterprise is exceptionally bright.

Hollinger Gets Power Rights

The Hollinger Consolidated has been given the right to develop a water power on the Abitibi River, following a number of conferences with representatives of the T. and N. O. Railway and the Abitibi Power and Paper Company. The site set apart for the Hollinger is known as Three Carrying Places portage and will allow for the development of about 40,000 h.p. if required. The control of the flow of water from the storage basin on Lake Abitibi will probably be under the direction of the Ontario Government. In the meantime, litigation between the Hollinger and the Northern Canada Power Company is unsettled.

Porcupine Crown

Some crosscutting is being done on the Porcupine Crown, along the north boundary. No other work is being contemplated on this property until the difficulties with the Thompson-Krist faction can be straightened out.

Lake Shore

In the regular monthly report of the Lake Shore Mine, manager R. C. Coffey points out that the mill ran 95¾ per cent. of the possible running time and handled 2,210 tons of ore during March.

The mill handled an average of over 71 tons of ore daily and the ore yielded an average of approximately $24.83 per ton. A continuation of this record would show an annual production of about $657,000 a year from the Lake Shore.

Montreal-Ontario

The merged properties of the Ontario Kirkland and the Montreal Kirkland are to be known as the Montreal-Ontario Gold Mines. The company has $5,000,000 authorized capital, made up of 5,000,000 shares of the par value of $1 each. Officials are confident of being able to place the enterprise on a paying basis before the year is out.

Lebel

A local syndicate is negotiating for property in the Lebel township part of the Kirkland Lake district. Identified with the syndicate are H. C. McCloskey, D. Angus and the Tough brothers. The Fetterly-Tobico-Perry claims have already been secured, while negotiations are under way for a group formerly known as the Pindle as well as for the Moffat Hall. The latter lies adjacent to the Bidgood in which the Tough brothers are interested and which is being managed by D. Angus.

Good Results at Depth

Within the next sixty days the Teck Hughes will have established an operating level at a depth of 980 feet, while the Wright Hargreaves will have its main shaft down to the 700 ft. level, with operations under way at the 200, 400, 550 and 700 ft. levels. Also the work of carrying the shaft of the Kirkland Lake Mining Company to 1,150 or 1,200 feet will be well under way. Also the Sylvanite will be operating at a depth of 800 feet, with lateral work well advanced at that depth. These details tend to show the general progress in the scope of mining work from one end of the Kirkland Lake camp to the other. A feature is that in each case where work has been carried to depth the extent of the ore has increased.

Tashota

A deal is being negotiated for the Nelson Hughes property, situated in the Tashota section of the Kowkash mining area. There are known to be low grade ore deposits on the property, and plans are being made to explore the deposits at depth by means of diamond drills.

Elstone-Dunkin

According to present indications the Elstone Dunkin property in Gauthier township may be tied up until about September. The company was involved in certain negotiations through the late Henry Cecil, and certain options hold good until September unless some other arrangement may be made before that time with the executors of the estate.

Teck-Hughes

While cutting a working station at the 7th level of the Teck-Hughes mine, high-grade ore has been encountered, according to advice just obtained. The information came as a surprise for the reason that it had generally been believed some cross-cutting would be necessary to reach the vein and that some drifting would be necessary before reaching the downward continuation of the rich ore-shoot found at the 600 ft. level.

The present reports about a rich strike at the 7th level which lies at a depth of 730 feet was referred today to D. L. Forbes, general manager of the Teck Hughes, but Mr. Forbes declared he had nothing to say. It is obvious that any statement at this time would be premature, as the importance of the development may be determined only by a reasonable amount of lateral work. However, should the discovery prove up with further work, it will tend to justify the recent optimism with regard to this enterprise. These developments will serve to change the destiny of the Teck-Hughes, in addition to being important to the Kirkland Lake field as a whole.

Shiningtree District

In an interview with M. P. McDonald, managing-director of the Atlas Gold Mines, it was learned that diamond-drilling operations are going ahead at a rapid rate on this property. The first hole has been completed to a depth of 200 feet and passed through what is known as the Evelyn vein, the core showing a width of 18 feet of vein matter, of which a five-foot section on the foot-wall was almost solid sulphides. The second hole is being driven to a depth of 400 feet and is already down about 200 feet. Mr. McDonald brought out samples of the core with him and these will be assayed at once.

Activity in the West Shiningtree gold area is increasing and the result of work is highly encouraging.

In addition to the diamond drill work announced on the Atlas, it has been learned that a number of other properties will be explored in this manner.

The question of sinking another 200 feet on the White Rock property is now being considered, and the company is stated to have funds for the work. Recent developments on this property proved the occurrence of some spectacular ore.

George Rogers of the Ribble Mines, operating the Wasapika, left a few days ago for the property, taking a crew of men along with him, and is preparing to carry out a carefully considered program of work.

Negotiations have been entered into with regard to letting contracts for diamond drilling on the Miller-Adair property, and this is expected to be ordered in the near future.

It is also reported locally that the owner of the Westree property are considering a diamond-drilling program.

Holtyrex

Two diamond drilling machines have been taken in for the purpose of exploring the Holtyrex property at depth. Attention will be directed toward exploring that area lying in a contract zone which passes over the property in a north-easterly direction. Harry Holland is in charge of operations while Smith and Travers have the diamond drilling contract.

THE SILVER MINES

Nipissing

The statement made by R. B. Watson, general manager of the Nipissing Mines, that the option on the Rochester property at Timmins would be dropped, came earlier than had generally been expected. Mr. Watson is quoted as saying that they had put down nine diamond-drill holes, some of which were as deep as 1,000 feet and while they did find gold values, the directors decided that the results were not sufficient to warrant them in believing that they had a mine in the Rochester, so they have cancelled the option.

The Nipissing Mines will probably produce close to three million dollars worth of silver during the current year and will realize close to one million dollars net profit, according to the information presented at the annual meeting by general manager Watson.

In spite of only a medium price for silver, the net profits during each of the first three months of 1922 averaged approximately $75,000, or at the rate of about $900,000 a year. As to this, the price of silver has recently been advancing and the indications appear to be that net profits will gradually increase.

Diamod drilling commenced about two weeks ago on the Gordon property in Northern Manitoba, on which the Nipissing holds an option. It is too soon to estimate the possibilities of this venture.

Concerning the company's oil leases in Kansas, the revenue is sufficient to pay expenses and may leave a small amount as profit. Nothing will be done on the company's iron property near New York until such time as costs come down and a suitable method of concentration may be decided upon.

A large number of shareholders attended the meeting, the old board of directors being unanimously re-elected.

McKinley-Darragh

Work has been resumed on the McKinley-Darragh mine, and about 75 men are to be employed. There are approximately 25,000 tons of broken ore in the mine, as well as other resources, and it is believed the enterprise may now show a fair margain of profit. The Sibleys who formerly controlled the McKinley-Darragh have reduced their interests in the mine, and this appears to have passed largely to T. R. Finucane. The new board of directors consists of the following: J. R. Starr, president; T. W. Finucane, vice-president; T. R. Finucane, treasurer; J. H. Spence, secretary, and with H. C. McCloskey and B. E. Finucane, directors.

Bailey

Work has been suspended temporarily on the Bailey mine, the reasons being financial. It is expected the work may be resumed within the next two months or so.

Gowganda

The Ontario Government is being urged to complete the work on the Gowganda road this year. The highway from Wig-wam lake to Gowganda, a distance of about seven miles, is the only part unfinished and the completion of this would provide a good motor road right from the railhead to the mines.

Nothing will be done this summer on the Collins property at Leroy Lake.

Silver Prices

March 31st.	Highest price	66.125
March 2nd.	Lowest price	63.000
	Average price	64.440

Notes From Nova Scotia

In Union Lies Strength.

The fusing of the Dominion and Scotia Coal Companies into the Empire Steel Company has had good results and has led to greater economy in both the coal and iron-ore industries. Boundary leases had been a prolific source of trouble between the two companies and had caused large expenditures of capital to operate duplicate systems, especially in the Wabana ore mines. At Sydney Mines two of the largest collieries had also been affected, and were much crippled in output. All efforts of the Labor Unions and citizens through the most influential bodies of the Province had failed and the coal lease question remained unsolved. Public opinion is slow to mature, but gradually the public mind began to perceive that there was only one solution to the question, and that lay in the two companies getting together. Mining experts had seen this years before, and had been quietly working towards such a union. When the news of the proposed Empire Steel Corporation was made known, it broke upon the ears of the employees and of the mining public with more of gladness than of regret. Only one of the leaders of the United Mine Workers has taken strong exception to the new Company, and he finds in it a means of forming a labor party. Whatever the outside public may think of the subsidiary companies and of the Empire Steel Corporation, the mining communities see in it the salvation of the iron-ore and the coal trades.

Men of large experience and clear vision, who in after years will be acknowledged by their countrymen as great Canadians, saw clearly that all industrial prosperity rests on low-cost production of the two basic commodities, coal and steel, succeeded in realizing their dreams and will see their efforts crowned with success.

With improvement in trade conditions the Empire Steel Corporation will stand as a bulwark of strength in the economic and industrial life of Canada.

Progress Due to Union.

The union of the two companies completed, the Company set about to get a thorough knowledge of all coal seams. These were prospected by means of a diamond drill and a large amount of new data was obtained. While this coal field has a large quantity of coal of excellent quality, the supply is far from being unlimited as is commonly stated.

The iron-ore measures were better known and little prospecting was necessary.

In the meantime the general conditions of the Collieries were surveyed, the regularity of the strata at the greatest vertical depths noted, together with all changes of dip in the measures. When it had been proved, as far as engineering skill can prove an undersea mineral field, that all indications pointed to vast supplies of coal extending many miles under the bed of the ocean, policies were laid down and plans mapped out for extracting the greatest possible amount of coal from the greatest possible distance.

Four mining problems immediately stood out which in land areas would not have had to be considered. These were: 1 ventilation, 2 motive power, 3 transportation underground, 4 crush of the superincumbent strata.

The Cape Breton collieries have a long way to go if indeed they will ever reach a depth at which the coal will crush and make it a constant factor of difficulty in winning coal. The dips of the seams are easy and none of the present working seams lie at any great depths.

Transportation of coal underground on main ways can be done almost as cheaply as overground, provided the main haulage-ways are well kept up. The problem confronting the Company is the underground transportation of workmen to and from the working faces. Men cannot be lowered into and drawn from a deep mine by way of long slopes without consuming much time. This shortens the working day at the face and it can easily be understood what an hour in transit each way means when an eight hour day is in force. Recently the miners of Nova Scotia applied for an eight hour day from bank to bank. If this is granted the most a miner in the deeper collieries will be able to do is five and a half hours work.

To revolutionize the motive power is the least of the large questions of the Empire Steel Corporation, although a large expenditure will be necessary. Electric power will in future be largely used in the collieries both for haulage and running purposes.

The Eight-hour Day.

The Eight-hour from Bank to Bank Bill, has been given a three month's hoist in the Halifax Legislature. This Bill was modelled after that of British Columbia, without any regard to the conditions of Nova Scotia collieries. Had the Bill passed, it would have proved a boomerang to the Labor Party that introduced it. But the members of this Party are shortsighted and at best can only see in one direction. They reason that if the miners in British Columbia have an eight hour day from bank to bank, the miners of Nova Scotia should have the same. They know that at the present time, more than an hour is consumed by miners travelling over the exceedingly long roadway, they know that these distances in the larger collieries cannot be reduced, but that they are growing longer with every working day. They know, or ought to know that eighty per cent. of the Cape Breton coal output, which is by far the largest producing centre in Nova Scotia, is taken from the undersea seams and that those must be followed to their inner most recesses by means of the best equipment known to mining. This means a large expenditure of capital. But if after this is done there is to be only a day of from five to six hours at the working face, then the Labour Party of Nova Scotia will have proved beyond doubt that they have succeeded in destroying the coal industry at a time when constructive effort was needed to forward it.

In the year 1919 the British Government appointed Mr. Sanky to investigate and to recommend remedial measures for the British miners who committed to a shorter day than eight hours. Mr. Sanky recommended a large increase in wages and a seven hour day. The Government was displeased with the seven hour day but granted both it and the wage increase. It took two disastrous strikes to prove to the British people that war wages could not be maintained. Now that wages have receeded to a low level a shifting movement is afoot to get back to an eight hour day, with the benefit of an additional hour's wages. It cannot be attained. But a worse factor than wages [illegible]

British Mining Industry in the large number of men now employed. In 1917, the British coal output was approximately 291,000,000 tons, the total number of men employed being 1,021,340. In 1920, the output had fallen to 263,000,000 tons with 1,248,224 men employed or an increase for a much reduced tonnage of 226,884 men.

The argument used by Labour Leaders in the past, that a colliery equipped with up-to-date machinery can hoist as much coal in eight, as it did in ten hours under the old system, may have a grain of truth in it, but it has been clearly demonstrated that the same amount of work cannot be done in seven as in eight or ten hours. The eight-hour day in all normal mining, seems to be the limit where production remains constant. Less than this brings low wages, loss of output, a languishing industry and a discontented mining class. To us in Nova Scotia it would mean a demand for increased wages at a time when the wage question has reached a most acute stage.

We have not considered here the competition of coal from the United States, coming from districts where a nine-hour day is the rule. The miners of Nova Scotia have an eight-hour day, with which they should be well satisfied.

Advertisements other than "Employment Wanted" or "Employees Wanted" will be inserted in this department at the rate of 20 cents per agate line (14 agate lines make one inch) $2.80 per inch, each insertion, payable in advance. Space measured from rule to rule. When four or more consecutive insertions of the same advertisement are ordered a discount of 25 per cent. will be allowed.

Advertisements of "Wanted Employment" or "Wanted word, net. Cash must accompany order. If box number is used, enclose ten cents extra for postage in forwarding replies. Minimum charge 50 cents.
Employees" will be inserted at the rate of two cents a

EDITORIAL

Of all ways whereby great wealth is acquired by good and honest means, none is more advantageous than mining; for although from fields that are well tilled (not to mention other things) we derive rich yields, yet we obtain richer products from mines; in fact, one mine is often much more beneficial to us than many fields. — Georgius Agricola — 1550 (*From Hoover's Translation*).

BRITONS FOR BRITISH DOMINIONS

The movement now on foot in Britain for "migration within the Empire" deserves the most serious attention of the various Dominions and Colonies. The problem is receiving the attention in the old land of a number of those master minds that have guided the destinies of the British Empire for two centuries. It is a vast problem, of vital importance to both Britain and the Dominions, and requires all the thought and energy that can be brought to bear upon it.

The facts are, briefly, these. Britain's population, trebled during the period of the industrial revolution of the last century, has now reached a maximum. Britain can no longer hope to increase her industry within the British Isles; in fact signs are not lacking that there will be a gradual recession in her ability to manufacture imported raw materials and sell them at a profit. Thus the natural increase of her population must find a means of livelihood elsewhere. The immediate necessity for emigration is unusually pressing, due to its stoppoge during the war years and the present industrial depression.

It is most desirable that this outflow of British people from the old land should be to British lands beyond the seas. Of all the Dominoins, Canada has room at present for the largest total number of settlers; and it is British settlers we need and want most.

Most of us have an unshakeable belief in the sterling qualities of the Britisher. He may strike; he may irritate us Canadians in a dozen different ways; but we believe in him, for we are of the same blood, if not, indeed, kith and kin. The Britisher is, essentially, the most adaptable of civilized men. It is this quality that has won for him the waste places of the earth. The present problem is to transfer the surplus of industrial workers in Britain to the vacant lands of Canada in such a way as to inflict a minimum of hardship upon the migratory thousands and to give them the best chances for success in the new land.

To those well-versed in the history of British migration we can well leave the formulating of a scheme adequate for the occasion, and sufficiently well-founded to endure for the coming century. Our Canadian government authorities will aid the settlement of the new-comers by every means in their power, and will have the co-operation of numerous private organizations and of a host of private individuals. What can we miners do as our but?

As pointed out recently in these columns, one of the most effective, as well as the most rapid means of producing wealth from Nature's store, is mining. Activity in mining promotes a corresponding activity and growth in agriculture, commerce, and industry. This increased activity in all branches of practical human endeavour is the surest means of attracting settlers and ensuring their successful absorption into our national economic structure.

If Canada is to do the best within her means to assist in the migration of British people and their retention within British dominions, we must rapidly find and develop the mineral resources that we are confident will soon make Canada the Empire's chief source of mineral products.

PIGS AND PROSPECTS

There is a certain difference between a mining prospect and a pedigreed bull calf that is not generally recognized. Likewise, there is a similarity between a mining prospect and a "pig in a poke" that is known only to the initiate. This difference and this similarity are worth some study.

When a farmer pays five thousand dollars for a bull calf, he does it on the basis of a pedigree, which he has examined carefully and finds to suit his purpose. This pedigree, back of a healthy young animal that is worth only a few dollars as beef, warrants his investment. The calf may die and leave him sorrowing, but he must take a chance on that.

The "pig in a poke" is the antithesis of sound investment. The porker is not as good a risk as a square throw of the dice or a poker game, because in his case the dice are loaded and the cards are stacked. If the pig is sound and worth the price, there will be no need of concealment.

Every day in the week and every week in the year the public are being asked to pay their good money to see a "pig in a poke", which has been dressed up to look like a bull calf of honourable lineage, just at present in this country as well as abroad certain mining [illegible] the centre of the stage with [illegible]. Behind the scenes are some promoters who [illegible] are about as sound as those of the animal [illegible]. With them there is sometimes, [illegible]

an engineer who is a party to the gross deception, though seldom does an engineer allow himself to associate with these theatrical gentry. Sometimes the "show" turns out to be a comedy, and then it is a failure so far as the actors and stage managers are concerned. Often it is a tragedy, and then it is customary for the chief actors to feel their bulging pockets, smile on one another, and prepare for another good run. In any case, the "star" of the show is slaughtered, and ceases to interest either public or performers.

A prospect is essentially a "pig in a poke," with the difference that it is so very young that, in spite of all appearances, it may possibly turn out to be a big healthy animal. A mine is different altogether; it has developed ore-reserves, and the means of guaranteeing a return on any reasonable amount of money spent for a mill or for further development.

To be more explicit, though somewhat axiomatic: the development of a prospect is built upon hope, as was the effort of the prospector who discovered it. **Predictions** are always speculative, and usually unwarranted. **Hopes** are necessary, and if well regulated, are useful.

Under present-day conditions, to trade upon the hopes of the engineer, and thus to raise the hopes of the investor, is the business of the promoter. If done within reason, this is legitimate; if reason is exceeded, as so often is done by unscrupulous promoters and brokers, the chances are that the whole scheme will prove a boomerang to the mining industry, missing (unfortunately) the promoter and broker on the way back.

Promoters and brokers are just as necessary for the development of our mining industry as are engineers. All three must work together if the maximum benefit is to accrue to the industry. Money must be raised to keep the engineer at work. But reputable engineers and brokers (who are the large majority) should join forces in a determined effort to purge their ranks of those parasites whose object it is to bleed the public's financial resources without any thought of a fair return.

CANADIAN CERAMICS SPECIALISTS FOR CANADA

On May 12th, there is to be held in Toronto a meeting of those interested in ceramics, for the purpose of discussing the proposed establishment of a special course in ceramics in Toronto University. The movement has originated with the officers of the Canadian Clay Products Association.

Canada's ceramics industry is at present in an embryonic state. The simplest clay products, brick and tile of various sorts, are manufactured at strategic points through the Dominion. One small firm manufactures floor tiles, and our manufacturers of enamelled-ware make a finished product. This, roughly, gauges our ceramics industry at present. We have no potteries, and we import our ever-increasing supplies of porcelain.

Our present dependence upon imported pottery and porcelain is not due to a lack of raw materials. Feldspar that has set a standard for this continent, if not for the world, is available in abundance, and is exported in large and growing quantities to the potteries of the United States. Clean silica rock is available at numerous places. China clay in deposits of large but undetermined extent have been located sixty miles from Montreal, and are now being developed commercially.

What we lack now for the establishment of an indigenous ceramics industry that will adequately provide for the needs of our country is the informed human effort that will put to use within our borders Nature's gifts of raw material. At present our young men who wish to become proficient ceramics engineers must go abroad for both their technical training and their practical experience. It is high time we tackled our own problem for ourselves, instead of relying upon our neighbors.

The field for the manufactured products of clay, silica and feldspar appear promising at present. Brick is gradually and surely replacing less substantial materials for dwellings. Intensive cultivation of the soil and improvement in methods of farming call for an increasing amount of drain tiles. The walls and floors of large buildings are composed, more and more, of hollow tiles within a framework of steel. Electrical development involves the use of a huge number of porcelain insulators.

The movement to train Canadian ceramics engineers in Canada is timely. We need a native ceramics industry of much larger dimensions than at present. The surest way to get it is to train young Canadians to do the work. When the Dominion's forests needed expert attention in the worst way, a forestry course was founded, and it constituted a centre from which emanated information and propaganda that have gone a long way toward solving the problem. The same is possible with ceramics.

The Journal hopes that this latest step towards the goal of Canadian industrial development will be made at the earliest possible moment.

IRON AND STEEL IN INDIA AND THE EMPIRE

India bids fair to outstrip soon in her production of iron and steel, all the British Dominions, and to become an important factor in world production. This has long been predicted by students of the world's resources of iron-ore and coal. It remained for a Bombay banker, Sir Jamshedpur Tata, with the co-operation of an American technical staff, to begin to fulfil this prediction.

In 1912 the first of a series of modern blast-furnaces was put in operation at Jamshedpur in the province of Bengal, as well as a complete steel works. During the war time this works supplied all the Eastern theatres of war with the railroad iron upon which military opera-

tions essentially depended. The timely enterprise of the Bombay banker may be said to have saved the East for Britain. Since 1912 the plant has been increased to include three blast-furnaces, and two more are in course of erection. A second company, the Bengal Iron Company, are also producing iron and ferro-manganese, and a third, the Indian Iron and Steel Company, is expected to begin production this year.

How do the British Dominions stand in comparison with India as iron producers? Canada at present leads; but unless radical changes are made in her methods of production, such as will take further advantage of her natural resources, she cannot long maintain the lead. The Nova Scotian industry has an abundance of ore and of coal; but the ore is rather low-grade and highly silicious, and the coal is in submarine strata, and so cannot be won so cheaply as the coal of some competitors in the iron and steel trade. The iron production of Central Canada is dependent for its existence upon imported ore and coal, and upon a protective tariff, and so cannot be considered seriously in world affairs.

South Africa, like India, has been considered a potential factor in the world's markets for iron and steel. Here, though, the development is still embryonic. There are good coking coal and good iron ore, both in abundance, as well as native labour. But the country offers only a very limited home market and is not yet well-developed by railway facilities, and a large export trade is not yet feasible. Nevertheless the pioneer furnace has been built, and we can logically hope that the Newcastle Iron and Steel Company will have a long and prosperous career.

Australia, like India and South Africa, is well provided with both coal and iron ore, in reasonably close proximity. In this case both are close to the coast, so the iron and steel plant at Newcastle, New South Wales, has the additional advantage of being located at a seaport. The plant is notable as representing the re-investment of earnings by the Broken Hill Proprietary company at their silver-lead-zinc mines in the interior. Unfortunately, perverse human nature has brought about a temporary (we hope) cessation of the operation of the plant. The wages of labour in Queensland are so high, and the productiveness of labour is so small, that even under the highly favourable natural conditions that exist at Newcastle and under protection of a high tariff, native iron and steel cannot compete with imported materials.

New Zealand is not so fortunate in her mineral resources for iron making as is her big neighbour. Her main resource of iron ore is the long beach [illegible] of titaniferous iron sand at Taranaki. A number of attempts have been made to smelt this ore commercially but none of them have been successful.

Meantime Britain holds her own in the [illegible] of iron and steel. Her iron ores are neither so high-grade nor so cheaply won as formerly, but scientific research is adding constantly to the material available. Her ironstone [illegible] are now used for the [illegible] in amount as the [illegible] product. British workmen [illegible] down to work in [illegible] the war years [illegible] and [illegible]

EDITORIAL NOTES

The article by Mr. S[illegible]sworth on another page [illegible] the districts to prominence for one of our principal feldspar producing districts. The production from the Verona district, and particularly from the Richardson quarry, has made Canadian feldspar famous. Lately feldspar of particularly fine quality, though not yet so easily [illegible], has been found in a number of other widely separated localities. It is probable that the production of this mineral in Canada will grow to much more important dimensions in the near future.

It is interesting to note, as an evidence of [illegible] of the infant Canadian ceramics industry, that a Canadian firm, the Frontenac Floor and Wall Tile Company, of Kingston, has secured the contract for furnishing the new Mount Royal Hotel, Montreal, with these little hexagons, squares and circles of porcelain. There are growing markets throughout the Dominion for materials of this sort.

In our weekly quotation, we print today one of the many wise sayings of Georgius Agricola. We do not claim him as a Canadian; but we find that, as a miner, he understood many of the truths that are applicable now to Canadian conditions, and are often forgotten.

TO THE BROKER

We gather from press despatches that gold stocks are "moving." Someone is making money. It is not the prospector! He, the prospector, speaks forthwith:

PROSPECTOR, addressing the Broker, [illegible]

Let you who do business in offices fine,
'Tis I who am left in the cold to repine.
The money you get is the money I sweat for,
And labour, [illegible]
For you make the profit though I do the job.
Believe me, [illegible]
And often I wonder [illegible]
I doubt it [illegible]
But someday [illegible]
And [illegible]

YNCIN

* Editor's Note.—[illegible] that only the [illegible] the word "hope." We accept the [illegible] in the spirit in which it is given. [illegible]

The Feldspar Situation*

By R. F. SEGSWORTH

Some weeks ago Mr. Ladoo's paper on conditions in the feldspar industry came to hand, and impressed one both by the soundness of the theories set out and by the fact that the findings given as to conditions in the industry corresponded closely with the results of our own more recent investigations. Recently Mr. Wainford's reply (1) thereto has been received and left the above impressions unaltered.

At the outset, we may leave to Mr. Ladoo for reply the criticism of the general scope of his enquiry, the form of his report, the question of whether or not his suggestions have been only destructive and not constructive and the possibility of submitting further evidence in support of his assertions. Suffice it to say in passing that the improvements suggested do not appear to be in use by Mr. Wainford's company, and that thirty-five or more years experience is no answer to the criticism of antiquated methods. In fact, the tone of reply rather suggests that a little retrospection has shown the criticisms to be rather applicable. Mines and mills are like human beings: they either improve or degenerate, and a policy of "laissez faire" in methods is useless.

The discussion naturally falls under two heads:

A. Mills and consumers.

B. Mines and producers.

A. With the first of these, we in Canada are but little concerned, owing to the almost entire absence of any grinding mills. At present there is in operation only one small mill. In view of the immense quantities and high grade of feldspar still to be mined in Ontario, the question of establishing mills in Ontario should be of interest to American grinders and consumers. The following figures show the production of crude feldspar in Canada, and in reading these it should be remembered that the Richardson mine at Verona, Ont., one of the largest producers of high grade feldspar on the American continent, has been shut down for the past four years, but is being re-opened within the next three months.

FELDSPAR SOLD (tons)

1911	1912	1913	1914	1915	1916	1917
17724	13733	15935	18060	15455	19488	19462
		1918	1919	1920		
		18782	15944	32000		

Up to the present, Canada has exported practically all its crude feldspar to the United States and imported from there nearly all its annual consumption of ground feldspar. At least 95 per cent. of the production of Canadian feldspar has come from the County of Frontenac in Ontario and the County of Ottawa in Quebec and 90 per cent. of the total Canadian production has come from the Verona district in the County of Frontenac near Kingston, Ontario. Recently deposits in the Buckingham district in the County of Ottawa have been opened which indicate the presence of a considerable quantity of feldspar of good quality. In 1900 the Verona district produced 4,000 tons; in 1920 it produced 32,000 tons. With improved transportation facilities, and the consequent re-opening of the largest quarry in the district, the next year should see this production practically doubled—a field well worthy of the consideration of the American grinders and consumers.

B. Mines and Producers. The conclusion to which Mr. Ladoo comes in this connection is that the great need of the industry at present is a continuous production of high grade feldspar of a uniform quality. To this Mr. Wainford's only answer is a challenge: "If any gentleman knows of a good deposit of feldspar near a railroad, we hope he will not be secretive, but show a broad spirit and put us in touch with this desirable spot." This challenge we accept.

(1). **Quantity.** We have referred already to the quantity of feldspar available in the Verona district. Perhaps it should be added that competent engineers have estimated that the Richardson Quarry contains at least 300,000 tons of high-grade feldspar; the same authorities believe that much greater tonnage is possible; but this tonnage they consider certain. Anticipating the improvements now being made in transportation facilities, some 4,000 tons of feldspar of a uniform grade are now ready for shipment.

(2). **Transportation.** There are a number of properties in this district, only a few of which have been developed. None of them have been on a railroad and this has held back greatly their development, as the bush road has been passable only during a few months of the year. However, this drawback is now being removed completely as a means of transportation will be completed as soon as the frost is out of the ground whereby shipments can be made at all seasons of the year. With the completion this Spring of these works, it is expected that all quarries in the district will be operating at full capacity.

(3). **Quality.** The analysis given in the Bulletins on Feldspar and records at Washington, London, Ottawa and Toronto earmark the Feldspars in the Verona district Ontario as being better than any produced in any country and in spite of the disadvantage in regard to lack of transportation facilities in the past they have always been able to get and keep a fair share of the high grade demand in the United States of America. This in itself is evidence that Canadian feldspar is in demand and well liked by those who use it. Bulletin No. 420 by Edson S. Bastin, issued by the United States Geological Survey is the most authoritative and comprehensive treatise on the feldspar situation in the Unite States. On page 9 of this report the analyses of two samples of ground commercial feldspar are given. Number 5 is from quarry in Maine, and Number 6 is from the Richardson mine at Verona. Speaking of these samples, Bastin says: "Samples Number 5 and 6 may be taken to represent as far as the percentage of quartz is concerned the two extremes among potash "spar" in commercial use. Number 6 is the best grade of Canadian Spar which is almost free from quartz and brings as high a price as any spar on the market."

---

(1) **Editor's note.**—At the meeting where Mr. Segsworth presented the above paper, Mr. R. H. Wainford, president of the Trenton Flint and Spar Company, gave a caustic rebuttal of Mr. Ladoo's conclusion that the feldspar industry is at present run on wasteful and archaic lines, capable of radical improvement by the introduction of modern methods and machinery.

* Discussion of R. B. Ladoo's report on "Conditions in the Feldspar Industry" recently reviewed in these columns, at a recent meeting of the Ceramics Society.

Under Grade and Prices, pages 21, Bastin says: "Most dealers recognize three grades of commercial spar: No. 1, No. 2 (Sometimes called Standard) and No. 3. No. 1 is carefully selected, free from iron bearing minerals, largely free from muscovite and contains little or no quartz, usualy less than 5 per cent. Analysis 6 of the table on page 9 (see above) shows the character of material of this grade, the feldspar analyzed having been imported from Canada." On the same page Bastin gives a list of prices for crude and ground feldspar; crude Canadian feldspar is quoted at 50c. a ton higher and the ground Canadian feldspar at $1.00 per ton higher than any other grade. In all publications on feldspar the Canadian feldspar is spoken of as the highest grade and analyses taken from Canadian quarries are given as examples of typical high grade, hard, potash feldspar. This together with the difference in price in favor of the Canadian feldspar indicates its high quality and its ability to compete with the best American feldspars. The discussion of a paper on feldspar read a year ago at a meeting of the American Ceramic Society at Columbus, Ohio, brought out the opinion that the Canadian feldspar was considered to be the kind of feldspar which the majority of the potters desired. Dr. W. G. Miller, Provincial Geologist for Ontario is too well-known an authority to need introduction and is noted for his conservatism. In a recent report to England he says: "The spar from the deposit to which I refer (the Richardson Quarry) is one of the purest and the deposit probably the greatest that has ever been worked in any country." In a pamphlet issued by the Imperial Mineral Resources Bureau of London, it is said: "In the Verona district the feldspar quarried is mainly high grade [illegible]." Practically all the pyrometric cones used in the United States are made by Professor Orton of the Ohio State University at Columbus, Ohio. [illegible] and against which all others are [illegible]. They are made of a mixture of feldspar, flint and other materials. Since 1909 [illegible] Canadian feldspar from the [illegible] feldspar to make these cones.

Geological Survey Parties in 1922

The Ontario Department of Mines during the field season of 1922, will carry on geological survey work from the western boundary to the eastern boundary of the Province; in all, nine geological parties will be in the field. At the head of these several parties will be the geologists on the Department's permanent staff, and also experienced geologists mostly from Canadian universities and elsewhere. The assistants are practically all university students of geology in their third or fourth year. In several instances, the Department is co-operating with that of Lands and Forests, under whose instructions surveyors are being sent to lay down base and meridian lines, traverse leading waterways, etc.

Beginning at the extreme west of the Province, the boundary line between Ontario and Manitoba is being extended northward from the point to which it was carried last year. This work is being done by a party under J. W. Pierce, O.L.S., the boundary commissioners being E. Deville for the Dominion, and L. V. Rorke for Ontario. The geological party sent out by the Mines Department will be under the charge of H. C. Hickeby, whose assistant is J. C. Macgillivray.

About 75 miles east of the Manitoba boundary, another geological survey party will explore along the English River, which is the boundary between the Districts of Patricia and Kenora. Dr. E. L. Bruce, of Queen's University, will be at the head of this party. Dr. Bruce is well fitted to do this work, having examined the iron ore resources of Lake St. Joseph in 1921 and prior to that having geologically mapped extensive areas in Northern Manitoba, including the Flin Flon copper deposit. His assistants will be G. B. Langford, J. G. McCrea and W. R. Dunbar.

The geology west of Lake Nipigon will be explored along base and meridian lines being run by surveyors sent out by the Lands and Forests Department. The Ontario Department of Mines will have a geologist attached to each of these two parties. It will be the duty of these geologists to examine the rock formations and minerals along the newly surveyed lines, and to report as to the possibility of finding workable ores. Very little is known about the rocks and minerals in the area west of Lake Nipigon. One of the land survey parties will be working west of the lake and the geology will be investigated by W. [illegible], of [illegible] University; the other land survey party will be working south-west of the lake, and the geology will be reported on by W. L. [illegible], also of [illegible] University.

R. G. McConnell, late Deputy Minister of Mines, Ottawa, will continue work in the Sault Ste. Marie area, which he began last year. He will also visit the Goudreau gold camp in order to keep the Department informed as to mining developments. This area is attracting considerable attention [illegible].

A. G. Burrows will spend the season in the Porcupine gold area, where he will examine the underground workings of all the mines. His report will be of great interest, as it will make public a knowledge of the ore bodies and structures. A [illegible] edition of his Report on Porcupine, and accompanying maps, are now out of print; this new work will [illegible] of the fourth edition of the report on Porcupine. As Porcupine is now one of the world's greatest gold camps, Mr. Burrows' report will be [illegible]. H. [illegible] will assist in the work.

Another party will be sent [illegible] to area south [illegible] the Porcupine camp. [illegible] namely Halcro, Reynolds, McKeown, [illegible], [illegible] and Dack, will be carefully explored. The geologist in charge will be R. W. [illegible], of Toronto University; assistants, C. [illegible], G. D. [illegible], P. W. [illegible].

P. E. Hopkins will [illegible] Sesekinika township in the Kirkland Lake gold area and also [illegible] the [illegible] of that area, namely [illegible] and Larder Lake. He will be assisted by W. [illegible], E. B. [illegible] and A. W. [illegible].

C. W. Knight, Assistant Provincial Geologist, will spend some time in the South Lorrain silver area, [illegible] miles south-east of Cobalt, [illegible] township, and he will keep in touch with [illegible] work in Cobalt. It is hoped to have Mr. Knight's report on Cobalt published about the end [illegible] of [illegible] 1922. It will be a complete [illegible] structural geology of the producing [illegible].

Prospectors of the Cariboo--II

BY ROBERT DUNN

(Continued from page 269.)

In discussing present day placer mining men in British Columbia the story of George Adams comes to mind. When I think of George my conception of Fenimore Cooper's famous character "The Pathfinder" always returns. He is [illegible] long and rangy, the type that can cut and make a hot pace on the winter or summer trails of the sub-arctic. He is a real "Pathfinder". I am not so sure about his marksmanship, but know that he has brought down a few moose and so far has been a good enough shot to avoid going seriously hungry when on the trail. A sourdough of sourdoughs, and while a dreamer, yet a [illegible] dreamer. George has left Atlin and started an hydraulicking enterprise on Thibert Creek, near Dease Lake. He took possession of a plant consisting of several monitors, a line of flume more or less dilapidated, sluice boxes, and some house covering. This had been left when the war broke out. The workings were then in charge of the late Warburton Pike, a distinguished big-game hunter, and the rest for the most part were young Englishmen. The last named were "rearin' to go" when news of war reached the North, and in justice it should be said that the one German in the crowd threw down his tools and went out with the party impelled by similar patriotic motives. When Adams took hold late in the season of 1919 he had to repair the flume in order to get water, make other repairs to the plant, clean up after his predecessors—for they had not even waited to make their final clean-up—and open up a new pit. He chose virgin ground for this, locating on what he judged to be the old channel of the stream. How sound his decision was may be estimated when it is said that from a few square feet of ground he took in only a few weeks $14,000 in coarse placer gold and nuggets.

The summers of 1920 and 1921 have been used by Adams in getting his proposition in shape for continuous operation. The re-building of the flume to assure a large and steady water service was one prob-

lem and the most important. There also was the transportation of additions to his equipment and its installation. All was set last season when the bank caved in and had to be cleared. So the past two years have been spent by this prospector and operator in hard work on the ground. He was "out" this winter but just for a few weeks. Already he has returned to Atlin. In December he and his wife came several hundred miles by dog team over the snow to Atlin. Thence he continued to the Coast and, his business completed, is back waiting the first opportunity to start work. All is now in readiness for sluicing and, if the ground is as rich as all indications seem to assure, his leases will be the nucleus of a highly-productive new placer field.

It is a real pleasure to know men of the George Adams class. They are peculiar to mining camps. Their simple directness is refreshing and their confident optimism is inspiring. When I first met George he was "out" after about 10 years straight "inside", and was shying at automobiles like an unbroken colt in heavy traffic. His last sally this year was that it looked like he'd make his "pile" and, as the Parliament Buildings looked good, might consider buying them for his town residence.

With our friend the prospector making elaborate preparations for a survey of the hinterland of the Omineca; with hydraulicking and dredging more than usually active in the Cariboo, Atlin, Dease Lake, and elsewhere in the Province; and in view of recent news that the Peace River Gold Dredging Co. Ltd. has entered upon dredging operations in a large way on thirty miles of ground between Fort St. John and the intersection of Half Way River on the Peace, it would appear that the production of the placers of British Columbia is due for a substantial increase.

If we consider future possibilities in the light of past experience there is justification for optimism. It was stated at the last annual meeting of the British Columbia Division of the Canadian Mining Institute that Williams Creek, Cariboo, produced between $8,000,000 and $9,0000,000 in gold. I looked up the Annual Report of the Minister of Mines for 1896 in this connection and find that these figures are misleading. They indicate only a part of the truth. Up to and including the season of 1895 a two and one half mile stretch of the placer ground of this creek, in other words that portion lying between the lower end of the Ballarat Claim to McCallum's Gulch yielded $19,320,000 in gold. It would be interesting to know whether there is another placer gold waterway in the world with such a record. Certainly these old statistics will be an eye-opener to many who have forgotten what was done by the miners of the Cariboo.

A sketch of Williams Creek accompanies this article. The well-known old claims are plotted and named. The gold production of some of the richest of these properties as recorded in 1896 is given as follows: Marysville, $300,000; Phelan and Hart, $250,000 each; Adams, $300,000; Cameron, $800,000; Ruby, $500,000; Forest Rose, $480,000; Watty, $300,000; Tinker, $300,000; Moffat, $250,000; Caledonia, $750,000; Aurora, $850,-$350,000; Ericson, $500,000; Barker, $600,000; Canadian, $350,000; Diller, $350,000; Black Jack and Bruns Tunnel, $675,000; Taff Vale, $300,000; Cunningham $250,000; Steele, $600,000; Phoenix, Bradley-Nicholson and British Queen, $680,000; Conklin's Gulch, $765,000; Mc Callum's Gulch, $200,000. Others range all the way from $25,000.

Turning to the report for the year 1897 a pertinent paragraph is found with reference to the production of the Cariboo District in general and Williams Creek in particular. To quote: "Since the year 1858 to the present it is estimated that over $35,000,000 in gold has been taken from the Cariboo gravel deposits, of which two and a half miles of Williams Creek yielded up over $20,000,000. The production of Williams Creek, Light-

"Aurora" Claim, Williams Creek, Cariboo, from which 483 ounces of Gold were taken in Twelve Hours.

ning, Lowhee, Antler, Grouse, Keithley, Hardscrabble, Cunningham Mosnito, Nelson and other creeks of those early days has become historic. Other creeks and untouched gravels may yet be found in this region, although the prospector has been searching for many years, but only twenty miles from Barkerville, it is claimed, lies ground that has been but scantily worked; however, the great interest that has now been aroused by the great Yukon discoveries will lead many to explore a great extent of territory in this northern country as yet untouched, to test many of the creeks by sinking to bed rock where only the bars have been tried."

And so to the early history of the Golden Cariboo closed. The eyes and the footsteps of prospectors turned to the Yukon. The halcyon days of the wonderful gold mining placer camps of that Territory also have passed away. Attention there now is held by the silver treasures of the Mayo. Its lure is powerful, but it lacks the magic of gold. Still the spirit that was manifested by "Caribooans", (that was Service's inspiration when he penned those verses in the "Land of the Midnight Sun") persists among the prospector and the frontiersman. Men are looking for the next great discovery and one wonders—has the great untrodden North still any hidden secrets such as were disclosed by the placers of Williams Creek and the Eldorado?

"The Prospectors' Shanty", verses written by James Anderson, tell the story of the life of the Cariboo miner so tunefully that perhaps it is worth quoting:

See yonder shanty on the hill,
'Tis but an humble diggin',
Some ten by six within the wa's—
Your head may touch the riggin'—
The door stands open to the south,
The fire outside the door;
The logs are clinket close wi' fog—
And nocht but mud the floor—
A knife an' fork, a pewter plate
An' cup of the same metal,
A teaspoon an' a sugar bowl,
A fryin' pan an' kettle;

The bakin' pan hangs on the wa'
Its purpose are twa-fold—
For mixin' bread wi' yeast or dough,
Or pannin' oot the braw gold!
A log or twa in place o' stools,
A bed without a hangin',
Are feckly a' the furnishin's
This little house belongin';
The laird an' tennant o' this sty,
I canna name it finer,
Lives free and easy as a lord,
Tho' but an "honest miner."

GOWGANDA AND OTHER SILVER AREAS

In Part III of the Annual Report of the Ontario Department of Mines (Vol. 30, 1921), Mr. A. G. Burrows describes the present appearance of what was hailed twelve years ago as a second Cobalt. The high hopes of those days have failed of fulfilment. Still, a district that had shipped, to the end of 1920, a total of close on six million ounces of silver, and whose annual production has not begun to decline seriously, is worth the added attention now given it by the Department.

Mr. Burrows has followed the fortunes of the Gowganda silver area from the beginning, as the representative of Ontario's geological staff. His present report is the result of thorough examination, and his conclusions represent mature deliberation. The following are some of the outstanding points, from the economic standpoint.

The silver bearing veins so far located are all associated, as at Cobalt, with an intrusive sill or laccolith of diabase of Keweenawan age. At Cobalt the productive veins are found at or near the lower part of the sill, either in the intruded rocks or in the diabase itself. At Gowganda, on the contrary, the production veins are almost altogether in the upper part of the sill, or close by in the greenstone and conglomerate cut by the diabase. For instance the Milles Lake O'Brien veins are in diabase, while the adjoining Milleret veins are in the conglomerate overlying the diabase. The veins of the Castle property extend from greenstone above the sill into the sill itself. These are in the present productive area, in the vicinity of Miller Lake. The first discoveries in the district, on the west side of Gowganda Lake, were veins wholly in the diabase, those of the Boyd Gordon and Mann claims being in the upper part of the sill, and those of the Bartlett claims (the exception to the rule), in the lower part.

The silver-bearing veins are composed mainly of calcite and quartz, often associated with little aplite dykes. Beautiful specimens of arborescent silver imbedded in black calcite are characteristic of the district, two of these being illustrated in the report. The paying ore shoots are ordinarily small, and on most of the properties have not been sufficient to repay consistent mining. The operating properties round Miller Lake have, though, yielded a handsome profit.

This new report by Mr. Burrows, bringing up to date the information about an old district, is timely in view of the renewed interest in the field being shown at present by prospectors and investors. It is such thorough pieces of geological work that have won for the geologists of the Ontario Department of Mines the reputation they enjoy.

NEW MAP READY

The Ontario Department of Mines has just published Map 30d., *Boston Shoal Gold Area*, district of Temiskaming, (scale $\frac{1}{4}$ mile = 1 inch), which is to accompany the report (now in the press) on that area by Messrs. A. G. Burrows and P. E. Hopkins. The report will be Part 6 of Volume 30 (1921).

One of the Journal's contributors, Mr. Roland H. Briggs, of London, England, has recently been elected an Associate Member of the Institution of Mining Engineers, as well as a member of the Society of Engineers. He has also been awarded lately the Bronze Medal of the London Chamber of Commerce for an essay on "Mining in North Wales".

Hardinge Company, 120 Broadway, New York, have issued a new condensed bulletin covering the Hardinge Conical Mill.

This bulletin covers in a concise manner the principle of operation of the mill, its adaptability to industrial and metallurgical grinding problems, and gives general dimensions covering the different types of mills, as well as tables showing sizes, powers, and capacities for different conditions of grinding.

News of Mining

According to the United States Bureau of Labor Statistics, the wholesale prices of metals and metal products are relatively lower than those of any other group of commodities. Taking prices that obtained during the year 1913 as a basis of 100, the wholesale prices of metals and metal products stand now at 111. Building materials, in which group the greatest rise is observable, stand at 202, whilst the group next lowest to metals is that of farm products, reported at 128.

The 33 1-3 per cent. import duty placed on chemicals entering Great Britain has had the effect of increasing prices by more than 15 per cent.

Only 18,200 short tons of crude potash salts was produced during 1921 in the United States. This represents a content of 7,618 tons of potash. About 80 per cent. of the production came from natural brines, but only a few plants, connected with cement plants and blast furnaces, reported continuous operation. The year's production was lower than that of any year since 1915.

Statements submitted at the annual meeting of the North Butte Mining Company, held at Duluth on April 17, show that their Adirondack vein, in the course of drifting done during the past year, varies in width from 1.8 feet on the 2,400-foot level, 4.2 feet on 3,400-foot level. On 3,600-foot level over 186 feet of drifting the vein averaged 3.1 feet in width and carried 7.7 pounds copper and 3.8 ounces of silver per ton.

The total exports of refined copper from the United States during the eight months ending February 28, 1922, amounted to 426,079,768 lbs., as compared with 302,147,047 lbs. during the corresponding period ending February 28, 1921. Germany took about 37.5 per cent. of the exported metal, Japan about 16.5 per cent., France over 15 per cent., while Belgium, Italy and Great Britain bought very much smaller quantities.

In a speech delivered at the Hotel Astor, New York, on April 21st, Mr. Thomas H. Watkins, president of the Pennsylvania Coal and Coke Corporation, declared that back of the coal strike lie "sinister influences at work to secure complete domination of coal production by a union not responsible for acts that might seriously affect the public welfare." The speaker further asserted that collective bargaining had "gradually faded away" and that for it "was substituted collective threatening." In Mr. Watkins' opinion the Sherman Laws and Clayton Acts prevent operators from co-operating to improve the general conditions of the coal industry, and militated against finding a cure for intermittency of employment in bituminous coal mining.

The 1921 output of iron ore in Russia amounted to 1.59 per cent. of the output in the year 1913, the manganese ore output to 1.04 per cent., and the copper output to 0.4 per cent. All labour is under Soviet control. Copper smelting has ceased entirely.

In reviewing last year's operations at the Rio Tinto, Spain, Sir Charles W. Fielding, K. B. E., stated at the company's recent annual meeting, that sales of copper bearing pyrites and of washed ore had fallen off because of the strike and because, also, of competitors having entered the market during the strike. It has been found, however, that Rio Tinto ore can hold its own in most of the markets. After touching on the past unsatisfactory condition of the copper market, Sir Charles made the following pronouncement: "Of all the large mines, our Company is able to produce its copper at the lowest cost per ton, and, therefore, while the market price of the metal, when below the normal, reduces your dividends, your Directors are able to ... carry on their operations without being too much influenced by the world's copper prices." The Rio Tinto Company now pays out £27,000 annually in pensions to old employees, and, in addition, has to meet heavy taxation and pay increased import and export taxes.

After acquiring oil claims in the Many Island district, 25 miles north-east of Medicine Hat, Alberta, The Harmony Estate (Transvaal) Development Company, Limited, obtained the consent of its shareholders to delete the word "Transvaal" from its name. The Chairman, Mr. R. W. Mitchell, announced that the company is negotiating for the acquisition of gold properties in Canada.

Tasmania produced 1,750,655 ounces of osmiridium during 1921. The stated value was £42,935.

A comprehensive plan for the development of Peruvian copper mines has been adopted by the Northern Peru Mining and Smelting Company, a subsidiary of American Smelting and Refining Company. Options on the Quiruvilca mines and on the Almiranta properties have been obtained. It is intended, also, to open several known anthracite veins and to build a hydro-electric plant, 2,000 h.p., near Quiruvilca.

The Geological Survey of China estimates the coal reserve of that country at 23½ billion tons. This estimate, it is stated, excludes small seams and comprises only tonnage to a limited depth. The iron ore reserves are estimated at one billion tons. China could readily supply the world's demand for antimony, as her deposits are singularly rich. In tin production China ranks next to the Malay States and Bolivia, and produces 10 per cent. of the world's output of tungsten. Although China consumes enormous quantities of silver, her production is less than 50,000 ounces annually.

The Transvaal Chamber of Mines has expressed willingness to meet representatives of the Labour Unions, with the proviso that it will not deal with certain persons who were identified with the Joint Executive that controlled the recent strike. It is also stipulated the foremen must hereafter be recognized as officials and must in no circumstances become members of workers' Unions. The re-employment of ex-strikers is the question most urgently requiring settlement.

News and Comments

by Alexander Gray

"High Finance."

Having a doubt as to whether the promoters of London are altoghter culpable for committing a misance by dumping the Davidson — or Porcupine-Davidson — upon london and presenting it as a Canadian mining proposition, rather than befoul the pages of THE CANADIAN MINING JOURNAL with a more offensive characterization of the thing it is preferable to describe it as "high." That it is somewhat unsanitary, is admitted on both sides of the Atlantic. If it is an exhibition of the 1922 Spring Styles in London, the Canada's most incorrigible will have to yield the palm and the cross to those who take or have taken the proffered shares.

For months a copy of the propectus has lain upon this desk. It embodies the reports of three pesons who led London to believe the properties had everything possible to commend them. Details of production and ore reserves as estimated need not be reproduced. The reasoning was far-fetched. The ore was represented to be as good as the Hollinger. That the average of the ore-reserves and what was alleged to be the grade milled, did not jibe with the average recovery as reported to the Ontario Mines Department, was explained by the absence of cyaniding facilities. A loss of around 50 per cent of the gross gold content was assumed by the reportees.

So the bells were hung upon London, by Londoners, and now they are unhappy. They ought not to be with their own offspring, nor can they disclaim the parentage. So captivated were they with the prospects, and positive information supplied by their own technical advisers, with whom they are perfectly satisfied, they took all there was in it, diluted the capital, reserved for the Directors a goodly stipend plus travelling expenses, and an overplus of "five per cent of the annual distributed profits of the company." Nor do those tit-bits end it. A salaried "one or more" (the more the merrier) Managing Director or Manager may be chosen from the Board, and the mandatory provision is that he or they shall be recompensed "as the Directors may determine."

Very considerately, the Preferred Shareholders have a participation in the profits (an impressive percentage) until the nominal worth of their shares is repaid to them. Before action is had in this respect the Directors have the ear-marked five per cent if there is divisible profit or if a distribution is ordered. Ordinary shareholders are on the long distance with a bad connection. Canadians in Ordinary got money for their holdings; then the string was pulled and it landed in the new London corporation. Thereupon the vendors were awarded the agreed proportion of the London Preferred and Ordinary issues. In brief this is how we decode the arrangement.

An apology is due to the chief sponsor resident in Pinner's Hall, for having intimated that he overlooked a Founder Interest in the corporation. His self-abnegation is the flaw in the picture.

Withal, it cannot longer be contended that London is not fully up-to-date. Between prescribed percentages, fixed salaries, fees and "exes", this is development de luxe.

Over-Dressing "Hattie"

There is evidence that the "Hattie", located in Coulson Township, is being rather meretriciously "dolled", which, it goes without much saying, is rather bad form for mortals, mines, or prospects. In directing attention to this, it is the special province of *The Canadian Mining Journal*, kindly to intimate that a "lady" mine should be circumspectly arrayed — neat but not gaudy, as it were. This does not imply that "Hattie" is not all she should be. Quite to the contrary; for Percy E. Hopkins of the Ontario Geological Bureau in his historical summary of gold mining in Ontario, distinctly states that "the Hattie encountered some rich showings during shaft sinking in 1921". So "Hattie" has some ornate furbelows, which even a rock-knocker could not but admire, it being his privilege to take note of them, and to do it minutely.

Possibly it is ungentlemanly to go further, and better to take the word of Mr Hopkins for it. And yet the "General Manager of Hattie Gold Mines" — who was Mining Recorder at Matheson "for many years" — lowered his guard — left an opening — when he indited an over-strained epistle to the public, containing this among other statements:

"There is ample precedent, not only in Canada but elsewhere for believing that the final results will justify present indications, namely, that a large deposit of extremely rich ore will eventually be mined from these workings. The $1,000,000 mined from the Croesus, only a few miles away, in the course of six months, is one illustration close at hand."

That is a trifle "de trop." Ignoring the comparison between "Hattie's" gorgeousness and Hollinger dowdiness (the "$17 average value" as against the Hollinger "about half of that"), the General Manager became rather involved when he threw the responsibility for success upon "final results" which are not always in accord with capitalization nor with the ephemeral production of a rich but short-lived neighbor. No doubt Croesus was a prize beauty. It was a delirious half year, however, and instead of the million credited to it by the ode to "Hattie" it is a matter of official history that the Croesus "up to the time operations ceased in February 1918 had produced 12,170 ounces or $259,753 in gold." What ore was extracted from that property is acknowledged to have been the richest ever mined in Ontario, but the exaggeration on behalf of "Hattie" suggests the need of censorship. A statement of the sort in a prospectus [illegible] It may be that [illegible] are likely to live to very great depths [illegible] the Croesus and it is admissible that [illegible] the General Manager might [illegible] upon the attitude [illegible] wealth [illegible].

A [illegible] regard for the integrity of Ontario mining [illegible] The General Manager [illegible] We [illegible] the [illegible] when the [illegible]

is apt to "furnish, at least, one car of high grade ore a week from development operations alone", and "this ought to return from $5,000, to $15,000 a car, on the basis of the values exposed":

"Hattie" is too ravishing — or has been made to appear so. But this conclusion does not mean that "Hattie" is not the "prospect" Mr. Hopkins says she is.

How to Make Business

So pre occupied are some of us with the economic ills we should forget, so wedded are many to their misfortunes, that but slight heed has been given to the significance of the appeal of the Anaconda Copper Company and Zinc Producers in general to their shareholders to popularize metal shingles. It is a mere detail, perhaps, to have John D. Ryan and his colleagues point out that copper and zinc are cheap and metal shingles economically effective. The same enterprising organization, by acquiring control of the American Brass Company, also undertakes to broaden the markets for copper and zinc as brass. Bulk consumption is sought. American companies need the business and are going after it, while Canadian metal industries are hesitant.

Undoubtedly the Nickel Industry will emerge from its depression by evolving new uses for the metals, but heartier co-operation by the public would hasten the revival of production. At Trail, more finished products are planned for. Without joepardizing export trade more asbestos might be fabricated. As to the Steel Industry; the tendency is to belittle the magnitude and importance of the greatest of Canadian mining enterprises. Germany has contracted for hundreds of thousands of tons of Wabana ore, while the integrity of the corporations producing this are questioned in banking and business circles. Independent steel companies in the States are combining for an offensive, and the arrangement is applauded. The British Empire corporation in Canada was created for the same purpose, and it is "given the hook" by those who ought to understand how vital it is that the coal and iron deposits of the Maritime Provinces be standardized and adequately financed for the greatest operations. Where there is need of accord, there is discord. It must be obvious that the American programme for the resumption of activity is more creditable than the Canadian idea of carping and indecision.

Wall Street View of Three Gold Mines

"Here", writes Mr. Hartleigh in the April 29th issue of *The Magazine of Wall Street*, we have several very interesting mines, particularly Hollinger, McIntyre and Dome. The first is an investment in the true sense of the word, with adequate reserves of payable ore blocked out, with extensive promising territory awaiting further development, and with first-class management equal to any operating problem that the company is likely to meet, if their record is significant in this respect. Hollinger Income Account and Balance Sheet indicate stability and increasing strength."

More in compliment could not be urged. It is frankly acknowledged that the return upon Hollinger shares at the market price, is not adequate. But the treasury, ore reserves and prospects, and certainty of greater milling capacity insuring larger dividends, make the Hollinger a speculative investment "in the true sense." That is the very reason why the chief owner of Hollinger deprecate market overvaluation of their shares. The present return must suffice, until a larger dividend can be assured continuously.

The point is made by Mr. Harleigh that the McIntyre is a most interesting mine with very bright prospects. He directs attention to the market position of McIntyre shares which, at the time he wrote, were on a 4 per cent. basis. Conceding that McIntyre milling capacity will be increased, that larger dividends should be forthcoming, anticipation of this (and it will take a year or two to establish) leads Mr. Hartleigh to maintain that McIntyre shares are too high. This is not recorded captiously. The same reasoning is applied to the Dome, in which case it is emphasized that there have been no estimates of ore reserves of late. Doubtless, Mr. Hartleigh reckons, the Dome structure does not lend itself to long-range forecasts, and yet the management is commended, as well as that of the McIntyre.

The factor of longevity is taken into account by *The Magazine of Wall Street*, notwithstanding it was a month or two ago only the same writer registered his belief that Canadian gold production is decreasing. Hollinger is hypothetically conceded a life as real mines, deserving of profound respect. Of the of "10 or 20 years". McIntyre and Dome are accepted trio, however, only one bears comparison with the Homestake, which distributed $31,000,000 in dividends since 1879. In ten years the Hollinger has paid its shareholders approximately $17,500,000. Homestake shares at $74 after all these years are on a 4 per cent. basis. The difference is that Homestake low grade ore is 60 per cent., free milling and the 43-year producing record makes it a criminal offence for anyone to quibble about its future. The past is beyond anything of that sort.

To have American journals devoted to the investment aspects of industries and mines concede the superiority of these Ontario properties, should inspire confidence that there will be others. There are others, and there will be more, if some of those in the stock exchange limelight do not "run past themselves", as was said of other men and things.

"Arrangements Made"

Daily newspaper announcements that P. Chester Thompson, President of Thompson Oil, Sanctuary Oil Company and Royal Canadian Syndicate, has made arrangements for the development of the Lake Pakowki section concession, may lead to something beyond a script-selling campaign. A Curb "dope" sheet published at New York, "The Eye", has it that the Pakowki "dome" is the superlatively greatest of its kind since the spheres were domed with the aurelian. Royal shares passed across the counter have been going at over $400 per unit. That Mr. Thompson is enterprising, is unquestioned. Last year he sought one or two hundred thousand acres of Canadian Pacific lands for exploration. He and his New York confrères control though the several incorporations enough acreage to be proved or disproved in a series of drilling seasons. As the Ottawa Government became a partner in the Pakowki matter, no doubt Mr. Slipper, who sponsors the Pakowki country will see to it that no rights are lost, to the Government or to the Thompson organization. It would be consolatory to have Southern Alberta more satisfactorily supplement the Fort Norman production, now reported to be "seven barrels a week!" "Charge, Chester, Charge!" Somehow we must find oil in the West.

Notes From Nova Scotia

Conciliation Board Begins Investigations

The members of the Conciliation Board appointed to inquire into the miners' wage dispute in Nova Scotia, met at the Court house in Sydney and after a short session adjourned to make an inspection of the collieries. The Board comprises D'Arcy Scott, Ottawa, (chairman), J. E. Moore, St. John, N.B., representing the Dominion Coal Company, and Isaac D. MacDougall, Inverness, representing the mine workers.

It is understood that the Board has instructions from the Minister of Labour to make a thorough investigation into all conditions at the collieries. Just why such instructions should be issued to this particular Board is hard to understand, seeing that two years ago a Royal Commission appointed by the Government made a most searching investigation into all conditions of mining and their report is in the hands of the Labour Department at Ottawa.

The instructions of the Minister however, may only be to make inquiry into the conditions affecting the wage dispute. If so, the matter will be simplified and can be carried through in a much shorter time. The Chairman has announced his intention of making full inquiry into wages, cost of producing coal, coal market prices and other conditions, and basing his award on things as he finds them. It is hoped that the award will bring peace to the coal miners of the Province. Four months have already been wasted in trying to reach an agreement that should have been made last November.

One of the chief arguments used by the mine workers of Nova Scotia in their wage dispute is "that mining towns have a much higher percentage of infant mortality than most other towns, because of malnutrition due to low wages and inability to procure proper nourishment for children." After being advertised and placed in a most unenviable light as the worst city in Canada for high death rate of children, it has been discovered that Government statistics are incorrect, that instead of 245 births registered, there were altogether upwards of 900 births, most of which were not registered. This changes the percentage of deaths from thirty to eight, and at the same time places Glace Bay well ahead of other large towns. So, unfortunately for some of the "Reds" among the miners, another part of their argument has been punctured.

Drawing Pillars from Submarine Seams

The Dominion Coal Company, Cape Breton, have begun drawing pillars for the first time in their largest undersea Colliery, No. 2. As another seam overlying this one is being worked by a separate shaft, it was found necessary to stop mining above until the pillar work below is well advanced.

It is reasoned out that if work is concentrated on pillar sections and these are rapidly extracted that the subsidence will be gradual and the strata will settle without danger of fractures running to the surface, which would not only be dangerous under heavy bodies of water, but would effect the workings of the upper seam.

The mining of coal undersea requires great care. So far it has been costly, as thick pillars had to be left while entering the submarine field. Heavy barrier pillars between sections must be left in case of an accident, or inrush of water. Now that the Collieries are reaching the stage where pillars can be drawn the necessity for continuous development will not be so great.

There is 1600 feet of cover over the pillars of this Colliery at the point of pillar attack. Between the upper and lower seams being worked there is 450 feet.

Before this step was taken the Company had the advice of a British expert who was brought over last fall to advise on this and other work. It was found that his opinions agreed with those of their own mining engineer, Mr. Herd. The best in mining science has been brought to bear on this problem, and success is undoubtedly assured.

The fact that a mine will be laid idle for a year or more with consequent loss of output shows that the Company at great cost is taking the utmost precautions to protect the lives of their workmen and to preserve their Collieries from all the dangers and loss of coal which would result from bad methods of mining. This is true conservation in mining, and will give the greatest possible percentage of coal under the difficult conditions of the Glace Bay coal fields.

While the pillar work of No. 2 Mine is being advanced according to policy, the workings of the upper mine will be put into first-class repair for large outputs when the mine reopens.

New Safety Lamp Tester.

A mechanical safety lamp tester has been made under the supervision of Alex. McEachern, Chief Inspector of the Dominion Collieries, Glace Bay. For years Mr. McEachern had been of the opinion that the lung test of safety lamps was not a safe test. No man who gives out three or four hundred lamps in an hour can blow these with the necessary force to prove their safe condition. It has long been suspected that deficient lamps have been responsible for mine explosions, yet these same lamps passed the lung test at the lamp stations. Experiments were carried out with four lamps to prove the efficiency of the new mechanical tester. Two of these lamps were first rendered unsafe by placing two plies of paper between the gasket and the glass. Several men applied the lung test but only two men were able to blow the lights out. The new tester instantly extinguished the lights in both lamps. The other two lamps were considered safe; but one was blown out at a pressure of three pounds. The other lamp stood a pressure of seven pounds. The ordinary lung test is one pound.

The safety lamp under the new test is enclosed in a cylinder making air tight joints above and below the glass joints when the air is applied, and all parts are subjected to the same pressure. A gauge is attached and set to the standard of pressure agreed upon. Besides the gauge, a gong set off by a pop valve will be attached.

Hugh McNeil, District Mechanical Superintendent, and Colliery Superintendent Wm. McKay, New Waterford, made the mechanical tester. It will be used at all the Dominion Collieries.

A number of the Government Mine Inspectors and Mine Officials from other districts were present at the final test. All were pleased with the results. All were pleased with the results. The Technical College, Halifax, has been asked to examine it and report their findings to the Government, after which it will be put into general use.

British Columbia Letter

The Cedar Creek Claims.

From the midst of a medley of confusing stories regarding the Cedar Creek gold discovery, Cariboo District, comes the account of Russell R. Walker, a well known British Columbia journalist, who has returned after spending two weeks or more on the ground.

Mr. Walker's statement of the conditions and the outlook may be accepted as authentic. Messrs Lynes and Platt are given as the original discoverers. "Instead of prospecting only along natural waterways," he says, "holes were dug hundreds of feet above the creek in the most unlikely locations. Experienced miners are puzzled over the strike and, looking at the pay dirt, it would never be expected that gold would be found. There is little or no wash where operations are being carried on near the 'glory hole.' Broken rock and shale are mixed with a black clay on bedrock and the placer expert admits himself completely 'stumped'.

"On the Platt claim, where three men have been working for weeks, over $100 a day is being taken out by the crudest methods. No sluices have been installed, but an ordinary rocker or cradle is being used. Most of the pay is being lost to be recovered later when more adequate methods are used. The present work is being done to ascertain the extent of the claim's wealth."

It is asserted that Messrs Lynes and Platt have found a buyer, a deal having been completed for $300,000 for two claims, $20,000 down and the balance payable as the gold is recovered. An engineer's report anticipates that the two claims will yield from $3,000,000 to $4,000,000.

Mr Walker continues: "Last fall the heavy rains hindered the work of prospecting and the miners were flooded out. However, they secured rich pay in different spots. I was shown where $300 was washed out of a yard of dirt. After taking out about $1,000, attention was turned to testing out the claims and the miners sunk to bedrock at different places. It soon was found that an old river bed had been discovered. This is about one hundred feet wide and shows good wash. A hole was put down but was prevented from reaching bedrock. Fond hopes are based on this channel and a pump has been ordered to drain the hole.

"Should pay be struck in this channel, Cedar Creek will come into its own. The old river course has not been definitely traced, but for at least five miles it can be followed. The gravel is not coarse and but few rocks are found. The wash is identical to that of Bullion Pit, one of the richest hydraulic properties ever operated in the Cariboo.

"But Cedar Creek does not appear to be a hydraulic proposition. There is a great deal of heavy timber, thick undergrowth and the prospect of many buried logs. It looks like a one-man game, with the prospect of the claims being cut up into small 'lays' and worked with rockers, grizzolys, and sluices. R. Crowe Sowards and associates are installing a dredge at the mouth of Cedar Creek and their progress is being watched with interest. The difficulty of obtaining water is likely to prove a handicap. At present the spring seepage is not very marked, and on the Platt claim only enough water was running into the ditch to enable the miners to rock four hours a day.

"The syndicate which purchased the Lynes-Platt property has applied for a water right at the head of the creek and may instal a dam. This summer their operations will be confined to rocking and sluicing. A 'sump' will be provided to gather sufficient water to wash, and from twenty to thirty men will be put to work."

On the point of the gold so far recovered, in connection with which they have been many accounts, Mr Russell states that "there is no doubt that hundreds of dollars have been washed out in one day by two men. Pockets have produced as high as $500 per cubic yard and I washed different pans of dirt picked at random, which showed values of from 15 to 20 cents. On the Platt and Lynes claim a good deal of rough gold is found while a few hundred yards off the yellow metal shows signs of having come some distance. There are few large nuggets and practically no flour gold. Two yards of dirt on the Platt claim yielded $300 in three hours. The gold was all fine. Some of it was rough. A short distance away coarser gold was found and the values occurred from within a few feet of the surface. Bedrock is only three feet down in some instances and twenty or more in others."

It will be several months before the new field is proven. Already there are over 350 men in the district and the ground on Cedar Creek has been taken up. The amateur without capital is cautioned to keep away. For the prospector with a summer's grub-stake the opportunity is there, as "there is gold a plenty but, like most of the good things of life, it comes to the "go-getter." The establishment of the boom city, to be known probably as Cedar Creek City, is predicted. But there is no evidence, nor is there likely to be, of the gunman, the booze emporium, or the dance hall. The carrying of guns already has been prohibited. Cedar Creek City will be a businesslike community. It is easy of access. One can leave Vancouver on Tuesday morning and be at his destination Friday afternoon. When the roads improve the run can be made easily from Williams Lake by motor, when Cedar Creek will be only two days travel from Vancouver.

Activity in Revelstoke District.

The Multiplex Mining Milling & Power Co. Ltd. held a meeting recently at Revelstoke, B. C. at which officers were elected as follows: President O. T. Bibb; secretary, J. Stevenson. It was decided that a small crew would be kept at work at the mine, which is situated close to Revelstoke. Development at present consists of drifting on the lead in the second level to tap a new ore-shoot which shows good concentrating ore at the surface.

The Waverley-Tangier group of mineral claims, Revelstoke Mining Division, has been bonded by Spokane and Chicago men, and the old workings are to be opened this year. The Waverley Mines Company has been incorporated with the capitalization of $600,000, and John Forbes who has considerable experience in mining in the West is in charge. There are two main veins; the Tangier, which varies from three to five feet in width, and the Waverley, which is from 18 inches to 4 feet wide. Both are fissure veins, and both have been traced on the surface for more than two thousand feet. From these there branch replacement

veins, similar to those found at the Florence mine near Ainsworth. The Company proposes building a new road a part of the distance from the C. P. R. to the property. The ore will be shipped on trailers drawn by a Holt Caterpillar tractor.

The Pioneer Mine and mill will be active this summer. The property is situated in the Bridge River district. A new cyanide plant is ready for operation.

The Trail Zinc Schedule.

The first zinc schedule ever issued by the Consolidated Mining & Smelting Company of Canada has been published. It marks a new departure in British Columbia mining, and should bring many properties of the Slocan and Ainsworth District from the class of doubtful enterprises to that of sure profit makers. The innovation is hailed by mine operators of the Kootenays as ushering in a new era for those sections as far as mining is concerned.

For straight zinc ores the schedule comes into effect at once, but for the great bulk of zinc ores— those that contain values in gold, silver and lead sufficient to make their recovery desirable—the schedule will take effect only when the Trail corporation has completed and is ready to operate its special custom zinc plant, on which construction is progressing. It is expected that this will be ready some time in June.

It is difficult to over-emphasize the importance of this announcement to the Kootenays. The Consolidated Company has conquered the complex ores of the Sullivan Mine. The Company now is extending the knowledge acquired to the treatment of the zinc ores of the Slocan and other districts for the benefit of independent owners and all potential shippers. As the zinc stopes of the Slocan are very numerous, ore that was formerly not available and that in fact was waste now becomes a distinct asset.

Summarized, the schedule provides a sliding scale of percentages of the zinc paid for, increasing with the zinc tenor of the ore, with payment for zinc at 3.6c. off the London quotation of the week of arrival. In 30 p.c. ore the Smelter will pay for 60 p.c. of the zinc, and this ratio increases until a maximum of 85 p.c. of the zinc is paid for in ore running 50 p.c. zinc or over.

In addition to payment for the zinc, the schedule also provides for payment of 80 p.c. of the gold, for 80 p.c. of the silver, and for 80 p.c., less 5 units, of the wet lead. The recoveries of these three metals will be in the smelting of residues after leaching out the zinc, and a scale of smelting charges is provided, decreasing as the zinc tenor of the ore increases and the percentage of residues lessens.

It is believed that this is the first time that so high a percentage of gold and silver has been paid for in a zinc ore. So far as the lead is concerned, it is the usual practice for the lead in a zinc ore to be penalized.

One comment made is that an outlet now is provided for zinc concentrates from the mills of the district. Where a Slocan mill, for instance, produces both lead concentrates and zinc concentrates it readily markets the lead concentrates, but it has been a different matter with the zinc concentrates. Some of the latter have been shipped to United States smelters but never with much prospect of reasonable profit because of freight charges and of tariff duties. In many of the mines in question a considerable part of the silver values is in the zinc concentrates, which heretofore has made the situation more difficult.

Placer Mining in Cranbrook District

Hydraulic placer-mining is to be continued this summer on Wild Horse and Perry Creeks, Cranbrook District. Leases are held on these waterways respectively, by the Gamble Mining Company, and the Wild Horse Creek Placer Gold Mining Co. A. J. Palmquist who is interested in the operations on Perry Creek, states that this property has been purchased from the original owners for $40,000. Last fall considerable work was done in improving the plant and making preparations for the start of work this year. There are 19,000 feet of fluming and 1600 feet of inverted syphon, giving a water elevation of 150 feet installed. He is looking forward to very successful results this season.

W. H. Armstrong, a prominent western contractor and mining man, died recently in Vancouver. A high tribute was paid to his work by members of the Vancouver Branch of the Canadian Institute of Mining and Metallurgy. It was pointed out that he had much to do with the founding of the fire-clay, refractories, and brick industry of Clayburn; the development of coal mining at Merritt, the development of the Ikeda Mine at Queen Charlotte Island, and exploration for coal and other minerals in the Similkameen District, Queen Charlotte Islands and other portions of the Province. Mr. Armstrong had long been a member of the Institute.

The last report of the Belmont Surf Inlet Mines, Ltd., is satisfactory. It shows that the mine made profits of $45,363.11 for the closing quarter of last year. As conditions are improving it is likely that the payment of dividends will be resumed shortly. During the early part of last year the Company operated at a loss. Recently however, development has progressed so well that important ore reserves have been blocked out, and an adequate supply of millfeed is assured. The Pugsley Mine is said to be producing ore averaging $15 a ton. This adjoins the original holdings of the Company.

Settlement of claims for damages against the Britannia Mining and Smelting Co., arising out of the disastrous slide of October 28th last, when 37 lives were lost at Britannia Beach, is under consideration. Claims for loss of relatives, personal injuries and damage to household effects and property aggregate $135,000. On behalf of the claimants it has been proposed that this sum be cut by 25 p.c. Unless the Company's representatives agree to these terms by May 10th next, action will be taken through the Courts.

There will be eight geological, and three topographical survey parties engaged this summer in British Columbia on the work of the Canadian Geological Survey. J. D. MacKenzie, head of the survey in this Province, returned recently from Ottawa, where he discussed with officials of the Department, plans for this summer's activities. He says that much work will be done in the Cariboo and Lillooet districts. "It is the policy of our office," Mr. MacKenzie stated, "to investigate regions where investigation is most needed. The purpose of a geological survey is to assist mining men in the development of new territory and wherever there is interest in new districts we try to give assistance."

Northern Ontario Letter

The Porcupine District

The second week in May finds the snow entirely gone from the bush throughout the mineral areas of Northern Ontario, with the possible exception of a few spots in the shaded areas of the swamps. Prospectors are showing evidence of greater activity than ever before in the history of the province. Careful observers are pointing to this as one of the most favorable signs in connection with the mining industry. Not only were the renewals of Miners' Licenses very heavy this spring, but mining recorders from one end of Ontario to the other are reporting a general increase in the number of new licenses being issued.

Districts that promise to be favored with a good deal of activity are the outlying section of Porcupine, the eastern part of the Kirkland Lake district, Goudreau gold area, the prospective placer area south of Lake Abitibi, the West Shining Tree district and the Lightning River field.

While the interest centres to a large extent on the prospective gold districts, yet the interest in certain of the silver areas is also on the increase. South Lorrain will come in for much activity, judging from the amount of work already under way and the large number of licenses being taken out by prospectors who are going into that district. Indeed, everywhere where there appears to be hope of finding precious metal in Northern Ontario, the smoke of the camp-fires of prospectors will be seen this summer.

Production in April

According to preliminary estimates the output of gold from the Porcupine and the Kirkland Lake gold areas amounted to close to $1,700,000 during the month of April, thereby attaining the highest point so far in the history of the industry in Ontario.

The Porcupine field was represented with three producers, namely, the Hollinger, Dome and McIntyre-Porcupine. These three mines produced approximately $1,475,000 during the month.

The Kirkland Lake field had five producers, namely, the Wright-Hargreaves, Lake Shore, Teck-Hughes, Kirkland Lake and Kirkland Lake Proprietary. These five mines produced approximately $215,000.

A feature of the April achievement was that it shows a current production of gold at the rate of well over $20,000,000 a year. Another feature of the situation is that activity is increasing in all directions, while at the producing mines there are big plans for increasing output.

The indications appear to be that a record of $2,000,000 a month will be made before another year is out with prospects of further substantial growth with the passing of the next few years.

Amendment to Town Sites Act

An amendment is being made to the Town Site Act, which is calculated to enable the holders of mining claims to lay out towns on the surface rights only, instead of being compelled to surrender mineral rights as well. Heretofore, on any townsite laid out, the Government took each fourth lot, along with the mineral rights. The new amendment will not include the mineral rights as is shown in the following bill:

Section 2 of the Town Sites Act is repealed and the following substituted therefor:—

(1) Subject to the provisions of subsection 2, where any lot or parcel of Crown Land sold, leased, located or staked out under any Act of this Legislature subsequent to the 19th day of March, 1910, is hereafter laid out as a townsite or subdivided into lots or parcels for town, village, park or summer resort purposes, one-quarter in acreage of all the lots or parcels shown on such plan or subdivision shall become the property of and be vested in the Crown.

(2) Where any land so laid out as a townsite, or so subdivided had been sold, leased, located or staked out under The Mining Act of Ontario, the ores and minerals under the surface of the land thus vested in the Crown, shall remain the property of and be vested in the person by whom the said townsite is laid out or land so subdivided and by all persons claiming under him.

This act will come into force on the first day of July, next. It will bring to an end an unreasonable situation.

Eight Miles of Shafts

Although the gold mining industry in Northern Ontario is comparatively young, it is nevertheless a point of interest to learn that the aggregate amount of shaft-sinking already amounts to close to eight miles, while the total length of drifts and cross-cuts will exceed 100 miles.

Approximate estimates of shaft-sinking at the gold mines follow:—

District	Feet.
Porcupine	16,000
Kirkland Lake	10,000
Boston Creek and Larder Lake	3,000
Bourke's and Munro	2,000
Matachewan and Shining Tree	1,300
North-Western Ontario	7,200
North Shore and Michipicoten	1,000
Total	40,500

In addition to the above figures, are numerous small test pits and works that would increase the total to at least eight miles.

Hollinger

During the four weeks period ended April 22nd, the Hollinger Consolidated treated 107,841 tons of ore, thereby maintaining its uniform record of recent months, the average being 2,887 tons every twenty-four hours. Allowing for a recovery of $9 a ton, the output for the period would amount to about $970,569, or at the rate of $12,617,397 a year. Everything considered it seems that the income of the Hollinger will exceed an average of a million dollars a month for the whole of the current year.

A vein is reported to have been cut during the course of doing some cross-cutting on the Porcupine Crown property at a point close to the boundry of the Hollinger. Whether or not the vein is of any special importance has not been announced.

In the checking up of the underground sampling of the Porcupine V. N. T. the mine is being found to be in even better physical condition than had generally been supposed. The outlook for the enterprise is good and the next few days will witness the work well on its way in connection with opening up the downward continuation of the present known ore-bodies.

McIntyre

The deep mining operations on the McIntyre-Porcupine are adding in a big way to the resources of the mine. Ore reserves will show a large increase at the end of the current fiscal year, according to reliable information. The company will close its biggest production record on June 3, in spite of which there will be an increase in ore reserves. It will only be a matter of a very short time when the new milling unit will be in operation, treating carbonaceous ores which were heretofore passed by. Some of this ore runs as high as $100 per ton in gold.

Another Consolidation

A movement is under way to bring about a consolidation of the Martin claim with the Preston-East Dome, according to information reaching here. These properties lie to the south and south-east of the Dome Mines and have the continuation of a tongue of porphyry formation which runs north and south from the Dome on to the Preston-East Dome.

From a geological point of view, the possibilities of these properties are attractive.

KIRKLAND LAKE FIELD

Sylvanite

The shaft on the Sylvanite mine has reached a depth of about 500 feet. Within the next week, the 520-ft. level will be reached and the work of cutting a working station will be commenced.

Developments at the 390-ft. level were favorable, the main ore body having been cut, in hich the values were such as to classify it as ore across a good stoping width.

The new electrically-driven hoist is in operation and everything is in shape to make good progress in the lateral work that is to be undertaken at the 520-ft. level. It is the plan of the management to carry on extensive development at this horizon.

Wright-Hargreaves

During the month of April the mill on the Wright-Hargreaves mine treated an average of 191 tons of ore daily, or a total of 5,730 tons for the 30-day period. Mill heads continued at normal thereby resulting in a recovery of around $70,000 for the month. This achievement compares with about 180 tons daily in March.

Underground development continues to be favourable, and the amount of ore broken as a reserve in the mine was at least equal to the amount sent to the mill. This favorable state of affairs is steadily adding to the favorable physical position of the enterprise.

Sinking operations are proceeding at a good rate and the 700-ft. level will be reached during the third week in May. This work has become increasingly important owing to the fact that what appears to be an entirely new orebody is lying right against the south wall of the shaft.

Teck-Hughes

During the month of April the Teck Hughes mill treated an average of 162 tons of ore daily during the period when the plant was in operation. The loss of time during the period amounted to five days, due to unavoidable causes, leaving 26 days of operation.

This is the highest average record so far in the history of the Teck-Hughes and indicates that the enlargements recently made are in full operation and giving high efficiency. No statement has been secured with regard to the average grade of the ore for the period, but this may be estimated at approximately $10 per ton, thereby indicating an output at the rate of between $40,000 and $50,000 monthly.

One of the more favorable features in connection with the development program has been the cutting of a new vein at the 730-ft. level, as formerly announced in these columns. A limited amount of drifting has been done and the mineralized body has a width of from six to eight feet. From two to four feet of this is high-grade ore, carrying visible gold and gold tellurides.

Another important feature is that instead of concentrating energy on the work of carrying the winze to the 1,000-ft. level, it has been decided to divide attention between this work and the work of opening up the 605-ft. and the 730-ft. levels. In order to do this, a hoist will be operated at the 500-ft. level. This will be employed in connection with further opening up the 605-ft. level as well as developing the 730-ft. level. Before the end of another week, the cross-cut at the 700-ft. level should reach the downward continuation of the main vein which at the 605-ft. level showed such rich ore. Another hoist is being installed at the 730-ft. level and this will be employed on the work of gradually sinking to the 1000-ft. level. This latter work will not be hurried, and it may be after the end of the current year before levels are established at 855 and 980 feet in depth.

The work now under way at the 730-ft. level is not only opening up a new ore-body, but it will within a few days open up the continuation of the main vein. Should this prove to be as rich as was the case at the 605-ft. level, it will be an exceedingly important development.

Tough-Oakes

The mill on the Tough-Oakes mine is handling about 70 tons of ore daily. During the time occupied in opening up a working level at the 500-ft. level, as well as completing the cross-cut to No. 11 vein, it is not expected that the ore will be of a uniform grade. Good progress is being made, however, and these points should be reached by about the end of May. It is also expected the first clean-up will be made in the mill during the last week in May.

Contracts for mining work on the Montreal-Ontario have been let and this operation is expected to go ahead on an important scale.

BRITISH COLUMBIA

The Mineral Province of Western Canada

Has produced Minerals valued as follows: Placer Gold, $76,177,403; Lode Gold, $105,557,977; Silver, $55,259,185; Lead, $18,330,575; Copper, $166,393,188; Zinc, $21,818,531; Coal and Coke, $225,409,505; Building Stone, Brick Cement, etc., $34,072,016; Miscellaneous Minerals, $1,210,639; Making its mineral production to the end of 1920 show an

Aggregate Value of $734,259,619

The substantial progress of the Mining Industry of this Province is strikingly exhibited in the following figures, which show the value of production for successive five-year periods: For all years to 1895, inclusive $94,547,241; for five years, 1896 1900, $57,605,967; for five years, 1901-1905, $96,509,968; for five years, 1906-1910, $125,534,474; for five years, 1911 1915, $112,072,603; for the year 1916, $42,290,462; for the year 1917, $37,010,392; for the year 1918, $41,782,474; for the year 1919, $33,296,313; 1920, $35,543,084; 1921, $28,066,-641.

Production During last ten years, $336,562,897

Lode-mining has only been in progress for about twenty-five years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those of any other Province in the Dominion, or any Colony in the British Empire.

Mineral locations are granted to discovers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with Mining Reports and Maps, may be obtained gratis by addressing.

VICTORIA, British Columbia.
THE HON. THE MINISTER OF MINES,

PROVINCE OF QUEBEC

MINES BRANCH

Department of Colonization, Mines and Fisheries

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, etc.

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

MINERS' CERTIFICATES. First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is $10.00, and it is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

WORKING CONDITIONS. During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

SIX MONTHS AFTER STAKING. At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

MINING LICENSE. The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year, and a fee of $10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days labour on each forty acres.

MINING CONCESSION. Notwithstanding the above, a mining concession may be acquired at any time at the rate of $5 an acre for SUPERIOR METALS, and $3 an acre for INFERIOR MINERALS.

The attention of prospectors is specially called to the territory in the North-Western part of the Province of Quebec, north of the height of land, where important mineralized beltsare known to exist.

PROVINCIAL LABORATORY. Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, MONTREAL, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The Bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

HONOURABLE J. E. PERRAULT,
MINISTER OF COLONIZATION, MINES AND FISHERIES, QUEBEC

EDITORIAL

Since by those unchanging laws of geological structure and geographical position which the Creator himself has established, this region must always....remain distinct from Canada on the one hand, and from New England on the other, the name Acadia must live; and I venture to predict that it will yet figure honourably in the history of the world.... Sir William Dawson, 1878.

QUALITY FIRST

"Mass production" is a term coined on this continent, and used to describe a method of manufacture developed in the United States and adopted in Canada. Its adoption has been tried in Europe, but there it has failed of success. Why? Because in Europe *quality* counts for more than it does here.

On this continent we have not yet progressed completely beyond what in the older lands would be called primitive conditions. After all, a considerable part of Canada's population is still composed of pioneers in all walks of life—farmers, manufacturers, lumbermen, prospectors, educationists, and so on. This has certain distinctive influences upon our entire community, one of these influences being our failure to give due regard to the effect of *quality*.

In some cases, "quality" is synonymous with "safety first," as in the construction of motor cars or of railroad rolling-stock. Where a defective steering mechanism or a cracked wheel means death, we do take precautions. Sometimes "quality" spells "success," as in the export of Western wheat or of Nova Scotian apples. The exporters of bacon are now trying hard to induce farmers to breed the proper quality of hog, so that Canada may keep this lucrative trade.

There is a continuous and world-wide movement towards the betterment of the quality of man's handiwork. It is true that, since the time of the wholesale introduction of machinery to aid work done by hand, the products of manufacture have in many cases not equalled the products of the former craftsmen. Still, in other instances mechanical aids have meant products of improved quality. In general, the tendency toward improved quality is continuously in evidence, and never more so than today, when the forces of organized research are brought to bear in its favour.

The mineral industry of Canada has, to an ever increasing degree, a reputation throughout the world for the quality of its products. The products of Trail's electrolytic refineries have, by their quality, won a market in the East in the face of world-wide competition. The talc of Madoc has an exclusive market. The feldspar of Ontario and Quebec has set an unequalled standard of excellence. Nickel and Monel metal are synonyms for fine quality. Cheaply produced cobalt makes possible the use of stellite, "the wonder metal." All foreign miners of asbestos try to equal "Canadian crude." Our manufacture of calcium carbide, synthetic acetic acid, and aluminum are not surpassed, and are on the way to pre-eminence.

But much remains to be done in order to take full advantage of the mineral resources with which our country is endowed, even those that are already discovered. There is being exported from Canada today feldspar whose quality is not excelled on the continent; yet three years ago Canadian feldspar exporters were in disrepute on account of the poor quality of 'spar they were shipping. Loose business organization and worse mining practice had been allowed, and Canada's feldspar trade inevitably suffered. Canada's reputation for good feldspar was traded upon for a temporary gain. Producers of feldspar might now band together to protect Canada's good name—an asset of distinctly tangible value in such a case.

There are now being developed the first deposits of china clay in Canada that give promise of being of first rate importance. Already the superficial parts have yielded an impure clay that has given remarkably fine results for certain uses. A consistent and thorough course of development may here result in providing the prime essential of a profitable pottery industry, based upon good clay and the best of feldspar.

The progress made in Canada's ferrous metallurgy during the war time, principally through the use of the electric furnace, seems to have been lost. This retrogression may be more apparent than real. We may with reason hope that the present rising tide of prosperity will witness the production on a large scale of electric furnace steel, which is now rapidly out stripping its competitors among high grade steels and for which our cheap hydro electric power makes Canada specially adapted.

The openings for the miner and the metallurgist along the line of quality are numerous. Some of the opportunities are obvious to the trained man, whose progress is at present impeded by lack of funds or for some similar reason. Other opportunities lie before men that are not trained sufficiently to see them, and so must await the coming of a man with knowledge and vision. Still other opportunities will come only in the course of time, and they are in endless succession. In any case, we will make no mistake in adopting "quality" as the watchword in our mining and metallurgical endeavours.

THE GOLDFIELDS GOLD DISTRICT

Today we print an abstract of Dr. Ellis Lon's report on the Goldfields gold district, the result of his examination of the area last summer. The Director of the Geological Survey has made available to the public through these pages a report

that would otherwise be delayed until the publication of the annual Summary Report. The Journal wishes to make hearty acknowledgment to Dr Collins for this public service.

There has been a good deal of mining development since Dr. Thomson made his field examination last summer, particularly on the Murphy claims, where the descending shaft has disclosed remarkable gold values in the vein. A private correspondent writes, "I never saw such rich gold ore "as I am taking out on the Murphy claims. I hope the "property will be given a fair chance." Another correspondent, after spending two weeks in the district, lately, writes, "The Goudreau Gold Mines, Ltd., that is the Mur"phy Mine, have completed the power line from Steep Hill "Falls, and have about eighty men working. They are "sinking two shafts. The No. 1 shaft is down eighty-odd "feet and is showing remarkable values. Every few feet "they run into very high grade ore, very spectacular. The "shaft is going down near a diabase dyke, which I suppose "accounts for the remarkable enrichment in places. Noth"ing else is going on in the district as yet, although some "wild cat companies are already selling, or trying to sell, "stock round Windsor."

The latter correspondent also says that about a thousand "snow shoe" claims have been staked during the winter, and that these are now at least five hundred prospectors and would-be prospectors in the new field. Certainly the Goudreau district is in for a "rush."

Judging from the information at present available, it is reasonable to conclude that the only prospect in the new Goudreau district that now gives promise of making a paying mine is the Murphy. Its similarity to the old Emily Mine to the north-east suggests that there are also possibilities in the latter. Meantime there is nothing in the district at a more advanced stage than a prospect, and a prospect is not yet a mine.

It is only reasonable to suppose that the intensive exploration consequent upon the present "rush" will result in the locating of further gold-bearing veins that will be worth the expenditure of the money necessary to explore and develop them. If the spectacular pockets of ore of the Murphy vein should be accompanied by sufficient ore of lesser, though workable, value to warrant consistent mining and milling operations, and if the Murphy vein should not prove unique in the area, Ontario will have taken another step forward as a gold producer.

A COMING METALLURGICAL CENTRE

The recent outbreak of discussion in the House of Commons at Ottawa on the proposed St. Lawrence Ship Canal was evidently premature, as it received no serious attention. It is a question of first-rate importance to our Dominion, and will no doubt, receive the attention its importance warrants when the time is ripe. Meantime it will be pertinent to point out a feature of the project that has so far received little public consideration—its relation to our mining and metallurgical industries.

It seems probable that both parts of the proposed development will have a marked effect on our mineral industry. To open our inland ports to sea-borne transportation is to make the centre of the continent more nearly an integral part of the great Atlantic market. This will help the mineral industry in some instances, by providing a more profitable outlet for its products, and will hinder it in other cases where cheaper transportation will mean keener competition by materials from without. The power of the St. Lawrence will be an aid in the cheap and effective manufacture of our raw mineral products, and, along with our other great water-powers, is bound to be one of the main factors in determining the character of Canada's industrial development during the next few decades.

Consider the question of iron ore. With the exception of the plants in Nova Scotia, Canada's iron industry is part of the fringe of the mid-continental iron-manufacturing field, dependent for its existence upon the ore of Minnesota and the coal of Pennsylvania, and for its unique prosperity dependent upon the barriers of rapids and falls in the Niagara and St. Lawrence rivers. When these barriers are removed, and the cheaper iron and steel of the Atlantic market are available, there is bound to be some re-adjustment. What it will be is for iron-masters to predict.

The farmers of the West have been the most ardent advocates of the new canal. They want cheaper transportation for their wheat to world markets. Maybe the grain carriers will bring back as ballast Welsh coal to Ontario's ports, in competition with coal from the United States, as is now being done in Nova Scotia and farther down the Atlantic coast.

There are already developed a number of small mineral industries that could branch out into a more extensive export business were cheaper transportation to distant markets available. Talc and feldspar are instances. But it is in the manufacture at home of our raw materials, and the shipment of the more valuable products that the most interesting possibilities lie.

The comparatively cheap electric power available at Niagara has been largely responsible for the growth of the hive of industry within its radius. Not only its direct use in electro-metallurgical manufacture, but its aid to manufacture as motive power, have been of incalculable benefit. But for metallurgical use, Niagara's importance is waning. There is now such a demand from domestic consumers and the users of electricity for motive power that the cost of the residue is almost prohibitive for metallurgical use. True, plenty of off-peak power will be available for a long time; but that will attract only a limited number of consumers with special requirements. Electro-chemists and metallurgists, and others requiring cheap power in large quantities, must look elsewhere.

Canada's share of the power it is proposed to develop on the St. Lawrence will not for a long time to come be required for the use of domestic consumers, as is the case at Niagara. The land adjoining will not support a large agricultural population, and there are plenty of other water-powers to supply outlying communities. Consequently St.

Lawrence power should remain available indefinitely for the purposes of electro-metallurgical and electro chemical manufacture. On this score the St. Lawrence is likely to become one of the world's chief centres of manufacture by means of electric power. It is on the road that the products of half a continent will take on their way to the world's markets. It will be most convenient, as well as profitable, to use cheap hydro-electric power to turn the raw materials into finished products *en route*.

When the time comes for a detailed discussion in Parliament of the St. Lawrence project, it might be well to lay more emphasis than formerly on its effect upon what is now our second industry, and what may, in the years to come, be our most important industry—mining and metallurgy.

EDITORIAL NOTES

Our Nova Scotia correspondent, in reporting the proceedings of the initial sittings of the Scott Conciliation Board, gives the impression of a logic and thoroughness not always characteristic of such proceedings. Up to the present the disputants appear to have been attempting to attain their ends by exaggerating facts, and concealing part of the truth. But the offer of the Company, reported by our correspondent, to open their books privately to the chairman of the Conciliation Board seems now to demonstrate a frankness that is beyond question. The main contention of the miners is that they are not getting their due fraction of the wealth they create. If the Company's books can demonstrate satisfactorily that the stock watering of former days is not now bearing with undue weight upon the miners of today, then the miners cannot logically claim better wages than the Company has offered them.

The hundred days during which air dried peat can be produced in Canada are now at hand. The Joint Peat Committee has ready at Alfred, Ontario, the apparatus it has succeeded in developing during former seasons. It is hoped and expected that this season's demonstration will show conclusively the feasibility of commercially producing peat from our bogs. There is no Waterloo to come at the end of this hundred days; but we hope there will be great rejoicing over the mastering of a problem that has defied solution for so long.

It was stated recently in Parliament that the Yukon Territory is subsidised from the Dominion treasury to the extent of $250 per annum per head of population. This would make it appear that this vast Territory is an unwarranted burden upon the country. But it is hardly so. Most of this expense is for the administration of justice over an area of 150,000 square miles. The expenditure of the comparatively small sum required annually to keep active the public institutions of Dawson and smaller centres is now more than justified by the renewal of mining activity due to the silver finds at Mayo.

In the monograph on "Platinum and Allied Metals" recently published by the Imperial Mineral Resources Bureau, it is suggested that in Canada prospecting for platinum "in situ" might reasonably be expected to result in valuable discoveries. Very little search of such a sort has been made, though there are promising areas readily accessible. Probably the difficulty and expense of the assay for platinum has been a serious deterrent. Our public assay offices might find it expedient to make some concession in favour of a trained searcher for platinum — that is, one whose samples are likely to be worth assaying.

The citizens of the Sydneys, Nova Scotia, have been hard hit by the industrial depression and the consequent closing of the steel works and the reduction of coal mining to small dimensions. Without the coal and steel industries, Sydney harbour would have on its shores only little fishing villages. The citizens are evidently suspicious that the industries upon which they depend for a living are being made the subjects of "high finance" rather than of legitimate industrial operation. At a mass meeting held recently, they asked that the Provincial Government investigate the "overhead" expenses of the constituent companies of the British Empire Steel Corporation, particularly as to their number and their salaries; also the question as to whether the directors are not operating in the interests of "stock-jobbing" rather them in the interests of the shareholders. These ideas are current, not alone in Sydney, and will bear frank explanation and rebuttal by the corporation.

AD AGRICOLAM

Let us go and the farmer and talk to our folk,
And get them to help us to throw off the yoke
Of the cities, the banks, and the people who don't
Produce a damned thing (though they might but
they won't).

And he went and he went in a kind of a way,
And he found it quite different from getting to-day,
For the touch and the taste of prestige once possessed
Overcame him, and made him a person obsessed.

He forgot that some other hard workers exist,
And that not everybody in town may resist
That he (maybe she) is the only producer,
(You are bound to be cranky, if that's what you do
are).

So we ask in our prayers for a natural thing,
And that's the whole reason my Muse makes me sing:
We ask, and we really can't ask for aught fairer,
That the farmer will treat as an equal the miner.

ANON

Goudreau Gold Area*

By E. Thomson

Gold was discovered in this district in 1918 but was at that time secondary in importance to the pyrite, both because of the smallness of the gold bearing veins and because of the demand for pyrite. It was not until the discovery of the Murphy gold property in Township 28, Range 26 in the Spring of 1921 that this region attained any prominence as a possible gold producer. During the summer of 1921 the district to the east and west of Goudreau was visited by A. G. Burrows of the Ontario Bureau of Mines staff who made a short official report on the more prominent gold properties. **

Location and Topography

The gold bearing area is in the vicinity of the town of Goudreau on the Algoma Central Railway, some 177 miles north of Sault Ste. Marie, Ontario, and about 17 miles south of Franz, the junction point of the Algoma Central Railway with the Canadian Pacific Railway. Gold has been found on both sides of the railroad, the older claims being to the east, the newer claims to the west of the right of way. The more important claims may be reached either by canoe route or by wagon road and are included for the most part in Township 28, Range 26; Township 27, Range 27; Township 26, Range 27, Algoma District.

The contours in this comparatively small area are of the same character as in the rest of that district. Undulating country alternates with marshy ground and the district is studded with lakes and streams. Most of the water to the west of Goudreau drains west into the Magpie River, while the streams and lakes to the east of Goudreau drain to the south and east into the Michipicoten River. The country on both sides of the Algoma Central Railway has been burnt over at least once and in several instances two or three times and only second-growth poplar and birch remain for the most part.

General Geology

The rocks in this district consist for the most part of acid and basic volcanics of the Keewatin formation, but these rocks have intercalated with them small bands of iron formation and are intruded by a boss of granite. All three of these formations are cut by diabase dikes of (probably) Keweenawan age which are so prevalent in this region. The latter have for the most part been intruded subsequent to the deposition of the gold ore, the veins being faulted by them in several places. The geological succession is briefly as follows:

Pleistocene deposits.
Diabase dikes of probable Keweenawan age.
Granite.
Iron formation.
Keewatin volcanics (acid and basic).

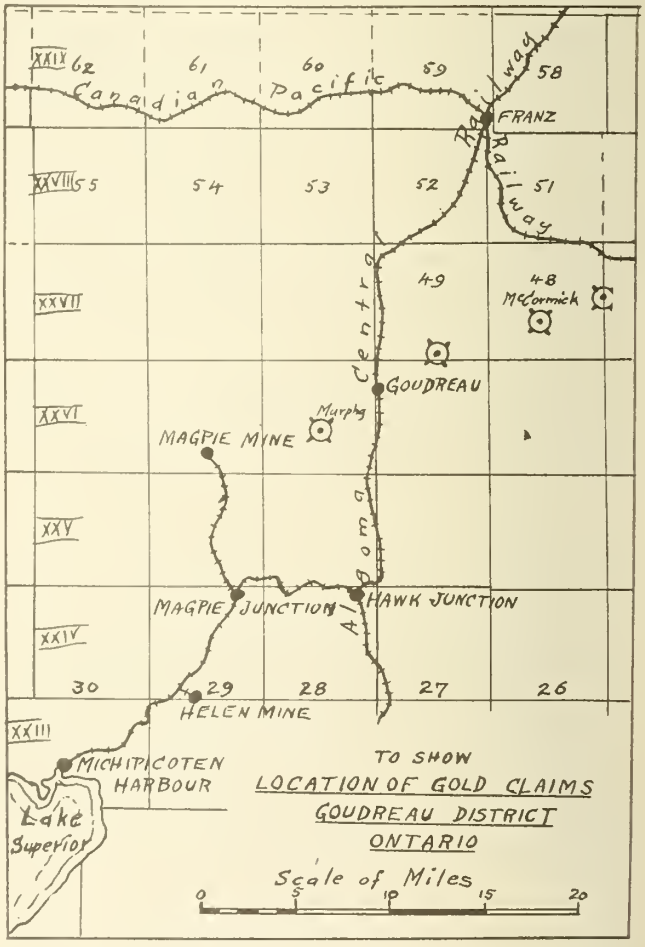
Dr. Collins' report on "The Ore Deposits of Goudreau and Magpie-Hawk Areas in Michipicoten District", (Summary Report, Canadian Geological Survey, 1918, Part E.) deals fully with the rock occurrences of the region. This may be summarized as follows:

Diabase dikes—These are of two varieties, a younger containing olivine, and an older quartz diabase. The gold veins are usually unaffected by the former, but are sometimes faulted by the latter.

Granite—The only granite in the area is a boss in the centre of Township 28, Range 26. Its close proximity to the Murphy gold vein would suggest its connection with the deposition of gold in the vein. The granite is intruded by the diabase dikes, but cuts the Keewatin rocks.

Iron formation—This has been fully described by Dr. Collins. Its main characteristic is the predominance of siderite and pyrite in its composition. The gold values in this formation are found to be due to veins and veinlets of gold bearing quartz that traverse it.

Keewatin Volcanics—These rocks, composing 80 to 90 percent of the rocks of the district, are of two distinct types, acid and basic. To the west of the Algoma Central Railway the basic types predominate, while to the east the acid flows are more common.

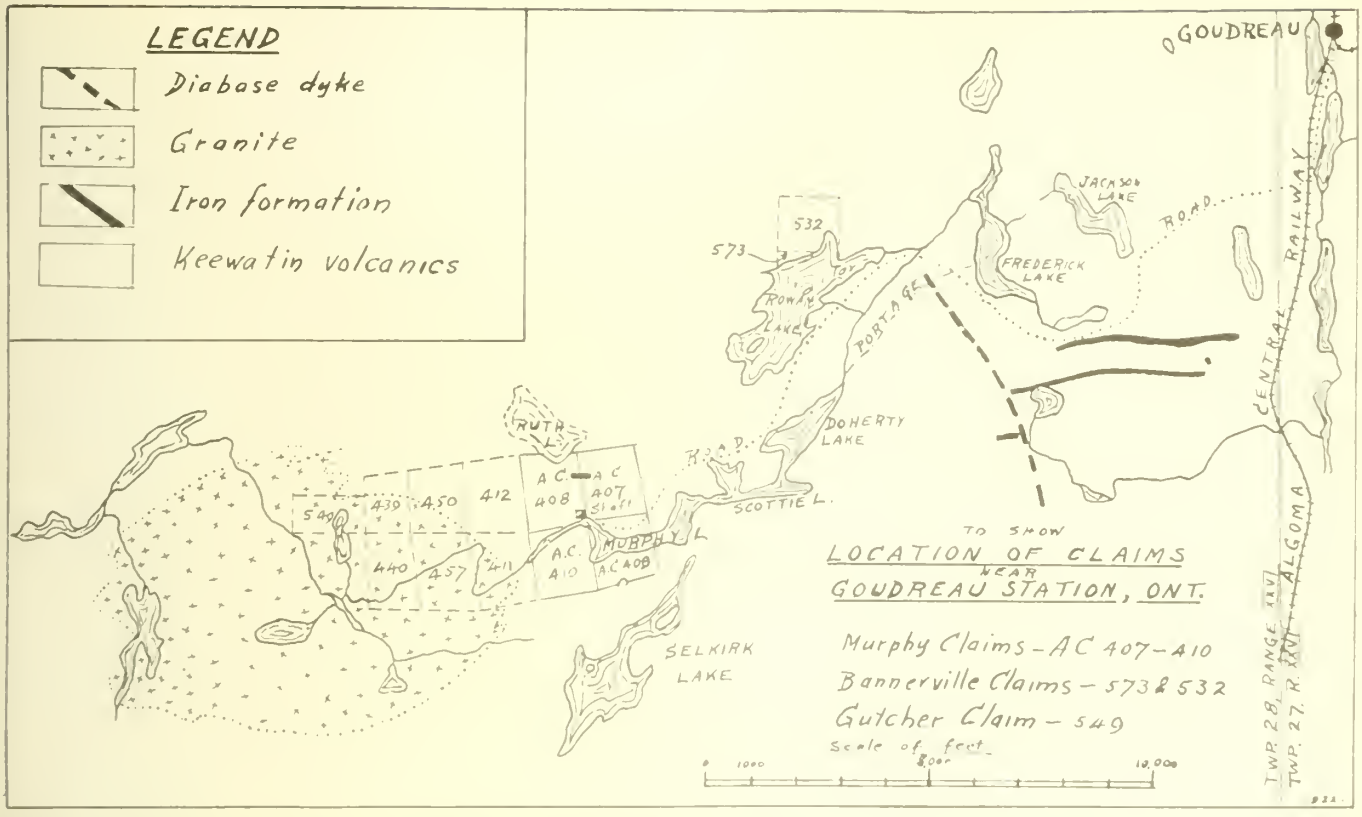


Basic Flows—These are, in the main, younger than the acid flows. They are, for the most part, fine-grained volcanics with the original texture and composition of a basalt but now very highly altered. In the vicinity of veins the rock frequently contains biotite, quartz, muscovite, and occasional needles of tourmaline, as a result of the hydrothermal action to which the veins may be ascribed. In places the usual basaltic character gives way to amygdaloids, vesicular lava and tuff.

Acid flows—These are mainly quartz porphyry and

*Abstract published by permission of the Director, Geological Survey, Ottawa.

** A. G. Burrows, Memorandum on Part of the Goudreau Gold Area, Canadian Mining Journal, Vol. XLII, No. 31, Aug. 5, 1921.



feldspar porphyry, though there is a felsite in which some gold-bearing veins occur.

Economic Geology

There are three distinct types of gold bearing quartz veins in the district. These may be described as follows:

Shear veins—These occur along the planes of schistosity, mostly in the acid volcanic schists, where the greater fissility of the rock seems to induce their presence. They are composed mainly of quartz, with minor amounts of carbonates in places, and characteristically contain tourmaline, which indicates their hydro thermal origin. The shear veins are seldom larger than stringers, and are not often close enough together to make mining profitable.

Cross veins—Veins cutting across the plane of schistosity of the schist have two phases which are described separately. Both are younger than the shear veins. The first variety occur mostly in the acid volcanics and in the iron formation, and contain pyrite and numerous black needles of tourmaline in addition to gold. They vary in width from a few inches to two feet or more. On the McCarthy-Webb property in Township 27, Range 27, they may be seen of a length up to twenty or thirty feet.

On the Gutcher claim (described in detail later) veins of this type cut the granite, and are very irregular in length and width. They are of quartz, and contain pyrite, covellite, chalcopyrite and muscovite, and a little gold.

All veins of this type are too small and irregular to be mined separately, and are not sufficiently close together to provide paying ore.

Fissure veins—Only on the Murphy claims have veins of this type been noticed. The main vein cuts across the strike of both acid and basic volcanic rock. It is cut by a younger diabase dyke and faulted slightly by it, thus marking its age as greater than that of the dyke. The fact that there is a narrow band of carbonate iron formation along the vein for part of its length suggests that the two are of the same age. This vein, too, contains tourmaline.

The fact that the Keewatin rocks of this vicinity are surrounded by a large area of granite, and that a boss of granite protrudes in the centre, suggests that the Keewatin rocks are completely underlain by granite, being merely a comparatively thin covering over it. If this is assumed to be the case, then the flow of solutions through the cracks and fissures of the overlying Keewatin rocks would be a natural consequence of the last stages of cooling of the granite magma. The presence of tourmaline in most of these veins tends to support this theory. That native gold has been found on the Gutcher claim in quartz veins of the pegmatite variety cutting the boss of granite would show that gold bearing solutions were not foreign to the granite body during its period of cooling.

Description of Properties

McCormick—This property, claim S.S.M. 2183, is about in the centre of Township 26, Range 27, east of Pine Lake. A pit nine feet deep has been sunk on a band of iron formation in basic volcanic rock. The iron formation, two and one half to four feet in width and 70 feet long contains pyrrhotite and quartz as well as smaller amounts of chalcopyrite, pyrite, sphalerite and iron carbonate. Gold values in the pit ore sand to vary from $16.60 on the surface to $19.20 at a depth of four feet. No values of consequence have been obtained from other parts of the band of iron formation.

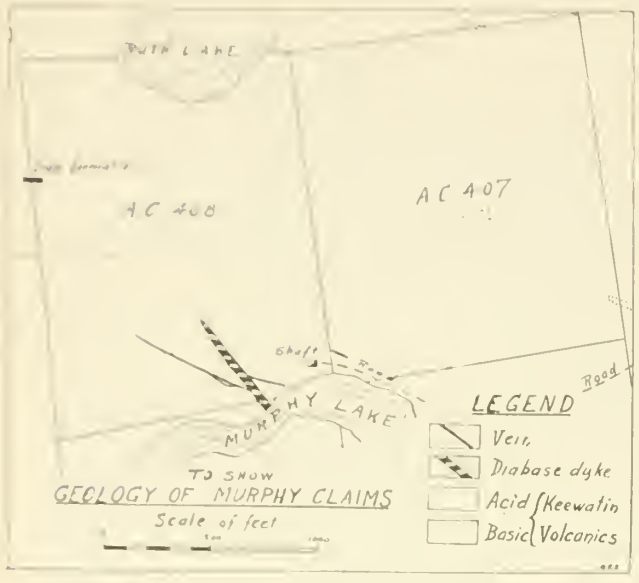
Fuller Block—The gold bearing veins on this property which adjoin the McCormick on the west are a small quartz stringer containing pyrrhotite, pyrite and chalcopyrite in addition to free gold. It occurs at the junction of acid and basic Keewatin volcanic rocks.

Claim—Claim 2181 is north of 2183. Gold values up to $9.00 per ton are said to have been got from a band of sulphide bearing basic volcanic rock at its contact with quartz porphyry.

On claim 2180, adjoining 2183 on the east, [illegible] pits have disclosed shear veins and cross veins containing native gold, all in basic volcanic rocks. All the veins appear to be too small to be a commercial value.

Claim 2189 is one claim east and south of the [illegible]. A

pit 25 feet deep has been sunk on some small quartz stringers said to carry values up to $3,400 per ton. They cut both basic and acid volcanic rocks, and are cut by a diabase dike.



(Acid Keewatin rocks within dotted lines.)

Webb—Claim 2470 is in Township 25, Range 27. Discontinuous "shear-veins" occurring in the planes of schistority of basic Keewatin rocks form a band said to extend for 1,700 feet, though only two to three hundred feet of this length was examined. Gold values have been obtained from this band, which is of irregular width.

Webb-McCarthy—Claims 2049 and 2050 are the south boundary of Township 27, Range 26. In acid volcanic rock there is a zone containing numerous "shear-veins" and "cross-veins", from two to sixteen inches in width. Tourmaline, pyrite and a little free gold are visible in the quartz of these veins.

The veins of claim 2051 have already been described in Dr. Collins' report, and no work of consequence has been done since he examined them. They are essentially similar to the veins of the adjoining claims described above.

Banville-Pagé—Claim 532 is on the north shore of Rowan Lake in Township 28, Range 26. Gold has been found in a contorted band of iron formation cut by numerous cross-stringers of quartz. The iron formation, six to ten feet in width consists principally of quartz and iron carbonate, and occurs in basic Keewatin schist. Chalcopyrite and an occasional flake of gold are to be seen in the stringers of quartz.

Gutcher—Claim 549, is in the western part of Township 28, Range 26. The gold-bearing veins, mentioned above, are in the boss of granite that protrudes on this claim, and are evidently of pegmatitic origin. One vein, one to three feet wide and two hundred feet long, shows free gold in places, as well as considerable accounts of pyrite, covellite and muscovite and a little chalcopyrite, malachite and ankerite. In a larger vein, twelve feet wide, no gold values were observed.

Murphy—Approximately in the centre of Township 28, Range 26, are claims 407, 408, 409 and 410. Most of the development work has been done on claim 408, near the north-east shore of Murphy Lake. The vein has been stripped for its entire length, 800 feet, and is from one to ten feet wide. It is composed of quartz, with numerous small needles of tourmaline, chalcopyrite, some bornite, pyrite and sphalerite, and native gold. The strike is from east and west to 205 deg., and the dip is from 60 deg. to the south to vertical. The country rock on both sides is impregnated with quartz and metallic sulphides for a foot or more.

Native gold has been found in numerous places along this vein, and a good "showing" was seen at the bottom of the pit, twenty feet deep at the time of this visit.

The vein on claim 408 is much the most promising in the district, and is the only one where gold values are at all consistent. As it is a "fissure" vein, it holds promise of values at depth.

This report describes only those claims that showed native gold at the time the examination was made. No mention is made of the numerous claims of less promise.

PRODUCTION OF STONE IN 1921.

Estimate by the United States Geological Survey.

About 62,400,000 short tons of stone was quarried in the United States in 1921, according to the United States Geological Survey, Department of the Interior. This is more than 20 per cent less than the production in 1920. The estimated value of this stone is $92,500,000, a decrease of 30 per cent as compared with 1920. The Geological Survey has difficulty in estimating the production so soon after the close of the year, for many producers do not send in their reports promptly. The quarries, too, are widely scattered and depend largely upon local demand. The figures given were obtained by comparing the reports of certain representative companies for 1920 and 1921. The repors compared for building, monumental, paving curbing, flux, and crushed stone represent more than 35 per cent of the total for each product.

Producers all over the country stated that both wages and prices had been reduced, and nearly all reported a decrease in the cost of production. High freight rates are said to have contributed largely to the general depression in the industry.

Building stone was in but little demand, and the returns at hand indicate a decrease in output of about 25 per cent. The output of monumental stone, which has shown practically no diminution during the last five years, apparently decreased more than 45 per cent. Paving blocks were in great demand, and increases were shown in the sales of curbing and flagging, facts that indicate a revival in street work in cities and towns. The campaign begun for the betterment of suburban and country roads caused an increase of nearly 8 per cent in the output of crushed stone. Depression in the metal-smelting industry was reflected in a decrease of more than 50 per cent in stone sold for fluxing and for use as refractory material. Decreases were noted also in the demand for agricultural limestone, and for stone used by alkali works, sugar refineries, paper mills, and in other manufacturing establishments.

The gold production of the United States in 1921 was 2,375,479 ounces, valued at $49,105,500. The annual production from dredging is substantial. From the beginning of the industry, in 1896, to the end of 1919, the total value is reported to be $153,342,048. The gold recovered by 91 dredges in 1919 was worth $10,346,216, and from 93 dredges in 1918 $10,342,100. It is interesting to find that dredges have been operating in the Phillipine Islands; in 1919 gold to the value of $217,455 was thus obtained.

News of Mining

The monazite sand deposits of Ceylon are now receiving considerable attention. Two years ago British operators shipped somewhat over 75 tons of the sand. It was then valued at about $250 per ton. The Department of Mineralogy, Ceylon has officially expressed willingness to assist in erecting plants for the extraction of thorium if a suitable market can be found.

Because Germans are at present not permitted to enter Australia, the erection of a large quantity of German lignite briquetting machinery in Victoria is being indefinitely held up.

In correcting statements made by John Brophy, president of District No. 2, United Mine Workers, Mr. G. Webb Shillingford, president of the Central Coal Association (Pa.), asserted unequivocally that the earnings of all mine employees in Central Pennsylvania for 1921 averaged $1,319.42 for 138 working days, a rate of $9.56 per day, or about $1.20 per hour for an eight-hour day.

Iron ore to the amount of 73,136 tons was exported to Great Britain from Algeria during January and February of this year. This is only half the quantity shipped during the corresponding period of 1921.

Considerable numbers of the Industrial Workers of the World Organization sailed from New York last week for Southern Russia. They propose to operate iron and steel works in the Urals on a Co-operative plan and to manage the enterprises themselves, meanwhile paying tribute to the Soviet Government.

The average price of sheet mica in Canada and the United States during the year 1921 was 16 cents per pound, just half of the average for the preceding year.

The "socialization" of coal mines in Czecho Slovakia has been adversely reported upon by a committe of the National Government. Out of 16 committee members, 10 voted *contra*.

The total number of blast furnaces erected in Great Britain is 486. During the quarter ending March 31st, 1922, only 97 were in blast.

At the annual meeting of the British Aluminium Company, Limited, held in London, Eng., last year's over-production was discussed at length. Two of the company's aluminium plants and one alumina plant have been closed. During the early months of this year production was much curtailed to facilitate the disposal of old stocks. Lower costs and higher prices are confidently expected in the near future.

The British Metal Corporation, Limited, dealers in non-ferrous metals, has entered into an agency agreement with the British America Nickel Corporation and will handle the latter company's products throughout Europe.

The adoption of stainless steel in colliery work is being strongly advocated in Great Britain. In these steels the chromium content runs from 12 to 14.5 per cent. Experiments and experience have greatly enlarged the applicability of these steels. They are now made both in machinable condition and in malleable form for the production of stainless sheet steel.

The Rand Chamber of Mines has donated $100,000 to the relief fund in aid of sufferers from the recent uprising. The Chamber has also signified its willingness to deal with *bona fide* labour and trades organizations. The mining situation is showing rapid improvement. The net result of the strike, so far as the gold mining industry is concerned, will be a pronounced reduction in working costs.

A joint committee of the Midland Institute of Mining, Civil and Mechanical Engineers and the Yorkshire Branch of the National Association of Colliery Managers has published a lengthy memorandum outlining an educational scheme for employees and officials. For employees from 14 to 16 years of age it is recommended that the statutory requirement of 320 hours per year be spread over 16 weeks averaging 7 hours per week (322 hours) distributed somewhat as follows:—

Physical training and health	1 hour
Literature, etc.	2½ hours
Mathematics and Science	2 hours
Handicraft	1½ hours

This arrangement is designed to combine vocational, technical and humanistic studies in a manner that, it is hoped, will prove effective and will not interfere with the day's work. For the training of candidates for official positions several alternatives are suggested, of which the following are most to be commended:

(a) Two years' courses in which full time is given for a complete yearly session of nine months.

(b) A three year course, in which six months each year are spent in full time study, leaving six months free for suitable employment. The second of these two alternatives has been received with most favour. It is calculated that a charge of 0.18 penny in an output of 10,000,000 tons of coal per annum for the county of Yorkshire would cover the cost of training 240 students yearly.

Calculated As at December 31st, 1921, the gold ore reserves of the Modder Deep Mine, the Rand, S. A. are reported as showing 1,357,000 tons, assay value averaging 9.3 dwts. over the whole. This is a slight increase of tonnage over estimates made 12 months before and a drop in value of one-tenth of a penny weight.

As a result of the acquisition of German South West Africa, the position of the British South African Diamond Syndicate has been greatly strengthened. The Syndicate has recently entered into an agreement with the largest producers, namely, the Prospecting South West Africa, De Beers, and Jagersfontein, governing the method of selling. Each company will put only limited amounts on the market. As Russia and the Belgian Congo are the only two outside competitors, South African producers now possess a practical monopoly of the world's diamond market and over production is no longer to be feared.

According to the latest comparative tests made in Great Britain to determine the comparative fuel value of coal and oil, it was found that in Yorkshire boilers both fuels were equally efficient, but that the cost of oil was 82 per cent. greater than that of coal. It is stated that the cost of oil will have to be reduced to 50 shillings per ton before it can successfully compete with coal as industrial fuel.

The British Government has made advances of money aggregating £41,250,000 under the Coal Mines (Emergency) Acts of 1920 and 1921. Under these Acts all collieries profits were pooled and the Government controlled the payment of standard profits, making up losses in cases when operations did not warrant the payment of a dividend. The sum of £9,900,000 has so far been returned to the Government; a further sum of £6,000,000 is looked upon as recoverable. The net deficiency, therefore, will be £25,350,000. To this must be added £16,000,000 representing the cost of administering the Coal Mines Control Agreement (Confirmation) Act of 1918, and the cost of wages subvention for three months after last year's coal strike was settled. The aggregate deficit is thus £41,350,000. Of this amount the sum of £13,450,000 was applied in wages. Offsetting this huge deficit is the fact that the limitation of profits largely benefited the inland consumer who received coal over a long period at prices less than the cost of production. Moreover, £25,000,000 accrued to the government between 1914 and 1921 in excess profits duty.

Eleven representative coal mining companies in South Wales earned profits aggregating £1,895,716 for the year 1920. In the following year profits amounted to less than one third of this, £605,517. For the two years, average interests were, respectively, 15.2 per cent and 5.5 per cent.

The total production of petroleum coke in Canada and the United States is 700,000 tons per annum. This is equivalent in weight to about one per cent. of the crude oil refined. After calcining, petroleum coke is ground, mixed with a binder and moulded into shapes suitable for many uses. It is utilized as carbon for arc lights and in the manufacture of electrodes.

The Imperial Oil Company last winter erected at Fort McMurray a 38' x 60' warehouse and will soon complete two storage tanks. Fort McMurray is the most northerly railway point in Alberta and is the centre of oil prospecting activities.

Despite the stagnant condition of the lead trade, more white lead was manufactured and sold in the United States during 1921 than in any previous year. The storage-battery industry, which consumes more lead than any other branch of the market except the manufacture of paint, operated about 60 per cent. of capacity. Normally, cigarette manufactures use 25,000 tons of lead in making foil. In 1921 the demand was 30 per cent. lower than normal.

The Franco-Belgian Coke Oven Corporation, of Brussels, is putting on the market a new type of regenerative coke oven, the Piette. The Piette is of the horizontal type, with vertical flues and transverse regenerators. Thirty-day tests made at St Louis, Mo., have given such satisfactory results that interest has been stimulated very widely amongst coke manufacturers.

Kentucky and Illinois fluorspar producers are now asking $17.50 per ton, f.o.b. mines, for guaranteed 85 per cent. spar, carrying 5 per cent. silica. For unguaranteed 80 per cent. spar, with silica as high as 6 per cent., the price is $16 f.o.b. mines.

The American Zinc, Lead and Smelting Company reports an operating loss of $260,100, for the year 1921. A loss of $338,312 is reported by the Utah Consolidated, whilst the Calumet and Hecla Mining Company shows a loss of $1,491,259.77, and the Old Dominion Copper Company a loss of $1,482,055.71.

The coke oven industry in Great Britain is now recovering in marked degree from the effects of the coal strike. Full recovery depends upon several factors, among the most important being the hoped for reduction in the price of materials, especially that of silica brick.

The Irish Peat Inquiry Committee has arranged for the translation, publication, and distribution of Hansding's "Handbook on the Mining and Utilization of Peat." The industrial exploitation of Irish peat bogs is commanding serious attention.

A newly patented Belgian device for indicating the deviation of diamond-drill bore holes from the vertical is being put on the market. It is composed of a rotating basin mounted in an axle driven by clockwork fixed to the walls of a tube fitted into the borehole in such a manner that the basin will fall on all the changes in the direction of the borehole when the tube is inserted. The basin is made of insulating material with an inserted radius of conducting metal or *vice versa*. The surface of the basin has the curvature of a sphere whose centre is situated at the centre of oscillation of a rocking beam suspended in the tube. The rocking beam carries at its lower part a number of brushes. These brushes, coming in contact with the radius, record exactly the course of the bore hole, records being precisely timed by the known times of oscillation.

In the near future the requirements of publicly owned power stations in Germany will be 12,000,000,000 units of electrical energy. The brown coal of the Cologne district is counted on the supply 1,500,000,000 units; the Central German brown coal area 2,000,000,000 units, the water-power stations of South Germany and Bavaria, 5,000,000,000 units, and the waste heat from large industrial plants, 1,000,000,000 units. Peat, lignite, refuse coal, and small water-powers will supply the balance.

The well of the Imperial Oil Company, Limited, near Fort Norman, is producing 10 barrels of oil per week, according to official reports received at Mounted Police Headquarters, Edmonton. Deeper drilling is planned at this well.

Under the Pittman Act, fixing the price of silver produced in the United States at 99⅝ cents, the Bureau of the Mint has purchased a total of 103,380,308 ounces. The purchases for the week ending April 22, were 103,700 ounces.

News and Comments

by Alexander Gray

Mining Corporation Awaiting Events

Of the mining Corporation of Canada it is to be said that it has been vigorous and vigilant in its policies. It set the pace in seeking desirable new properties, whether in Alaska or Labrador, fully realizing the gay life of Cobalt has its limitations. To conserve its cash, it suspended dividends. Although President Watson told his shareholders at London there is no likelihood of the immediate resumption of distributions, it is complimentary to himself and his colleagues that they continue to be "bullish" on Canada. The corporation was fortunate in acquiring the Buffalo property at the bargain counter. Instead of being almost exhausted, the Buffalo last year accounted for nearly twice as many ounces as the mine was thought to possess at the time of the transfer, and the ore reserves remaining are counted on to yield a further 1,500,000 ounces of silver. That will be of material assistance in bringing forward the Flin Flon property, concerning which Mr. Watson was purposely none too optimistic, but which has very substantial features warranting the expenditure of millions upon development, plant and a railroad. An assured 16,000,000 tons, he said, has a gold content approximately valued at $26,000,000; $13,000,000 in silver, and$11,000,000 in copper. That makes it appear as though the combined precious and copper content average $9.37 gross per ton. The gold content of $1.625, and $0.812 silver, ignoring zinc as a factor other than metallurgical, and the copper value of $6.937 (presumably with copper taken at a normal market price) require the best metallurgical practice.

At any rate the recoverable values as stated, confirm general knowledge. Mr Watson expects the recovery will be from 78 to 80 per cent. of the ore values about $120,000,000. "But do not forget", he admonished his audience, "there is a vast difference" between that spot value in "the Wilderness, in Manitoba, and that same amount of money in the bank on which we can draw cheques and pay dividends". What the profits will be, Mr. Watson did not venture to forecast. There are "ifs" in the case. Unless there is railway transportation and hydro-electric power it is a certainty "it will be some years before a profit can be realized out of the property". Avoiding metallurgical mistakes, developing the area and securing what is needful, means that the Mining Corporation has a potential asset that cannot be prematurely productive and toward which the other mines of the corporation will have to contribute large sums. Until the 90 miles of railway is finished and quicker and cheaper development is possible, the Flin Flon must wait. The locality is undergoing extensive exploitation, other companies are being promoted, the Elbow lake discoveries have added interest; but Mr Watson truly prepared the scenario and it is for the Manitoba Government to put on the film. Flin Flon quality and quantity are incentive to find more. The Mandy Mine owners had high grade copper and hurdled with enough of it by water and land routes to win a profit.

Undoubtedly the district has great richness," said Mr. Watson, and "the more discoveries made" the sooner, perhaps, "the Government will build a railway".

Dome Mines In Strong Position

Against an issued capital of $4,290,003, after setting aside $476,667 applicable for the return of capital, in accordance with the policy of the Company, Dome Mines of Porcupine wound up its fiscal year with 56.36 per cent. of its capital liabilities ($2,417,930) in liquid assets represented in Government and Provincial Bonds $125,000, Other Bonds, $1,257,313; Call Loans, $625,000, and Cash, $137,717, to which may be added Inventories valued at $272,900. The reservation for plant depreciation and mine exhaustion, and the practically cash assets as stated, leave little to wish for unless it be an understanding that the mining position is comparably strong. Current earnings are the complement of all reasonable requirements and General Manager Depencier is "safety-first" personified. The latest Dome innovation is the payment of 25 cents as a cash rather than a percentage dividend. Redemption of capital is proceeding.

East Kootenay Mining Power Demand.

Team work is giving "pep" to at least a portion of the British Columbia Mining Industry. Combined railway and banking influences are backing the Consolidated Mining & Smelting Company. Mines, money and perfect metallurgy, more milling capacity planned, call for the prompt provision of power "sufficient to produce" all the reduction works are capable of treating, besides what is needed for the general purposes of the Sullivan Mine, where, to quote General Manager Blaylock, "there is an exceedingly large tonnage of ore developed and a very much greater tonnage awaiting development". Equipment is out of line with Sullivan requirements. To remedy this, arrangements will be made with the East Kootenay power company in which Montreal Capital is invested. Nor will unnecessary time be lost in negotiations. Knowing how to do it, and doing it, in British Columbia may cause Northern Ontario to do likewise, where cash customers are clamorous. For that matter British Columbia needs all the activity it can muster, for its mineral production in 1921 amounted to $28,000,611 as against $35,513,081 in 1920. For a grand aggregate tonnage mined in that provincial year, of 1,562,651 the value was $12,923,398, to which $23,200 for placer gold may be added without exciting enthusiasm.

Another Try For Oil

Having made [illegible] to get [illegible] and to demand [illegible] the combination of Senator Cluny, Col. Cornwall, W. W. Butler, two or three [illegible] Concrete, and others to make the group international, is making another frontal attack on Great Slave Lake—Athabasca Hay River country. Geologist O'Neill started this. Exploration work of the sort is expensive. Mr. O'Neill's positive statements have been made during three years and his promotions have provided the funds to prove his statements. All of which reaffirms that Ottawa was penurious and pettifoggish in its policy regarding petroleum areas before there is oil worth mentioning. Nothing impedes our Company activities to be particular. The [illegible] going to find oil, if it is to be found, in great quantity.

Canada's Copper Deposits

In calling attention to Canada's copper mines and copper potentialities, the Imperial Mineral Resources Bureau reaffirms what repeatedly has been urged by *The Canadian Mining Journal*. It is not so all important that the domestic consumption of copper "has hitherto been about 20,000 tons per annum, or less than half the production of British Columbia alone," as it is to have a progressive policy by which importations of copper and copper products will at least be minimized. American capital has been accounting for, and is still accounting for, practically all of the copper produced in British Columbia. The presence of this capital is welcomed and more of it is desirable. A more complete performance within Canada is, however, a perfectly natural ambition, now the Trail, Port Colborne and Nickelton refineries are capable of any and all demands upon them. Imports of copper in various forms are so many deductions. Brass, too, can be home made.

It is true the Consolidated Mining and Smelting Company have gone slowly about the development of their own copper properties and that the Canada Copper Company suspended operations owing to the metal market and high freights; but the comment of the Imperial Resources Bureau does not coincide with that of those who maintain that Canada's copper rating cannot compare with other countries. Possibly Montana, Arizona, Utah, Nevada, Chile and Peru are distinctive as assured sources of the red metal. Alaska, too, is contributory. Anyox was brought along when it was thought Granby was in the throes. Howe Sound areas are not despicable. Once upon a time Swansea was the refining center. New Jersey superseded it. In the opinion of the Imperial Mineral Resources Bureau, "Canada possesses very important and well-developed copper deposits and a great number of smaller mines and 'prospects' widely scattered over the Dominion from the Yukon to Nova Scotia. Canada is remarkable, among copper producing countries, for its immense deposits of copper-nickel ore in Ontario.... Canadian copper-ore deposits are of the most varied description, some carrying copper glance, others containing gold, some gold and silver, and others various base metals, particularly silver-lead and zinc."

Momentum is what is needed.

Copper Outlook Slowly Improving

Probably because they cannot get quick market action (the rapid turnover that represents brokerage) those of the Curb environment find no virtues in the copper industry. They profess apprehension over the modified resumption of operations. Production of 75,000,000 to 100,000,000 pounds each month from mid-summer on makes them pessimistic, and they point out that the "Copper Combine" (meaning the Copper Export Association) was not very confident or else it would not have dropped the price of the metal to 12 1-4c. 12 1-2c. Besides, one Curb pamphleteer lodges this "oh-be-doleful" complaint against those who have copper production in hand:

> "Heavy sales last month (April), estimated in the press at 150,000,000 pounds, were, as usual, only of the 'paper' variety. Actual movement into consumption was only fractionally of this large magnitude. Transfers of metal from refineries to warehouses of selling agencies should not be interpreted as real sales. This explains how practically all the copper companies which have reported upon 1921 operations have 'disposed' of their unsold supplies".

Why renewed activity at copper properties should give Curb solons conniptions is no mystery: they have other uses for popular funds. They would have the public believe juggling with metal supplies is going on, that the red metal masters are sleight-of-hand performers who are planning discomfort and increasing their own agonies by increasing production! Instead of doing anything of this sort, though, Mr. Stephen Birch, speaking for the Kinnecott and other of the largest copper corporations, asserts that the industry is proceeding in an orderly manner toward better metal markets and consequent prosperity. No runaway markets are anticipated. Instead of the market being 12 1-4—12 1-2 cents, as the Curb authority averred, Mr. Birch, than whom there is no better authority declares "copper is being sold to-day at 13 cents and many of the large producers are entirely sold out. The outlook for the copper industry is favorable and the surplus of copper on hand has been reduced from 390,000 tons a year ago, to 230,000 tons to-day." Undoubtedly the bulk of the surplus is held by the Copper Export Association. Significantly enough, too, Germany is the largest buyer of copper—and is paying cash for it. Everything depends upon resumption of operations and the ability to sell the product. There is no need of the charge of subterfuge emanating form the Curb.

Chance of a Life Time

The retiring disposition responsible for the advertisement of a "Gold Mining Opportunity," without divulging his name, imparts the information that $25,000 cash will secure one-third interest in a "real" good mine upon which $75,000 has already been spent. It is further represented that favorable reports have been made by a galaxy of eminent engineers, among them "Dr. J. Austen Bancroft, Asst. Gen. Manager Consolidated Mining and Smelting Company, of Canada." As Dr. Bancroft never was Assistant General Manager of the Consolidated Mining and Smelting Company, and as his report upon this anonymous property was not a thing to enthuse over, the "come on" advertisement will hardly accomplish its purpose. The property is "free and clear" of everything, (including enough ore to justify the terms used), and there is the added assurance that an operating company will be organized—and a market made, no doubt. In directing attention to this advertising habit of whispering promoters, the intention is to prevent the abuse of the reports of reputable scientists, who regard the property as a *prospect* of some merit. A year or two ago (in this connection) newspapers of two continents displayed specious advertising about Labrador having the Mother Lode of Canada, one offshoot being near the Transcontinental Railway in Quebec. London sat up and took notice. An alert mining engineer visited Quebec and inspected this "real" gold mine; but he was very impolite about it and told his escort there wasn't a ton of ore actually blocked out. He did not say the ground was not worth a try. It was the undeveloped condition and the location that caused him to be blunt as a bludgeon. So why not be frank and above-board instead of using the names of professional men in an unwarranted way?

From the Rainbow's Tip

No one would care much whether the Southern Alberta moisture will insure this year's crop, or the professional rainmaker absents himself, if a small part of the reports from Lethbridge are verified. In the West Butte Sweet Grass Hills, it is wired, gold and platinum-bearing ore has been found. "Three lots of samples sent to Montreal show: Class 1.—Gold, $493; Class 2.—$250; Class 3.—Gold $83. Platinum averaged 1 1-2 per cent." Negotiations have been opened with London. Money is sought for development. Why it is sought—and why a ton or two of platinum and gold ought not to be extracted without further ado, is for London to ascertain. The platinum content is a trifle too low for the credulous, and rather high for the incredulous. A happier mean might have induced Montreal to bite off a bit of the platinum or iridium, or

whatever it is, if for no other reason than to determine whether the gold content as stated is worth while, as a by-product. Montreal seems to have been kept in the dark about the analyses, until the secret leaked out in Lethbridge. And yet there might be more in that Butte than there is in a lot of Sweet Grass oil country. Oil and platinum by the pound are the sum of sublime content. Or has another Grimm been born?

Conroversy Over Canada's Horoscope

Campbell of Cassidy and Corless of Coniston have locked horns over Canada's mineral resources, their extent, diversity and relative magnitude as among the nations. They are at variance in their view of Canada's horoscope in the matter of minerals, Mr.Campbell being the aggressor in the negative end of the argument. Mr. Corless had no idea he was arousing his fellow-member of the Institute of Mining and Metallurgy when he wired to Prime Minister King that "ninety per cent. of Canada contains inconceivable wealth in minerals." Mr. Cambell caustically retorts that Mr. Corless indulged in "extravagance" of statement, was intemperate, when he said that.

Furthermore, Mr. Corless is charged with having made a mis-statement. Proceeding to contest the issue (which is incapable of general solution until a few decades have elapsed and more work is done), Mr. Campbell is combative. The outcome of the discussion will be as momentous as the ultimate decision whether Quiller-Couch is correct in assuming that a total abstainer is incapable of lofty flights in literature, or whether George Bernard Shaw is justified in claiming the privilege of ascertaining "how much he had when he said it"—meaning that Quiller Couch must offer more than idle assertion.

To begin with, Mr. Campbell was rather couchant when he opined that Canadian mineral resources do not or cannot conform to the utmost of our national aspirations. He deprecated false hopes. According to his view Canada knows the best and the worst. Controverting this Mr. Corless voiced the conviction of many that the pre-Cambrian areas of Canada have only begun to assert their economic worth. Mr. Campbell does not see it—prefers to have it blocked out—will not concede it is here. Mr. Corless did not intend to have the "inconceivable wealth" he divined taken too literally. Rather it is believed he has enough confidence in the geological ages represented to presume that history as established elsewhere will be repeated hereabouts.

The futility of extreme optimism or pessimism need not be emphasized. Mr. Corless is the more admirable of the contestants in that he is in favor of an intensive programme. Urging the exploitation of Canadian mineralized areas, and having the courage of his convictions, Mr. Corless did not infer that every quarter-section of "ninety per cent." of Canada "contains inconceivable wealth in minerals." An "average crop" will suffice. Phenomenal yields usually are localized. Rhodes, with that optimism which Mr. Corless displays, was photographed in the act of addressing his Chartered Company shareholders and telling them "Rhodesia is mineralized from end to end." He erred on the side of optimism; but that is the way to create diversions.

"Fling your heart across first; the rest will follow," said von Valkenhayn to the youthful Crown Prince of Germany, in whom he was cultivating intrepidity. Mr. Corless is heartening; Mr. Campbell would be disheartening; to go out, stick a hole anywhere, and in nine cases out of ten tap untold wealth." Not at all. The earth is not so prolific as all that. Nor have the borrowings and sorrowings for and about "frantic railway expansion" the slightest application. Mr. Campbell, like Lot's wife, is perverse. The fact that our mineral production barely pays our coal bill, is a structural defect that will be rectified in due course. Being overbuilt with railroads is burdensome; but this was the experience of the United States and every other country where opportunity beckoned to governments and private capital. Mr. Campbell is too well informed not to be aware that nearly every western railway in the United States went through receiverships. Again and again there was default. Europe financed the United States. It was the mineral developments that gave speculative impetus to the Rocky Mountain and Pacific States; it was the overflow from California and Nevada that started things in British Columbia, Alaska and the Yukon.

The return upon capital, all things considered, has been ample. Canada's economic scales cannot be balanced by "watchful waiting." Had unintentional reactionaries held sway, progress would have been deferred. Even Anyox was condemned. So was the Sullivan Mine. The Nickel fields provided more agonies than profits. Quebec Asbestos underwent discredit. There is utter disregard of the wealth contained in the Wabana iron deposits and Maritime coals. If the bill for imported coals is excessive, it is for Canada to reduce it.

"The optimist is always right," declared Sir Percy Fitzpatrick when a member of the mining firm of Wernher, Beit, Eckstein. That affirmation undoubtedly was an exaggeration; but sporting spirit is what makes the world move.

NOTES FROM THE FIELD

By R. E. HORE

Holtyrex

A Smith and Traverse diamond drill outfit has arrived at the Holtyrex property. Some of the crew have recently returned from Mexico where the drilling company did some work. Mr W. Young and Mr Smith will visit the Holtyrex and make arrangements for the drilling campaign.

La Rose O'Brien

The judgment in the LaRose O'Brien dispute is arousing much comment. By this judgment La Rose apparently loses ground that was not in dispute in the early stages of the fight. The Violet shaft becomes the property of the O'Brien and La Rose will be required to compensate for ore extracted. It is a serious blow for La Rose company.

Gold Mining Active

At Porcupine and Kirkland Lake there is now unusual activity. The producing mines are doing better than ever and there is a revival in prospecting and exploration. It is freely predicted that this will be a very busy year in all the gold areas.

Silver Mining Brighter

While activity in the silver areas is overshadowed by gold mining this year, there is a noticeable improvement in the silver areas also. The McKinley Darragh Savage is resuming operations. The price of silver has advanced far enough to arouse hopes that others now idle will soon be in action again.

Sudbury has Good Views

At Sudbury there are rumors that some smelting and refining will be under way in International Nickel plants before long. There is considerable ore on hand and mining operations will not necessarily be resumed for some time. But to have a smelter unit in action and some smoke will improve spirits at Sudbury.

Book Reviews

PLATINUM AND ALLIED METALS (1913—1919). Imperial Mineral Resources Bureau, 1922. His Majesty's Stationery Office, London, S.W.1. pp. 2s. net

This volume gives a good resumé of the occurrence and production of these precious metals within the British Empire, and summarizes the occurrences elsewhere. A bibliography is appended.

The world's production of platinum comes principally from placers, the small residue being mainly attributed to the nickel ores of Sudbury. To date, about 11,000,000 troy ounces of platinum have been produced, 90 per cent. of it from Russia, 7 per cent from Columbia, 2 per cent. from Borneo and the remaining 1 per cent. equally from the United States, Australia and Canada.

Areas of dunite in the central Ural Mountains are the source from which the streams of the district have gathered the precious metal. The platinum is associated in the rock with chromite, but never in sufficient quantity to be profitably mined.

The alluvial deposits in Columbia that are worked for platinum have evidently got their supply of the metal from conglomerate beds of Tertiary age, composed of boulders of basic rocks, originally of Jurassic and Triassic age.

The platinum of the Borneo placers is associated with gold and diamonds, and has its origin in areas of olivine-gabbro and metamorphosed sediments in the uplands.

Platinum is of wide-spread occurrence throughout Canada, but at present is recovered principally from the nickel ores of Sudbury. The association of platinum with chromite has been noted in Quebec, Ontario and British Columbia. It is suggested that as the chromite-bearing rocks have never been properly examined for platinum, such a search might well repay the prospector.

Osmiridium, next in commercial importance to platinum in the group, is produced mainly in Tasmania. It also is associated with serpentine rocks. Placers rich in the alloy are so extensive that Tasmania seems assured of a virtual monopoly of its production for some time to come.

MODERN TUNNELING. By David J. Brunton and John A. Davis, with new chapters on Railroad Tunneling by J. Vipond Davies. — Second Edition, revised and enlarged. — Published by John Wiley and Sons, Inc., New York.

No technical treatise is modern if it is ten years old. Some such volumes, but not many, may survive because of their intrinsic historical value. The majority are relegated to the "dump."

The first edition of Modern Tunneling, we remember very well. Its distinguished senior author, Mr. David W. Brunton, is a man who has given a wonderful impetus to sound mining and professional literature, and has done more than his bit in simplifying and improving mining practice. His co-adjutor, Mr. John A. Davis, is a worthy associate of a genuinely great United States citizen and engineer. Mr. John Vipond Davies' contributions to this well-ordered volume attest his fitness for the task.

It is not seemly to bestow unqualified encomiums upon any printed product. It is the reviewer's opinion that far too much space has been allotted to the bibliographical lists that form integral parts of the volume. These lists might easily and profitably have been condensed in small type as an appendix, or else have been omitted entirely. So much for fault-finding.

What is particularly noticeable about the book is the clear cut, logical method of treatment. The theme is developed in an introductory chapter with a crisp sketch of the history of tunneling. (Editor's note—The differentiated spelling of the last preceding word is a matter of taste, not of accuracy.) The succeeding chapters deal in due sequence (as indicated by their captions) with "Modern mining and water tunnels," "Choice of power for tunnel work," "Air compressors." "Ventilation," "Incidental surface equipment," "Rock-drilling machines," "Haulage," "Incidental underground equipment," "Drilling methods," "Blasting," "Methods of mucking," "Timbering," "Safety," and "Cost of tunnel-work.". In this edition (as noted above) there is added a comprehensive review of railroad (railway) tunnelling practice.

It will be seen that the scope of "Modern Tunneling" is wide. It may be stated, without reserve, that every phase of this highly important branch of mining and civil engineering is dealt with in an adequate manner. The reviewer must not paint lilies. Suffice it to say that this is a good book, written (not compiled) by men that love their work.

Because the reviewer is certain that further editions of the volume will be demanded by an appreciative circle of readers, he takes the liberty of suggesting that the full-page illustration opposite page 16, entitled "**Fig. 3. Starting a tunnel by hand-drilling,**" be excised. Something serious, he fears, is going to happen to the man holding the starter.—C.

PERSONALS

Mr. Chas. Camsell, Deputy Minister of Mines, and Prof. Stafford Kirkpatrick of Ottawa are among those honored by Queen's University last week.

Mr. C. M. Teasdale died at Flin Flon, Manitoba, on April 22. He surveyed a large number of mining claims in the west, particularly in the Pas district, and was interested in several claims there. At Cobalt in 1906 he was in charge of parties doing survey work for the Bureau of Mines. His family reside in Toronto. In his college days he was Varsity's mile runner.

Mr. Robert Bryce has returned to Toronto after examining properties at Kirkland Lake.

Mr. G. C. Bateman returns to Cobalt this week after a trip to California.

Mr. W. M. Hotchkiss is now residing at Cobalt again.

Mr. C. H. Hitchcock of Sudbury is in California.

Mr. Harry Kee is at Porcupine in charge of operations on the Goldale property.

TASHOTA CLAIMS UNDER OPTION

The Hull Rivett-Goad-Kipper Claims, six in number, lying 2 1-2 miles east of Tashota station, Canadian Government Railways, north of Lake Superior, have been taken under option by the Coniagas management. The price is $150,000. All papers have been signed, sealed, and delivered, and work will begin at once.

I visited this camp some years ago and after my inspection felt assured that these claims would sooner or later be tried out by one of the big companies. The whole district is most promising, but unfortunately the immense amount of drift makes rock exposures few and far between, and anything like close detailed prospecting is as yet impossible.

Tellurides are found in some of the veins, carrying, as is usual, a high percentage of gold. — *Charles A. Bramble.*

Notes From Nova Scotia

The Conciliation Board

All the eyes of Nova Scotia are focused on what is now known as the "Scott" Conciliation Board which is sitting in Sydney and the adjacent mining districts.

The board is composed of D'Arcy Scott, Ottawa, chairman, J. E. Moore, St.John, N.B. representing the Dominion Coal Company and Isaac D. McDougall, Inverness, representing the miners.

The board spent a strenuous week and went into three collieries to see conditions underground. This entailed much labor to the members; but the workmen wanted it and the board was anxious to gratify their wishes. Suffice it to say that one visit was all that was necessary, as after seeing the interior workings of one mine all evidence submitted to the Board afterwards was thoroughly understood. The miners seemed to take what I would designate a cruel delight in seeing men wholly unaccustomed to mine travelling follow them down into the far recesses of the different collieries. The board members showed themselves equal to the occasion, although they no doubt suffered from the unwonted toil.

Peculiar interest was taken in the work of the board owing to the fact that it is the second board to sit on the same case and to look into the long drawn out agitation that raged round the collieries after the Gillen Award had been rejected.

There is much conjecture as to what the new Award will be and what may happen should it prove unfavorable. While not expressing any opinion we can keep our minds easy as to the future while awaiting the verdict. Of one thing we are sure, and that is the work of the present board is so thorough, no other board need come after.

Examining the Colliery Villages

The board convened in Sydney Court House and after getting its bearings immediately adjourned to visit the collieries. This was the unexpected, and Secretary McLachlin was caught napping, and to use a sporting term, caught out. In his speeches and through the Labor Herald, the irrepressible and irresponsible J. B. had boasted that he would have an imposing array of new exhibits in the form of hungry women and rag-clad children. Whether or not the chairman had heard of this motley army there was no time given to marshal it. The direct action of the board in going out to see the miner in his home was too much for the disgusted McLachlin, who refused to go round with them and impart the information so necessary to men unfamiliar with colliery conditions. This was attended to by other more courteous union leaders. In the colliery villages the houses were entered and the size, number of rooms, etc., were ascertained. Questions were freely asked and just as freely answered.

Here and there were groups of happy, hearty, fairly well clad children playing in the streets just as boys and girls have always played and as we are told by the "exiled seer of lonely Patmos Isle," they will play in the streets of the New Jerusalem. No emaciation from malnutrition due to low wages was seen either here or any other place.

Meantime the miners, who are quick to see things, smiled at the adroitness of the chairman who had out generaled their fighting leader, and seemingly decided that they must be careful in their conduct at the sittings of the Board. Now and again they broke out in applause, but it was most interesting to watch the painful expression on their faces when the chairman in his own quiet way designated their hero worship as noise.

The Chairman's Opening Pronouncement

The Statement of the Board delivered by Mr. Scott in his own quiet, dignified manner had a wonderfully soothing effect in the whole Island, and tended to create an atmosphere of peace which remained undisturbed to the end. Part of his statement is as follows:

"We realise what the decision of this Board means to the miners and to the whole of Canada. The situation is a difficult one and unfortunately has been advertised largely one way or the other. We come here with open minds and free from partiality. It is the wish of the Hon. Mr. Murdock, Minister of Labor, that this Board shall visit every locality affected, and hear whatever evidence there is to be submitted. We will hear any one who has something to offer pertinent to the question. We are anxious to see every locality affected and will be glad to go into the mines.

"The mining industry is not unlike a number of other industries which have been affected by the war and the after-the-war conditions. Let us take the dairy industry in which I am vitally interested," said Mr. Scott, "New Zealand butter is being imported into Canada and sold at a lower price than it can be produced by the Canadian farmer. Trade conditions must be considered in all questions, and while the eastern farmer has been affected by lower prices, so also has the western farmer, who today receives a price several times lower than he secured for his product a few years ago.

"I don't make these remarks to discourage the men who are interested in the welfare of the miners," said Chairman Scott, "I simply point them out as analagous situations which show the change of conditions in recent years. I am in full sympathy with labor and especially the workingman who has a large family, and I desire to see that the living wage paid the working man is as large as it is possible to give. Certainly we must consider market conditions when dealing with these questions. Just as the Canadian farmer must meet competition in butter and wheat, so also must the coal companies meet competition from the United States coal mines. I believe if all the coal mines in Nova Scotia were closed the only effect in the Montreal coal market would be an increase of a few cents per ton in the price of coal, and this increase would only remain for a short time at that.

"The coal industry is not in any way a monopoly. I have had some experience in dealing with railway labor, which is considerable of a monopoly. Railway labor is in a better position to dictate the rate of wages, because freight rates go up or down to meet the cost of operation and the railways must always be operated.

"Our investigation will be as general and broad as we can make it looking over the entire situation. We want to see labor get its just and fair return. The sittings will be carried on with decorum and let there be no time wasted.

"It will be futile and useless to stage unnecessary demonstrations with the end in view of pandering to a jury. That will have no effect on my colleagues and myself, who are acting more in the capacity of judges."

D. H. Macdougall Presents Company's Case

At the opening session of the second day, D. H. Macdougall, 1st Vice-President of the Steel Corporation presented a lengthy statement on behalf of the Company. He dealt with the coal trade as it now is, with wages before and during the war, with the merger, with housing con-

ditions and various other matters affecting present industrial conditions.

Mr Macdougall stated that the volume of business had dropped off and there was keen competition for what was left of it by American and British coal. The three main markets were the railways, the bunker trade and the Montreal trade. Ships from all over the world may be classed in the bunker trade, but with the lowering of British prices vessels were now bunkering on other the side of the water for the round trip. The bunker trade has completely collapsed so far as Nova Scotia was concerned.

United States companies cutting pulp wood in Canada were importing Virginia coal at a cost lower than it could be purchased at the pit mouth in Nova Scotia. Virginia coal had been brought into Montreal and English coal was being brought to Canada as ballast.

A Wage Basis and Cost Sheets.

Mr Macdougall said the wages the Coal Company were able to pay to their Employees must always be based on the willingness of the consumer to pay the selling price. He claimed the coal trade in Nova Scotia had dropped off at an enormous rate due to industrial depression while the consumption of coal at the steel plants was nil. Foreign coal was sold in Nova Scotia, while no shipments of coal were made to the United States.

Mr. Macdougall said that a rate of $2.85 per day with steady work assured was better than a high rate and only intermittent employment. The average wage in 1914 was $2.46. In 1921 it was $5.73.

Surface labor had received an increase of 140 per cent. underground labor 145 per cent. and coal miners 136 per cent. He claimed that the mine workers under the adjusted Gillen Award were better off by from 30 to 35 per cent., now than they were in 1914. The rate was 78 per cent higher than the 1914 rate while the cost of living was only 47 per cent higher today than in 1914.

The rent of workmen's houses were $6 and $8 per month and employees received house coal for $2.25 per ton. No change in these had been made during the war.

The cost sheets would be submitted to the board but, said Mr. MacDougall, it would be unfair to ask these cost sheets to be given to the public.

Merger Critics Answered.

Answering the criticism with regard to the alleged "water" in the Besco capitalisation, Mr. Macdougall declared that neither upon the ordinary shares of the company nor upon the shares exchanged therefore—that is the second preference and ordinary shares of Besco—nor upon this additional stock of $19,500,000 have any dividends been paid for over a year past; and there does not appear under existing conditions to be any immediate prospect of payment of dividends.

As bearing upon the returns to the shareholders it is desired to point out, said the Besco Vice-President, that shortly prior to the consolidation in 1921 additional capital to the amount $3,500,000 was put into the Dominion Companies by British financiers upon which they have had also had to forego any return for the past year.

Mr. Macdougall went on to say that the profits of the Company were invested in improvements to the collieries and the plants. These profits, accumulated until the time of the merger, amounted to $25,858,749.64.

After referring to the Award of the Gillen board; which placed the minimum rate at $2.85 per day, and a subsequent offer by the company of $3.00 per day, Mr. Macdougall said the company was influenced in accepting the $3.00 rate because of an ardent desire to bring about an amicable settlement of the wage dispute as at that time there was an opportunity afforded of securing contracts but that opportunity has now passed.

A short statement of the Miners will be given next week, also the resultat evidence of the Coal Company. The wages earned will be startling to the public.

Accidents in 1921.

The Mines Report of Nova Scotia for 1921, shows an increase of three fatal accidents over that of last year. The deaths from falls of stone and coal numbered fifteen, from mine cars or trips in motion, eight; from mine gas, two, and from other classes, four.

Falls of stone and of coal have always been the cause of most deaths in our coal mines in spite of all the precautions taken against such accidents. Moving trips or mine cars make a close second. It is the belief of most men that many of these accidents can be averted, but while men persist in evading the Mines Regulation Act, by riding on loaded trips for the purpose of getting out of the mine a little quicker or refraining to place proper supports where needed, the death toll will continue to be large. There is however, the unavoidable accident which neither experience, good judgment or keen observation can prevent.

Twenty-nine men were fatally injured in the coal mines of Nova Scotia in 1921. The number per 1,000 men employed was 2.36 against 2.30 in 1920. Per million tons of coal 5.39 were killed against 4.81 last year.

The statistics of the American mines have not come to hand, but a comparison with 1920 is favorable to Nova Scotia, being 2.36 against 2.91 United States.

Compared by Counties, Cape Breton is far in the lead of all others, with the Glace Bay district down to 1.37 per thousand men employed.

Compared with the mines of Britain, Belgium, and France, the Nova Scotia accident rate is still high, as these countries average well under one per thousand. There is no doubt that old countries, with a professional mining class, have a great advantage over those comparatively new, that have to make miners from all classes of labor as the industry develops.

In output per man killed, the American mines lead all others. This is largely due to thick coal seams and the easy working conditions of most of these.

In Canada as in the United States, great efforts are being made to make coal mining safe, and considering the cosmopolitan makeup of the mining classes, the complexity of mining by the introduction of much machinery underground, and the rapid development of the industry during the past twenty years there is no cause for discouragement.

Great Britain has granted exploring rights in Palestine to the Standard Oil Company. As Palestine is British mandatory territory, this action places United States nationals on an equality with the national Governments that were signatories to the Versailles Treaty. The United States, if will be remembered, was not a signatory.

The gold production of Australia has been steadily declining for many years. Last year the production was 759,297 ounces, against 948,672 ounces for 1920, and 2,720,902 ounces in 1911. The cost of production in Australia is now so high that the gold mines still in operation virtually make their profit from the existing premium on gold.

British Columbia Letter

The Northern Districts

It is stated that the Granby Mining and Smelting Company is contemplating the installation at Anyox this summer, of a new hydro-electric plant involving a substantial expenditure. The idea is to entirely eliminate the necessity for steam-generated power in the operation of the Company's plant. As a preliminary step, the water storage dam, to which reference already has been made, is under construction. The contract for this work has been given a Vancouver firm, known as Dredging and Contracting, Ltd.

The Big Missouri Mine, Salmon River Valley, Portland Canal Mining Division, is to be developed this summer. Messrs. Trites, Woods and Wilson, who are identified with the Premier Mining Company, are reported to have taken a working bond on this property. They are said to be satisfied that the Big Missouri can be made to produce and to pay dividends on the investment required to bring it to the status of a shipping mine.

A syndicate known as the Dunwell Mines Ltd., has been formed to take over and to develop the Dunwell and Stewart Mines in the Glacier Creek section of the Portland Canal Mining Division. These properties are within 5 miles of the town of Stewart. Considerable work was done on the Stewart in early days, including the driving of two thousand feet of tunnels. There are three leads in width from 6 to 24 feet. Ore values run from $25 a ton, although some fine values of native silver were found from time to time. No work was done on the Dunwell, other than 300 feet of surface stripping on the main lead, which is 67 feet wide. The new Company has a capitalization of $350,000.

It is reported that D. C. Jackling, Bart. Thane and G. T. Jackson have acquired an interest in the Fish Creek Mining Company. If this is so, important development is anticipated on the property of this company, which is situated in the Salmon River Section near the Alaska Boundary, during the forthcoming season.

The Daly Alaska Mining Company has been organized under the laws of the State of Washington, to take over, develop and operate, the New Alaska Group of mineral claims, which is situated on the Alaskan side of the line, 11 miles from tidewater at Hyder. It is tapped by the Salmon River wagonroad, so that there are no transportation difficulties. Pat Daly, well known northern B. C. operator, believes that the New Alaska is destined to become an important producer. Last year's work is said to have shown up a large lead of good milling ore, running $85 a ton in all values.

The Cedar Creek Placers.

In the Annual Report of the Minister of Mines just issued, is published a statement by L. A. Dodd, Gold Commissioner at Barkerville, concerning the Cedar Creek gold field. It should be remembered, however, that Mr. Dodd visited the district in the fall of 1921, and that there may have been important changes in conditions since that time. His observations, however, are of interest, in view of the developments of the past few months.

Mr. Dodd examined the pits there, two in number, about 50 feet long, 4 to 5 feet wide, and less than 3 feet in depth. From then up to the time of his departure, some 60 ozs. of gold had been recovered. He continues: "Shortly above the second pit from the Creek the ground takes a sharp rise, and so far no trace of the run of gold has been found in it, although a great number of holes have been sunk in all the draws of the neighborhood.

"An effort to drain some of the deeper ground made by the owners of the back location is being carried on. In digging the drain some fine gold was found, until the ground began to get over 6 feet deep, after which no traces of gold have been discovered. This drain starts in the Lynes and Platt (original discoverers) ground.

"All the ground is very heavily covered by second-growth timber, and one could only get around by following paths, cut by prospectors and along the location lines. I followed the location lines back a distance of over 6,600 feet from the Creek, much farther than where any work had been done. It would appear to me that the overburden with the exception of a short portion of the Lynes and Platt locations runs all the way from 25 to 75 feet deep, which means that the ground cannot be worked advantageously, except by hydraulicking. Lynes and Platt have been using the seepage water for rockers. This is sufficient for this purpose for a short part of the season only, there being practically no water when the weather is dry.

"Lynes and Platt informed me that they had been looking for the discovery since May last. Mr. Lynes, who is a native of the district, had been informed by an old-timer that gold existed, but not where they found it, which was some distance above the old Cedar Creek workings. They do not consider they have made wages during the time they have been engaged in the area.

"The nearest stream of water which might be used for hydraulicking is Rapid River, which would necessitate a ditch line some 12 to 15 miles in length. It would appear to me that there might also be a possibility that the ground might be dredged provided the seepage water could be utilized and is found in sufficient quantities to float a dredger, there being a large muskeg off to one side, from which Cedar Creek flows."

Ore receipts at the Trail Smelter of the Consolidated Mining and Smelting Co. for the week from April 8th to 14th inclusive, totalled 8,089 tons. Of this 7,927 tons came from Company Mines. There was a contribution of 78 tons from No. 1 Mine, Ainsworth District; and 84 tons from the Silversmith Mines, Sandon.

Arrangements are being made for an International Mining Convention to be held at Nelson, B. C., from the 3rd to the 7th of July next. In this connection, a representative collection of provincial ores is being assembled for display.

George Clothier, resident mining engineer for the Portland Canal District, recently paid a short visit to Victoria prior to commencing his active work in the mining sections of the Salmon and Bear Rivers. He looks forward to much development this season and is anxious to have considerable road and trail work undertaken. The extent of the latter, it is understand, depends entirely upon the funds available. These are known to be rather short as the government, in com-

mon with corporations and individuals, is finding it necessary to economize wherever possible.

Portland Canal District.

The Marmot River region of Portland Canal is reported to be due for a notable advance this year, mining men interested claiming that someof the properties under development are likely to make showings rivaling the Premier and other of the Salmon River claims. The Patricia Group is to be opened up on a considerable scale and there are many other promising prospects. Owners are hoping that transporation facilities will be improved.

It is announced that the Premier Mine shipped up to about the end of April from the first of the year 23,700 tons of ore During the last two weeks of April 1600 tons were sent to the smelters at Anyox B. C. and Tacoma, Wn.

A. G. Thompson, general manager of the Kitselas Mountain Copper Company Ltd., Usk B. C. has returned from Portland, Ore. and reports that arrangements have been made for the continuance of tunnel and other work on the property. J. D Galloway, resident mining engineer, referring to this Company's operations in 1921 says that developement of No. 2 vein (blind vein) exposed in the crosscut tunnel was resumed. "This vein", he continues, "had been developed by a winze a few feet deep and this winze was deepened to 30 feet. The vein improved in size and values with this work, there being five feet of pretty well mineralized quartz at the bottom. Average samples by the management are said to show it to be a satisfactory grade of ore. As working in this winze was expensive and troublesome owing to a considerable stream of water, it was decided to run a lower crosscut tunnel so as to cut this vein at a point below the bottom of the winze. This crosscut will be about 400 feet long to strike the vein and will give a depth of 80 feet below the top of the winze. The crosscut was started on Augnst 1 and the work is being continued steadily." This, apparently, is the work to which Mr. Thompson refers, which will be carried on this year.

Slocan

The Oro and Gold Reef Claims, Lemon Creek, Slocan District, are to be opened up this year. A small Ross Mill is to be installed and operated by George A. Hird and W. Munro, of Vancouver.

Cariboo Placers

The Cariboo Exploration Company's placer leases, situated above the junction of the Swift and Cotton rivers, on the Quesnel-Barkerville road, are to be prospected this summer. H. C. Foster, of the Foster Engineering Co. Fernie B. C. has arranged to have the ground drilled and plant has been ordered for the purpose. The ground was obtained on a $100,000 option from James Harrison and comprises some four and a half miles along the Swift River.

The rush to the Cedar Creek section of the Cariboo con-tinues. Work, however, still is impeded by the snow. In a few weeks the season will be in full swing after which it will not be long before authentic reports are received regarding the riches of the claims staked and the probabilities of further discoveries. Whatever the developements, all are agreed that the flurry of interest and the resulting inflow of men intent on prospecting the country must have a good effect. It will likely lead to the finding of other good paying claims because there is gold in all the placers of the Cariboo, the only difficulty in recent years being to find it concentrated in areas of such compass as to make it worth the while to work. Another result should be thedirecting of attention to the hydraulicking and dredging possibilities. There is every reason to believe that many leases that have been held without development now will find the capital needed for the acquirement of the plant required for their exploitation.

An interesting recent development at Cedar Creek is the staking of the Lynes and Platt original claim by Frank McQueen,of Vancouver, under the Mineral Act. The former are holding under the Placer Act. This entitles them to all placer gold in the ground. It does not, however, give them what gold there may be in place. Mr. McQueen has a theory that the gold being found comes but a short distance and that, with stripping of the surface and the exposing of bedrock, gold will be discovered in place. This is his object in staking under the Mineral Act and his action has led many holders of placer claims in thevicinity to secure mineral as well as placer rights.

Surf Inlet Mine

The Annual report of the Belmont Surf Inlet Mines, Ltd., operating the Surf Inlet Mine on Princess Royal Island has been issued and is of much interest. Up to the end of 1921 the Company had been paying 10 per cent. dividend, but last year its net profit was only 10,509.08. increased to $80,568.25 by the difference in exchange and miscellaneous income. It cost $ 622,222.09 to earn $632,220.09.

Some concern is manifested because at the low figure at which the reserves are placed, but it is stated authoritatively that this is a conservative estimate and that development to be undertaken this year will place a very different complexion upon the situation.

Trail Ore Receipts

A record tonnage of ore was received at the Trail Smelter Canadian Consolidated Mining and Smelting Co., for the four months ending on April 30th last, the total being 150,493 tons. Last year's figure for the first quarter was 139,857 tons,so that there has been a substantial improvement. Receipts for the last week of April were 9,173 tons of which 8,992 tons were from the property of the Company. Among the independent shippers were: The Black Rock, Northport, Washington; the Ottawa, Slocan Citp; the Republic. Washington; the Silversmith, Sandon; and the Wind Pass Chu Chua.

The coal strike in the Crow's Nest Field already is having its effect on mining in the British Columbia interior. Anticipating that there will be a shortage of fuel, the Consolidated Mining and Smelting Co. is curtailing its operations at Rossland, as the ore from these mines requires more coke in its reduction than does the ore from the Sullivan mine. Some of the men being released at Rossland are going to the Sullivan, and others to the smelter.

Dolly Varden Properties in Dispute.

The Consolidated gold interests of Cripple Creek, Colorado, are taking legal proceedings which may lead to the foreclosure of the Dolly Varden, silver mine, the Wolf Group of Mineral Claims adjoining the mine and the Dolly Varden Railroad, all of which are situated in the Kitsault Valley, Alice Arm, B. C. George Wingfield, of the Consolidated, who claims to have a $200,000 interest in the property, has brought suit to recover on his security. Paul C. Chiene, receiver for the creditors of the Dolly Varden Mines Co., and the Dolly Varden Company, has been added as a party to the action, which primarily is against the Taylor Engineering Co.

Northern Ontario Letter

THE GOLD MINES

Power House Flooded

High water on the Mattagami River flooded the power house at Wawaitin Falls and caused a temporary curtailment of power. This lasted only a few days and the situation has now adjusted itself. Meanwhile, the enlarged storage basin caused by the big dam at Kenogamessee has been completely filled and this, it is believed by the power company, will assure to all the mines their full power requirements throughout the dry summer months.

McIntyre Ore Reserves

In view of continued favorable developments on levels previously opened up, as well as good results at depths down to 1,875 feet, it has been learned on good authority that the McIntyre-Porcupine will show a substantial increase in ore reserves at the end of the company's fiscal year ending June 30. Not only will the report show a greater production than every before in a single year, but is believed likely to show close to two dollars in new ore to each dollar produced for the period.

Newray

At the annual meeting of the Newray Company which will be held on May 16, certain offers for 1,600,000 treasury shares will be considered. It has been intimated that the Coniagas Mines of Cobalt have shown some interest in the proposition, while it has long been known that the McIntyre-Porcupine is seriously interested. There is known to be an encouraging amount of low-grade ore on the Newray, while it is also true that some patches of high grade occur.

Dome's April Record

During the month of April, according to official advice to your correspondent, the Dome Mines established a record that is far in excess of any previous achievement in the company's history. A feature of the record is that while the mill treated an average of 912 tons of ore daily, the average grade of the ore was over $14 per ton and resulted in a recovery of $13.76 from each ton treated.

Tonnage treated in April	27,354
Gold produced	$377,438

Perhaps the outstanding feature of this achievement is that with costs of not much over $4 per ton, the net profit amounted to about $9 per ton, or approximately $250,000 in net profit for the month.

Another feature is that the April production was at the rate of $4,529,256 a year, or close to one hundred per cent. of the issued capital of $4,766,000.

It is significant that net profits should reach $250,000 for a single month, or at the rate of $3,000,000 a year. This is at the rate of approximately 63 per cent. of the company's issued capital, a net profit at the rate of $6.30 a share annually.

Official figures for the four months ended April 30th, show a gross yield of close to $1,300,000. It is to be noted particularly that the Dome is now treating the highest grade gold ore of any mine in Canada, with the exception of the Lake Shore at Kirkland Lake. The difference is that the Lake Shore is treating 70 tons daily while the Dome is treating between 900 and 1000 tons daily. It is this fact that has brought the Dome to a prominent position among the world's great gold mines.

New Shaft for Larder Lake District

Contracts for 300 or 400 feeet of sinking have been let by the Crown Reserve Mining Company. This work is to be done on the company's property in the Pancake Lake section of the Larder Lake district.

The property has been equipped with a first class mining plant, and the management is hopeful of establishing a paying gold-mining enterprise. The exploration work is being carried on by use of diamond drills, and the core of one of the holes showed especially promising gold values.

Progress on V. N. T.

Following the de-watering of the workings on the Porcupine V. N. T. Mines, the checking up of the values has been going on. At one point, assays of upwards of $28 per ton occur across a width of four feet.

It has been reported that in addition to continuing the main shaft to a depth of 900 feet, with lateral work at the present depth of 600 feet and with working levels at 750 and 900 feet deep, it has been arranged to carry on exploration work with a diamond drill. In this way, the several hundred of feet of territory lying between the present main ore body and the boundary of the adjoining Hollinger Consolidated can be explored. It is an importan fact that this intervening territory has never been explored underground although at surface there are a number of outcrops in which visible gold was found during the course of surface exploration.

Lebel Crystal Lake

Surface work on the Lebel Crystal Lake property has recently been attended with promising results. Red and grey porphyry has been found to occur in a big dike on that part of the property lying along the boundary between Lebel and Gauthier townships. Iron pyrite mineralization is heavy, and the dike is understood to carry encouraging gold values.

The Kirkland Lake Road

Some uncertainty still exists with regard to the Ontario Government continuing work this year in the easterly extension of the Kirkland Lake highway. This road is macadamized through the producing section of the district, a distance of about five or six miles. An additional four miles or more of a stretch has been graded. Property owners are now asking that the road be continued another half dozen miles so as to connect up with that part of the old road from Dane station to the Argonaut mine at Beaverhouse Lake. It is understood the Argonaut stands willing to lend its assistance in the work.

A plan is now under way to petition the government for this additional assistance.

In the meantime, the promoters of the proposed light railway project are courting the Drury cabinet. Influential men at Kirkland Lake have expressed the opinion that this is only a "harmless flutation" on the part of Premier Drury, while those interested in the project are seriously of the opinion that the Government may be induced to guarantee bonds to the extent of $15,000 a mile.

The macadam road is a real success, and the leading operators favor this method of transportation.

100 New Houses for Timmins

Arrangements have been made by the Hollinger Consolidated Gold Mines to erect another 100 houses this summer in the town of Timmins. These houses

will be similar to the 150 erected last year.

Housing accommodation in Timmins is taxed to the limit. With the enlargement of the Hollinger mill to upwards of 7,000 tons daily capacity as compared with under 4,000 tons at present, the company will employ an additional 1,000 men, making a total force of about 3,000 as compared with 2,000 at present.

Montreal—Ontario

The Montreal-Ontario, which is the name of the merged Ontario-Kirkland and Montreal-Kirkland, is letting contracts for considerable underground work, and a general scheme is being mapped out. Horace Young is in charge of the operation, and the next few months are expected to witness a working out of the mining problems that were the cause of disappointment under the former management. The adoption of a mining method that will prevent dilution of the ore with the loose waste rock that lies adjacent to the ore, is expected to result in this enterprise being placed upon a substantial producing basis in a reasonably short time.

Cobalt District

According to preliminary estimates, the silver mines of the Cobalt and surrounding districts produced approximately 750,000 ounces of silver during the month of April, the valuation of the output being approximately $510,000.

The price of silver continued strong throughout the month, this strength continuing right up to the time of writing. Mine operators point to the war conditions in China as reason for believing that a further increase may be reasonable to expect.

In view of the McKinley-Darragh having resumed operations, the production of silver from the Cobalt field will be increased by approximately 8 to 10 per cent. beginning with thee month of June.

Silver production during April at the Nipissing mine was a little below normal, according to the regular monthly report issued to the president and directors by Hugh Park, manager.

Re-financing of Maidens Mine

The Maidens Silver Mining Company, Ltd., has arranged a new plan of financing and is to be re-incorporated into the Canadian Lorrain Silver Mines, with an authorized capital of $2,000,000 made up of 2,000,000 shares of the par value of $1 each. The agreement was entered into December 1st and was ratified on January 21st. Application was made and the new charter received on April 18th.

According to this agreemennt, the authorized capital of the new company will be disposed of as follows:—

To the bondholders	484,000 shares.
To shareholders of old company	375,000 shares.
For reorganization purposes	141,000 shares.

After these allotments are made, the treasury will contain 1,000,000 shares with which it is planned to finance aggressive operations. It is stated that about 60,000 treasury shares are being disposed of as a means of raising money with which to pay the expenses of dewatering the mine and having an engineer's report made.

A pooling agreement has been entered into and this is calculated to protect the market during the period in which financing will be done.

High-grade Ore from Castle-Trethewey

In view of the success achieved during recent weeks on the property of the Castle-Trethewey, a substantial shipment of high-grade ore is assured in due course. Already a considerable quantity has been bagged, in addition to which a large amount of medium-grade ore has been put in sight.

Activity in South Lorrain

Judging from the number of Miners' Licenses being issued to prospectors and mining men who are interested in the South Lorrain district, it would appear as though this old area is to enjoy a general revival of activity this year.

This renewed interest is entirely due to the outstanding success achieved on the Keeley Silver Mines as well as the encouragement being met with on the Haileybury Frontier property.

Another Change in Mining Act

Quite a stir has been caused among prospectors by the latest amendment to the Ontario Mining Act, whereby the working conditions will automatically be changed back to a total of 240 days' work on each mining claim.

It will be recalled that one of the first acts of the present Minister of Mines was to reduce the work to 200 days, and to allow twelve months in which to perform the first instalment .....

EDITORIAL

It is my firm conviction that Canada's future greatness will depend more upon her mineral production than upon any other of her natural resources.—*A. E. Barlow*—1913.

MINING ACTIVITY INCREASING

Led by the activity in gold mining, there is now a noticeable and general improvement throughout Canada in the metal mining industry. The producing gold mines are not only making larger outputs, but have greatly improved their resources on development. There is now commencing a period of unprecedented activity in the making of new gold mines in Ontario. There is also evidence of an improvement in the conditions of silver mining. The present price of silver, higher than for some time past, and the lower cost of labour and supplies, present an opportunity for profitable mining that did not exist last year. At Sudbury there are reports of some smelting to be done this summer by the International Nickel Company, though it will probably be some time before the smelting of ore at present broken and available will warrant the resumption of mining operations.

From British Columbia there are reports that Anyox and Britannia will be the scenes of much activity this year. The Granby company is now operating at a profit once more, after a period where the high cost of production and the low selling price of copper resulted in a deficit. The Britannia company has a 2,500,000 ton mill under construction. The Premier mine is being operated in a highly successful way, and has already paid $900,000 in dividends this year. Lead and zinc production at Trail have been very large, as well as moderately profitable in spite of low prices. The zinc resources and production of the Sullivan mine now dominate the Western market; in fact, it has been said that the only real trouble now with the Sullivan ore is that there is too much of it!

In the East, the British Empire Steel Corporation, which dominates, and indeed almost comprises, the coal and iron trade of the Maritime provinces, reports a fairly successful year, in spite of the most adverse conditions.

Facts such as these, in conjunction with the reported increase of activity in the mining and metallurgical centres of the United States, augur well for the progress of Canada's metal industry during the remainder of this year.

CANADIAN FREIGHT RATES

On the sixth day of July, a few short weeks from today, the much discussed Crowsnest Pass Agreement, suspended during the last year of the War, becomes effective once again—that is, the Agreement, being a statutory enactment, must be dealt with as such; it must be retained as it stands on the Statute Book, or abrogated. The only other alternative is temporary suspension, a makeshift piece of evasion.

The Agreement has been threshed out most pneumatically in the House of Commons. Some sense, and infinite non-sense, have characterized the debate. Incidentally, the pucrilities that mark the interchange of exacerbities between the Premier and the Leader of the Opposition are creditable to neither. They do not make pleasant reading in Hansard.

The Crowsnest Pass Agreement was entered into by the Government of the Dominion of Canada and the Canadian Pacific Railway in 1897. The purpose of the Agreement was to bind the Railway to make reductions in freight rates for certain specific classes of merchandise in return for subsidies granted by the Government. Reductions were to apply on these specific classes of merchandise, whether in "carloads or otherwise," when shipped from any point east or west of Fort William, by rail, or by lake and rail. Thirteen classes of merchandise were enumerated, chiefly covering shipments of fresh fruit, agricultural implements, paints, household furniture, manufactured iron, glass, live stock, etc. At the same time a substantial lessening of rates on flour and wheat was agreed upon. The consideration, in the form of subsidies granted to the Canadian Pacific Railway, was something more than four million dollars, or about $11,000 per mile towards the construction and completion of its Crowsnest Pass subsidiary.

As an extraordinary war measure, this Agreement was suspended by Order in Council on July 27th, 1918, along with all other rate limiting agreements. The suspension lapses on July 6th, 1922.

To secure a just perspective we must contrast, very briefly indeed, the situation as it was a quarter of a century ago with that of today. When the Agreement was signed the Canadian Pacific was operating 7,400 miles of track, as compared with 11,000 miles at the present time. The subsidies mentioned above were designed to aid in opening up mineral lands and to have the effect of lessening freight rates until the volume of traffic should have increased to a point where such lessened rates would be profitable to the railway. At that time the shipment of fruit from West to East had not begun. Nor was the coal trade then much more than a hope. The value of the territory to be opened up, and the profit to the railway therefrom, were alike matters of pure speculation.

The scope of the Agreement was ill defined. No understanding was arrived at as to whether it would or would not apply over all subsequent extensions of the Canadian Pacific. This is a matter yet to be decided. At best, the Agreement was a slip-shod attempt at freight-rate control.

It would be unprofitable to recite the numerous arguments for and against the further suspension of the agreement on July 6th. The central points of the whole situation are apparent. They are these:

The Canadian Pacific has vast reserves of physical assets and cash. It is a well managed, dividend paying institution.

The Government Railways are in desperate plight. They are not well managed, neither are they dividend paying. Yearly and daily they are piling up deficits.

The Board of Railway Commissions has no legal authority to deal with the Agreement.

Western members of Parliament are clamorous for renewal of the Agreement and for lower freight rates generally.

The Railway Managements claim that their earnings will stand no reduction.

Now, it does not seem to us to be meeting the question fairly at all, to urge, as do certain Parliamentarians, that the Canadian Pacific should be bled to ease the situation temporarily. Such a course would make Canada a laughing-stock. Nor is the gradual reduction of rates a remedy to be recommended; much less in any radical reduction. The problem can be summed up in a few words:—How can our freight earnings be increased? From what source can new freight be derived in sufficient volume to justify a recession in rates?

The solution of the question demands statesmanlike qualities in those whom the nation charges with the task of solving it. Those of our representatives at Ottawa who have sufficient ability to form opinions based on the experience of other countries, will perceive the impossibility of making our railways pay and, therefore, the impracticability of freight-rate reductions, before such time as our mineral industries have so advanced as to contribute at least twice as much to the freight traffic as they do at present.

The more attention Ottawa pays to the mining industry, the sooner will our railway deficits be replaced by surpluses.

THE EMPIRE'S MINERALS

In the world's production of mineral wealth, the British Empire bulks large; and in the Empire's total, Canada takes second place only to the mother-land, whose output of coal will keep her long in the lead. Apart from coal and iron, Canada's mineral production is the most important item of the Empire's total; and this item is increasing with such rapidity, and holds so much promise for the future, that many eyes are now being turned toward the hills and mountains of our country, many of them rich with hidden store of wealth.

Hitherto, little attention, either official or private, has been given in Britain to the mineral wealth of the Empire's largest Dominion. This is no longer the case. The upheaval of war resulted, among other advances, in the formation of the Imperial Mineral Resources Bureau. Such an institution was decided on at the Imperial Conference of 1917, when it was clearly seen that the various anomalies of mineral production throughout thte Empire not only hindered the successful prosecution of the war, but prevented profitable economic development during times of peace. In 1919 the Imperial Mineral Resources Bureau received its Royal Charter, as an Imperial body, independent of direct Governmental control. Since that time, the work of its twelve governors, its 150 special correspondents and its hundreds of temporary members, specially co-opted for specific purposes, has already had remarkable results.

The Bureau's methods are characteristic of British thoroughness. Each mineral of importance is considered by a special committee, who gather the material available from the most reliable sources throughout the Empire. A memorandum is prepared, and a copy sent to each member of the committee concerned; then, at a general meeting, it is gone through, word by word, and finally published, after a process of preparation that ensures not only its authenticity, but also its coherence and balance.

Canada's representative in the Imperial Mineral Resources Bureau is Dr. W. G. Miller, Ontario's Provincial Geologist. Canada has no son more worthy to represent her in this Imperial gathering. Always known as a scientist of wide outlook and penetrating judgment, Dr. Miller will represent Canada fairly and judicially in the little grey volumes that are now circulating throughout the world.

That Canada's representative in this Bureau is a sound optimist, is well illustrated in the three reports reviewed today on another page. It is such peeps into the future that fire the imaginations of prospector, investor and operator, and inspire them with the energy and the courage necessary to find and develop the ore-deposits that will one day show that Canada is the Empire's chief treasure-house of mineral wealth.

EDITORIAL NOTES

A view of the railway stations in Northern Ontario is a good indication of the activity in prospecting to be expected throughout the Northland during the present season. The men of canoe and pack are now on the water-routes in larger numbers than for some years past, and will soon be lost to sight in the fastnesses of their respective fields. Gold is what most of them are after. Even while snow covered the rocks, hundreds of claims have been staked. The work that really counts for progress has just now commenced. There is ample promise that this year's activities will see the delimited gold-bearing areas extended far from the original discoveries.

As a foretast of his final report, the description in the *Engineering and Mining Journal-Press,* by Mr. Cyril W. Knight, of the Ontario Department of Mines, of the silver deposits of Cobalt, is extremely interesting. His is a welcome prediction, that profitable silver mining will continue in the famous camp for many years to come. His work of the past two years, to be continued during the present season, has mainly in view the aiding of profitable mining by means of a careful and comprehensive geological study.

The Council of the Institution of Mining and Metallurgy, London, England, preserves strict control of the professional conduct of members of the Institution. Cases of unprofessional procedure are investigated and summarily dealt with. Lately the Council placed itself on record, in unequivocal language, respecting the moral and professional obligations of the engineer to his employer. The Council's pronouncement is positive and unqualified. Strong emphasis is put upon "the necessity of recognizing "that an employer has the right to be consulted before "any information relating to his affairs is made public. "This obligation does *not* depend upon any contract that "may have been entered into between an engineer and an "employer, or whether it has terminated or not." To this the *Canadian Mining Journal* fully subscribes.

A very earnest and equally vocal United States Senator whose name (it is not easy to believe!) is "Dial," passionately denounces any and all liberties taken with Standard time. The Senator is from the sunny South. Lord Byron wrote of the effect of hot climate on temperament. Senator Dial lends point to Byron's verse. He condemns utterly those who dare meddle with the measurement of time as ordained by the Almighty! Three cheers for the Senator! Let no scoffer arise and recommend treatment by "dialysis" for the Senatorial thought processes.

Another crusader against the evils of modernity is that dear old biological sport, Mr. Williams J. Bryan. With the perseverance of all the departed saints, Mr. Bryan is fighting the growth of evolutionary thought. Indeed, almost did he succeed in having the teaching of evolutionary principles expunged from the curricula of the State schools of Kentucky. Some sons of Belial accuse the ebullient editor of the "Commonwealth" of playing to the gallery. Fie! Fie! Mr. Bryan is a sincere *devolutionist*!

The new plant for the concentration and sintering of lean magnetic iron ore at Babbit, Minn., will begin to produce in quantity during May. It is considered now that the problem that remains to be solved is a system of mining that will give a minimum of cost. So far as the mill is concerned, everything that comes up goes through the whole process without any handling, no selection or cobbing, just a steady stream of earth's crust pouring in at one end, and coming out at the other in two streams, sintered ore and tailings. It sounds rather like the oft-pictured ideal sausage machine, where the animal walks in at one end, and comes out at the other end in sausage cases—but with the sausage machine there are no tailings!

MINING VOLUMES FOR SALE

The following volumes, left by the late Professor J. C. Gwillim, of Queen's University, and now the property of Mrs. Gwillim, are for sale.

Those interested in any of these volumes are invited to correspond with Prof. G. J. MacKay, Queen's University, Kingston, Ontario.

Mineral Industry—Vols. I to X. (Vols. I, VI, VIII, and IX are absolutely out of print.)

Canadian Mining Journal—Vol. 28 (1907) to Vol. 37 (1911).

Journal of the Federated Canadian Mining Institute—Vol. 2 (1897) and Vol. 3 (1898).

Journal and Transactions of the Canadian Mining Institute—Vol. 3 (1900) to Vol. 22 (1919). Summer Excursion (1908). One volume General Index and Summary of Papers, Vols. 1 to 10. One volume.

Transactions of the American Institute of Mining Engineers—Vols. 31 (1901) to [illegible] (1911).

Note.—All the above are well bound and in good condition except Transactions C. M. I. Vol. 11, which is paper covered.

The effect of the Rand strike was very disastrous upon gold production. January's production was only [illegible] and that of February nearly 77,000 ounces. The total for the March quarter is expected to be in the neighbourhood of [illegible] ounces. [illegible] full output [illegible] cannot be expected until July. A recent estimate [illegible] production is 75 per cent for April, [illegible] per cent for May and June respectively, and [illegible] per cent for July, subject of course to any untoward changes.

The British Ministry of Labour reports that, between the first of the year and the end of March, changes in wage rates have brought about a reduction in weekly wages of £1,210,000, affecting nearly 2,000,000 workers, and an increase of £3,100, affecting 31,000 employees.

THE PROSPECT

Mister, the world's three-quarters
Is filled with stuff like this
And that's what I aim
At doing [illegible]
I want ten thousand [illegible]
[illegible]
M[illegible] my pardner [illegible]
Knows [illegible] what we got
You'll [illegible]
[illegible]
That [illegible]
Say, Mister, [illegible]
[illegible] we [illegible] got gold
But look at [illegible] quartz
You don't need to be told
That [illegible]!

ANON.

Geology and Mineral Resources of Rice Lake and Oiseau River Areas, Manitoba

Under the above title, Part C, 1921, of the Summary Report of the Geological Survey of Canada has just been issued. In it Dr. H. C. Cooke gives the evidence collected during his examination of the two areas during last summer and during the subsequent work in the laboratory. The 35 pages of text and diagram are a model of close and consistent geological reasoning, and deserve more space than can be given them here, where the pointed and lucid conclusions of economic importance must be given more notice. Geological maps of both areas, on a scale of approximately a mile to an inch, are included.

An addition to the Survey's reports that will prove most acceptable to the average reader is the word-picture of the geologic history of the district, given as a summary on pages 34 and 35. This is as vivid as a lucid writer can make it, and, coming after the detailed evidence of the report, is most convincing. It pictures the outpouring in primordial times of successive flows of igneous materials to form beds of volcanic rocks such as basalt and tuff. Submergence, either regional or local, resulted in the deposition of sediments, all these rocks belonging to the Rice Lake series. Then came folding, and the intrusion of batholiths of granite, followed by a period of faulting and the formation of schisted zones. A second intrusion followed, this time of basic dykes and sills. Within the sills there was differentiation by gravity, and deposits of nickel-bearing sulphides gathered on the lower, basic side. Further faulting and folding forced the whole series into an inclined position, when a second granite intrusion occurred. From this later granite there came solutions that, escaping through the sheared zones of the older rocks, left there their load of silica, carbon dioxide, sulphur and iron, with minor amounts of gold and copper.

Nickel Ore

Dr. Cooke demonstrates that the nickel ore of both the Oiseau and Maskwa regions originated as mentioned above. In this connection he gives a tip to the prospector. "Attention may be called to the fact that ore-bodies cannot occur in connexion with any bodies of gabbro other than the large sills that have undergone the differentiation described. Bodies of gabbro of all sizes are to be found in many places throughout the district—dykes, which even an untrained observer can see to be of similar composition from edge to edge. It is absolutely useless to search for ore-bodies in the neighborhood of such masses; the effort is merely a waste of time and money." Dr. Cooke gives the prospector credit for acumen and reasoning power beyond the ordinary, and makes no mistake in doing so. He also points out the possibility of using the magnetometer as an aid in prospecting drift-covered areas — a method that has been of great practical use in locating similar ore in the Sudbury district.

Gold Ore

The deposits of gold ore are characterized as difficult of access and, in general, low-grade. This has prevented any important mining development by well-established companies. "Others, however," says Dr. Cooke, "less well-advised, have established workings foredoomed to failure by the poverty of the deposits exploited; and in still other instances more or less work has been done by companies as a basis of extensive stock-selling campaigns."

In his summary description of the gold deposits, Dr. Cooke says:

"The gold deposits of Rice Lake district are vein fillings and replacements in belts of schist formed by earlier faulting. The principal veins are found in shear zones that cut through the older rocks to contact with the later granite, rather than in shear zones that do not so terminate. The veins gradually decrease in size with increasing distance from the granite contact; and their composition varies in such a way as to indicate deposition from hot concentrated solutions in and close to the granite, and from cool dilute solutions at a distance. It is, therefore, concluded that the vein materials were deposited from solutions emanating from the later granite.

"The shear zones are found in the Rice Lake series and the earlier granite. The later granite also was jointed, and the joints were filled with auriferous quartz. Such veins are mostly small, although lenses 3 to 4 feet in width have been found. Prospecting in the later granite, therefore, although probably less apt to be rewarded than in the older formations, may reveal the presence of small deposits of fairly rich ore.

"The vein materials are principally quartz, albite, iron carbonate, pyrite, chalcopyrite, and free gold. The carbonate is characteristically deposited at a distance from the granite, the quartz closer to it, the albite in or very close to it. The sulphides may or may not carry gold values.

"The free gold appears, in most cases at least, to have been deposited in the quartz after it was shattered by movement. In great part it seems to have been deposited fairly close to the later granite, although found in small quantities at quite considerable distances away.

"The bodies of quartz, like the shear zones in which they occur, vary greatly in width from place to place, forming lenses both in horizontal and vertical section. Small bodies of the later granite may have formed enriched veins like the larger bodies, but the veins so formed are commonly rather short.

"Apparently, therefore, the most favourable localities for prospecting lie in the Rice Lake series or the earlier granite, near a contact with the later granite. The earlier granite may be recognized by the belts of schist and the basic dykes that cut it. The later granite is not thus cut, although it may be more or less jointed."

This report demonstrates clearly, once more, the value of geological study to the prospector and miner. Clear-cut conclusions of distinct and direct practical value are characteristic of the work of the modern economic geologist. . .

WANTED — A GRUBSTAKER

A correspondent in New Westminster, B. C. has lately located, one hundred miles east of Vancouver, a series of quartz veins containing visible gold. He describes them as from 6 inches to 48 inchees in width, in a diorite rock,and of undetermined length. He would like a partner, on a 50 - 50 basis, to provide money for development. This prospector's address can be had on application to the Journel.

From the treatment of 314,820 tons of gold ore and tailings, the Oregum Gold Mining Company of India, Limited, extracted 101,592 ounces, at a gross profit of £246,397.

The Uses of Concrete in Mines

By ANTON S. ROSING

Mining is an industry that labors under unusual difficulties. The hazards of above-ground construction and industries are accentuated below ground because of confined quarters, distance from the base of supplies and difficulties of summoning aid in emergencies. Fire, a serious enough proposition in case of surface structures, is many times more serious in a mine, where the heat and smoke are confined and intensified, forestalling adequate fire-fighting measures and preventing work, if not even the escape of the employees. Once fire has attained headway there are almost no effectual means of combatting it except sealing or flooding the mine, both of which entail complete stoppage of operations for long periods. Fire-fighting in mines must, therefore, consist largely of preventative measures, which simply means careful attention to fireproof construction at vital points and possible points of beginning, and the erection of fire and smoke-proof barriers between various divisions of the mine.

Concrete-lined Hoist Room at Bunker Hill and Sullivan Mine, Kellog, Idaho

As with fire, water forms a more serious menace below ground than above. Many a mine has proved unprofitable because of pumping expenses. And as with fire, again, preventative measures are the most effective, and construction and materials must be used that will effectively and continuously exclude water and resist rot and decay. Construction at vital points in mines should always have this point carefully in view. Structures must be built so that time and wear does not result in weakening and leakage, with the resulting losses and expenses of shut downs for repairs. This is especially true of the main artery of the mine, the mine shaft. If it is to give continuous, uninterrupted, water tight service, its construction must be sound and the proper materials must be used.

The First Concreted Shaft

It is less than two decades since the first concrete lined mine shaft was built in 1903 at the Tug River mine in West Virginia. Within that time, however, concrete shaft linings have not only become recognized as the superior type of lining, but a variety of designs and methods of construction have been developed that enable the erection of fireproof, gas and water tight, and repair proof shaft linings of almost any form and under almost any condition. In Europe the value of these features has long been recognized, and mine shafts have been lined with masonry and even cast iron in the effort to obtain dryness, fire safety and freedom from maintenance expenses. But the American types of concrete linings represent a long stride in advance, from the standpoint of economy, safety, speed of erection and adaptability to unusual conditions.

A similar application of American ingenuity is to be found in the increasing use of standardized concrete units in the replacing of wooden posts for timbering or for mine props. These units may be used over and over without difficulty and have the added advantage over wood that they are rot proof and can be depended on to serve their purpose without renewal as long and under whatever conditions they are used. Standardized, pre cast units are also used in the construction of bulkheads and stoppings where the rot-proof, gas and water tight features of concrete are valuable.

Indeed throughout the mine, wherever there is need for strength to sustain walls and roofs, for fire safety, water tightness, adaptability to unusual conditions and for speed of erection, there concrete is being used to an ever increasing degree because it serves as no other material can. A few of the principal adaptations of concrete to mine work will be here described.

SHAFT LINING

Concrete is now recognized as the best material for the lining of mine shafts, and is almost universally used for that purpose in this country. It is also rapidly displacing other forms of shaft lining in European and South African mines.

The reasons for this are: first, that the concrete lining is fireproof; second, it is waterproof and all the troubles due to seepage attaching to other forms of lining are permanently eliminated; third, it is permanent and need not be replaced or repaired during the life of the mine; fourth, it can be adapted to any form of shaft; the shaft need not be limited to any certain shape on account of the rigidity of the lining material. A concrete lined shaft may be square, circular, elliptical, oblong, or a combination of all these shapes in its cross section as occasion may require.

The usual method of lining shafts with concrete is in successively lower sections of suitable height, the work being done at the time the shaft is sunk. When the sinking has progressed sufficiently to make a workable job of concreting, substantial forms of wood or steel are built and the bottom opening between the form and the rock is sealed. The annular space between the form and the surrounding rock or earth is then filled with concrete from above, the mixer being placed on the surface in close proximity to the shaft opening. The concrete is either shot from the mixer through a pipe into a hopper emptying directly into the forms or, as is the usual method, lowered in buckets to a platform or hopper at the top of the forms. When the forms have been entirely filled they are left in place until the concrete has entirely set. Thereupon they can be removed, cleaned, and used again for the next lower section when this has been excavated, and this operation is repeated until the bottom of the shaft has been reached. In using this method the greatest care must be exercised that the closure joint of one section to the one next above is made watertight.

BEFORE —

The Main Haulage Way in Ray Consolidated —

In some instances, notably in the case of relining old shafts, the lining is done from the bottom of the shaft upwards, the old lining being removed from below as the placing of new lining progresses. In every other particular this method is similar to the one described above. This method may also under certain conditions be used in lining new shafts but would be limited to cases where no trouble is encountered from excessive seepage or from slipping of the rock or soil.

Concrete Shaft Timbers

Concrete mine timbers are used for the replacement of the wooden timbers in mine shafts where it is not desirable to employ the monolithic type of concrete lining. These timbers are pre-molded on the surface and after thorough seasoning are taken into the shaft and put in the position of the decayed or broken wooden timbers. The timber may be square, rectangular, or T-shaped in cross section and the ends so shaped that they will interlock and hold each other firmly in place.

In the case of existing shaft linings of wood or steel, when it is desired to increase their fire-resisting and waterproof qualities without replacing the lining itself, this may be done by enclosing the existing lining timbers in a cement plaster on wire netting or expanded metal. The mortar can best be applied by means of an apparatus like the cement gun.

Cementation in Wet Ground

In shaft sinking, if a water-bearing stratum is encountered, the difficulty may be overcome by means of a process first developed in France and now known as cementation. The process consists in drilling a number of holes arranged in a circle surrounding the shaft site into the water-bearing stratum. Into these holes is then pumped a cement grout until the fissures are entirely filled. When this has set, the sinking may proceed and no further trouble will be had from that stratum.

Shaft Lining of Concrete Slabs

A novel and efficient method for lining mine shafts from the top downward at the time of sinking has been devised by a Scotch mining engineer. This method consists of the successive interlocking of sections of pre-molded reinforced concrete blocks or slabs of Z-shaped cross section. The sections are hung one on another from the top downward, the top section being hung in the strong crow's-ring let into the standing rock at the top of the shaft. Several successive rings of the lining having been placed in position, the annular space between the lining and the surrounding rock is sealed at the bottom and the enclosed space filled with a cement mortar of suitable strength and consistency injected through holes provided in the slabs for that purpose. This mortar when set firmly binds the lining to the rock, which then carries the weight of the lining and no danger exists of breaking one section by the weight of the lower ones. The mortar also serves to effectively seal all joints and make the lining absolutely watertight.

This method dispenses with all form work in the shaft and permits the shaft sinking and shaft lining to be carried on simultaneously and without appreciably interfering with each other, the slabs having, of course, been made in sufficient quantity in advance to permit of rapid and continuous work.

A non destructible, homogeneous, fire and waterproof lining is thus produced giving uninterrupted service without maintenance expense throughout the life of the mine.

GALLERY LININGS

The best way to line galleries and passage-ways is by a monolithic reinforced concrete lining. The forms should be of the standard section, collapsible type, of wood or steel which may be erected, taken down, and moved ahead as the work progresses. This type, which is the most economical of form material, insures the greatest speed in erection and removal, insures uniform passageway area,

and may be used a great number of times without renewal.

The concrete may be mixed on the surface, lowered in buckets, and moved on cars to the form to be filled, or it may be mixed in the mine in convenient proximity to the work. In the latter case care must be exercised in regard to the materials used. Mineral ore, coal or other unsound materials should not be used for the aggregate but only clean gravel or sound rock broken to suitable size. Mine water should also not be used for the concrete as it generally contains acids, but clean fresh water should be brought from the surface.

The passageway thus lined has the great advantage of being fire and waterproof. It is also free from the annoyances due to the suspension of all traffic at frequent intervals by reason of rocks falling on the track from the roof, and once the lining is in place it will require no further thought nor worry nor will it require any expense whatever for maintenance.

The passageway should be concrete lined as soon as possible after being opened. If this is done a much thinner lining will be required than will be the case when disintegration has set in, caused by contact of air-currents with the rock.

either case it will be absolutely fireproof and an effective fire and gas barrier. If of the monolithic type the same comments on the methods of construction apply as to gallery linings.

SHOPS, TRACK TIES, ETC.

Shops, stables, hay rooms, and powder bins and similar structures may be built of monolithic concrete cast in place or of pre molded concrete blocks set in cement mortar. Either method will result in a fire and water proof and permanent structure.

Track ties should be of pre molded concrete blocks of suitable length and cross section and thoroughly seasoned before being used.

Water-bearing rock crevices in unlined galleries, shafts or rooms may be effectively plugged by shooting cement mortar into them with the cement gun. Existing mine structures may also by the same method be made fire resisting by a coating of cement mortar applied on an expanded metal or wire enclosure.

More than ever mining engineers are finding that their job is more than that of simply building a workable mine. They must build mines that can be worked continuously and efficiently with the minimum of stoppage and the

— AFTER

— Mining Company's Mine at Ray, Arizona

PROPS AND TIMBERS

A serious difficulty in mine operation is the necessity for the frequent renewal of wooden timbers and props occasioned by the intensive wet rot that in some cases makes imperative their renewal every six months, and occasionally much more frequently. This is an expense that adds considerably to the cost of operating and maintaining the mine. This difficulty is solved and the attendant expense eliminated by the substitution of concrete timbers.

These are pre molded in a suitable shed on the surface and are usually 8 by 8 inches in size and of various lengths to suit local conditions. The edges should be beveled to prevent chipping in handling, and after having been molded the timbers should be permitted to season for two or three weeks or longer during which time they should be watered daily. When so made they can be used again and again, indefinitely, or left in one place as long as may be required, and no expense is attached to the timbering of the mine other than the cost of labor for placing it, and moving it from place to place as may be required.

BULKHEADS AND STOPPINGS

These may be constructed of either monolithic concrete cast in place or of pre molded concrete blocks set in cement mortar. The former method is preferable as it insures an absolutely tight contact with the surrounding rock and a perfectly gas-tight wall throughout. But in

minimum of avoidable expense. Fire hazards must be eliminated in every possible way. Precautions must be taken with construction that will prevent accidents and injury to personnel, which often not only prove annoyingly expensive but reduce the efficiency of labor. Leakage and rotting must be avoided in the materials of construction so that replacements will be reduced and the failure of material from unseen causes eliminated. It is because of concrete's certainability to resist fire, water, wear and rot that it is so being used increasingly as a construction material in mining.

UNDERMINED GRAVEL — PAID $200 FINE

Before Magistrate Atkinson at Iroquois Falls on May 10 Walter Monohan of Matheson was charged by the Ontario Department of Mines with undermining in an open gravel pit contrary to Rule 131 Section 161 of the Mining Act. He was fined $200 and costs.

It is not generally recognized by the public that the [illegible] of the fatal accidents in mining and quarrying operations [illegible] to a contravention of this regulation [illegible] out of all proportion to the numbers engaged in sand and gravel pits. It is natural to undermine the sides of a pit and gravity induces a fall of ground. And the inevitability of accidents in such a case has given rise to the prohibiting by law of the practice.

Gold Copper and Tin--1913-1919

BOOK REVIEW

The three latest publications of the Imperial Mineral Resources Bureau are now being distributed. They consist of three exhaustive reviews of the world's output and resources of gold, tin and copper respectively, and constitute parts of an elaborate series covering each important branch of the mineral industry for the period 1913 1919. Each of these three reviews is worthy of separate notice.

1.—GOLD, 1913-1919.—Throughout this report there is evidence of careful and painstaking selection and compilation. What figures and comparative statistics are given have not been chosen at random. The text is well edited.

The report, which, from its dimensionss, attains the dignity of deserving the appellation "volume," opens with a general geological sketch, touches on metallurgical progress, the price of gold, and the world's production, and then presents more than 300 pages of matter pertaining to the gold-bearing fields of the British Empire and of Foreign Countries.

On many pages there are facts and figures that are either new to the generality of readers, or have been forgotten by many. A glance at a few of these will not be amiss.

On page 9, reference is made to the successful use of the chlorine process of refining bullion at the Royal Mint, Ottawa, and to its adoption in Porcupine. The "Marathon" rod mill, for the comminution of lead and copper ores is also mentioned. Both these innovations in modern practice are noteworthy.

Very interesting indeed is the description (pp. 10 and 11) of the arrangement made in 1919 between the Bank of England, the Union (South Africa) Government and the gold producers, the latter represented by the Transvaal Chamber of Mines. Briefly it is as follows:—The gold producers consign all gold, refined and unrefined, to the Bank of England, witholding only enough to meet local currency needs. The Bank turns the gold over to the producers' refiners. The sale is negotiated by the producers' appointed agents, Messrs. Rothschild, at the best competitive price obtainable. The Bank has authority to issue licences for the re-export of the gold, at any time within five weeks of its arrival of the Bank. This period is lenthened by three or four weeks as the consignors cable London the amount of each shipment. All freight, insurance, refining, assaying and marketing charges are borne by the producers. The Bank is authorized to make interest-bearing advances against the gold. The effect of the whole arrangement is to provide a free market for the producers' gold. Australian producers, organized as the Gold Producers' Association, Limited, have a similarly advantageous market.

The world's production of gold is next summarized. For the period 1493-1600 (108 years) the annual output is estimated at slightly less than 250,000 ounces. The increase is not marked until the discovery of gold in California in 1848. Before this time, from 1760 onward, the Russian Empire led the world, its gold being won mostly from placers. During the period 1851-1860 (10 years) the annual average was 6,400,000 ounces. It is now close to twenty million ounces.

Of this vast total, the British Empire was credited with 67.20 per cent. in 1919, the United States with 16.52 and other countries with 16.28 per cent. The Union of South Africa contributed 47.15 per cent. of the whole; Canada, 4.34 per cent. It will be seen that Canada has yet a long road to travel before it can be esteemed a competitor of the Transvaal.

It will not be uninstructive here to compare three great gold mines, one each in the United States, the Transvaal and Canada. The Homestake, discovered in 1876, was equipped with 740 stamps in 1880. Later the number was increased to 1,020. In 1912, more than 1,500,000 tons of ore were milled, the average cost per ton being about $3.20, and the recovery of gold and silver approximately $4.40 per ton. Up to the end of 1912 (35 years) the total bullion output was $115,000,000, of which 25½ per cent. was paid out in dividends, or roughly, $29,000,000. The proved ore reserves amounted to 15,000,000 tons; probable ore, 40,000,000 tons. Since then, production has fallen greatly, owing to extrinsic causes, labour and high cost of supplies being the chief factors in the decline. Ball mills have now replaced the stamps in great part.

On the Government Gold Mines Areas, (Modderfontein), Transvaal, the developed ore reserves, at the end of 1920, were 10,291,000 tons, the average value per ton being 34.85 shillings and the stoping width 77 inches. This estimate included all ore of a value of $4 and over. But, until recently, costs were increasing so rapidly that millions of tons of lower grades of ore have to be eliminated from estimates.

Up to the end of 1921, the Hollinger had paid out $16,558,000 in dividend, out of a production of $41,193,-935 (period of less than 11 years), and at that date reported about 3½ million tons of developed ore reserves, valued at $36,644,154.

The comparison is given meaning when it is remembered that the Hollinger is not yet in the prime of its production whilst the other mines have, presumably, seen their best days.

While there is much material throughout the Report that invites either comment or quotation, the limits of space will permit neither. Suffice it to say that Europe, Africa, Asia, Australia and the Americas are not neglected. Care and discrimination have been used in choosing and editing the huge mass of information comprised in this really praiseworthy volume.

2.—COPPER, 1913-1919.—One of the opening paragraphs of this report is highly significant of the fact that renewed prospecting for copper is a *sine qua non* if a cheap supply is to be counted on in the future. "It is important to realize that these enriched [secondary] deposits have yielded in the past a large part of the world's production, and that the maintenance of a supply of cheap copper will depend in large measure on the discovery of new areas of such enriched deposits, which are most likely to be found in regions of small rainfall, particularly in tropical countries." It is pointed out that large tracts of Africa, northern and eastern Asia, and south and central America still invite the explorer and prospector. Of these regions, we may add, the British Empire embraces no small part.

The world's production of copper was only 9,000 long tons per annum at the beginning of the nineteenth century; and at the close, somewhat over half-a-million tons. Over-production marked the war period. Normal requirements today probably approximate one million tons annually. Producing more than half the world's total, the United States ranks an easy first, with Chile, second and Japan third. Canada ranks sixth. The United Kingdom,

from being an important producer sixty years ago, has fallen from its high estate to a position of negligibly small account.

In the consumption of copper, before the war, the order of importance was United States, Germany, England and France.

Eighteen pages are assigned to a summary of Canada's copper resources. In this summary we are glad to notice that Manitoba comes in for due attention.

Even casual reading of the volume indicates two things very plainly, — the tremendous potentialities of various parts of the Empire, and the absolute necessity of organized exploration and prospecting.

A comparison of pre-war and post-war costs per pound of copper produced shows that they ranged in 1913, from 8.65 cents (Utah) to 14.23 cents (Calumet and Hecla); while in 1918 the corresponding range was 11.26 cents (Inspiration) and 21.05 cents (Calumet and Hecla).

The geological information interspersed throughout the volume gives it added value and meaning.

3.—TIN, 1913-1919.—What the average mining man and prospector does *not* know about tin is contained in extant literature, tin has been little regarded in Canada, and less looked for.

The only important ore of tin is cassiterite, the oxide. The great bulk of the world's output is derived from alluvial deposits. Vein workings are as yet unimportant. The present methods of smelting tin are essentially crude, and electrolytic refining has not yet been brought to a point where its advantage over older methods is firmly established.

A graph, showing average prices per ton for 140 years, indicates a widely fluctuating market. In 1870, the price was less than £70 per ton. During the later years of the Napoleonic wars, the price rose to nearly £160, fell thereafter, rose again during the Crimean campaign, and then displayed irregular movements (approximate periods of high prices recurring every 5 or 7 years) until the late war, when the ascent to £380 per ton was spectacularly rapid. Of late years it has fallen once more, the present price being round £165 per long ton.

Of the world's total output, the British Empire contributes slightly over half. In this production the Federated Malay states are by for the largest factor, Australia coming next, followed by Nigeria, United Kingdom and South Africa in order of naming. Of foreign countries, Bolivia ranks highest, contributing about one-fifth of the world's total, the Dutch East Indies ranking a good second. The aggregate smelting capacity of the various leading consuming and producing countries exceeds the annual supplies of ore, considerably.

It is somewhat anomalous that, while the United States consumes more than 40 per cent. of the world's production it produces practically no tin. In both the United States and Canada there have been local flurries over the discoveries of tin-bearing veins in granite and granite-porphyry dykes; but nothing has come of them.

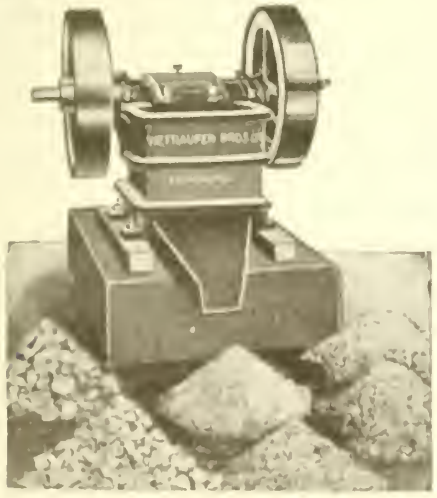
There seems to be no valid reason why payable tin deposits should not be discovered in the northern half of this continent. Incidentally, tin may be replaced in commerce by other metals, but there will ever be a strong demand for it.

To all three of the volumes thus hastily noticed are appended copious bibliographies. No Canadian who wishes to widen his point of view should neglect this opportunity of securing these excellent publications from the Imperial Mineral Resources Bureau, London, England, through H. M. Stationery Office, Imperial House, Kingsway, London, W. C.

The reviewer finds that he has omitted mention of the fact that Dr. W. G. Miller has taken a very active part in the work of the Bureau, as Canada's representative. Thus are the ties of Empire wrought and strengthened.

A CANADIAN LABORATORY CRUSHER

Heretofore it has been the universal custom to use imported crushers in the laboratories of Canada, and indeed, it has been, until recently, necessary to do so. Now there is on the market a Canadian made crusher that has been tested and proved in use sufficiently to demonstrate its sterling qualities, and it will not longer be necessary to depend upon its imported competitors.



Wettlaufer Brothers, Ltd., of Toronto, known chiefly as manufacturers of concrete mixers, hoists, rolls, etc., manufacture a crusher, illustrated herewith, that will handle almost any crushing problem where only small quantities of rock material are to be reduced. It will break rock from 3" size to a coarse sand in one operation, and is adjustable while running. It has only three bearings. The jaw plates are of manganese steel. The crushing is accomplished by means of the combined horizontal and vertical movement of the moving jaw, which is so highly effective in such a type of crusher.

This Canadian made crusher will doubtless find its way into many a laboratory throughout the mining districts of Canada as its qualities become more widely known.

A combination drum and scoop type feeder, the largest size of which has a capacity rating of 2,000 tons of dry ore per twenty four hours, has recently been designed. Such a combination enables the feeder to take a large initial feed and several hundred per cent circulating load as well.

Aside from its large capacity, all parts are reversible. This enables the purchaser to reduce his stock when he has mills operating in opposite directions, as by merely changing the parts the same feeder can be used on a mill rotating in clockwise or counter clockwise direction. Parts are made replaceable to take care of ordinary wear, so that the cost of renewing parts is small.

The initial feed is fed by a chute to the opening in the drum. A scoop on the outside of the drum operates in the ordinary feed box, but it does not have to handle large material; therefore, wear is greatly reduced and there is no danger of breakage to the box.

This feeder is manufactured by the Hardinge Company, 120 Broadway, New York, N. Y.

News of Mining

The oil shales of the Wolgan Valley, New South Wales, yield from 100 to 150 gallons of oil per ton. The oil bearing shales do not exceed four feet in thickness. It is here that the plan of burning the shales *in situ*, for the distillation of oil and the generation of power from gas, is being tried. Success has crowned the first experiments. Labour troubles are responsible primarily for this radical departure from accepted practice.

The British Institution of Petroleum Technologists started in 1918 an inquiry into the available quantity of cannel coal in Great Britain for utilization as a source of gasoline, fuel oil, and other kindred products. In its report, a special committee stated that it is practicable and commercially fusible to retort at least 1,200 tons of cannel and similar coals per day. The average yield would be 300,000 gallons of crude oil daily. The agitation of labour for the substitution of the shovel for the fork has a bearing on the amount of material ultimately available. High-ash residues are pronounced usable in producers as sources of power gas and ammonia. Low-ash residues can be briquetted. Carbonization at two temperatures is the key-note of the problem.

The Boston Montana Mining Company is reported to have begun legal proceedings against the mining engineer who recently reported adversely on its property. After publication of the (Herzig) report the company's brokers, Harris and Company, refused to act any longer in the capacity of fiscal agents for the company.

Stasite, Kasolite, Curite, Dewindtite, are the names of four new radioactive minerals identified by Professor Alfred Schyep, University of Ghent, Belgium. The fifth and sixth minerals have not yet been named. The first four are hydrous oxides of lead and uranium. The two nameless minerals are, respectively, a hydrous silicate of uranium and a uranium hydroxide.

The income account of the Phelps Dodge Corporation shows an operating loss of $8,539,068.22 for the year 1921. The Inspiration Consolidated Copper Company's loss for the year was $1,790,241.18, whilst the deficit of the North Butte Mining Company was $326,575,70.

At the Baltimore meeting of the American Electrochemical Society, April 27-29, Mr. M. C. Gilman, of Winnipeg, stated that there would soon be hydro-electric energy available in the Winnipeg district to the amount of 320,000 h.p., with a further undeveloped reserve of 250,000 h.p. A plant now nearing completion represents an outlay of only $75 per horse power, a figure much lower than corresponding costs at Niagara Falls. Mr. Gilman laid especial stress upon the abundance of accessible raw materials for the manufacture of alloys, abrasives, etc. The Society's next meeting is to be held in Montreal in September.

It is stated, unofficially, that potash compounds are now being used in Germany for the desulphurization of cast iron.

A movement to place potash upon the free list of the United States tariff is being sponsored by Senator Harris, of Georgia. The Senator claims that any other arrangement will be unduly costly to the farmers, who are the most important users.

Drilling by the Texon Oil and Land Company, in Reagan County, Texas, has revealed the presence of potash deposits that may prove commercially valuable. Samples from a depth of 1,150 feet down to a depth of 1,325 feet, contain from 2.46 per cent. potash to 8.29 per cent. The latter percentage holds for only nine feet. It will be necessary to check up all present figures by means of core drilling.

Reports from South Africa, apparently authentic, state that recent investigations there have demonstrated the existence of iron ore deposits and coking coal seams sufficiently large to warrant the immediate erection of blast-furnaces, a steel plant and by-product ovens. The project is to be financed by English and South African capitalists.

The prohibition of German trade with Australia ceases on August 1st of this year. Australians interested in the development of the domestic iron and steel industry express great alarm at the prospect of German competition. An agitation is on foot to renew the trade prohibition in modified form.

In a statement issued late in March, Mr. Colin Fraser, managing director of the Associated Smelters, Port Pirie, New South Wales, asserted that underground operations at Broken Hill could not be continued if the 35-hour week remained in force. Both mines and smelters would have to close unless costs are materially reduced. Competition with Canada, United States, and Burma, is now, according to Mr. Fraser, impossible. The Sulphide Corporation also has announced the practical closing down of its smelters because of the 35-hour week.

Adverse conditions in Norway caused the total cessation of nickel ore, molybdenite, and chrome ore mining during 1921.

Holding that foreign competition necessitated the step, the Australian Federal Arbitration Court has reduced the basic wage at the Port Pirie smelters to 12s. 8d. per day. It was formerly 14s. 8d.

The ore milled at the Transvaal Crown Mines during 1921 amounted to 2,177,000 tons, the total yield being £2,700,625. Working costs were 24s. 11½d. per ton; an increase of 1s. 2 8-10d. The payable ore reserves have an average gold content so close to working costs that the success of the property is largely dependent upon the enhanced price paid for gold — the "premium."

A representative of the Australian Chemical Institute, who visited Canada last year, refers to the method of excavating, drying and harvesting peat at the Alfred (Ont.) Demonstration Plant, as a "costly and tedious procedure." It is to be hoped that this snap opinion will be voluntarily retracted before long.

News and Comments

by Alexander Gray

Coniagas and Newray

No better evidence of abiding faith in the Ontario North Country has been forthcoming of late than the decision of the Coniagas Company to take control of and to operate Newray Mines, at Porcupine. It means more than is involved in the terms of the transfer to have Mr. Alexander Longwell accept a place upon the Newray board and to have Mr. Fraser Reid in charge; for the Coniagas always has been a standard of mining integrity and the money it made for its chief owners always has been available for reproductive purposes. Coniagas principals have tried out various propositions, at Brnee Mines, Porcupine, Larder Lake, and elsewhere. Their metallurgical works at Thorold are all-Canadian. An old and valued Coniagas Superintendent, Mr. Redington, was so familiar years ago with the Rea—or Newray as it now is known—that the incoming administration had first-hand information about the underground situation justifying this latest enterprise. Developments at the McIntyre, no doubt, were an added incentive.

At one time, the Newray ground was regarded as among the most attractive in Porcupine. Dr. Simon, an international geologist, coming from London, India and West Australia to Porcupine, told the writer the outcropping ore-body was the most impressively defined of any he had noted. Of course the geological conditions there differed from those of the Hollinger and McIntyre. That did not deter the Consolidated Goldfields of South Africa from participating in the Rea developments. Whether the blame rests upon the ground or the management, operations were suspended. Further work was talked of by the McIntyre people. Now the property will be given a chance under the best auspices; and the sporting spirit displayed prompts the hope that it will be rewarded. Mr. Redington ought to know the ground.

Granby Results in 1921

Making copper at a cost of 11.63c. a lb. in a most distressful year in which the average market price of the metal was 12.65c. and being subjected to tax levies that drew upon surplus when more capital was urgently required, prompted Executive Vice President Crabbs to pointedly remark in the annual report of the Granby Consolidated Mining and Smelting Company:

"During the three years of deflation the company has been further burdened by the retroactive tax assessments of both the Dominion of Canada and the Province of British Columbia, 1917 and 1918, taxes of the latter Government occasioning over half the decrease in surplus shown in the balance sheet.

"The decision reached to continue operation throughout the period covered by this report has conserved for your future operations a cohesive, efficient organization, working harmoniously in all departments."

And yet the popular decision as expressed by revenue departments at Ottawa and at Provincial seats is that extreme penalties must be imposed whether or not working capital be impaired and operations hindered. During the year the Granby Company had to sell 30,000 shares at $25 for additions to the hydro-electric power department. This expenditure, it is expected, will effect an economy amounting to $150,000 to $200,000 per annum. That the management is keenly alive to the need of economy throughout, and that it has succeeded while "so many perplexing problems" confronted it, is indicated by the reduction of the cost of producing copper from 15.94c. in 1920, during which year, however, the plant was only getting into its stride.

The sum and substance of the Granby year is that the properties could not surmount copper market conditions, even had taxation been less onerous. Shareholders without dividends, patiently awaiting revival, had to finance the company by taking up $750,000 worth of shares, and had to acquiesce in the extraction of a large slice of their surplus for taxes. There was a profit and loss deficit of $145,609 compared with a surplus of $497,298 at the end of 1920. The net income in 1921 was $12,828 after all expenses and charges were made, but before depreciation, compared with a deficit of $687,012 in 1920. Gross revenues of $7,234,519, contrast with $6,684,123 in 1920. Allowances for depreciation made a deficit of $287,161 for last year.

Working "for the fun of it," at Trail and Anyox, sooner or later may suggest amelioration of taxation, at least until business is brighter, and until it is certain that 1921 marked "the culmination of the depression in the copper trade." Vice President Crabbs holds that things should go better now because they could not be worse than they were last year, when a demoralized copper market "established a low average not encountered in the nineteen years next preceding." On that account, in view of the turnover and economies effected, Granby reports progress. Granby is Canada's biggest individual copper producer.

In 1921 the margin of 1.14c. per lb. between the cost of and the price obtained for Granby's copper production is proof strong as Holy Writ that every economy is necessary in this department. To produce 29,970,661 lbs. of copper, 193,283 oz. of silver, and 8,838 oz. of gold, and hardly break even after meeting fixed charges, taxes and depreciation, would have a dampening effect upon the ardor of copper-mining capitalists, were it not understood that tomorrow is another day. As 47,104,280 lbs. of copper was sold, which was 7,134,630 lbs. more than was produced in the period the chances are that 1920 cost on the carry over affected earnings. No doubt the premium metal constituted a "consolation purse" made up it was

"Canadian Money for Italy"

This is the display line over a cable announcing that Canadian and American capitalists specially interested in hydro-electric developments have investigated and will invest in Italian water powers. No one begrudges this capital to our Ally; but there is an impression that Canadian money can have profitable employement nearer home. Barcelona investments have invoked little enthusiasm. Mexican projects are nothing to brag about. Canada, especially Canadian mining areas, could do with more power.

Minerals Separation Litigation Ended

"Peace hath its victories no less renowned than war." Recognizing the unwisdom of further acrimonious litigation, the parties to all proceedings involving Minerals Separation patents, processes, and penalties, have announced an amicable settlement. Mr. Charles Hayden, a central figure in porphyry copper organizations, who is also Chairman of the International Nickel Board, being the spokesman. The great importance of this not only to the Minerals Separation Corporation, which is to have a much larger sphere, but to the Utah, Ray, Chino and Nevada Consolidated Copper Companies, as well as to the Butte and Superior company, will be recognized, more especially as Mr. Hayden explains:

"The litigation between the Minerals Separation Company and the companies named has been settled out of court to the satisfaction of both sides. From now on, the above-mentioned companies become licensees of the Minerals Separation North American Corporation. The settlement was based upon the principle of a reasonable license fee for the use of Minerals Separation flotation processes for the past and the future without penalties of any kind."

What this means to metal producers and the Minerals Separation people need not be emphasized. The Guggenheim, Granby, Lewisohn and Thompson companies do not appear in the agreement. Having the Clark, Phelps-Dodge, Ryan, Calumet and Hecla, Hayden-Stone-Jackling corporations among their licensees has the happiest auguries for Minerals Separation. Prolonged litigation has been wasteful in every sense. Now Minerals Separation will be freer to enter broader fields with the support of most influential factors in metals markets. So all is well that ends well.

Saddest of Words:—"It Might Have Been"

With "enough in sight" to hold a few pogroms and absorb the floating supplies of rubles, despondent denizens of New York's northern suburbs are in revolt against the base deception of a section of the Bolsheviki down that way. Arrests are slight recompense for their betrayal based upon the alleged discovery of a deposit of gold and platinum near Yonkers—practically next door to the Mint. To be told through the medium of a prospectus that there is $10,000,000,000 at outcrop—$8,000,000,000 in gold and $2,000,000,000 in platinum—to part with $1,000,000 for working capital, and then to find they had been buncoed, was a rude awakening that calls for hanging, drawing and quartering, and incineration of the remnants. Not only was the $10,000,000,000 an assured asset, but the phrasing of the prospectus was so plausibly devised as to make the estimate altogether too conservative; for offshoots (more stringers hardly worth mentioning) contained another $100,000,000. Hence the alacrity with which those of the Trotsky Cult (who despise wealth that is not communal) passed along their hoardings. They have lost their lucre—and what confidence they had in humankind—and may start bomb factories in reprisal. Nothing of this sort, it is hoped, will transpire in connection with the Sweet Grass Albertan deposit of platinum and gold, where the latter is subordinate, however. And yet, as Ade has just said: "A man is up against an analysis who is trying to make a paralysis."

Prejudicing Canadian Zinc

However justifiable it may have been during war-time stress, the arrangement by which the Imperial authorities will take large quantities of Australian zinc for years at a price above the market is hardly fair to competitors. It is one of the things Westminster does without mature deliberation. Canada entered upon large expenditure to meet metal requirements in an emergency. It has had to create export markets since then. Granting that Canada to a limited extent can hold its own against the field, it is significant that Japan has been purchasing thousands of tons of electrolytic zinc in Australia. This zinc is said to be of higher grade than much of the American retorted product, and it is obtainable at lower costs and by ocean freight. Japan naturally buys in the cheapest market. Patriotism that pampers one section to the impairment of others is lop-sided.

The Silver Lining

The Orient is making the pace in the markets for gold and silver bullion. Indian and Chinese exchange rates have advanced to the highest of the year. Competition between New York and Bombay for the Transvaal gold has been keen, and most of the gold has been going to India. Silver has risen 17½ cents since its low price of February and the outlook for the metal at the moment is roseate. All of which indicates that Asia is thriving. Since the middle of February India has taken £3,000,000 gold.

DEVELOPING SHININGTREE PROPERTIES

Three gold mining companies are now developing properties in the Shiningtree area, Ontario, and good results are being obtained. It is probable that work will shortly be commenced on neighbouring properties.

The Wasapika Mine has been re-opened by Ribble Mines, Ltd., with Mr. Geo. R. Rogers in charge of operations. At the Atlas, diamond-drilling is in progress under the direction of Mr. M. P. MacDonald. At the White Rock, good ore has been encountered in drifting on the second level.

Notes From Nova Scotia

The Miners' Case

At the sittings of the Scott Conciliation Board, reported in part in these pages last week, President Baxter of the United Mine Workers of America local followed Vice-President D. H. MacDougall of the British Empire Steel Corporation, and in a very able manner presented the miners' side of the case.

Mr. Baxter is a Lowland Scot of the quiet, canny and considerate type. He is just enough of a radical to keep abreast of the times, but is neither revolutionary nor reactionary; a rather safe man for workmen to follow and operators to trust.

In his opening remarks he said: "it was not the intention of the Mine Workers of Nova Scotia to press for the same wages prevailing in the United States." This cleared up the situation considerably for it had been rumored that the American Miners wage basis was just what was to be demanded before the Board. To ask this basis was to violate an understanding that the U. M. W. of A. had made with the Dominion Coal Company when recognition was given them. It was agreed by the United Mine Workers that Nova Scotia conditions would always be kept in mind when wages were being discussed and wage agreements made. Any departure from this understanding would no doubt lead to an open rupture between the Company and its employees, and would end in the Union losing the check-off.

President Baxter stated "that while making no attempt to force wages up, he stood firmly by the policy of J. L. Lewis, International President, who stated that no change downwards in the prevailing wage rates would be tolerated." Continuing, President Baxter said that the minimum rate of the Nova Scotia Collieries was $2.85 while in the American bituminous mines it was $7.50.

Wages and the cost of living were not declining in the same proportion. The reduction in wages last January was so much greater than the fall in the cost of living, that "real wages" was a thing of the past. Whatever margin of wages existed during the later part of the war over and above what was necessary to sustain life, had been more than wiped out. "Real wages" as such means the sum of the "exertions and sacrifices" necessary to maintain life. The common measure of such "exertion and sacrifice" is money; the "cost of living" means the amount of money paid out for subsistence, and a change in the cost of living means any variation in the volume of such payments. The present wage rate will not allow a workman a bare existence, for it is fallen far below a living wage.

After a further review of the wage question, President Baxter dealt with the mining conditions underground and the living conditions of the miners. He presented sixteen clauses emphasising different features of the case. The principal ones among these, apart from wages, were "the eight-hour day", "riding rakes into and in the mine," "the proper housing of employees," "increases to be given for night work and double shifted places, and for pushing boxes and pitching seams."

Housing Conditions

Referring to the housing situation, President Baxter stated that he was sure no member of the Board who had visited the houses thought the conditions were ideal. The standard of living in the mining districts was not as high as it should be and housing conditions had much to do with lowering the standards. The Board has power to deal with this question. He quoted John Mitchell, the American labour leader, on the American standard of living for an unskilled labourer "a six room house with the usual modern conveniences with a chance for privacy; enough wages to provide furniture, clothing and education for his children, and provision for accident, illness and death." On the small wage of a Nova Scotia miner this standard could not be reached.

Chairman Scott said he was impressed by the lack of drainage. Some houses were over-crowded, while others were occupied by two or three persons. Could not the Union regulate this condition? Again, the municipality had some responsibility in the matter of drainage. Mr. Baxter replied that the Company owned the streets and were wholly liable for their condition. Mr. MacCann for the Company, stated that the municipality had again and again been offered the property of the streets and refused to take them over, although they used them for laying water mains and other purposes.

The establishment of riding rakes in all collieries has been a bone of contention between company officials and the workmen for a number of years. The walk underground was very long and hard and, if men were conveyed to and from their work, better service would be given and larger outputs obtained.

Coal Production per Man

Following up his explanation of the wage clauses, President Baxter gave a table of the average coal production per man on the pay roll in Nova Scotia as taken from the Government Blue Book from the period of 1916 to 1921. He submitted statistics of the average production of the British Empire Steel Company for the same period. They are as follows:

	Long Ton.	Short Ton.
1916	1.70	1.90
1917	2.00	2.40
1918	1.79	2.00
1919	1.85	2.07
1920	1.78	1.99
1921	1.96	2.19

He claimed the figures showed that the organization of the Company was superior now to what it had ever been, and that the output of two tons per man, representing as it did every man employed, was good production. In this respect he said that the improvement shown had come from both the Company and the men.

President Baxter dealt with all the other clauses at considerable length and succeeded in making a splendid case.

The matter of local contracts was presented by Lewis MacCormick, Sub District Board Member. He stated that the Company had found it good policy to place as many of their detal men as they could on contract rates. For instance, drivers were paid so much per ton hauled and road makers so much per ton of the output of their district while pipe men were also paid by the tonnage of the district. Since the reduction of last January the distances for driving were increased and other changes made that affected local contract men in consequence of which local contracts were set aside for day work. As there were important classes upon which the output of the mine depended, the inducement should be large enough to cause all detal men to apply for local contract rates.

Secretary-Treasurer McLachlan's Evidence

James B. McLachlan, Secretary Treasurer of the U. M.

W., on Saturday afternoon presented at Glace Bay a further statement before the Scott Conciliation supporting the miners case. Mr. McLachlan delivered his evidence to the Board in his usual aggressive manner. He stated that the Montreal Agreement was not a luxurious one, but he demanded that it be maintained to provide a living wage for the workers. He denounced the Company Stores in bitter terms.

He declared further that he did not believe the Company's assertion regarding its financial position, and quoted from lengthy statements to show the profits and surpluses of the Corporation during the war period. Mr. McLachlan placed in evidence pay sheets of a large number of miners showing the average wage earned by these men, who, he said, were not the "nebulous, ethereal characters which the Company claim were getting one thousand dollars per year." He argued that the Board did not know of any man who received $1,000 or $1,700 per year, while an employee of the Company, as claimed by the Company's statement before the tribunal.

Secretary McLachlan said a peculiar question had arisen before the Board with respect to a living wage. The term, he said, was an elastic one, but he believed there could be some general conception arrived at. The wage rate of 1921 in the coal mines was enough to live on but anything lower than that rate was not a living wage. He argued that high wages would naturally follow over-production, but in this case large production was being put as a reason for low wages. "One thing I do know," said the U. M. W. Sec'y. with emphasis, "the miners are going to get a living out of this industry and there will be no peace until they do." In reply to Chairman Scott's enquiry, whether the lack of working days or lowness of the rate was mainly responsible for the unsatisfactory conditions, the U. M. W. Sec'y. submitted the pay sheets of a brattice man, showing total earnings of $68.20 for twenty-nine days and a total amount taken home in cash of $6.21 per week, the deductions to company store, doctor, hospital, etc., being $15.64 per week.

The Company Stores

Mr. McLachlan then directed some criticism to the company stores. He said the stores gave out charity doles to the men during the idle times and then when work resumed in the mine, refused to give any credit until the old accounts were wiped out. One man gave evidence showing that he had been idle for a considerable time and had run in debt to the company store. When he started work the manager of the store agreed that $2.00 per week should be kept off for back payments, but this had not been carried out. The Chairman at this point asked the Company if this statement was correct. The reply was that having no special knowledge of the case they would submit a statement later on as evidently some mistake had been made, for the agreements between the store managers and the men were usually carried out. Replying to a query from Chairman Scott, why the miners did not leave the Company store, Mr. McLachlan said that necessity forced the men to deal at these stores. "They can't get away from them, because they become so much in debt that merchants elsewhere won't give them credit." It was true, he admitted, that some men signed a power of attorney for the store manager to take the wages, but this was necessary to obtain any credit.

The U. M. W. Sec'y. said the death rate in the mines of Nova Scotia was greater than in any other part of the world. The Mines Department at Halifax was antiquated and the Inspectors were either old mine managers or other cast-off's; at best they were only fifth rate men, as the Government would not pay sufficient salary to keep a good man. Canada boasted of the best mining laws in the world, but these laws were the worst enforced. The work is hazardous, as the following figures will show. The death rate per 1000 men in the United States from 1911 was 2.78, in Nova Scotia it was 3.75, in British Columbia 5.39$\frac{3}{4}$, in Great Britain 1.30, Prussia 2.35, France 1.31, Belgium 1.06, Austria, 1.21.

Mr. McLachlan declared that the Mine Managers were often more guilty of violations than the men, who, he asserted, were often forced to go before a magistrate, lay a charge against themselves, give evidence in the case and commit perjury in order to secure a certificate from the magistrate and thus get back a job in the mine.

Gas in Mines

McLachlan cited a case at Sydney Mines in the pit in which he was employed. When the shot-firer came to fire the shot in the room, there was'nt enough oxygen in the air to permit of a match remaining lighted. Even a lighted newspaper was snuffed out. A few days later the place was filled with gas, and the lives of 600 men endangered. He had reported the case to the Mines Inspector, but that official declared he would have to take the matter up with the mine manager. He did so and "while I was threatened with court action at the time for making the statements I have made here, I never was arrested. That official did'nt have the Mine Manager arrested. Instead he was promoted. I think he should have been sent in prison."

H. J. MacCann, Asst. General Manager of the Dominion Coal Company, asked Mr. McLachlan, when the case referred to existed at Sydney Mines. Mr. McLachlan said that it was back in 1907.

The U. M. W. Sec'y followed this up with the charge that No. 24 mine was full of gas some months ago, and when the men complained, after being forced to leave the working face because of the gas, the colliery was shut down and the men forced to remain idle.

The same condition exists at No. 11 mine, but the men did not complain because they feared the Company would immediately stop work there and the miners wanted to continue. "I wanted to bring this before the Board, but the men in my Local said not to or the Company would close the pit. That's the spirit abroad here now." In addition to this Mr. McLachlan said many other things in his statement on behalf of the miners.

The facts, as known to the fully informed, show that these accusations are without foundation.

Evidence of Ministerial Association

A new feature at this Conciliation Board sitting was the appearance of members of the Ministerial Association, who gave evidence of the effect of the prolonged agitation on the morals of the workmen.

Wages and housing conditions were touched on and the clerical committee pointed to the uplifting effect of good surroundings. Clergymen of all denominations, Catholic and Protestant, appeared before the Board. The Church has decided that it will be represented in all phases of the life of the people on all future struggles.

Mining Examinations are to be held shortly, at which a large number of students will attend. The mining schools of Nova Scotia have become popular and have been of great benefit to the young men desiring to rise from the ranks. Connected with the schools are classes where preparatory instruction in English and methematics are given free to all who average attendance reaches a prescribed standard. Nova Scotian collieries are largely in the hands of the graduates of these schools.

British Columbia Letter

Survey of Iron Ore Resources Undertaken

A complete and thorough survey of the iron ore resources of British Columbia is to be commenced this summer. The Canadian Geological Survey (British Columbia Branch) has agreed to undertake this important work in co-operation with the Provincial Department of Mines. The object is to obtain conclusive information as to the possibility of this Province supporting an iron and steel plant of large capacity. Dr. G. A. Young, who has been the Survey Branch's specialist on iron ore formations for years, having prepared reports on the iron ores of New Brunswick and on the iron bearing rocks of the Belcher Islands in Hudson's Bay, is to be assigned to the same duty in this Province and will begin his field investigations in the course of a few weeks.

The appointment of Dr. Young to this task is the direct result of representations made by Hon. Wm. Sloan, Minister of Mines, who, in an interview yesterday, explained that, while it was known that ample iron ore of the necessary quality existed in British Columbia for the maintenance of a modest sized furnace, there was not that exact information as to tonnage of the raw material to assure the continuous operation of a plant of large capacity. For this reason he had sought the co-operation of the Canadian Geological Survey, through the Hon. Charles Stewart, Minister of Mines at Ottawa, and his deputy, Mr. Charles Camsell. It was a pleasure to be able to announce that, as a result of the resulting correspondence, an arrangement had been made which would settle the question of the extent of British Columbia's iron ore deposits. There was no doubt that the success of the efforts of the Department of Mines would be welcomed by the mining men of the Province, and Mr. Sloan wanted it stated that the cordial and prompt response of Hon. Mr. Stewart and his officials were appreciated.

In a letter to the Ottawa Department under date of the 24th January last Mr. Sloan asked for "the co-operation of the Geological Survey Branch of Canada in a geological and topographical survey of the iron ore deposits of this province." He suggested that, if agreeable, Dr. Young be allocated to this work because of his previous experience in this class of investigation, and pointed out that favorable consideration would be appreciated "not only by myself as Minister of Mines, but by all who are interested in the development of the mining industry of this Province."

Mr. Camsell replied under date of 10th February that Dr. Young was making a "preliminary summation of all published information on the iron ore deposits of the Province." Later came a communication from Dr W H Collins, Director of the Survey, which was responsible for the satisfactory closing of negotiations. He said that Dr Young would be given instructions to proceed with the proposed work in this Province providing the Provincial Department of Mines was prepared to do that part which properly came within its purview.

It was explained by Dr Collins that his understanding of the wishes of this Province was that "the iron ore resources of the Province should be inventoried in a manner which will admit of determining whether there are enough iron ores suitably located and of satisfactory qualities to supply a future iron and steel industry on the Coast if other essential requirements for such an industry are obtainable. If I am correct in this assumption," he continues, "it would appear necessary to make a rather careful estimate of the productive possibilities of all the larger iron ore deposits of the Province. This will be an undertaking of considerable magnitude, to the successful accomplishment of which the Geological Survey can only contribute in part. A heavy share of it will have to be done by your Department of Mines."

That the work should start with a geological examination by the Geological Survey Branch, which would serve to classify the more promising deposits in their order of prospective importance and would yield other information regarding the character of the deposits and the nature of the ores, was the opinion expressed by Dr. Collins. After making such a reconnaissance it would be possible for Dr. Young to advise "what trenching and drilling should be undertaken to ascertain more precisely the extent and character of the deposits which appeared to warrant intensive exploration." It is trenching and drilling of properties found to be of sufficient importance to warrant such development that the Province must provide for, and Dr. Collins' request for information as to the Government's willingness or otherwise to co-operate in this respect was given careful consideration by the Government.

Finally, under date of 11th inst. Mr. Sloan was able to telegraph Dr. Collins that "this matter has been fully considered by the Executive and am pleased to say that the proposal as outlined is entirely agreeable to this Government." He confirmed and amplified this by a letter of the same date saying that "the Government of British Columbia is prepared to proceed with the trenching and drilling necessary to supplement the work to be undertaken by Dr. Young. The suggestion that Dr. Young may be asked to undertake this survey is very much appreciated as it is recognized that he is exceptionally well qualified to carry it to a satisfactory conclusion." The hope was added that Dr. Young might be able to get into the field at an early date.

There are many large iron deposits that come to mind in considering those that are likely to have special attention. No doubt those of Vancouver Island and the coast sections will be carefully inspected. In the interior there are the Sand Creek Iron Deposits, situated about eight and one half miles from the Kootenay Central Ry. This property carries hematite, which makes it of unusual interest in British Columbia, where magnetites predominate. Some development has been done in the past, but never sufficient to demonstrate the tonnage of commercial ore that may be available. Another well-known interior body of iron ore that, without a doubt, will be explored are the Kitchener Iron Deposits, which cross the Crow's Nest Pass Railway at a point near the town of Kitchener and extend in a northerly direction for approximately eight miles. The ore found here, too, must be given every consideration because it is a hematite, and, from reports thus far obtaining and judging by the small amount of development already done, has commercial possibilities. On Cherry Creek near Kamloops there is a deposit of magnetite. There are three distinct zones in the main vein of this ore body, the central one being a high grade dense magnetite, free from impurities. This must be explored with a view to ascertaining the tonnage that it may be expected to yield. In northern British Columbia there are, among other iron ore resources, the limonite deposits of

the Zymoetz River section. Various estimates of the tonnage obtainable here have been made in the past. It will be the duty of the Survey, for which arrangements have been concluded, to make a thorough exploration of this area also with a view to determining the extent to which it may be depended upon to contribute to the maintenance of a British Columbia iron and steel industry.

Coast Coal Production Curtailed

The strike of coal miners in the United States and in District 18, (Eastern British Columbia and the Province of Alberta) is not having any effect on the production of the collieries of Vancouver Island. Within the last few weeks the domestic demand has fallen off and the bunker trade, which has been depressed for some months, has not shown an improvement. The result is that the mines of Comox (Canadian Collieries), Extension (same Company), Nanaimo, (Canadian Western Fuel Corporation) and Nanoose have been working short time. In some places the mines have been producing only two or three days a week. The only exception to this is at Ladysmith, where the Canadian Collieries have mines which supply practically the whole of their local market.

In the coal mining centres of the Coast there is a disposition to blame the imported fuel oil for present unsatisfactory trade conditions. A duty on foreign oil is considered the only solution and a deputation of British Columbians recently waited on the Dominion Government seeking the imposition of such a duty. Their request was promised consideration.

The Coal Strike in Crow's Nest District

In the Crow's Nest District, British Columbia, the coal strike situation shows no signs of change either for the better or the worse. There are no indications of a compromise. The mines are idle and many of the miners have obtained employment elsewhere, chiefly at lumber camps where their pay is considerably less than their own work yields. There is no excitement whatver and no disorder of any kind. Firemen and pumpmen remained at their work and the overmen and firebosses are caring for the most urgent underground repairs. What is known as the 'Knowles' Conciliation Board has been sitting in coal mining centres of British Columbia and Alberta taking evidence with a view to arriving at a satisfactory basis for settlement. The opinion of most disinterested observers is that the miners made a tactical blunder in not accepting the offer of the Company, viz., to continue at work under a scale of wages much similar to that provided by the 1917 agreement, all increases over this that might subsequently be incorporated in the agreed upon scale to be made retroactive. The U. M. W. of A. representatives, however, insisted upon the maintenance of the present scale of wages during the strike period, with no retroactive clause in the Company's favor should the final decision adversely affect the men's case.

Major A. W. Davis the New Resident Mining Engineer

Major A. W. Davis, E.M., D.S.O., has been appointed Resident Mining Engineer of Mineral Survey District No. 3, British Columbia. His headquarters will be the town of Kamloops. He will assume the duties of his new office on the 15th May next. Major Davis succeeds the late R. W. Thomson, who died some months ago. District No. 3, over which he will exercise supervision, is a central section of the Province with considerable mining possibility. While the aggregate output of the district at present is not large, comparatively speaking, there is a variety of mining, including placer, lode, and coal. Major Davis is a graduate of McGill University, Montreal. He came to British Columbia in 1898, and later joined the Canadian Consolidated Mining and Smelting Co., ultimately becoming one of its leading engineers. At the outbreak of the war he immediately enlisted. In France he was chosen to form the first Canadian Tunnelling Company. This duty he carried out with such energy and effectiveness that he was awarded the Distinguished Service Order in recognition of his services. Since returning to the Province he has been engaged in private practice at Nelson. His choice by the Provincial Government is popular among mining men of the West.

H. S. Munro, general manager of the Granby Consolidated Mining Smelting and Power Co., has returned to Anyox after an absence of some weeks. He reports that the output of the Anyox Plant for April approximated 9[illegible],123 tons. While there was no improvement in the copper market, the mine and smelter would be maintained as near as possible at capacity.

Cedar Creek placer gold discoveries are taking hundreds of men from Victoria, Vancouver, Seattle and other Pacific Coast Cities. While the snow has not entirely disappeared as yet, work has commenced on some of the claims. Messrs. Platt and Lyne, owners of Discovery, state that their property is not for sale and that it will be developed this season. The Cariboo Country will have the most thorough "combing" for gold as a result of the present excitement, since the rush of '62.

Major R. H. Crichton, who is interested in the Homestake Mine, Kitsault River, Alice Arm, says that his Company expects to resume development this month and to reach the producing stage before the end of the year.

High grade ore is being mined and sacked at the Esperanza Mine, Alice Arm. Water has stopped work on the upper workings but it will be resumed as soon as the snow goes. The Esperanza shipped ninety tons of ore to the smelter recently and is a promising property.

Iron has been discovered in the Lardeau District, B.C. There is a large body upon which nine claims have been staked. A sample assayed: Iron oxides, 77 per cent.; silica, 2.9; carbonic acid, 7.8; lime and magnesia, 5.2; with some water. Because of the high percentage of iron, and the lack of other elements in such quantity as to hinder treatment, the discovery is considered of more than usual importance.

A. Rasmusson, of Skagway, president of the Bank of Alaska, reports that there is a large influx into the Yukon this year. The silver camp at Mayo is attracting many, and if the present rate of development continues there will be an important town there in a few years. Three large companies, he says, are operating and are taking out extremely rich ore. Mr. Rasmusson is en route to New York.

The erection of a 30-ton flotation plant on its property, 12 miles south of Salmo, B.C., is proposed by the Trail Mining Company. The plant will cost $18,000 and will be driven by direct water power, the installation of which is expected to cost about $5,000. The Company has driven 350 feet on a 16 foot vein, which is said to average throughout that distance 9 ounces per ton in silver and 16 per cent. lead. A test shipment sent to the Trail Smelter brought returns of $26 a ton in silver and lead.

Livingstone Wernicke, geologist for the Treadwell interests at Mayo, was one of the first to leave for Mayo with the opening of navigation on the Yukon.

Northern Ontario Letter

THE GOLD MINES

A visit this week to all the producing mines of the Porcupine district, as well as to other properties in the development stage, clearly shows that although operations are on a large scale and great success is being achieved, yet the future holds even greater activity in store, with promise of greatly enlarged production of gold. Hollinger, Dome and McIntyre produced an aggregate of approximately $1,550,000 during the month of April. This is at the rate of $18,600,000 a year. In addition to this there is the enlargement to the McIntyre mill, which will be brought into use during the third week in June and which will add close to $100,000 a month to the output, thereby bringing the total of these three mines a rate of approximately $20,000,000 a year. Then again, added to this are the plans of the Hollinger to increase its milling equipment by fifty per cent. This may take place during the coming year and might reasonably add another $3,000,000 a year to the aggregate production.

Coniagas and Newray

The Coniagas having secured a working option on the Newray, this property will receive the benefit of work by one of the more highly efficient mine managements of the country. The terms of the deal are that the Coniagas shall receive treasury stock in the Newray at the rate of one share for every 35 cents spent on development work. It is provided that the Coniagas shall spend a minimum of $4,000 a month on the enterprise.

V. N. T.

The mine having been de-watered, mining operations resume this week at full blast on the Porcupine V. N. T. Mines and attention is turning again with renewed interest to this property.

Development work will centre entirely on the north western claim, situated adjacent to the Hollinger Consolidated and the Porcupine Crown mines. Besides having produced $808,000 from comparatively shallow workings, and on having close to $750,000 in ore in sight, there are a number of parallel veins on this north western claim in which visible gold occurs at outcrop and on which no underground work has as yet been done. The present program of development on the main vein will not only be for the purpose of continuing the main shaft from its present depth of 600 feet to a depth of 900 feet, but will also be the starting point for later lateral operations in a northwesterly direction right to the Hollinger boundary.

A feature of the situation is that the deposits already developed and being worked assure the mine of substantial gold production, while further success in opening up payable ore bodies in parallel veins would place the enterprise among the more important mines. It is toward this end that work is now in full swing under the competent management of N. J., Evered, who is thoroughly familiar with the mine. Drifting is now under way at 600 feet deep, while sinking is under way from 600 toward 900 feet deep. Diamond drilling is also under way.

Disputed Mining claims.

The dispute over mining claims that were originally held by C. E. Pinelle and were later re staked for alleged failure to perform assessment work is due to come up this week. It is understood, however, that an application has been placed by Mr. Pinelle before Mining Commissioner T. E. Godson, K.C., for a postponement of the hearing.

More than usual interest attaches to the case due to its connection with exemption of claimholders from assessment work while in the Canadian army as well as for a long period after the close of the war. Also, further interest is added in that the outcome of the dispute will have a vital bearing on a deal which is now pending for the Moffat-Hall Gold Mines.

Clifton Porcupine Financing

A good deal of favorable comment is heard in local mining circles with regard to the method adopted by the Clifton Porcupine Mines in its present campaign to raise capital with which to erect a mill.

The directors of the company have expressed faith in the undertaking and are showing the courage of their convictions by paying out of their own pockets the cost of marketing 170,000 treasury shares at 30 cents each.

The work already done on the Clifton-Porcupine has placed considerable ore in sight. This is officially estimated at 10,000 tons containing an average of $15 a ton. In view of the work having occurred at only two levels and being limited in extent, this would indicate a good future for the mine.

Money now being raised will be used to erect a small mill and to carry work to deeper levels. In this way it is planned to place the enterprise on a paying basis, which will provide money necessary for further mill enlargement according to the volume of ore developed.

Dome

Official figures to this paper, which show that the ore being treated at the Dome Mines is yielding close to $14 per ton, are being pointed to by stockholders as an indication that the Company could now make capital repayments of one dollar every three months instead of twice a year as has generally been expected.

Already the treasury surplus is greater than what is necessary, and this fact gives rise to the belief that capital repayment may actually be made at the rate of four dollars a year, in addition to regular dividends of one dollar a year. Such a rate of disbursement, amounting to five dollars annually on each share would require $2,380,000, or at the rate of approximately $199,000 a month. The April achievement actually exceeded this amount by about $50,000.

A gross production of $300,000 monthly, or over, on ore that averages from $12 to $15 per ton, shows a net profit of approximately two thirds, or about $200,000. As to this, the production figures for the past four months show the following:

January	$300,000
February	$307,000
March	$312,000
April	$377,000

These official figures clearly show that the company has been realizing net profits at the rate of over $200,000 a month since the beginning of the year, or at the rate of over five dollars a year on each issued share.

Lake Shore

A great deal of comment is heard in connection with the question of equipping the Lake Shore mine with a larger mill. The present plant has a capacity for handling about 70 tons of ore daily as against an ore reserve of possibly 400,000 tons containing about $15 a ton. This plant, with such a volume of ore behind it, has been likened to "the

neck of a bottle" and has give rise to general speculation as to the date on which a decision may be made to install additional equipment.

Drifting at the 600-ft. level, the deepest point so far reached on the Lake Shore, has advanced over a total length of about 1,800 feet. It is obvious that by next spring, at which time the main shaft may reach a depth of 800 ft. that the work at the present deep level will have advanced pretty well to the boundaries of the property and will leave the management free to push development work immediately onthe 900 ft. level. It is considered probable that by that time the plans and specifications for a large milling plant will have been prepared.

New Power Development on Montreal River

Preliminary work is in full swing in connection with developing hydro-electric energy at Indian Chutes on the Montreal River. A siding is being laid at Beacon's Siding and a wharf is being built where the T. and N. O. Railway tracks pass close to the shore of Elk Lake. It will be possible to tranship from freight cars to scows with a minimum of effort.

There are now about 30 or 40 men employed, and this force will probably be increased in a short time.

Although no official statement has been issued, it is understood that sufficient bonds have been sold to encourage the belief that this new power development will be carried through with all possible speed. Incidentally, it points the way to widespread activity in the Fort Matachewan district, where the chief handicap has been the absence of reasonably cheap motive power.

Lebel

A group of financial men in New York have bought out the Sutherland interests in the Munroe-Kirkland group of claims, which lie just east of the Lebel Lode properties in Lebel township. In addition to having purchased the Sutherland interest, they have secured a working option on the remaining interest and will carry on aggressive work.

It was learned today that the Sutherlands were paid in cash, while the funds for conducting exploration and development work has also been provided. A first consideration will be the completion of assessment work on such of the claims as have not yet been patented. This work will be directed toward an effort to locate the extension of the big vein system located last season on the Lebel Lode property.

The energetic development of the Lebel Lode and the Munroe-Kirkland is an important extension of the work along the zone of enrichment, the western part of which is now the source of a large gold production and the eastern part of which is developing rapidly and favorably.

Bidgood

Some rich ore is being developed at the 400-ft. level of the Bidgood Gold Mines. Drifting is proceeding in both directions and already a substantial shoot of good ore has been opened up. The gold content of the vein at the present point of operation is such as to indicate a high-grade milling proposition across a good stoping width.

This enterprise holds a place among the more energetic and conservative new mining operations in Northern Ontario and is developing in such a manner as to make it likely that the question of installing a mill will be favourably considered before the passing of many months.

A promising gold discovery is reported to have been made in the south-eastern part of the township of Eby, close to the boundary of the township of Otto. Samples brought out contain visible gold, but the owners of the claims and the exact location are withheld for the time being.

THE SILVER MINES

McKinley-Darragh

The mill on the McKinley-Darragh will go into operation today, according to official advice. A force of about 30 men has been at work for the past two weeks or more getting things in shape. This force is now being increased to about 65 or 70 men.

It is planned to handle approximately 150 tons of ore daily. This will come in part from the 25,000 tons of broken ore in the mine as well as from further mining, and production may approximate 50,000 ounces of silver monthly, or about $35,000 a month at the present price of silver.

Already there is evidence that would indicate a cost of perhaps not more than 50 cents for each ounce of silver produced, or a net profit of 20 cents on each ounce. Further increase in quotations for silver would automatically increase the margin of net profit.

Activity at Elk Lake

The work of de-watering the Paragon-Hitchcock mine is under way and it is understood a plan of operation is being arranged. In addition to this, there are various rumors with regard to prospects of work being resumed on a number of other Elk Lake properties. The high price of silver and the great demand for this metal in the Far East is having a favorable influence.

Some rich specimens of silver ore have been brought in by prospectors who recently restaked a number of properties between Elk Lake and Silver Lake.

The re-treatment of tailings at the Coniages mine is again under way and this branch of work will swell the current production considerably. In addition to this, the general mining and milling operations will continue at normal rate.

EDITORIAL

There is land of such a nature that if you sow, it does not yield crops; but if you dig, it nourishes many more than if it had borne fruit. — Xenophon — circ. 400 B. C.

THE MINERAL BANK OF CANADA

The mining industry, as the second in importance of the country's basic industries, might naturally have received more attention than it has in Mr. Fielding's budget of last week. Porcelain pump parts and four-inch pipe will not upset seriously the balance of the industry. What is the joke about those porcelain pump parts and pipes?

Mr. Fielding's pronouncement, accompanying the presenting of his budget, is a more serious affair. He discusses the nation's financial problem, but offers only a partial solution in the way of suggested measures, and none at all for the ensuing year. He has inherited from his predecessors in office a load of debt that they had not only failed to diminish but on which they had failed to pay the interest. In this hastily-prepared budget he is not able to propose constructive financial measures; he strikes a mean between the so-called Liberal principle of tariff reduction, and an increase in the semi-direct sales tax. The salutory effects of the direct income tax will be felt no more this year than last; yet direct taxation seems to be about the only corrective available for the extravagance and waste in the expenditure of funds, both private and public, that cause the Canadian to be known throughout the world as a spendthrift.

As is natural in the case of such a measure, the present Budget affects principally trade and commerce. It has little to do, directly, with the basic industries of the country—the indigenous and essential industries upon which the whole structure of the nation is built. It is the Dominion's role to tax everyone in the country, as nearly as possible in just proportion. Upon the Provincial and other local authorities devolves the responsibility for levying taxes of a particular nature; and so it is mainly with these latter that the incomes of mining and metallurgical works must be divided.

Meantime we have Mr. Fielding's admonitions to guide us. We must remember that the public coffer is no longer inexhaustible. We must cease our demands for sawdust wharves and other public works for which there is no pressing necessity. We must do our best to learn the meaning of economy, both national and personal.

The budget is not, and never can be, a really constructive measure of finance. In the present case, the nearest approach to a constructive measure is Mr. Fielding's plea for self-denial and economy. If he had been able to embody this idea in his budget, he would have taken one more step toward the ideal he expressed. Mr. Fielding is confident that a solution for our difficulty can and will be found. What will that solution be?

The only possible way for us to increase our national income up to the point where we can begin to pay our debts is to develop more fully our natural resources. To create more capital by saving will go a long way toward making us solvent; but only by drawing to a greater extent upon Mother Nature's bank account will we be able to discharge even our current obligations. Only by agricultural and mining development can this be accomplished. Economy, both national and personal, will help in large degree to create the capital necessary for this development.

It is commonly assumed that in the development that is to come, agriculture will take the leading part, and will be the essential item for progress. We doubt this. It was not so in the southern half of the continent. The fertile lands of the middle west in the United States remained untilled up to the time when the California goldfields provided the capital for a rapid expansion of agricultural operations, and drew men westward. Settlement in our own clay belt in Northern Ontario and Quebec, a region of vast possibilities for agriculture, has been stimulated mainly by mineral development.

Rapid settlement requires huge amounts of capital, and mineral deposits within our own borders are a source of capital upon which we, as a nation, need pay no interest. Thus it may well be that the sound national financial policy for the coming decades is to make available for use the funds of the great Mineral Bank of Canada.

CO-OPERATION AND PROGRESS

There is an impression, still current in some quarters though it no longer applies, that the asbestos industry of Quebec is run on the archaic lines of secrecy and exclusiveness that were the vogue in industry during the last century. This inheritance from Mediaeval times may have been cherished until recently in the asbestos camp; but today the majority of the operators realize that only by the broad minded policy of co-operation will the camp reap the full benefit of its resources, and the individual companies gain a maximum of profit from their pits.

The prevalence of the modern idea was well illustrated at a meeting of the Thetford branch of the Canadian Institute of Mining and Metallurgy, held in Thetford on

Monday of this week. Advantage was taken of the presence in the camp of a number of outside specialists in crushing problems to hold an informal discussion on crushing.

The metallurgical problem of the camp consists simply and solely in crushing and fibreizing the rock, and collecting and sorting the fibre, the latter two being simple of solution. The real problem is to crush the containing rock without destroying, that is cutting or breaking, the fibre.

The discussion showed a surprising diversity in the methods used in the various mills. This is due, no doubt, to the rule-of-thumb fashion in which mechanisms and practices have been developed in the past. But there is now being conducted in the camp some systematic research work, with a view to discovering the principles that underlie the economical crushing and fibreizing of the asbestos rock. The result of this is bound to be, here as elsewhere, the discovery of the best possible method, based on principles rather than on trial and error. It is true that the nature of the rock and of the fibre varies so throughout the camp that completely uniform practice is impossible, but this is no more than the case of the average mining camp, and indeed makes the need for the determination of the principles concerned all the more imperative. If certain fundamental principles are once determined, applicable to all cases, then the peculiar problems of each particular case can be tackled with some prospect of success; the one is foundation work, the other, superstructure.

As mentioned repeatedly by Mr. T. C. Denis in his Annual Report on Mining Operations in Quebec, the conditions under which the asbestos industry of Quebec is operating are changing very rapidly. Until comparatively recently there has been no competitor worthy of the name for Quebec asbestos. This is no longer the case. Competition for the asbestos market grows keener every year. Rhodesia is the main alternative source of supply; but there are many producing areas of smaller dimensions. The competition is world-wide, and is affected both by the development of known deposits and the discovery of new ones.

Quebec has now no monopoly of the asbestos market; but she has still a firm hold on it. Quebec asbestos is the criterion of quality, and is not yet equalled in the world. The producing area is well served by railways and is only 170 miles from Montreal, 80 miles from Quebec and 400 miles from New York. The ore reserves are very large; there is at least as much paying rock proved by development as has been extracted to date in the camp, and the limits are unknown. The factors for which Nature is responsible are all in favour of Quebec's continued pre-eminence. The human factor, notoriously uncertain in all cases, and especially a matter of comment in this case, seems to be under the control of men who will guide the destinies of the field in the safest possible way.

To an outsider it would seem that here, as is so commonly the case elsewhere, scientific research is what is most urgently needed in order to get the best products at lowest costs. This can be done best by means of a co-operative effort involving all concerned. But it is not essential that all should join in the movement. The spirit of research and of co-operation is a living, progressive thing, and is bound to win through in spite of difficulties. In this case, opposition to progressive measures is a rapidly diminishing quantity, and will soon be negligible. The meeting mentioned above is a demonstration of the spirit that is abroad in the camp today.

Soon it may be that the backs of the Quebec asbestos operators will be against the wall. Some are very near it now, and hardly realize it. Severe competition will inevitably force co-operation for mutual protection. A united Quebec asbestos industry can hold its own against the world.

THE RUSH

The open season for "rushes" is twelve months in the year; but just at this time these peculiar manifestations of gregarious human nature are likely to be most numerous. They are more spectacular than useful; yet they are bound to occur. A good rush can be organized and manipulated by one knowing old-timer; yet a thousand men will, unconsciously and fervently, do his bidding and serve his ends.

What constitutes the psychology of a rush? Why will five hundred men travel post-haste and at any sacrifice to the vicinity of a reputed "strike", when they know that only fifty, or five, of them will have aught for their pains? To answer this question would be to solve one of the riddles of human nature. Here we will merely try to delineate a few of the features, good and bad, that accompany and result from these mad stampedes after the mineral wealth that another man has discovered.

To begin with, the rush seldom includes any considerable proportion of real prospectors. The genuine prospector has a minimum of the gregarious instinct, and follows his calling, quietly and persistently, without much regard to the vagaries of the mob outside. True, he is usually the cause of the rush and becomes involved in it whether he will or not; for when he makes a promising strike and its merits (or supposed merits) become bruited abroad, he is sure to be overwhelmed with friends, old and new. Some old-timers resent such an intrusion on their privacy and such a disturbance of their exclusive right—the right of discovery. But nowadays the wide-awake prospector, with a shrewd eye on the ultimate dollar, encourages others to flock round his diggings, though only after he has done his level best to skim the cream for himself. This practice has been carried ever farther in some instances (alas! that it must be told!) Prospectors have been known even to stimulate a rush, in order to be able, under cover of the excitement, to unload their worthless claims upon unsuspecting enthusiasts. But this unworthy practice is not commonly indulged in by the real denizen of the clean, wholesome woods.

There are men with real prospecting ability who make a practice of following the rushes, one after another, as a more profitable alternative to the search for an original discovery. These men have more an eye to the almighty dollar than an instinct for their work. Their impulse is not so much to reveal Nature's secrets as to collect cold cash as rapidly and as easily as possible. Of course, this latter is characteristic of all of us, unless we except that rare bird, a practical Socialist or Communist. But when a prospector makes it a habit to concentrate his energies upon merely following up and taking advantage of the original work of a fellow-prospector, he has lost something of the fine ideal that is properly ascribed to the men of his calling. "The play's the thing" — not the receipts at the box-office.

The majority composing a rush are a non-descript crew — mainly greenhorns and miscellaneous hangers-on. Every man must learn to practice his calling. Unless the young man ambitious to become a prospector is lucky enough to become "pardner" to an old-timer, he is likely to be sucked into the maelstrom of a rush. There he will pick up a certain amount of prospector lore, though it will be well diluted with the vapourings of his get-rich-easy and get-rich-quick companions. It will not be easy to distinguish between truth and mere talk; it is all too easy to confuse genuine and counterfeit in the excitement of the race for fortune. But for the guidance of the inexperienced it is a safe rule that the old-timer who keeps himself busy with pan or rocker, or pick and shovel, is the right man to follow; the wisdom of him who spends his energy in words is more than likely to be folly or knavery.

The motley crew that comprise the major part of any stampede are hardly worth consideration. Some want excitement. Many, with the financial sense preponderating, are keen to make a quick and profitable "turn-over." Some are mere human leeches of the numerous recognized varieties. Fortunately the "bad men" of olden time are now extinct.

Above all, and through all, stands forth the work of the pioneer who located "discovery". Sometimes he has a fortune as his reward; often his share is only a pittance. But the appreciation of the discerning is for him, and for him is the reward of good work, faithfully done.

EDITORIAL NOTES

The story we print in this issue of the Journal, of the Canadian Associated Goldfields of Larder Lake, savours more of the time of the South Sea Bubble than of today. The facts as recited seem incredible; yet we know them to be the truth. Here there is one more proof of the gullibility of the general public—if proof be needed. The amazing thing is that the managers, or manipulators, of the concern have been able to convince their share holders, and possibly themselves to some extent, in spite of the evidence adduced by the best professional engineers they could find. The sad part is that among the thousands of purses that have been depleted are a large fraction that are so ill-filled that the loss will be felt keenly. We hope the recital of the story of Canadian Associated Goldfields will help investors to discriminate between legitimate and illicit mining stock flotations.

The Imperial Parliament in London has just passed a measure designed to aid the "migration within the Empire" alluded to frequently in these columns during recent weeks. The new law makes provision for the expenditure of three million pounds annually for fifteen years in assisting British settlers to become established in the various Dominions and colonies. There is an understanding that the Governments of the latter shall likewise lend assistance to the newcomers, and that the settlers shall be of a sort likely to succeed in agricultural occupations. The Motherland has, as usual, taken the lead and the main responsibility. We must now do our share. As pointed out repeatedly in these columns, we in Canada can best prepare for an influx of population by a rapid and sound development of our mining industry.

The Geological Survey at Ottawa has asked for applications for the position of Associate Geologist on its staff, the applicant to have had a thorough experience in the geology of the Maritime Provinces. The salary offered by the Civil Service Commission is, as usual, ridiculous as compared with the standing it requires in the applicant; yet the honour of associating with men of the character and calibre of our Dominion geologists, and the opportunity presented to a man of science for following up his chosen work will, we are sure, bring to the Survey the right man—if, indeed, it does not bring back to the fold one who has temporarily left for distant and greener fields.

MAXIMS

(Mr. Kipling will, no doubt, resent the liberties here taken with his poetry. If he knew how hard this imitator has had to strive for rhymes, he would feel, not anger, but pity.)

My son, if I, Hafiz, thy father,
Endeavour to sell thee my stock
In a mine, or a prospect, or quarry,
Prepare thy young soul for a shock.
It will teach thee that (sweet cupidity)
Is wisdom that no one can mock.

My son, if promoters approach thee,
Unfeelingly point to the door;
They have nothing that could'st not get cheaper
At bootleg, or tickets, or ore.
They are marked on the listings of suckers,
All those that are lacking in lore.

VATES

Notes on Prospecting in the Cariboo, B. C.*

By W. A. Johnston, Geol. Survey of Canada.

The recent discovery of placer gold on Cedar Creek, in the Quesnel district, British Columbia, is drawing prospectors once more to Cariboo, the oldest and most famous of the gold fields of the Province. The writer examined parts of the Cariboo district in 1921 and offers the following notes on the district in the hope that they may be of some value to the prospectors in their search for placer gold.

Discovery of Cedar Creek, 1862

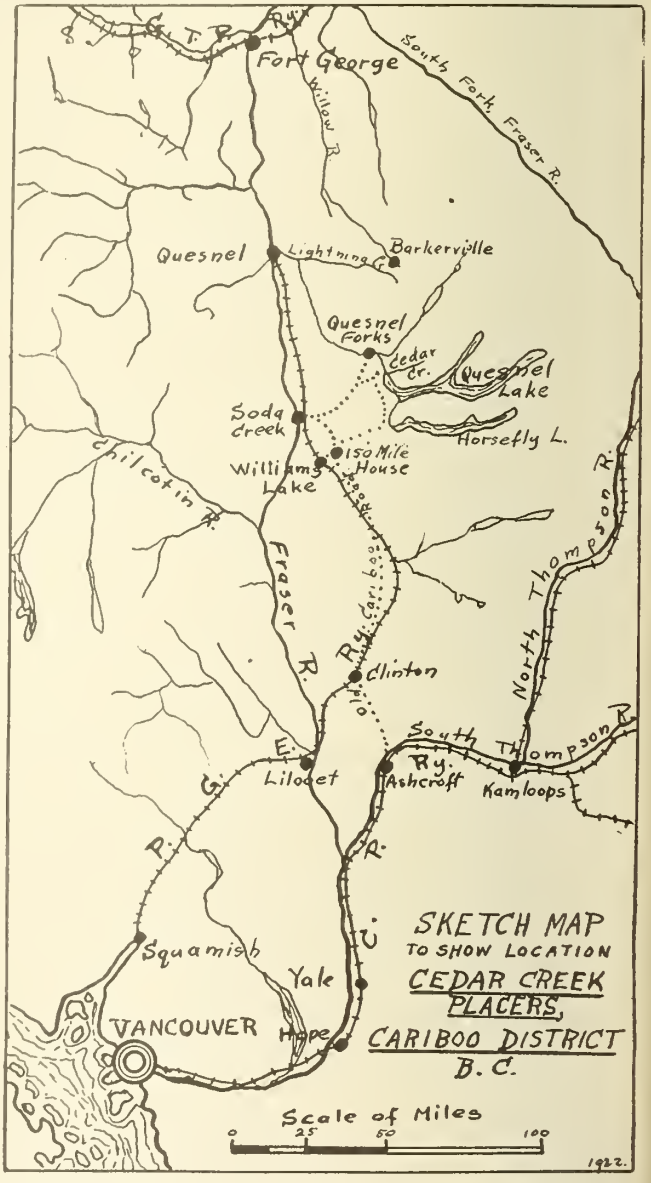
Cedar Creek is a small stream flowing into Quesnel Lake from the east, about 3 miles above the old dam at the foot of the Lake. It was first ascended by a prospecting party in 1862, but apparently, because of the important discoveries in the deep ground of Williams Creek, early in the year, was abandoned until 1865. The discovery of Cedar Creek was credited to J. E. Edwards, one of the prospectors of the famous Aurora claim at the mouth of Conklin gulch, a tributary of Williams Creek. The Cedar Creek diggings proved to be valuable, yielding steadily as well as largely for some time. Bancroft states in his history of British Columbia that the Aurora claim, with flues and sluices costing $8,000, yielded mostly in 1866, $20,000; the Moosehead claim, costing $2,000 to open, paid $7,000 the first year; the Barker claim also located in 1866, and costing $7 000 to open, paid $2,000 in a year; and the discovery claim was yielding in September 1866, $15.00 to $20.00 a day at a point where it was shallow. These claims were apparently all in the bed of the creek; the part found to be gold bearing extended upstream about 1 1-2 miles from the mouth. In September 1867 both the Aurora and Discovery were averaging $20. a day to the man. The Aurora Company in July 1867, completed a flume 2000 feet in length, dumping into Quesnel lake. Some of the ground on the bedrock yielded $2.25 to the pan and the pay dirt was from 6 to 8 feet thick. G. M. Dawson states that in 1886 the creek was largely in the hands of Chinese miners who worked it for several years by the hydraulic method on a fairly large scale. Coquette creek on Poquette creek below Cedar creek on the same side was also found to be gold-bearing in 1866. It was worked by the Chinese for several years. Several bars on the south Fork of the Quesnel and near the Forks were rich. Roses gulch on the east side between the Forks and the dam and the famous buried channel known as the Bullion property on the west side have been worked for many years.

A Tip to Prospectors

It is important for present day prospectors to know that in the 60's several thousand prospectors, many of whom were energetic and capable, were in Cariboo district and pretty thoroughly tested very many of the creeks. There are comparatively few creeks in the region in which careful search will not reveal traces of the work of the early prospector. The present-day prospector should search carefully for traces of old workings, before sinking expensive shafts, and he may be fairly certain if he finds them that the ground was well tested in the early days, unless it was deep or the water pressure was excessive. It is true, however, that the early prospector's efforts were largely restricted to testing the ground on the bars and in the beds of the present creeks and that only a few benches or high level channels were found or were searched for. The recent discovery on a bench or high level channel 600 or 700 feet above Cedar Creek shows that such channels do occur, and these are the channels the prospector should search for particularly.

The Origin of Placer Deposits

Placer gold deposits are not formed by the grinding down of rocks by glaciers as is sometimes popularly supposed. The action of glaciers is either to pluck out masses of rock and transport them in the direction of flow of the ice or to grind up the rock so fine that it is



carried away by streams. In either case there can be no appreciable concentration of gold in the channel of the glacier. Placer gold is formed by wearing away of gold-bearing rocks by streams, and is concentrated in the bed of the stream because it is too heavy to be transported by the streams, unless it is very finely divided. The greater the amount of rock eroded and the higher the original content of gold in the rock the richer the placers will be. There is evidence in the Cariboo district that hundreds, if not thousands, of feet of rock

* Published by permission of the Director, Geological Survey, Ottawa.

have been eroded in past ages, and as the rocks were in places gold-bearing, conditions were favorable for the formation of rich placers. A disturbing factor came in, however, when glaciers spread over the country, during the ice age which ended only a few thousand years ago. Many of the surface deposits consisting of sand, gravel and stony clay was formed by the glaciers or by streams issuing from the ice. The placer deposits were formed mainly before the glaciers came into existence but some, for example the bar deposits along Quesnel river, have been formed in post-glacial time, by stream erosion of the glacial drift and of the ancient placer deposits. The gold in the post-glacial placers is mostly fine; in the old channels it is coarse. The rock channels in which the present streams flows are mainly pre-glacial in age, but in places narrow, rock-walled canons are post-glacial in age. The latter rarely contain much gold. The drift deposits conceal and partly fill many of the ancient rock channels and render difficult the discovery of the gold-bearing gravels underlying the drift. The ancient gravels are distinguished from the glacial gravels by their more weathered, rusty character and by the inclusion in them of heavy minerals such as iron pyrites, galena, barytes, etc. Gold is not always present, for its presence depends upon whether the rocks from which the gravels were derived were gold-bearing. The glaciers partly destroyed the ancient placers and eroded the bedrock in places but in many places the effect of glaciation was merely to cause the placers to be buried beneath drift and in a few places the gold gravels are found practically at the surface. The presence of rotted rock near the surface in the cracks and joints of which placer gold is found shows that the rock at such places was not eroded by the glaciers to any great extent, and that it, at one time, was in the bed of a stream. The glacial drift contains little gold, but occasionally boulder-like masses of the gold-bearing gravels are included in it. Glaciation has rendered difficult the finding and recovery of the gold, but has prolonged the life of the placers of this region. If the region had not been glaciated, practically all the gold would probably have been recovered within a few years after the first discoveries.

Characteristics of Cariboo Placers

The stream valleys in the Quesnel lake and Quesnel river sections of Cariboo are frequently steep-sided and 300 to 500 feet or even more in depth, and parts of them are of different character and of different ages. The newer, lower channels are narrower and have steeper sides than the older high level channels, of which only fragments, as a rule, remain, for they have been in part cut away by the streams that have formed the new channels. In attempting to locate and trace the high level channels and benches, the surface of the bedrock should be considered rather than the surface of the drift; for this may fill inequalities in the surface of the bedrock and be itself in the form of terraces. The old channels are partly confined to the valleys of the present streams and occur as benches extending for short distances along one side or the other of the present valleys. If the old channel was gold bearing, the present creek will be enriched in the parts beneath where the old channel crossed from one side to the other, or in other words where the present channel has been cut down beneath the old channel. Some of the old channels may be independent of and cut across the present channels, and the streams in the old channels may have flowed in different directions from the present streams. The direction of flow of the old stream is occasionally indicated by "shingling" in the gravels, that is the the stones overlap downstream and dip upstream. The gradient of the ancient channels was probably only a few feet to the mile, so that if one portion is found, its extension should be looked for at nearly the same level.

Lava Flows May Cover Placers.

Another factor of importance in the Quesnel river area is the presence of lava flows and the possibility that gold placers are buried beneath them. The lava flows do not occur in the Barkerville area but are exposed near Quesnel Forks, along the trail leading to Quesnel lake, and at other places along Quesnel river. They are probably mostly of Tertiary age. It is possible that in places they fill ancient valleys and overlie gold-bearing gravels as is the case in California, but no important discoveries of this character have been made up to the present in British Columbia so far as known. The lava-buried gravels can be prospected only in those places where the streams have cut through the lava, and these places are not numerous. A few occur in the vicinity of Quesnel Forks and doubtless at other places and are well worth investigating.

The facts that discoveries of placer gold have been made in recent years in parts of the Cariboo district, which were supposed to have been thoroughly prospected in the early days, and that some of these discoveries are in high-level channels which were not recognized formerly, shows that the area is still worthy of careful prospecting. The Quesnel Lake and Quesnel river section is easy of access but is difficult to prospect because of the dense covering of timber and underbrush, which renders difficult travelling away from the trails; but for this reason it has probably not been as well prospected as other parts of the region.

THE END OF BOTTOMLEY

By Alexander Gray

At first blush it may appear that the conviction of, and seven-year sentence meted out to, Horatio Bottomley, is of no more than local interest. The result of the trial has deeper significance than the average reader attaches to it, because Bottomley, at 62 years, is a shining example of what should befall all such as he, who fleece the public while posing as leaders of thought and as benefactors. Bottomley was a mining promoter. His repute in that sphere was a long way from the best. He belonged to the Whittaker Wright, Terah Hooley school. The tragedy of Dufferin rests with men of their ilk. Wright was directly responsible for the ruin and death of Dufferin. The wonder is, in view of Bottomley's career in connection with the manipulation of mining shares, that he ran so long. By demagoguery and preying upon the frailties of human nature, he developed a large following, entered the Imperial Parliament, and many accepted his utterances on John Bull as gospel. Bottomley was *bull* personified. Really he was Editor, not owner, in perpetuity, although the public in general thought otherwise. Frittering in patriotism cost those who confided in him, over $500,000 and the chances are he will not survive his sentence. At any rate, his consummate nerve (of a kind) is more remarkable, if not admirable, than was the cowardice of Wright. Knowing short shrift would be given to him, Wright sat in a room adjoining the court, awaiting the verdict. He had a dose of cyanide secreted on his person. It had been covertly conveyed to him. This he swallowed, and that was his ignominious end. His betrayal of Dufferin was unpardonable. Bottomley deserves no sympathy. The patriotic pickpocket is the meanest sort of predator.

Canadian Associated Goldfields of Larder Lake

CAPITALIZED AT $30,000,000, FINANCED BY THE PUBLIC, DIRECTED BY MACKAY INTERESTS, CONDONED BY THE GOVERNMENT

BY ALEXANDER GRAY

In ye olden time the stage had serio-comics who admixed the sentimental and the jocose at slight expense. The artistry differed from the melodramatic. Audiences from pit to gallery applauded the performers—but here our parallel fails; for the stage-acting of what is now known as Canadian Associated Goldfields of Larder Lake, nominal capital $30,000,000, has not won the unanimous approval of the Ontario public. This corporation has not only induced levity, but has provided so much "sob stuff" that it now deserves a curtain call "lest we forget".

The short-memoried public has by now almost forgotten the halcyon days when "Highland Mary" and the "Silver Bird" were tickling their fancy, and bringing oodles of cash into the elaborate offices of Frank Law. Overworked letter-carriers trekked between the Toronto Post-Office and the Law counting-house (where most of the legal statutes governing the sale of mining shares were being violated). An army of clerks broke speed limits sorting letters containing remittances, while others devoted themselves to out-going correspondence describing the charms (mostly literary) of "Highland Mary" and the "Silver Bird". Frank Law was the acknowledged wizard of finance; he was the croupier with the long reach; but he rather over-reached, and the longer arm of a more powerful Law bundled him, Mary and the Bird into a large stone building where "financing" was not part of the daily routine.

Occasionally others have lapsed—the authors of "King Solomon's Mines", for instance. But these matters, though parts of such recent history, are now almost forgotten.

Punishment meted out to offenders has, however, had a restraining influence upon those who would flagrantly abuse the mails. It also brought about a limp censorship of prospectuses. Extravagant claims and covert attempts at the diversion of monies were officially scrutinized. Cobalt "bloom" no longer justified capital issues by the million; "quartz" without gold lost its hypnotic influence. Spell-binders were restrained from sequestrating all the public's small change. But that was after hundreds of millions of lithographed papers had become so many tributes to the asininity of humankind—paper of no value to junk dealers, and not amenable to vacuum cleaning until shredded.

Larder Lake on the Screen

Antedating a lot of the deviltry of the Portage Bay and Montreal River districts was the Larder Lake furore. When "bloom" and silver lost their lure, gold drew the adventurous, and stakes on frozen lakes, snow, swamps—anywhere—attested their activities. Every area staked for gold was an "old Lady of Threadneedle Street" in embryo. The Harris-Maxwell property was considered a mammoth affair. "You can put the whole thing through the mill, down to indeterminate depths," or words to that effect, declared an impetuous optimist The Dr. Reddick!—Oh, it was ready at the grass-roots for a mill! Gold!—Why, the wealth of the Incas, the treasures of Ophir, the ducats of the Spanish adventurers, were as petty cash compared with what the Harris-Maxwell-Reddick held in store! When 1906-7 ice and snow went out, there was no telling what might happen to the gold-standard!

Incidentally, Brock was commissioned to geologize the locality; and that his findings were in strict accord with the facts, is now fully proved, a decade and a half later.

Larder Lake, Abitibi Lake, Opasatika Lake—other waters when land ran short—were staked by prospectors or tucked up the governmental sleeve. Those that doubted the arrival of an Eldorado were arch-pessimists. Quebec, disappointed at not having shared in the silver development, dispatched Obalski to the Pontiac district, where he made a flying survey. The excitement was passed on to Chibogomo, where Harvie, concurring with Broek's Larder Lake conclusion, naively diagnosed Chibogomo as a section where "the gold is found to be rather widely distributed." Rawther!

Reddick Rushed Production

This was the overture. Among the occupants of front seats was Bannell Sawyer, indefatigable in pursuit of prospects. He saw in the Reddick one of those opportunities (physical and psychological) that must be taken at the flood. Nothing could be easier than to raise working capital for it. Mr. Sawyer succeeded in putting the Reddick before the public. In his zeal he brought it to the milling stage-with a second-hand mill, a pair of copper plates that defied good amalgamation, an assay office and the other requisites. He was strongly advised by this Manager to force the pace; Reddick millions in the ground were idle millions. That Mr. Sawyer was, at the moment (a critical moment), sincere, no one who knew his ardent disposition will dispute. Being an L. L. D., now he understands that "a little learning" in mining matters was not exactly safe for him. However, his Manager urged production, and the Reddick mill was rushed along.

Meanwhile, as an interlude, London was reported to be seeking control at a price about 1,000 per cent, (or was it 2,000 per cent. ?) above the Montreal share-market price of Reddicks. Mr. Sawyer considered Canadians obtuse in allowing London to get ahead of them. With commendable reserve he described how preposterous it was for the Rothschilds and Rand magnates to offer paltry sums for Reddick shares, when soon the mill would be running and there would be required a bucket elevator to take amalgam to the refinery. "'Tis to laugh!" chortled Mr. Sawyer. Inefficient amalgamating appliances had no terrors for him. He was buoyant to the point of explosion on the occasion when some of us warned him he was riding to a fall.

Enter De Pencielr — Exit Redick

Amalgam from the first clean-up was duty retorted, taken to the Ottawa Mint, and Canadian-made gold pieces were ordered. I am the proud possessor of one of these souvenirs. There were not many, for the Reddick died a'borning, of infantile paralysis. When I asked Mr. Sawyer where his mill-feed came from, he replied, "From the dumps." "Who made up the dump?," I impertinently inquired. "It was just as it came from the mine," quoth he.

Perhaps it was so. Somehow the dump was exhaustible—or working capital was, anyhow. A share market

was made, to the accompaniment of a noise like a battery in action. Ludicrously enough, two knightly Londoners, sojourners in Montreal, became interested, and awoke to find themselves plus Reddick shares but minus cash. They had to cable for funds to continue their journey.

At this juncture, a development treatment was prescribed for the ailing property, and Mr. Sawyer retained H. P. De Pencier to administer the dose, announcing that at last he had found a man big enough for such a mine. In divining Mr. De Pencier's true quality, Mr. Sawyer did not realize the sequel. Mr. De Pencier was not disposed to accept the Reddick on faith. He found that the milling ore averaged less than $1. a ton, and without further ado forswore the management. The Reddick went into liquidation, was sold under the hammer, and a trio of heros bought it in.

Capitalized, Nevertheless

To begin with, the trio had no misgivings as to their bargain. In their reckoning, the alchemy of wealth had come their way; it remained for them but to gather in the money. But their attention was given first to their Harris-Maxwell property, or Goldfields, Ltd., though the district was now in dis-favor, and though it had been found that (as Harvie intimated) the gold was "found to be rather widely distributed".

Harris-Maxwell shares were cherished by their owners. They had a "quarrying proposition" in which they, as charter members, were going to split the honors with John D. Rockefeller's original partners, Hearst and his Homestake crowd, and Agassiz' first associates in Calumet and Hecla. It was wonderful to behold this unanimity induced by the Three Horsemen among the Reddickites and the entranced Harris-Maxwellians. Ferruginous dolomite continued to grow in favour as a potential source of gold brick, and the roster of those of the Larder Lake cult was extended. The lucky owners of part of the Goldfields capital stock of $3,000,000, or any of the others with nominal issues of a few millions apiece, talked knowingly of carbonates and tellurides. Gold-mining companies were incorporated annually with total capital stock of from $250,000,000 to $320,000,000; but these enriched mainly the Provincial exchequer. Larder Lake was well represented among this galaxy of beauties; but only the Reddick and the Harris-Maxwell reached the producing stage. A grab sample of the companies created as early as 1907 has educational value. Here it is:

Companies.	Capitalization.
Empire	$1,000,000
Gold Belt	1,250,000
Gold Horse Shoe	1,500,000
Highland Mary	3,000,000
Independence	4,000,000
International	5,000,000
Big Four	1,000,000
Bonanza	1,000,000
Goldfields	1,500,000
Gold Reefs	40,000
Consolidated Gold Mines	1,000,000
Exploration & Development	500,000
Le Roi	1,000,000
Little Larder	2,000,000
Martin	1,000,000
Proprietary	3,000,000
Tourneme	2,000,000
Tighe	1,000,000

This display is fragmentary and inadequately representative of the expectations entertained during what was the year of panic elsewhere. The total of $33,790,000 is about eleven per cent. greater than the present day capital of the Canadian Associated Goldfields of Larder Lake. However, it was vouchsafed a while ago that the Associated had "assets" approximating about two thirds of the nominal 1907 capital of the eighteen companies enumerated; so the balances are adjusted in sofar as they can be until milling capacity of the Associated is shown to be not all wind-milling.

The Associated Merger

Larder Lake is now "sweet sixteen"—that is, it disclosed gold first in 1906. Unfortunately, pre-natal defects and early indiscretions have spoiled the bloom of youth.

Having concluded the first act, we can go on with the play. Enter Associated Goldfields of Larder Lake. The Reddick scene had been short; it had "got the hook" almost as soon as it came on the stage. The Harris Maxwell had spoken a line or two—"made a small contribution" to the world's store of gold, is the way Mr. Percey E. Hopkins describes it in his report on Ontario's gold. The Kerr-Addison was on the play-bill, but without a speaking part.

In more ways than one Larder Lake was a stock work affair. To date its total gold production has been "approximately $50,000."; yet this production has acted like Ponce de Leon's far-sought spring of perpetual youth in keeping alive the decrepit properties of the district.

The next scene is a quilting party, in the vein of light (but low) comedy. Bannell Sawyer withdraws to "Millionaires' Row," and George A. Mackay enters with the Tourneme property, and an attached $2,000,000 capital stock. The Tourneme prospectus was a work of art. I am doubtful whether or not his brother, R. W. Mackay, was his co-adjutor in the Tourneme. That is a detail. Dr. Mackay began early with a roseate outlook on life, and presumed the Tourneme was of a piece with the Reddick and Harris-Maxwell, as reported. The natural consequence was a patch work construction, with Reddick, Harris-Maxwell and their respective mills and Tourneme as the main piece and Lucky Boy, Kerr Addison and Gold King to fill out the corners, Raven Falls having a place near the centre. This was going to form a magic carpet, on which one could wish one's self directly into the golden streets of the New Jerusalem.

Mackay brothers were undismayed by the former records of their gold mines; no, they were super-men, fit to succeed where these engineer fellows had fallen short of success. A mystery market in shares of Associated Goldfields of Larder Lake developed, an enthusiastic following supported the claims of the modest promoters, and by easy stages the shares advanced in value. It was an exceedingly neat job. It became a favor to let a friend have a few shares for a consideration. When influential capitalists proffered their assistance, provided their engineers examined the workings, the "no help needed" sign was hung out. On April 16th, 1920, when Associated Goldfields had a bulging treasury, a series of bore holes was announced by Manager Moore and the brothers Mackay as heralding a gold production never before equalled in Canada. Dr. Mackay in his address in Toronto on that date to Associated Shareholders, spoke of huge ore bodies with an average value of $5 a ton, in which were included two long lenses of high grade ore (at $11.45 a ton from 40 to 140 feet wide, which diamond drilling had established to a depth of at least 500 feet. To mill this vast quantity of ore a mill of at least 1000 tons daily capacity was to be immediately erected, to be ultimately increased in size to 10,000 tons capacity.

A Set Back

All appearances seemed to corroborate the Mackay claims—to the uninitiated. That was two years ago. Meanwhile the Hopkins report to the Provincial government, suggesting "detailed mining" was correctly interpreted by the initiate. The Associated company kept on drilling, but an outside engineer was retained to verify the Moore data. He did not take any samples. The drill core sampling and Manager Moore's tabulated results, convinced Clifford E. Smith that Associated shareholders needed a guardian. He could not assent to the assumption that there was a paying milling average. The original conclusion of Mr. De Pencier was reaffirmed by Mr. Smith. There was a great quantity of ore that might run a dollar to the ton, and more ore that would run less. Mr. Smith advised against the Moore plan of development. He recommended that small prospecting shafts be sunk on the foot-wall, to ascertain whether there might be local enrichments. This, he thought, would cost about $10,000. If there was nothing better than what the present workings contained, Mr. Smith favored the abandonment of the properties—which President Mackay, a few months previous, had arrayed as probably warranting an ultimate milling capacity of 10,000 tons a day. President Mackay disclaimed this advice. His share-holders were, he asserted, more than ever impressed with the potentialities of the properties; they preferred to sink a central shaft so situated as to reach the area, penetrated by several bore-holes, where the two lenses were presumed to carry their "exceptional values". President Mackay let a contract for this shaft. At that time he, Mr. Cook of Ottawa and Mr. L. A. Smith had supplied whatever assay plans and geological data there were. Associated officials were either fully informed, or oblivious to the obvious.

What George A. Gray Found

Looking around for some one competent to swing a collection of mines, an elastic mill that could be stretched to 10,000 tons daily, and manage the hydro-electric plant while prosecuting the development of high grade, and the low-grade section from 400 to 500 feet wide, George A. Gray, then with the Dome Mines, was induced to become General Manager of the Canadian Associated. President MacKay was well within the facts when he publicly stated that Mr. Gray knew his business and had the respect of those with whom he served. Moreover, Mr. Gray, it is understood, had been so impressed with what was divulged about Asociated workings and values that he was flattered by the opportunity. In December, 1920, the capitalization of the Associated company had been increased to $30,000,000 (each shareholder had received four shares for one); so it was not amiss for Mr. Gray to think on January 1st., 1921, that he was the keystone in a triumphal arch under which shareholders and he were going to march to millions. But now Mr Gray acts as though he inserted the sigh in silence. He found there was enough acreage, abundant money and script, two stamp-mills, a developed water-power, 22 miles of pole line, and a three compartment shaft down 65 feet on the Kerr-Addison ground, which was considered the most attractive for immediate milling purposes. So far: so smug. It was when he, being inquisitive, had a squint at the core sections, vertical, angular and horizontal, and a composite working map of the Harris-Maxwell and learned there was no assay plan of the Harris-Maxwell, that he registered misgivings. The Harris-Maxwell was developed by a shaft to 429 feet; lateral work done amounted to 244 feet on the 3rd level; 1705 feet on the 4th level, and 2528 feet on the fifth level. Investigation showed that 4,000 tons had been taken from an open pit and 3,000 tons from stope on the 54-foot level, reached by incline shaft. Dr Mackay milled this tonnage under his agreement with the Harris-Maxwell shareholders; but Mr. Gray did not have the record of the milling returns and no assay plans, let it be emphasized. Not only that; there was no information about three drill holes.

Mr. Gray took note of the legendary core values and the places where channels had been cut by samplers. He also jarred a crew loose from their work in barren green schist. Then he made an accurate survey of the properties and the workings throughout and entered upon a sampling campaign. On the 3rd level he took 147 samples along 297 feet; on the 4th level, 921 samples along 2,169 feet, which he re-checked; and 480 samples along 1234 feet—1548 samples in all. Putting it mildly he was a trifle dazed with the results. He went after the contact conditions on the 3rd level—and was rewarded with an ore shoot 2 feet wide and extending laterally for 70 feet. Without eliminating the higher values, the average was $9. He raised two rounds on this showing; in 8 feet the values dwindled to a trace,. 42c., 42c., $1.65. Apart from this 70-foot shoot there was nothing to be jubilant about on the 3rd level. It was the apex of a better-grade section that extended from the 3rd to the 5th level, he found out afterwards. However, he went at the 4th. level. On the contact with the dolomite and the greenstone he got $3.72, $7.04, $4.13, $4.50—nothing to write home about. Some schist went .21c., 42c., nil, etc. The other work in the dolomite on this level gave him, for example, $1.65, $1.24, occasionally a little more, generally very much less. One assay of $72.75 and another of $106.37 did not sweeten the ore shoot as it existed on this 4th level. The shoot was 90 feet long—twenty feet longer than it was on the 3rd level—and the following will give an idea how the values ran:

.62	$1.24	$3.31
$1.75	.83	16.70
2.38	2.04	1.65
1.75	4.96	3.31
1.24	2.38	2.48
.73	1.75	.56
3.32	.83	.42
1.24	.62	Trace
7.75	.62	2.07
1.65		2.48
		1.24

These will suffice. Where the results as given call for explanation, it may be said that Mr. Gray had many samples put through two and three times and then averaged. Much of the sampling yielded nothing, traces or a few cents. The better values were found in a broken quartz section in crossent 402.

Worse And More Of It

Between the 4th and 5th levels, green dolomite cut into the shaft. This affected the 5th level, where the only value in sight was a patch of free gold between the green and brown dolomite, as the position was described at the time. Sampled in three sections, 1'6" wide along 18 feet, there was free gold. There was a raise and a sub level planned—but the apparition faded before he got there. A. 160 foot shoot on this 5th level was too erratic to be useful, what teasers there were being too far apart, and at both extremities there was nothing. Between 501 and 502 crossents, here is a partial record, by sections:

$ .83	$ .62	$29.14	$ .83	$ 2.89
1.60	4.85	.62	.62	4.13
.62	.62	.83	3.10	.83

$ .42	$ .62	$ 1.65	$ .42	$ 2.19
.62	.42	.62	.83	.43
.83	.42	1.24	2.08	.83
$ .83	$ .42	$ .83	$ .83	$ .83
12.16	7.44	2.50	2.48	1.65
.62	.64	6.62	1.24	.62
$ 6.15	$ 9.50	$ 1.24	$ .62	$ 2.07
.83	9.50	2.07	.83	.42
1.04	1.24	.83	1.04	1.65
	$ .42	$ .83	$ .83	
	32.66	4.15	.42	

Space restrictions do not permit of the recounting of all the results. The foregoing portrays the best there is. The blanks are unmentionable. The average width of five feet of this shoot, between the 3rd and 5th levels, represents about 1,800 tons of ore, and on the 5th level, 55 feet of it averaged $2.60. Drilling on the horizontal on the fifth level disclosed nothing of merit.

In the 1800 feet of holes, the highest assay was $1.20. This was on the contact of the green with the gray dolomite. No. 2, of those holes, a vertical hole to intersect the vein, was put down 500 feet. It revealed no values over $1. No. 3 hole, to a depth of 339 feet had no values. Other holes feeling for extensions did not pick up anything below the 5th level. Two horizontal holes, on the 5th level, about 700 and 670 feet respectively, to test a porphyry section noted in the lower workings showed the formation to be the same as it appeared at surface. More drilling toward the Gold King, a distance of 700 feet, got nothing. Two more holes from the same set-up on the 5th level, underneath the lake, found only green schist, although some claims were made that there were showings on a near-by island. Still more drilling, to locate a bit of porphyry, failed of results.

Reddick and Kerr-Adison Results

Most of the drilling on these properties was done by Mr. Gray's predecessors. Mr. Gray sampled one section of the Reddick. In an old stope he found 4 feet of ore going $9.90, for a distance of 28 feet. This was where the Reddick got its sovereigns from, on the 80-foot level. A small section between the dolomite and schist went $3, $1.65, etc. Here and there a good assay was secured. Anyhow the Reddick had some records available. As the Kerr Addison and the Reddick had been exploited simultaneously by diamond drill, the results are conclusive. It is not proposed to give those results consecutively. One hole was put down underneath a Reddick glory hole where there was 5 feet of $26.40 ore. Then there was 10 feet of barren rock, and then 5 feet of $4 ore. Proceeding into the Kerr-Addison, four more holes went down. At one place there was 5 feet of $4 ore, and 125 feet away there were two assays of $5.60 and $5. The next hole went down 400 feet, and the best it could do was: $2.20, $4.60, $3.00, $4.20 and $12.60. Near this, another hole notified its highest result as $1.00. A diagonal hole put down 650 feet had some high spots, far apart. One went $20.00, and another $75.20. There were a few more, and they made Dr. Mckay wax eloquent however inconclusive when considered in connection with the other holes, there being no lateral or vertical continuity of enrichment. To establish this more fully it may be stated that a further hole on the Kerr Addison (the property that led to the $30,000,000 capitalization) yielded $4.60 and 20 feet from the bottom of the hole there was a $2 result. There was nothing in another hole until it was almost finished. Then $36 over 5 feet was reported, after the hole was down 400 ft. Next: at 100 and 110 ft. two assays of $7 and $12 are on the list. In the remainder of the core, two assays of $3.20 and $2.40, were the best, others being below $1.00. In the next hole, aside from four assays of $16.00, $3.40 $2.60 and $6.80, excepting one of $1.80 and $ 1.60, the others were mostly blanks. One more hole showed up $7.60, $3.00, $1.00, $2.20, $2.00, $1.00, $0.60, $2.20 and $6.00, across 5 feet, 180 feet away. At a depth of 105 feet another hole presented $3.20, and $6.40 at a depth of 300 feet. Still another gave one assay of $7.40, over 5 feet, one more of $5.60 at a depth 90 feet more, and of $4.60, at 100 feet, —zero being the judgment on the remainder of the core. A hole that penetrated to 280 feet gave one result of $30; the balance was under $1.00. Then there was a hole that evoked enthusiasm when it gave an assay of $15.40 at a depth of 55 feet. It was barren until 90 feet was reached and $14.20 was reported.

Erroneous Assumptions

This exhibit might be continued throughout. Isolated enrichments were without vertical or lateral continuity. No attempt is made to keep the records of the drill holes in their chronological order. The management persisted with a fatuity that is incomprehensible to mining men of experience; and the administration had increased the capital to $30,000,000. President Mackay arriving at the conclusions voiced in his speech. He always flouted engineers. To say that "high grade" lenses had been proved to exist for a lateral distance of "2,000 feet" was worse than nightmare. If there were any sleep-walkers, they were shareholders. Undoubtedly Manager Moore lumped his core sections in an entirely unjustifiable manner, and struck an average that was merely a bad dream. The most cursory examination of the core records and results demonstrated the hopelessness of the situation. A hungry mass of rock with values quite unrelated, appear to have induced the Associated Board and Management to persist. It is a coincidence that Harris Max well data disappeared.

At any rate, taking the drilling results as outlined (Messrs. Cook and Moore being responsible for most of the work) the three compartment shaft was down a short distance when George A. Gray assumed the management. Between 18 and 10 feet in this shaft, it will be recalled that the presence of some free gold was promptly communicated to the public. There was no more of it, that was mentionable, until a depth of 190 feet was reached. At that point, there was a pocket of specimen rock. It was a mere "kidney", without dimensions of moment. At a depth of 190 feet in the shaft, there was another similar pocket, though not so rich. The shaft was in barren rock all the way down to 316 feet, except that in cutting a station at the first of 175 foot level a few specks of gold were observed. Work began on the first level near No. 21 borehole which cut the south contact. In the south crosscut there was one 3 foot section that gave $0.20. The spot was re cut and it went 21 cents. It was more of a vug than a pocket nine inches square not much to brag about as a source of mill feed. In the north crosscut, a start was made on 6 feet of $5.10 ore, one check assay giving $11.20. When the spot was cut under, the find was proved to be a cooling crack in which assays of 12c and a trace formed a basis for cut-off of stringers. In a little greywacke $3.11, $2.06, etc. and other fair were picked up, 20 feet away. On another wall about twenty seven feet away, 3 feet of slightly schisted broken quartz gave $35.12 and $2.38. Further along by twen-

ty-one feet, the values were 83c and 63c. A drift was started on a cooling crack and was carried in for 90 feet. There was $2.48 in the heading. Three samples across 6 feet for a lateral distance of 1' 7" yielded $3.93, $14.88, and 11c. A check taken from one side gave 21c, 21c, and 11c. The check taken from the other side went 95c, nil, $1.52. A round out of the drift went $3.31 and 21c. A section below this went 21c. One spot went $28.41 along three feet.

Piling on The Agonies

George Gray had a heavy track and an impost that would put a less courageous manager among the also-rans. His first lateral development made him sicker than hope deferred. Taking up the 2nd or 300-foot level, he thought he would try out both contacts. On the south wall there was nothing. Where there was some oxidation and a cooling crack with a showing of free gold, he started a drift. The crack lasted 5 feet. In a distance of 106 feet he encountered two more pockets. He went 40 feet before he got a $6.20 assay, a trace, $8.27 and $1.26. Going to the right about, north from the north crossent there was 3 feet of $11.57 ore. On the opposite there was a blank. On the west wall, 24 feet away, there was a lonesome $24.40 over 3 feet, the opposite wall being blank.

It is unnecessary to enumerate more results. Mr. Gray having explored the underground in connection with some of the drilling, realized the folly of it all, after doing 1150 feet of lateral work. He was completely convinced that pastures new were preferable. He had kept President Mckay and the Board fully advised on what was transpiring. During his brief incumbency he had done half as much work as was accomplished in the twelve or thirteen years previously.

Last October he took advantage of a dispute with a contractor to propose to pull the pumps and stop the travesty. President Mackay was fatuous. Certain of his colleagues of the Board decided to face the inevitable; it was a case of death-bed repentance and a resolution was passed restricting operations to surface prospecting. That there was an utter absence of sound judgment and frankness throughout, cannot be questioned, however much the Directors were guided by their advisors. In lumping his core and striking an average, Mr. Moore erred. As a notation opposite one borehole, notwithstanding there was nothing below 350 feet, he wrote that from 400 to 675 feet, "the core was principally chlorite schist with very little quartz", yet this showed "infiltration from surrounding and higher-grade ore surrounding this stratum."

No more extraordinary stunts have been preformed in the history of the Ontario North Country. As to Canadian Goldfields shareholders. What are they going to do about it? "There are none so blind as those who will not see".

Now for some pertinent questions:

How many shares did officials sell while all of this was going on, and the generality of shares were pooled?

Why did President Mackay say Manager Gray's report was not ready for the last Annual Meeting, when the Directors already had resolved to stop underground work on the wonderful Kerr-Addison?

Where are those "assets", approximating $23,000,000? Are they in the weakened treasury, the practically abondoned properties, a later prodigy that cost $6,000, or the Raven Falls power plant?

Is it all a laughing, a crying, or another sort of matter to have this grotesque "financing" end in a fiasco?

P. S., and Sequel

Stories with throbs, if not sobs, should have a sequel. A Happy Ending is not always possible. What became of the Larder Lake properties and their be-millioned potentialities, never has been the subject of official statement to shareholders. To all intents and purposes, they are on their way to the crushing stage. Unofficially it is known that work was concentrated at another area, also in the Larder. This ground was bought for about $6,000, a modest amount for a $30,000,000 corporation. A plant was installed and the power line was extended to it. Mr. Rolfe is in charge. The property adjoins that drilled by Crown Reserve, where a low-grade section may or may not make a mine; at any rate it will not be sufficient for Associated capitalization. Instead of Associated shareholders being confided in, and the truth imparted as to the mining situation at the Kerr-Addison, Harris-Maxwell, Reddick, etc., here is what they received ten days ago:

"Telephone, Adelaide 5682.

"Canadian Associated Goldfields, Limited

"306-7-8 C. P. R. Building, Toronto.

"May 8th, 1922.

"Dear Sir:—

"Your Directors wish to advise that the work is progressing well at the mines. Our shaft has now reached a depth of three hundred and twenty-five feet, which should be considered very satisfactory. At the three hundred and seventy-five foot level another station will be cut and from here a crosscut will be run across our ore body. Everything possible is being done to drive this work vigorously.

"The demand for power is rapidly growing in our district.

"On the adjoining property the Crown Reserve Mining Company have erected a complement of large and substantial buildings, and have commenced sinking a large three compartment shaft.

"A number of other companies are also starting operations in the vicinity.

"Yours very truly,

"R. W. MACKAY,

"Secretary."

This is what is in sight after several years of misguided effort. Secretary Mackay writes of "progress" at the *"Mines"*! It is charitable to draw the inference that this is a lapse.

Correspondence

FELDSPAR IN QUEBEC

Editor's Note: The following letter from Mr. Melkman setting forth the claims of Quebec as a potential producer of feldspar, is much to the point. We can hardly subscribe to his statement that previous writers in the Journal have ignored Quebec's feldspar production and potentialities; but we can add to his statement the fact that to-day Quebec is supplying from the Buckingham district, a large fraction of the Dominion's feldspar production.

To the Editor,

Canadian Mining Journal.

Sir,

I have followed with the greatest interest the various articles which have appeared within the past few months in your valuable columns, dealing with the exploitation of feldspar properties in Canada.

Most of the gentlemen who have contributed to these articles seem to take it for granted that there is only one part of the Dominion of Canada capable of pro-

viding foreign markets with good feldspar, and that, according to them, is the province of Ontario. I do not know whether all of these gentlemen have any special interest in Ontario, but I take it that any writing dealing with Canadian feldspar should be broad-minded enough in its scope to describe other potential sources of supply, even though they be located in Quebec Province.

I have special reference to the last article on feldspar by Mr. Segsworth which appeared in your issue of the 12th May, wherein Mr. Segsworth seems to absolutely ignore the existance of any feldspar at all within the province of Quebec. I will endeaver to show Mr. Segsworth and anyone else interested in the subject that there is more high grade potash feldspar to be had within the province of Quebec than in any other part of the world, not excluding Ontario.

Mr. Segsworth's article seems to lay special stress upon the potentialities of the Richardson feldspar quarries, and he mentions an available tonnage of three hundred thousand tons of 'spar. I am quite satisfied that there isn't any such tonnage left in the Richardson quarry, and it is more than likely that Mr. Segsworth was carried away by his enthusiasm.

I should very much like to have some of these gentlemen from Ontario visit what is known in our Departments of Mines at Quebec and Ottawa as the Maniconagan Bay Feldspar Mine, situated in the Seigniory of Mingan, on the St. Lawrence Gulf, opposite the island of Anticosti, consisting of a peninsula about one and-a-half mile long by about three eighths of a mile in width, surrounded entirely by deep water. This property was recognized as far back as 1863 by the late Sir William Logan, and Dr. T. Sterry Hunt, both of the Candian Geological Survey, as he largest known deposit of feldspar. Subsequent examinations of the same property by numerous eminent engineers have confirmed this report, and one only needs to look at the reports on this property by Mr. J. B. Tyrrell of Toronto; Mr. H. S. Denny of the Denny Engineering Company of London, England; Mr. Hugh Spence of the Department of Mines at Ottawa; Mr. A. Gordon Spencer of Montreal; Professor J. T. Singewald, Jr. of John Hopkins University, Baltimore, and others, to come to the conclusion that either these gentlemen were laboring under a delusion, or else it is a fact not to be denied that the Maniconagan Bay Feldspar Deposit is the greatest in existence.

I will quote the last few lines from Mr. Tyrrell's report as follows:-

"Several millions of tons of feldspar in this form, which is the 'Standard Feldspar' of commerce, could be mined or quarried from this little peninsula above the level of the tide water and afterwards, if desired, doubtles very much more could be secured below tide water level." As the feldspar occurs right on the edge of tide-water, where the rock could be loaded into ocean going vessels at trifling cost, it should be possible to mine or deliver it anywhere on the Atlantic Coast or in England at a very cheap rate per ton."

Is there anyone in Canada inclined to call Mr. Tyrrell a dreamer? I hardly think so. That being the case, we may safely assume that there are millions of tons of commercial feldspar in sight on this property. What is more, ninety per cent of this spar is milkwhite in appearance.

I became identified with the development of this property in 1918, and while no feldspar has been shipped from this mine so far, due to the fact that there is no wharf capable of accommodating vessels, the development work carried on during that time has more than proved the statements contained in the reports by the above named engineers. It would be like gilding gold to describe the results obtained from the work performed. We simply proved what the engineers claimed.

A new company, just organized, will commence the permanent exploitation of this property in the course of this year, and it will not be very long before Ontario will have to admit that Quebec is perfectly capable of holding its own, and more, in the feldspar business.

It would not be fair to point to the tremendous feldspar resources in this property alone when speaking of Quebec, and in full justice to other owners of important felspar deposits within Quebec, I would point out that in the Gatineau River District and in the region of Buckingham there exist several feldspar quarries equal in extent and value to the best known in the Verona District, Ontario. In this respect I must disagree with what has been stated in the past, viz: that the deposits of the Ottawa neighborhood in Quebec are inferior to those of the Verona district. Can anyone think of a more valuable feldspar deposit than the one belonging to Mr. M. J. O'Brien and known as the Villeneuve Quarry?

True enough, transportation problems and high rail freight rates so far have interfered with the intensive working of these deposits, but assuming that proper transportation facilities were at the disposal of these Quebec operators they could hold their own against any of the Ontario producers.

In Mr. Segsworth's article he mentions that certain industrial companies outside of Canada prefer Ontario feldspar to any other. This doesn't seem correct, if we admit that the Maniconagan Bay Felspar deposit contains millions of tons of high grade potash feldspar, analysing:-

65 per cent. Silicon Oxide
19 per cent. Alumina
12 per cent. Potash
3 per cent. Soda
0.25 per cent Ferric Oxide
0.75 per cent. Moisture

This is not a random analysis, and I assure you, Mr. Editor, that this property can furnish vast quantities of feldspar analysing exactly as the above figures. The melting point of this 'spar is 1317° C.

I submitted large samples of this feldspar to the Royal Porcelain Works at Charlottenburg in Sweden, and they determined that it was the best spar they ever handled. You must remember that the Royal Porcelain Works at Charlottenburg were the very first porcelain manufacturers to use feldspar at all, about one hundred and thirty years ago. Of course, this feldspar has also been tried out by numerous consumers in the United States and there certainly is no question as to the fact that if we take the Maniconagan Bay spar deposit together with some of the other Quebec deposits already mentioned, the time is not far distant that Quebec will take the front rank in the feldspar field and will maintain that position throughout generations to come.

While I do not deny that Ontario has been very successful so far as regards the production and sale of feldspar, I claim that it was and is due to the fact that until this date Quebec has not made any effort in this line. We are about to see a decided change in this position, and if there are any of the Ontario gentlemen to doubt this, time will tell.

Yours etc.

Montreal, May 23rd 1922. S. E. Melkman

News of Mining

Writing in *Saturday Evening Post*, Mr. Ellis Searles, editor of the *United Mine Workers' Journal*, quoted Mr. J. D. A. Morrow, vice president of the National Coal Association, as giving evidence to the effect that the labour cost in the production of bituminous coal in the United States is $1.972 per ton, and that the average retail selling price is $10.41. Mr. Morrow immediately wrote a correction of Mr. Searles' apparent misquotation. Mr. Morrow states emphatically that the National Coal Association has nothing to do with retailing; that about 88 per cent. of the total production of bituminous coal is bought in carload lots by the user and never passes through the hands of the retailer; and that the cost to the consumer is simply the mine price plus the freight rate, which rate is paid by the consumer. Mr. Morrow shows the labour cost in the unionized fields is the only remaining item that has not been reduced.

Recent discussion of spontaneous combustion of coal in mines, especially the discussion held before the South Staffordshire and Warwickshire Institute of Mining Engineers, held at Birmingham, has thrown considerable light on a vexed question. Adequate insulation is the proper means of preventing combustion due to the absorption of oxygen. It is now believed that fire will occur from natural causes wherever iron pyrite is present in sufficient quantities exposed to air. Control legislation is being sought.

The Government of the Argentine Republic has purchased 10 storage tanks (capacity, 6,000 to 8,000 tons) for erection in the oilfield at Comodoro Riva-davia. A large British tank steamer has also been purchased. The Anglo-Persian Oil Company is already operating in the district, as also are Belgian, Argentine and German syndicates.

Several decades ago the erection of a small blast-furnace at Corral, Chile, marked what was intended to be the beginning of a large iron and steel industry. Now the chief activity is confined to a steel plant, capacity 2,000 tons of steel per annum, which sells direct to the State Railway. The Compania Shilena Electro-Metallurgica, is the operating company. The plant is being enlarged this year.

A tax of approximately eight cents per ton is to be levied on coal produced in the Bihar and Orissa districts, India. As this would presumably be followed by taxation in other provinces, it is being vigorously opposed.

The production of iron ore in Alsace and Lorraine shows decided improvement. Last year (1921) the output per man for each shift (hewers and trammers) was 8.22 tons. This compares very favourably with 7.80 tons, 6.66 tons, 6 tons and 7.06 tons, the individual shift output during respectively the years 1920, 1919, 1918 and 1913. The output average for all underground, and surface workers during 1921 was 3.43 tons, as against 4.39 tons in 1913.

The Fordney (U.S.) Tariff Bill is attracting much attention amongst steel manufacturers in Great Britain. It is claimed that if the proposed duties be imposed, the effect will be disastrous to the export trade in engineering tools, high speed steels, cutlery, etc. A deputation of English steel manufacturers has sailed for Washington to present their views on the subject. The ostensible object of the Fordney Bill is protection against German competition.

Careful surveys of the situation show that metal mining in the United States is not yet observably affected by the coal strike. Only a few of the larger copper mining and smelting plants are idle. Others are working at from 40 to 80 per cent. capacity. Gold and zinc and lead mining are rapidly returning to normal.

The operating profit of the East Butte Copper Mining Company for the year 1921, was $201,835.48. The cost of production per pound, calculated on copper delivered at New York, was 11.2804 cents. The Mohawk Mining Company showed a similar profit of $270,271.80. The cost to the Company of producing refined copper was 15.598 cents per pound.

An English observer, Colonel Harry E. Aykroyd, writing in the Petroleum Times, points out that the great profits yielded by the oil industry have constituted a drawback to scientific investigation of available oil-bearing shales. The externally-heated retort, remarks Colonel Aykroyd, is slowly but surely giving way to the internally-heated type. The use of the latter type makes possible the treatment of great bodies of shales, high in sulphur content, in Norfolk and elsewhere. Norfolk shale will yield only 22 pounds of ammonium sulphate in the former type of retort, as compared with more than 60 pounds in the internally-heated retort. The oil yield for each per cent. of volatile hydrocarbon contained in the shale is also increased by 25 to 37 per cent. The development of the oil shale deposits of Great Britain would, it is claimed, add not less than £1,000,000,000 to the wealth of the nation, employ large numbers of men, and make the country self-sustaining as regards petroleum.

In the Connellsville coal field many striking coke workers and miners are returning to work on account of the failure of the United Mine Workers organization to supply strike "benefit" funds. The State Police have notified strikers that absolutely no intimidation will be tolerated. Production of coal hereabouts is about one-third of what it was immediately before the strike was declared.

From the latest available official figures it is learned that Canada was the largest consumer of zinc oxide exported from the United States during 1920. The quantity taken by Canada was 4,924 tons; all Europe took only 1,168 tons.

Alaska produced 26 short tons of tin concentrate in 1920. This fell 60 tons below the production of the previous year. It represented 16 tons of recoverable metallic tin and was won by a dredge operating in the tin-bearing placers of the York district of Seward Peninsula. Near Hill City, South Dakota, the National Tin Corporation reports mining and milling 800 tons of tin ore, which produced 12 tons of concentrate.

Notes From Nova Scotia

Scott Board has Finished its Work

The Scott Conciliation Board concluded its labours in Halifax on May the 24th. The work done by the Board was almost equal to that accomplished by the Royal commission two years ago. The Award in its main features shows little change from that of the Gillen Board. The offer of the Dominion Coal Company of March 21st., to establish the minimum wage at $3.00 per day instead of $2.85, has been included. A number of minor adjustments have been recommended.

How the Award will be accepted by the workmen is the general query, but the anxiety of the earlier winter months over the Gillen Award is absent. The public have had all they want of investigation into the affairs of the Dominion Coal Company and they are satisfied that the miners of Nova Scotia should now get down to work. Neither the Coal Company nor the miners can afford to reject the award. The party failing to accept it will lose public symphathy and that means everything in the winning of a wage dispute. The Award of the Conciliation Board is the decision of the public, for once a dispute of this nature passes from the contending parties to a third party for settlement, it is considered a public question and the findings are virtually, if not actually, binding. For after all, public opinion is the great arbiter of all public questions, and whether we accept the verdict gracefully or reject it with wrath, we must inevitably bow before it. The public may not have any visible power to enforce its decrees, but once made they remain firm and immutable. If, for a time, we are able to evade them as was done in the case of the Gillen Award, the price exacted is very heavy, and at best is a dead loss. Even had the Scott Award carried increases, these would have had to be large to reimburse the miners for loss sustained during the hopless campaign of striking on the job.

Hearings of the Board on the Mainland

The sittings held in Stellarton, Pictou County and Springhill, Cumberland County, developed no new features of the case, except that the Pictou miners complained bitterly of lack of employment and the Springhill men of over crowding. This later feature is due to the loss of one of the slopes which occurred some years ago. A splendid spirit was exhibited by the Springhill men towards the mine officials and the Dominion Coal Company.

The rebuttal evidence of the Coal Company was submitted and the summing up of their case was done in a masterly way by D. H. MacDougall, Vice President. Robert Baxter for the men again touched on the salient features of the case. Mr. Baxter made out a good case and won the respect of the Board and all interested who heard him.

W. Herd, Company Mining Engineer, stated that the Collieries were in safe condition, that No. 24 mine, which Mc. McLachlan said very dangerous, was a safe mine, and no gas had been found in it since it was opened. No. 11 mine was also in safe condition, and Princess at Sydney Mines was as safe as any mine that the Company had.

A statement showing all wages earned in all collieries was submitted. The earnings of many men were very large and the average good. J. B. McLachlan had challanged the Comapny to produce a miner earning over $1000 during last year. A list showing the names of 118 men was entered, whose wages ranged from $1,550 to $3,686 per year. Of these,

13	workmen	earned	over	$1,550,
12	"	"	"	1,600
11	"	"	"	1,700
19	"	"	"	1,800
17	"	"	"	2,000
14	"	"	"	2,100
7	"	"	"	2,200
5	"	"	"	2,300
3	"	"	"	2,400
2	"	"	"	2,500
2	"	"	"	2,600
2	"	"	"	2,800
2	"	"	"	2,900
2	"	"	"	3,062
1	"	"	"	3,401
1	"	"	"	3,686

Hundreds of other workmen were well over $1,000, and the year 1921 had much broken time.

The Mines are Safe

What diabolical spirit has possession of Sec'y. McLachlan of the United Mine Workers, who wants to blight and blast everything and everyone that he cannot control? The public were ready to give the case of the miners a thorough investigation to ascertain the truth and reach a common ground, but when Mr. McLachlan went out of his way to tell the world that No. 24 Colliery had been in a dangerous condition through gas, while no gas had ever been found in it, it was freely admitted that the case of the men was in the hands of a man incapable of sanely presenting it or of telling the truth and it was sure to suffer. His picture of men being terrorized to the point of hiding such conditions is openly characterized by all self respecting miners as "bull" and "bluff," for there is not one miner anywhere in the Company's employ who fears to report a dangerous condition. It is not in the nature of miners to be afraid of the employers. They never were and never will be. But they are afraid to lose their lives, and for this reason if for no other they will and do report unsafe condition.

The Mines Regulation Act of Nova Scotia makes provision for the Examination of any coal mine by a committee of the workmen when it is thought necessary. No. 24 mine was reported unsafe at a meeting of the U. M. W. of A., and a committee was immediately appointed and sent into the mine to examine it. They returned and reported that no gas was found in the mine. Yet knowing this, Sec'y. McLachlan broadcast that the mine was dangerous. The most dangerous and destructive force around the collieries is Mr. McLachlan himself, there is enough explosive mixture in McLachlan's make up to send him off at any time. To drive his arguments home McLachlan referred to an instance in his own mining experience which on being

[illegible] had to admit occurred 15 years ago. No man knows better than McLachlan that there has been tremendous improvement since 1907 in everything that pertains to the miners' welfare.

Progress in the Collieries

Since the Organization of the Empire Steel Company when it became known that old collieries on the eve of closing were to be continued, great changes have taken place. Collieries are now being remodelled for larger outputs; underground airways and travelling roads are being repaired and put in first class condition; a Safety Department, officered by experienced men, with a live man at the head, has been organized to prevent accidents. But the opening up of new collieries, the remaking of others, the repairing of airways and the putting in of riding raikes cannot be done in a day and McLachlan knows that this could not have been done at all if the organization of the British Empire Steel Corporation had not taken place. McLachlan alone refuses to do anything but damn a corporation which had it been organized years ago, would have prevented the expenditure on capital account of many millions of dollars and would have operated every colliery on the island to full capacity instead of having them crippled and cribbed in by boundary leases everywhere.

Not satisfied with mis-stating the facts as to the condition of Glace Bay collieries, Mr. McLachlan goes about to place the coal industry of Canada in a most unfavourable light. He states that they are the worst governed collieries in the world, and have the highest accident rate. But here again he perverts the truth, for Canada has a smaller accident rate than that of the United States as mentioned in the Canadian Mining Journal of May 19th. But what does McLachlan know of the conditions of other mining districts of Canada, and what had it to do with the case before the Board?

Giving further rein to his love of destructions, he goes out of his way to make a dastardly attack on the Mines Department at Halifax. He characterized that Department as antiquated, the Mines Inspectors as poorly paid, fifth-rate men, who failed to enforce the law. That the Inspectors were denied a chance to vindicate themselves and to state the conditions of the collieries which they supervised, was a gross injustice to them. Either the Board or the Mines Department should have insisted upon the evidence of the Inspectors. These men are faithful, hard-working, experienced officials, who would not for one moment permit any condition to exist such as was stated by McLachlan. Indeed these statements would never have been made before the Board if the attitude of the Mines Department in such cases had not been well known. Similar statements have been uttered again and again from free-speech platforms, where freedom is restricted to the pleasure of a howling mob who will hear no side of a question but their own. This kind of freedom, they label (or I should say *libel*) democracy. Until the miners of Nova Scotia come to understand that their business must be in the hands of sound, thinking men, men who are constructive, not destructive, they will never get anywhere. Moral reformers who believe they have discovered a fundamental weakness in the social structure and that it must be pulled down, whether anything else takes place or not, are not good leaders. Such moral critics, for a little cheap applause, would pull down the pillars of the earth if they could.

Thanks to the red-blooded men of Canada, the "reds" who abuse the privileges of free speech and free democracies are doomed to failure, with the terrible penalty impending of having to get down to work once more to earn a living.

PORT ARTHUR NOTES

By J. J. O'Connor

Dr. W. L. Goodwin, of the Department of Mines, Toronto, has completed two most successful Prospectors' Classes, one at Port Arthur, and the other at Fort William. The former had an average attendance of 23, while the latter was about the same. Many of those attending the Port Arthur course, also took advantage of the course held in Fort William.

These classes are highly instructive, and of prime benefit to prospectors in equipping them for work in the field. In addition to the classes held during the day, illustrated lectures were given in the evening, that were well attended by citizens, as well as, men engaged in prospecting. Dr. Goodwin's well-known facility in imparting his widespread knowledge of the geology and mineralogy of Northern Ontario, was highly appreciated by the attendants, and is certain to have its reflection in this year's field work.

Not in twenty-five years, has the outlook for general mining activity been so bright, as it is at the opening of this season. Mining operations are being carried on at the Lake of the Woods, in the Manitou district, where the stamps of the Laurentian mill are dropping, at Sturgeon Lake, Minaki area, Wabigoon Lake, and active prospecting and investigation in the Island Falls district; while at Schreiber, the McKellar-Longworth, and the Jackson properties are being actively and agressively developed with splendid prospects of satisfactory results. The old Empress Mine at Jackfish, east of Schreiber, has been dewatered, and it is expected to be in operation within a short time. Further east, at Goudreau, results are being obtained in the development of the Goudreau Gold Mine, that are exceeding all expectations in the richness of the ore that is being encountered. It is stated, $50,000. in gold was taken out of the first 55 feet of No. 1 shaft.

These operations cover an area over five hundred miles in length, with extensive mineral-bearing areas intervening, mostly unprospected and unknown. When the attention that is their due is given the areas, they may reasonably be expected to contain mineral deposits of economic value.

Gold, for the moment, is the fashionable metal with mining men and prospectors, and exceptional attention is being paid to the gold-bearing areas this season. We may now hope for modern methods, applied by experienced mining men, who do not conceive it to be the first duty of a mining company to erect a stamp mill before developing the mine, as was done in the past, resulting in the erection of 26 stamp mills between Port Arthur, and the Lake of the Woods, when there was not enough ore developed to supply a tenth of them. When intelligent mining methods are applied, this part of Ontario may be expected to give a good account of itself, and redeem it reputation. The interests that are now directing their attention to this part of the Province, are of the class that will give this section an opportunity to advance.

The Southern Rhodesian gold output for March 1922 amounted to 54,643 fine ounces as compared with 51,422 fine ounces for February 1922 and 31,995 fine ounces for March 1921.

British Columbia Letter

Mining Convention at Nelson

The International Mining Convention to be held at Nelson, B. C., from July 3rd to 7th promises to attract representative mining men from all sections of the Pacific Northwest. A tentative programme has been drawn up, which sets Monday, the opening day, for inspection of mineral exhibits and manufacturers' displays. Tuesday is to be "American Day" in connection with which there will be some special features in honour of American visitors and for the observance of the July 4th celebration. S. S. Fowler of Riondel will preside, and Lieut.-Governor W. C. Nichol will formally open the Convention. Our "Dominion and Provincial representatives" is the subject of an address to be delivered by Mayor C. F. McHardy to which Governor Elcott of Oregon, and J. B. White of Spokane will respond. An address is to be given by T. A. Rickard, of the Engineering and Mining Journal-Press, on "English-Speaking People". There will be lectures on Kootenay mining and smelting on Wednesday, while Thursday will be "Prospectors' Day". Hon. Wm. Sloan, Minister of Mines, will speak on "British Columbia's Mineral Resources and Industrial Progress." The Provincial Government is co-operating in a number of ways, notably by the preparation of moving pictures, illustrating the mining industry of the Province. These will be shown during the Convention.

Smelter Accepts Zinc Ores

The acceptance by the Trail Smelter of the Consolidated Mining and Smelting Co. of zinc ore already is having a marked effect on the industry of the Slocan district. The Whitewater Deep mine will resume operations on its zinc-silver property immediately. The Lucky Jim mine, which has been idle for some time, is also expected to be producing early this summer. Generally speaking there is a revival of interest and many properties that have been out of operation owing to the penalties against zinc and high labour cost are expected to be back on the shipping list before long.

Trout Lake

It has been reported that the Mining Recorder's office at Trout Lake, B. C. is to be removed, the official business to be handled by Government officials in an adjacent Mining Division. The mining men of the district do not like this idea, and are vigorously protesting. They point out that there is considerable mining in their particular section, and judging from news received from that part of the country these contentions seem to be justified. Among activities reported from Trout Lake district are the following. Mrs. Jowett's claims, "Foggy Day", have been bonded by a Spokane syndicate who will begin work on the 1st of July. The Ethel Mining Company of Spokane announce that work will be started on the "Nettie L." as soon as the snow leaves. James Livingstone is developing the "Copper Chief". It also is reported that there will be development during the season on the "Okanagan," "Silver Cup," "Bad Shot" and "Noble Five."

Alice Arm

The Silver Bar Mining and Development Mining Co. Ltd. has been organized in Vancouver, B.C., for the purpose of developing some of the mining prospects of the Alice Arm District, Northern British Columbia.

Some fine specimens of high grade sulphide silver ore have been brought from the Black Diamond Group, Alice Arm. The owner says that he has a well-defined vein which increases in width with depth. It is the intention to continue development during the summer.

A small vein of high-grade ruby and brittle silver has been found in a rock quarry, a short distance from the town of Alice Arm. The quarry is being operated by the Government to supply rock for public works. These showings are to be developed later on.

Mining men and Prospectors of the Alice Arm district are in difficulties because of lack of transportation up the Kitsault valley. The Dolly Varden Railroad has been closed down and the Company does not appear to be prepared to maintain a service this season. The Provincial Government has been asked, it is understood, to take such steps as are necessary to provide the operators of this section with the means of transporting supplies and ore from mines and prospects to tidewater. There is no present indication of how the problem is to be solved.

Premier

Mr. H. A. Guess, Vice-President of the American Smelting and Refining Co. and a prominent officer of the Premier Mining Co., passed through Victoria recently "en route" to the Premier Mine, Portland Canal Mining Division. It is his intention to inspect the Premier Mine and plant and other properties in that locality. The suggestion is made that Mr. Guess may consider proposals that have been made to his company for the purchase of prospects adjoining the property of the Premier Mining Co.

The Roseberry-Surprise mine, Slocan District, is employing about 20 men and shipping ore at intervals.

Major Angus Davis, before his appointment to the position of Resident Mining Engineer, Kamloops, is said to have examined the MacAllister group operated by the Slocan Mining and Development Co. R. A. Grimes is in charge of these operations. Major Davis is reported to have recommended the driving of a lower tunnel to prove the ore body at greater depth. Mr. Grimes is installing a compressor and proposes beginning development along these suggested lines.

G. D. B. Turner, a well-known western mining engineer, has left for Stewart, B.C., to direct operation on the Dunwell Mines, Ltd., and the Indian properties, Portland Canal Mining Division. He will have personal charge of the work on these properties during the summer.

The Exchange group of mineral claims, situated between the Indian and the Bush with the Premier to the south, in the valley of Cascade Creek, is reported to be showing up extremely well. Some samples carrying high values in gold and silver have been brought from this property.

C. B. Hosmer, of Montreal, has been elected vice president of the Consolidated Mining and Smelting Co., in place of George Summer.

Operations are to be resumed at the Cork Province Mine under the management of W. Y. Williams, formerly superintendent of the Granby Company's Boundary Mine. The mine has produced silver-lead ore to the value of more than $170,000, all of which has come from stopes above the 300 ft. level.

The erection of a cyanide plant is contemplated by the Bullock Gold Mines, Ltd. The Mine is situated on Poplar Creek.

R. H. Stewart, who has been in Texas for some time in the interest of the Thompson Aldridge Co. of New York, has returned to British Columbia, and has been examining properties at Sandon.

L. A. Dodd, who are been Gold Commissioner at Barkerville, B.C., for some years, has been transferred to Nanaimo, B.C.

The Nickel Plate Mine near Hedley, one of the largest gold producers in British Columbia, has resumed operations after a lengthy period of inactivity.

G. S. Blaylock, for many years General Manager of the Consolidated Mining and Smelting Co. has been elected a Director of that Company.

The operations of the Tidewater Copper Co., Sidney Inlet, west coast of Vancouver Island, are of unusual interest. The Company is using nothing but water power to provide power for mine and mill. It is mining and milling its ore at a cost of only $2.10 per ton. It is making a recovery of 95 p. c. of the copper content of its ore, and is producing a concentrate running between 35 and 40 per cent. of copper.

The semi-annual examination for Assayer's Certificates was held last week under the auspices of the Provincial Bureau of Mines, Victoria. There were two candidates, both of whom were successful, viz., J. D. Boulding and G. S. Rogers.

Ore Receipts at Trail

For the week ending May 7th, there were received at the Trail Smelter of the Consolidated Mining and Smelting Co. 7,944 tons of ore for treatment. The Company's properties contributed 7,603 tons, so that there were custom shippers to the extent of over 600 tons. The Florence Mine at Princess Creek shipped 32 tons of lead ore, while the Standard at Silverton sent 127 tons of zinc ore. Other independent shippers were: Mollie Hughes, New Denver; 15 tons; Paradise, Lake Windermere, 48 tons; Silversmith, Sandon, 76 tons; and the Black Rock, Northport, 43 tons.

Galena for Radio Apparatus

Scientific advances in connection with radio work, and the growing popularity on the American Continent of radio broadcast services, are likely to open to mining men of British Columbia a new market for a certain type of ore which, it is possible, is to be found in the Province in considerable quantity.

The mineral combination that radio men want is commonly termed "steel galena." This is a lead sulphide of a peculiar crystalline form. A sample of what is in demand was forwarded recently to the Provincial Bureau of Mines. In appearance it is a very fine-grained ore and the piece that reached the Bureau was very nearly pure galena with practically no impurities, assaying 86 per cent lead.

This foreign specimen was compared with specimens of number "steel galena" of British Columbia as shown by the Bureau's Mineral Exhibit. Some local samples were found of high standard and it is understood that as a result, New York interests now are making investigations with a view to ascertaining whether the supplies of which they are in need may be obtained in this Province.

There is some promise of an important market being developed for the product of some of the mines of this Province and the outcome of investigations now in progress will be watched with interest.

GOOD REPORTS FROM PAS MINERAL BELT NORTHERN MANITOBA

By Reece H. Hague

With the recent opening of navigation between The Pas and the mineral belt, excellent reports have been received from various properties on which work is under way, and considerable activity is anticipated this summer throughout the whole belt from Herb Lake to Elbow Lake.

Elbow Lake

On the Murray property at Elbow Lake the Hollinger interests have stripped the ore-body and carried out extensive trenching. Test pits are now being sunk and everything is in readiness for sampling and assaying at the plant that has been established on the property. Visible gold is said to be distributed freely throughout the trenches and in the pits over a large area, and the ore body is expected to carry high and uniform values. Other finds are reported from the same district, extending through Island Lake, Claw Lake and Barb Lake.

The Exploration Company Ltd., of London, England, have a staff of men engaged in trenching the Hanna and other gold bearing properties at Elbow Lake, operations being under the supervision of A. Walza, mining engineer of New York, who has taken the place of Walter A. Ru-Keyser, called to New York on the death of his father.

Diamond drilling is in progress on the Gordon property at Copper Lake, which is under option to the Nipissing people. Mr. Gordon left for his property with the first open water.

Herb Lake

Men engaged on the Bingo prospect at Herb Lake report a new discovery which promises to be more important than the other veins previously known to exist. The latter carried high values in gold and were favorably reported on by Professor DeLury of Manitoba University.

Herb Lake, which was the first gold-bearing district to be discovered in Northern Manitoba, may yet prove a factor in the gold production of the Dominion. Discoveries there include the Bingo, Rex, and Northern Manitoba, on all of which attractive ore has been found.

The Bingo Company was recently reorganized in England with the Earl of Hardwicke as chairman of the board of directors. A 90-foot shaft was sunk on the property some time ago, and the veins strengthened at depth and values improved. The new vein discovered is said to run parallel with the others and to be from three to six feet in width. If this proves up it should enhance the value of the property considerably.

The Pas mineral belt will receive such an overhauling by prospectors and mining engineers this summer as it has never before had. Every boat is taking fresh parties out and mining men in the district are hopeful that the next few months will see many more finds of importance. The district has hardly been scratched, up to the present, and the majority of finds have been more or less stumbled upon. Prospectors have confined their prospecting to the lake shores but intend to defy the flies this summer and go inland.

The Transvaal gold output for April 1922 amounted to 511,338 fine ounces, as compared with 681,382 fine ounces for April 1921.

Northern Ontario Letter

Power Development not yet Assured

Just at a time when assurance of the right to develop power on the Abitibi River appeared probable for the Hollinger Consolidated Gold Mines, something unforeseen seems to have developed and this question is still uncertain. Despite the conferences held between representatives of the largest interests in this part of Northern Ontario, no official statement has ever been issued in respect to the final result; and in the meantime, an official of the Hollinger has stated to the Journal correspondent that there is still some uncertainty about the matter.

Gold Centre

British and American capital is being interested in the Gold Centre property, situated in that part of the Porcupine field lying between the Dome and the Hollinger-McIntyre areas. W. E. Simpson, manager of the Miller Independence Mines of Boston Creek, will have charge of the operation.

Mill for Clifton-Porcupine

Arrangements are being made to erect a 15-ton mill on the Clifton-Porcupine property. It is believed such a mill will result in sufficient production to pay for the further development of the property.

The shaft on the Paymaster property is to be continued to a depth of 400 feet. Results have been encouraging on this property.

Progress at V. N. T.

A special visit to the Porcupine V. N. T. Gold Mines by the representative of the Journal found mining operations in full swing. Not only is the work of sinking the shaft from the 600-ft. level under way, but drifting operations are being carried on in the big ore body at the 600-ft. level.

N. J. Evered, general manager, stated that the dewatering of the mine was accomplished in about two weeks and at a remarkably low cost. He said that the underground workings, including timber, were found to be in excellent condition and that rapid progress is assured. A total of five machines are employed and the shaft will be pushed to a depth of 900 feet. A station will be cut at a depth of 750 feet, but lateral operations may not be undertaken at that point until the 900-ft. level is reached.

In addition to these underground operations, a diamond drill machine has been employed and is now actually at work, exploring that area lying between the main vein and the boundary of the adjoining Hollinger Consolidated.

Night Hawk Lake

Interest is keen in the territory lying along the north east shore of Night Hawk Lake, in th Porcupine Mining Division, some fifteen miles north east from the producing section of the Porcupine district. The outstanding success on the Night Hawk-Peninsula Gold Mines has encouraged widespread interest.

Among those who are identified in exploring and developing property in the Night Hawk district are a group of prospectors and business men of South Porcupine who have secured claims along the strike of the proven ore bodies. This syndicate has completed arrangements to employ a diamond drill for the purpose of locating, if possible, the mineralized area. The properties are reached by boat from Connaught station on the Porcupine branch of the T. & N. O. Railway.

McIntyre Mill Enlargement

The new milling unit on the McIntyre-Porcupine will be ready for operation by June 20th, and will increase the capacity of the mill to between 750 and 800 tons daily, as compared with a present limit of about 550 tons daily. This increase was to have taken place this week, but unforeseen delays occured in placing foundations as well as in slow delivery of some of the equipment.

A feature of the recent development work on the McIntyre has been the discovery of a porphyry intrusion at depth which does not show at surface. This has altered the course of one of the main ore bodies in such a way as to throw it over on the west claim of the McIntyre,instead of passing across the boundary on to the Acme side of the Hollinger. This indicates that the McIntyre will have nearly a quarter of a mile more in length of vein than had been formerly counted upon The development is one of importance.

At the present time the McIntyre is employing approximately 360 men, and the ore outlet system has reached a high state of perfection, thus assuring full tonnage with which to operate the enlarged plant at full capacity. Beginning with the new fiscal year on July 1st, next, the McIntyre may be expected to produce approximately $10,000 daily, or at the rate of about $3,500,000 annually.

Developments at a depth of 1,875 feet are favorable.

Dome Reserves

With a force of 550 men and with approximately fifty machines operating underground, the work of developing the Dome Mines is now going on at a rate that eclipses any other period in the past on this mine. Large ore reserves have been blocked out at and above the 800-ft. level, and further big tonnages have been placed in sight at 1,000 and 1,150 feet. In addition to this, further sinking has been carried on and a station is now being established at a depth of 1,600 feet.

These details of progress at the Dome are official to the Journal. They show that in addition to the recent official figures about record production, the development of the mine is going forward at a pace that would appear to indicate an enlargement of the mill as the next necessary step for the Dome

The question of mill enlargement was mentioned to an official of the company, but no confirmation of a reported big addition could be secured It is considered not unlikely that Mr. Bache, president of the Dome, may make important reference to this at the forthcoming annual meeting of the company.

At any rate, production is now at a higher rate than was ever before considered possible, while the development work is far ahead of milling requirements All of this points to the possibility of the mine taking a place among the world's great gold producers

Shiningtree District Active

Activity is spreading throughout the whole of the West Shiningtree gold area This has been occasioned in part by the general wide interest in gold mining the world over and is in part due to the recent favorable results on properties in the West Shiningtree field itself

Arrangements have been made to carry on work at

a depth of 300 feet on the White Rock property, owned by business men of Sudbury. Diamond drilling is being carried on with good results on the Atlas property, while work is also under way on the Wasapika. A deal is pending for the Herrick property, and the underground workings are now being de-watered preparatory to being sampled by a representative of English capital. Contracts have been let for shaft sinking on the Kingston property, while a force of men is now engaged in exploring the surface of the Hologden Mines preparatory to carrying on underground work.

Shakespeare Mine has Changed Hands

The old Shakspeare Mine, situated south-west of Sudbury, has been secured by Mr. Calvin of North Bay. The property was worked in the years 1905, 1906 and 1907 with encouraging results. A shaft was put down 300 feet and a small stamp mill was installed. Some $38,000 in gold was recovered during the short period of operation of the mill.

Information from the Ontario Department of Mines with reference to the Shakespeare is as follows:

"The ore is made up of interbanded lenses and stringers of quartz and chlorite schist. The contact with the granite lies to the north on the other side of the valley, probably half a mile away. The lode is 40 feet wide, having an ore zone on either side. Iron pyrites is the principal sulphide. A shaft with several levels has been sunk to a depth of 300 feet or more."

Newray

Having acquired a working option on the Newray Mines of Porcupine, whereby it will be possible to secure control of the enterprise, the Coniagas company of Cobalt will carry on an extensive campaign of development. It is probable that the minimum expenditure of $4,000 a month will be far below the amount that will actually be spent during the currency of the option. An official of the Coniagas declared that preliminary work would commence immediately.

One of the leading mining men of Porcupine who is familiar with the Newray was interviewed and expressed the opinion that the potentia ities of the property are second to none in the Porcupine district with the exception of the present producers. It is well known that high-grade ore occurs in patches, while there is a substantial tonnage that contains about five dollars per ton in gold. With these showings and with favorable geological conditions, the outlook is regarded as being very favorable for the Coniagas company extending its mining activity for another long period of years thro g'i its acquisition of the Newray.

Considerable prospecting is being done in the township of McArthur, on the strength of last winter's discovery of ore in which gold, platinum and silver occur. Prospectors who went in with canoes early this spring by way of the Mattagami and Grassy rivers are expected out at an early date and will bring with them additional samples and a more detailed description of the new prospects.

According to information just obtained here, the old Golden Rose property near Emerald Lake, in the Temagami Forest Reserve, has been purchased by Oscar Smith, of the Smith and Travers diamond drilling firm. This is the second time for the property to change hands during the past few months, Mr. Sweeny of New York having acquired it only a few months ago.

Those behind the work of developing power on the Montreal River at Indian Chutes are confident of being able to complete the work by the end of the current year. It has been estimated that about 3,000 h. p. will be developed.

A meeting will be held at an early date when the shareholders of the Frame-Porcupine Mines will be asked to ratify a deal whereby the property shall be sold to another company which holds seven mining claims in the Porcupine district. No details of the proposition have so far been announced, although the intimation of the purpose of the forthcoming meeting has been obtained through official circles.
